(SX3) Eichler shifts. For $j \geq 0$ and $v \in \Phi$ let $D_{j,v}$ be the diagonal $i_j \times i_j$ matrix with entries $M/\mathrm{bs}_v(e_{l+1})$, $0 \leq l < i_j$. For $x = (x_v)_{v \in \Phi}$ with $x_v \in \mathrm{M}_{i_j \times k}(\mathbb{C})$, the **Eichler shift** with parameter x is $\mathrm{Es}_j(x) \in G_\infty$,

$$\mathrm{Es}_j(x)_v = u(a_v, 0), \qquad a_v = \begin{pmatrix} D_{j,v}^* x_v \\ 0 \end{pmatrix} \in \mathrm{M}_{\varrho \times k}(\mathbb{C}),$$

the unipotent element fixing $f_0, \ldots, f_\varrho$ that moves X_0 along $e_1, \ldots, e_{i_j}$ by the rows of $D_{j,v}^* x_v$.

(SX4) Orbit kernel bound. For $y \in G_1$ and $0 \leq i \leq \varrho$ let $Z^{(i)}(y)$ be the submatrix of $Z(y)$ on the rows and columns $\{0, \ldots, i-1\} \cup \{\varrho\}$ (the products of the subframe $e_1, \ldots, e_i, z$ with its image). For $\gamma \in G(E)$, $j \geq 0$ and $v \in \Phi$, with $i = i_j$, the **orbit kernel bound** is

$$\mathrm{Kb}_j(\gamma, v) = |\det D_{j,v}|^{-2k}\, \frac{(2b^{74n})^{(i+1)i} \left(2^{i+1}\, b^{2(6n+2)(j-i)}\right)^k}{|\det Z^{(i)}(\gamma_v)|^{k+i}}$$

if $\det Z^{(i)}(\gamma_v) \neq 0$, and $\mathrm{Kb}_j(\gamma, v) = 0$ otherwise.

(SX5) Lattice translates. Let $c \in \mathcal{C}$, $j \geq 0$, $\gamma, p_0, p \in G(E)$ and $l = (l_0, \ldots, l_{i_j - 1}) \in \mathrm{M}_{k \times i_j}(E)$ with columns $l_a \in X_0$. Then p is a **lattice translate** of p_0 by l (for c, γ, j) if every l_a lies in the definite part $L_c \cap X_0(\mathbb{A}_f)$ of the class lattice and, for $0 \leq b \leq \varrho$,

$$p f_b \equiv p_0 f_b + M \sum_{a < i_j} h(e_{a+1}, \gamma f_b)\, l_a \pmod{\langle e_1, \ldots, e_\varrho \rangle}.$$

(SX6) Column lattice at infinity. For $c \in \mathcal{C}$ and an integer $i \geq 0$, the **column lattice at infinity** is the additive group

$$\Lambda_{c,i}^\infty = \{(v(q)^*)_{v \in \Phi} :\ q \in \mathrm{M}_{k \times i}(E) \text{ with every column in } L_c \cap X_0(\mathbb{A}_f)\} \subseteq \prod_{v \in \Phi} \mathrm{M}_{i \times k}(\mathbb{C}),$$

where $v(q)$ is the entrywise image of q under v and * is the conjugate transpose; so the entry (l, a) of the component at v is $\overline{v(q_{al})}$.

Theorem 5.3.2. *Let $\mathfrak{S}$ be admissible with Weil data, and $\Omega \subseteq \bar{G}$.*

(i) $\sum_{c,c'} \sum \mathrm{size}(\gamma)\, \mathrm{size}(\gamma') \leq \mathcal{D}_{\mathrm{id}}/b^{kf}$, *over the pairs near over an agreeing block for (c, c') that are not in the same link class.*

(ii) For $q \in \mathbb{N}$, $q \geq 1$: $\sum_{c,c'} \sum \mathrm{size}(\gamma)\, \mathrm{size}(\gamma') \leq (b^{2f}/q)^k \mathcal{D}_{\mathrm{main}}$, *over the pairs near over an agreeing block in the same link class with γ over some (c, s, c') of meet norm $\geq q$.*

(iii) If $w \geq 0$ and $\mathrm{LM}(\{\mathsf{g} \neq 0\}, \Omega) \leq w\nu^2$, then $\mathrm{SM}(A^{\mathrm{cut}}_{\Gamma^*}, \Omega) \leq w + \mathcal{D}_{\mathrm{id}}/b^{kf}$.

(iv) If $q \in \mathbb{N}$, $q \geq 1$, and every $s \in \Omega$ has meet norm $\geq q$, then $\mathrm{LM}(\{\mathsf{g} \neq 0\}, \Omega) \leq (b^{2f}/q)^k \mathcal{D}_{\mathrm{main}} \nu^2$.

Proof. Throughout, $\tau_{\mathrm{sz}} \geq 1$, $\tau_{\mathrm{sz}}^4 = b^{kf}$, $\mathcal{D}_{\mathrm{id}} \geq 0$, and by (FA6) $\mathcal{D}_{\mathrm{main}} \geq b^{11kf}\mathcal{D}_{\mathrm{id}} \geq 0$; hence $\mathcal{D}^{\mathrm{sz}}_j \leq \mathcal{D}_{\mathrm{main}}$ for every cell rank j (for $j \leq \varrho$, $\mathcal{D}^{\mathrm{sz}}_j = \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^{16} \leq \mathcal{D}_{\mathrm{id}} \leq \mathcal{D}_{\mathrm{main}}$). For a pair (γ, γ') near over the agreeing block (c, s, c') write j, j' for the cell ranks, $G = \mathsf{g}^*(j, c, c', \gamma)$, $G' = \mathsf{g}^*(j', c, c', \gamma')$, $d = \mathrm{disc}(L_{12})$, c^+ for the link corank and $l = k - \dim_E X_0(\gamma, \gamma')$. By Lemma 5.3.13 (iii),

$$l \leq c^+ + (j - \varrho)_+. \tag{5.35}$$

(i). Apply Lemma 5.3.3 with $B = \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^{10}$ and $P(c, c')$ the set of pairs of (i). Let $(\gamma, \gamma') \in P(c, c')$.

- If $c^+ = 0$, then $\operatorname{link}\gamma = \operatorname{link}\gamma'$ by Lemma 5.3.13 (iv); as the pair is not in one link class, $\mathsf{g}(\gamma)\mathsf{g}(\gamma') = 0$, and by Lemma 5.3.13 (v) $\mathsf{g}(\gamma) = \mathsf{g}(\gamma') = 0$. By (TA5) $j, j' \leq \varrho$, so $l = 0$ by (5.35), and $\mathcal{D}^{\mathrm{sz}}_j = \mathcal{D}^{\mathrm{sz}}_{j'} = \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^{16}$. By Proposition 5.3.64 with $x = 1$, $d^2 \leq GG'$. Take $\eta = 1$, $D = \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^{16}$; then $\tau_{\mathrm{sz}}^{l+6} D\eta^{-k} = \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^{10} = B$.
- If $c^+ \geq 1$, take $\eta = (M/2)^{c^+ f}$ and $D = \mathcal{D}_{\mathrm{main}}$. By Proposition 5.3.64 with $x = 1$, $(d\eta)^2 \leq GG'$, and $\mathcal{D}^{\mathrm{sz}}_j, \mathcal{D}^{\mathrm{sz}}_{j'} \leq D$. By (5.35), $l \leq c^+ + 1$. Put $y = \tau_{\mathrm{sz}}(2/M)^{kf}$. Since $M \geq b^{19} \geq 2b$ (FG6), $y \leq \tau_{\mathrm{sz}}^4(2/M)^{kf} = (2b/M)^{kf} \leq 1$, so $y^{c^+} \leq y$, and with (FA6)

$$\begin{aligned}\tau_{\mathrm{sz}}^{l+6} D\eta^{-k} &\leq \tau_{\mathrm{sz}}^{c^+ + 7}(2/M)^{c^+ kf}\mathcal{D}_{\mathrm{main}} = \tau_{\mathrm{sz}}^7 y^{c^+}\mathcal{D}_{\mathrm{main}} \\ &\leq \tau_{\mathrm{sz}}^8 (2/M)^{kf}(M/b^6)^{kf}\mathcal{D}_{\mathrm{id}} \leq \tau_{\mathrm{sz}}^8 b^{-5kf}\mathcal{D}_{\mathrm{id}} = \frac{\mathcal{D}_{\mathrm{id}}}{\tau_{\mathrm{sz}}^{12}} \leq B.\end{aligned}$$

So the hypotheses of Lemma 5.3.3 hold, and the sum of (i) is at most $\tau_{\mathrm{sz}} B = \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^9 \leq \mathcal{D}_{\mathrm{id}}/\tau_{\mathrm{sz}}^4 = \mathcal{D}_{\mathrm{id}}/b^{kf}$.

(ii). Apply Lemma 5.3.3 with $B = \tau_{\mathrm{sz}}^7 \mathcal{D}_{\mathrm{main}}/q^k \geq 0$ and $P(c, c')$ the set of pairs of (ii). Let $(\gamma, \gamma') \in P(c, c')$, near over the agreeing block (c, s, c'), and s' with meet norm $\geq q$ such that γ is a term over (c, s', c'). As $s = \mathrm{red}(h_c^{-1}\gamma h_{c'}) = s'$, the meet norm of s is at least q. The pair is in one link class, so $\mathsf{g}(\gamma) \neq 0$ and $\operatorname{link}\gamma = \operatorname{link}\gamma'$; hence $c^+ = 0$ (Lemma 5.3.13 (iv)), $\varrho < j$ (TA5), and $l \leq 1$ by (5.35). By Proposition 5.3.64 with $x = q$, $(dq)^2 \leq GG'$. Take $\eta = q$ and $D = \mathcal{D}_{\mathrm{main}}$: then $\mathcal{D}^{\mathrm{sz}}_j, \mathcal{D}^{\mathrm{sz}}_{j'} \leq D$ and $\tau_{\mathrm{sz}}^{l+6} D\eta^{-k} \leq \tau_{\mathrm{sz}}^7 \mathcal{D}_{\mathrm{main}}/q^k = B$. Hence the sum of (ii) is at most $\tau_{\mathrm{sz}} B = \tau_{\mathrm{sz}}^8 \mathcal{D}_{\mathrm{main}}/q^k = (b^{2f}/q)^k \mathcal{D}_{\mathrm{main}}$.

Γ^* **is stable,** by Lemma 5.3.18 (ii).

(iii). Let $c, c' \in \mathcal{C}$ and $s \in \Omega$. By Lemma 5.3.17 for $T = \Gamma^*$, using $\Gamma^* \cap \{\mathsf{g} \neq 0\} = \{\mathsf{g} \neq 0\}$,

$$\|A^{\mathrm{cut}}_{\Gamma^*}(c, s, c')\|^2 \leq \sum_L \|A^{\mathrm{cut}}_{\{\mathsf{g}\neq 0\}\cap \operatorname{link}^{-1}(L)}(c, s, c')\|^2 + \nu^2 \sum_{(\gamma,\gamma') \in \mathcal{A}(c,s,c')} \mathrm{size}(c, c', \gamma)\,\mathrm{size}(c, c', \gamma'),$$

where $\mathcal{A}(c, s, c')$ is the set of pairs of near representatives of Γ^* for (c, c') over (c, s, c'), satisfying the conditions of their cell ranks, with s agreeing, that are not in one link class. Every pair in $\mathcal{A}(c, s, c')$ is near over an agreeing block for (c, c') and not in one link class, and the sets $\mathcal{A}(c, s, c')$ for different s are disjoint, because a term determines $s = \mathrm{red}(h_c^{-1}\gamma h_{c'})$. Summing over c, c' and $s \in \Omega$ and dividing by ν^2, the first terms give $\nu^{-2}\mathrm{LM}(\{\mathsf{g} \neq 0\}, \Omega) \leq w$ and the second terms give at most the sum of (i). So $\mathrm{SM}(A^{\mathrm{cut}}_{\Gamma^*}, \Omega) \leq w + \mathcal{D}_{\mathrm{id}}/b^{kf}$.

(iv). For a subspace L let $T_L = \{\mathsf{g} \neq 0\} \cap \mathrm{link}^{-1}(L)$; it lies in Γ^* and is stable by Lemma 5.2.25 (i), (ii). For $c, c' \in \mathcal{C}$ and $s \in \Omega$, Proposition 5.3.19 (ii) gives

$$\|A^{\mathrm{cut}}_{T_L}(c,s,c')\|^2 \leq \nu^2 \sum_{\gamma,\gamma' \in \mathcal{N}_L(c,s,c')} \mathrm{size}(c,c',\gamma)\,\mathrm{size}(c,c',\gamma'),$$

with $\mathcal{N}_L(c,s,c')$ the near representatives of T_L for (c,c') over (c,s,c') satisfying the conditions of their cell ranks, empty unless s agrees. A pair (γ,γ') on the right is near over an agreeing block for (c,c'), lies in one link class ($\mathsf{g} \neq 0$ for both, both links equal L), and γ is a term over (c,s,c') with meet norm of s at least q. The map $(s,L,\gamma,\gamma') \mapsto (\gamma,\gamma')$ is injective, since s is determined by γ and $L = \mathrm{link}\,\gamma$. Summing over c, c', $s \in \Omega$ and L, all terms being nonnegative, $\mathrm{LM}(\{\mathsf{g} \neq 0\}, \Omega)$ is at most ν^2 times the sum of (ii), that is, at most $(b^{2f}/q)^k \mathcal{D}_{\mathrm{main}} \nu^2$. □

Lemma 5.3.3. *Let $\mathfrak{S}$ be an admissible filling datum with Weil data, let $B \geq 0$, and for $c, c' \in \mathcal{C}$ let $P(c,c')$ be a set of pairs near over an agreeing block for (c,c'). Suppose that for every $(\gamma,\gamma') \in P(c,c')$, with cell ranks j, j' of γ, γ', $d = \mathrm{disc}(L_{12})$ and $l = k - \dim_E X_0(\gamma,\gamma')$, there are real numbers $\eta > 0$ and D with*

$$(d\eta)^2 \leq \mathsf{g}^*(j,c,c',\gamma)\,\mathsf{g}^*(j',c,c',\gamma'), \qquad \mathcal{D}^{\mathrm{sz}}_j \leq D, \qquad \mathcal{D}^{\mathrm{sz}}_{j'} \leq D, \qquad \tau_{\mathrm{sz}}^{l+6} D \eta^{-k} \leq B.$$

Then

$$\sum_{c,c' \in \mathcal{C}} \sum_{(\gamma,\gamma') \in P(c,c')} \mathrm{size}(c,c',\gamma)\,\mathrm{size}(c,c',\gamma') \leq \tau_{\mathrm{sz}} B.$$

Proof. Let $(\gamma,\gamma') \in P(c,c')$, both terms over (c,s,c') with s agreeing, of cell ranks j, j' (so each satisfies the conditions of its cell rank), and write $G = \mathsf{g}^*(j,c,c',\gamma)$, $G' = \mathsf{g}^*(j',c,c',\gamma')$, d, l as in the statement, and c^+ for the link corank of γ,γ'.

The discriminant is at least 1 and the gauges are positive. The meet norm of s is a product of primes, so it is at least 1, and $x = 1$ is admissible in Proposition 5.3.5. Applied to (γ,γ') it shows that the common part P of γ with γ' at c is a lattice of rank $\dim_E X_0(\gamma,\gamma')$; applied to (γ',γ) (the term γ' is over (c,s,c') and satisfies the conditions of cell rank j') it gives $\mathrm{ti}(h_c^{-1}\gamma' h_{c'}) \geq 1$. Hence $d \geq 1$ by Lemma 5.3.4 (ii). By Proposition 5.3.64 with $x = 1$ (so $\epsilon = 1$),

$$d^2 \leq (2/M)^{2c^+ f}\, G\, G'. \tag{5.36}$$

Both gauges are ≥ 0, since $\mathsf{g}^{\max} \geq \prod_v |\mathsf{g}(\gamma)|_v \geq 0$; as the left side of (5.36) is ≥ 1, $GG' > 0$ and so $G > 0$, $G' > 0$.

The corank and the discriminant are bounded. Both γ and γ' are near terms over (c,s,c') satisfying the conditions of their cell ranks, so $G, G' \leq b^{n^3 f}$ by Lemma 5.3.16. By (FG6) and $b \geq 2$, $M \geq b^{19} \geq 2b^{18}$, so $2/M \leq b^{-18}$, and (5.36) gives

$$1 \leq d^2 \leq b^{-36c^+ f}\, b^{2n^3 f}.$$

As $b > 1$ and $f \geq 1$, this yields $18c^+ \leq n^3$ and $d \leq b^{n^3 f}$. By Lemma 5.3.13 (iii), $k \leq \dim_E X_0(\gamma,\gamma') + c^+ + (j - \varrho)_+$ with $(j-\varrho)_+ \leq 1$ (as $j \leq \varrho + 1$), and $\dim_E X_0(\gamma,\gamma') \leq \dim_E X_0 = k$. Hence

$$0 \leq l \leq c^+ + 1 \leq n^3/18 + 1 \leq n^3.$$

One pair. Let η, D be as in the hypothesis. Then $D \geq \mathcal{D}^{\mathrm{sz}}_j \geq 0$, $n_p > 0$, and by (TA13) $\mathrm{size}(c,c',\gamma)^2 = \tau_{\mathrm{sz}}^4 \mathcal{D}^{\mathrm{sz}}_j / (n_p G^k) \leq \tau_{\mathrm{sz}}^4 D/(n_p G^k)$, and likewise for γ'. Multiplying, taking square roots and using $GG' \geq (d\eta)^2 > 0$,

$$\mathrm{size}(c,c',\gamma)\,\mathrm{size}(c,c',\gamma') \leq \frac{\tau_{\mathrm{sz}}^4 D}{n_p\,(GG')^{k/2}} \leq \frac{\tau_{\mathrm{sz}}^4 D \eta^{-k}}{n_p}\, d^{-k} = \frac{\tau_{\mathrm{sz}}^{l+6} D \eta^{-k}}{\tau_{\mathrm{sz}}^{l+2} n_p}\, d^{-k} \leq \frac{B}{\tau_{\mathrm{sz}}^{l+2} n_p}\, d^{-k}.$$

Summation. For $0 \le l \le n^3$ let $Q_l(c,c')$ be the set of pairs near over an agreeing block for (c,c') with $\dim_E X_0(\gamma,\gamma') + l = k$ and $\operatorname{disc}(L_{12}) \le b^{n^3 f}$. By the two preceding steps every pair of $P(c,c')$ lies in $Q_l(c,c')$ for its own $l \in \{0,\dots,n^3\}$ and its summand is at most $B\, d^{-k}/(\tau_{\mathrm{sz}}^{l+2} n_p)$. All summands being nonnegative, Proposition 5.3.66 gives

$$\sum_{c,c'} \sum_{P(c,c')} \text{size} \cdot \text{size} \le \sum_{l=0}^{n^3} \frac{B}{\tau_{\mathrm{sz}}^{l+2} n_p} \sum_{c,c'} \sum_{(\gamma,\gamma') \in Q_l(c,c')} \operatorname{disc}(L_{12})^{-k} \le \sum_{l=0}^{n^3} B = (n^3+1)B.$$

Finally $n \le b$ by (FG6), so $n^3 + 1 \le 2b^3 \le b^4 \le b^{kf/4} = \tau_{\mathrm{sz}}$, because $b \ge 2$ and $kf \ge 16$ by (FG6). This gives the bound $\tau_{\mathrm{sz}} B$. □

Lemma 5.3.4. *Let $\mathfrak{S}$ be a filling datum, $c,c' \in \mathcal{C}$, $s \in \bar{G}$, γ,γ' terms over (c,s,c'), $k' = h_c^{-1}\gamma' h_{c'}$, $m = \dim_E X_0(\gamma,\gamma')$, and P the common part of γ with γ' at c.*

(i) $[P : L_{12}]$ divides $\operatorname{ti}(k')$.

(ii) If P is a lattice of rank m and $\operatorname{ti}(k') \ge 1$, then L_{12} is a lattice of rank m and

$$1 \le \operatorname{disc}(L_{12}) = \operatorname{disc}_m(P)\,[P : L_{12}] \le \operatorname{disc}_m(P)\operatorname{ti}(k').$$

Proof. Write $A = \langle e_1,\dots,e_\varrho\rangle$, $L = L_c$, $A_{\hat{\mathcal{O}}} = \bigoplus_a \hat{\mathcal{O}} e_a$, and $\varphi'(x) = (h(\gamma' f_b, x))_{0\le b\le \varrho}$ for $x \in V(\mathbb{A}_f)$. Since h_c acts on X_0 only, $L \cap A(\mathbb{A}_f) = h_c(L_0 \cap A(\mathbb{A}_f)) = A_{\hat{\mathcal{O}}}$. By (LT1), $x \in L \cap X_0(\mathbb{A}_f)$ lies in $L_c(\gamma')$ iff $\varphi'(x) \in M\,R'$, where $R' = \varphi'(A_{\hat{\mathcal{O}}})$.

Step 1 (a rational identity). Let $t \in A \oplus X_0$ have X_0-part $x \in X_0(\gamma,\gamma')$ and $t \perp \gamma f_b$ for all b. Then $\gamma'\gamma^{-1}t - t \in A + \gamma' A$. Indeed, $\sigma = \gamma^{-1}t$ is orthogonal to the frame, so it has no e^*-coordinates and z-coordinate 0; t has neither. Hence $t \perp X + \gamma X$ and $p = ([t],[\sigma]) = (x,\sigma_0)$ lies in $\operatorname{link}\gamma$, σ_0 the X_0-part of σ, with source $p^{\mathrm{s}} = x$. As $x \in X_0(\gamma,\gamma')$ there is $y \in X_0$ with $(x,y) \in \operatorname{link}\gamma \cap \operatorname{link}\gamma'$, of source x; by injectivity of the source on $\operatorname{link}\gamma$ (Lemma 5.2.28 (iii)), $y = \sigma_0$. So $(x,\sigma_0) \in \operatorname{link}\gamma'$: there is $t' \perp X + \gamma' X$ with $[t'] = x$, $[\gamma'^{-1}t'] = \sigma_0$. Then $t - t'$ and $\sigma - \gamma'^{-1}t'$ are orthogonal to X with middle part 0, so they lie in A, and $\gamma'\gamma^{-1}t - t = \gamma'(\sigma - \gamma'^{-1}t') + (t' - t) \in \gamma' A + A$.

Step 2 (the image of the common part). Let W be the E-space of the $t \in A \oplus X_0(\gamma,\gamma')$ with $t \perp \gamma f_b$ for all b; as these are E-linear conditions, $W(\mathbb{A}_f)$ is the space of $y \in (A \oplus X_0(\gamma,\gamma'))(\mathbb{A}_f)$ with $h(\gamma f_b, y) = 0$ for all b, and by Step 1 the map $y \mapsto (\gamma'\gamma^{-1} - 1)y$ sends $W(\mathbb{A}_f)$ into $(A + \gamma' A)(\mathbb{A}_f)$. Let $v \in P$. Then $v \in \operatorname{sat}_c(X_0(\gamma,\gamma')) \subseteq X_0(\gamma,\gamma')(\mathbb{A}_f)$ and $v \in L_c(\gamma)$, so there is $a \in A_{\hat{\mathcal{O}}}$ with $y := v - Ma \in W(\mathbb{A}_f)$, and $y \in L$. Let $k = h_c^{-1}\gamma h_{c'}$. Then $h_c^{-1}(\gamma'\gamma^{-1})h_c = k'k^{-1} \in K$ has reduction $ss^{-1} = 1$ (K is a group by Lemma 5.2.24 (ii), and the reduction is multiplicative), so $(k'k^{-1} - 1)L_0 \subseteq ML_0$ by Lemma 5.2.24 (iii) and $(\gamma'\gamma^{-1} - 1)L \subseteq ML$. Hence $(\gamma'\gamma^{-1} - 1)y \in ML \cap (A + \gamma' A)(\mathbb{A}_f) = M(L \cap (A + \gamma' A)(\mathbb{A}_f))$. Moreover $\varphi'(\gamma'\gamma^{-1}y) = (h(f_b, \gamma^{-1}y))_b = (h(\gamma f_b, y))_b = 0$. Therefore, with $Q = \varphi'(L \cap (A + \gamma' A)(\mathbb{A}_f))$,

$$\varphi'(v) = -\varphi'((\gamma'\gamma^{-1} - 1)y) + M\varphi'(a) \in MQ + MR' = MQ,$$

since $A_{\hat{\mathcal{O}}} \subseteq L \cap (A + \gamma' A)(\mathbb{A}_f)$ gives $R' \subseteq Q$.

Step 3 (the index). By Step 2, $v \mapsto M^{-1}\varphi'(v) + R'$ is a homomorphism $P \to Q/R'$. Its kernel is $P \cap L_c(\gamma') = L_{12}$. So P/L_{12} embeds in Q/R'. The map φ' sends $L \cap (A + \gamma' A)(\mathbb{A}_f)$ onto Q and $A_{\hat{\mathcal{O}}}$ onto R', and it kills $\gamma' A_{\hat{\mathcal{O}}}$, because $h(\gamma' f_b, \gamma' e_a) = h(f_b, e_a) = 0$. Here $\gamma' A_{\hat{\mathcal{O}}} = h_c k'(L_0 \cap A(\mathbb{A}_f)) \subseteq L$. So Q/R' is a quotient of

$$T = (L \cap (A + \gamma' A)(\mathbb{A}_f))/(A_{\hat{\mathcal{O}}} + \gamma' A_{\hat{\mathcal{O}}}),$$

and h_c (which fixes A, with $h_c k' A = \gamma' A$) identifies T with the quotient defining $\mathrm{ti}(k')$. If $\mathrm{ti}(k') = 0$ there is nothing to prove; otherwise T is finite of order $\mathrm{ti}(k')$, and $|P/L_{12}|$ divides $|Q/R'|$, which divides $|T|$. This proves (i).

Step 4 (sublattices). Let $L'' \subseteq L'$ be $\hat{\mathcal{O}}$-submodules of $X_0(\mathbb{A}_f)$ with $L' = B\hat{\mathcal{O}}^m$ a lattice of rank m ($B = x\alpha$, x of rank m over E, $\alpha \in \mathrm{GL}_m(\mathbb{A}_f)$) and $d = [L' : L''] \geq 1$. Then $dL' \subseteq L''$, so L'' is determined by its components $L''_w \subseteq L'_w$, equal to L'_w for $w \nmid d$; each L''_w has finite index in the free module L'_w of rank m over the discrete valuation ring $\hat{\mathcal{O}}_w$, hence $L''_w = B\, g_w \hat{\mathcal{O}}_w^m$ with $g_w \in \mathrm{M}_m(\hat{\mathcal{O}}_w)$, $\det g_w \neq 0$, and $g_w = 1$ for $w \nmid d$. With $g = (g_w) \in \mathrm{GL}_m(\mathbb{A}_f)$, $L'' = x(\alpha g)\hat{\mathcal{O}}^m$ is a lattice of rank m, and by the elementary divisor theorem $[L' : L''] = \prod_w |\det g_w|_w^{-1} = [\det g]$. Hence, by Definition 5.1.8,

$$\mathrm{disc}_m(L'') = [\det(g^* B^* B g)]^{1/2} = [\det g]\,[\det B^* B]^{1/2} = [L' : L'']\,\mathrm{disc}_m(L').$$

(ii). By (i) and $\mathrm{ti}(k') \geq 1$, $1 \leq [P : L_{12}] \leq \mathrm{ti}(k')$. Step 4 with $L' = P$, $L'' = L_{12}$ gives that L_{12} is a lattice of rank m with $\mathrm{disc}(L_{12}) = \mathrm{disc}_m(P)[P : L_{12}] \leq \mathrm{disc}_m(P)\,\mathrm{ti}(k')$. Finally let B be a basis matrix of L_{12} as in (LT3). Its columns lie in $L \cap X_0(\mathbb{A}_f)$, and $h(L, L) = h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24 (i), so B^*B (the form of X_0 is the unit form) has entries in $\hat{\mathcal{O}}$. Its determinant is $\overline{\det \alpha}\det(x^*x)\det\alpha$, a unit of $\mathbb{A}_f$, since $\det(x^*x) \neq 0$ (the unit form is positive definite at an infinite place and x has rank m). So $\det(B^*B) \in \hat{\mathcal{O}} \cap \mathbb{A}_f^\times$ and $\mathrm{disc}(L_{12})^2 = [\det B^* B] = [\hat{\mathcal{O}} : \det(B^*B)\hat{\mathcal{O}}] \geq 1$. □

Proposition 5.3.5. *Let $\mathfrak{S}$ be a filling datum with Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$ agreeing, γ a term over (c, s, c') satisfying the conditions of cell rank j, $\gamma' \in G(E)$, $k = h_c^{-1}\gamma h_{c'}$, c^+ the link corank of γ, γ', $m = \dim_E X_0(\gamma, \gamma')$, P the common part of γ with γ' at c, and $x \in \mathbb{N}$ at most the meet norm of s, such that $x = 1$ unless $\varrho < j$ and $c^+ = 0$. Then $\mathrm{ti}(k) \geq 1$, P is a lattice of rank m, and there are a finite family $q = (q_\rho)_{\rho \in R}$ of pairs spanning $\mathrm{link}\,\gamma \cap \mathrm{link}\,\gamma'$, pairs $y = (y_l)_{l < c^+}$ in $\mathrm{link}\,\gamma$, $\epsilon \in \mathrm{GL}_{c^+}(\mathbb{A}_f)$ and a matrix $\sigma \in \mathrm{M}_{R \times c^+}(\mathbb{A}_f)$ such that:*

- *(i) a combination $\sum_l \tau_l y_l$ ($\tau_l \in E$) lies in $\mathrm{link}\,\gamma \cap \mathrm{link}\,\gamma'$ only if $\tau = 0$, and q and y together span $\mathrm{link}\,\gamma$;*
- *(ii) the family $\left(\sum_\rho \sigma_{\rho l} q_\rho + \sum_{l'} \epsilon_{l'l} y_{l'}\right)_{l < c^+}$ has integral lifts for (c, γ);*
- *(iii) $\left(\mathrm{ti}(k) \cdot \mathrm{disc}_m(P) \cdot x\right)^2 \cdot \mathrm{lkd}(y, \epsilon) \leq \mathfrak{g}^*(j, c, c', \gamma)^2$.*

Proof. Write $L = \mathrm{link}\,\gamma \cap \mathrm{link}\,\gamma'$ and $L^0 = \{p \in L : \mathrm{zf}(p) = 0\}$, and

$$\Gamma = \max\Big(\prod_v |\mathfrak{g}(\gamma)|_v, N^f \mathrm{mn}_j(\gamma)\Big).$$

Step 1: three orthogonal bases. Let $\beta = (\beta_i)_{i<t}$ be a basis of L^0, $\eta = (\eta_l)_{l<r}$ a basis of the orthogonal complement of L^0 in L for the link metric, and $y = (y_l)_{l<t'}$ a basis of the orthogonal complement of L in $\mathrm{link}\,\gamma$. Then $(\beta|\eta)$ is a basis of L, $(\beta|\eta|y)$ is a basis of $\mathrm{link}\,\gamma$, and the three families are mutually orthogonal for the link metric. A pair p with $\mathrm{zf}(p) = 0$ has both members in X_0 (LK4); so by (LT2), $X_0(\gamma, \gamma')$ is the set of first members of the elements of L^0, i.e. the span of the first members of the β_i. If $\mathrm{zf}(\eta)\tau = 0$ for $\tau \in E^r$, then $\eta\tau \in L^0$ is a combination of the β_i, so $\tau = 0$: the $2 \times r$ matrix $\mathrm{zf}(\eta)$ has rank r. Finally $t + r = \dim L$ and $t + r + t' = \dim \mathrm{link}\,\gamma = \dim X_0 + 1$ (Lemma 5.2.28 (i)), so $t' = \dim X_0 + 1 - \dim L = c^+$ (LT5).

Step 2: the lattice of the link. By Lemma 5.3.6 for the basis $(\beta|\eta|y)$: $\mathrm{ir}_j(k) \geq 1$, $\mathrm{ir}_j(k^{-1}) \geq 1$, $\mathrm{ti}(k) \geq 1$, and there is $g \in \mathrm{GL}_{t+r+t'}(\mathbb{A}_f)$ such that $(\beta|\eta|y)g$ has level lifts for (c,γ) and

$$\mathrm{ti}(k)^2 \,\mathrm{lkd}((\beta|\eta|y), g) \leq \Big(\frac{M^{2\min(\varrho,j)f}\,\mathfrak{g}^\sharp(j,c,c',\gamma)}{N^f}\Big)^2. \tag{5.37}$$

Step 3: two orthogonal splittings. By Lemma 5.3.11 (i) for the orthogonal families $(\beta|\eta)$ and y and the matrix g, there are a_{12}, $\epsilon \in \mathrm{GL}_{c^+}(\mathbb{A}_f)$ and σ such that $(\beta|\eta)a_{12}$ and $(\beta|\eta)\sigma + y\epsilon$ have level lifts and $\mathrm{lkd}((\beta|\eta), a_{12})\,\mathrm{lkd}(y,\epsilon) = \mathrm{lkd}((\beta|\eta|y), g)$. Again by Lemma 5.3.11 (i), for β, η and a_{12}, there are a, $a' \in \mathrm{GL}_r(\mathbb{A}_f)$ and σ_0 such that βa and $\beta\sigma_0 + \eta a'$ have level lifts and $\mathrm{lkd}(\beta, a)\,\mathrm{lkd}(\eta, a') = \mathrm{lkd}((\beta|\eta), a_{12})$. Hence

$$\mathrm{lkd}(\beta, a)\,\mathrm{lkd}(\eta, a')\,\mathrm{lkd}(y,\epsilon) = \mathrm{lkd}((\beta|\eta|y), g). \tag{5.38}$$

Step 4: the common part. The β_i are linearly independent pairs in $\mathrm{link}\,\gamma$ with $\mathrm{zf}(\beta_i) = 0$, and βa has level lifts. By Lemma 5.3.11 (ii), with W the span of the first members, which is $X_0(\gamma,\gamma')$ by Step 1: $t = \dim X_0(\gamma,\gamma') = m$, the common part $P = \mathrm{sat}_c(X_0(\gamma,\gamma')) \cap L_c(\gamma)$ (LT4) is a lattice of rank m, and $\mathrm{disc}_m(P)^2 \leq \mathrm{lkd}(\beta, a)$.

Step 5: the part seen by the z-forms. We check the hypotheses of Lemma 5.3.11 (iii) for η, a' and $w = \beta\sigma_0 + \eta a'$. The η_l lie in $\mathrm{link}\,\gamma$ and $\mathrm{zf}(\eta)$ has rank r (Step 1); w has level lifts, hence integral lifts, and $\mathrm{zf}(w) = \mathrm{zf}(\beta)\sigma_0 + \mathrm{zf}(\eta)a' = \mathrm{zf}(\eta)a'$. By Lemma 5.3.13 (iii), $m + r = \dim L \leq m + 1 + \max(j - \varrho, 0)$, so $r \leq 1 + \max(j - \varrho, 0)$. If $x \neq 1$, then $\varrho < j$ and $c^+ = 0$ by hypothesis; so $\mathfrak{g}(\gamma) \neq 0$ (conditions of cell rank) and $\mathrm{link}\,\gamma = \mathrm{link}\,\gamma'$ (Lemma 5.3.13 (iv)), and by Lemma 5.3.13 (iv) $\dim L = m + 2$, i.e. $r = 2$. Hence

$$x^2\,\mathrm{mn}_j(\gamma)^2 \leq \mathrm{lkd}(\eta, a')\,\Gamma^2. \tag{5.39}$$

Step 6: assembly. Put $q = (\beta|\eta)$, indexed by $R = \{0,\dots,t-1\} \sqcup \{0,\dots,r-1\}$; it spans L. The family y has c^+ members (Step 1), lies in $\mathrm{link}\,\gamma$, is linearly independent modulo L, and $(q|y)$ spans $\mathrm{link}\,\gamma$: this is (i). The family $q\sigma + y\epsilon$ has level lifts, hence integral lifts, for (c,γ): this is (ii). For (iii), all factors being nonnegative, Step 4, (5.39), (5.38) and (5.37) give

$$\begin{aligned}\big(\mathrm{ti}(k)\,\mathrm{disc}_m(P)\,x\big)^2 \mathrm{lkd}(y,\epsilon)\,\mathrm{mn}_j(\gamma)^2 &\leq \mathrm{ti}(k)^2\,\mathrm{lkd}(\beta,a)\,\mathrm{lkd}(y,\epsilon)\,\mathrm{lkd}(\eta,a')\,\Gamma^2\\ &\leq \Big(\frac{M^{2\min(\varrho,j)f}\,\mathfrak{g}^\sharp(j,c,c',\gamma)}{N^f}\Big)^2\Gamma^2.\end{aligned}$$

By Lemma 5.3.9 (ii), applicable since $i_\gamma i'_\gamma \geq 1$ (Step 2), $\mathfrak{g}^\sharp(j,c,c',\gamma)/N^f = \mathrm{mn}_j(\gamma)/(i_\gamma i'_\gamma)$ and $\Gamma/(i_\gamma i'_\gamma) = \mathfrak{g}^{\max}(j,c,c',\gamma)$, so the right side equals $\big(M^{2\min(\varrho,j)f}\mathfrak{g}^{\max}(j,c,c',\gamma)\big)^2\mathrm{mn}_j(\gamma)^2 = \mathfrak{g}^*(j,c,c',\gamma)^2\,\mathrm{mn}_j(\gamma)^2$. Dividing by $\mathrm{mn}_j(\gamma)^2 > 0$ (Lemma 5.3.9 (i)) gives (iii). The first two claims, $\mathrm{ti}(k) \geq 1$ and that P is a lattice of rank m, were shown in Steps 2 and 4. □

Lemma 5.3.6. *Let $\mathfrak{S}$ be a filling datum with Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, γ a term over (c,s,c') satisfying the conditions of cell rank j, $k = h_c^{-1}\gamma h_{c'}$, and $v = (v_l)_{l\in\sigma}$ a basis of $\mathrm{link}\,\gamma$ over E. Then:*

(i) $\mathrm{ir}_j(k) \geq 1$, $\mathrm{ir}_j(k^{-1}) \geq 1$ *and* $\mathrm{ti}(k) \geq 1$;

(ii) there is $e \in \mathrm{GL}_\sigma(\mathbb{A}_f)$ such that the family $ve = \big(\sum_{l'} e_{l'l}v_{l'}\big)_{l\in\sigma}$ has level lifts for (c,γ) and

$$\mathrm{ti}(k)^2\,\mathrm{lkd}(v,e) \leq \Big(\frac{M^{2\min(\varrho,j)f}\,\mathfrak{g}^\sharp(j,c,c',\gamma)}{N^f}\Big)^2.$$

Proof. Let $\omega = \mathrm{ir}_j(k)\,\mathrm{ir}_j(k^{-1})\,\mathrm{ti}(k)$. By Lemma 5.3.7, $\omega \neq 0$, and there is $e_0 \in \mathrm{GL}_\sigma(\mathbb{A}_f)$ such that ve_0 has integral lifts for (c,γ) and $\mathrm{lkd}(v,e_0)\,\omega^2 \leq \mathrm{mn}_j(\gamma)^2$.

(i). The three indices are natural numbers with nonzero product, so each is at least 1.

(ii). By Lemma 5.3.10, applied to the family ve_0, there is an integral $B \in \mathrm{GL}_\sigma(\mathbb{A}_f)$ with $[\det B] \leq M^{2\min(\varrho,j)f}$ such that ve_0B has level lifts for (c,γ). Put $e = e_0B$. By (LK6), $\mathrm{lkd}(v,e) = \mathrm{lkd}(v,e_0)\,[\det B]^2$, so

$$\mathrm{ti}(k)^2\,\mathrm{lkd}(v,e) \leq M^{4\min(\varrho,j)f}\,\frac{\mathrm{lkd}(v,e_0)\,\omega^2}{(\mathrm{ir}_j(k)\,\mathrm{ir}_j(k^{-1}))^2} \leq \Big(\frac{M^{2\min(\varrho,j)f}\,\mathrm{mn}_j(\gamma)}{\mathrm{ir}_j(k)\,\mathrm{ir}_j(k^{-1})}\Big)^2.$$

By Lemma 5.3.9 (ii) (with $h_c^{-1}\gamma h_{c'} = k \in K$ and $i_\gamma i'_\gamma \geq 1$ by (i)), $\mathrm{mn}_j(\gamma)/(\mathrm{ir}_j(k)\,\mathrm{ir}_j(k^{-1})) = \mathfrak{g}^\sharp(j,c,c',\gamma)/N^f$, which gives (ii). □

Lemma 5.3.7. *Let $\mathfrak{S}$ be a filling datum with Weil data, $c,c' \in \mathcal{C}$, $s \in \bar{G}$, γ a term over (c,s,c') satisfying the conditions of cell rank j, $k = h_c^{-1}\gamma h_{c'}$, $v = (v_l)_{l\in\sigma}$ a basis of $\mathrm{link}\,\gamma$, and $\omega = \mathrm{ir}_j(k)\,\mathrm{ir}_j(k^{-1})\,\mathrm{ti}(k)$. Then $\omega \neq 0$, and there is $e \in \mathrm{GL}_\sigma(\mathbb{A}_f)$ such that ve has integral lifts for (c,γ) and*

$$\mathrm{lkd}(v,e)\,\omega^2 \leq \mathrm{mn}_j(\gamma)^2.$$

Proof. Write $j' = \min(j,\varrho)$, $\mathcal{B} = \{a : j' \leq a < \varrho\}$, $I = X \cap \gamma X$, $W = (X+\gamma X)^\perp$, $\Phi(t) = ([t],[\gamma^{-1}t])$ for $t \in W(\mathbb{A}_f)$, and $r = 2\varrho + \dim X_0 + 1 = \dim V$. By Lemma 5.2.28 (i), Φ maps W onto $\mathrm{link}\,\gamma$ with kernel I, and $\#\sigma = \dim X_0 + 1$.

Step 0: coordinates. The element $h_c \in \mathrm{U}(X_0)(\mathbb{A}_f)$ is an isometry fixing f_a, f_a^*, z; $h_{c'}$ likewise. By Lemma 5.2.24 (i), L_0 is self-dual for h, hence so is L_c. Let $\mathrm{cc}_c\colon V(\mathbb{A}_f) \to \mathbb{A}_f^r$ be the coordinates in the $\hat{\mathcal{O}}$-basis h_c(lattice basis) of L_c, and J the Gram matrix of that basis, so $h(x,y) = \mathrm{cc}_c(x)^* J \mathrm{cc}_c(y)$, $J^* = J$, J is integral and, L_c being self-dual, $\det J \in \hat{\mathcal{O}}^\times$. The lattice basis contains the f_a ($a < \varrho$), and no other vector of it has a component along f_a; so the cc_c-coordinate of x at f_a is its f_a-coordinate in $V = X \oplus X^* \oplus X_0 \oplus Ez$, which is integral for $x \in L_c$. Moreover $f_a \in L_c$ and $\gamma f_a = h_c k h_{c'}^{-1} f_a = h_c k f_a \in L_c$, as $kL_0 = L_0$ (Lemma 5.2.24 (ii)).

Step 1: vectors of I. For $a \in \mathcal{B}$ (so $j \leq a < \varrho$) the conditions of cell rank give $x^{(a)}, y^{(a)} \in E^{\varrho+1}$ supported on $\{0,\dots,a\}$, $x_a^{(a)} \neq 0$, with $\sum_b x_b^{(a)} f_b = \gamma \sum_b y_b^{(a)} f_b$; this vector lies in $X \cap \gamma X = I$. The matrix of the $f_{a'}$-coordinates ($a' \in \mathcal{B}$) of these vectors is triangular with nonzero diagonal, so suitable combinations $w_a \in I$ ($a \in \mathcal{B}$) have $f_{a'}$-coordinate $\delta_{aa'}$ for $a' \in \mathcal{B}$; in particular $\dim I \geq \varrho - j'$.

Step 2: a rational lift. Choose $t_l \in W$ with $\Phi(t_l) = v_l$ and replace t_l by

$$t_l - \sum_{a\in\mathcal{B}} (f_a\text{-coordinate of } t_l)\, w_a;$$

as $I \subseteq W$ and $\Phi(I) = 0$, still $t_l \in W$, $\Phi(t_l) = v_l$, and now the f_a-coordinates of t_l vanish for $a \in \mathcal{B}$. The family $u = (w_a)_{a\in\mathcal{B}} \cup (t_l)_{l\in\sigma}$ is linearly independent: applying Φ to a vanishing combination kills the w_a and gives a relation among the v_l, and then the $f_{\mathcal{B}}$-coordinates give the rest.

Step 3: primitive completion. Let $Y = \mathrm{cc}_c(u)$, a matrix over $\mathbb{A}_f$ with a left inverse (a rational left inverse of u composed with cc_c^{-1}). The saturation $S_Y = \hat{\mathcal{O}}^r \cap Y\mathbb{A}_f^{\mathcal{B}\sqcup\sigma}$ is at each finite place w a direct summand of $\mathcal{O}_w^r$ (the quotient is torsion free), free of rank $\#\mathcal{B}+\#\sigma$, and equals $Y_w\mathcal{O}_w^{\mathcal{B}\sqcup\sigma}$ for almost all w; so $S_Y = Yg$ with $g \in \mathrm{GL}_{\mathcal{B}\sqcup\sigma}(\mathbb{A}_f)$, and any $\hat{\mathcal{O}}$-basis of S_Y is primitive. By the Iwasawa decomposition of GL_n over a non-archimedean local field with respect to the standard

parabolic subgroup of block upper triangular matrices (blocks $\mathcal{B}$, σ), applied at each place, with the trivial decomposition at the almost all places where g is integral, write $g = \begin{pmatrix} \alpha & \varsigma \\ 0 & e \end{pmatrix} \eta_0$ with $\alpha \in \mathrm{GL}_{\mathcal{B}}(\mathbb{A}_f)$, $e \in \mathrm{GL}_\sigma(\mathbb{A}_f)$, $\eta_0 \in \mathrm{GL}(\hat{\mathcal{O}})$; then $P := Y \begin{pmatrix} \alpha & \varsigma \\ 0 & e \end{pmatrix} = Y g \eta_0^{-1}$ is a basis of S_Y, hence primitive and integral. Its columns are $\mathrm{cc}_c(x_a)$, $x_a = \sum_{a'} \alpha_{a'a} w_{a'} \in L_c \cap I(\mathbb{A}_f)$ ($a \in \mathcal{B}$), and $\mathrm{cc}_c(n_l)$, $n_l = \sum_a \varsigma_{al} w_a + \sum_{l'} e_{l'l} t_{l'} \in L_c$. Since $\Phi(n_l) = \sum_{l'} e_{l'l} v_{l'}$, the family ve has integral lifts for (c, γ) (LK5), by the vectors u and the coefficients $\begin{pmatrix} \varsigma \\ e \end{pmatrix}$. The $f_{a'}$-coordinates ($a' \in \mathcal{B}$) of x_a are the entries $\alpha_{a'a}$; by Step 0, α is integral, and $[\det \alpha] = [\hat{\mathcal{O}}^{\mathcal{B}} : \alpha \hat{\mathcal{O}}^{\mathcal{B}}]$.

Step 4: the data of Jacobi's identity. Let $F = \mathrm{cc}_c(f_0, \dots, f_{\varrho-1}, \gamma f_0, \dots, \gamma f_{j'-1})$, integral by Step 0, with $m_1 = \varrho + j'$ columns; P has $m_2 = (\varrho - j') + \dim X_0 + 1$ columns, and $m_1 + m_2 = r$. The columns of P are coordinates of vectors of $W(\mathbb{A}_f)$, orthogonal to $X + \gamma X$, so $F^* J P = 0$. Let $Q = \mathrm{cc}_c((f_a^*)_{a \in \mathcal{B}}, z, \gamma z)$, $m_3 = \#\mathcal{B} + 2$, and $t = N$. Then $\mathcal{M}$ of Lemma 5.3.8 is the Gram matrix for h of the vectors f_a ($a < \varrho$), γf_a ($a < j'$), f_a^* ($a \in \mathcal{B}$), z, γz, with N added to the diagonal entries of the last m_3.

Step 5: $[\det \mathcal{M}] = (N^{2f} \mathrm{mn}_j(\gamma))^2$. Order the vectors as

$$(f_0, \dots, f_{\varrho-1}, z\,;\, \gamma f_0, \dots, \gamma f_{j'-1}, (f_a^*)_{a \in \mathcal{B}}, \gamma z),$$

two blocks of $\varrho + 1$ (a simultaneous permutation of rows and columns, which does not change the determinant). The first diagonal block is the Gram matrix $\mathrm{diag}(0, \dots, 0, -N)$ of the frame plus N at z, i.e. 0. The upper right block $G_{12} = (h(f_a, g_b))$ has, for $g_b = \gamma f_b$ ($b < j'$) and $g_b = \gamma z$ ($b = \varrho$), the column b of $Z(\gamma)$, and for $g_b = f_b^*$ ($b \in \mathcal{B}$) the standard column ε_b ($h(f_a, f_b^*) = \delta_{ab}$, $h(z, f_b^*) = 0$). Expanding along these standard columns, $\det G_{12}$ is the minor of $Z(\gamma)$ on the rows and columns $\{a < j'\} \cup \{\varrho\}$, which is $\underline{\delta_*(\gamma)}$ (for $j = \varrho + 1$ both sets are $\{0, \dots, \varrho\}$). The lower left block is G_{12}^*, so $\det \mathcal{M} = \pm \delta_*(\gamma) \overline{\delta_*(\gamma)}$, and $[\det \mathcal{M}] = |N_{E/\mathbb{Q}} \delta_*(\gamma)|^2 = (N^{2f} \mathrm{mn}_j(\gamma))^2$ by Lemma 5.3.9 (i); it is nonzero, so $\det \mathcal{M}$ is a unit.

Step 6: the matrix R. For $t, t' \in W(\mathbb{A}_f)$: $[t] - t$ and $[\gamma^{-1} t] - \gamma^{-1} t$ lie in $X(\mathbb{A}_f)$, which is isotropic and orthogonal to t', $\gamma^{-1} t'$ and z; so $h([t], [t']) = h(t, t') = h([\gamma^{-1} t], [\gamma^{-1} t'])$, $h(z, [t]) = h(z, t)$, $h(z, [\gamma^{-1} t]) = h(\gamma z, t)$. For $a = y_0 + \lambda z$, $b = y_0' + \lambda' z$ in V_0, (LK1) gives $\langle a^+, b^+ \rangle_+ = h(a, b) + 2N \bar{\lambda} \lambda' = h(a, b) + 2N^{-1} \overline{h(z, a)} h(z, b)$. With (LK3),

$$\langle \Phi(t), \Phi(t') \rangle_{\mathrm{mt}} = h(t, t') + N^{-1} (\overline{h(z, t)} h(z, t') + \overline{h(\gamma z, t)} h(\gamma z, t')). \tag{5.40}$$

Now

$$R = P_0^* R_u P_0 \quad \text{with} \quad P_0 = \begin{pmatrix} \alpha & \varsigma \\ 0 & e \end{pmatrix}$$

and R_u the matrix of $h(u_x, u_y) + N^{-1} \sum_q \overline{h(q, u_x)} h(q, u_y)$, q over f_a^* ($a \in \mathcal{B}$), z, γz. As $h(f_a^*, x)$ is the f_a-coordinate of x: the w_a lie in I, which is orthogonal to W and to z (as $I \subseteq X$) and to γz (as $I \subseteq \gamma X$), and have $f_{\mathcal{B}}$-coordinates δ; the t_l have $f_{\mathcal{B}}$-coordinates 0. Hence $R_u = \mathrm{diag}(N^{-1} \cdot 1_{\mathcal{B}},\ (\langle v_l, v_{l'} \rangle_{\mathrm{mt}})_{l,l'})$ by (5.40). So $\det R = \overline{\det P_0} \det P_0\, N^{-\#\mathcal{B}} \det(\langle v_l, v_{l'} \rangle_{\mathrm{mt}})$, a unit by Lemma 5.2.28 (v), and $[\det R] = [\det \alpha]^2 N^{-2f\#\mathcal{B}} \,\mathrm{lkd}(v, e)$.

Step 7: the identity. By Lemma 5.3.8, F is injective, $i(F)$ is finite, and $(N^{2f} \mathrm{mn}_j(\gamma))^2 = N^{2f(\#\mathcal{B}+2)}\, i(F)^2\, [\det \alpha]^2 N^{-2f\#\mathcal{B}} \,\mathrm{lkd}(v, e)$, i.e.

$$\mathrm{mn}_j(\gamma)^2 = i(F)^2\, [\det \alpha]^2 \,\mathrm{lkd}(v, e). \tag{5.41}$$

Step 8: $\mathrm{ir}_j(k)$ *divides* $[\det \alpha]$. Let $\varphi \colon \hat{\mathcal{O}}^{\varrho} \to \sum_a \hat{\mathcal{O}} r_a(k)$, $c \mapsto \sum_a c_a r_a(k) = (h(k f_b, \sum_a c_a f_a))_b$. It is onto, so $\mathrm{ir}_j(k) = [\hat{\mathcal{O}}^{\varrho} : \hat{\mathcal{O}}^{\{a<j'\}} + \ker \varphi] = [\hat{\mathcal{O}}^{\mathcal{B}} : \pi_{\mathcal{B}}(\ker \varphi)]$, $\pi_{\mathcal{B}}$ the projection to the

coordinates in $\mathcal{B}$. For $a \in \mathcal{B}$ let $c(x_a) \in \hat{\mathcal{O}}^\varrho$ be the f-coordinates of $x_a \in I(\mathbb{A}_f)$ (Step 0). As $kf_b = h_c^{-1}\gamma f_b$ and h_c fixes X, $h(kf_b, x_a) = h(\gamma f_b, x_a) = 0$, since $x_a \in \gamma X(\mathbb{A}_f)$ and $\gamma X \perp \gamma X + E\gamma z$. So $c(x_a) \in \ker\varphi$ and $\pi_{\mathcal{B}}(c(x_a))$ is column a of α: $\alpha\hat{\mathcal{O}}^{\mathcal{B}} \subseteq \pi_{\mathcal{B}}(\ker\varphi)$, and $\mathrm{ir}_j(k)$ divides $[\det\alpha]$.

Step 9: $\mathrm{ir}_j(k^{-1})\,\mathrm{ti}(k)$ *divides* $i(F)$. Applying h_c^{-1} (an isometry with $h_c^{-1}L_c = L_0$, $h_c^{-1}f_a = f_a$, $h_c^{-1}\gamma f_a = kf_a$), $i(F) = [S : F']$ with $F' = L_X + \sum_{a<j'}\hat{\mathcal{O}}kf_a$ and $S = L_0 \cap U$, U the $\mathbb{A}_f$-span of f_a ($a < \varrho$), kf_a ($a < j'$), of rank $\varrho + j'$ (F is injective). As $U \subseteq (X + kX)(\mathbb{A}_f)$ and $\dim(X + kX) = \dim(X + \gamma X) = 2\varrho - \dim I \le \varrho + j'$ (Step 1; $kX = h_c^{-1}\gamma X$), $U = (X + kX)(\mathbb{A}_f)$. So $F' \subseteq L_X + kL_X \subseteq S$ and $[S : F'] = \mathrm{ti}(k)\,[L_X + kL_X : F']$. As $F' \supseteq L_X$, $[L_X + kL_X : F'] = [kL_X : kL_X \cap F']$, and $kL_X \cap F' = k(L_X^{<j'} + D)$ with $L_X^{<j'} = \bigoplus_{a<j'}\hat{\mathcal{O}}f_a$ and $D = \{x \in L_X : kx \in L_X\}$; hence $[L_X + kL_X : F'] = [\hat{\mathcal{O}}^{\mathcal{B}} : \pi_{\mathcal{B}}(c(D))]$. On the other hand, as in Step 8, $\mathrm{ir}_j(k^{-1}) = [\hat{\mathcal{O}}^{\mathcal{B}} : \pi_{\mathcal{B}}(\ker\varphi')]$ for $\varphi'(c) = (h(k^{-1}f_b, \sum_a c_a f_a))_b = (h(f_b, k\sum_a c_a f_a))_b$, and $c(D) \subseteq \ker\varphi'$ because $kx \in X(\mathbb{A}_f)$ is orthogonal to the frame for $x \in D$. Hence $\mathrm{ir}_j(k^{-1})$ divides $[L_X + kL_X : F']$, and $\mathrm{ir}_j(k^{-1})\mathrm{ti}(k)$ divides $i(F)$.

Conclusion. By Steps 8 and 9, ω divides $[\det\alpha]\,i(F)$, which is a nonzero natural number; so $\omega \neq 0$ and $\omega \le [\det\alpha]\,i(F)$, and (5.41) gives $\mathrm{lkd}(v,e)\,\omega^2 \le \mathrm{mn}_j(\gamma)^2$. □

Lemma 5.3.8. *Let E be a CM field, $m_1, m_2, m_3 \ge 0$ integers and $m = m_1 + m_2$. Let $J \in \mathrm{M}_m(\hat{\mathcal{O}})$ with $J^* = J$ and $\det J \in \hat{\mathcal{O}}^\times$; $F \in \mathrm{M}_{m\times m_1}(\hat{\mathcal{O}})$; $P \in \mathrm{M}_{m\times m_2}(\hat{\mathcal{O}})$ primitive, i.e. its columns are part of an $\hat{\mathcal{O}}$-basis of $\hat{\mathcal{O}}^m$; $Q \in \mathrm{M}_{m\times m_3}(\mathbb{A}_f)$; and $t \in \mathbb{A}_f^\times$ with $\bar{t} = t$. Suppose $F^*JP = 0$, and put*

$$\mathcal{M} = \begin{pmatrix} F^*JF & F^*JQ \\ Q^*JF & Q^*JQ + t\cdot 1 \end{pmatrix}, \qquad R = P^*(J + t^{-1}JQQ^*J)P.$$

If $\det\mathcal{M}$ and $\det R$ are units of $\mathbb{A}_f$, then $y \mapsto Fy$ is injective on $\mathbb{A}_f^{m_1}$, $\{u \in \mathbb{A}_f^m : P^*Ju = 0\} = F\mathbb{A}_f^{m_1}$, the index $i(F) = [\{y \in \mathbb{A}_f^{m_1} : Fy \in \hat{\mathcal{O}}^m\} : \hat{\mathcal{O}}^{m_1}]$ is finite, and

$$[\det\mathcal{M}] = [t]^{m_3}\,i(F)^2\,[\det R].$$

Proof. All determinants are taken over the commutative ring $\mathbb{A}_f$; $\det(Z^*) = \overline{\det Z}$ and $[\bar{x}] = [x]$.

Dual bases. Complete P to $U = (C \mid P) \in \mathrm{GL}_m(\hat{\mathcal{O}})$, and put $U' = J^{-1}(U^*)^{-1} \in \mathrm{GL}_m(\hat{\mathcal{O}})$, so that $U^*JU' = 1$; write $U' = (C' \mid P')$ with C' the first m_1 columns. Every matrix Z with m rows satisfies $Z = U'(U^*JZ)$, because $U'U^*J = 1$. In particular, as $P^*JF = (F^*JP)^* = 0$,

$$U^*JF = \begin{pmatrix} G \\ 0 \end{pmatrix}, \qquad G := C^*JF \in \mathrm{M}_{m_1}(\hat{\mathcal{O}}), \qquad F = C'G. \tag{5.42}$$

An enlarged family. On $\mathbb{A}_f^m \oplus \mathbb{A}_f^{m_3}$ consider the matrix $\hat{J} = \begin{pmatrix} J & 0 \\ 0 & t\cdot 1 \end{pmatrix}$ and the square matrix of size $m + m_3$

$$T = \begin{pmatrix} F & Q & P \\ 0 & 1 & Y \end{pmatrix}, \qquad Y = -t^{-1}Q^*JP,$$

whose three column blocks we call f, q, p. Using $J^* = J$, $\bar{t} = t$ and $F^*JP = 0$: $f^*\hat{J}p = F^*JP = 0$; $q^*\hat{J}p = Q^*JP + tY = 0$; $p^*\hat{J}p = P^*JP + Y^*tY = P^*JP + t^{-1}P^*JQQ^*JP = R$; and the block of $(f \mid q)$ is $\mathcal{M}$. Hence $T^*\hat{J}T = \begin{pmatrix} \mathcal{M} & 0 \\ 0 & R \end{pmatrix}$, and

$$\overline{\det T}\,\det T\,\det J\,t^{m_3} = \det\mathcal{M}\,\det R. \tag{5.43}$$

The determinant of T. Right multiplication by $\begin{pmatrix} 1 & 0 & 0 \\ 0 & 1 & -Y \\ 0 & 0 & 1 \end{pmatrix}$ (determinant 1) turns T into $\begin{pmatrix} F & Q & P-QY \\ 0 & 1 & 0 \end{pmatrix}$, so $\det T = \pm \det(F \mid P-QY)$, with $P-QY = P+t^{-1}QQ^*JP$. By the first paragraph, $(F \mid P-QY) = U' \cdot U^*J(F \mid P-QY)$, and by (5.42) the matrix $U^*J(F \mid P-QY)$ is block upper triangular with diagonal blocks G and $P^*J(P+t^{-1}QQ^*JP) = R$. Hence $\det T = \pm \det U' \det G \det R$.

Conclusion. Inserting this into (5.43) and cancelling the unit $\det R$,

$$\det \mathcal{M} = \epsilon\, t^{m_3}\, \overline{\det G}\, \det G\, \overline{\det R}, \qquad \epsilon = \overline{\det U'}\, \det U'\, \det J \in \hat{\mathcal{O}}^\times.$$

As $\det \mathcal{M}$ is a unit, so is $\det G$; so $G \in \mathrm{GL}_{m_1}(\mathbb{A}_f)$ and $F = C'G$ is injective. Taking generalised indices, $[\det \mathcal{M}] = [t]^{m_3}[\det G]^2[\det R]$. Since $U' \in \mathrm{GL}_m(\hat{\mathcal{O}})$, a vector $C'x$ is integral exactly when x is; so $Fy = C'Gy \in \hat{\mathcal{O}}^m$ if and only if $Gy \in \hat{\mathcal{O}}^{m_1}$, i.e. $\{y : Fy \in \hat{\mathcal{O}}^m\} = G^{-1}\hat{\mathcal{O}}^{m_1}$, which contains $\hat{\mathcal{O}}^{m_1}$ because G is integral, with index $[\hat{\mathcal{O}}^{m_1} : G\hat{\mathcal{O}}^{m_1}] = [\det G]$. Thus $i(F) = [\det G]$ is finite and the identity follows. Finally, writing $u = U'x$ with $x = (x_1, x_2)$, we have $P^*Ju = P^*JU'x = x_2$ (the last m_2 rows of $U^*JU' = 1$), so $P^*Ju = 0$ if and only if $u \in C'\mathbb{A}_f^{m_1} = F\mathbb{A}_f^{m_1}$. □

Lemma 5.3.9. *Let $\mathfrak{S}$ be a filling datum and $\gamma \in G(E)$ satisfying the conditions of cell rank j.*

(i) $|N_{E/\mathbb{Q}}\delta_*(\gamma)| = N^{2f}\,\mathrm{mn}_j(\gamma)$*; in particular* $\delta_*(\gamma) \neq 0$ *and* $\mathrm{mn}_j(\gamma) > 0$.

(ii) Let $c, c' \in \mathcal{C}$ with $h_c^{-1}\gamma h_{c'} \in K$ and $i_\gamma i'_\gamma \neq 0$. Then

$$\mathrm{g}^\sharp(j,c,c',\gamma) = \frac{N^f\,\mathrm{mn}_j(\gamma)}{i_\gamma i'_\gamma}, \qquad \mathrm{g}^{\max}(j,c,c',\gamma) = \frac{\max\big(\prod_v |\mathrm{g}(\gamma)|_v,\ N^f\mathrm{mn}_j(\gamma)\big)}{i_\gamma i'_\gamma}.$$

Proof. Throughout, h is linear in its second argument, so that $Z(\gamma)y$ is the vector

$$\big(h(f_a, \gamma \sum_b y_b f_b)\big)_a$$

for $y \in E^{\varrho+1}$. The frame vectors $f_a = e_{a+1}$, $a < \varrho$, are isotropic and orthogonal to every frame vector, and $h(z,z) = -N$; hence for $x \in E^{\varrho+1}$

$$h\Big(f_a, \sum_b x_b f_b\Big) = 0 \ (a < \varrho), \qquad h\Big(z, \sum_b x_b f_b\Big) = -N x_\varrho, \qquad h\Big(\sum_b x_b f_b, \sum_b x_b f_b\Big) = -N\bar{x}_\varrho x_\varrho. \tag{5.44}$$

For $\xi \in E$ we use $|N_{E/\mathbb{Q}}\xi| = \prod_v |\xi|_v^2$ over the f complex places, and $N_{E/\mathbb{Q}}(N) = N^{2f}$.

(i), the case $\varrho < j$. Then $j = \varrho + 1$, the index set $\{a : a < j\} \cup \{\varrho\}$ is $\{0, \dots, \varrho\}$, and $\delta_*(\gamma) = \det Z(\gamma) = D_{\varrho+1}(\gamma)$. By definition $\mathrm{mn}_{\varrho+1}(\gamma) = |N_{E/\mathbb{Q}}D_{\varrho+1}(\gamma)|/N^{2f}$, which is the claim.

(i), the case $j \leq \varrho$. Let B be the square matrix of size $\varrho+1$ whose rows of index $a < j$ are those of $Z(\gamma)$ and whose rows of index $a \geq j$ are those of the identity matrix. It is block upper triangular with diagonal blocks the leading $j \times j$ block of $Z(\gamma)$ and an identity block, so $\det B = D_j(\gamma)$, which is nonzero by the conditions of cell rank j. Let $y = B^{-1}\varepsilon_\varrho$, ε_ϱ the last standard basis vector. Reading $By = \varepsilon_\varrho$ row by row:

$$(Z(\gamma)y)_a = 0 \ (a < j), \qquad y_a = 0 \ (j \leq a < \varrho), \qquad y_\varrho = 1. \tag{5.45}$$

Let B' be B with its row ϱ replaced by the row ϱ of $Z(\gamma)$. Expanding $\det B'$ successively along the rows $a = j, \dots, \varrho - 1$, each of which is the a-th standard row vector, deletes these rows and the same columns with sign $+1$; what remains is the minor of $Z(\gamma)$ on the rows and columns $\{a : a < j\} \cup \{\varrho\}$, so $\det B' = \delta_*(\gamma)$. On the other hand, expanding along row ϱ, $\det B' = \sum_b Z(\gamma)_{\varrho b} C_{\varrho b}$ with the cofactors $C_{\varrho b}$ of B, and $C_{\varrho b} = (\operatorname{adj} B)_{b\varrho} = \det B \cdot (B^{-1})_{b\varrho} = D_j(\gamma)\, y_b$. Hence

$$\delta_*(\gamma) = (Z(\gamma)y)_\varrho \cdot D_j(\gamma). \tag{5.46}$$

We show that $t = \gamma \sum_b y_b f_b$ lies in the span of the frame. By the conditions of cell rank j there are ζ with $\zeta\bar\zeta = 1$ and, for each a with $j \le a \le \varrho$, vectors $x^{(a)}, y^{(a)} \in E^{\varrho+1}$ with $\sum_b x_b^{(a)} f_b = \gamma \sum_b y_b^{(a)} f_b$, $y_a^{(a)} = 1$ and $y_b^{(a)} = 0$ for $b > a$. The vectors $y^{(\varrho)}, y^{(\varrho-1)}, \dots, y^{(j)}$ and $\varepsilon_0, \dots, \varepsilon_{j-1}$ form a basis of $E^{\varrho+1}$ (triangular with ones on the diagonal), so $y = \sum_{a=j}^{\varrho} d_a y^{(a)} + \sum_{b<j} c_b \varepsilon_b$ with $d_a, c_b \in E$. Then $t = \sum_b x_b f_b + \gamma \sum_{b<j} c_b f_b$ with $x = \sum_a d_a x^{(a)}$. For $a' < j$ the first identity of (5.44) and (5.45) give

$$0 = (Z(\gamma)y)_{a'} = h(f_{a'}, t) = \sum_{b<j} c_b\, h(f_{a'}, \gamma f_b) = \sum_{b<j} Z(\gamma)_{a'b}\, c_b,$$

so $c = 0$, the leading $j \times j$ block of $Z(\gamma)$ being invertible. Thus $t = \sum_b x_b f_b$. As γ is an isometry, the last identity of (5.44) applied to x and to y gives $-N\bar x_\varrho x_\varrho = h(t,t) = h(\sum_b y_b f_b, \sum_b y_b f_b) = -N\bar y_\varrho y_\varrho = -N$, so $\bar x_\varrho x_\varrho = 1$ and $|x_\varrho|_v = 1$ at every infinite place v. By the middle identity of (5.44), $(Z(\gamma)y)_\varrho = h(z,t) = -N x_\varrho$, and (5.46) gives $\delta_*(\gamma) = -N x_\varrho D_j(\gamma)$. Taking absolute norms, $|N_{E/\mathbb{Q}}\delta_*(\gamma)| = N^{2f}\, |N_{E/\mathbb{Q}} D_j(\gamma)| = N^{2f} \mathrm{mn}_j(\gamma)$, since $\max(j - \varrho, 0) = 0$.

In both cases $\mathrm{mn}_j(\gamma) > 0$ because $D_j(\gamma) \neq 0$, and therefore $\delta_*(\gamma) \neq 0$.

(ii). By (TA12) and (i), $\mathsf{g}^\sharp(j, c, c', \gamma) = |N_{E/\mathbb{Q}}\delta_*(\gamma)|/(i_\gamma i'_\gamma N^f) = N^f \mathrm{mn}_j(\gamma)/(i_\gamma i'_\gamma)$. For the maximal gauge, $\mathsf{g}^{\max} = \max(\mathsf{g}^\sharp, \prod_v |\mathsf{g}(\gamma)|_v)$. If $\mathsf{g}(\gamma) = 0$, both sides of the claimed identity equal $N^f \mathrm{mn}_j(\gamma)/(i_\gamma i'_\gamma)$. If $\mathsf{g}(\gamma) \neq 0$, the conditions of cell rank give $\varrho < j$, i.e. $j = \varrho + 1$; then $\min(j, \varrho) = \varrho$ and both indices of (GT1) are 1 (the two sums of row lattices coincide), so $i_\gamma = i'_\gamma = 1$ and both sides equal $\max(N^f \mathrm{mn}_j(\gamma), \prod_v |\mathsf{g}(\gamma)|_v)$.

□

Lemma 5.3.10. *Let $\mathfrak{S}$ be a filling datum, $c \in \mathcal{C}$, $\gamma \in G(E)$ satisfying the conditions of cell rank j, and $w = (w_l)_{l\in\sigma}$ a family of adelic pairs with integral lifts for (c, γ). Then there is $B \in \mathrm{GL}_\sigma(\mathbb{A}_f)$ with entries in $\hat{\mathcal{O}}$ and $[\det B] \le M^{2\min(\varrho, j) f}$ such that $wB = (\sum_{l'} B_{l'l} w_{l'})_{l\in\sigma}$ has level lifts for (c, γ).*

Proof. Let $L_X = \bigoplus_{a=1}^{\varrho} \hat{\mathcal{O}} e_a$, $I = X \cap \gamma X$, and let $\Pi\colon X(\mathbb{A}_f) \to \mathbb{A}_f^{\varrho+1}$, $\Pi(x) = (h(\gamma f_b, x))_{0\le b\le\varrho}$; Π is given by a matrix over E.

Step 1: the kernel of Π is $I(\mathbb{A}_f)$. Since Π is rational, it suffices to show $\{x \in X : \Pi(x) = 0\} = I$. If $x \in I$, then $x \perp \gamma X$ (γX is isotropic) and $x \perp \gamma z$ ($z \perp X$). Conversely let $x \in X$ with $x \perp \gamma X$ and $x \perp \gamma z$. Then $x' = \gamma^{-1} x$ is isotropic, orthogonal to X and to z. In $V = X \oplus X^* \oplus X_0 \oplus Ez$ (X^* the span of the e_a^*) we have $X^\perp = X \oplus X_0 \oplus Ez$, so $x' = x_1 + y_0 + \lambda z$ with $x_1 \in X$, $y_0 \in X_0$; $h(z, x') = -N\lambda = 0$ gives $\lambda = 0$, and then $0 = h(x', x') = h(y_0, y_0)$ gives $y_0 = 0$, the form of X_0 being the unit form. So $x' \in X$ and $x \in \gamma X$.

Step 2: $\dim_E \Pi(X) \le \min(\varrho, j)$. By Step 1, $\dim \Pi(X) = \varrho - \dim I$. If $j \ge \varrho$ there is nothing to show. If $j < \varrho$, the conditions of cell rank give, for each a with $j \le a < \varrho$, vectors $x^{(a)}, y^{(a)} \in E^{\varrho+1}$ supported on $\{0, \dots, a\}$ with $x_a^{(a)} = \zeta \neq 0$ and $\sum_b x_b^{(a)} f_b = \gamma \sum_b y_b^{(a)} f_b$. As $a < \varrho$, this vector lies in $X \cap \gamma X = I$, and the $\varrho - j$ vectors obtained are linearly independent (their coefficient vectors $x^{(a)}$ are triangular with nonzero diagonal entries). So $\dim I \ge \varrho - j$.

Step 3: the module $L_\Pi = \Pi(L_X)$. It is a finitely generated $\hat{\mathcal{O}}$-module, isomorphic to $L_X/(L_X \cap I(\mathbb{A}_f))$, which is torsion free ($I(\mathbb{A}_f)$ is an $\mathbb{A}_f$-subspace) and of rank $d_\Pi = \dim_E \Pi(X)$ at every finite place; hence $L_\Pi \cong \hat{\mathcal{O}}^{d_\Pi}$, and $\#(L_\Pi/ML_\Pi) = [\hat{\mathcal{O}} : M\hat{\mathcal{O}}]^{d_\Pi} = M^{2fd_\Pi} \le M^{2f\min(\varrho,j)}$ by Step 2, since $[\hat{\mathcal{O}} : M\hat{\mathcal{O}}] = |N_{E/\mathbb{Q}}(M)| = M^{2f}$.

Step 4: the matrix B. Let (t_ρ), u give integral lifts of w, and $n_l = \sum_\rho u_{\rho l} t_\rho \in L_c$. No vector of the lattice basis other than e_a has a component along e_a, and h_c does not change these components, so the e_a-coordinates of elements of L_c lie in $\hat{\mathcal{O}}$; as $n_l \perp X$, its e_a^*-coordinates vanish. Hence $n_l = \alpha_l + n_l'$ with $\alpha_l \in L_X$ and $n_l' \in (X_0 \oplus Ez)(\mathbb{A}_f)$; note $L_X \subseteq L_c$. Let $F\colon \hat{\mathcal{O}}^\sigma \to L_\Pi$, $F(x) = \Pi(\sum_l x_l \alpha_l)$, and $\Sigma = F^{-1}(ML_\Pi)$. Then F induces an injection $\hat{\mathcal{O}}^\sigma/\Sigma \to L_\Pi/ML_\Pi$, so $[\hat{\mathcal{O}}^\sigma : \Sigma] \le M^{2f\min(\varrho,j)}$ by Step 3. A submodule of finite index of $\hat{\mathcal{O}}^\sigma$ is free over each $\mathcal{O}_w$ of rank $\#\sigma$ and equal to $\mathcal{O}_w^\sigma$ for almost all w, so $\Sigma = B\hat{\mathcal{O}}^\sigma$ with $B \in \mathrm{GL}_\sigma(\mathbb{A}_f)$ integral, and $[\det B] = [\hat{\mathcal{O}}^\sigma : \Sigma] \le M^{2\min(\varrho,j)f}$.

Step 5: wB has level lifts. The family wB has integral lifts by (t_ρ) and uB, with vectors $n_l^B = \sum_{l'} n_{l'} B_{l'l} = \alpha_l^B + n_l'^B$, $\alpha_l^B = \sum_{l'} \alpha_{l'} B_{l'l} \in L_X$. As the column l of B lies in Σ, $\Pi(\alpha_l^B) \in ML_\Pi$: there is $\omega_l \in L_X$ with $\Pi(\alpha_l^B) = M\Pi(\omega_l)$, so $\iota_l = \alpha_l^B - M\omega_l \in I(\mathbb{A}_f)$ by Step 1. Choose a basis (b_i) of I over E and write $\iota_l = \sum_i \mu_{il} b_i$ with $\mu_{il} \in \mathbb{A}_f$. The vectors t_ρ and b_i are orthogonal to $X + \gamma X$ ($I \perp X + \gamma X$, as X and γX are isotropic and contain I), and

$$n_l'' = n_l^B - \iota_l = \sum_\rho (uB)_{\rho l} t_\rho - \sum_i \mu_{il} b_i = M\omega_l + (n_l^B - \alpha_l^B)$$

lies in L_c, with X-part $M\omega_l \in \bigoplus_a M\hat{\mathcal{O}} e_a$ and remaining part $n_l'^B \in (X_0 \oplus Ez)(\mathbb{A}_f)$. Its image under $t \mapsto ([t], [\gamma^{-1}t])$ equals that of n_l^B, which is $(wB)_l$, because this map vanishes on $I(\mathbb{A}_f)$ (Lemma 5.2.28 (i)). So $(t_\rho) \cup (b_i)$ with the coefficients uB and $-(\mu_{il})$ give level lifts of wB (LK7). □

Lemma 5.3.11. *Let $\mathfrak{S}$ be a filling datum, $c, c' \in \mathcal{C}$ and $\gamma \in G(E)$. For a family $m = (m_i)_{i\in\mathcal{I}}$ of pairs and a matrix a over $\mathbb{A}_f$ with rows $\mathcal{I}$ and columns $\mathcal{I}'$, write $ma = (\sum_i a_{il} m_i)_{l\in\mathcal{I}'}$; $(m|y)$ is the concatenation of two families.*

(i) Orthogonal splitting. *Let $m = (m_i)_{i\in\mathcal{I}_1}$ and $y = (y_l)_{l\in\mathcal{I}_2}$ be families of pairs over E with $\langle m_i, y_l\rangle_{\mathrm{mt}} = 0$ for all i, l, and $g \in \mathrm{GL}_{\mathcal{I}_1\sqcup\mathcal{I}_2}(\mathbb{A}_f)$ such that $(m|y)g$ has level lifts for (c,γ). Then there are $a_1 \in \mathrm{GL}_{\mathcal{I}_1}(\mathbb{A}_f)$, $a_2 \in \mathrm{GL}_{\mathcal{I}_2}(\mathbb{A}_f)$ and a matrix σ over $\mathbb{A}_f$ with rows $\mathcal{I}_1$ and columns $\mathcal{I}_2$ such that ma_1 and $m\sigma + ya_2$ have level lifts for (c,γ) and $\mathrm{lkd}(m, a_1)\,\mathrm{lkd}(y, a_2) = \mathrm{lkd}((m|y), g)$.*

(ii) The part in X_0. *Let $m = (m_i)_{i\in\mathcal{I}}$ be linearly independent pairs in $\operatorname{link}\gamma$ with $\mathrm{zf}(m_i) = 0$, and $a \in \mathrm{GL}_{\mathcal{I}}(\mathbb{A}_f)$ such that ma has level lifts for (c,γ). Then the first members p_i of the m_i lie in X_0; with $W = \sum_i Ep_i$, $\dim_E W = \#\mathcal{I}$, the module $\mathrm{sat}_c(W) \cap L_c(\gamma)$ is a lattice of rank $\#\mathcal{I}$, and $\mathrm{disc}_{\#\mathcal{I}}\big(\mathrm{sat}_c(W) \cap L_c(\gamma)\big)^2 \le \mathrm{lkd}(m, a)$.*

(iii) The part seen by the z-forms. *Let $s \in \bar{G}$ agree, let γ be a term over (c, s, c') satisfying the conditions of cell rank j, $x \in \mathbb{N}$ at most the meet norm of s, and $r \in \mathbb{N}$ with $r \le 1 + \max(j - \varrho, 0)$ and $r = 2$ if $x \ne 1$. Let $y = (y_l)_{l<r}$ be pairs in $\operatorname{link}\gamma$ such that the $2 \times r$ matrix $\mathrm{zf}(y)$ has rank r, $a \in \mathrm{GL}_r(\mathbb{A}_f)$, and $w = (w_l)_{l<r}$ a family of adelic pairs with integral lifts for (c,γ) and $\mathrm{zf}(w) = \mathrm{zf}(y)\,a$. Then*

$$x^2\,\mathrm{mn}_j(\gamma)^2 \le \mathrm{lkd}(y, a) \cdot \max\Big(\prod_v |\mathsf{g}(\gamma)|_v,\ N^f \mathrm{mn}_j(\gamma)\Big)^2.$$

Proof. Throughout, h is linear in the second argument and extended sesquilinearly to adelic vectors; $|N_{E/\mathbb{Q}}\xi| = \prod_v |\xi|_v^2$ for $\xi \in E$; for $\xi \in E^\times$, $[\xi] = |N_{E/\mathbb{Q}}\xi|$ (product formula), and $[\delta] = [\hat{\mathcal{O}} : \delta\hat{\mathcal{O}}] \geq 1$ for $\delta \in \hat{\mathcal{O}} \cap \mathbb{A}_f^\times$, $[\delta] = 1$ for $\delta \in \hat{\mathcal{O}}^\times$ (Definition 5.1.8).

Two remarks on lifts. (a) If w has level (or integral) lifts for (c,γ) by (t_ρ) and u, and θ is a matrix over $\hat{\mathcal{O}}$, then $w\theta$ has level (integral) lifts by (t_ρ) and $u\theta$: the new vectors $\sum_{l'} n_{l'}\theta_{l'l}$ lie in the $\hat{\mathcal{O}}$-module L_c, and their X-parts $\sum_{l'} \alpha_{l'}\theta_{l'l}$ lie in $\bigoplus_a M\hat{\mathcal{O}}e_a$. A subfamily of a family with level lifts has level lifts. (b) If w has integral lifts by (t_ρ), u, with $n_l = \sum_\rho u_{\rho l}t_\rho \in L_c$, then, as $n_l \perp X$ and $\gamma^{-1}n_l \perp X$, the members of w_l are the classes of n_l and $\gamma^{-1}n_l$ in $(X_0 \oplus Ez)(\mathbb{A}_f)$ (that is, n_l and $\gamma^{-1}n_l$ minus their X-parts), and since $z \perp X$,

$$\mathrm{zf}(w_l) = \big(h(z,n_l),\, h(z,\gamma^{-1}n_l)\big) = \big(h(z,n_l),\, h(\gamma z,n_l)\big). \tag{5.47}$$

(i). By the Iwasawa decomposition of GL_n over a non-archimedean local field with respect to a standard parabolic subgroup, at each finite place w the component g_w is a product of a block upper triangular matrix (blocks $\mathcal{I}_1$, $\mathcal{I}_2$) and an element of $\mathrm{GL}_{\mathcal{I}_1\sqcup\mathcal{I}_2}(\mathcal{O}_w)$; for almost all w, $g_w \in \mathrm{GL}_{\mathcal{I}_1\sqcup\mathcal{I}_2}(\mathcal{O}_w)$ and the triangular factor may be taken 1. Hence $g = \begin{pmatrix} a_1 & \sigma \\ 0 & a_2 \end{pmatrix}\theta$ with $a_1 \in \mathrm{GL}_{\mathcal{I}_1}(\mathbb{A}_f)$, $a_2 \in \mathrm{GL}_{\mathcal{I}_2}(\mathbb{A}_f)$ and $\theta \in \mathrm{GL}_{\mathcal{I}_1\sqcup\mathcal{I}_2}(\hat{\mathcal{O}})$. By (a), $(m|y)g\theta^{-1} = (ma_1 \,|\, m\sigma + ya_2)$ has level lifts, and so do its two subfamilies. Since $\langle m_i, y_l\rangle_{\mathrm{mt}} = 0$, the Gram matrix of $(m|y)$ for the link metric is block diagonal, with determinant the product of those of m and of y; and $[\det g] = [\det a_1][\det a_2][\det\theta] = [\det a_1][\det a_2]$. Multiplying gives $\mathrm{lkd}((m|y),g) = \mathrm{lkd}(m,a_1)\,\mathrm{lkd}(y,a_2)$ by (LK6).

(ii), the Gram matrix. Write $m_i = (p_i + \lambda_i' z,\ p_i' + \lambda_i z)$ with $p_i, p_i' \in X_0$. By (LK4), $\mathrm{zf}(m_i) = (-N\lambda_i', -N\lambda_i) = 0$, so $\lambda_i = \lambda_i' = 0$ and the source of m_i is p_i. By Lemma 5.2.28 (ii), $\langle m_i, m_{i'}\rangle_{\mathrm{mt}} = \langle p_i, p_{i'}\rangle_+ = p_i^* p_{i'}$, the form of V_0^+ on X_0 being the unit form. The m_i are linearly independent, so by Lemma 5.2.28 (v) $\det(p^*p) \neq 0$ for the matrix p with columns p_i; hence the p_i are linearly independent, $\dim W = \#\mathcal{I} =: d$, and $\mathrm{lkd}(m,a) = |N_{E/\mathbb{Q}}\det(p^*p)|\,[\det a]^2$.

(ii), the columns of pa lie in $L = \mathrm{sat}_c(W) \cap L_c(\gamma)$. Let (t_ρ), u give level lifts of ma, with $n_l = \sum_\rho u_{\rho l}t_\rho = \alpha_l + n_l'$ as in (LK7). By (b), n_l' is the first member of $(ma)_l$, i.e. $n_l' = (pa)_l := \sum_i a_{il}p_i \in W(\mathbb{A}_f)$, and by (5.47) and $\mathrm{zf}(ma) = \mathrm{zf}(m)a = 0$, $h(z,n_l) = h(\gamma z, n_l) = 0$. As $e_a \in L_0$ is fixed by $h_c \in \mathrm{U}(X_0)(\mathbb{A}_f)$, $\alpha_l \in \bigoplus_a M\hat{\mathcal{O}}e_a \subseteq L_c$, so $(pa)_l = n_l - \alpha_l \in L_c \cap W(\mathbb{A}_f) = \mathrm{sat}_c(W)$. Moreover $n_l \perp \gamma X$ (the t_ρ are orthogonal to γX) and $h(\gamma z, n_l) = 0$, so $h(\gamma f_b, (pa)_l + M\cdot M^{-1}\alpha_l) = 0$ for $0 \leq b \leq \varrho$ with $M^{-1}\alpha_l \in \bigoplus_a \hat{\mathcal{O}}e_a$; by (LT1), $(pa)_l \in L_c(\gamma)$.

(ii), the lattices. Let ℓ be a left inverse of p over E. For an $\hat{\mathcal{O}}$-module L' with $(pa)\hat{\mathcal{O}}^d \subseteq L' \subseteq \mathrm{sat}_c(W)$ put $\Lambda' = \{y \in \mathbb{A}_f^d : py \in L'\}$, so $L' = p\Lambda'$ and $a\hat{\mathcal{O}}^d \subseteq \Lambda' \subseteq \ell L_c$. At every finite place w, Λ'_w lies between the $\mathcal{O}_w$-lattices $a_w\mathcal{O}_w^d$ and $\ell L_{c,w}$ of E_w^d, so it is a finitely generated torsion-free, hence free, $\mathcal{O}_w$-module of rank d; for almost all w both bounds are $\mathcal{O}_w^d$ (then a_w, ℓ and $L_{c,w}$ are integral and standard). Thus $\Lambda' = g'\hat{\mathcal{O}}^d$ with $g' \in \mathrm{GL}_d(\mathbb{A}_f)$, and $L' = pg'\hat{\mathcal{O}}^d$ is a lattice of rank d (LT3). This applies to $L' = L$ and to $L' = P' := (pa)\hat{\mathcal{O}}^d$. With $L = pg'\hat{\mathcal{O}}^d \supseteq P'$, $a = g'\theta$ with $\theta = g'^{-1}a$ integral, and by (LT3)

$$\mathrm{disc}_d(P')^2 = \prod_w |\det(a^*p^*pa)|_w^{-1} = \mathrm{disc}_d(L)^2\,[\det\theta]^2 \geq \mathrm{disc}_d(L)^2,$$

since $[\det\theta] \geq 1$ ($\det\theta \in \hat{\mathcal{O}} \cap \mathbb{A}_f^\times$). Finally $\mathrm{disc}_d(P')^2 = \prod_w |\det(p^*p)|_w^{-1} \prod_w |\det a\,\overline{\det a}|_w^{-1} = |N_{E/\mathbb{Q}}\det(p^*p)|\,[\det a]^2 = \mathrm{lkd}(m,a)$.

(iii), a minor and Liouville's inequality. Let $\varepsilon_1, \varepsilon_2$ and u_γ be as in Lemma 5.3.12. As $\mathrm{zf}(y)$ has rank r and two rows, $r \leq 2$ and there is an injective $\varsigma\colon \{0,\dots,r-1\} \to \{1,2\}$ such that the minor δ_0 of $\mathrm{zf}(y)$ on the rows $\varsigma(0),\dots,\varsigma(r-1)$ is nonzero. Identify pairs with vectors of

$E^{2(\dim X_0+1)}$ and let Q be the matrix of the link metric; it is positive definite at every infinite place (Lemma 5.2.28 (v)). Let ε_ς be the matrix with the columns $\varepsilon_{\varsigma(i)}$, and y also the matrix with the columns y_l. By Lemma 5.3.12 (i), $\varepsilon_\varsigma^* Q y$ is the submatrix of $\mathrm{zf}(y)$ on the rows ς, so $\det(\varepsilon_\varsigma^* Q y) = \delta_0 \neq 0$, and $\det(\varepsilon_\varsigma^* Q y\, a)$ is the minor δ of $\mathrm{zf}(w) = \mathrm{zf}(y)a$ on the rows ς, a unit of $\mathbb{A}_f$. We show $x \leq [\delta]$. Let (t_ρ), u give integral lifts of w, $n_l \in L_c$ as in (b), and $n_l = h_c n_l^0$ with $n_l^0 \in L_0$; put $k = h_c^{-1}\gamma h_{c'} \in K$, with $\mathrm{red}(k) = s$. The elements h_c, $h_{c'}$ of $\mathrm{U}(X_0)(\mathbb{A}_f)$ fix e_a and z; hence by (5.47) the entries of $\mathrm{zf}(w)$ are $h(z, n_l^0)$ and $h(kz, n_l^0)$, and $h(e_a, n_l^0) = h(e_a, n_l) = 0$, $h(ke_a, n_l^0) = h(\gamma e_a, n_l) = 0$. The vector z belongs to the lattice basis, so $z \in L_0$, and $kz \in L_0$ by Lemma 5.2.24 (ii); by Lemma 5.2.24 (i) all entries of $\mathrm{zf}(w)$ lie in $\hat{\mathcal{O}}$, so $\delta \in \hat{\mathcal{O}} \cap \mathbb{A}_f^\times$ and $[\delta] \geq 1$. This settles the case $x \leq 1$. If $x \neq 1$, then $r = 2$, ς is a bijection, and $\delta = \pm \det \begin{pmatrix} h(z,n_1^0) & h(z,n_2^0) \\ h(kz,n_1^0) & h(kz,n_2^0) \end{pmatrix}$; as s agrees, Lemma 5.3.15 (iii) gives that the meet norm of s is at most $[\delta]$, so $x \leq [\delta]$. Now Lemma 5.3.14, applied to Q, the matrices ε_ς and y, the identity and a (in place of v, v') and x, gives

$$x^2 \leq \left|N_{E/\mathbb{Q}} \det(\varepsilon_\varsigma^* Q \varepsilon_\varsigma)\right| \cdot \left|N_{E/\mathbb{Q}} \det(y^* Q y)\right| [\det a]^2 = \left|N_{E/\mathbb{Q}} \det(\varepsilon_\varsigma^* Q \varepsilon_\varsigma)\right| \cdot \mathrm{lkd}(y, a). \tag{5.48}$$

(iii), the selected Gram determinant. Let $\Gamma = \max(\prod_v |\mathsf{g}(\gamma)|_v, N^f \mathrm{mn}_j(\gamma))$. By Lemma 5.3.12 (ii), $\varepsilon_\varsigma^* Q \varepsilon_\varsigma$ is the empty matrix if $r = 0$, the 1×1 matrix (N) if $r = 1$, and, if $r = 2$, the Gram matrix $N \begin{pmatrix} 1 & \bar{u}_\gamma \\ u_\gamma & 1 \end{pmatrix}$ up to a simultaneous permutation of rows and columns, with determinant $N^2(1 - \bar{u}_\gamma u_\gamma)$. For $r = 0$: $\mathrm{mn}_j(\gamma)^2 \leq (N^f \mathrm{mn}_j(\gamma))^2 \leq \Gamma^2$. For $r = 1$: $|N_{E/\mathbb{Q}}(N)|\, \mathrm{mn}_j(\gamma)^2 = (N^f \mathrm{mn}_j(\gamma))^2 \leq \Gamma^2$. For $r = 2$: $r \leq 1 + \max(j - \varrho, 0)$ forces $j = \varrho + 1$, so $\mathrm{mn}_j(\gamma) = |N_{E/\mathbb{Q}} D_{\varrho+1}(\gamma)|/N^{2f}$, and by Lemma 5.3.12 (iii)

$$\begin{aligned} |N_{E/\mathbb{Q}}(N^2(1 - \bar{u}_\gamma u_\gamma))|\, \mathrm{mn}_j(\gamma)^2 &= |N_{E/\mathbb{Q}}(D_{\varrho+1}(\gamma)\overline{D_{\varrho+1}(\gamma)}(1 - \bar{u}_\gamma u_\gamma))| \\ &= |N_{E/\mathbb{Q}}\mathsf{g}(\gamma)| = \Big(\prod_v |\mathsf{g}(\gamma)|_v\Big)^2 \leq \Gamma^2. \end{aligned}$$

In all cases $|N_{E/\mathbb{Q}} \det(\varepsilon_\varsigma^* Q \varepsilon_\varsigma)|\, \mathrm{mn}_j(\gamma)^2 \leq \Gamma^2$; multiplying (5.48) by $\mathrm{mn}_j(\gamma)^2$ gives the claim. □

Lemma 5.3.12. *Let $\mathfrak{S}$ be a filling datum and $\gamma \in G(E)$. Let $u_\gamma \in E$ be the z^+-coordinate of $\Upsilon_\gamma^{-1}(z^+) \in V_0^+ = X_0 \oplus Ez^+$, and let $\varepsilon_1, \varepsilon_2 \in \mathrm{link}\,\gamma$ be the pairs with sources $\varepsilon_1^{\mathrm{s}} = -\Upsilon_\gamma^{-1}(z^+)$ and $\varepsilon_2^{\mathrm{s}} = -z^+$.*

(i) For every $q \in \mathrm{link}\,\gamma$: $(\langle \varepsilon_1, q\rangle_{\mathrm{mt}}, \langle \varepsilon_2, q\rangle_{\mathrm{mt}}) = \mathrm{zf}(q)$.

(ii) $\big(\langle \varepsilon_a, \varepsilon_b\rangle_{\mathrm{mt}}\big)_{a,b=1,2} = N \begin{pmatrix} 1 & \bar{u}_\gamma \\ u_\gamma & 1 \end{pmatrix}$.

(iii) If γ satisfies the conditions of cell rank j, then $\mathsf{g}(\gamma) = D_j(\gamma)\overline{D_j(\gamma)}\,(1 - \bar{u}_\gamma u_\gamma)$.

Proof. The form h, hence $\langle \cdot, \cdot \rangle_+$, is linear in the second and conjugate linear in the first argument. The pairs $\varepsilon_1, \varepsilon_2$ exist and are unique because $p \mapsto p^{\mathrm{s}}$ is a bijection of $\mathrm{link}\,\gamma$ onto V_0^+ (Lemma 5.2.28 (iii)). For $p, q \in \mathrm{link}\,\gamma$ we use $\langle p, q\rangle_{\mathrm{mt}} = \langle p^{\mathrm{s}}, q^{\mathrm{s}}\rangle_+$ (Lemma 5.2.28 (ii)), $q^{\mathrm{t}} = \Upsilon_\gamma(q^{\mathrm{s}})$, and that Υ_γ is an isometry of $\langle \cdot, \cdot \rangle_+$, so $\langle \Upsilon_\gamma^{-1} a, b\rangle_+ = \langle a, \Upsilon_\gamma b\rangle_+$.

(i). Write $q = (y_0 + \lambda' z,\ y_0' + \lambda z)$ with $y_0, y_0' \in X_0$, so that $q^{\mathrm{s}} = y_0 + \lambda z^+$, $q^{\mathrm{t}} = y_0' + \lambda' z^+$ and, as $X_0 \perp z$ and $h(z, z) = -N$, $\mathrm{zf}(q) = (-N\lambda', -N\lambda)$ (LK4). Since $X_0 \perp z^+$ and $\langle z^+, z^+\rangle_+ = N$,

$$\begin{aligned} \langle \varepsilon_1, q\rangle_{\mathrm{mt}} &= -\langle \Upsilon_\gamma^{-1} z^+, q^{\mathrm{s}}\rangle_+ = -\langle z^+, \Upsilon_\gamma q^{\mathrm{s}}\rangle_+ = -\langle z^+, q^{\mathrm{t}}\rangle_+ = -N\lambda', \\ \langle \varepsilon_2, q\rangle_{\mathrm{mt}} &= -\langle z^+, q^{\mathrm{s}}\rangle_+ = -N\lambda. \end{aligned}$$

(ii). Write $\Upsilon_\gamma^{-1}z^+ = w_0 + u_\gamma z^+$ with $w_0 \in X_0$. Then $\langle\varepsilon_1,\varepsilon_1\rangle_{\mathrm{mt}} = \langle\Upsilon_\gamma^{-1}z^+,\Upsilon_\gamma^{-1}z^+\rangle_+ = \langle z^+,z^+\rangle_+ = N$, $\langle\varepsilon_2,\varepsilon_2\rangle_{\mathrm{mt}} = N$, $\langle\varepsilon_1,\varepsilon_2\rangle_{\mathrm{mt}} = \langle w_0+u_\gamma z^+, z^+\rangle_+ = N\bar{u}_\gamma$ and $\langle\varepsilon_2,\varepsilon_1\rangle_{\mathrm{mt}} = \langle z^+, w_0 + u_\gamma z^+\rangle_+ = Nu_\gamma$.

(iii), the case $\mathsf{g}(\gamma) = 0$. By the conditions of cell rank, $j \le \varrho$, so at the index $a = \varrho \ge j$ there are ζ with $\zeta\bar{\zeta} = 1$ and $x, x' \in E^{\varrho+1}$ with $\sum_b x_b f_b = \gamma\sum_b x'_b f_b$, $x_\varrho = \zeta \ne 0$, $x'_\varrho = 1$. By Lemma 5.3.13 (i), Υ_γ maps X_0 into X_0; being injective, it maps X_0 onto X_0, and being an isometry it maps the orthogonal complement Ez^+ of X_0 in V_0^+ onto itself. So $\Upsilon_\gamma^{-1}z^+ = u_\gamma z^+$ and $N = \langle\Upsilon_\gamma^{-1}z^+,\Upsilon_\gamma^{-1}z^+\rangle_+ = \bar{u}_\gamma u_\gamma N$, whence $1 - \bar{u}_\gamma u_\gamma = 0$, and both sides of (iii) vanish.

(iii), the case $\mathsf{g}(\gamma) \ne 0$. Then $\varrho < j$, i.e. $j = \varrho + 1$, and $D_{\varrho+1}(\gamma) = \det Z(\gamma) \ne 0$. Let $c \in E^{\varrho+1}$ be the column of index ϱ of the adjugate of $Z(\gamma)$; then $Z(\gamma)c = \det Z(\gamma)\,\varepsilon_\varrho$, and c_ϱ, the cofactor of the entry (ϱ,ϱ), is the leading principal minor $D_\varrho(\gamma)$. By Lemma 5.2.28 (vi) with $c' = D_{\varrho+1}(\gamma)$, $\Upsilon_\gamma(y_0 + D_\varrho(\gamma)z^+) = -(D_{\varrho+1}(\gamma)/N)\,z^+$ for some $y_0 \in X_0$. Hence $\Upsilon_\gamma^{-1}z^+ = -(N/D_{\varrho+1}(\gamma))(y_0 + D_\varrho(\gamma)z^+)$ and $u_\gamma = -ND_\varrho(\gamma)/D_{\varrho+1}(\gamma)$. Therefore

$$D_{\varrho+1}(\gamma)\overline{D_{\varrho+1}(\gamma)}\,(1-\bar{u}_\gamma u_\gamma) = D_{\varrho+1}(\gamma)\overline{D_{\varrho+1}(\gamma)} - N^2 D_\varrho(\gamma)\overline{D_\varrho(\gamma)} = \mathsf{g}(\gamma)$$

by (TA4), with $j = \varrho + 1$. □

Lemma 5.3.13. *Let* $\mathfrak{S}$ *be a filling datum and* $\gamma,\gamma' \in G(E)$. *Put* $X_0^\gamma = \{x \in X_0 : \Upsilon_\gamma(x) \in X_0\}$ *(inside* V_0^+*), and* $(j-\varrho)_+ = \max(0, j-\varrho)$.

(i) If $\mathsf{g}(\gamma) \ne 0$, *then* $\dim X_0^\gamma = k-1$. *If some* $\zeta \ne 0$ *and* $x, x' \in E^{\varrho+1}$ *satisfy* $f\cdot x = \gamma f\cdot x'$, $x_\varrho = \zeta$, $x'_\varrho = 1$, *then* $X_0^\gamma = X_0$. *Hence, if* γ *satisfies the conditions of cell rank* j, $\dim X_0^\gamma + (j-\varrho)_+ = k$.

(ii) $X_0(\gamma,\gamma') \subseteq X_0^\gamma \cap X_0^{\gamma'}$, *and* $\dim X_0^\gamma + \dim(\operatorname{link}\gamma \cap \operatorname{link}\gamma') \le \dim X_0(\gamma,\gamma') + k + 1$.

(iii) If γ *satisfies the conditions of cell rank* j, *then*

$$\dim(\operatorname{link}\gamma\cap\operatorname{link}\gamma') \le \dim X_0(\gamma,\gamma') + 1 + (j-\varrho)_+, \qquad k \le \dim X_0(\gamma,\gamma') + c^+ + (j-\varrho)_+.$$

(iv) $c^+ = 0$ *if and only if* $\operatorname{link}\gamma = \operatorname{link}\gamma'$. *If* $\mathsf{g}(\gamma) \ne 0$ *and* $\operatorname{link}\gamma = \operatorname{link}\gamma'$, *then* $X_0(\gamma,\gamma') = X_0^\gamma$ *and* $\dim(\operatorname{link}\gamma\cap\operatorname{link}\gamma') = \dim X_0(\gamma,\gamma') + 2$.

(v) If γ *and* γ' *satisfy the conditions of cell ranks* j *and* j' *and* $\operatorname{link}\gamma = \operatorname{link}\gamma'$, *then* $\mathsf{g}(\gamma) = 0$ *if and only if* $\mathsf{g}(\gamma') = 0$.

Proof. Recall from Lemma 5.2.28: $p \mapsto p^{\mathrm{s}}$ and $p \mapsto p^{\mathrm{t}}$ are bijections of $\operatorname{link}\gamma$ onto V_0^+ (of dimension $k+1$), Υ_γ is an isometry of $\langle\cdot,\cdot\rangle_+$ with $\Upsilon_\gamma(p^{\mathrm{s}}) = p^{\mathrm{t}}$ on the link, and $\Upsilon_\gamma = \Upsilon_{\gamma'}$ iff the links agree. Let K_0 be the space of pairs whose two members lie in X_0 (both z-coordinates 0). For $p = (x,y) \in K_0$, $p^{\mathrm{s}} = x$ and $p^{\mathrm{t}} = y$.

(i). X_0^γ is the kernel of the linear form $x \mapsto$ (z^+-coefficient of $\Upsilon_\gamma x$) on X_0, so its dimension is $k-1$ or k. Let $\mathsf{g}(\gamma) \ne 0$; then $\det Z(\gamma) \ne 0$ by Lemma 5.2.26 (ii). Suppose $X_0^\gamma = X_0$. Then $\Upsilon_\gamma X_0 = X_0$ (dimension), so Υ_γ maps the orthogonal complement Ez^+ of X_0 in V_0^+ to itself. Let c be the last column of the adjugate of $Z(\gamma)$, so $Z(\gamma)c = \det Z(\gamma)\,\varepsilon_\varrho$, and y_0 the X_0-part of $\gamma f\cdot c$. By Lemma 5.2.28 (vi), $\Upsilon_\gamma(y_0 + c_\varrho z^+) = -(\det Z(\gamma)/N)z^+$, so $y_0 + c_\varrho z^+ \in \Upsilon_\gamma^{-1}(Ez^+) = Ez^+$ and $y_0 = 0$. By Lemma 5.2.26 (i) (with $D = \det Z(\gamma)$, $y_\varrho = c_\varrho = D_\varrho(\gamma)$), $\mathsf{g}(\gamma) = N\,h(y_0,y_0) = 0$, a contradiction. So $\dim X_0^\gamma = k-1$.

For the second assertion let $t \perp X + \gamma X$, and write λ', λ for the z-coordinates of t and $\gamma^{-1}t$. Since $t, \gamma^{-1}t \perp X$ and the e_a are orthogonal to z, $h(f\cdot x, t) = \bar{\zeta}\,h(z,t) = -N\bar{\zeta}\lambda'$ and

$h(f\cdot x',\gamma^{-1}t)=-N\lambda$; these are equal because $h(f\cdot x,t)=h(\gamma f\cdot x',t)=h(f\cdot x',\gamma^{-1}t)$. So $\lambda=\bar\zeta\lambda'$ on the whole link. For $x_0\in X_0$ take $p\in\operatorname{link}\gamma$ with $p^{\mathrm s}=x_0$, i.e. $\lambda=0$; then $\lambda'=0$ as $\bar\zeta\neq0$, so $\Upsilon_\gamma x_0=p^{\mathrm t}\in X_0$. Thus $X_0^\gamma=X_0$.

Finally let γ satisfy the conditions of cell rank j. If $j=\varrho+1$ then $\mathsf g(\gamma)\neq0$ and $\dim X_0^\gamma=k-1$. If $j\le\varrho$, the first condition at $a=\varrho\ge j$ gives x,x' as above with $\zeta\bar\zeta=1$, so $X_0^\gamma=X_0$. In both cases $\dim X_0^\gamma+(j-\varrho)_+=k$.

(ii). If $x\in X_0(\gamma,\gamma')$, there is $y\in X_0$ with $p=(x,y)\in\operatorname{link}\gamma\cap\operatorname{link}\gamma'$; then $\Upsilon_\gamma x=\Upsilon_\gamma(p^{\mathrm s})=p^{\mathrm t}=y\in X_0$, and likewise for γ'. The map $p\mapsto p^{\mathrm s}$ is injective on $\operatorname{link}\gamma$ and sends $\operatorname{link}\gamma\cap K_0$ onto X_0^γ (for $x\in X_0^\gamma$ the pair with source x is $(x,\Upsilon_\gamma x)\in K_0$) and $\operatorname{link}\gamma\cap\operatorname{link}\gamma'\cap K_0$ onto $X_0(\gamma,\gamma')$. With $A=\operatorname{link}\gamma\cap K_0$ and $B=\operatorname{link}\gamma\cap\operatorname{link}\gamma'$, both in $\operatorname{link}\gamma$,

$$\dim X_0^\gamma+\dim B=\dim(A+B)+\dim(A\cap B)\le(k+1)+\dim X_0(\gamma,\gamma').$$

(iii). Insert $\dim X_0^\gamma=k-(j-\varrho)_+$ from (i) into (ii) for the first inequality; the second is the first with $c^+=k+1-\dim(\operatorname{link}\gamma\cap\operatorname{link}\gamma')$ (no truncation occurs, since the intersection has dimension at most $k+1$).

(iv). Both links have dimension $k+1$, so $c^+=0$ iff the intersection is the whole of each, iff they are equal. Let the links be equal and $\mathsf g(\gamma)\neq0$. Then $\Upsilon_{\gamma'}=\Upsilon_\gamma$, and for $x\in X_0^\gamma$ the pair $(x,\Upsilon_\gamma x)$ lies in $K_0\cap\operatorname{link}\gamma=K_0\cap\operatorname{link}\gamma\cap\operatorname{link}\gamma'$, so $x\in X_0(\gamma,\gamma')$; with (ii), $X_0(\gamma,\gamma')=X_0^\gamma$, of dimension $k-1$ by (i), while the intersection of the links has dimension $k+1$.

(v). Equal links give $\Upsilon_\gamma=\Upsilon_{\gamma'}$, hence $X_0^\gamma=X_0^{\gamma'}$. By (i), $\dim X_0^\gamma=k-1$ if $\mathsf g(\gamma)\neq0$ and $=k$ if $\mathsf g(\gamma)=0$ (then $j\le\varrho$ by the third condition of cell rank), and the same for γ'; so $\mathsf g(\gamma)=0$ iff $\mathsf g(\gamma')=0$. □

Lemma 5.3.14. *Let E be a CM field, τ,σ finite sets, $Q\in\mathrm M_{\tau\times\tau}(E)$ with $\Phi_w(Q)$ positive definite hermitian for every infinite place w, $a,b\in\mathrm M_{\tau\times\sigma}(E)$ with $\det(a^*Qb)\neq0$, $v,v'\in\mathrm{GL}_\sigma(\mathbb A_f)$, and $x\ge0$ a real number with $x\le[\det(v^*\,a^*Qb\,v')]$. Then*

$$x^2\le[\det v]^2\,\bigl|N_{E/\mathbb Q}\det(a^*Qa)\bigr|\,\bigl|N_{E/\mathbb Q}\det(b^*Qb)\bigr|\,[\det v']^2.$$

Proof. One place. Fix an infinite place w and put $A=\Phi_w(a^*Qa)$, $B=\Phi_w(a^*Qb)$, $C=\Phi_w(b^*Qb)$, square matrices of size $|\sigma|$. The block matrix $\begin{pmatrix}A&B\\B^*&C\end{pmatrix}=\Phi_w((a\,|\,b)^*Q(a\,|\,b))$ is positive semidefinite. We claim $|\det B|^2\le\det A\det C$. If A is positive definite, the Schur complement $C-B^*A^{-1}B$ is positive semidefinite, so $\det C\ge\det(B^*A^{-1}B)=|\det B|^2/\det A$ (determinants are monotone on positive semidefinite matrices). If A is singular, pick $u\neq0$ with $u^*Au=0$; positivity of the block matrix on vectors (su,y), $s\in\mathbb C$, gives $|u^*By|^2\le(u^*Au)(y^*Cy)=0$ for all y, so $u^*B=0$ and $\det B=0$. Hence

$$|\Phi_w\det(a^*Qb)|^2\le\Phi_w\det(a^*Qa)\cdot\Phi_w\det(b^*Qb),$$

the right side being a product of nonnegative reals.

All places. For $\alpha\in E$, $|N_{E/\mathbb Q}(\alpha)|=\prod_w|\Phi_w(\alpha)|^2$, all infinite places being complex. Raising the inequality above to the square and multiplying over w,

$$\bigl|N_{E/\mathbb Q}\det(a^*Qb)\bigr|^2\le\bigl|N_{E/\mathbb Q}\det(a^*Qa)\bigr|\,\bigl|N_{E/\mathbb Q}\det(b^*Qb)\bigr|.$$

Finite places. By Definition 5.1.8, $[\cdot]$ is multiplicative, $[\det v^*]=[\overline{\det v}]=[\det v]$, and $[\det(a^*Qb)]=|N_{E/\mathbb Q}\det(a^*Qb)|$ since $\det(a^*Qb)\in E^\times$. So

$$0\le x\le[\det v]\,\bigl|N_{E/\mathbb Q}\det(a^*Qb)\bigr|\,[\det v'],$$

and squaring and inserting the previous inequality gives the claim. □

Lemma 5.3.15. *Let $\mathfrak{S}$ be a filling datum with Weil data and $k \in K$ with $s = \mathrm{red}(k)$ agreeing. A* place above M *is $v = w$ or $v = \bar{w}$ with $w \in S_0 \cup S_1$; $\mathbb{F}_v$ is its residue field and $\bar{k}_v$ the reduction modulo v of the (integral) matrix of k.*

(i) Let v be a place above M, $0 \le a < \varrho$ and $x, y \in \mathbb{F}_v^{\varrho+1}$ with $f \cdot x = \bar{k}_v f \cdot y$, $x_b = y_b = 0$ for $b > a$. Then there are x', y' with $f \cdot x' = \bar{k}_v f \cdot y'$, $x'_{a+1} = x_a$, $y'_{a+1} = y_a$ and $x'_b = y'_b = 0$ for $b > a+1$.

(ii) s meets at (w, ϵ) if and only if the spans of f and $\bar{k}_v f$ over $\mathbb{F}_v$ have a nonzero common vector, where $v = w$ if $\epsilon = 0$ and $v = \bar{w}$ if $\epsilon = 1$.

(iii) Let $t_1, t_2 \in L_0$ with $h(e_a, t_l) = h(ke_a, t_l) = 0$ for $1 \le a \le \varrho$, $l = 1, 2$, and suppose $\delta = \det \begin{pmatrix} h(z,t_1) & h(z,t_2) \\ h(kz,t_1) & h(kz,t_2) \end{pmatrix} \in \mathbb{A}_f^\times$. Then (meet norm of s) $\le [\delta]$.

Proof. Let J be the Gram matrix of h in the lattice basis; by Lemma 5.2.24 (i) and its proof, J has integer entries, $J^{\mathsf{T}} = J$ and $J \in \mathrm{GL}(\hat{\mathcal{O}})$, and $k^{\pm 1}$ are integral. By (FG2) the places $w, \bar{w}$ ($w \in S_0 \cup S_1$) are $4f$ distinct places; the residue field of a place above p_i has at least p_i elements. By the Chinese remainder theorem, for each place v above M there is a map $\ell_v \colon \mathbb{F}_v \to \hat{\mathcal{O}}$ with $\ell_v(0) = 0$, $\ell_v(\theta) \equiv \theta \bmod v$ and $\ell_v(\theta) \equiv 0$ modulo every other place above M.

(ii). From $k^* J k = J$ we get $\bar{k} = (k^*)^{\mathsf{T}} = J^{-1}(k^{-1})^{\mathsf{T}} J$ (entrywise conjugate). Reduction modulo $\bar{w}$ of an integral α corresponds, under the conjugation isomorphism $\mathbb{F}_{\bar{w}} \cong \mathbb{F}_w$, to reduction modulo w of $\bar{\alpha}$. Hence $\bar{k}_{\bar{w}}$ corresponds to the reduction modulo w of $J^{-1}(k^{-1})^{\mathsf{T}} J$, which is the inverse adjoint g of s_w for the reduced form J. As f has integer coordinates, f and $\bar{k}_{\bar{w}} f$ have a common nonzero vector iff f and gf have one over $\mathbb{F}_w$, which is meeting at $(w, 1)$; the case $\epsilon = 0$ is the definition.

(i). Put $\mu = x_a$, $\mu' = y_a$. The vector $\mu f_{a+1} - \mu' \bar{k}_v f_{a+1}$ lies in $\langle f_b, \bar{k}_v f_b : b \le a \rangle$ if and only if every linear form m on $\mathbb{F}_v^r$ vanishing on these vectors satisfies $\mu\, m(f_{a+1}) = \mu'\, m(\bar{k}_v f_{a+1})$; and if it does, adding the resulting relation to $f \cdot x = \bar{k}_v f \cdot y$ gives x', y'. Fix such m and $r \in \hat{\mathcal{O}}$. Let $B_v = S_0 \cup S_1$ if $v = w$, and $B_v = \{\bar{w}' : w' \in S_0 \cup S_1\}$ if $v = \bar{w}$. For $v'' \in B_v$ and $\theta \in \mathbb{F}_v$, $\overline{\ell_v(\theta)} \equiv 0 \bmod v''$, because $\ell_v(\theta) \equiv 0 \bmod \bar{v}''$ and $\bar{v}'' \notin B_v \ni v$. Lifting coordinatewise by ℓ_v, let $\tilde{x}, \tilde{y} \in \hat{\mathcal{O}}^{\varrho+1}$ and the linear forms $\tilde{m}$, $\tilde{m}'$ be the lifts of x, y, m and $m \circ \bar{k}_v$. As J is unimodular there are $\tilde{v}, \tilde{v}' \in L_0$ with $h(\tilde{v}, \cdot) = \tilde{m}$, $h(\tilde{v}', \cdot) = \tilde{m}'$; and $\tilde{m}(f_b) = \tilde{m}'(f_b) = \ell_v(0) = 0$ for $b \le a$, since the f_b are basis vectors. By Weil data E contains a primitive cube root of unity ζ_3; $\tau = -\zeta_3$ is integral with $\tau + \bar{\tau} = 1$. For $(\xi, \nu) \in \{(\tilde{x}, \tilde{v}), (\tilde{y}, \tilde{v}')\}$ put $x_e = r\, f \cdot \xi$, which lies in $L_0 \cap \langle e_1, \dots, e_{a+1} \rangle(\mathbb{A}_f)$ and is isotropic, with $h(\nu, x_e) = 0$; put $\varsigma = \tau h(\nu, \nu)$, so $\varsigma + \bar{\varsigma} = h(\nu, \nu)$; and let $\mathrm{E}(q) = q + h(\nu, q) x_e - h(x_e, q)(\nu + \varsigma x_e)$. Expanding $h(\mathrm{E}q, \mathrm{E}q')$ with these three identities shows that E is an isometry of $V(\mathbb{A}_f)$. With $F_c = \langle e_1, \dots, e_c \rangle$: $h(x_e, \cdot)$ vanishes on $X^\perp \supseteq F_\varrho$ and $h(\nu, \cdot)$ on F_{a+1}, so E fixes F_{a+1} pointwise, sends $q \in F_c$ ($c > a+1$) to $q + h(\nu, q) x_e \in q + F_{c-1}$ and $q \in X^\perp$ to $q + h(\nu, q) x_e \in q + X$; an isometry stabilising $F_\bullet$ and trivial on F_c / F_{c-1} and on $X^\perp / X$ is trivial on the dual quotients too, so $\mathrm{E} \in \mathsf{U}(\mathbb{A}_f)$. Its matrix is integral ($x_e, \nu \in L_0$ and J is integral), so $\mathrm{E} \in K$. As $h(x_e, f_b) = 0$, $\mathrm{E} f_b = f_b + h(\nu, f_b) x_e$, whence $\sigma(\mathrm{E}) = r \sum_{b \ge 1} h(\nu, f_b) \xi_{b-1}$. Let u, u' be E for $(\tilde{x}, \tilde{v})$ and $(\tilde{y}, \tilde{v}')$. For $v'' \in B_v$ the coefficients $\bar{r}\,\overline{\xi_b}$ of $h(x_e, \cdot) = \sum_b \bar{r}\,\overline{\xi_b}\, h(f_b, \cdot)$ vanish modulo v'', and $x_e \equiv 0$ modulo $v'' \ne v$. Hence, modulo v, $u \equiv 1 + r(f \cdot x)\, m$ and $u' \equiv 1 + r(f \cdot y)(m \circ \bar{k}_v)$, while $u \equiv u' \equiv 1$ modulo the other places of B_v. Since $\bar{k}_v f \cdot y = f \cdot x$, $\bar{u}\bar{k}_v = \bar{k}_v + r(f \cdot x)(m \circ \bar{k}_v) = \bar{k}_v \bar{u}'$ modulo v; so $uk \equiv ku'$ modulo every place of B_v. If $B_v = S_0 \cup S_1$ this is $\mathrm{red}(u)\, s = s\, \mathrm{red}(u')$. Otherwise, by the computation in (ii), the

reduction modulo $\bar{w}'$ of an element of K determines its reduction modulo w' through the bijection $\alpha \mapsto J^{-1}(\alpha^{-1})^{\mathsf{T}}J$ (after conjugating coefficients), so again $\mathrm{red}(u)\, s = s\, \mathrm{red}(u')$. Agreement gives $\psi_f(-\sigma(u)/(M\varpi)) = \psi_f(-\sigma(u')/(M\varpi))$ for every $r \in \hat{\mathcal{O}}$, i.e. $\psi_f(-rd/\varpi) = 1$ for all $r \in \hat{\mathcal{O}}$, where $d = M^{-1}\big(\sum_b \tilde{m}(f_b)\tilde{x}_{b-1} - \sum_b \tilde{m}'(f_b)\tilde{y}_{b-1}\big)$. As ϖ generates the different, $\hat{\mathcal{O}}$ is its own dual for $(\alpha,\beta) \mapsto \psi_f(-\alpha\beta/\varpi)$ (local self-duality, Tate's thesis), so $d \in \hat{\mathcal{O}}$; by (FG2) the difference of the two sums vanishes modulo v. Reducing modulo v and using $m(f_b) = m(\bar{k}_v f_b) = 0$ for $b \le a$ and $x_b = y_b = 0$ for $b > a$, this reads $\mu\, m(f_{a+1}) = \mu'\, m(\bar{k}_v f_{a+1})$.

(iii). Let A be the set of the places v above M at which (in the sense of (ii)) s meets. Put $\delta_0 = \det\big(h(t_l,z), h(t_l,kz)\big)_l$; then $\delta = \bar{\delta}_0$, $\delta_0 \in \hat{\mathcal{O}}$ (as $t_l, z, kz \in L_0$) is a unit of $\mathbb{A}_f$, and $[\delta] = [\delta_0] = [\hat{\mathcal{O}} : \delta_0\hat{\mathcal{O}}]$. Let $v \in A$. There are x, y over $\mathbb{F}_v$, $x \neq 0$, with $f \cdot x = \bar{k}_v f \cdot y$; let a be the largest index with $(x_a, y_a) \neq (0,0)$. By (i), applied $\varrho - a$ times, there are x', y' with $f\cdot x' = \bar{k}_v f \cdot y'$ and $(x'_\varrho, y'_\varrho) = (x_a, y_a) \neq (0,0)$. Apply the reduction modulo v of $h(t_l,\cdot)$ (integral on L_0): as $h(t_l, e_a) = h(t_l, ke_a) = 0$, the identity $f\cdot x' - \bar{k}_v f\cdot y' = 0$ gives $x'_\varrho\, h(t_l,z) - y'_\varrho\, h(t_l,kz) \equiv 0 \bmod v$ for $l = 1,2$. So the reduction of the matrix of δ_0 kills the nonzero vector $(x'_\varrho, -y'_\varrho)$, and $\delta_0 \equiv 0 \bmod v$. Hence $\hat{\mathcal{O}}/\delta_0\hat{\mathcal{O}}$ maps onto $\prod_{v\in A}\mathbb{F}_v$ (Chinese remainder theorem), and

$$(\text{meet norm of } s) = \prod_{v\in A} p_{i(v)} \le \prod_{v\in A} |\mathbb{F}_v| \le [\hat{\mathcal{O}} : \delta_0\hat{\mathcal{O}}] = [\delta].$$

□

Lemma 5.3.16. *Let $\mathfrak{S}$ be an admissible filling datum with Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, and γ a near term over (c,s,c') satisfying the conditions of cell rank j. Then $\mathsf{g}^*(j,c,c',\gamma) \le b^{n^3 f}$.*

Proof. Put $k = h_c^{-1}\gamma h_{c'}$ and $B = b^{270n^2 f}$. For $\xi \in E$, $|N_{E/\mathbb{Q}}\xi| = \prod_v |\xi|_v^2$.

The minor norm and the term discriminant. By Lemma 5.2.20, $\prod_v |D_l(\gamma)|_v^2 \le B$ for every l. Hence $\mathrm{mn}_j(\gamma) = |N_{E/\mathbb{Q}} D_j(\gamma)|/N^{2\max(j-\varrho,0)f} \le |N_{E/\mathbb{Q}} D_j(\gamma)| \le B$, as $N \ge 1$. By Lemma 5.2.26 (ii), $\mathsf{g}(\gamma)$ is totally positive or 0; at each infinite place, complex conjugation of E becoming complex conjugation, $|\mathsf{g}(\gamma)|_v = |D_{\varrho+1}(\gamma)|_v^2 - N^2|D_\varrho(\gamma)|_v^2 \le |D_{\varrho+1}(\gamma)|_v^2$, so $\prod_v |\mathsf{g}(\gamma)|_v \le B$.

The maximal gauge. By Lemma 5.3.6 (i), $i_\gamma = \mathrm{ir}_j(k) \ge 1$ and $i'_\gamma = \mathrm{ir}_j(k^{-1}) \ge 1$. By Lemma 5.3.9 (ii) and (FA5), $N \le b^{60n}$,

$$\mathsf{g}^{\max}(j,c,c',\gamma) = \frac{\max\big(\prod_v |\mathsf{g}(\gamma)|_v,\ N^f \mathrm{mn}_j(\gamma)\big)}{i_\gamma i'_\gamma} \le \max(B,\ b^{60nf}B) = b^{60nf}B,$$

since $b \ge 1$.

The level gauge. By (FG6), $M \le b^{23}$, and $\min(\varrho, j) \le n$, so $M^{2\min(\varrho,j)f} \le b^{46nf}$. Hence $\mathsf{g}^*(j,c,c',\gamma) \le b^{(46n+60n+270n^2)f} \le b^{376n^2 f}$. By (FG6), $\varrho \ge 10^5$, so $n \ge 376$ and $376n^2 \le n^3$; as $b \ge 1$, $\mathsf{g}^*(j,c,c',\gamma) \le b^{n^3 f}$. □

Lemma 5.3.17. *Let $\mathfrak{S}$ be an admissible filling datum with Weil data, $T \subseteq \Gamma^*$ stable, $c, c' \in \mathcal{C}$ and $s \in \bar{G}$. Let $\mathcal{N}$ be the set of near representatives $\gamma \in T$ for (c,c') that are terms over (c,s,c') and satisfy the conditions of their cell rank if s agrees, and $\mathcal{N} = \emptyset$ otherwise. Then*

$$\|A_T^{\mathrm{cut}}(c,s,c')\|^2 \le \sum_L \|A^{\mathrm{cut}}_{T\cap\{\mathsf{g}\neq 0\}\cap \mathrm{link}^{-1}(L)}(c,s,c')\|^2 + \nu^2 \sum_{(\gamma,\gamma')} \mathrm{size}(c,c',\gamma)\,\mathrm{size}(c,c',\gamma'),$$

the first sum over all E-subspaces L, the second over the pairs $(\gamma,\gamma') \in \mathcal{N}\times\mathcal{N}$ that are not in the same link class.

Proof. **Pieces.** For $\gamma \in G(E)$ let its piece be $\pi(\gamma) = \star$ if $\mathsf{g}(\gamma) = 0$ and $\pi(\gamma) = \operatorname{link}\gamma$ otherwise, $\star$ a symbol distinct from all subspaces. For a piece p put $T_p = T \cap \pi^{-1}(p)$ and $a_p = \|A^{\mathrm{cut}}_{T_p}(c,s,c')\|$. Each T_p is stable and contained in Γ^*: for $u, u' \in \mathsf{U}(E)$, $\pi(u^{-1}\gamma u') = \pi(\gamma)$ by Lemma 5.2.25 (i), (ii), and T is stable. For a subspace L, $T_L = T \cap \{\mathsf{g} \neq 0\} \cap \operatorname{link}^{-1}(L)$.

The block is at most the sum of its pieces. For each term γ over (c,s,c'), $\|A^{\mathrm{cut}}_{\gamma}(c,c')\|$ is at most its cut amplitude majorant (the norm of a Bochner integral is at most the integral of the norm, and $A_\gamma = 0$ when the integrand is not integrable). By Lemma 5.2.29 (ii) (cut case, with $d = c'$) these majorants have a finite sum over the terms of T over (c,s,c'), so the series $A^{\mathrm{cut}}_T(c,s,c')$ converges absolutely and may be regrouped along the partition $T = \bigsqcup_p T_p$: $A^{\mathrm{cut}}_T(c,s,c') = \sum_p A^{\mathrm{cut}}_{T_p}(c,s,c')$, with only countably many nonzero summands. Hence $\|A^{\mathrm{cut}}_T(c,s,c')\| \le \sum_p a_p$ and

$$\|A^{\mathrm{cut}}_T(c,s,c')\|^2 \le \Big(\sum_p a_p\Big)^2 = \sum_L a_L^2 + \sum_{(p,p')\notin\Delta} a_p a_{p'},$$

where Δ is the set of pairs (L,L) with L a subspace. The first sum is the first sum of the statement.

The other products. By Proposition 5.3.19 (ii) applied to the stable set $T_p \subseteq \Gamma^*$, $a_p \le \nu \sum_{\gamma\in\mathcal{N}_p} \operatorname{size}(c,c',\gamma)$, where $\mathcal{N}_p = \mathcal{N} \cap \pi^{-1}(p)$ is the set of near representatives of T_p over (c,s,c') entering there. So

$$\sum_{(p,p')\notin\Delta} a_p a_{p'} \le \nu^2 \sum_{(p,p')\notin\Delta} \sum_{\gamma\in\mathcal{N}_p,\ \gamma'\in\mathcal{N}_{p'}} \operatorname{size}(c,c',\gamma)\operatorname{size}(c,c',\gamma').$$

The map $(p,p',\gamma,\gamma') \mapsto (\gamma,\gamma')$ on the index set on the right is injective, since $p = \pi(\gamma)$ and $p' = \pi(\gamma')$. Its image consists of pairs in $\mathcal{N}\times\mathcal{N}$ that are not in the same link class: if $\mathsf{g}(\gamma)\mathsf{g}(\gamma') \neq 0$ and $\operatorname{link}\gamma = \operatorname{link}\gamma' = L$, then $(p,p') = (L,L) \in \Delta$. As all summands are nonnegative, the right side is at most ν^2 times the second sum of the statement. □

Lemma 5.3.18. *Let $\mathfrak{S}$ be a filling datum, $\gamma \in G(E)$ and $u, u' \in \mathsf{U}(E)$, and put $\gamma' = u^{-1}\gamma u'$.*

(i) $D_j(\gamma') = D_j(\gamma)$ for $0 \le j \le \varrho+1$, so $\mathsf{g}(\gamma') = \mathsf{g}(\gamma)$; $\gamma' X = X$ if and only if $\gamma X = X$; and γ' has agreeing characters if and only if γ has.

(ii) The sets $R(E)$, Γ^* and $\{\gamma \in G(E) : \gamma$ has agreeing characters$\}$ are stable; complements in $G(E)$ and intersections of stable sets are stable.

(iii) Every $\gamma \in R(E)$ has $\mathsf{g}(\gamma) = 0$ and $\gamma X = X$; in particular $R(E) \cap \Gamma^* = \emptyset$.

Proof. Write $F_b = \langle e_1, \dots, e_b\rangle$, so $F_\varrho = X$. Let $g \in \mathsf{U}(E)$. It stabilises each F_b and acts trivially on F_b/F_{b-1}, so $ge_b \in e_b + F_{b-1}$; it stabilises $X^\perp \ni z$ and acts trivially on $X^\perp/X$, so $gz \in z + X$. Hence $gf_l = \sum_{a\le l} T(g)_{al} f_a$ with an upper unitriangular matrix $T(g) \in \mathrm{M}_{\varrho+1}(E)$, and $gX = X$.

(i). Since u is an isometry, $h(f_j, u^{-1}\gamma u' f_l) = h(uf_j, \gamma u' f_l)$, and expanding uf_j and $u'f_l$ in the frame,

$$Z(\gamma') = T(u)^*\, Z(\gamma)\, T(u').$$

$T(u)^*$ is lower and $T(u')$ upper unitriangular, so the leading principal $j\times j$ block of $Z(\gamma')$ is the product of the leading $j\times j$ blocks of $T(u)^*$, $Z(\gamma)$ and $T(u')$, and its determinant is $D_j(\gamma)$. Hence $D_j(\gamma') = D_j(\gamma)$ for all j, and $\mathsf{g}(\gamma') = |D_{\varrho+1}(\gamma)|^2 - N^2|D_\varrho(\gamma)|^2 = \mathsf{g}(\gamma)$. As $uX = u'X = X$, $\gamma' X = u^{-1}\gamma X$, which equals X if and only if $\gamma X = uX = X$. For agreement, it suffices to

show: if δ has agreeing characters, then so has $a\delta a'$ for all $a, a' \in \mathsf{U}(E)$ (apply it to γ with $(a, a') = (u^{-1}, u')$, and to γ' with $(a, a') = (u, u'^{-1})$). Let $w, w' \in \mathsf{U}(E)$ with $w\, a\delta a' = a\delta a'\, w'$. Then $(a^{-1}wa)\delta = \delta(a'w'a'^{-1})$ with $a^{-1}wa,\ a'w'a'^{-1} \in \mathsf{U}(E)$, so $\psi(a^{-1}wa) = \psi(a'w'a'^{-1})$. By Lemma 5.2.44 (i) ($\mathsf{U}(E) \subseteq \mathsf{U}(\mathbb{A}_f)$), ψ is multiplicative on $\mathsf{U}(E)$, so $\psi(a^{-1}wa) = \psi(w)$ and $\psi(a'w'a'^{-1}) = \psi(w')$; hence $\psi(w) = \psi(w')$.

(ii). $R(E)$ is a group containing $\mathsf{U}(E)$ ($\mathsf{U}(E)H(E)$ is a group as $H(E)$ normalises $\mathsf{U}(E)$: H fixes the e_a, e_a^* and z, so conjugation by it preserves the flag, its graded pieces and the triviality on $X^\perp/X$), so $u^{-1}\gamma u' \in R(E)$ if and only if $\gamma \in R(E)$. The set of elements with agreeing characters is stable by (i). Γ^* is defined by the conditions $\mathsf{g} \neq 0$, or agreeing characters, $\mathsf{g} = 0$ and $\gamma X \neq X$, each invariant under $\gamma \mapsto u^{-1}\gamma u'$ by (i); so Γ^* is stable. Complements and intersections of stable sets are stable, since stability says that $\gamma \mapsto u^{-1}\gamma u'$ maps the set onto itself.

(iii). Let $\gamma = gh$ with $g \in \mathsf{U}(E)$ and $h \in H(E)$. As h fixes the frame, $\gamma f_l = g f_l = \sum_{a \le l} T(g)_{al} f_a$, and $\gamma X = gX = X$. The Gram matrix of the frame is

$$(h(f_j, f_a))_{j,a} = \mathrm{diag}(0, \dots, 0, -N),$$

since the e_b are isotropic and orthogonal to each other and to z, and $h(z, z) = -N$. So $Z(\gamma) = \mathrm{diag}(0, \dots, 0, -N)\, T(g)$: its rows of index $< \varrho$ vanish. As $\varrho \ge 1$, $D_\varrho(\gamma) = 0$ and $D_{\varrho+1}(\gamma) = 0$, so $\mathsf{g}(\gamma) = 0$. Thus γ satisfies neither defining condition of Γ^*. □

The first input of the pair bound is the orbit bound Proposition 5.3.19: a large gauge of a term makes the sum of the cut amplitude majorants over its double coset small, and for a stable set of remaining terms every cut amplitude sum is at most ν times the sum of the sizes of its near representatives. The method is Schur's test [256]. The majorant of one term is at most a product of two Schur integrals (Lemma 5.3.20), which are summed over the orbit of the term under the frame-fixing unipotent groups (Lemma 5.3.22). The orbit splits into few classes of lattice translates, so that the orbit sum becomes an integral; in our reading this is the usual comparison of a lattice sum with an integral in the geometry of numbers [52]. The integral is controlled by integration in stages and by an upper bound for an integral of Hua's type, of negative powers of $\det(P + B^*B)$ over matrices B (Lemma 5.3.27; see [138]). The remaining statements of the group sort the terms: amplitude sums vanish over a block that does not agree, a term with vanishing discriminant has a cell rank, and the terms of nonzero discriminant satisfy an open-cell bound (Lemma 5.3.32).

The second input is the gain Proposition 5.3.64, and its idea is a congruence. Lifts of the links of two terms over one block pair integrally modulo M, so, in our reading, a nonzero Gram determinant of link vectors, an algebraic integer after division by the appropriate power of M, has norm at least one (Lemma 5.3.65).

Proposition 5.3.19. *Let $\mathfrak{S}$ be admissible with Weil data.*

(i) If γ is a term over (c, s, c') of cell rank $j \neq 0$, then

$$\Big(\sum_{\delta \in \mathsf{U}_c^0 \gamma \mathsf{U}_{c'}^0} \mathrm{maj}_\delta^{\mathrm{cut}}(c, c')\Big)^2 \le \Big(\nu\, \#I\, \tau_{\mathrm{sz}}^2 (b^{13}/M^2)^{\min(\varrho, j)kf}\Big)^2 \Big(\frac{N^f}{\mathsf{g}^\sharp(j, c, c', \gamma)}\Big)^k.$$

(ii) If $T \subseteq \Gamma^*$ is stable, then for all c, s, c'

$$\|A_T^{\mathrm{cut}}(c, s, c')\| \le \nu \sum_\gamma \mathrm{size}(c, c', \gamma),$$

the sum over the near representatives $\gamma \in T$ over (c, s, c') at their cell rank for which s agrees.

Proof. Write $W = W^{\mathrm{cut}}$, $\mathrm{maj}_\delta = \mathrm{maj}_\delta^{\mathrm{cut}}(c,c')$, $\mathcal{O}(\gamma) = \mathsf{U}_c^0(M)\gamma\mathsf{U}_{c'}^0(M)$, $t_\gamma = h_c^{-1}\gamma h_{c'}$ and $\operatorname{Nm}\mathsf{g}(\gamma) = \prod_v |\mathsf{g}(\gamma)|_v$.

Preliminaries.

(P1) If γ is a term over (c,s,c'), $u \in \mathsf{U}_c^0(M)$ and $u' \in \mathsf{U}_{c'}^0(M)$, then $t_{u\gamma u'} = (h_c^{-1}uh_c)\, t_\gamma\, (h_{c'}^{-1}u'h_{c'})$ with outer factors in $\mathrm{K}(M) = \ker \mathrm{red}$, so $u\gamma u'$ is a term over (c,s,c').

(P2) For $u \in \mathsf{U}_c^0(M)$ and $v \in \Phi$, $u_v = B_v^{-1}v(u)B_v$ with B_v diagonal lies in $\mathsf{U} \subseteq R$ and fixes every f_a. Hence $(u_\infty y)_v^{-1} f_b = y_v^{-1} f_b$, so $u_\infty y$ and y have the same Gram–Schmidt data and rational triangle, and $\ell(u_v y_v) = \ell(y_v)$ as ℓ is an infimum over R; thus $u_\infty y$ is boxed iff y is. If y witnesses that γ is near, $u_\infty y$ witnesses that $u\gamma u'$ is near, since $(u\gamma u')^{-1}u \cdot y = u'^{-1} \cdot (\gamma^{-1}y)$.

(P3) If $\mathrm{maj}_\delta \neq 0$, some y has $\beta_c(y)\beta_{c'}(\delta^{-1}y)\|W(y)\|\|W(\delta^{-1}y)\| \neq 0$; then y and $\delta^{-1}y$ are reduced and all their components lie in the cut by (BS2), so they are boxed and δ is near.

(P4) As γ is an isometry, $h(f_a, \gamma^{-1}f_b) = h(\gamma f_a, f_b) = \overline{h(f_b, \gamma f_a)}$, so $Z(\gamma^{-1}) = \overline{Z(\gamma)}^{\mathsf{T}}$, $D_l(\gamma^{-1}) = \overline{D_l(\gamma)}$, $\mathsf{g}(\gamma^{-1}) = \mathsf{g}(\gamma)$ and $\mathrm{mn}_j(\gamma^{-1}) = \mathrm{mn}_j(\gamma)$. If γ satisfies the conditions of cell rank j with the constant ζ, so does γ^{-1} with $\bar\zeta$: from $f \cdot x = \gamma f \cdot y$ with $x_a = \zeta$, $y_a = 1$, put $x' = \bar\zeta y$, $y' = \bar\zeta x$; then $f \cdot x' = \gamma^{-1}f \cdot y'$, $x'_a = \bar\zeta$, $y'_a = \bar\zeta\zeta = 1$, and the entries above a vanish. If γ is a term over (c,s,c'), then γ^{-1} is a term over (c', s^{-1}, c) with $t_{\gamma^{-1}} = t_\gamma^{-1}$.

(P5) A γ satisfies the conditions of at most one cell rank. Suppose it satisfies those of $j < j'$. Then $j \leq \varrho$, so $\mathsf{g}(\gamma) = 0$ and $j' \leq \varrho$. Take x, y for $a = j$: $f \cdot x = \gamma f \cdot y$, $y_j = 1$, $y_b = 0$ for $b > j$. For $l < j' \leq \varrho$, $f_l = e_{l+1}$ is orthogonal to every frame vector, so $0 = h(f_l, f \cdot x) = h(f_l, \gamma f \cdot y) = \sum_{b<j'} Z(\gamma)_{lb}\, \phi(y_b)$, with ϕ the identity or the conjugation of E according to the variable in which h is linear. The nonzero vector $(\phi(y_b))_{b<j'}$ is killed by the leading $j' \times j'$ block, so $D_{j'}(\gamma) = 0$, a contradiction. Every $\gamma \in \Gamma^*$ satisfies the conditions of some cell rank $j \geq 1$: if $\mathsf{g}(\gamma) \neq 0$, then $j = \varrho + 1$ works, the pair condition being empty and $D_{\varrho+1}(\gamma) = \det Z(\gamma) \neq 0$ by Lemma 5.2.26 (ii); if $\mathsf{g}(\gamma) = 0$, γ has agreeing characters and Lemma 5.3.31 (ii) gives some $j \leq \varrho$. The value $j = 0$ is impossible: the pairs at $a < \varrho$ give $\gamma f \cdot y^{(a)} \in \langle f_0, \dots, f_a\rangle$ for vectors $f \cdot y^{(a)}$ with $y_a^{(a)} = 1$ and $y_b^{(a)} = 0$ $(b > a)$, which span $X = \langle e_1, \dots, e_\varrho\rangle$; so $\gamma X = X$ and $\mathsf{g}(\gamma) = 0$, and $\gamma \notin \Gamma^*$. Hence the cell rank of $\gamma \in \Gamma^*$ is the unique such j, it is at least 1, and by Lemma 5.2.25 (iii) it does not change under $\gamma \mapsto u^{-1}\gamma u'$ $(u, u' \in \mathsf{U}(E))$.

Proof of (i). Let $i = i_j$. By Lemma 5.3.20 with shift i and the Cauchy–Schwarz inequality for sums in $[0,\infty]$,

$$\Big(\sum_{\delta \in \mathcal{O}(\gamma)} \mathrm{maj}_\delta\Big)^2 \leq \sum_{\delta \in \mathcal{O}(\gamma)} \mathrm{Si}(c,c',\delta,i) \cdot \sum_{\delta \in \mathcal{O}(\gamma)} \mathrm{Si}(c',c,\delta^{-1},i).$$

Inversion maps $\mathcal{O}(\gamma)$ bijectively onto $\mathsf{U}_{c'}^0(M)\gamma^{-1}\mathsf{U}_c^0(M)$. By (P4), γ^{-1} is a term over (c', s^{-1}, c) satisfying the conditions of cell rank j, with $\mathrm{mn}_j(\gamma^{-1}) = \mathrm{mn}_j(\gamma)$ and $t_{\gamma^{-1}} = t_\gamma^{-1}$. Applying Lemma 5.3.22 to γ and to γ^{-1}, the right side is at most

$$\Big(\nu\, \#I\, \tau_{\mathrm{sz}}^2 (b^{13}/M^2)^{ikf}\Big)^2 \Big(\frac{\mathrm{ir}_j(t_\gamma)\, \mathrm{ir}_j(t_\gamma^{-1})}{\mathrm{mn}_j(\gamma)}\Big)^k.$$

By Lemma 5.3.6 (i), $i_\gamma = \mathrm{ir}_j(t_\gamma) \geq 1$ and $i'_\gamma = \mathrm{ir}_j(t_\gamma^{-1}) \geq 1$, and by Lemma 5.3.9 (ii), $\mathsf{g}^\sharp(j,c,c',\gamma) = N^f \mathrm{mn}_j(\gamma)/(i_\gamma i'_\gamma)$; so the last factor is $(N^f/\mathsf{g}^\sharp(j,c,c',\gamma))^k$.

Proof of (ii). Fix c, s, c' and a stable $T \subseteq \Gamma^*$. For a term γ the norm of the Bochner integral $A^{\mathrm{cut}}_\gamma(c, c')$ is at most maj_γ, and $\sum \mathrm{maj}_\gamma < \infty$ over the terms of T over (c, s, c') by Lemma 5.2.29 (ii); so the block of every subset of T is an absolutely convergent sum, and blocks add over disjoint unions. If s does not agree, $A^{\mathrm{cut}}_T(c, s, c') = 0$ by Lemma 5.3.30, and there is nothing to prove; let s agree.

For $1 \le j \le \varrho + 1$ let T_j be the set of $\gamma \in T$ of cell rank j. By (P5) the T_j partition T, are stable, and every $\gamma \in T_j$ satisfies the conditions of cell rank j; so $\|A^{\mathrm{cut}}_T\| \le \sum_j \|A^{\mathrm{cut}}_{T_j}\|$. Fix j, let $K = \{\gamma : \mathrm{Nm}\,\mathfrak{g}(\gamma) > N^f \mathrm{mn}_j(\gamma)\}$, stable by Lemma 5.2.25 (ii), and split $T_j = (T_j \cap K) \sqcup (T_j \setminus K)$. In both parts, for a term γ, $i_\gamma, i'_\gamma \ge 1$ by Lemma 5.3.6 (i), so Lemma 5.3.9 (ii) applies.

On $T_j \cap K$: $\mathfrak{g} \ne 0$, so $j = \varrho + 1$ by (TA5). Then $\mathrm{ir}_{\varrho+1} = 1$ by (GT1) (the two lattices coincide), so $\mathfrak{g}^{\max}(\varrho + 1, c, c', \gamma) = \mathrm{Nm}\,\mathfrak{g}(\gamma)$, $i_{\varrho+1} = \varrho$ and $\mathcal{D}^{\mathrm{sz}}_{\varrho+1} = \mathcal{D}_{\mathrm{main}}$; the summand of Lemma 5.3.32 is $\mathrm{size}(c, c', \gamma)$, and that lemma gives $\|A^{\mathrm{cut}}_{T_j \cap K}\| \le \nu \sum \mathrm{size}(c, c', \gamma)$ over the near representatives $\gamma \in T_j \cap K$ over (c, s, c').

On $T' = T_j \setminus K$: by (P1) and stability, the terms of T' over (c, s, c') are the disjoint union of the orbits $\mathcal{O}(\rho)$, $\rho \in R_{c,c'}$ a term of T' over (c, s, c'). Hence $\|A^{\mathrm{cut}}_{T'}\| \le \sum_\rho \sum_{\delta \in \mathcal{O}(\rho)} \mathrm{maj}_\delta$. If the inner sum is nonzero, some $\delta \in \mathcal{O}(\rho)$ is near by (P3), so ρ is near by (P2), i.e. a near representative; ρ has cell rank $j \ge 1$, and (i) bounds the inner sum by

$$\nu \, \#I \, \tau_{\mathrm{sz}}^2 (b^{13}/M^2)^{ikf} (N^f / \mathfrak{g}^\sharp)^{k/2},$$

$i = i_j \ge 1$, $\mathfrak{g}^\sharp = \mathfrak{g}^\sharp(j, c, c', \rho)$. As $\rho \notin K$, $\mathfrak{g}^{\max} = \mathfrak{g}^\sharp$, and this bound is at most

$$\nu \, \mathrm{size}(c, c', \rho) = \nu \tau_{\mathrm{sz}}^2 \sqrt{\mathcal{D}^{\mathrm{sz}}_j / (n_p (M^{2if} \mathfrak{g}^\sharp)^k)} :$$

squaring and using $n_p N^{kf} \#I = \mathcal{D}_{\mathrm{id}}$, this is equivalent to $\#I \, (b^{13}/M)^{2ikf} \mathcal{D}_{\mathrm{id}} \le \mathcal{D}^{\mathrm{sz}}_j$, and indeed $\#I \le b^{2kf} = \tau_{\mathrm{sz}}^8$ by (FA7), $b^{13}/M \le b^{-6}$ by (FG6), so the left side is at most $\tau_{\mathrm{sz}}^{8-48i} \mathcal{D}_{\mathrm{id}} \le \tau_{\mathrm{sz}}^{-40} \mathcal{D}_{\mathrm{id}}$, while $\mathcal{D}^{\mathrm{sz}}_j = \mathcal{D}_{\mathrm{id}} / \tau_{\mathrm{sz}}^{16}$ for $j \le \varrho$ and $\mathcal{D}^{\mathrm{sz}}_j = \mathcal{D}_{\mathrm{main}} \ge b^{11kf} \mathcal{D}_{\mathrm{id}}$ for $j = \varrho + 1$ by (FA6), both at least $\tau_{\mathrm{sz}}^{-40} \mathcal{D}_{\mathrm{id}}$ as $\tau_{\mathrm{sz}} \ge 1$.

Adding the two parts and summing over j gives $\|A^{\mathrm{cut}}_T(c, s, c')\| \le \nu \sum_\gamma \mathrm{size}(c, c', \gamma)$ over the near representatives $\gamma \in T$ over (c, s, c'), each at its cell rank, with s agreeing. □

Lemma 5.3.20. *Let $\mathfrak{S}$ be a filling datum, $c, c' \in \mathcal{C}$, $\delta \in G(E)$ and $i \ge 0$ an integer. Then, in $[0, \infty]$,*

$$\mathrm{maj}^{\mathrm{cut}}_\delta(c, c')^2 \le \mathrm{Si}(c, c', \delta, i) \, \mathrm{Si}(c', c, \delta^{-1}, i).$$

Proof. Write $W = W^{\mathrm{cut}}$, so $\|W(y)\| = \prod_v \|W^\flat_v(y_v)\|$ and $\|W(y) \otimes \overline{W(x)}\| = \|W(y)\| \, \|W(x)\|$ (a rank-one tensor). Put $m(y) = \beta_c(y) \beta_{c'}(\delta^{-1} y) \|W(y)\| \, \|W(\delta^{-1} y)\|$, so that $\mathrm{maj}^{\mathrm{cut}}_\delta(c, c') = \int m$, and $\vartheta(y) = \prod_v \mathrm{Vr}_{\delta_v}(y_v)$, which is positive by Lemma 5.3.21 (i). All functions below are Borel and take values in $[0, \infty]$.

The two Schur integrals. Put

$$A(y) = \beta^{\mathrm{bx}}_c(y) \|W(y)\|^2 \beta^{\mathrm{bx}}_{c'}(\delta^{-1} y) \, \vartheta(y)^{-(k+i)}, \qquad B(y) = \beta^{\mathrm{bx}}_{c'}(\delta^{-1} y) \|W(\delta^{-1} y)\|^2 \beta^{\mathrm{bx}}_c(y) \, \vartheta(y)^{k+i}.$$

By (SX2), $\int A = \mathrm{Si}(c, c', \delta, i)$. Since $\gamma \mapsto \gamma_\infty$ is a homomorphism, $(\delta^{-1})_v = \delta_v^{-1}$ and $(\delta^{-1})^{-1} x = \delta x$, so

$$\mathrm{Si}(c', c, \delta^{-1}, i) = \int_{G_\infty} \beta^{\mathrm{bx}}_{c'}(x) \|W(x)\|^2 \beta^{\mathrm{bx}}_c(\delta x) \prod_v \mathrm{Vr}_{\delta_v^{-1}}(x_v)^{-(k+i)} \, dx.$$

The measure of G_∞ is the product of the Cayley measures of the factors, each invariant under left translations by Lemma 5.2.41; by Tonelli's theorem the substitution $x = \delta^{-1}y$ leaves the integral unchanged, and $\mathrm{Vr}_{\delta_v^{-1}}(\delta_v^{-1}y_v) = \mathrm{Vr}_{\delta_v}(y_v)^{-1}$ by Lemma 5.3.21 (ii). Hence $\mathrm{Si}(c', c, \delta^{-1}, i) = \int B$.

The pointwise bound $m^2 \le AB$. If $m(y) = 0$ there is nothing to show. Otherwise $\beta_c(y) \neq 0$, so y is reduced, and $W_v^\flat(y_v) \neq 0$ for every v, so by (BS2) every y_v lies in the cut, $\ell(y_v) \le b^{6n+2}$; hence y is boxed and $\beta_c^{\mathrm{bx}}(y) = \beta_c(y)$. In the same way $\delta^{-1}y$ is boxed and $\beta_{c'}^{\mathrm{bx}}(\delta^{-1}y) = \beta_{c'}(\delta^{-1}y)$. As $0 < \vartheta(y) < \infty$, the powers of $\vartheta(y)$ cancel and $A(y)B(y) = m(y)^2$.

Conclusion. By the Cauchy–Schwarz inequality for nonnegative functions,

$$\Big(\int m\Big)^2 \le \Big(\int \sqrt{AB}\Big)^2 \le \int A \int B,$$

which is the assertion. □

Lemma 5.3.21. *Let $\varrho \ge 1$ and κ be as in Definition 5.1.6, and $\gamma, y \in G_1$.*

(i) $\mathrm{Fv}(y) > 0$*; hence* $\mathrm{Vr}_\gamma(y) > 0$.

(ii) $\mathrm{Vr}_{\gamma^{-1}}(\gamma^{-1}y) = \mathrm{Vr}_\gamma(y)^{-1}$.

(iii) If $u \in G_1$ fixes $f_0, \dots, f_\varrho$, then $\mathrm{Fv}(uy) = \mathrm{Fv}(y)$ *and* $\mathrm{Vr}_\gamma(uy) = \mathrm{Vr}_{u^{-1}\gamma}(y)$.

Proof. In the basis $e_1, \dots, e_\varrho$, the basis of X_0, z, $e_1^*, \dots, e_\varrho^*$, the entries of J_1 are the values of h_1 on pairs of basis vectors, so $J_1 e_a = e_a^*$, $J_1 e_a^* = e_a$, $J_1 x = x$ for $x \in X_0$ and $J_1 z = -z$. Let F be the $r \times (\varrho+1)$ matrix with columns $f_0, \dots, f_\varrho$ and $P = (1 - J_1)F$, with columns $e_a - e_a^*$ $(1 \le a \le \varrho)$ and $2z$; thus $\mathrm{Fv}(y) = |\det(P^* y^{-1} F)|$.

(i) Suppose $\det(P^* y^{-1} F) = 0$, and choose $0 \neq x \in \mathbb{C}^{\varrho+1}$ with $P^* y^{-1} F x = 0$; put $w = y^{-1}Fx$. The columns of P are $\varrho+1$ nonzero, pairwise orthogonal vectors of the (-1)-eigenspace V_- of J_1, which has dimension $\varrho+1$ by the list above; so they span V_-, and w is orthogonal to V_-. As J_1 is hermitian and unitary, $V_-^\perp$ is the $(+1)$-eigenspace, so $J_1 w = w$ and $h_1(w, w) = \|w\|^2$. On the other hand $y^{-1} \in G_1$ preserves h_1, and the frame vectors satisfy $h_1(f_a, f_b) = 0$ unless $a = b = \varrho$, $h_1(z, z) = -1$; hence $h_1(w, w) = h_1(Fx, Fx) = -|x_\varrho|^2$. So $\|w\|^2 \le 0$, $w = 0$, $Fx = yw = 0$, and $x = 0$ because the columns of F are distinct basis vectors, a contradiction. Hence $\mathrm{Fv}(y) > 0$ for every y, and $\mathrm{Vr}_\gamma(y) = \mathrm{Fv}(\gamma^{-1}y)/\mathrm{Fv}(y) > 0$.

(ii) $\mathrm{Vr}_{\gamma^{-1}}(\gamma^{-1}y) = \mathrm{Fv}(\gamma\gamma^{-1}y)/\mathrm{Fv}(\gamma^{-1}y) = \mathrm{Fv}(y)/\mathrm{Fv}(\gamma^{-1}y) = \mathrm{Vr}_\gamma(y)^{-1}$, both frame volumes being positive by (i).

(iii) As u^{-1} fixes every f_b, $(uy)^{-1}F = y^{-1}u^{-1}F = y^{-1}F$, so $\mathrm{Fv}(uy) = \mathrm{Fv}(y)$. Then $\mathrm{Vr}_\gamma(uy) = \mathrm{Fv}(\gamma^{-1}uy)/\mathrm{Fv}(uy) = \mathrm{Fv}((u^{-1}\gamma)^{-1}y)/\mathrm{Fv}(y) = \mathrm{Vr}_{u^{-1}\gamma}(y)$. □

Lemma 5.3.22. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, $1 \le j \le \varrho+1$, and γ a term over (c, s, c') satisfying the conditions of cell rank j. Then*

$$\sum_{\delta \in \mathsf{U}_c^0(M)\,\gamma\,\mathsf{U}_{c'}^0(M)} \mathrm{Si}(c, c', \delta, i_j) \le \nu\, \#I\, \tau_{\mathrm{sz}}^2 \Big(\frac{b^{13}}{M^2}\Big)^{i_j k f} \Big(\frac{\mathrm{ir}_j(h_c^{-1}\gamma h_{c'})}{\sqrt{\mathrm{mn}_j(\gamma)}}\Big)^k.$$

Proof. Put $i = i_j$, $O = \mathsf{U}_c^0(M)\,\gamma\,\mathsf{U}_{c'}^0(M)$ (a countable set, as $G(E)$ is countable), $\mathrm{ir} = \mathrm{ir}_j(h_c^{-1}\gamma h_{c'})$, and

$$F(y) = \sum_{p \in O} \mathrm{Sw}_{c', p, i}(y) \qquad (y \in G_\infty),$$

a countable sum of nonnegative Borel functions, hence Borel. By monotone convergence,

$$\sum_{\delta\in O}\mathrm{Si}(c,c',\delta,i)=\int_{G_\infty}\beta_c^{\mathrm{bx}}(y)\prod_{v\in\Phi}\|W_v^\flat(y_v)\|^2\,F(y)\,dy. \tag{5.49}$$

F **is invariant under $\mathsf{U}_c^0(M)$.** Let $u\in\mathsf{U}_c^0(M)$. Then $p\mapsto up$ is a bijection of O. Each f_b has coordinates in $\{0,1\}$ and $B_vf_b=\mathrm{bs}_v(f_b)f_b$ for the diagonal matrix B_v of basis scales, so $u_vf_b=B_v^{-1}v(u)B_vf_b=f_b$ for every v and b, as $uf_b=f_b$. Hence $\mathrm{Fv}(u_vy_v)=\mathrm{Fv}(y_v)$, since $(u_vy_v)^{-1}f_b=y_v^{-1}f_b$, and $(up)_\infty^{-1}u_\infty y=p_\infty^{-1}y$; so $\mathrm{Sw}_{c',up,i}(u_\infty y)=\mathrm{Sw}_{c',p,i}(y)$, and summing over $p\in O$ gives $F(u_\infty y)=F(y)$.

The average over a fundamental domain. Let $Y=\prod_v\mathrm{M}_{i\times k}(\mathbb{C})$ with Lebesgue measure, $\Lambda=\Lambda_{c,i}^\infty\subseteq Y$ the column lattice at infinity (SX6), and let D be the Borel set of Lemma 5.3.23 for c and i, with $1\le\int_D dx<\infty$. The map $x\mapsto\mathrm{Es}_j(x)$ is continuous with values in $\prod_v\mathsf{U}^0$ (SX3). Let $u\in G_\infty$ with all $u_v\in\mathsf{U}^0$ and let y be boxed. By Lemma 5.3.24, O is the union of a family $\mathcal{B}$ of at most ir^k sets B, each containing a p_B of which every element of B is a lattice translate. For each $B\in\mathcal{B}$, Lemma 5.3.25 (with B, p_B, u, y) gives a Borel $\phi_B\ge0$ on Y with $\int_Y\phi_B\le\prod_v\mathrm{Kb}_j(\gamma,v)$ and $\sum_{p\in B}\mathrm{Sw}_{c',p,i}(u\,\mathrm{Es}_j(x)\,y)\le\tau_{\mathrm{sz}}\sum_{w\in\Lambda}\phi_B(w+x)$. Since the translates $w+D$ ($w\in\Lambda$) cover Y up to a null set and are pairwise disjoint up to null sets, $\int_D\sum_{w\in\Lambda}\phi_B(w+x)\,dx=\sum_w\int_{w+D}\phi_B=\int_Y\phi_B$. Hence, with all terms nonnegative,

$$\int_D F(u\,\mathrm{Es}_j(x)\,y)\,dx\le\sum_{B\in\mathcal{B}}\int_D\sum_{p\in B}\mathrm{Sw}_{c',p,i}(u\,\mathrm{Es}_j(x)\,y)\,dx\le\mathrm{ir}^k\tau_{\mathrm{sz}}\prod_v\mathrm{Kb}_j(\gamma,v)\le\Big(\int_D dx\Big)\,C_0,$$

where $C_0=\mathrm{ir}^k\tau_{\mathrm{sz}}\prod_v\mathrm{Kb}_j(\gamma,v)$ and the last step uses $\int_D dx\ge1$.

Integration in stages. By Lemma 5.3.28 with the measure space (Y,dx), the map Es_j in the role of t, $A=D$, $C=C_0$ and the invariant function F, the right side of (5.49) is at most $C_0\,\nu\,\#I$. By Lemma 5.3.29 ($j\ge1$),

$$\sum_{\delta\in O}\mathrm{Si}(c,c',\delta,i)\le\nu\,\#I\,\mathrm{ir}^k\,\tau_{\mathrm{sz}}\cdot\tau_{\mathrm{sz}}\Big(\frac{b^{13}}{M^2}\Big)^{ikf}\mathrm{mn}_j(\gamma)^{-k/2}=\nu\,\#I\,\tau_{\mathrm{sz}}^2\Big(\frac{b^{13}}{M^2}\Big)^{ikf}\Big(\frac{\mathrm{ir}}{\sqrt{\mathrm{mn}_j(\gamma)}}\Big)^k.$$

□

Lemma 5.3.23. *Let $\mathfrak{S}$ be a filling datum over a field E that carries Weil data, $c\in\mathcal{C}$ and $i\ge0$ an integer. Let $Y=\prod_{v\in\Phi}\mathrm{M}_{i\times k}(\mathbb{C})$ with Lebesgue measure dx in the real and imaginary parts of the entries. Then there is a Borel set $D\subseteq Y$ with $1\le\int_D dx<\infty$ whose translates $w+D$ ($w\in\Lambda_{c,i}^\infty$) are pairwise disjoint and cover Y.*

Proof. Write $x_1,\dots,x_k$ for the standard basis of $X_0=E^k$, $L=L_c\cap X_0(\mathbb{A}_f)$, and $L_E=\{x\in X_0:\ x\in L\}$ ($X_0\subseteq X_0(\mathbb{A}_f)$ diagonally). Put $\Lambda=\Lambda_{c,i}^\infty$.

The definite part L is an open compact $\hat{\mathcal{O}}$-module on which the form is integral. By (FG3), L_0 is the $\hat{\mathcal{O}}$-span of the standard basis of V with x_k replaced by $x_k/\bar\pi+z/N$; the vector z itself is a basis vector. An element $\sum_{a<k}\alpha_ax_a+\alpha_k(x_k/\bar\pi+z/N)+\alpha_zz+(\text{terms in the }e_b,e_b^*)$ with all coefficients in $\hat{\mathcal{O}}$ lies in $X_0(\mathbb{A}_f)$ if and only if the e_b,e_b^*-coefficients vanish and $\alpha_z=-\alpha_k/N$, which is integral if and only if $\alpha_k\in N\hat{\mathcal{O}}$; then $\alpha_k/\bar\pi\in\pi\hat{\mathcal{O}}$, as $N=\pi\bar\pi$. Hence

$$L_0\cap X_0(\mathbb{A}_f)=\textstyle\bigoplus_{a<k}\hat{\mathcal{O}}x_a\oplus\pi\hat{\mathcal{O}}x_k\ \subseteq\ \hat{\mathcal{O}}^k.$$

The element $h_c\in\mathrm{U}(X_0)(\mathbb{A}_f)$ acts on $V(\mathbb{A}_f)$ through the embedding $\mathrm{U}(X_0)\subseteq G$: it preserves $X_0(\mathbb{A}_f)$ and the hermitian form. So $L=h_cL_0\cap X_0(\mathbb{A}_f)=h_c(L_0\cap X_0(\mathbb{A}_f))$ is the image of an

open compact $\hat{\mathcal{O}}$-submodule of $\mathbb{A}_f^k$ under an $\mathbb{A}_f$-linear homeomorphism, hence an open compact $\hat{\mathcal{O}}$-submodule, and $h(x,y) = h(h_c^{-1}x, h_c^{-1}y) \in \hat{\mathcal{O}}$ for $x, y \in L$, since the unit form takes values in $\hat{\mathcal{O}}$ on $\hat{\mathcal{O}}^k$.

L_E is a free $\mathbb{Z}$-module of rank $2fk$. The sets $m\hat{\mathcal{O}}^k$ ($m \geq 1$ an integer) form a basis of neighbourhoods of 0 in $\mathbb{A}_f^k$, and $\mathbb{A}_f^k$ is the increasing union of the open sets $m^{-1}\hat{\mathcal{O}}^k$. As L is open and compact there are integers $m_1, m_2 \geq 1$ with $m_1\hat{\mathcal{O}}^k \subseteq L \subseteq m_2^{-1}\hat{\mathcal{O}}^k$. Intersecting with E^k and using $E \cap \hat{\mathcal{O}} = \mathcal{O}_E$ gives $m_1\mathcal{O}_E^k \subseteq L_E \subseteq m_2^{-1}\mathcal{O}_E^k$. Since $\mathcal{O}_E$ is a free $\mathbb{Z}$-module of rank $[E:\mathbb{Q}] = 2f$, the subgroup L_E of the free module $m_2^{-1}\mathcal{O}_E^k$ is free, of rank $2fk$ because it contains $m_1\mathcal{O}_E^k$. In particular a $\mathbb{Z}$-basis of L_E is a $\mathbb{Q}$-basis of E^k.

Λ is spanned by an $\mathbb{R}$-basis of Y. For $q \in \mathrm{M}_{k\times i}(E)$ put $q^\infty = (v(q)^*)_{v\in\Phi} \in Y$; the map $q \mapsto q^\infty$ is additive, and by (SX6) $\Lambda = \{q^\infty : q \in L_E^i\}$, where L_E^i denotes the matrices with all columns in L_E. The map $E \otimes_{\mathbb{Q}} \mathbb{R} \to \prod_{v\in\Phi} \mathbb{C}$, $x \otimes t \mapsto (t\,v(x))_v$, is an isomorphism of real vector spaces, because E is totally imaginary of degree $2f$ and Φ contains exactly one embedding from each pair of complex conjugate embeddings (the classical Minkowski embedding). Applied entrywise and followed by conjugate transposition, it shows that the $\mathbb{R}$-linear extension $\mathrm{M}_{k\times i}(E) \otimes_{\mathbb{Q}} \mathbb{R} \to Y$ of $q \mapsto q^\infty$ is an isomorphism. Let $g_1, \ldots, g_{2fki}$ be a $\mathbb{Z}$-basis of L_E^i (by the previous step, $L_E^i \cong L_E^i$ is free of rank $2fki$); it is a $\mathbb{Q}$-basis of $\mathrm{M}_{k\times i}(E)$, so $w_j = g_j^\infty$ ($1 \leq j \leq 2fki$) is an $\mathbb{R}$-basis of Y, and $\Lambda = \bigoplus_j \mathbb{Z}w_j$.

The euclidean products of points of Λ are integers. Let $\langle y, y'\rangle = \sum_v \sum_{l,a} \mathrm{Re}(\overline{y_{v,la}}\, y'_{v,la})$; the real and imaginary parts of the entries form an orthonormal basis for it, so dx is the Lebesgue measure of this euclidean structure. For $q, q' \in L_E^i$ the entries of the component at v of q^∞ are $\overline{v(q_{al})}$, and since every embedding of the CM field E commutes with complex conjugation,

$$\langle q^\infty, q'^\infty\rangle = \sum_{v\in\Phi} \mathrm{Re}\, v(w), \qquad w = \sum_l \sum_a q_{al}\overline{q'_{al}}.$$

Here $w = \sum_l h(q'_l, q_l)$ for the columns $q_l, q'_l \in L_E \subseteq L$ (or its conjugate, according to the side on which h is linear), so $w \in E \cap \hat{\mathcal{O}} = \mathcal{O}_E$ by the first step. The embeddings of E are the $v \in \Phi$ and their conjugates, so $\sum_v \mathrm{Re}\, v(w) = \frac{1}{2}\mathrm{Tr}_{E/\mathbb{Q}}(w)$. By the Weil data E contains a primitive 5040-th root of unity ζ, and $\mathrm{i} = \zeta^{1260}$ satisfies $\mathrm{i}^2 = -1$; so $\mathbb{Q}(\mathrm{i}) \subseteq E$ and $\mathrm{Tr}_{E/\mathbb{Q}}(w) = \mathrm{Tr}_{\mathbb{Q}(\mathrm{i})/\mathbb{Q}}(\mathrm{Tr}_{E/\mathbb{Q}(\mathrm{i})}(w))$ with $\mathrm{Tr}_{E/\mathbb{Q}(\mathrm{i})}(w) \in \mathcal{O}_E \cap \mathbb{Q}(\mathrm{i}) = \mathbb{Z}[\mathrm{i}]$, whose traces to $\mathbb{Q}$ are even. Hence $\langle q^\infty, q'^\infty\rangle \in \mathbb{Z}$.

The fundamental parallelepiped. The Gram matrix $(\langle w_j, w_l\rangle)_{j,l}$ is an integer matrix, positive definite as the w_j are linearly independent, so its determinant is an integer ≥ 1. Let $D = \{\sum_j t_j w_j : \ 0 \leq t_j < 1\}$, a Borel set. Every $y \in Y$ is $\sum_j s_j w_j$ for unique $s \in \mathbb{R}^{2fki}$, and $y = \sum_j \lfloor s_j \rfloor w_j + \sum_j (s_j - \lfloor s_j \rfloor) w_j$ is its unique decomposition as an element of $\Lambda = \bigoplus_j \mathbb{Z}w_j$ plus an element of D; so the translates $w + D$ ($w \in \Lambda$) are pairwise disjoint and cover Y. Finally $\int_D dx$ is the absolute value of the determinant of $(w_1, \ldots, w_{2fki})$ in an orthonormal basis, that is $\det(\langle w_j, w_l\rangle)^{1/2}$, which lies in $[1, \infty)$. (For $i = 0$, $Y = \Lambda = D = \{0\}$ and $\int_D dx = 1$.) □

Lemma 5.3.24. *Let $\mathfrak{S}$ be a filling datum with Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, and γ a term over (c, s, c') satisfying the conditions of cell rank j. Then $\mathrm{ir}_j(h_c^{-1}\gamma h_{c'})$ is a positive integer, and the double coset $\mathsf{U}_c^0(M)\,\gamma\,\mathsf{U}_{c'}^0(M)$ is the union of at most $\mathrm{ir}_j(h_c^{-1}\gamma h_{c'})^k$ sets B, each containing an element p_B such that every $p \in B$ is a lattice translate of p_B (for c, γ, j).*

Proof. Write $A = \langle e_1, \ldots, e_\varrho\rangle$, so $A^\perp = A \oplus X_0 \oplus Ez$ and $V = A^\perp \oplus \langle e_1^*, \ldots, e_\varrho^*\rangle$; for $w \in V(\mathbb{A}_f)$ the coefficient of e_a^* is $h(e_a, w)$ and the coefficient of z is $-h(z,w)/N$. Let $k_0 = h_c^{-1}\gamma h_{c'} \in K$, $i = i_j = \min(\varrho, j)$, and let X be the $\varrho \times (\varrho+1)$ matrix over E with entries $X_{ab} = h(e_a, \gamma f_b)$ ($1 \leq a \leq \varrho$, $0 \leq b \leq \varrho$), with rows X_a; $X_{\leq i}$ denotes its first i rows. As $h_c, h_{c'}$ fix the frame

vectors and preserve h, $h(f_{b''}, k_0 f_b) = h(f_{b''}, \gamma f_b)$ for all frame vectors $f_{b''}, f_b$, so X consists of the rows $0, \dots, \varrho - 1$ of $Z(\gamma)$, the rows of $f_0, \dots, f_{\varrho-1} = e_1, \dots, e_\varrho$.

Step 1: $X_{\le i}$ has rank i, and the rows X_a ($a > i$) are E-combinations of $X_1, \dots, X_i$. By (TA5), for every a with $j \le a \le \varrho$ there are $x, y \in E^{\varrho+1}$ with $f \cdot x = \gamma f \cdot y$, $y_a = 1$ and $y_b = 0$ for $b > a$, so $\gamma f_a = f \cdot x - \sum_{b<a} y_b \gamma f_b$. Since $e_{a'}$ is orthogonal to every frame vector, $X_{a'a} = -\sum_{b<a} y_b X_{a'b}$ for all a': column a of X is an E-combination, with coefficients independent of the row, of the columns $b < a$. By induction on $a = j, \dots, \varrho$, every column $a \ge j$ of X is an E-combination of the columns $b < j$. If $j \le \varrho$, then $i = j$, and the block of X on the rows $1, \dots, j$ and columns $0, \dots, j-1$ is the leading $j \times j$ block of $Z(\gamma)$, of determinant $D_j(\gamma) \ne 0$ (TA5); so $X = X_{\cdot,<j} C$ with $C = (X_{\le j,<j})^{-1} X_{\le j}$, and every row $X_a = X_{a,<j}(X_{\le j,<j})^{-1} X_{\le j}$ is an E-combination of $X_1, \dots, X_j$, and $X_{\le j}$ has rank j. If $j = \varrho + 1$, then $i = \varrho$, $X_{\le i} = X$ consists of ϱ rows of the invertible matrix $Z(\gamma)$ ($\det Z(\gamma) = D_{\varrho+1}(\gamma) \ne 0$), so it has rank ϱ, and the second claim is empty. In both cases there is $\xi' \in \mathrm{M}_{(\varrho+1)\times i}(E)$ with $X_{\le i}\, \xi' = 1_i$.

Step 2: the index. Let $R = \sum_{a=1}^{\varrho} \hat{\mathcal{O}} X_a$ and $R_i = \sum_{a \le i} \hat{\mathcal{O}} X_a$, submodules of $\mathbb{A}_f^{\varrho+1}$. The rows $r_a(k_0)$ of (GT1) are $r_a(k_0)_b = h(k_0 f_b, e_a) = \overline{X_{ab}}$, and complex conjugation is a ring automorphism of $\mathbb{A}_f$ preserving $\hat{\mathcal{O}}$; hence $\mathrm{ir}_j(k_0) = [R : R_i]$. By Step 1 there is an integer $d \ge 1$ with $dX_a \in \sum_{a' \le i} \mathcal{O}_E X_{a'}$ for all a, so $dR \subseteq R_i \subseteq R$; as R is a finitely generated $\hat{\mathcal{O}}$-module and $\hat{\mathcal{O}}/d\hat{\mathcal{O}}$ is finite, R/dR is finite. So $\mathrm{ir}_j(k_0) = [R : R_i]$ is a positive integer.

Step 3: the change of the frame along the double coset. Let $p = u\gamma u'$ with $u \in \mathsf{U}_c^0(M)$, $u' \in \mathsf{U}_{c'}^0(M)$. As u' fixes the frame, $pf_b = u\gamma f_b$. Write $\gamma f_b = w_b + \sum_a X_{ab} e_a^*$ with $w_b \in A^\perp$. The element u lies in the unipotent radical of the stabiliser of the flag $\langle e_1 \rangle \subset \cdots \subset A$, so it acts trivially on $A^\perp/A$, and $(u-1)w_b \in A$. Hence

$$pf_b - \gamma f_b \equiv \sum_{a=1}^{\varrho} X_{ab}\,(u-1)e_a^* \pmod{A}.$$

The vector $(u-1)e_a^*$ has no e^*- and no z-coefficient: $h(e_{a'}, (u-1)e_a^*) = h(u^{-1}e_{a'}, e_a^*) - h(e_{a'}, e_a^*) = 0$ and likewise for z, as u fixes $e_{a'}$ and z. Moreover $(u-1)e_a^* = h_c(t-1)e_a^*$ with $t = h_c^{-1} u h_c \in K(M)$ (RD2) and $h_c^{-1} e_a^* = e_a^*$; by (iii) of Lemma 5.2.24 and $e_a^* \in L_0$, $(t-1)e_a^* \in ML_0 \cap (A \oplus X_0)(\mathbb{A}_f)$. In the lattice basis an element of L_0 with vanishing e^*- and z-coefficients has coefficient $\alpha_k \in N\hat{\mathcal{O}}$ at $x_k/\bar{\pi} + z/N$ (x_k the last basis vector of X_0), so its A-part lies in $\bigoplus_a \hat{\mathcal{O}} e_a \subseteq L_0$ and its X_0-part in L_0; thus $L_0 \cap (A \oplus X_0)(\mathbb{A}_f) = (L_0 \cap A(\mathbb{A}_f)) \oplus (L_0 \cap X_0(\mathbb{A}_f))$, and the same holds for $ML_0 = M \cdot L_0$. As h_c preserves A and X_0, the X_0-part $\mu_a(u)$ of $(u-1)e_a^*$ lies in $M(L_c \cap X_0(\mathbb{A}_f))$. Let $Y_p \in \mathrm{M}_{k\times(\varrho+1)}(E)$ have as column b the X_0-part of $pf_b - \gamma f_b$. Then $pf_b - \gamma f_b \in A \oplus X_0$ and

$$Y_p = \mu(u)\, X, \qquad \mu(u) = (\mu_1(u), \dots, \mu_\varrho(u)), \quad \mu_a(u) \in M(L_c \cap X_0(\mathbb{A}_f)).$$

Step 4: colouring. Fix $g \in \mathrm{GL}_k(\mathbb{A}_f)$ with $L_c \cap X_0(\mathbb{A}_f) = g\,\hat{\mathcal{O}}^k$ (an open compact $\hat{\mathcal{O}}$-submodule of $\mathbb{A}_f^k$, free as $\hat{\mathcal{O}}$ is a product of principal ideal domains). By Step 3, $\mu(u) = Mg\,\omega$ with $\omega \in \mathrm{M}_{k\times\varrho}(\hat{\mathcal{O}})$, so every row of $M^{-1}g^{-1}Y_p = \omega X$ lies in R. Colour p by the classes of the k rows of $M^{-1}g^{-1}Y_p$ in R/R_i; this takes at most $[R : R_i]^k = \mathrm{ir}_j(k_0)^k$ values. (Y_p depends only on p, not on the choice of u, u'.) Let B be a colour class and $p_B \in B$. For $p \in B$ put $D = Y_p - Y_{p_B} \in \mathrm{M}_{k\times(\varrho+1)}(E)$; its rows satisfy $M^{-1}g^{-1}D = \omega' X_{\le i}$ with $\omega' \in \mathrm{M}_{k\times i}(\hat{\mathcal{O}})$. Let $l = M^{-1}D\xi' \in \mathrm{M}_{k\times i}(E)$ with ξ' of Step 1. Then $l = g\,\omega' X_{\le i}\xi' = g\,\omega'$, so every column of l lies in $L_c \cap X_0(\mathbb{A}_f)$, and $Ml\, X_{\le i} = Mg\,\omega' X_{\le i} = D$. By Step 3 for p and for p_B, $pf_b - p_B f_b \in A \oplus X_0$ with X_0-part the column b of $D = M\sum_{a<i} l_a\,(X_{a+1,b})$, where l_a is column a of l ($0 \le a < i$) and

$X_{a+1,b} = h(e_{a+1}, \gamma f_b)$; that is,

$$pf_b \equiv p_B f_b + M \sum_{a<i} h(e_{a+1}, \gamma f_b)\, l_a \pmod{A} \qquad (0 \le b \le \varrho),$$

and p is a lattice translate of p_B by l (SX5). □

Lemma 5.3.25. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, γ a term over (c, s, c') satisfying the conditions of cell rank j, and $i = i_j$. Let $B \subseteq \mathsf{U}^0_c(M)\,\gamma\,\mathsf{U}^0_{c'}(M)$ and $p_0 \in B$ be such that every $p \in B$ is a lattice translate of p_0 (for c, γ, j). Let $u \in G_\infty$ with $u_v \in \mathsf{U}^0$ for every v, and let $y \in G_\infty$ be boxed. Put $Y = \prod_{v\in\Phi} \mathrm{M}_{i\times k}(\mathbb{C})$ with Lebesgue measure dx and $\Lambda = \Lambda^\infty_{c,i} \subseteq Y$. Then there is a Borel function $\phi\colon Y \to [0,\infty]$ with $\int_Y \phi\, dx \le \prod_{v\in\Phi} \mathrm{Kb}_j(\gamma, v)$ such that for every $x \in Y$*

$$\sum_{p\in B} \mathrm{Sw}_{c',p,i}(u\,\mathrm{Es}_j(x)\,y) \le \tau_{\mathrm{sz}} \sum_{w\in\Lambda} \phi(w+x).$$

Proof. Let $O = \mathsf{U}^0_c(M)\gamma\mathsf{U}^0_{c'}(M)$; for $p \in B$ fix $l(p) \in \mathrm{M}_{k\times i}(E)$ with columns in $L_c \cap X_0(\mathbb{A}_f)$ such that p is a lattice translate of p_0 by $l(p)$. Write $\pi_0(w)$ for the X_0-coordinates of a vector w, $A = \langle e_1, \dots, e_\varrho\rangle$, and $D_v = D_{j,v}$ (SX3), a real diagonal matrix with entries $d_{v,a} = M/\mathrm{bs}_v(e_{a+1})$.

Step 0: the elements of O. Let $p = u_1\gamma u_1' \in O$. As u_1, u_1' fix the frame, $h(f_a, pf_b) = h(f_a, \gamma f_b)$, so $Z(p) = Z(\gamma)$; every pair (x', w') of (TA5) for γ is one for p ($f\cdot x' = u_1 f \cdot x' = u_1\gamma f \cdot w' = pf \cdot w'$), so p satisfies the conditions of cell rank j with the same c; and $h_c^{-1} p h_{c'} = (h_c^{-1}u_1 h_c)(h_c^{-1}\gamma h_{c'})(h_{c'}^{-1}u_1' h_{c'}) \in K(M)KK(M) = K$ has reduction s, so p is a term over (c,s,c'). By Lemma 5.3.36 (i), applied to p and to γ, $Z(p_v) = S_v\, v(Z(p))\, S_v = S_v\, v(Z(\gamma))\, S_v = Z(\gamma_v)$ with $S_v = \mathrm{diag}(\mathrm{bs}_v(f_a))_a$, and p_v has norm-one pairs from j in the sense of Lemma 5.3.26: a pair (x', w') of (TA5) with $x'_a = c_0$, $c_0\bar{c}_0 = 1$, gives $f\cdot\tilde{x} = p_v f \cdot \tilde{w}$ with $\tilde{x}_b = \mathrm{bs}_v(f_a)v(x'_b)/\mathrm{bs}_v(f_b)$, $\tilde{w}_b = \mathrm{bs}_v(f_a)v(w'_b)/\mathrm{bs}_v(f_b)$, so $\tilde{w}_a = 1$, $|\tilde{x}_a| = |v(c_0)| = 1$ and $\tilde{x}_b = \tilde{w}_b = 0$ for $b > a$. Both properties persist under left multiplication by elements of G_1 fixing the frame.

Step 1: the moved X_0-parts. For $a \in \mathrm{M}_{\varrho\times k}(\mathbb{C})$ the formula of $u(a,b)$ in Definition 5.1.6 gives $u(a,0)^{-1} = u(-a,0)$ and, for $g \in \mathsf{U}^0$ and $w \in V_1$, $\pi_0(g^{-1}w) = \pi_0(w) + a_g^*\epsilon(w)$ for a matrix a_g depending only on g, where $\epsilon(w) = (h(e_{a+1}, w))_{a<\varrho}$ are the e^*-coordinates of w; for $g = u(a,0)$, $a_g = a$. Fix v and $x \in Y$, and let $g_v = u_v \mathrm{Es}_j(x)_v \in \mathsf{U}^0$. For $p \in B$, $\epsilon(p_v f_b)$ is the column b of the rows $0, \dots, \varrho-1$ of $Z(p_v) = Z(\gamma_v)$, the same for all $p \in O$. Hence, with $\gamma_{0,v} = u_v^{-1}(p_0)_v$ and the definition (SX3) of the Eichler shift,

$$\pi_0(g_v^{-1}p_v f_b) - \pi_0(\gamma_{0,v} f_b) = \pi_0(p_v f_b) - \pi_0((p_0)_v f_b) + \sum_{a<i} Z(\gamma_v)_{ab}\,(D_v x_v)^*_a.$$

By (SX5) the X_0-part of $pf_b - p_0 f_b$ is $M\sum_{a<i} h(e_{a+1}, \gamma f_b)\, l(p)_a$; rescaling ($\mathrm{bs}_v = 1$ on X_0) and using $Z(\gamma_v)_{ab} = \mathrm{bs}_v(e_{a+1})\mathrm{bs}_v(f_b)\, v(h(e_{a+1}, \gamma f_b))$, the first difference is $\sum_{a<i} Z(\gamma_v)_{ab}\, d_{v,a}\, v(l(p)_a)$. As $l(p)^\infty_v$ has the rows $v(l(p)_a)^*$,

$$\pi_0(g_v^{-1}p_v f_b) = \pi_0(\gamma_{0,v} f_b) + \sum_{a<i} Z(\gamma_v)_{ab}\,\big(\mathcal{A}_v(p,x)\big)^*_a, \qquad \mathcal{A}_v(p,x) = D_v\big(l(p)^\infty_v + x_v\big),$$

for every frame index b. Moreover $\mathrm{Vr}_{p_v}(g_v y_v) = \mathrm{Vr}_{g_v^{-1}p_v}(y_v)$, because g_v fixes the frame, so $\mathrm{Fv}(g_v y_v) = \mathrm{Fv}(y_v)$ and $p_v^{-1} g_v y_v = (g_v^{-1}p_v)^{-1} y_v$ (SX1).

Step 2: the majorant. As y is boxed, it is reduced, so by Lemma 5.2.21 and (RD5) $y_v \in \mathrm{Bx}(b^{27}\ell(y_v)) \subseteq \mathrm{Bx}(b^{37n})$, since $\ell(y_v) \le b^{6n+2}$ and $27+6n+2 \le 37n$. By (i) of Lemma 5.3.9,

$\delta_*(\gamma) \neq 0$, so, by Lemma 5.3.36 (i), $\delta_v = \det Z^{(i)}(\gamma_v) = \prod_{a\in\{0,\dots,i-1\}\cup\{\varrho\}} \mathrm{bs}_v(f_a)^2\, v(\delta_*(\gamma)) \neq 0$. Apply Lemma 5.3.26 at each v with y_v, $\rho = b^{37n}$, $\theta = b^{6n+2}$, $\gamma_0 = \gamma_{0,v}$ (which has norm-one pairs from j and $Z(\gamma_{0,v}) = Z(\gamma_v)$ by Step 0), and $k \geq 7$ (FG6): it gives a Borel ϕ_v^0 with $\int \phi_v^0 \leq (2b^{74n})^{(i+1)i}(2^{i+1}b^{2(6n+2)(j-i)})^k/|\delta_v|^{k+i}$ and $\mathrm{Vr}_g(y_v)^{-(k+i)} \leq \phi_v^0(\mathcal{A})$ for the g described there. Put $\phi_v(X) = \phi_v^0(D_vX)$ and $\phi(X) = \prod_v \phi_v(X_v)$. The real-linear map $X \mapsto D_vX$ of $\mathrm{M}_{i\times k}(\mathbb{C})$ multiplies the row a by $d_{v,a}$ and has Jacobian $|\det D_v|^{2k}$, so $\int \phi_v = |\det D_v|^{-2k}\int \phi_v^0 \leq \mathrm{Kb}_j(\gamma, v)$ by (SX4), and $\int_Y \phi\, dx \leq \prod_v \mathrm{Kb}_j(\gamma, v)$ by Tonelli's theorem. By Steps 0 and 1 (with $g = g_v^{-1}p_v$ and $\mathcal{A} = \mathcal{A}_v(p, x)$), for $p \in B$

$$\prod_v \mathrm{Vr}_{p_v}\big((u\,\mathrm{Es}_j(x)\,y)_v\big)^{-(k+i)} \leq \prod_v \phi_v^0(D_v(l(p)_v^\infty + x_v)) = \phi(l(p)^\infty + x).$$

Step 3: packing over one lattice point. Fix x, put $y' = u\,\mathrm{Es}_j(x)\,y$, and for $w \in \Lambda$ let $B_w = \{p \in B : l(p)^\infty = w\}$; since $q \mapsto q^\infty$ is injective, l is constant on B_w, and $l(p)^\infty \in \Lambda$ for all $p \in B$ by (SX6). For $p \in B_w$, $\mathrm{Sw}_{c',p,i}(y') \leq \beta_{c'}(p^{-1}y')\,\phi(w + x)$ (Step 2 and $\beta_{c'}^{\mathrm{bx}} \leq \beta_{c'}$), and if it is nonzero then $p^{-1}y'$ is boxed, so $\ell((p^{-1}y')_v) \leq b^{6n+2}$; p is a term over (c, s, c') (Step 0). For $p, p' \in B_w$, $pf_b - p'f_b \in A$ by (SX5), so $\big((p^{-1}y')_v\big)^{-1}f_b - \big((p'^{-1}y')_v\big)^{-1}f_b = y_v'^{-1}(p_v - p_v')f_b \in y_v'^{-1}(A \otimes_{E,v} \mathbb{C})$, as $B_v^{\pm1}$ preserve the span of $e_1, \dots, e_\varrho$. Let $V \subseteq \prod_v (\mathbb{C}^r)^{\varrho+1}$ be the real subspace of the families $(y_v'^{-1}a_{v,b})_{v,b}$ with $a_{v,b} \in \langle e_1, \dots, e_\varrho\rangle_{\mathbb{C}}$; $\dim_{\mathbb{R}} V \leq 2f\varrho n$. By Lemma 5.2.31 (pairs (c', p), $p \in B_w$, $R = 1$, weights $\mathrm{Sw}_{c',p,i}(y')$, constant $\phi(w + x)$),

$$\sum_{p\in B_w} \mathrm{Sw}_{c',p,i}(y') \leq b^{12n^3\varrho f}\,\phi(w + x) \leq \tau_{\mathrm{sz}}\,\phi(w + x),$$

since $k \geq 1000(2\varrho + 2)^9 \geq 48n^3\varrho$ (FG6) gives $12n^3\varrho f \leq kf/4$. Summing over $w \in \Lambda$ (the B_w partition B, all terms are nonnegative) gives the claim. □

Lemma 5.3.26. *Let $k \geq 7$, $0 \leq j \leq \varrho+1$, $i = \min(\varrho, j)$, $\rho, \theta \geq 0$, and $y \in \mathrm{Bx}(\rho)$ with $\ell(y) \leq \theta$. Say that $g \in G_1$ has* norm-one pairs from j *if for every a with $j \leq a \leq \varrho$ there are $x, w \in \mathbb{C}^{\varrho+1}$ with $\sum_b x_b f_b = g\sum_b w_b f_b$, $|x_a| = 1$, $w_a = 1$ and $x_b = w_b = 0$ for $b > a$. For $g \in G_1$ and $0 \leq b \leq \varrho$ let $\pi_0(gf_b) \in \mathbb{C}^k$ be the coordinates of gf_b in the basis of X_0. Let $\gamma_0 \in G_1$ have norm-one pairs from j, $Z = Z(\gamma_0)$, and suppose $\delta = \det Z^{(i)}(\gamma_0) \neq 0$. Then there is a Borel function $\phi\colon \mathrm{M}_{i\times k}(\mathbb{C}) \to [0, \infty]$ with*

$$\int \phi(A)\, dA \leq \frac{(2\rho^2)^{(i+1)i}\,\big(2^{i+1}\theta^{2(j-i)}\big)^k}{|\delta|^{k+i}}$$

(dA Lebesgue measure in the real and imaginary parts of the entries) such that $\mathrm{Vr}_g(y)^{-(k+i)} \leq \phi(A)$ for every $g \in G_1$ that has norm-one pairs from j, satisfies $Z(g) = Z$, and satisfies

$$\pi_0(gf_b) = \pi_0(\gamma_0 f_b) + \sum_{a<i} Z_{ab}\,A_a^* \qquad (b \in \{0, \dots, i-1\} \cup \{\varrho\}),$$

where A_a is the row a of A and $A_a^* \in \mathbb{C}^k$ its conjugate transpose.

Proof. For $x \in \mathbb{C}^{\varrho+1}$ write $f \cdot x = \sum_b x_b f_b$. Put $\Sigma = \{0, \dots, i-1\} \cup \{\varrho\}$ and $\Sigma' = \{0, \dots, i-1\}$, ordered as integers; matrices indexed by Σ are triangular with respect to this order, and $Z^{(i)} = Z_{\Sigma,\Sigma}$, $\delta = \det Z^{(i)}$. Let $V_- = (1 - J_1)V_1$ be the (-1)-eigenspace of J_1 and $N_y = yV_-$.

Step 0: elementary facts. (a) J_1 is hermitian and $J_1^2 = 1$, so it is unitary; for $g \in G_1$, $g^*J_1g = J_1$ gives $g^{-1} = J_1g^*J_1$ and $\|g^{-1}\|_{\mathrm{op}} = \|g\|_{\mathrm{op}}$. (b) $h(f_a, f_b) = 0$ unless $a = b = \varrho$, and $h(z, z) = -1$; so $h(f \cdot x, f \cdot x) = -|x_\varrho|^2$, and for $g \in G_1$ also $h(g\,f \cdot x, g\,f \cdot x) = -|x_\varrho|^2$. Hence

the Gram matrix $(h(u_a,u_b))_{a,b}$ of any finite family in $g\langle f_0,\dots,f_\varrho\rangle$ is negative semidefinite, and $f\cdot x = g\,f\cdot w$ implies $|x_\varrho| = |w_\varrho|$. (c) J_1 exchanges e_a and e_a^*, fixes X_0 and negates z; so V_- has the basis $(1-J_1)f_b$ $(0\le b\le\varrho)$, namely $e_{b+1}-e_{b+1}^*$ and $2z$. For $x\in V_-$ and $w\in V_1$, $h(x,w) = \langle J_1x,w\rangle = -\langle x,w\rangle$; also $h(e_a,w)$ is the e_a^*-coordinate of w and $h(z,w)$ is minus its z-coordinate. (d) For $x\in V_-$, $h(yx,yx) = h(x,x) = -\|x\|^2$, so $-h$ is positive definite on N_y; for $w\in V_1$ and $\nu\in N_y$, $|h(w,\nu)| = |h(y^{-1}w,y^{-1}\nu)| = |\langle y^{-1}w,y^{-1}\nu\rangle| \le \|y^{-1}w\|\,\|y^{-1}\nu\|$ and $-h(\nu,\nu) = \|y^{-1}\nu\|^2$. (e) Let $\nu_b = y(1-J_1)f_b$, a basis of N_y, and $P(g) = (h(\nu_a,gf_b))_{a,b}$ for $g\in G_1$. By (c), $h(\nu_a,gf_b) = h((1-J_1)f_a,y^{-1}gf_b) = -\langle(1-J_1)f_a,(g^{-1}y)^{-1}f_b\rangle$, so $|\det P(g)| = \mathrm{Fv}(g^{-1}y)$; by (i) of Lemma 5.3.21 this is positive, and $\mathrm{Vr}_g(y) = |\det P(g)|/|\det P(1)|$. In particular the map $N_y\to\mathbb{C}^{\varrho+1}$, $\nu\mapsto(h(f_a,\nu))_a$, is bijective (its matrix in the basis ν_b is $P(1)^*$).

Step 1: the ratio on the subframe. Let $g\in G_1$ have norm-one pairs from j, and let $\omega_l\in N_y$ $(l\in\Sigma)$ satisfy: (i) $h(f\cdot x,\omega_l) = 0$ for all l whenever $f\cdot x = g\,f\cdot w$ with $x_\varrho = 0$; (ii) $\Phi = (h(\omega_l,f_b))_{l,b\in\Sigma}$ is invertible. We show

$$\mathrm{Vr}_g(y) = \frac{|\det(h(\omega_l,gf_b))_{l,b\in\Sigma}|}{|\det\Phi|}. \tag{5.50}$$

Let $P = P(1)$, $N = P^{-1}P(g)$, so $|\det N| = \mathrm{Vr}_g(y)$ by Step 0 (e). If $\nu = \sum_a t_a\nu_a\in N_y$, then $(h(\nu,f_b))_b = \bar t^{\mathrm T}P$, hence $(h(\nu,f_b))_b N = \bar t^{\mathrm T}P(g) = (h(\nu,gf_b))_b$; and if $f\cdot x = g\,f\cdot w$, then $Px = P(g)w$, i.e. $Nw = x$. Let $E\in\mathrm{M}_{(\varrho+1)\times\Sigma}$ be the inclusion matrix (columns the unit vectors ϵ_b, $b\in\Sigma$), $\Psi = (h(\omega_l,f_b))_{l\in\Sigma,\,0\le b\le\varrho}$, so $\Phi = \Psi E$, and $p = \Phi^{-1}\Psi$, so $pE = 1$. Put $M = 1+(NE-E)p$. For $b\in\Sigma$, $M\epsilon_b = N\epsilon_b$. For $b\notin\Sigma$ we have $i\le b<\varrho$, hence $j\le\varrho$, $i = j\le b$, and the norm-one pair at b gives x,w with $f\cdot x = g\,f\cdot w$, $|x_b| = 1$, $w_b = 1$ and $x_{b'} = w_{b'} = 0$ for $b'>b$; as $b<\varrho$, $x_\varrho = 0$, so $px = 0$ by (i) and $Mx = x = Nw$. Taking $x = w = \epsilon_b$ for $b\in\Sigma$, the matrices Ξ, Ξ' with columns x, w $(b = 0,\dots,\varrho)$ are upper triangular with $|\det\Xi| = 1 = \det\Xi'$ and $N\Xi' = M\Xi$, so $|\det N| = |\det M|$. By Sylvester's identity $\det M = \det(1+p(NE-E)) = \det(pNE)$, and $pNE = \Phi^{-1}(h(\omega_l,gf_b))_{l,b\in\Sigma}$ by the first remark applied to each ω_l. This is (5.50).

Step 2: a triangular basis for (y,Z). Let $D = Z_{\cdot,\Sigma}(Z^{(i)})^{-1}\in\mathrm{M}_{(\varrho+1)\times\Sigma}(\mathbb{C})$; its rows in Σ form 1_Σ. By Step 0 (e) there are $\omega_l^0\in N_y$ with $h(f_a,\omega_l^0) = D_{al}$; they are linearly independent, as $h(f_a,\omega_l^0) = \delta_{al}$ for $a\in\Sigma$. Their Gram matrix for $-h$ is positive definite (Step 0 (d)); by the Cholesky decomposition of its inverse there is an invertible lower triangular $T\in\mathrm{M}_\Sigma(\mathbb{C})$ with $T^*(-h(\omega_l^0,\omega_m^0))_{l,m}T = 1$. Put $\omega_m = \sum_l\omega_l^0T_{lm}$. Then $\omega_m\in N_y$, $h(\omega_l,\omega_m) = -\delta_{lm}$, $h(f_a,\omega_m) = (DT)_{am}$, and $h(f_a,\omega_m) = T_{am}$ for $a\in\Sigma$. The family ω and T depend only on y and Z. Let $g\in G_1$ have norm-one pairs from j and $Z(g) = Z$. Then ω satisfies (ii) of Step 1 with $\Phi = T^*$, and (i): if $f\cdot x = g\,f\cdot w$ with $x_\varrho = 0$, then $w_\varrho = 0$ by Step 0 (b), and $\sum_a\bar x_aZ_{ab} = h(f\cdot x,gf_b) = h(g\,f\cdot w,gf_b) = h(f\cdot w,f_b) = -\bar w_\varrho[b=\varrho] = 0$ for all b, so $h(f\cdot x,\omega_m) = (x^*DT)_m = 0$. By (5.50),

$$\mathrm{Vr}_g(y) = |\det(h(\omega_l,gf_b))_{l,b\in\Sigma}|/|\det T|. \tag{5.51}$$

Step 3: the lower bound. For $g\in G_1$ with $Z(g) = Z$ put $\omega'_m = \sum_{b\in\Sigma}gf_b\,((Z^{(i)})^{-1}T)_{bm}$ $(m\in\Sigma)$. Then $h(f_a,\omega'_m) = (Z_{\cdot,\Sigma}(Z^{(i)})^{-1}T)_{am} = h(f_a,\omega_m)$, so $d_m = \omega'_m-\omega_m$ is h-orthogonal to $f_0,\dots,f_\varrho$; by Step 0 (c) it has no e^*- and no z-coordinate, so $d_m\in\langle e_1,\dots,e_\varrho\rangle\oplus X_0$. Let $Y_g\in\mathrm{M}_{k\times\Sigma}(\mathbb{C})$ have as column m the X_0-coordinates of d_m; since the e_a are isotropic and orthogonal to X_0, on which h is the standard form, $(h(d_l,d_m))_{l,m} = Y_g^*Y_g$. With $Q = (h(\omega_l,\omega'_m))_{l,m}$, expanding $h(\omega'_l-\omega_l,\omega'_m-\omega_m)$ gives

$$(-Q)+(-Q)^*-(1+Y_g^*Y_g) = -\big(h(\omega'_l,\omega'_m)\big)_{l,m},$$

which is positive semidefinite by Step 0 (b), as $\omega'_m \in g\langle f_0,\dots,f_\varrho\rangle$. Hence the hermitian part $\frac12((-Q)+(-Q)^*)$ of $-Q$ dominates $\frac12(1+Y_g^*Y_g)$, which is positive definite. By the Ostrowski–Taussky inequality $|\det X| \ge \det\frac{X+X^*}{2}$ for a matrix X with positive definite hermitian part H_X (write $X = H_X^{1/2}(1+\mathrm{i}K)H_X^{1/2}$ with K hermitian; the eigenvalues $1+\mathrm{i}\lambda$, $\lambda\in\mathbb{R}$, have modulus ≥ 1), and by the monotonicity of the determinant on positive definite matrices ($A \ge B > 0$ gives $B^{-1/2}AB^{-1/2} \ge 1$),

$$|\det Q| \ge 2^{-(i+1)}\det(1+Y_g^*Y_g) = 2^{-(i+1)}\det(1_k + Y_gY_g^*).$$

Now $Q = (h(\omega_l, gf_b))_{l,b\in\Sigma}(Z^{(i)})^{-1}T$, so if g also has norm-one pairs from j, (5.51) gives $|\det Q| = \mathrm{Vr}_g(y)|\det T|^2/|\delta|$, and

$$|\delta|\,\det(1_k + Y_gY_g^*) \le 2^{i+1}|\det T|^2\,\mathrm{Vr}_g(y). \tag{5.52}$$

Step 4: the majorant. Let g be as in the statement, with matrix A. For $b\in\Sigma$ the hypothesis says that the X_0-coordinates of gf_b and $\gamma_0 f_b$ differ by $\sum_{a<i} Z_{ab}A_a^*$; as the rows $a<i$ lie in Σ, the X_0-coordinates of ω'_m for g and for γ_0 differ by $\sum_{a<i}A_a^*(Z^{(i)}(Z^{(i)})^{-1}T)_{am} = \sum_{a<i}A_a^*T_{am}$, while ω_m does not depend on g. So $Y_g = Y_{\gamma_0} + A^*T_{\Sigma',\Sigma}$, $A^*\in \mathrm{M}_{k\times i}(\mathbb{C})$ the matrix with columns A_a^*. As T is lower triangular, $T_{a\varrho}=0$ for $a<i$: the column ϱ of Y_g is the column y_z of Y_{γ_0}, and the columns in Σ' are $(Y_{\gamma_0})_{\cdot,\Sigma'} + A^*T_1$ with $T_1 = T_{\Sigma',\Sigma'}$. With $P_0 = 1_k + y_zy_z^*$ (positive definite), $c_0 = ((Y_{\gamma_0})_{\cdot,\Sigma'})^* \in \mathrm{M}_{i\times k}(\mathbb{C})$ and $B(A) = T_1^*A + c_0$,

$$1_k + Y_gY_g^* = P_0 + B(A)^*B(A).$$

Define the continuous, hence Borel, function

$$\phi(A) = \Big(\frac{2^{i+1}|\det T|^2}{|\delta|}\Big)^{k+i}\det\big(P_0 + B(A)^*B(A)\big)^{-(k+i)}.$$

By (5.52) and $\mathrm{Vr}_g(y)>0$, $\mathrm{Vr}_g(y)^{-(k+i)} \le \phi(A)$ for every such g.

Step 5: the integral. As T is triangular, $\det T = \det T_1\cdot T_{\varrho\varrho}$, so T_1 is invertible. By Lemma 5.3.27 with P_0, T_1^*, c_0 in the roles of P, S, c ($k\ge 7$),

$$\int\phi(A)\,dA \le \Big(\frac{2^{i+1}|\det T|^2}{|\delta|}\Big)^{k+i}\frac{|\det T_1|^{-2k}}{(\det P_0)^k} = \frac{\big(2^{i+1}|\det T|^2\big)^i\big(2^{i+1}|T_{\varrho\varrho}|^2/\det P_0\big)^k}{|\delta|^{k+i}}.$$

It remains to show (B1) $|\det T| \le \rho^{i+1}$ and (B2) $|T_{\varrho\varrho}|^2 \le \theta^{2(j-i)}\det P_0$; then

$$\int\phi \le (2\rho^2)^{(i+1)i}(2^{i+1}\theta^{2(j-i)})^k/|\delta|^{k+i}.$$

(B1) $\det T = \prod_m T_{mm}$ and $T_{mm} = h(f_m,\omega_m)$; by Step 0 (d), $\|y^{-1}\omega_m\| = 1$ and $y\in \mathrm{Bx}(\rho)$, $|T_{mm}| \le \|y^{-1}f_m\| \le \rho$.

(B2), case $j\le\varrho$, so $i=j$. Starting from the norm-one pair of γ_0 at ϱ and subtracting, for $b=\varrho-1,\dots,i$ in turn, the current b-th coordinate of w times the pair at b (which has $w_b=1$ and vanishes above b), we obtain x,w with $\gamma_0\,f\cdot w = f\cdot x$, $w_\varrho = 1$ and $w_b = 0$ for $i\le b<\varrho$; by Step 0 (b), $|x_\varrho| = 1$. Since w is supported on Σ, for $a\in\Sigma$, $(Z^{(i)}w_\Sigma)_a = h(f_a,\gamma_0\,f\cdot w) = h(f_a, f\cdot x) = -x_\varrho[a=\varrho]$, so $(Z^{(i)})^{-1}\epsilon_\varrho = -w_\Sigma/x_\varrho$. The column ϱ of T is $T_{\varrho\varrho}\epsilon_\varrho$, so for $g=\gamma_0$, $\omega'_\varrho = t\,f\cdot x$ with $t = -T_{\varrho\varrho}/x_\varrho$. Hence $h(\omega'_\varrho,\omega'_\varrho) = -|t|^2|x_\varrho|^2 = -|T_{\varrho\varrho}|^2$ and $h(\omega'_\varrho, d_\varrho) = \bar t\,h(f\cdot x, d_\varrho) = 0$, and

$$-1 = h(\omega_\varrho,\omega_\varrho) = h(\omega'_\varrho - d_\varrho, \omega'_\varrho - d_\varrho) = -|T_{\varrho\varrho}|^2 + |y_z|^2.$$

So $|T_{\varrho\varrho}|^2 = 1 + |y_z|^2 = \det P_0$, which is (B2) as $j - i = 0$.

(B2), case $j = \varrho + 1$, so $i = \varrho$, $\Sigma = \{0, \dots, \varrho\}$ and $j - i = 1$. As $\ell(y) \le \theta$, there is $s \in R$ with $\|sy\|_{\mathrm{op}} < \theta$; writing $s = u_1 h_1$ with $u_1 \in \mathsf{U}$, $h_1 \in H$, the element h_1 is unitary and normalises U, so $u = h_1^{-1} u_1 h_1 \in \mathsf{U}$ and $\|uy\|_{\mathrm{op}} = \|h_1^{-1} sy\|_{\mathrm{op}} < \theta$. The unipotent radical U of the stabiliser of the isotropic flag acts trivially on $F^\perp/F$, $F = \langle e_1, \dots, e_\varrho \rangle$, and $z \in F^\perp$; so $u^{-1}z = z + \sum_{a<\varrho} c_a f_a$, and since $T_{a\varrho} = 0$ for $a < \varrho$, $h(u^{-1}z, \omega_\varrho) = T_{\varrho\varrho}$. By Step 0 (d) and (a), $|T_{\varrho\varrho}| \le \|y^{-1}u^{-1}z\| \le \|(uy)^{-1}\|_{\mathrm{op}} = \|uy\|_{\mathrm{op}} \le \theta$. As $\det P_0 = 1 + |y_z|^2 \ge 1$, $|T_{\varrho\varrho}|^2 \le \theta^2 \det P_0$.

This proves the bound for $\int \phi$ and the lemma. (For $i = 0$, $\mathrm{M}_{0\times k}(\mathbb{C})$ is a point, T_1 is empty and the argument applies verbatim.) □

Lemma 5.3.27. *Let $k \ge 7$ and $i \ge 0$ be integers, $P \in \mathrm{M}_k(\mathbb{C})$ hermitian positive definite, $S \in \mathrm{GL}_i(\mathbb{C})$ and $c \in \mathrm{M}_{i\times k}(\mathbb{C})$. Then*

$$\int_{\mathrm{M}_{i\times k}(\mathbb{C})} \det\bigl(P + (SA + c)^*(SA + c)\bigr)^{-(k+i)}\, dA \;\le\; |\det S|^{-2k} (\det P)^{-k},$$

where dA is Lebesgue measure in the real and imaginary parts of the entries (for $i = 0$ the space is a point of mass 1).

Proof. For $Q \in \mathrm{M}_k(\mathbb{C})$ positive definite and row vectors $w \in \mathbb{C}^k$, $Q + w^*w$ is positive definite, so all determinants below are positive reals and the integrands are continuous and positive. Lebesgue measure on $\mathbb{C}^k$ is taken in the real and imaginary parts of the coordinates.

Step 1: one row. Let $r \ge k$ and Q positive definite. Then

$$\int_{\mathbb{C}^k} \det(Q + w^*w)^{-(r+1)}\, dw \le \frac{\pi^k}{k!} (\det Q)^{-r}. \tag{5.53}$$

Write $Q = C^*C$ with $C = Q^{1/2}$ invertible and substitute $w = yC$. The map $y \mapsto yC$ is $\mathbb{C}$-linear on $\mathbb{C}^k$ with complex determinant $\det C$, so its real Jacobian is $|\det C|^2 = \det Q$. Moreover $Q + C^*y^*yC = C^*(1_k + y^*y)C$ and $\det(1_k + y^*y) = 1 + yy^* = 1 + |y|^2$ (Sylvester's determinant identity), so $\det(Q + w^*w) = \det Q\,(1 + |y|^2)$. Since $r + 1 \ge k + 1$ and $1 + |y|^2 \ge 1$,

$$\int_{\mathbb{C}^k} \det(Q + w^*w)^{-(r+1)} dw = (\det Q)^{-r} \int_{\mathbb{C}^k} (1 + |y|^2)^{-(r+1)} dy \le (\det Q)^{-r} \int_{\mathbb{C}^k} (1 + |y|^2)^{-(k+1)} dy.$$

In polar coordinates on $\mathbb{C}^k = \mathbb{R}^{2k}$, with the area $2\pi^k/(k-1)!$ of the unit sphere S^{2k-1} and the substitution $s = t^2$,

$$\begin{aligned}\int_{\mathbb{C}^k} (1 + |y|^2)^{-(k+1)} dy &= \frac{2\pi^k}{(k-1)!} \int_0^\infty \frac{t^{2k-1}\, dt}{(1+t^2)^{k+1}} = \frac{\pi^k}{(k-1)!} \int_0^\infty \frac{s^{k-1}\, ds}{(1+s)^{k+1}} \\ &= \frac{\pi^k}{(k-1)!} \mathrm{B}(k, 1) = \frac{\pi^k}{k!},\end{aligned}$$

which gives (5.53).

Step 2: the rows one at a time. For an integer $m \ge 0$, Q positive definite and row vectors $b_1, \dots, b_m \in \mathbb{C}^k$ put

$$J_m(Q) = \int_{(\mathbb{C}^k)^m} \det\Bigl(Q + \sum_{a=1}^m b_a^* b_a\Bigr)^{-(k+m)} db_1 \cdots db_m.$$

We show $J_m(Q) \le (\pi^k/k!)^m (\det Q)^{-k}$ by induction on m; for $m = 0$ it is an equality. For the step from m to $m + 1$, integrate first over b_{m+1} (Tonelli's theorem, the integrand being nonnegative

and continuous): for fixed $b_1, \dots, b_m$ apply (5.53) with $Q' = Q + \sum_{a \le m} b_a^* b_a$, positive definite, and $r = k + m \ge k$; the inner integral is at most $(\pi^k/k!)\det(Q')^{-(k+m)}$. Integrating over $b_1, \dots, b_m$ gives $J_{m+1}(Q) \le (\pi^k/k!)J_m(Q) \le (\pi^k/k!)^{m+1}(\det Q)^{-k}$.

Step 3: the affine change of variables. The map $A \mapsto B = SA + c$ is an affine bijection of $\mathrm{M}_{i\times k}(\mathbb{C})$ whose linear part $A \mapsto SA$ is $\mathbb{C}$-linear and acts as S on each of the k columns, so its complex determinant is $(\det S)^k$ and its real Jacobian $|\det S|^{2k}$. If $b_1, \dots, b_i$ are the rows of B, then $B^*B = \sum_a b_a^* b_a$. Hence the left side of the claim equals $|\det S|^{-2k} J_i(P) \le |\det S|^{-2k}(\pi^k/k!)^i (\det P)^{-k}$.

Step 4: $\pi^k/k! \le 1$ for $k \ge 7$. Since $\pi < 3.15$ and $3.15^7 < 3078 < 5040 = 7!$, the claim holds for $k = 7$, and $\pi^{k+1}/(k+1)! = \frac{\pi}{k+1} \cdot \pi^k/k! < \pi^k/k!$ for $k \ge 7$. With Step 3 this proves the lemma. □

Lemma 5.3.28. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data and $c \in \mathcal{C}$. Let (X, m) be a measure space with m s-finite, $t\colon X \to G_\infty$ measurable with $t(x)_v \in \mathsf{U}^0$ for all $x \in X$ and $v \in \Phi$, $A \subseteq X$ measurable with $0 < m(A) < \infty$, $C \in [0, \infty]$, and $F\colon G_\infty \to [0, \infty]$ Borel with $F(u_\infty y) = F(y)$ for all $u \in \mathsf{U}_c^0(M)$ and $y \in G_\infty$. If*

$$\int_A F\big(u\, t(x)\, y\big)\, dm(x) \le m(A)\, C$$

for every $u \in G_\infty$ with $u_v \in \mathsf{U}^0$ for all v and every boxed $y \in G_\infty$, then

$$\int_{G_\infty} \beta_c^{\mathrm{bx}}(y) \prod_{v\in\Phi} \|W_v^\flat(y_v)\|^2\, F(y)\, dy \le C\, \nu\, \#I.$$

Proof. Write $Q(y) = \prod_{v\in\Phi} \|W_v^\flat(y_v)\|^2$, $\mathbf{1}_{\mathrm{bx}}$ for the indicator of the boxed points, and $H = \prod_{v\in\Phi} \mathsf{U}^0 \subseteq G_\infty$; we identify $u \in \mathsf{U}_c^0(M)$ with u_∞, so that $\Gamma = \{u_\infty : u \in \mathsf{U}_c^0(M)\}$ is a countable subgroup of G_∞.

Step 1: groups, measures and invariances. (a) $\Gamma \subseteq H$: for $u \in \mathsf{U}_c^0(M)$, $u_v = B_v^{-1} v(u) B_v$ with B_v the diagonal matrix of basis scales; $v(u)$ lies in the unipotent radical of the stabiliser of the flag $\langle e_1\rangle \subset \cdots \subset \langle e_1, \dots, e_\varrho\rangle$ and conjugation by the diagonal B_v preserves that flag, so $u_v \in \mathsf{U}$; and $u_v f_b = B_v^{-1} v(u) \mathrm{bs}_v(f_b) f_b = f_b$, as $u f_b = f_b$. (b) H is a closed subgroup of G_∞ and unimodular (U^0 is a connected nilpotent Lie group); fix a Haar measure dh on H, which is then invariant under right translations and under $h \mapsto h^{-1}$. The measure dy is invariant under left and right translations of G_∞, by Lemma 5.2.41 in each factor. (c) For $h \in H$ and $y \in G_\infty$: $Q(hy) = Q(y)$, since each $W_v^\flat$ is a Bessel function and $h_v \in \mathsf{U}$ gives $W_v^\flat(h_v y_v) = \mathrm{wave}(\sigma(h_v)) W_v^\flat(y_v)$ with $|\mathrm{wave}(c)| = |\exp(c - \bar{c})| = 1$; and hy is boxed if and only if y is, because $(h_v y_v)^{-1} f_b = y_v^{-1} f_b$ for all b (so the Gram–Schmidt matrices T and the rational triangle entries agree) and $\ell(h_v y_v) = \ell(y_v)$ ($s \mapsto s h_v$ is a bijection of $R \supseteq \mathsf{U}$). The same invariance of Q holds for $h \in \mathsf{U}_\infty$. (d) Boxed points are reduced, so $\beta_c^{\mathrm{bx}} = \beta_c^0 \mathbf{1}_{\mathrm{bx}}$, and $\beta_c^{\mathrm{bx}} \le \beta_c$.

Step 2: disintegration along orbits. Let $L \subseteq G_\infty$ be a closed unimodular subgroup with Haar measure dl and $\varphi\colon G_\infty \to [0, \infty)$ Borel with $\int_L \varphi(ly)\, dl = 1$ for every y. Then for every Borel $g\colon G_\infty \to [0, \infty]$

$$\int_{G_\infty} g(y)\, dy = \int_{G_\infty} \varphi(a) \int_L g(la)\, dl\, da. \tag{5.54}$$

Indeed, by Tonelli's theorem (G_∞ and L are σ-compact), the left invariance of da under $a \mapsto l^{-1}a$, and the invariance of dl under inversion, the right side is $\int_L \int \varphi(l^{-1}a) g(a)\, da\, dl = \int g(a) \int_L \varphi(l^{-1}a)\, dl\, da = \int g(a)\, da$. For $L = H$ such a φ exists: by the existence of Bruhat functions for closed subgroups (Bourbaki, Intégration, ch. VII, §2, no. 4) there is a continuous $\varphi_0 \ge 0$

with $\int_H \varphi_0(yh)\,dh = 1$ for all y, and $\varphi(y) = \varphi_0(y^{-1})$ satisfies $\int_H \varphi(hy)\,dh = \int_H \varphi_0(y^{-1}h^{-1})\,dh = 1$. For $L = \mathsf{U}_\infty$ with du (a two-sided Haar measure invariant under inversion, Definition 5.1.6) take $\varphi = \prod_v \varphi_v(y_v)$, where φ_v is a cutoff of total du-mass 1 on every U-orbit of G_1, the one by which the quotient integrals over $\mathsf{U}\backslash G_1$ are formed; then $\int_{\mathsf{U}_\infty} \varphi(uy)\,du = \prod_v \int_{\mathsf{U}} \varphi_v(u_v y_v)\,du_v = 1$.

Step 3: the bound on one orbit. Let $a \in G_\infty$ be boxed and put $p(h) = \beta_c^0(ha)$, $F_a(h) = F(ha)$ for $h \in H$. Then $\sum_{\gamma\in\Gamma} p(\gamma h) = 1$ for every h (RD6), hence also $\sum_\gamma p(\gamma^{-1}h) = 1$, and $F_a(\gamma h) = F_a(h)$ for $\gamma \in \Gamma$ by the invariance of F. For $t \in H$, by right invariance of dh, the insertion of $\sum_\gamma p(\gamma^{-1}h) = 1$, monotone convergence, the substitution $h \mapsto \gamma h$ and the Γ-invariance of F_a,

$$\int_H p\,F_a\,dh = \int_H p(ht)F_a(ht)\sum_\gamma p(\gamma^{-1}h)\,dh = \sum_\gamma \int_H p(\gamma ht)F_a(ht)\,p(h)\,dh = \int_H F_a(ht)\,p(h)\,dh.$$

Apply this with $t = t(x)$, integrate over $x \in A$ and use Tonelli's theorem (m is s-finite) and the hypothesis with $u = h$ and the boxed point a:

$$m(A)\int_H p\,F_a\,dh = \int_H p(h)\int_A F\big(h\,t(x)\,a\big)\,dm(x)\,dh \le m(A)\,C\int_H p\,dh.$$

As $0 < m(A) < \infty$, $\int_H p(h)F(ha)\,dh \le C\int_H \beta_c^0(ha)\,dh$.

Step 4: integration in stages. By (5.54) for $L = H$ and Step 1 (c), (d), the left side of the claim is

$$\begin{aligned}\int_{G_\infty} \varphi(a)\,\mathbf{1}_{\mathrm{bx}}(a)\,Q(a)\int_H \beta_c^0(ha)\,F(ha)\,dh\,da &\le C\int_{G_\infty} \varphi(a)\,\mathbf{1}_{\mathrm{bx}}(a)\,Q(a)\int_H \beta_c^0(ha)\,dh\,da\\ &= C\int_{G_\infty} \beta_c^{\mathrm{bx}}\,Q\,dy,\end{aligned}$$

using Step 3 at the boxed a (for a not boxed both integrands vanish) and (5.54) again. By Step 1 (d), $\int \beta_c^{\mathrm{bx}} Q\,dy \le \int \beta_c Q\,dy$.

Step 5: the class-cut Bessel integral. By (5.54) for $L = \mathsf{U}_\infty$, the U_∞-invariance of Q and Lemma 5.2.33,

$$\begin{aligned}\int_{G_\infty} \beta_c Q\,dy &= \int_{G_\infty} \varphi(a)Q(a)\int_{\mathsf{U}_\infty} \beta_c(ua)\,du\,da = \nu\int_{G_\infty} \varphi\,Q\,dy\\ &= \nu\prod_{v\in\Phi}\int_{G_1} \varphi_v\|W_v^\flat\|^2 dy_v = \nu\prod_v \int_{\mathsf{U}\backslash G_1} \|W_v^\flat\|^2,\end{aligned}$$

by Tonelli's theorem for the product measure. By (BS1) each factor is at most $\#I_v$, and $\#I = \prod_v \#I_v$. Hence the left side of the claim is at most $C\,\nu\,\#I$. □

Lemma 5.3.29. *Let $\mathfrak{S}$ be an admissible filling datum, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, $1 \le j \le \varrho + 1$, and γ a term over (c, s, c') satisfying the conditions of cell rank j. Then $\mathrm{mn}_j(\gamma) > 0$ and*

$$\prod_{v\in\Phi} \mathrm{Kb}_j(\gamma, v) \le \tau_{\mathrm{sz}}\Big(\frac{b^{13}}{M^2}\Big)^{i_j k f}\,\mathrm{mn}_j(\gamma)^{-k/2}.$$

Proof. Put $i = i_j$, so $1 \le i \le \varrho$ (as $j \ge 1$), and $A = \{0, \dots, i-1\} \cup \{\varrho\}$; note that $A = \{a : a < j\} \cup \{\varrho\}$ both for $j \le \varrho$ (then $i = j$) and for $j = \varrho + 1$ (then $i = \varrho$ and $A = \{0, \dots, \varrho\}$), so the minor of $Z(\gamma)$ on the rows and columns A is the subframe minor $\delta_*(\gamma)$. Write $(x)_+ = \max(x, 0)$.

$D_j(\gamma)$ **is a nonzero algebraic integer, and** $\mathrm{mn}_j(\gamma) > 0$**.** By Lemma 5.2.24 (i), $h(L_0, L_0) \subseteq \hat{\mathcal{O}}$. Let $k' = h_c^{-1}\gamma h_{c'} \in K$. The elements $h_c, h_{c'}$ of $\mathsf{U}(X_0)(\mathbb{A}_f)$ fix the frame vectors and preserve h, so $h(f_a, \gamma f_b) = h(h_c^{-1}f_a, h_c^{-1}\gamma h_{c'} f_b) = h(f_a, k' f_b)$; as $f_a, f_b \in L_0$ and $k'L_0 = L_0$ (Lemma 5.2.24 (ii)), this lies in $\hat{\mathcal{O}} \cap E = \mathcal{O}_E$. Hence $D_j(\gamma) \in \mathcal{O}_E$, and $D_j(\gamma) \neq 0$ by (TA5), so $|N_{E/\mathbb{Q}} D_j(\gamma)| \geq 1$. By (TA12) this gives $\mathrm{mn}_j(\gamma) \geq N^{-2(j-\varrho)_+ f} > 0$; positivity is also (i) of Lemma 5.3.9.

The subframe determinants. Let $v \in \Phi$ and $S_v = \mathrm{diag}(\mathrm{bs}_v(f_0), \dots, \mathrm{bs}_v(f_\varrho))$. By Lemma 5.3.36 (i), $Z(\gamma_v) = S_v\, v(Z(\gamma))\, S_v$. Hence every principal minor of $Z(\gamma_v)$ is the image under v of the same minor of $Z(\gamma)$ times the squares of the scales of its indices. As $\mathrm{bs}_v(f_a) = \mathrm{rs}_v^{\varrho-a}/\sqrt{N}$,

$$|\det Z^{(i)}(\gamma_v)| = \prod_{a \in A} \mathrm{bs}_v(f_a)^2\, |v(\delta_*(\gamma))| = \frac{W_v^2}{N^{i+1}}\, |v(\delta_*(\gamma))|, \qquad W_v = |\mathrm{rs}_v|^{\sum_{a<i}(\varrho-a)} \geq 1,$$

by (FA4). Since E is totally imaginary and Φ holds one embedding of each conjugate pair, $\prod_v |v(x)| = |N_{E/\mathbb{Q}} x|^{1/2}$ for $x \in E$, and by (i) of Lemma 5.3.9, $\prod_v |v(\delta_*(\gamma))| = N^f \mathrm{mn}_j(\gamma)^{1/2}$. In particular every $\det Z^{(i)}(\gamma_v)$ is nonzero, and

$$\prod_{v \in \Phi} |\det Z^{(i)}(\gamma_v)| = \Big(\prod_v W_v\Big)^2 N^{-if}\, \mathrm{mn}_j(\gamma)^{1/2}.$$

By (SX3), $|\det D_{j,v}| = \prod_{l<i} M\sqrt{N}/|\mathrm{rs}_v|^{\varrho-l} = (M\sqrt{N})^i / W_v$.

The product. Put $C_0 = (2b^{74n})^{(i+1)i} \big(2^{i+1} b^{2(6n+2)(j-i)}\big)^k$, the place-independent numerator of (SX4). Then

$$\begin{aligned}\prod_v \mathrm{Kb}_j(\gamma, v) &= \frac{\prod_v W_v^{2k}\, (M\sqrt{N})^{-2ikf}\, C_0^f}{(\prod_v W_v)^{2(k+i)} N^{-if(k+i)} \mathrm{mn}_j(\gamma)^{(k+i)/2}} \\ &= \Big(\prod_v W_v\Big)^{-2i} M^{-2ikf} N^{i^2 f} C_0^f\, \mathrm{mn}_j(\gamma)^{-(k+i)/2}.\end{aligned}$$

Use $W_v \geq 1$, $\mathrm{mn}_j(\gamma)^{-i/2} \leq N^{(j-\varrho)_+ fi}$ (first step) and $i + (j-\varrho)_+ = j$:

$$\prod_v \mathrm{Kb}_j(\gamma, v) \leq \Big((2b^{74n})^{i+1} N^j\Big)^{if} \Big(\frac{2^{i+1} b^{2(6n+2)(j-i)}}{M^{2i}}\Big)^{kf} \mathrm{mn}_j(\gamma)^{-k/2}.$$

The first factor is at most τ_{sz}**.** By $2 \leq b$, $N \leq b^{60n}$ (FA5), $i+1 \leq n$ and $j \leq n$: $(2b^{74n})^{i+1} N^j \leq b^{(74n+1)n + 60n^2} \leq b^{135n^2}$, so the first factor is at most $b^{135n^2 \varrho f}$. By (FG6), $k \geq 1000(2\varrho+2)^9 \geq 540n^3 \geq 540n^2\varrho$, so $135n^2\varrho f \leq kf/4$ and the first factor is at most $b^{kf/4} = \tau_{\mathrm{sz}}$.

The second factor is at most $(b^{13}/M^2)^{ikf}$**.** It suffices that $2^{i+1} b^{2(6n+2)(j-i)} \leq b^{13i}$. If $j \leq \varrho$, then $j = i \geq 1$ and $2^{i+1} \leq 4^i \leq b^{13i}$. If $j = \varrho+1$, then $i = \varrho$, $j - i = 1$ and $2(6n+2) = 12\varrho + 16$; as $2^9 \leq b$, $2^{\varrho+1} \leq b^{(\varrho+1)/9}$, and $(\varrho+1)/9 + 12\varrho + 16 \leq 13\varrho$ because $\varrho \geq 10^5$ (FG6).

Together, $\prod_v \mathrm{Kb}_j(\gamma, v) \leq \tau_{\mathrm{sz}}\, (b^{13}/M^2)^{i_j kf}\, \mathrm{mn}_j(\gamma)^{-k/2}$. □

Lemma 5.3.30. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$ and $T \subseteq G(E)$ stable. If s does not agree, then $A_T(c, s, c') = 0$, for the full and for the cut amplitude sums.*

Proof. Fix $W \in \{W^{\mathrm{full}}, W^{\mathrm{cut}}\}$ and write $K(\gamma, y) = W(y) \otimes \overline{W(\gamma^{-1} y)}$. As s does not agree, there are integral $u, u' \in \mathsf{U}(\mathbb{A}_f)$ (that is, in K) with $\bar{u} s = s \bar{u}'$ and $\psi(u) \neq \psi(u')$, where $\bar{u} = \mathrm{red}(u)$.

Step 1: the character. By Lemma 5.2.44: ψ restricted to $\mathsf{U}(\mathbb{A}_f)$ is a homomorphism to the unit circle (i); for $g \in \mathsf{U}(\mathbb{A}_f)$ and $h \in \mathrm{U}(X_0)(\mathbb{A}_f)$, $h^{-1}gh \in \mathsf{U}(\mathbb{A}_f)$ and $\psi(h^{-1}gh) = \psi(g)$ (ii); and $\psi(k) = 1$ for $k \in \mathsf{U}(\mathbb{A}_f) \cap \mathrm{K}(M)$ (iii).

Step 2: rational approximation. The set $O = \mathsf{U}(\mathbb{A}_f) \cap h_c u\, \mathrm{K}(M)\, h_c^{-1}$ is open in $\mathsf{U}(\mathbb{A}_f)$ and contains $h_c u h_c^{-1}$, which lies in $\mathsf{U}(\mathbb{A}_f)$ by Step 1 (ii) with $h = h_c^{-1}$. By strong approximation for the unipotent group U over E^+ (Theorem A.4.7, S the archimedean places) there is $x \in \mathsf{U}(E) \cap O$: $h_c^{-1} x h_c = uk$ with $k \in \mathrm{K}(M)$. As $h_c^{-1} x h_c \in \mathsf{U}(\mathbb{A}_f)$ by Step 1 (ii), $k = u^{-1} h_c^{-1} x h_c \in \mathsf{U}(\mathbb{A}_f) \cap \mathrm{K}(M)$, and by Step 1, $\psi(x) = \psi(h_c^{-1} x h_c) = \psi(u)\psi(k) = \psi(u)$; moreover $h_c^{-1} x h_c \in K$ has reduction $\bar{u}$. Likewise there is $x' \in \mathsf{U}(E)$ with $h_{c'}^{-1} x' h_{c'} \in u' \mathrm{K}(M)$, of reduction $\bar{u}'$, and $\psi(x') = \psi(u')$.

Step 3: the substitution permutes the terms. Let X be the set of terms of T over (c, s, c'). For $\gamma \in X$, $h_c^{-1} x \gamma x'^{-1} h_{c'} = (h_c^{-1} x h_c)(h_c^{-1} \gamma h_{c'})(h_{c'}^{-1} x' h_{c'})^{-1} \in K$ has reduction $\bar{u} s \bar{u}'^{-1} = s$, and $x \gamma x'^{-1} \in T$ as T is stable; so $\gamma \mapsto x \gamma x'^{-1}$ maps X to X, bijectively (its inverse is $\gamma \mapsto x^{-1} \gamma x'$, by the same argument). Thus $x X x'^{-1} = X$.

Step 4: the substitution normalises the unipotent groups. Conjugation by x is a bijection of $\mathsf{U}_c(M)$: for $v \in \mathsf{U}_c(M)$, $xvx^{-1} \in \mathsf{U}(E)$ and $h_c^{-1} x v x^{-1} h_c = k_x (h_c^{-1} v h_c) k_x^{-1} \in \mathrm{K}(M)$ with $k_x = h_c^{-1} x h_c \in K$, $\mathrm{K}(M)$ being normal in K; and likewise with x^{-1}. The same holds for x' and $\mathsf{U}_{c'}(M)$.

Step 5: the kernel on the terms. Let $Z = X \times G_\infty$, $\mu = (\text{counting measure}) \otimes dy$, the group Γ_X, its countable subgroup $\Delta = \mathsf{U}_c(M) \times \mathsf{U}_{c'}(M)$ and $\beta_0(\gamma, y) = \beta_c(y)\beta_{c'}(\gamma^{-1} y)$ be as in (ii) of Lemma 5.2.36: Γ_X acts on Z by $(a, b) \cdot (\gamma, y) = (a \gamma b^{-1}, a \cdot y)$, by measurable maps that preserve integrals against μ, and $\sum_{\delta \in \Delta} \beta_0(\delta \cdot z) = 1$ for every $z \in Z$. By Step 3, $\delta_0 = (x, x') \in \Gamma_X$, and by Step 4, $\delta_0^{-1} \Delta \delta_0 = \Delta$. The kernel K is measurable on Z and Δ-invariant: for $(v, v') \in \Delta$, $W(v \cdot y) = W(y)$ and $W(v' \cdot w) = W(w)$ by Lemma 5.2.42, and $(v \gamma v'^{-1})^{-1}(v \cdot y) = v' \cdot \gamma^{-1} y$. For $z = (\gamma, y) \in Z$, $(x \gamma x'^{-1})^{-1}(x \cdot y) = x' \cdot \gamma^{-1} y$, and $W(x \cdot y) = \psi(x)^{-1} W(y)$, $W(x' \cdot w) = \psi(x')^{-1} W(w)$ by Lemma 5.2.43; as $|\psi(x')| = 1$ (Step 1),

$$K(\delta_0 \cdot z) = \psi(x)^{-1}\, \overline{\psi(x')^{-1}}\, K(z) = c_0\, K(z), \qquad c_0 = \psi(x)^{-1}\psi(x') = \psi(u)^{-1}\psi(u') \neq 1.$$

Step 6: conclusion. $\int_Z \beta_0 \|K\|\, d\mu = \sum_{\gamma \in X} \mathrm{maj}_\gamma$, the sum of the amplitude majorants of the terms of T over (c, s, c'), which is finite by Lemma 5.2.29 (ii). By (iii) of Lemma 5.2.45, applied to Γ_X, $\Lambda = \Delta$, the cutoff β_0, $F = K$ and the twist δ_0 with the constant c_0 (here $\Delta \cap \delta_0^{-1} \Delta \delta_0 = \Delta = \delta_0^{-1} \Delta \delta_0$, of index 1 in both), $\int_Z \beta_0 K\, d\mu = 0$. As $\beta_0 K$ is integrable on Z, Fubini's theorem gives $\int_Z \beta_0 K\, d\mu = \sum_{\gamma \in X} A_\gamma(c, c') = A_T(c, s, c')$. Hence $A_T(c, s, c') = 0$. □

Lemma 5.3.31. *Let $\mathfrak{S}$ be a filling datum and $\gamma \in G(E)$ with agreeing characters. Say that $(\mu, \mu') \in E^2$ occurs at $a \in \{0, \dots, \varrho\}$ if $f \cdot x = \gamma f \cdot y$ for some $x, y \in E^{\varrho+1}$ with $x_a = \mu$, $y_a = \mu'$ and $x_b = y_b = 0$ for $b > a$.*

(i) If (μ, μ') occurs at a, then it occurs at every l with $a \leq l \leq \varrho$, and $\mu\bar{\mu} = \mu'\bar{\mu}'$.

(ii) If $\mathsf{g}(\gamma) = 0$, let j be the least integer in $\{0, \dots, \varrho + 1\}$ such that some ζ with $\zeta\bar{\zeta} = 1$ has $(\zeta, 1)$ occurring at every $a \geq j$. Then $j \leq \varrho$, and γ satisfies the conditions of cell rank j.

Proof. Eichler elements. Let $1 \leq a \leq \varrho$, $\xi \in E^{\varrho+1}$ with $\xi_b = 0$ for $b \geq a$, $r \in E$, and $v \in V$ with $h(v, f_b) = 0$ for $b < a$. Put $x_e = r\, f \cdot \xi \in F_a = \langle e_1, \dots, e_a \rangle$, $\varsigma = \frac{1}{2} h(v, v)$ (so $\varsigma + \bar{\varsigma} = h(v, v)$) and

$$\mathrm{E}(w) = w + h(v, w)\, x_e - h(x_e, w)\, (v + \varsigma x_e) \qquad (w \in V).$$

As x_e is isotropic and $h(v, x_e) = 0$, E is the Eichler transformation of (x_e, v), an isometry of V (expand $h(\mathrm{E}w, \mathrm{E}w')$). It lies in $\mathsf{U}(E)$: for $w \in F_c$ we have $h(x_e, w) = 0$ and, if $c \leq a$, $h(v, w) = 0$,

so $\mathrm{E}w = w$ for $c \le a$ and $\mathrm{E}w \in w + F_a \subseteq w + F_{c-1}$ for $c > a$; for $w \in X^\perp$, $\mathrm{E}w \in w + X$. So E preserves the flag $F_\bullet$ and acts trivially on the quotients F_c/F_{c-1} and $X^\perp/X$, hence (being an isometry) on the dual quotients; that is, E is in the unipotent radical U of the stabiliser of $F_\bullet$. Since $h(x_e, f_b) = 0$ for all b ($x_e \in X$, X isotropic and orthogonal to z), $\mathrm{E}f_b = f_b + h(v, f_b)x_e$, whose f_{b-1}-coefficient is $r\,h(v, f_b)\xi_{b-1}$; hence

$$\sigma(\mathrm{E}) = r \sum_{b=1}^{\varrho} h(v, f_b)\, \xi_{b-1}. \tag{5.55}$$

(i), one step. Let (μ, μ') occur at $a < \varrho$ through (x, y). The vector $\mu f_{a+1} - \mu'\gamma f_{a+1}$ lies in $\langle f_b, \gamma f_b : b \le a\rangle$ if and only if every linear form m on V that kills f_b and γf_b for all $b \le a$ satisfies $\mu\, m(f_{a+1}) = \mu'\, m(\gamma f_{a+1})$; and if it does, adding the resulting relation to $f \cdot x = \gamma f \cdot y$ shows that (μ, μ') occurs at $a + 1$ (the old coefficients at $a + 1$ are 0). Let m be such a form. As h is nondegenerate, $m = h(\gamma v, \cdot)$ for some $v \in V$; then $h(\gamma v, f_b) = 0$ and $h(v, f_b) = h(\gamma v, \gamma f_b) = 0$ for $b \le a$. Let $t \in E$ and $r = -tM\varpi$. Apply the construction above with $a + 1$ in place of a: to $(\xi, v) = (x, \gamma v)$, giving $u \in \mathsf{U}(E)$, and to $(\xi, v) = (y, v)$, giving $u' \in \mathsf{U}(E)$. By (5.55), since $h(\gamma v, f_b) = h(v, f_b) = 0$ for $b \le a$ and $x_{b-1} = y_{b-1} = 0$ for $b - 1 > a$,

$$\sigma(u) = r\mu\, m(f_{a+1}), \qquad \sigma(u') = r\mu'\, h(v, f_{a+1}) = r\mu'\, m(\gamma f_{a+1}).$$

Conjugating, $\gamma u'\gamma^{-1}$ is the Eichler transformation of $(\gamma\, rf \cdot y, \gamma v) = (rf \cdot x, \gamma v)$ with $\varsigma = \frac{1}{2}h(v, v) = \frac{1}{2}h(\gamma v, \gamma v)$, that is $\gamma u'\gamma^{-1} = u$, so $u\gamma = \gamma u'$. By agreement $\psi(u) = \psi(u')$, i.e. $\psi_f(t\mu\, m(f_{a+1})) = \psi_f(t\mu'\, m(\gamma f_{a+1}))$ for every $t \in E$. Put $c = \mu\, m(f_{a+1}) - \mu'\, m(\gamma f_{a+1}) \in E$. The continuous character $t \mapsto \psi_f(tc)$ of $\mathbb{A}_f$ is trivial on the dense subgroup E, hence trivial; if $c \ne 0$, c is a unit of $\mathbb{A}_f$ and ψ_f would be trivial. So $c = 0$, as required.

(i), conclusion. By induction, (μ, μ') occurs at every $l \in \{a, \dots, \varrho\}$. At $l = \varrho$ take (x, y): since $e_1, \dots, e_\varrho$ are isotropic and orthogonal to z, $h(f \cdot x, f \cdot x) = -N\mu\bar{\mu}$, and $h(\gamma f \cdot y, \gamma f \cdot y) = h(f \cdot y, f \cdot y) = -N\mu'\bar{\mu}'$; so $\mu\bar{\mu} = \mu'\bar{\mu}'$.

Prescribed tails. Suppose $(\zeta, 1)$ occurs at every $a \ge j$. Then for every $w \in E^{\varrho+1}$ there are x, y with $f \cdot x = \gamma f \cdot y$ and $y_a = w_a$ for $a \ge j$: by descending induction on j, if (x, y') has $y'_a = w_a$ for $a > j$, add $(w - y')_j$ times a pair (X, Y) realising $(\zeta, 1)$ at j ($Y_j = 1$, $X_b = Y_b = 0$ for $b > j$). The same holds for γ^{-1}, for which $(\bar{\zeta}, 1)$ occurs at every $a \ge j$ (from $f \cdot X = \gamma f \cdot Y$ follows $f \cdot (\bar{\zeta}Y) = \gamma^{-1}f \cdot (\bar{\zeta}X)$).

(ii). The set of admissible j contains $\varrho + 1$ (the condition is empty), so j is defined. Every nonzero common vector $f \cdot x = \gamma f \cdot y$ has an index $l \ge j$ with $x_l \ne 0 \ne y_l$: let l be the largest index with $(x_l, y_l) \ne (0, 0)$; by (i), $x_l\bar{x}_l = y_l\bar{y}_l$, so both are nonzero; $\zeta = x_l/y_l$ has $\zeta\bar{\zeta} = 1$, and $(\zeta, 1)$ occurs at l (through $(x/y_l, y/y_l)$), hence at every $a \ge l$ by (i); by minimality $j \le l$.

Since $\mathsf{g}(\gamma) = 0$, Lemma 5.2.25 (iv) gives a nonzero common vector, so $j \le l \le \varrho$.

$D_j(\gamma) \ne 0$: otherwise there is $y \ne 0$ with $y_a = 0$ for $a \ge j$ and $(Z(\gamma)y)_a = 0$ for $a < j$. Let $w \in E^{\varrho+1}$. By the prescribed tails for γ^{-1} there are X, Y with $f \cdot Y = \gamma^{-1}f \cdot X$, i.e. $f \cdot X = \gamma f \cdot Y$, and $X_a = \bar{w}_a$ for $a \ge j$. Then, as the rows $a < j$ of $Z(\gamma)y$ vanish,

$$\sum_a w_a(Z(\gamma)y)_a = \sum_a \bar{X}_a(Z(\gamma)y)_a = h(f \cdot X, \gamma f \cdot y) = h(\gamma f \cdot Y, \gamma f \cdot y) = h(f \cdot Y, f \cdot y) = -N\bar{Y}_\varrho y_\varrho = 0,$$

since $y_\varrho = 0$ ($j \le \varrho$). So $Z(\gamma)y = 0$. By Lemma 5.2.28 (vi) with $c' = 0$, $\Upsilon_\gamma(y_0 + y_\varrho z^+) = 0$ for the X_0-part y_0 of $\gamma f \cdot y$, so $y_0 = 0$; by Lemma 5.2.26 (i) with $D = 0$, $\gamma f \cdot y$ has neither e^*- nor z-coordinates, so $\gamma f \cdot y = f \cdot x$ for some x, and $x \ne 0$ because γf is linearly independent and $y \ne 0$. By the previous paragraph some $l \ge j$ has $y_l \ne 0$, a contradiction.

Finally $j \le \varrho$ and $\mathsf{g}(\gamma) = 0$, so the equivalence $\varrho < j \iff \mathsf{g}(\gamma) \ne 0$ holds (both sides are false). With the choice of j and $D_j(\gamma) \ne 0$, γ satisfies the conditions of cell rank j. □

Lemma 5.3.32. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, and $T \subseteq G(E)$ stable with $\mathsf{g}(\gamma) \neq 0$ for every $\gamma \in T$. Then for all $c, c' \in \mathcal{C}$ and $s \in \bar{G}$*

$$\|A_T^{\mathrm{cut}}(c,s,c')\| \leq \nu \sum_{\gamma} \tau_{\mathrm{sz}}^2 \sqrt{\frac{\mathcal{D}_{\mathrm{main}}}{n_p (M^{2\varrho f} \prod_v |\mathsf{g}(\gamma)|_v)^k}},$$

the sum over the $\gamma \in T$ over (c,s,c') that are near representatives for (c,c').

Proof. Fix c, c' and s. For $\delta \in G(E)$ write $K_\delta^\sigma(y) = W^\sigma(y) \otimes \overline{W^\sigma(\delta^{-1} y)}$ ($\sigma \in \{\mathrm{full}, \mathrm{cut}\}$), and for $x > 0$ let $\mathrm{ob}(x) = \tau_{\mathrm{sz}}^2 \sqrt{\mathcal{D}_{\mathrm{main}}/(n_p (M^{2\varrho f} x)^k)}$, so that the summand of the statement is $\nu\, \mathrm{ob}(\prod_v |\mathsf{g}(\gamma)|_v)$. Let $\mathbf{1}_{\mathrm{red}}$ be the indicator of the reduced points; by Lemma 5.2.21 it is a box partition of unity for c.

A cutoff through chosen representatives. In each double coset $q = \mathsf{U}_c^0(M)\, \delta\, \mathsf{U}_{c'}(M)$ choose one element r_q, a near representative for (c,c') if q contains one, and let R be the set of the r_q. Put $\varphi(\delta, y) = \mathbf{1}_R(\delta) \mathbf{1}_{\mathrm{red}}(y)$; each $\varphi(\delta, \cdot)$ is Borel. For $\gamma \in T$ a term over (c,s,c') we have $\mathsf{g}(\gamma) \neq 0$, so by Lemma 5.3.33 with $\omega = \mathbf{1}_{\mathrm{red}}$, $\sum_{(u,u')} \varphi(u \gamma u'^{-1}, u \cdot y) = 1$ for every y, the sum over $\mathsf{U}_c(M) \times \mathsf{U}_{c'}(M)$. By Lemma 5.2.40 (cut case) for the stable set T,

$$\|A_T^{\mathrm{cut}}(c,s,c')\| \leq \sum_{\substack{\gamma \in T \\ \text{over } (c,s,c')}} \|J_\gamma\|, \qquad J_\gamma = \int_{G_\infty} \varphi(\gamma, y)\, K_\gamma^{\mathrm{cut}}(y)\, dy.$$

Terms that do not contribute. If $\gamma \notin R$, then $J_\gamma = 0$. If $\gamma \in R$ is not a near representative for (c,c'), then by the choice of R its double coset $\mathsf{U}_c^0(M) \gamma \mathsf{U}_{c'}(M)$ contains no near representative for (c,c'), so by Lemma 5.3.34 $K_\gamma^{\mathrm{cut}}(y) = 0$ at every reduced y; hence the integrand of J_γ vanishes and $J_\gamma = 0$.

A near representative. Let $\gamma \in R \cap T$ be a term over (c,s,c') and a near representative for (c,c'), and $x = \prod_v |\mathsf{g}(\gamma)|_v$. By Lemma 5.3.63 (i), $x \geq 1$; put $\varepsilon = \nu\, \mathrm{ob}(x)/2 \geq 0$, so that $\prod_v \mathrm{PB}(\gamma_v, \deg_v, b^{37n}, \#I_v) \leq \varepsilon^2$ by Lemma 5.3.63 (iii). The weight $\omega = \mathbf{1}_{\mathrm{red}}$ is Borel with values in $[0,1]$. It is invariant under every $t \in G_\infty$ whose components fix $f_0, \dots, f_\varrho$, since reducedness of y depends only on the vectors $y_v^{-1} f_b$ (RD4) and $(t_v y_v)^{-1} f_b = y_v^{-1} f_b$. If $\omega(y) \neq 0$ and $\ell(y_v) \leq b^{6n+2}$, then by (RD5) $y_v \in \mathrm{Bx}(b^{27} \ell(y_v)) \subseteq \mathrm{Bx}(b^{6n+29}) \subseteq \mathrm{Bx}(b^{37n})$, as $b \geq 1$ and $6n + 29 \leq 37n$. As γ is a near term with $\mathsf{g}(\gamma) \neq 0$, Lemma 5.3.35 gives

$$\|J_\gamma\| \leq \varepsilon + \int_{G_\infty} \varphi(\gamma, y)\, \|K_\gamma^{\mathrm{full}}(y) - K_\gamma^{\mathrm{cut}}(y)\|\, dy.$$

The integral is one summand of the sum in Lemma 5.3.60 for the stable set T and the cutoff φ, so it is at most $\nu/(2b^{k^3 f})$, and by Lemma 5.3.63 (ii) this is at most $\nu\, \mathrm{ob}(x)/2$. Hence $\|J_\gamma\| \leq \nu\, \mathrm{ob}(x)$.

Conclusion. Summing over the terms $\gamma \in T$ over (c,s,c'), only near representatives for (c,c') contribute, each at most $\nu\, \mathrm{ob}(\prod_v |\mathsf{g}(\gamma)|_v)$, which is the statement. □

Lemma 5.3.33. *Let $\mathfrak{S}$ be a filling datum, $c, c' \in \mathcal{C}$, $R \subseteq G(E)$ a set containing exactly one element of each double coset $\mathsf{U}_c^0(M)\, \delta\, \mathsf{U}_{c'}(M)$ ($\delta \in G(E)$), ω a box partition of unity for c, and $\gamma \in G(E)$ with $\mathsf{g}(\gamma) \neq 0$. Then for every $y \in G_\infty$*

$$\sum_{(u,u') \in \mathsf{U}_c(M) \times \mathsf{U}_{c'}(M)} \mathbf{1}_R(u \gamma u'^{-1})\, \omega(u \cdot y) = 1.$$

Proof. **Trivial stabilisers.** Let $\delta \in G(E)$ with $\mathsf{g}(\delta) \neq 0$, $p \in \mathsf{U}_c^0(M)$ and $w \in \mathsf{U}_{c'}(M)$ with $p\delta = \delta w$. We show $w = 1$, hence $p = 1$. As p fixes every f_a, $w\delta^{-1}f_a = \delta^{-1}pf_a = \delta^{-1}f_a$ for $0 \leq a \leq \varrho$. By Lemma 5.2.26 (ii), $\det Z(\delta) \neq 0$; since $h(f_a, \delta^{-1}f_b) = h(\delta f_a, f_b) = \overline{Z(\delta)_{ba}}$, the matrix $(h(f_a, \delta^{-1}f_b))_{a,b} = Z(\delta)^*$ is invertible. Hence there are $y_0, \dots, y_{\varrho-1}$ in the span of $\delta^{-1}f_0, \dots, \delta^{-1}f_\varrho$ with $h(e_{a+1}, y_b) = \delta_{ab}$ for $0 \leq a, b < \varrho$, and w fixes them. Let $Y = \langle y_0, \dots, y_{\varrho-1}\rangle$. The pairing h between X and Y is perfect; so $\dim Y = \varrho$, $Y \cap X^\perp = 0$, $X \cap Y^\perp = 0$, and $V = Y \oplus X^\perp$ as $\dim X^\perp = r - \varrho$. Now $w \in \mathsf{U}(E)$ is an isometry that preserves X and acts trivially on $X^\perp/X$. For $x \in X$ and $t \in X^\perp \cap Y^\perp$ the vectors $wx - x$ and $wt - t$ lie in X, and for $y \in Y$, $h(wx - x, y) = h(wx, wy) - h(x, y) = 0$ and likewise $h(wt - t, y) = 0$; so both lie in $X \cap Y^\perp = 0$. Since $X \cap (X^\perp \cap Y^\perp) \subseteq X \cap Y^\perp = 0$ and $\dim(X^\perp \cap Y^\perp) \geq r - 2\varrho$, $X^\perp = X \oplus (X^\perp \cap Y^\perp)$, and w is the identity on $X^\perp + Y = V$.

One representative pair per coset. For $x \in \mathsf{U}_c(M)$ put $a(x) = \sum_{u' \in \mathsf{U}_{c'}(M)} \mathbf{1}_R(x\gamma u'^{-1}) \in [0, \infty]$. Fix x and put $\delta = x\gamma$; then $\mathsf{g}(\delta) = \mathsf{g}(\gamma) \neq 0$ by Lemma 5.2.25 (ii). The double coset $\mathsf{U}_c^0(M)\delta\mathsf{U}_{c'}(M)$ contains exactly one $r \in R$, so there is a pair $(q, u') \in \mathsf{U}_c^0(M) \times \mathsf{U}_{c'}(M)$ with $q\delta u'^{-1} \in R$. If (q_1, u_1) and (q_2, u_2) are two such pairs, then $q_1\delta u_1^{-1} = q_2\delta u_2^{-1} = r$, so $p\delta = \delta w$ with $p = q_2^{-1}q_1 \in \mathsf{U}_c^0(M)$ and $w = u_2^{-1}u_1 \in \mathsf{U}_{c'}(M)$, and the first step gives $q_1 = q_2$, $u_1 = u_2$. Hence, for every $x \in \mathsf{U}_c(M)$,

$$\sum_{q \in \mathsf{U}_c^0(M)} a(qx) = \sum_{q \in \mathsf{U}_c^0(M)} \sum_{u' \in \mathsf{U}_{c'}(M)} \mathbf{1}_R(qx\gamma u'^{-1}) = 1.$$

The partition of unity. By the defining property of a box partition of unity for c (RD5), applied to the weight a, $\sum_{u \in \mathsf{U}_c(M)} a(u)\,\omega(u \cdot y) = 1$ for every y. Expanding $a(u)$ (a sum of nonnegative terms) gives the statement. □

Lemma 5.3.34. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, $c, c' \in \mathcal{C}$, $\gamma \in G(E)$, and $y \in G_\infty$ reduced with $W^{\mathrm{cut}}(y) \otimes \overline{W^{\mathrm{cut}}(\gamma^{-1}y)} \neq 0$. Then the double coset $\mathsf{U}_c^0(M)\,\gamma\,\mathsf{U}_{c'}(M)$ contains a near representative for (c, c').*

Proof. **Two invariances.** (a) $\ell(sx) = \ell(x)$ for $s \in R$, $x \in G_1$, as R is a group. For $u \in \mathsf{U}(E)$ and $v \in \Phi$, $u_v = B_v^{-1}v(u)B_v$ with B_v diagonal in a basis adapted to the flag $\langle e_1\rangle \subset \cdots \subset \langle e_1, \dots, e_\varrho\rangle$; $u_v \in G_1$ (RD1), it stabilises the flag and acts trivially on its successive quotients and on those of the refined flag, so $u_v \in \mathsf{U} \subseteq R$. Hence $\ell((u \cdot x)_v) = \ell(x_v)$ for $x \in G_\infty$. (b) If moreover $uf_b = f_b$ for all b, then $u_v f_b = B_v^{-1}v(u)\mathrm{bs}_v(f_b)f_b = f_b$, so $(u_v x_v)^{-1}f_b = x_v^{-1}f_b$; as reducedness depends only on the moved frames $x_v^{-1}f_b$ (RD4), $u \cdot x$ is reduced if and only if x is, and by (a) $u \cdot x$ is boxed if and only if x is.

Step 1: both points are in the cut. Some entry $W^{\mathrm{cut}}(y)_i W^{\mathrm{cut}}(\gamma^{-1}y)_{i'}$ of the kernel is nonzero, so $W_v^\flat(y_v) \neq 0$ and $W_v^\flat((\gamma^{-1}y)_v) \neq 0$ for every $v \in \Phi$. By (BS2) the cut functions vanish outside the cut, so $\ell(y_v) \leq b^{6n+2}$ and $\ell((\gamma^{-1}y)_v) \leq b^{6n+2}$ for every v. As y is reduced, y is boxed.

Step 2: reducing $\gamma^{-1}y$. Let $Q \subseteq \mathsf{U}_{c'}(M)$ contain exactly one element of each coset $\mathsf{U}_{c'}^0(M)u'$ and $a = \mathbf{1}_Q$; then $\sum_{u_0 \in \mathsf{U}_{c'}^0(M)} a(u_0u') = 1$ for every $u' \in \mathsf{U}_{c'}(M)$. By Lemma 5.2.21, $\mathbf{1}_{\mathrm{red}}$ is a box partition of unity for c', so (RD5) gives $\sum_{u \in \mathsf{U}_{c'}(M)} a(u)\mathbf{1}_{\mathrm{red}}(u \cdot \gamma^{-1}y) = 1$; hence there is $u \in \mathsf{U}_{c'}(M)$ with $u \cdot \gamma^{-1}y$ reduced. By (a) and Step 1 its components have Bessel length at most b^{6n+2}, so $u \cdot \gamma^{-1}y$ is boxed.

Step 3: a near element and its representative. Put $\delta_1 = \gamma u^{-1}$. Since $\gamma \mapsto \gamma_\infty$ is a homomorphism (RD1), $\delta_1^{-1}y = u \cdot \gamma^{-1}y$, which is boxed, and y is boxed: δ_1 is a near term. Let $r \in R_{c,c'}$ be the representative of $\mathsf{U}_c^0(M)\,\delta_1\,\mathsf{U}_{c'}^0(M)$, $r = a_1\delta_1 b_1$ with $a_1 \in \mathsf{U}_c^0(M)$, $b_1 \in \mathsf{U}_{c'}^0(M)$. By (b), $a_1 \cdot y$ is boxed and $r^{-1}(a_1 \cdot y) = b_1^{-1} \cdot (\delta_1^{-1}y)$ is boxed; so r is a near term, hence a near

representative for (c,c'). Finally $r = a_1\gamma(u^{-1}b_1)$ with $u^{-1}b_1 \in \mathsf{U}_{c'}(M)$, as $\mathsf{U}^0_{c'}(M) \subseteq \mathsf{U}_{c'}(M)$ and the latter is a group ($K(M)$ and $\mathsf{U}(E)$ are groups); so $r \in \mathsf{U}^0_c(M)\,\gamma\,\mathsf{U}_{c'}(M)$. □

Lemma 5.3.35. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, and $\gamma \in G(E)$ a near term with $\mathsf{g}(\gamma) \neq 0$. Let $\omega\colon G_\infty \to [0,1]$ be Borel with $\omega(ty) = \omega(y)$ whenever every $t_v \in G_1$ fixes $f_0,\dots,f_\varrho$, and such that $\omega(y) \neq 0$ and $\ell(y_v) \leq b^{6n+2}$ imply $y_v \in \mathrm{Bx}(b^{37n})$. Let $\varepsilon \geq 0$ with $\prod_{v\in\Phi} \mathrm{PB}(\gamma_v, \deg_v, b^{37n}, \#I_v) \leq \varepsilon^2$. Write $K^\sigma(y) = W^\sigma(y) \otimes \overline{W^\sigma(\gamma^{-1}y)}$ for $\sigma \in \{\mathrm{full}, \mathrm{cut}\}$. Then*

$$\Big\| \int_{G_\infty} \omega(y)\, K^{\mathrm{cut}}(y)\, dy \Big\| \leq \varepsilon + \int_{G_\infty} \omega(y)\, \|K^{\mathrm{full}}(y) - K^{\mathrm{cut}}(y)\|\, dy.$$

Proof. Put $\rho = b^{37n}$, $\gamma' = \gamma^{-1}$, so $\gamma'_v = (\gamma_v)^{-1}$, and $\mathrm{PB}_v = \mathrm{PB}(\gamma_v, \deg_v, \rho, \#I_v)$.

Step 1: hypotheses of the local bound. By Lemma 5.3.36 (iii) and (ii), $\mathsf{g}_1(Z(\gamma'_v)) = \mathsf{g}_1(Z(\gamma_v)) = s_v^2\, v(\mathsf{g}(\gamma))$ with $s_v > 0$ (the squared frame scales are positive by (FA4)), and $v(\mathsf{g}(\gamma)) > 0$ as $\mathsf{g}(\gamma) \neq 0$ is totally positive (Lemma 5.2.26 (ii)). As $\mathrm{PB}(y,\dots)$ depends on y only through $\mathsf{g}_1(Z(y))$, $\mathrm{PB}(\gamma'_v, \deg_v, \rho, \#I_v) = \mathrm{PB}_v$. Since γ is near, there is a boxed y_0 with $\gamma^{-1}y_0$ boxed. A boxed point x is reduced with $\ell(x_v) \leq b^{6n+2}$, so by Lemma 5.2.21 and (RD5) $x_v \in \mathrm{Bx}(b^{27}\ell(x_v)) \subseteq \mathrm{Bx}(\rho)$, as $6n+29 \leq 37n$. Put $y' = \gamma^{-1}y_0$: then $y'_v \in \mathrm{Bx}(\rho)$ and $(\gamma'_v)^{-1}y'_v = y_{0,v} \in \mathrm{Bx}(\rho)$; and $\rho \geq b$.

Step 2: local open-cell bounds and their product. By Lemma 5.3.37 at each v (for $\mathfrak{B}_v$, γ'_v, y'_v, ρ) there are $\mathcal{X}_v$ and an open-cell bound (A_v, ν_v, m_v, t_v) for $(W_v, \gamma'_v, \rho, \deg_v)$: A_v compact, m_v a probability measure, t_v measurable with frame-fixing values, ν_v finite with $\nu_v(G_1) \leq \mathrm{PB}_v$, the kernels

$$k^v_{(i,j)}(x,z) = W_{v,i}(\gamma'_v t_v(x) z)\, \overline{W_{v,j}(t_v(x)z)} \qquad ((i,j) \in I_v \times I_v)$$

an L^2 contraction from $(G_1, dy|_{A_v})$ to $(\mathcal{X}_v, m_v)$ with bound ν_v, and, for m_v-almost every x, every $z \in \mathrm{Bx}(\rho)$ with $\ell(\gamma'_v t_v(x) z) \leq \rho$ lies in A_v. These kernels are bounded and measurable (W_v is bounded and continuous, t_v measurable). Let $A = \prod_v A_v$, $m = \bigotimes_v m_v$, $\nu = \bigotimes_v \nu_v$, and for $x \in \mathcal{X} = \prod_v \mathcal{X}_v$

$$N(x) = \sum_{(i,j)\in I\times I} \Big| \int_A \omega(z) \prod_v k^v_{(i_v,j_v)}(x_v, z_v)\, dz \Big|^2.$$

By Lemma 5.3.59 with $\phi = \omega$ (Borel, values in $[0,1]$), $\int_{\mathcal{X}} N\, dm \leq \int \omega^2 d\nu \leq \prod_v \nu_v(G_1) \leq \prod_v \mathrm{PB}_v \leq \varepsilon^2$.

Step 3: a good shift. The set $\mathcal{X}'$ of x such that for every v each $z \in \mathrm{Bx}(\rho)$ with $\ell(\gamma'_v t_v(x_v) z) \leq \rho$ lies in A_v has full m-measure, its complement being a finite union of sets $\{x : x_v \in Q_v\}$ with $m_v(Q_v) = 0$. If $N > \varepsilon^2$ on $\mathcal{X}'$, then $\int N\, dm > \varepsilon^2$, as $m(\mathcal{X}') = 1$ and $N - \varepsilon^2 > 0$ there; so there is $x \in \mathcal{X}'$ with $N(x) \leq \varepsilon^2$. Let $s = (t_v(x_v))_v \in G_\infty$; each s_v fixes the frame, so $\omega(sz) = \omega(z)$ and $(s_v z_v)^{-1} f_a = z_v^{-1} f_a$.

Step 4: the adjoint kernel and its support. For $\sigma \in \{\mathrm{full}, \mathrm{cut}\}$ let $F^\sigma(y) = \omega(y)\, W^\sigma(\gamma' y) \otimes \overline{W^\sigma(y)}$. Since ω is real, $F^\sigma(y)$ is the conjugate transpose of $\omega(y)K^\sigma(y)$; conjugate transposition is a real linear isometry of $\mathbb{C}^{I\times I}$ for the euclidean norm and commutes with integration, so $\|\int F^{\mathrm{cut}}\| = \|\int \omega K^{\mathrm{cut}}\|$ and $\|F^{\mathrm{full}}(y) - F^{\mathrm{cut}}(y)\| = \omega(y)\|K^{\mathrm{full}}(y) - K^{\mathrm{cut}}(y)\|$. If $F^{\mathrm{cut}}(sz) \neq 0$, then $\omega(sz) \neq 0$, and $W^\flat_v(s_v z_v) \neq 0$, $W^\flat_v(\gamma'_v s_v z_v) \neq 0$ for every v; by (BS2), $\ell(s_v z_v) \leq b^{6n+2}$ and $\ell(\gamma'_v s_v z_v) \leq b^{6n+2} \leq \rho$; by the hypothesis on ω, $s_v z_v \in \mathrm{Bx}(\rho)$, hence $z_v \in \mathrm{Bx}(\rho)$; as $x \in \mathcal{X}'$, $z_v \in A_v$. So $z \mapsto F^{\mathrm{cut}}(sz)$ vanishes outside the compact set A; it is bounded and measurable, hence integrable, and so is $F^{\mathrm{full}}(s\,\cdot)$ on A.

Step 5: the bound. By the left invariance of the Cayley measures (Lemma 5.2.41) and Step 4,

$$\int_{G_\infty} F^{\mathrm{cut}}(y)\,dy = \int_A F^{\mathrm{cut}}(sz)\,dz = \int_A F^{\mathrm{full}}(sz)\,dz - \int_A (F^{\mathrm{full}} - F^{\mathrm{cut}})(sz)\,dz.$$

The entry (i,j) of $F^{\mathrm{full}}(sz)$ is $\omega(z)\prod_v k^v_{(i_v,j_v)}(x_v,z_v)$, so the first integral has norm $N(x)^{1/2} \le \varepsilon$. The second has norm at most $\int_{G_\infty} \|F^{\mathrm{full}} - F^{\mathrm{cut}}\|(sz)\,dz = \int_{G_\infty} \omega(y)\|K^{\mathrm{full}}(y) - K^{\mathrm{cut}}(y)\|\,dy$, again by left invariance. With Step 4 this is the claim. □

Lemma 5.3.36. *Let $\mathfrak{S}$ be a filling datum, $\gamma \in G(E)$ and $v \in \Phi$, and put*

$$S_v = \mathrm{diag}(\mathrm{bs}_v(f_0), \dots, \mathrm{bs}_v(f_\varrho)) \quad \textit{and} \quad s_v = \prod_{a=0}^{\varrho} \mathrm{fs}(v,a).$$

(i) $Z(\gamma_v) = S_v\, v(Z(\gamma))\, S_v$, and $\mathrm{bs}_v(f_a)^2 = \mathrm{fs}(v,a)$; hence $D_l(Z(\gamma_v)) = \prod_{a<l} \mathrm{fs}(v,a)\, v(D_l(\gamma))$ for $0 \le l \le \varrho+1$.

(ii) $\mathsf{g}_1(Z(\gamma_v)) = s_v^2\, v(\mathsf{g}(\gamma))$.

(iii) For $y \in G_1$, $Z(y^{-1}) = Z(y)^*$ and $\mathsf{g}_1(Z(y^{-1})) = \mathsf{g}_1(Z(y))$.

Proof. **(i)** Let $B_v = \mathrm{diag}(\mathrm{bs}_v)$, a real diagonal matrix in the standard basis, and H_v the Gram matrix of $V \otimes_{E,v} \mathbb{C}$ in that basis (entries 1 for the pairs (e_a, e_a^*), the identity on X_0, $-N$ at z). As $\mathrm{bs}_v(e_a)\mathrm{bs}_v(e_a^*) = 1$, $\mathrm{bs}_v = 1$ on X_0 and $\mathrm{bs}_v(z)^2 = 1/N$, the matrix $B_v^* H_v B_v$ is the Gram matrix J_1 of V_1. By (RD1), $\gamma_v = B_v^{-1} v(\gamma) B_v$. The frame vectors are standard basis vectors with $B_v f_a = \mathrm{bs}_v(f_a) f_a$, so

$$Z(\gamma_v)_{ab} = f_a^* J_1 \gamma_v f_b = (B_v f_a)^* H_v\, v(\gamma)\, (B_v f_b) = \mathrm{bs}_v(f_a)\mathrm{bs}_v(f_b)\, v(h(f_a, \gamma f_b)).$$

By (RD1), $\mathrm{bs}_v(f_a) = \mathrm{rs}_v^{\varrho-a}/\sqrt{N}$ with rs_v real, so $\mathrm{bs}_v(f_a)^2 = \mathrm{fs}(v,a)$. Taking the leading principal minor of order l of $S_v\, v(Z(\gamma))\, S_v$ gives the formula for D_l.

(ii) By (i) and $\mathrm{fs}(v,\varrho) = 1/N$, and since $v(\alpha\bar\alpha) = |v(\alpha)|^2$ for α in the CM field E,

$$\begin{aligned}\mathsf{g}_1(Z(\gamma_v)) &= s_v^2 |v(D_{\varrho+1}(\gamma))|^2 - \Big(\prod_{a<\varrho} \mathrm{fs}(v,a)\Big)^2 |v(D_\varrho(\gamma))|^2 \\ &= s_v^2 (|v(D_{\varrho+1})|^2 - N^2 |v(D_\varrho)|^2) = s_v^2\, v(\mathsf{g}(\gamma)).\end{aligned}$$

(iii) y preserves the form h_1 of V_1, so $Z(y^{-1})_{ab} = h_1(f_a, y^{-1} f_b) = h_1(y f_a, f_b) = \overline{h_1(f_b, y f_a)} = \overline{Z(y)_{ba}}$. The determinant and the leading principal minors of $Z(y)^*$ are the conjugates of those of $Z(y)$, which have the same moduli; so $\mathsf{g}_1(Z(y^{-1})) = \mathsf{g}_1(Z(y))$. □

Lemma 5.3.37. *Let $\mathfrak{B}$ be a Bessel system for (ϱ, k, b, f) with Bessel function W, index set I and degree* deg. *Let $\gamma, y \in G_1$ with $\mathsf{g}_1(Z(\gamma)) > 0$, $y \in \mathrm{Bx}(\rho)$ and $\gamma^{-1} y \in \mathrm{Bx}(\rho)$, where $\rho \ge b$. Then there are a measurable space $\mathcal{X}$ and (A, ν, m, t) that is an open-cell bound for $(W, \gamma, \rho, \deg)$; that is, $t\colon \mathcal{X} \to G_1$ is measurable with values in the elements fixing $f_0, \dots, f_\varrho$, and (A, ν, m) is a kernel bound for $(W, \gamma t, t, \rho, \mathrm{PB}(\gamma, \deg, \rho, \#I))$.*

Proof. Let $Z = Z(\gamma)$ and $n = \varrho + 1$; then $\rho \ge b \ge 8r \ge 8n \ge 8$.

Sizes. By Lemma 5.3.41 (iv), applied with y, and since $y^{-1}\gamma f_c = (\gamma^{-1}y)^{-1} f_c$, $|Z_{ac}| \le \|y^{-1} f_a\|\, \|(\gamma^{-1}y)^{-1} f_c\| \le \rho^2$ for all a, c. Hence $\|Z\| \le n\rho^2 \le \rho^3$ and $\mathsf{g}_1(Z) \le |\det Z|^2 \le \|Z\|^{2n} \le$

ρ^{6n}. Put $M = \rho^{9n}/\mathfrak{g}_1(Z)$, defined as $\mathfrak{g}_1(Z) > 0$. Then $M \geq \rho^{3n} \geq \rho \geq b$, $M^{-1} = \mathfrak{g}_1(Z)\rho^{-9n} \leq \mathfrak{g}_1(Z)$ and $|Z_{ac}| \leq \rho^2 \leq M^2$.

Reduction to the Gram section. By Lemma 5.3.47 (i), $Z \in \Omega_{\rm cell}$, and by (iii) there are $g_1, g_2 \in G_1$ fixing $f_0, \dots, f_\varrho$ with $\gamma = g_1^{-1}\gamma_Z g_2$. An element fixing the frame lies in R (Lemma 5.5.30 (i)); so $s = g_1^{-1} \in R$. Let $\mathcal{X} = \mathrm{U}(k) \times \mathsf{U}^0$ with its Borel σ-algebra and $t(h, v) = g_2^{-1}(vh)^{-1}$. Then t is continuous, hence measurable, its values fix $f_0, \dots, f_\varrho$ (so lie in R), and

$$\gamma\, t(h, v) = g_1^{-1}\gamma_Z g_2 g_2^{-1}(vh)^{-1} = s\,\gamma_Z(vh)^{-1}.$$

The kernel bound. By Lemma 5.3.38 with $M \geq b$, Z, s and t, there are A, ν and m such that (A, ν, m) is a kernel bound for $(W, \gamma t, t, M, C)$, where

$$C = M^{10^5 n^4} \frac{(\#I)^2}{\deg \cdot c_G(\mathfrak{g}_1(Z)/2)^{k-1}} = \mathrm{PB}(\gamma, \deg, \rho, \#I).$$

All clauses of a kernel bound except the last do not involve the size. For the last: for m-almost every x, every $z \in \mathrm{Bx}(M)$ with $\ell(\gamma t(x)z) \leq M$ lies in A; as $\rho \leq M$, $\mathrm{Bx}(\rho) \subseteq \mathrm{Bx}(M)$ and $\ell(\gamma t(x)z) \leq \rho$ implies $\ell(\gamma t(x)z) \leq M$. Hence (A, ν, m) is a kernel bound for $(W, \gamma t, t, \rho, \mathrm{PB}(\gamma, \deg, \rho, \#I))$, and (A, ν, m, t) is an open-cell bound for $(W, \gamma, \rho, \deg)$. □

Lemma 5.3.38. *Let $\mathfrak{B}$ be a Bessel system for (ϱ, k, b, f) with Bessel function W, index set I and degree* deg. *Let $M \geq b$, let Z be a complex $(\varrho+1) \times (\varrho+1)$ matrix with $\mathfrak{g}_1(Z) \geq M^{-1}$ and $|Z_{ac}| \leq M^2$ for all a, c, let $s \in R$ and let $t\colon \mathrm{U}(k) \times \mathsf{U}^0 \to R$ be a map; put $g(h, v) = s\gamma_Z(vh)^{-1}$. Then there are a set $A \subseteq G_1$, a measure ν on G_1 and a measure m on $\mathrm{U}(k) \times \mathsf{U}^0$ such that (A, ν, m) is a kernel bound for (W, g, t, M, C), where*

$$C = M^{10^5 n^4} \frac{(\#I)^2}{\deg \cdot c_G\,(\mathfrak{g}_1(Z)/2)^{k-1}}.$$

Proof. Scales. $M \geq b \geq 8r \geq 8n \geq 8$. Put $M_0 = M^{9n}$, $L = M_0^5$ and $P = L^n = M^{45n^2}$; then $8r \leq M \leq L \leq P$, $P \geq M^5 \geq b^5$ and $P \geq M^{9n}$.

The tube. By Lemma 5.3.39 ($L \geq 8r$) there are A and $\mathcal{Q} \subseteq \mathsf{U}^0$ such that A is a tube of size L along U^0 with base $\mathcal{Q}$: A is compact, $\|y\| \leq L^{10} \leq P^{20}$ for $y \in A$, $0 < dv(\mathcal{Q}) < \infty$, $\mathcal{Q}y \subseteq A$ when $\|y\| \leq L$, and $dv(\{v : vy \in A\}) \leq 3\,dv(\mathcal{Q})$ for every y. Taking $y = 1$, $\mathcal{Q} \subseteq A$, so $\|v\| \leq P^{20}$ for $v \in \mathcal{Q}$.

Mass of $\|W\|^2$ on the tube. Apply Lemma 5.3.42 with $w = \|W\|^2$ (Borel and left R-invariant, as wave has modulus 1 and ρ is unitary), $\phi = \mathbf{1}_A$, $K = 3\,dv(\mathcal{Q})$ and the bound P^{40}: if $s' \in \mathsf{U}$ and $y, s'y \in A$, every entry of $F^*s'F$ is an entry of $s' = (s'y)y^{-1}$, of absolute value at most $\|s'y\|\,\|y^{-1}\| = \|s'y\|\,\|y\| \leq P^{40}$ (Lemma 5.3.41 (iv)). With (BS1),

$$\int_A \|W\|^2 dy \leq 3\,dv(\mathcal{Q})\,(2P^{40})^{2n^2}\,\#I. \tag{5.56}$$

The measures. Let $c = c_G(\mathfrak{g}_1(Z)/2)^{k-1} > 0$, $\mu = \mu_{\mathfrak{g}_1(Z)/2} = c\,dh \otimes dv$, $S = \mathrm{U}(k) \times \mathcal{Q}$, so $\mu(S) = c\,dv(\mathcal{Q}) \in (0, \infty)$, $m = \mu(S)^{-1}\mu(\cdot \cap S)$, a probability measure, $K = P^{2000n^2}\deg^{-1}\#I$ and $\nu = \mu(S)^{-1}K\,\mathbf{1}_A\|W\|^2 dy$.

The contraction. We apply Lemma 5.3.43 with A, $(\mathrm{U}(k) \times \mathsf{U}^0, \mu)$, S, s, the continuous map $g_0(h, v) = \gamma_Z(vh)^{-1}$ (so $g = sg_0$), t and K. Let β be Borel, integrable and zero off A; then $\beta(y) = 0$ when $\|y\| > P^{20}$, and S lies in the fixer ball of radius P^{20}. By Lemma 5.3.56 (iii)

($M \geq 8n$, $|Z_{ac}| \leq M^2$, $\mathsf{g}_1(Z) \geq M^{-1}$, $P \geq M^{9n}$), every Y with $\|Y - Z\| < P^{-6}$ is bounded in the cell by P and has $\mathsf{g}_1(Y) \geq \mathsf{g}_1(Z)/2 > 0$. As W has Schur's bound $(P, \deg^{-1} \#I)$ and $P \geq 8r$, Lemma 5.3.44 (with $c = \mathsf{g}_1(Z)/2$, $D = \deg^{-1} \#I$, $\phi = \beta$) gives

$$\int_S \Big\| \int \beta(y) W(g_0(x)y)\, dy \Big\|^2 d\mu(x) \leq P^{2000n^2} \deg^{-1} \#I \int |\beta|^2 dy = K \int |\beta|^2 dy.$$

So the kernels $(x, y) \mapsto W_i(g(x)y)\overline{W_j(t(x)y)}$ are an L^2 contraction from $(G_1, dy|_A)$ to $(\mathrm{U}(k) \times \mathsf{U}^0, m)$ with bound ν.

The mass of ν. By (5.56), ν is finite and

$$\nu(G_1) \leq \frac{P^{2000n^2} \#I}{\deg\, c\, dv(\mathcal{Q})}\, 3\, dv(\mathcal{Q}) (2P^{40})^{2n^2} \#I = 3 \cdot 2^{2n^2} P^{2080n^2} \frac{(\#I)^2}{\deg\, c} \leq M^{10^5 n^4} \frac{(\#I)^2}{\deg\, c} = C,$$

Capture. m is carried by S. Let $x = (h, v)$ with $v \in \mathcal{Q}$, and $z \in \mathrm{Bx}(M)$ with $\ell(g(x)z) \leq M$. By Lemma 5.3.56 (i) ($M \geq n$), Z is bounded in the cell by $M_0 \geq M^{8n}$, so Z is invertible with $\|Z^{-1}\| \leq M_0$. By Lemma 5.3.57 (with M and $T = M_0$), $\|v^{-1}z\| \leq M_0^5 = L$, so $z = v\,(v^{-1}z) \in \mathcal{Q} \cdot \{\|y\| \leq L\} \subseteq A$. Finally A is compact and m is a probability measure, so (A, ν, m) is a kernel bound for (W, g, t, M, C). □

Lemma 5.3.39. *Let $L \geq 8r$. Then there are a set $\mathcal{K} \subseteq G_1$ and a set $\mathcal{Q} \subseteq \mathsf{U}^0$ such that $\mathcal{K}$ is a tube of size L along U^0 with base $\mathcal{Q}$.*

Proof. Write $\|\cdot\|$ for operator norms and $S(a, b) = \mathrm{sk}(b) - \frac{1}{2}aa^*$. For $t > 0$ let

$$B_t = \{u(a, b) :\ \|a\| \leq t,\ \|S(a, b)\| \leq t^2\} \subseteq \mathsf{U}^0.$$

Properties of B_t. (1) $B_t B_{t'} \subseteq B_{t+t'}$: by Lemma 5.3.40 (i), $u(a, b)u(a', b') = u(a + a', b'')$ with $b'' = b + b' + \beta(a, a')$, and $S(a + a', b'') = S(a, b) + S(a', b') - aa'^*$, whose norm is at most $t^2 + t'^2 + tt' \leq (t + t')^2$, while $\|a + a'\| \leq t + t'$. (2) The set $u^{-1}(B_t) \subseteq \mathcal{P}$ is closed and bounded ($\|\mathrm{sk}(b)\| \leq \frac{3}{2}t^2$ and sk is a linear bijection), hence compact; so B_t is compact and, u being injective (Lemma 5.3.40 (i)), $dv(B_t)$ is the Lebesgue measure of $u^{-1}(B_t)$, finite. (3) Under $\delta_t(a, b) = (ta, t^2 b)$ one has $S(\delta_t(a, b)) = t^2 S(a, b)$, so $u^{-1}(B_t) = \delta_t(u^{-1}(B_1))$ and $dv(B_t) = t^{d_0} dv(B_1)$ with $d_0 = 2\varrho k + 2\varrho^2$; and $dv(B_1) > 0$, as $u^{-1}(B_1)$ contains the nonempty open set $\{\|a\| < \frac{1}{2},\ \|\mathrm{sk}(b)\| < \frac{1}{2}\}$. (4) For $v = u(a, b) \in B_t$, $\|v\| \leq 1 + 2\|a\| + \|S(a, b)\| \leq (1 + t)^2$, since X, W, D are isometries. (5) If $v \in \mathsf{U}^0$, $T \geq 1$ and $\|v\| \leq T$, then $v \in B_T$: by Lemma 5.3.40 (i), $a = X^* v W$ and $S(a, b) = X^* v D$ have norms at most $\|v\| \leq T \leq T^2$.

The tube. Put $t_0 = r^2 L^2$, $\mathcal{Q} = B_{t_0}$, $Y_L = \{y \in G_1 : \|y\| \leq L\}$ (closed and bounded in the matrices, hence compact) and $\mathcal{K} = \mathcal{Q} Y_L$, the image of the compact set $\mathcal{Q} \times Y_L$ under multiplication, hence compact. $\mathcal{Q}$ is compact, so Borel, and $0 < dv(\mathcal{Q}) < \infty$ by (2), (3). For $v \in \mathcal{Q}$ and $y \in Y_L$, by (4), $\|vy\| \leq (1 + t_0)^2 L \leq L^{10}$, because $L \geq 8r \geq 8$ gives $1 + r^2 L^2 \leq 1 + L^4/64 \leq L^4$. By construction $vy \in \mathcal{K}$ for $v \in \mathcal{Q}$ and $\|y\| \leq L$.

Slices. Let $y \in G_1$ and $S_y = \{v \in \mathsf{U}^0 : vy \in \mathcal{K}\}$, a closed subset of U^0 ($\mathcal{K}$ is closed), hence dv-measurable. Suppose $S_y \neq \varnothing$ and fix $v_0 \in S_y$, $v_0 y = q_0 z_0$ with $q_0 \in \mathcal{Q}$, $z_0 \in Y_L$; put $g = q_0^{-1} v_0 \in \mathsf{U}^0$, so $gy = z_0$. Let $v \in S_y$, $vy = qz$ with $q \in \mathcal{Q}$, $z \in Y_L$. Then $q^{-1} v g^{-1} = (q^{-1}vy)(gy)^{-1} = z z_0^{-1} \in \mathsf{U}^0$ has norm at most $\|z\|\, \|z_0^{-1}\| = \|z\|\, \|z_0\| \leq L^2$ (Lemma 5.3.41 (iv)), so it lies in B_{L^2} by (5), and $v g^{-1} \in B_{t_0} B_{L^2} \subseteq B_{t_0 + L^2}$ by (1). Hence $S_y g^{-1} \subseteq B_{(1 + r^{-2})t_0}$, and by the right invariance of dv (Lemma 5.3.40 (ii)) and (3),

$$dv(S_y) = dv(S_y g^{-1}) \leq (1 + r^{-2})^{d_0}\, dv(\mathcal{Q}) \leq e^{d_0/r^2} dv(\mathcal{Q}) \leq 3\, dv(\mathcal{Q}),$$

because $d_0 = 2\varrho(k + \varrho) \leq (2\varrho + k)^2 \leq r^2$. □

Lemma 5.3.40. *(i)* sk *is an* $\mathbb{R}$*-linear bijection of* $\mathrm{M}_\varrho(\mathbb{R})$ *onto the skew-hermitian* $\varrho\times\varrho$ *matrices. For* $a,a'\in\mathrm{M}_{\varrho\times k}(\mathbb{C})$ *let* $\beta(a,a')\in\mathrm{M}_\varrho(\mathbb{R})$ *be given by* $\mathrm{sk}(\beta(a,a'))=\frac12(a'a^*-aa'^*)$. *Then* u *is injective,* $X^*u(a,b)W=a$, $X^*u(a,b)D=\mathrm{sk}(b)-\frac12aa^*$, *and*

$$u(a,b)\,u(a',b')=u(a+a',\,b+b'+\beta(a,a')),\qquad u(a,b)^{-1}=u(-a,-b).$$

(ii) For every Borel $f\colon\mathsf{U}^0\to[0,\infty]$ *and* $w\in\mathsf{U}^0$: $\int f(wv)\,dv=\int f(vw)\,dv=\int f(v^{-1})\,dv=\int f(v)\,dv$.

(iii) Let $h\in H$ *act on* X_0 *by the unitary matrix* h_0 *in the basis* $x_1,\dots,x_k$. *Then* $hu(a,b)h^{-1}=u(ah_0^*,b)$, *and* $\int f(hvh^{-1})\,dv=\int f(v)\,dv$ *for every Borel* $f\colon\mathsf{U}^0\to[0,\infty]$.

(iv) For every Borel $f\colon G_1\to[0,\infty]$,

$$\int_{G_1}f(s)\,ds=\int_H\int_{\mathsf{U}^0}f(vh)\,dv\,dh=\int_H\int_{\mathsf{U}^0}f(hv)\,dv\,dh=\int_{G_1}f(s^{-1})\,ds.$$

(v) There is a Borel $\chi\colon G_1\to[0,1]$ *with* $\int_{\mathsf{U}^0}\chi(vy)\,dv=1$ *for every* $y\in G_1$.

Proof. Throughout, X,W,D have orthonormal columns taken from one orthonormal basis, so $X^*X=1$, $W^*W=1$, $D^*D=1$ and $X^*W=X^*D=W^*D=0$. Write $S(a,b)=\mathrm{sk}(b)-\frac12aa^*$.

(i). $\mathrm{sk}(b)_{ll}=\mathrm{i}\,b_{ll}$; for $l<l'$ the map $(b_{ll'},b_{l'l})\mapsto\mathrm{sk}(b)_{ll'}=((b_{ll'}-b_{l'l})+\mathrm{i}(b_{ll'}+b_{l'l}))/\sqrt2$ is an $\mathbb{R}$-linear bijection $\mathbb{R}^2\to\mathbb{C}$, and $\mathrm{sk}(b)_{l'l}=-\overline{\mathrm{sk}(b)_{ll'}}$. A skew-hermitian matrix is the same as an arbitrary purely imaginary diagonal together with arbitrary entries above the diagonal, so sk is a bijection onto the skew-hermitian matrices; $\frac12(a'a^*-aa'^*)$ is skew-hermitian, so β is well defined and $\mathbb{R}$-bilinear. Multiplying out with the relations above, $X^*u(a,b)W=a$ and $X^*u(a,b)D=S(a,b)$; since $\mathrm{sk}(b)=S(a,b)+\frac12aa^*$, the pair (a,b) is determined by $u(a,b)$. Put $N=u(a,b)-1$ and $N'=u(a',b')-1$. Of the nine products of a term of N with a term of N' only $(XaW^*)(-Wa'^*D^*)=-Xaa'^*D^*$ survives (every other one contains W^*X, D^*X or D^*W). Hence

$$u(a,b)u(a',b')=1+X(a+a')W^*-W(a+a')^*D^*+X\big(S(a,b)+S(a',b')-aa'^*\big)D^*,$$

and $S(a,b)+S(a',b')-aa'^*=\mathrm{sk}(b+b')+\frac12(a'a^*-aa'^*)-\frac12(a+a')(a+a')^*=S(a+a',b+b'+\beta(a,a'))$. As $u(0,0)=1$ and $\beta(a,-a)=0$, $u(a,b)u(-a,-b)=1$.

(ii). Let $w=u(a_0,b_0)$. By (i), $wu(a,b)=u(\phi(a,b))$ with $\phi(a,b)=(a_0+a,\,b_0+b+\beta(a_0,a))$, an affine bijection of $\mathcal{P}$ whose linear part $(a,b)\mapsto(a,b+\beta(a_0,a))$ is block unitriangular, hence of determinant 1; so ϕ preserves Lebesgue measure and $\int f(wv)\,dv=\int f(u(\phi(a,b)))\,d(a,b)=\int f(u(a,b))\,d(a,b)=\int f\,dv$. The same argument with $(a,b)\mapsto(a+a_0,b+b_0+\beta(a,a_0))$ gives right invariance, and with $(a,b)\mapsto(-a,-b)$ inversion invariance.

(iii). In the basis, $h=1+W(h_0-1)W^*$ is unitary, $hX=X$, $hD=D$, $hW=Wh_0$, $W^*h^{-1}=h_0^*W^*$ and $D^*h^{-1}=D^*$. Hence $hu(a,b)h^{-1}=1+Xah_0^*W^*-Wh_0a^*D^*+XS(a,b)D^*=u(ah_0^*,b)$, because $(ah_0^*)^*=h_0a^*$ and $(ah_0^*)(ah_0^*)^*=aa^*$. Right multiplication by the unitary h_0^* is a Euclidean isometry of $\mathrm{M}_{\varrho\times k}(\mathbb{C})$, so $(a,b)\mapsto(ah_0^*,b)$ preserves Lebesgue measure, and $\int f(hvh^{-1})\,dv=\int f\,dv$.

(iv). The measure dv is σ-finite (u is continuous and injective, and $dv(u(C))$ is the Lebesgue measure of C for compact $C\subseteq\mathcal{P}$), so the first equality is the definition of ds with Tonelli's theorem. For fixed h, $hv=(hvh^{-1})h$ and (iii) give $\int f(hv)\,dv=\int f(vh)\,dv$. Finally $(vh)^{-1}=h^{-1}v^{-1}$, so by (ii) and the inversion invariance of the Haar measure dh of the compact group H,

$$\int f(s^{-1})\,ds=\int_H\int f(h^{-1}v^{-1})\,dv\,dh=\int_H\int f(h^{-1}v)\,dv\,dh=\int_H\int f(hv)\,dv\,dh.$$

(v). For $y \in G_1$ the $\varrho \times r$ matrix D^*y has rank ϱ, as y is invertible; let $(D^*y)^+ = (D^*y)^*\big(D^*y(D^*y)^*\big)^{-1}$, a right inverse depending continuously on y. Put

$$\begin{aligned}\alpha(y) &= -\big(W^*y(D^*y)^+\big)^*,\\ C(y) &= X^*y(D^*y)^+ + \tfrac{1}{2}\alpha(y)\alpha(y)^*,\\ \mathfrak{c}(y) &= \Big(\alpha(y),\ \mathrm{sk}^{-1}\big(\tfrac{1}{2}(C(y)-C(y)^*)\big)\Big) \in \mathcal{P},\end{aligned}$$

a continuous map $G_1 \to \mathcal{P}$. Let $v = u(a,b)$. Since $D^*v = D^*$, $W^*v = W^* - a^*D^*$ and $X^*v = X^* + aW^* + S(a,b)D^*$, we have $(D^*vy)^+ = (D^*y)^+$, $\alpha(vy) = \alpha(y) + a$, $X^*vy(D^*y)^+ = X^*y(D^*y)^+ - a\alpha(y)^* + S(a,b)$, and so

$$C(vy) = C(y) + \mathrm{sk}(b) + \tfrac{1}{2}\big(\alpha(y)a^* - a\alpha(y)^*\big) = C(y) + \mathrm{sk}\big(b + \beta(a,\alpha(y))\big).$$

The added matrix is skew-hermitian, so $\mathfrak{c}(u(a,b)y) = \big(\alpha(y)+a,\ \mathfrak{c}_2(y) + b + \beta(a,\alpha(y))\big)$, $\mathfrak{c}_2$ the second component. For fixed y this is an affine bijection of $\mathcal{P}$ with linear part $(a,b) \mapsto (a, b+\beta(a,\alpha(y)))$, which preserves Lebesgue measure. Let $E \subseteq \mathcal{P}$ be a cube of Lebesgue measure 1 and $\chi = \mathbf{1}_E \circ \mathfrak{c}$. Then χ is Borel and $\int_{U^0} \chi(vy)\,dv = \int_{\mathcal{P}} \mathbf{1}_E\big(\mathfrak{c}(u(a,b)y)\big)\,d(a,b) = 1$. □

Lemma 5.3.41. *(i) For $s \in R$ the $(\varrho+1)\times(\varrho+1)$ matrix F^*sF is upper unitriangular and $sF = F\,(F^*sF)$. For $s,t \in R$: $F^*stF = (F^*sF)(F^*tF)$ and $F^*s^{-1}F = (F^*sF)^{-1}$.*

(ii) For $s \in R$, $y \in G_1$ and $t \in G_1$ fixing $f_0,\dots,f_\varrho$: $Z(syt) = \big((F^*sF)^{-1}\big)^* Z(y)$.

(iii) For every upper unitriangular complex $(\varrho+1)\times(\varrho+1)$ matrix m and every complex $(\varrho+1)\times(\varrho+1)$ matrix Z: $\mathfrak{g}_1(m^*Z) = \mathfrak{g}_1(Z)$.

(iv) For $y \in G_1$: $y^{-1} = J_1y^*J_1$ and $\|y^{-1}\| = \|y\| \geq 1$. For $\gamma, y \in G_1$ and $0 \leq a,b \leq \varrho$: $|Z(\gamma)_{ab}| \leq \|y^{-1}f_a\|\,\|y^{-1}\gamma f_b\|$.

(v) If $s \in R$, $y \in G_1$ and $Z(y)$, $Z(sy)$ are invertible, then $F^*sF = \big(Z(y)Z(sy)^{-1}\big)^*$; in particular every entry of F^*sF has absolute value at most $\|Z(y)\|\,\|Z(sy)^{-1}\|$.

Proof. (i). By Lemma 5.5.30 (i), $sf_b - f_b \in \langle f_a : a < b\rangle$ for $s \in R$ and $0 \leq b \leq \varrho$. Hence $sF = FN$ for an upper unitriangular N, and $N = F^*FN = F^*sF$. For $s,t \in R$, $stF = s\,F(F^*tF) = F(F^*sF)(F^*tF)$; multiplying by F^* gives $F^*stF = (F^*sF)(F^*tF)$. Taking $t = s^{-1} \in R$ gives $(F^*sF)(F^*s^{-1}F) = F^*F = 1$.

(ii). As t fixes the frame, $tF = F$. From $s^*J_1s = J_1$ we get $J_1s = (s^{-1})^*J_1$. With (i) for s^{-1}, $s^{-1}F = F(F^*s^{-1}F)$, so

$$Z(syt) = F^*J_1syF = (s^{-1}F)^*J_1yF = (F^*s^{-1}F)^*F^*J_1yF = \big((F^*sF)^{-1}\big)^*Z(y).$$

(iii). The matrix m^* is lower unitriangular, so $\det(m^*Z) = \det Z$. For row and column indices $a,b < \varrho$, $(m^*Z)_{ab} = \sum_{c\leq a}(m^*)_{ac}Z_{cb}$ involves only indices $c < \varrho$; so the leading principal block of order ϱ of m^*Z is the product of the leading blocks of order ϱ of m^* (unitriangular, determinant 1) and of Z. Hence $D_\varrho(m^*Z) = D_\varrho(Z)$ and $\mathfrak{g}_1(m^*Z) = |\det Z|^2 - |D_\varrho(Z)|^2 = \mathfrak{g}_1(Z)$.

(iv). From $y^*J_1y = J_1$ and $J_1^2 = 1$, $(J_1y^*J_1)y = 1$, so $y^{-1} = J_1y^*J_1$. As J_1 is unitary, $\|y^{-1}\| = \|y^*\| = \|y\|$, and $1 = \|yy^{-1}\| \leq \|y\|^2$. Since $y^{-1} \in G_1$ preserves h, $Z(\gamma)_{ab} = h(f_a, \gamma f_b) = h(y^{-1}f_a, y^{-1}\gamma f_b)$, and $|h(v,w)| = |v^*J_1w| \leq \|v\|\,\|J_1w\| = \|v\|\,\|w\|$ by the Cauchy–Schwarz inequality.

(v). By (ii) with $t = 1$, $Z(sy) = \big((F^*sF)^{-1}\big)^*Z(y)$, so $Z(y)Z(sy)^{-1} = Z(y)Z(y)^{-1}(F^*sF)^* = (F^*sF)^*$. An entry of a matrix is bounded by its operator norm, and $\|Z(y)Z(sy)^{-1}\| \leq \|Z(y)\|\,\|Z(sy)^{-1}\|$. □

Lemma 5.3.42. *Let $w, \phi\colon G_1 \to [0,\infty]$ be Borel with $w(sy) = w(y)$ for all $s \in R$ and $y \in G_1$, and let $K \in [0,\infty]$ and $M \geq 1$. Suppose that $\int_{\mathsf{U}^0} \phi(vy)\,dv \leq K$ for every $y \in G_1$, and that every entry of $F^* sF$ has absolute value at most M whenever $s \in \mathsf{U}$ and $y \in G_1$ satisfy $\phi(y) \neq 0$ and $\phi(sy) \neq 0$. Then*

$$\int_{G_1} \phi\, w\, dy \leq K\,(2M)^{2n^2} \int_{\mathsf{U}\backslash G_1} w.$$

Proof. The inner integral. We show $\int_{\mathsf{U}} \phi(uy')\,du \leq K(2M)^{2n^2}$ for every $y' \in G_1$. If $\phi(uy') = 0$ for all $u \in \mathsf{U}$ there is nothing to prove. Otherwise fix $u_1 \in \mathsf{U}$ with $\phi(u_1 y') \neq 0$ and put $y'' = u_1 y'$. As du is right invariant (Lemma 5.2.34 (iv)), by the definition of du and Tonelli's theorem,

$$\int_{\mathsf{U}} \phi(uy')\,du = \int_{\mathsf{U}} \phi(uu_1 y')\,du = \int \int_{\mathsf{U}^0} \phi(v\,\mathrm{Ut}(x)\,y'')\,dv\,dx.$$

Let x and $v \in \mathsf{U}^0$ be such that $\phi(v\,\mathrm{Ut}(x)\,y'') \neq 0$. Then $s = v\,\mathrm{Ut}(x) \in \mathsf{U}$ and $\phi(y'') \neq 0 \neq \phi(sy'')$, so every entry of $F^* sF$ has absolute value at most M. By Lemma 5.3.41 (i), $F^* sF = (F^* vF)(F^* \mathrm{Ut}(x) F) = T(x)$, since v fixes the frame. Hence $|x_{ab}| \leq M$ for all $a < b$: the integrand vanishes unless x lies in the box $B_M = \{x : |x_{ab}| \leq M \text{ for all } a < b\}$. The inner integral over v is at most K, so

$$\int_{\mathsf{U}} \phi(uy')\,du \leq K\,\mathrm{vol}(B_M) = K\,(\pi M^2)^{n(n-1)/2} \leq K\,(4M^2)^{n^2} = K\,(2M)^{2n^2},$$

using $\pi M^2 \leq 4M^2$, $4M^2 \geq 1$ and $n(n-1)/2 \leq n^2$.

Unfolding. By Lemma 5.5.30 (vi), applied to ϕw, with its measure on R the image of $du \otimes dh$ under $(u,h) \mapsto uh$ (dh the Haar probability measure of H), and by the left R-invariance of w,

$$\int_{G_1} \phi w\, dy = \int_{\mathsf{U}\backslash G_1} \int_H \int_{\mathsf{U}} \phi(uhy)\, w(uhy)\,du\,dh\,dy = \int_{\mathsf{U}\backslash G_1} w(y) \int_H \int_{\mathsf{U}} \phi(u\,hy)\,du\,dh\,dy.$$

By the first part with $y' = hy$ the double inner integral is at most $K(2M)^{2n^2}$, as dh has mass 1. This gives the claim. □

Lemma 5.3.43. *Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be a unitary representation on $\mathbb{C}^I$, I finite, and $W\colon G_1 \to \mathbb{C}^I$ a continuous Bessel function of type ρ. Let $A \subseteq G_1$ be compact, (T,μ) a measure space, $S \subseteq T$ measurable with $0 < \mu(S) < \infty$ and $m = \mu(S)^{-1}\mu(\cdot \cap S)$; let $s \in R$, $g\colon T \to G_1$ measurable, $t\colon T \to R$ a map and $K \in [0,\infty)$. Suppose that*

$$\int_S \Big\| \int_{G_1} \beta(y)\, W(g(x)y)\,dy \Big\|^2 d\mu(x) \leq K \int_{G_1} |\beta|^2\,dy$$

for every Borel integrable $\beta\colon G_1 \to \mathbb{C}$ vanishing outside A. Then the kernels

$$(x,y) \mapsto W_i(sg(x)y)\,\overline{W_j(t(x)y)}, \qquad (i,j) \in I \times I,$$

are an L^2 contraction from $(G_1, dy|_A)$ to (T,m) with bound $\nu = \mu(S)^{-1} K\,\mathbf{1}_A \|W\|^2 dy$.

Proof. For $q \in R$ write $q = uh$ with $u \in \mathsf{U}$, $h \in H$ (Lemma 5.5.30 (i)) and $c(q) = \mathrm{wave}(\sigma(u))\rho(h)$, a unitary operator of $\mathbb{C}^I$ with $W(qy) = c(q)W(y)$ for all y. Let ϕ be bounded and Borel. As A is compact, $dy(A) < \infty$ (Lemma 5.5.17 (iii)), so $\psi = \mathbf{1}_A \phi$ is integrable, and so are $\beta_j = \psi\,\overline{W_j}$ (W is bounded); each β_j is Borel and vanishes outside A.

Removing the shifts. Fix $x \in T$ and write $g = g(x)$, $t = t(x)$. For fixed i, the vector $\bigl(\int \psi(y) W_i(sgy) \overline{W_j(ty)}\, dy\bigr)_j$ is the complex conjugate of

$$\int \overline{\psi(y) W_i(sgy)}\, W(ty)\, dy = c(t) \int \overline{\psi(y) W_i(sgy)}\, W(y)\, dy$$

(a linear map commutes with the integral); as $c(t)$ is unitary,

$$\sum_j \Bigl| \int \psi(y) W_i(sgy) \overline{W_j(ty)}\, dy \Bigr|^2 = \sum_j \Bigl| \int \beta_j(y) W_i(sgy)\, dy \Bigr|^2.$$

Summing over i and using $W(sgy) = c(s) W(gy)$ with $c(s)$ unitary,

$$\sum_{i,j} \Bigl| \int_A \phi(y) W_i(sgy) \overline{W_j(ty)}\, dy \Bigr|^2 = \sum_j \Bigl\| \int \beta_j(y) W(sgy)\, dy \Bigr\|^2 = \sum_j \Bigl\| \int \beta_j(y) W(g(x)y)\, dy \Bigr\|^2.$$

The right side is a measurable function of x: g is measurable and $g' \mapsto \int \beta_j(y) W(g'y)\, dy$ is continuous by dominated convergence (W is continuous and bounded).

Integrating. By the hypothesis applied to each β_j,

$$\begin{aligned} \int_T \sum_{i,j} \Bigl| \int_A \phi\, k_{ij}(x, \cdot)\, dy \Bigr|^2 dm(x) &= \mu(S)^{-1} \sum_j \int_S \Bigl\| \int \beta_j W(g(x)\,\cdot) \Bigr\|^2 d\mu \\ &\le \mu(S)^{-1} K \sum_j \int |\beta_j|^2 dy = \mu(S)^{-1} K \int_A |\phi|^2 \|W\|^2 dy, \end{aligned}$$

which is $\int |\phi|^2 d\nu$. □

Lemma 5.3.44. *Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be a unitary representation on $\mathbb{C}^I$, I finite, let $P \ge 8r$, $c > 0$ and $D \in [0, \infty)$, and let F be a Bessel function of type ρ with Schur's bound (P, D). Let Z be a complex $(\varrho+1) \times (\varrho+1)$ matrix such that every Y with $\|Y - Z\| < P^{-6}$ is bounded in the cell by P and satisfies $\mathsf{g}_1(Y) \ge c$. Let $\phi\colon G_1 \to \mathbb{C}$ be Borel and integrable with $\phi(y) = 0$ whenever $\|y\| > P^{20}$. Then, with $\mathcal{B}$ the fixer ball of radius P^{20},*

$$\int_{\mathcal{B}} \Bigl\| \int_{G_1} \phi(y)\, F\bigl(\gamma_Z(vh)^{-1} y\bigr)\, dy \Bigr\|^2 d\mu_c(h, v) \le P^{2000 n^2} D \int_{G_1} |\phi|^2\, dy.$$

Proof. Convolutions and their derivatives. Apply Lemma 5.3.45 to (V_w), ϕ and $M = P^{20}$: we obtain the alphabet L of quadruples of basis vectors, $\#L = r^4$, the weights ψ_i with $|\psi_i| \le |\phi|$, and the continuous functions $W_i(g) = \int \psi_i(y) V_{\pi(i)}(gy)\, dy$ with $\|W_i(sg)\| = \|W_i(g)\|$ for $s \in R$; $W_\varnothing(g) = \int \phi(y) F(gy)\, dy$. As $|\pi(i)| = |i|$ and $P \ge 1$, Schur's bound gives for $|i| \le 2n^2$

$$\int_{\mathsf{U} \setminus G_1} \|W_i\|^2 \le P^{2|i|} D \int |\psi_i|^2 \le P^{4n^2} D \int |\phi|^2 =: K_0. \tag{5.57}$$

Coordinates and the cube. Let $\mathcal{D} = \{0,1\} \times \{0, \dots, \varrho\}^2$, so $\#\mathcal{D} = 2n^2$, and for $x \in \mathbb{R}^{\mathcal{D}}$ let $E(x)$ be the matrix with entries $x_{0ab} + \mathrm{i}\, x_{1ab}$; the map $x \mapsto Z + E(x)$ carries Lebesgue measure to dY (Lebesgue measure of real and imaginary parts). Let $\varepsilon = P^{-8}$, $C = [0, \varepsilon]^{\mathcal{D}}$ and $Q = \{Y : \|Y - Z\| < P^{-6}\}$, an open set. For $x \in C$, $\|E(x)\| \le (\sum_j x_j^2)^{1/2} \le (2n^2)^{1/2} P^{-8} < P^{-6}$, as $2n^2 < P^4$ ($n \le r \le P/8$); so $Z + E(x) \in Q$. Let $\Omega = \mathrm{U}(k) \times \mathsf{U}^0$ with σ the restriction of μ_c to $\mathcal{B}$ (σ-finite), and

$$f_i(x, (h, v)) = W_i(\gamma_{Z + E(x)}(vh)^{-1}),$$

a Borel function of (x,h,v) (W_i is continuous and $Y\mapsto\gamma_Y$ is Borel, Lemma 5.3.47 (ii)). Then $f_\varnothing(0,(h,v))=\int\phi(y)F(\gamma_Z(vh)^{-1}y)\,dy$, so the left side of the claim is $\int_\Omega\|f_\varnothing(0,\omega)\|^2d\sigma(\omega)$.

The cube integrals. Let $|i|\le 2n^2$. Every $Y\in Q$ is bounded in the cell by P and has $\mathsf{g}_1(Y)\ge c$, and $\|W_i\|^2$ is Borel and left R-invariant. By the change of variables $Y=Z+E(x)$, Lemma 5.3.46 (with this $P\ge 1$, c, Q) and (5.57),

$$\int_C\int_\Omega\|f_i(x,\omega)\|^2d\sigma\,dx\le\int_Q\int_{\mathrm{U}(k)\times\mathsf{U}^0}\bigl\|W_i(\gamma_Y(vh)^{-1})\bigr\|^2d\mu_c(h,v)\,dY\le(2P^2)^{2n^2}K_0.$$

Partial derivatives. Let $\omega=(h,v)\in\mathcal{B}$ and $g_\omega=(vh)^{-1}$; as h is unitary and by Lemma 5.3.41 (iv), $\|g_\omega^{-1}\|=\|g_\omega\|=\|vh\|=\|v\|\le P^{20}$. Let i be a word, $d\in\mathcal{D}$, and x,t with $x[d\mapsto t]\in C$. The line $p(s)=Z+E(x[d\mapsto s])$ has $p'(s)=E_d$, the matrix with one entry 1 or i, so $\|E_d\|=1$; let J be the open interval of the s around t with $p(s)\in Q$ (Q is open and convex). For $s\in J$, $p(s)$ is bounded in the cell by $P\ge 4$, so by Lemma 5.3.56 (iv) $Y\mapsto\gamma_Y$ is real differentiable at $p(s)$ with derivative of norm at most P^{25}, and $\|\gamma_{p(s)}^{-1}\|=\|\gamma_{p(s)}\|\le P^{18}$ (Lemma 5.3.41 (iv)). Hence $\gamma(s)=\gamma_{p(s)}g_\omega$ is differentiable on J with $\gamma'(s)=\gamma(s)X(s)$, where

$$X(s)=g_\omega^{-1}\gamma_{p(s)}^{-1}(D\gamma_{p(s)}[E_d])g_\omega,\qquad\|X(s)\|\le P^{20}P^{18}P^{25}P^{20}=P^{83}.$$

By Lemma 5.3.45 (iii) with $M=P^{20}$ and $C=P^{83}$, $s\mapsto f_i(x[d\mapsto s],\omega)=W_i(\gamma(s))$ is differentiable at t with derivative of norm at most $P^{123}\sum_{l\in L}\|f_{li}(x[d\mapsto t],\omega)\|$.

Sobolev. By Lemma 5.3.55 with $\Lambda=P^{123}$, $\#L=r^4$, $\varepsilon=P^{-8}\le 1$ and $K=(2P^2)^{2n^2}K_0$,

$$\int_\Omega\|f_\varnothing(0,\omega)\|^2d\sigma\le\Bigl(2P^8\bigl(1+r^8P^{246}\bigr)\cdot 2P^2\Bigr)^{2n^2}K_0\le\bigl(P^{265}\bigr)^{2n^2}P^{4n^2}D\int|\phi|^2\le P^{2000n^2}D\int|\phi|^2,$$

which is the claim. □

Lemma 5.3.45. *Let $\rho\colon\mathrm{U}(k)\to\mathrm{U}(I)$ be a unitary representation on $\mathbb{C}^I$, I finite, and let (V_w) be Bessel functions of type ρ indexed by the words w in the alphabet of pairs (a,b) of basis vectors, such that $\frac{d}{dt}V_w(\gamma(t))=\sum_{a,b}X_{ab}V_{(a,b)w}(\gamma(t))$ whenever γ is a curve in G_1 with $\gamma'(t)=\gamma(t)X$. Let $M>0$ and let $\phi\colon G_1\to\mathbb{C}$ be Borel and integrable with $\phi(y)=0$ whenever $\|y\|>M$. Let L be the set of quadruples $l=(a,b,c,d)$ of basis vectors. For words i in L define $\psi_i\colon G_1\to\mathbb{C}$ and a word $\pi(i)$ in pairs by $\psi_\varnothing=\phi$, $\pi(\varnothing)=\varnothing$ and, for $l=(a,b,c,d)$,*

$$\psi_{li}(y)=\psi_i(y)\,\frac{(y^{-1})_{ad}\,y_{cb}}{M^2},\qquad\pi(li)=(a,b)\pi(i),$$

and put $W_i(g)=\int_{G_1}\psi_i(y)\,V_{\pi(i)}(gy)\,dy$ for $g\in G_1$. Then:

(i) $|\psi_i|\le|\phi|$ on G_1 for every word i;

(ii) every V_w is continuous; every W_i is continuous, and $\|W_i(sg)\|=\|W_i(g)\|$ for $s\in R$, $g\in G_1$;

(iii) if J is an open interval, $C\ge 0$ and $\gamma\colon J\to G_1$ is differentiable with $\gamma'(t)=\gamma(t)X(t)$ and $\|X(t)\|\le C$ for all $t\in J$, then for every $t_0\in J$ the function $t\mapsto W_i(\gamma(t))$ is differentiable at t_0, with derivative of norm at most $M^2C\sum_{l\in L}\|W_{li}(\gamma(t_0))\|$.

Proof. Let $B_w=\sup_{G_1}\|V_w\|<\infty$.

(i). If $\phi(y)=0$, then $\psi_i(y)=0$ for all i. If $\phi(y)\neq 0$, then $\|y\|\le M$, so $|y_{cb}|\le\|y\|\le M$ and $|(y^{-1})_{ad}|\le\|y^{-1}\|=\|y\|\le M$ (Lemma 5.3.41 (iv)); each letter multiplies by a factor of absolute value at most 1. Induction on $|i|$.

(ii). Let $\mathfrak{g}=\{Y : Y^*J_1+J_1Y=0\}$ be the Lie algebra of the closed subgroup G_1 of $\mathrm{GL}_r(\mathbb{C})$; $Y\mapsto\exp Y$ maps a neighbourhood of 0 in $\mathfrak{g}$ onto a neighbourhood of 1 in G_1. For $g\in G_1$ and $Y\in\mathfrak{g}$ the curve $t\mapsto g\exp(tY)$ lies in G_1 and has derivative $g\exp(tY)\,Y$, so by the derivative law $t\mapsto V_w(g\exp(tY))$ is differentiable with derivative of norm at most $\sum_{a,b}|Y_{ab}|B_{(a,b)w}\le r^2\|Y\|\max_{a,b}B_{(a,b)w}$. By the mean value inequality $\|V_w(g\exp Y)-V_w(g)\|\le r^2\|Y\|\max_{a,b}B_{(a,b)w}$, so V_w is continuous at g. As $|\psi_i(y)V_{\pi(i)}(gy)|\le|\phi(y)|B_{\pi(i)}$ with ϕ integrable, W_i is continuous by dominated convergence. Let $s\in R$; by Lemma 5.5.30 (i), $s=uh$ with $u\in\mathsf{U}$, $h\in H$, and $V_{\pi(i)}(sgy)=\mathrm{wave}(\sigma(u))\rho(h)V_{\pi(i)}(gy)$. A linear map commutes with the integral, so $W_i(sg)=\mathrm{wave}(\sigma(u))\rho(h)W_i(g)$, and $|\mathrm{wave}(\sigma(u))|=1$ and the unitarity of $\rho(h)$ give $\|W_i(sg)\|=\|W_i(g)\|$.

(iii). Fix i and put $w=\pi(i)$. For $y\in G_1$ the curve $t\mapsto\gamma(t)y$ in G_1 has derivative $\gamma(t)X(t)y=(\gamma(t)y)(y^{-1}X(t)y)$, so by the derivative law $t\mapsto V_w(\gamma(t)y)$ is differentiable on J with derivative $\sum_{a,b}(y^{-1}X(t)y)_{ab}V_{(a,b)w}(\gamma(t)y)$. As $(y^{-1}Xy)_{ab}=\sum_{c,d}(y^{-1})_{ad}X_{dc}y_{cb}$,

$$\frac{\partial}{\partial t}\bigl(\psi_i(y)V_w(\gamma(t)y)\bigr)=M^2\sum_{l=(a,b,c,d)\in L}X(t)_{dc}\,\psi_{li}(y)\,V_{\pi(li)}(\gamma(t)y).$$

By (i) and $|X(t)_{dc}|\le\|X(t)\|\le C$, its norm is at most $M^2C\,|\phi(y)|\sum_l B_{\pi(li)}$, an integrable function of y independent of t. By differentiation under the integral sign (the mean value inequality and dominated convergence, applied to each coordinate), $t\mapsto W_i(\gamma(t))$ is differentiable at t_0 with derivative $M^2\sum_l X(t_0)_{dc}W_{li}(\gamma(t_0))$, of norm at most $M^2C\sum_l\|W_{li}(\gamma(t_0))\|$. □

Lemma 5.3.46. *Let $P\ge1$ and $c>0$, and let Q be a Borel set of complex $(\varrho+1)\times(\varrho+1)$ matrices such that every $Z\in Q$ is bounded in the cell by P and satisfies $\mathsf{g}_1(Z)\ge c$. Let $w\colon G_1\to[0,\infty]$ be Borel with $w(sy)=w(y)$ for all $s\in R$ and $y\in G_1$. Then*

$$\int_Q\int_{\mathrm{U}(k)\times\mathsf{U}^0}w\bigl(\gamma_Z(vh)^{-1}\bigr)\,d\mu_c(h,v)\,dZ\le(2P^2)^{2n^2}\int_{\mathsf{U}\backslash G_1}w.$$

Proof. Let χ be the Borel function of Lemma 5.3.40 (v), with $\int_{\mathsf{U}^0}\chi(vy)\,dv=1$ for every y, and put $\chi_Q(y)=\chi(y)\mathbf{1}_Q(Z(y))$, a Borel function ($y\mapsto Z(y)$ is continuous). We compare both sides with $\int_{G_1}\chi_Q w\,dy$.

Unfolding. We apply Lemma 5.3.42 with $\phi=\chi_Q$, $K=1$ and $M=P^2\ge1$. First, $\int_{\mathsf{U}^0}\chi_Q(vy)\,dv\le\int_{\mathsf{U}^0}\chi(vy)\,dv=1$. Second, let $s\in\mathsf{U}$ and $y\in G_1$ with $\chi_Q(y)\neq0\neq\chi_Q(sy)$. Then $Z(y),Z(sy)\in Q$, so both are invertible with $\|Z(y)\|\le P$ and $\|Z(sy)^{-1}\|\le P$, and by Lemma 5.3.41 (v) every entry of F^*sF has absolute value at most P^2. Hence

$$\int_{G_1}\chi_Q\,w\,dy\le(2P^2)^{2n^2}\int_{\mathsf{U}\backslash G_1}w.\tag{5.58}$$

Along the fixer. Let $Z\in Q$; then $Z\in\Omega_{\mathrm{cell}}$, so $Z(\gamma_Z)=Z$ by Lemma 5.3.47 (ii). Let s and s' fix $f_0,\dots,f_\varrho$ and let $s'=vh$ with $v\in\mathsf{U}^0$, $h\in H$; then $s'\in R$ and $F^*s'F=1$, so $Z(s'\gamma_Zs)=Z(\gamma_Z)=Z$ by Lemma 5.3.41 (ii). Hence $\chi_Q(s'\gamma_Zs)=\chi(s'\gamma_Zs)$ and, by the R-invariance of w, $w(s'\gamma_Zs)=w(\gamma_Zs)$. With Lemma 5.3.40 (iv) and (v),

$$\int_{G_1}(\chi_Qw)(s'\gamma_Zs)\,ds'=w(\gamma_Zs)\int_H\int_{\mathsf{U}^0}\chi(v\,h\gamma_Zs)\,dv\,dh=w(\gamma_Zs).$$

By Tonelli's theorem and the inversion invariance of ds (Lemma 5.3.40 (iv)),

$$\int_{G_1}\int_{G_1}(\chi_Q w)(s'\gamma_Z s)\,ds\,ds' = \int_{G_1} w(\gamma_Z s)\,ds = \int_{G_1} w(\gamma_Z s^{-1})\,ds = \int_H\int_{\mathsf{U}^0} w(\gamma_Z(vh)^{-1})\,dv\,dh.$$

Mean value. By Lemma 5.3.48 for $f=\chi_Q w$, restricting the outer integral to $Q\subseteq\Omega_{\mathrm{cell}}$ and using $c_G\,\mathfrak{g}_1(Z)^{k-1}\ge c_G\,c^{k-1}$ on Q ($k\ge 1$),

$$\int_Q c_G\,c^{k-1}\int_H\int_{\mathsf{U}^0} w(\gamma_Z(vh)^{-1})\,dv\,dh\,dZ \le \int_{G_1}\chi_Q\,w\,dy.$$

The left side is the left side of the claim (definition of μ_c; the integrand is Borel in (Z,h,v) as $Z\mapsto\gamma_Z$ is Borel, Lemma 5.3.47 (ii)). Together with (5.58) this proves the claim. □

Lemma 5.3.47. *(i) For a complex $(\varrho+1)\times(\varrho+1)$ matrix Z: $Z\in\Omega_{\mathrm{cell}}$ if and only if $\mathfrak{g}_1(Z)>0$.*

(ii) For every Z, $\gamma_Z\in G_1$; for $Z\in\Omega_{\mathrm{cell}}$, $Z(\gamma_Z)=Z$; and $Z\mapsto\gamma_Z$ is Borel measurable, and continuous on the open set Ω_{cell}.

(iii) If $Z\in\Omega_{\mathrm{cell}}$ and $\gamma\in G_1$ with $Z(\gamma)=Z$, then $\gamma=g^{-1}\gamma_Z g'$ for some $g,g'\in G_1$ fixing $f_0,\dots,f_\varrho$.

Proof. Write $h(x,y)=x^*J_1y$, so that $Z(y)=F^*J_1yF$, and $n=\varrho+1$; ε_ϱ is the last unit vector of $\mathbb{C}^n$ and $E_{\varrho\varrho}=\varepsilon_\varrho\varepsilon_\varrho^{\mathsf{T}}$. The columns of F and F' are $2n$ distinct standard basis vectors, so $F^*F=F'^*F'=1$ and $F^*F'=0$, and from the Gram matrix J_1,

$$F^*J_1F=-E_{\varrho\varrho},\qquad F^*J_1F'=1-E_{\varrho\varrho},\qquad F'^*J_1F'=E_{\varrho\varrho} \tag{5.59}$$

(e_a pairs with e_a^*, z with nothing in F', $h(z,z)=-1$, $h(x_{k_0},x_{k_0})=1$, the e_a^* are isotropic and orthogonal to x_{k_0}).

(i) If $\det Z=0$, then $\mathfrak{g}_1(Z)=-|D_\varrho(Z)|^2\le 0$ and $Z\notin\Omega_{\mathrm{cell}}$. If $\det Z\ne 0$, then $\mathrm{ic}(Z)=D_\varrho(Z)/\det Z$ (cofactor formula), so $\mathfrak{g}_1(Z)=|\det Z|^2(1-|\mathrm{ic}(Z)|^2)$, positive if and only if $|\mathrm{ic}(Z)|<1$.

Dual families. For $W\in\Omega_{\mathrm{cell}}$ let $\zeta=\varepsilon_\varrho^{\mathsf{T}}W^{-1}$ be the last row of W^{-1} and $F^\vee(W)=F\,\mathrm{Co}(W)+F'\,\mathrm{dg}(W)$. We claim

$$F^*J_1F^\vee(W)=1,\qquad F^\vee(W)^*J_1F^\vee(W)=-\zeta^*\zeta. \tag{5.60}$$

By (5.59), $F^*J_1F^\vee(W)=-E_{\varrho\varrho}\mathrm{Co}(W)+(1-E_{\varrho\varrho})\mathrm{dg}(W)$; the first term has only the last row, $-\mathrm{Co}(W)_{\varrho\cdot}=\varepsilon_\varrho^{\mathsf{T}}$, and the second is $1-E_{\varrho\varrho}$; the sum is 1. Next, with $C=\mathrm{Co}(W)$, $D=\mathrm{dg}(W)$ and (5.59),

$$F^\vee(W)^*J_1F^\vee(W)=-C^*E_{\varrho\varrho}C+C^*(1-E_{\varrho\varrho})D+D(1-E_{\varrho\varrho})C+DE_{\varrho\varrho}D.$$

As the last row of C is $-\varepsilon_\varrho^{\mathsf{T}}$, $C^*E_{\varrho\varrho}C=E_{\varrho\varrho}$; $DE_{\varrho\varrho}D=\eta(W)^2E_{\varrho\varrho}$; and $(1-E_{\varrho\varrho})D=1-E_{\varrho\varrho}$. So the entry (b,c) is $[c<\varrho]\,\overline{C_{cb}}+[b<\varrho]\,C_{bc}+\delta_{b\varrho}\delta_{c\varrho}(\eta(W)^2-1)$. With $C_{ab}=-c_b\,\overline{\zeta_a}\,\zeta_b$ ($a<\varrho$), $c_b=\frac12$ ($b<\varrho$), $c_\varrho=1$ and $\eta(W)^2-1=-|\zeta_\varrho|^2$: for $b,c<\varrho$ the entry is $-\frac12\overline{\zeta_b}\zeta_c-\frac12\overline{\zeta_b}\zeta_c$; for $b<\varrho=c$ it is $-\overline{\zeta_b}\zeta_\varrho$; for $c<\varrho=b$ it is $-\overline{\zeta_c}\zeta_\varrho=-\overline{\zeta_\varrho}\zeta_c$; for $b=c=\varrho$ it is $-|\zeta_\varrho|^2$. In all cases it is $-\overline{\zeta_b}\zeta_c=(-\zeta^*\zeta)_{bc}$.

For $Z\in\Omega_{\mathrm{cell}}$ also $Z^*\in\Omega_{\mathrm{cell}}$, with $\mathrm{ic}(Z^*)=\overline{\mathrm{ic}(Z)}$, so $\eta(Z^*)=\eta(Z)$, and comparing entries $(((Z^*)^{-1})_{\varrho a}=\overline{(Z^{-1})_{a\varrho}})$, $\mathrm{Co}(Z^*)=\mathrm{Co}'(Z)$; hence $F^\vee(Z^*)=F\,\mathrm{Co}'(Z)+F'\,\mathrm{dg}(Z)$.

(ii) For $Z \notin \Omega_{\mathrm{cell}}$, $\gamma_Z = 1 \in G_1$. Let $Z \in \Omega_{\mathrm{cell}}$, $S = F^\vee(Z)Z$ and $M = \gamma_Z$, so $M = 1 + (S - F)F^* + \big((F(Z^*)^{-1} - S\,\mathrm{Co}'(Z))\mathrm{dg}(Z)^{-1} - F'\big)F'^*$. By the orthonormality relations, $MF = S$, $MF' = (F(Z^*)^{-1} - S\,\mathrm{Co}'(Z))\mathrm{dg}(Z)^{-1}$, hence

$$MF^\vee(Z^*) = S\,\mathrm{Co}'(Z) + MF'\,\mathrm{dg}(Z) = F(Z^*)^{-1},$$

and $Mx_i = x_i$ for $i \neq k_0$. Let U be the span of the columns of F and F' (that is, of e_a, e_a^*, z, x_{k_0}) and U' the span of the x_i, $i \neq k_0$; $V_1 = U \oplus U'$, orthogonally for h, and h is nondegenerate on U. The columns of $X = (F \mid F^\vee(Z^*)) = (F \mid F')\left(\begin{smallmatrix} 1 & \mathrm{Co}'(Z) \\ 0 & \mathrm{dg}(Z) \end{smallmatrix}\right)$ form a basis of U, as $\mathrm{dg}(Z)$ is invertible ($\eta(Z) > 0$). M maps them to the columns of $Y = (S \mid F(Z^*)^{-1})$, which lie in U. By (5.59) and (5.60) (for $W = Z$ and $W = Z^*$, with $\zeta' = \varepsilon_\varrho^{\mathsf{T}}(Z^*)^{-1}$, so $\zeta'^* = Z^{-1}\varepsilon_\varrho$), the two Gram matrices agree blockwise:

$$S^*J_1S = Z^*(-\zeta^*\zeta)Z = -(\zeta Z)^*(\zeta Z) = -E_{\varrho\varrho} = F^*J_1F,$$
$$S^*J_1F(Z^*)^{-1} = Z^*\big(F^\vee(Z)^*J_1F\big)(Z^*)^{-1} = 1 = F^*J_1F^\vee(Z^*),$$

$$\big(F(Z^*)^{-1}\big)^*J_1F(Z^*)^{-1} = -Z^{-1}E_{\varrho\varrho}(Z^{-1})^* = -\zeta'^*\zeta' = F^\vee(Z^*)^*J_1F^\vee(Z^*),$$

using $\zeta Z = \varepsilon_\varrho^{\mathsf{T}}$ and taking adjoints for the remaining block. Since the Gram matrix of X is invertible, so is that of Y, so the columns of Y are a basis of U; thus M maps U isometrically onto U and is the identity on $U' \perp U$, so $M^*J_1M = J_1$ and $\gamma_Z \in G_1$. Moreover $Z(\gamma_Z) = F^*J_1MF = F^*J_1F^\vee(Z)\,Z = Z$ by (5.60). Finally $\Omega_{\mathrm{cell}} = \{\mathsf{g}_1 > 0\}$ is open by (i), and on it the entries of γ_Z are polynomials in the entries of Z, Z^{-1}, their conjugates and $\eta(Z)^{\pm1} = (1 - |\mathrm{ic}(Z)|^2)^{\pm1/2}$, continuous functions; off it $\gamma_Z = 1$. So $Z \mapsto \gamma_Z$ is continuous on Ω_{cell}, constant on its closed complement, and Borel measurable.

(iii) For $s \in G_1$ with $Z(s) = Z$, the family $(F \mid sF)$ of $2n$ vectors has the Gram matrix

$$\Gamma = \begin{pmatrix} -E_{\varrho\varrho} & Z \\ Z^* & -E_{\varrho\varrho} \end{pmatrix},$$

as s is an isometry. Exchanging the two block columns and taking the Schur complement of the invertible block Z, $|\det\Gamma| = |\det Z|\,|\det(Z^* - E_{\varrho\varrho}Z^{-1}E_{\varrho\varrho})| = |\det Z|\,|\det(Z^* - \mathrm{ic}(Z)E_{\varrho\varrho})|$, and $\det(Z^* - \mathrm{ic}(Z)E_{\varrho\varrho}) = \det Z^*\,(1 - \mathrm{ic}(Z)((Z^*)^{-1})_{\varrho\varrho}) = \overline{\det Z}\,(1 - |\mathrm{ic}(Z)|^2)$; so $|\det\Gamma| = \mathsf{g}_1(Z) > 0$ and the $2n$ vectors are linearly independent. Apply this to $s = \gamma$ and to $s = \gamma_Z$ (by (ii)): the linear map sending $(F \mid \gamma F)$ to $(F \mid \gamma_Z F)$ is an isometry between the subspaces they span, and by Witt's theorem it extends to some $g \in G_1$. Then $gF = F$ and $g\gamma F = \gamma_Z F$, so $g' = \gamma_Z^{-1}g\gamma \in G_1$ fixes $f_0, \dots, f_\varrho$, and $\gamma = g^{-1}\gamma_Z g'$. □

Lemma 5.3.48. *For every Borel function $f\colon G_1 \to [0,\infty]$,*

$$\int_{\Omega_{\mathrm{cell}}} c_G\,\mathsf{g}_1(Z)^{k-1} \int_{G_1}\int_{G_1} f(s'\gamma_Z s)\,ds\,ds'\,dZ \le \int_{G_1} f(y)\,dy.$$

Proof. Let $w(Z) = \mathbf{1}_{\Omega_{\mathrm{cell}}}(Z)\,\mathrm{vol}(S^{2k-1})\,2^{-(\varrho+1)}\,\mathsf{g}_1(Z)^{k-1}$ and let λ be the image of $w(Z)\,dZ \otimes ds$ under $(Z, s') \mapsto s'\gamma_Z$; the map is Borel, as $Z \mapsto \gamma_Z$ is Borel (Lemma 5.3.47 (ii)) and multiplication is continuous. By Lemma 5.3.50, λ is s-finite and below the Gram fibre at the frame, so by Lemma 5.3.53, with $c = \mathrm{vol}\,\mathrm{U}(r)/(\mathrm{vol}\,\mathrm{U}(k)\,2^{\varrho+1})$,

$$(\lambda * ds)(B) \le c\int_{G_1} \mathbf{1}_B\,dy \qquad \text{for every Borel } B \subseteq G_1.$$

Approximating f from below by an increasing sequence of nonnegative simple Borel functions and using monotone convergence on both sides, $\int f\,d(\lambda * ds) \le c\int f\,dy$. By the definition of the convolution as an image measure and by Tonelli's theorem (all measures s-finite, the integrand Borel and nonnegative),

$$\int_{G_1} f\,d(\lambda * ds) = \int_{G_1}\int_{G_1} f(gs)\,ds\,d\lambda(g) = \int w(Z)\int_{G_1}\int_{G_1} f(s'\gamma_Z s)\,ds\,ds'\,dZ.$$

Since $w(Z)/c = \mathbf{1}_{\Omega_{\mathrm{cell}}}(Z)\operatorname{vol}\mathrm{U}(k)\operatorname{vol}(S^{2k-1})\,\mathtt{g}_1(Z)^{k-1}/\operatorname{vol}\mathrm{U}(r) = \mathbf{1}_{\Omega_{\mathrm{cell}}}(Z)\,c_G\,\mathtt{g}_1(Z)^{k-1}$, dividing by $c>0$ gives the claim. □

Definition 5.3.49. Measures are positive and may take the value ∞; in $[0,\infty]$ we put $0\cdot\infty = \infty\cdot 0 = 0$. A topological space carries its Borel σ-algebra, and a Borel measure on it is a measure on this σ-algebra. The symbols X, B, π, β, μ, ν, λ, K, C, S, m, E are local to this definition.

(BY1) Below a fibre measure. Let X and B be topological spaces, μ a Borel measure on X, ν a Borel measure on B, $\pi\colon X\to B$ a Borel measurable map and $\beta\in B$. A Borel measure λ on X is **below the fibre measure** $d\mu/d\nu$ **of** π **over** β if for every lower semicontinuous function $K\colon X\to[0,\infty]$ and every $C\in[0,\infty]$ the following holds: if β has a neighbourhood in B such that

$$\int_{\pi^{-1}(S)} K\,d\mu \le C\,\nu(S) \qquad \text{for every open set } S \text{ of } B \text{ contained in this neighbourhood,}$$

then

$$\int_X K\,d\lambda \le C.$$

(BY2) Below the Gram fibre. Let $N\ge 1$, let $J\in\mathrm{M}_N(\mathbb{C})$ be a hermitian involution and let $m\ge 0$ be an integer. Let Herm_m be the real vector space of hermitian $m\times m$ matrices. The **Gram map** of J is

$$\Gamma_J\colon \mathrm{M}_{N\times m}(\mathbb{C})\to\mathrm{Herm}_m, \qquad \Gamma_J(Y) = Y^*JY.$$

The space $\mathrm{M}_{N\times m}(\mathbb{C})$ carries the measure dY, the Lebesgue measure of the real and imaginary parts of the entries Y_{ab}, and Herm_m carries the measure dT, the Lebesgue measure of the diagonal entries T_{aa} and of the real and imaginary parts of the entries T_{ab} with $a<b$; for $m=0$ both spaces are one point and both measures are the unit point mass. The group $\mathrm{U}(J)$ carries the topology induced from $\mathrm{M}_N(\mathbb{C})$. Let $E\in\mathrm{M}_{N\times m}(\mathbb{C})$. A Borel measure λ on $\mathrm{U}(J)$ is **below the Gram fibre at** E if the image of λ under the map $\mathrm{U}(J)\to\mathrm{M}_{N\times m}(\mathbb{C})$, $g\mapsto gE$, is below the fibre measure dY/dT of Γ_J over $\Gamma_J(E)$ in the sense of (BY1).

Lemma 5.3.50. *Let $F\in\mathrm{M}_{r\times(\varrho+1)}(\mathbb{C})$ be the matrix whose columns are the coordinate vectors of $f_0,\dots,f_\varrho$, let dZ be the Lebesgue measure of the real and imaginary parts of the entries of complex $(\varrho+1)\times(\varrho+1)$ matrices, and let λ be the image of the measure*

$$\mathbf{1}_{\Omega_{\mathrm{cell}}}(Z)\,\frac{2\pi^k}{(k-1)!\,2^{\varrho+1}}\,\mathtt{g}_1(Z)^{k-1}\,dZ\otimes ds$$

under $(Z,s)\mapsto s\gamma_Z$. Then λ is an s-finite Borel measure on G_1 that is below the Gram fibre at F (for $J=J_1$).

Proof. Put $n = \varrho + 1$ and $T_0 = \Gamma_{J_1}(F) = F^* J_1 F = -E_{\varrho\varrho}$ by (5.59). For invertible Z let ζ be the last row of Z^{-1}, so $\mathrm{ic}(Z) = \zeta_\varrho$. All spaces are finite-dimensional real vector spaces or closed subsets of them, hence separable and metrizable.

Step 1: three changes of variables. (a) For $Z \in \mathrm{GL}_n(\mathbb{C})$, the map $p \mapsto pZ$ of $\mathrm{M}_{(\varrho+k)\times n}(\mathbb{C})$ multiplies each of the $\varrho + k$ rows on the right by Z, a complex-linear map of $\mathbb{C}^n$ of real determinant $|\det Z|^2$; so its real determinant is $|\det Z|^{2(\varrho+k)}$. (b) For $A \in \mathrm{GL}_n(\mathbb{C})$ let $c_A(T) = A^* T A$ on Herm_n. Since $c_{AB} = c_B \circ c_A$, $A \mapsto |\det c_A|$ is a homomorphism $\mathrm{GL}_n(\mathbb{C}) \to \mathbb{R}_{>0}$, trivial on $\mathrm{SL}_n(\mathbb{C})$, which is its own commutator subgroup. Writing $A = A' \operatorname{diag}(d, 1, \dots, 1)$ with $A' \in \mathrm{SL}_n(\mathbb{C})$ and $d = \det A$: for $\operatorname{diag}(d, 1, \dots, 1)$, $T_{00} \mapsto |d|^2 T_{00}$, $T_{0b} \mapsto \bar{d} T_{0b}$ ($b > 0$, real determinant $|d|^2$ each), the other coordinates are fixed; so $|\det c_A| = |\det A|^{2n}$ for the coordinates of dT. (c) The columns of $J_1 F$ are $e_1^*, \dots, e_\varrho^*, -z$. So the map $\Theta(Z, p) = J_1 F Z + Rp$, $\mathrm{M}_n(\mathbb{C}) \times \mathrm{M}_{(\varrho+k)\times n}(\mathbb{C}) \to \mathrm{M}_{r\times n}(\mathbb{C})$, puts the rows $0, \dots, \varrho - 1$ of Z into the rows of $e_1^*, \dots, e_\varrho^*$, minus row ϱ of Z into the row of z, and the rows of p into the rows of $e_1, \dots, e_\varrho, x_1, \dots, x_k$. These row sets partition the r rows. So Θ permutes the real coordinates up to sign and preserves Lebesgue measure.

Step 2: tuples with given products with the frame. Let $Z \in \Omega_{\mathrm{cell}}$, $K \colon \mathrm{M}_{r\times n}(\mathbb{C}) \to [0, \infty]$ Borel, and $T' = (Z^{-1})^* T Z^{-1}$ for $T \in \mathrm{Herm}_n$. We claim

$$\int K(J_1 F Z + Rp)\, dp = \frac{\pi^k |\det Z|^{2(k-1)}}{2^\varrho (k-1)!} \int_{\mathrm{Herm}_n} \mathbf{1}_{\{T'_{\varrho\varrho} > -1\}} (1 + T'_{\varrho\varrho})^{k-1} \int_{G_1} K\big(sY^\vee(T')Z\big)\, ds\, dT. \tag{5.61}$$

By (a), substituting $p = p'Z$, the left side is $|\det Z|^{2(\varrho+k)} \int K\big((J_1 F + Rp')Z\big)\, dp'$. By Lemma 5.3.51 (ii), applied to $Y \mapsto K(YZ)$, this is $|\det Z|^{2(\varrho+k)} \int G(T')\, dT'$ with $G(T') = \frac{\pi^k}{2^\varrho (k-1)!} \mathbf{1}_{\{T'_{\varrho\varrho} > -1\}} (1 + T'_{\varrho\varrho})^{k-1} \int K(sY^\vee(T')Z)\, ds$. By (b) for $A = Z^{-1}$, $\int G(T')\, dT' = |\det Z|^{-2n} \int G\big((Z^{-1})^* T Z^{-1}\big)\, dT$, and $2(\varrho + k) - 2n = 2(k-1)$.

Step 3: a parametrisation of the fibres. Apply Lemma 5.5.13 (i) to $\pi = \Gamma_{J_1}$ on the space $\mathrm{M}_{r\times n}(\mathbb{C})$ (in the role of the space X there) with $\mu = dY$, $B = V = \mathrm{Herm}_n$ with $\nu = dT$, $\beta = T_0$, and $P = \mathrm{M}_n(\mathbb{C}) \times G_1$ with $\mu_P = \mathbf{1}_{\Omega_{\mathrm{cell}}}(Z)\, dZ \otimes ds$, an s-finite Borel measure. For $(T, (Z, s)) \in B \times P$ let $T' = (Z^{-1})^* T Z^{-1}$ if $\det Z \neq 0$ and $T' = 0$ otherwise, and

$$\psi(T, (Z, s)) = sY^\vee(T')Z, \qquad w(T, (Z, s)) = \mathbf{1}_{\Omega_{\mathrm{cell}}}(Z)\, \frac{\pi^k |\det Z|^{2(k-1)}}{2^\varrho (k-1)!}\, \mathbf{1}_{\{T'_{\varrho\varrho} > -1\}} (1 + T'_{\varrho\varrho})^{k-1};$$

both are Borel (Ω_{cell} is open by Lemma 5.3.47 (i), inversion is continuous on $\mathrm{GL}_n(\mathbb{C})$, and $Y^\vee$ is continuous). The hypotheses of (i): dT is positive on nonempty open sets and finite on bounded ones. If $w(T, (Z, s)) \neq 0$, then $Z \in \Omega_{\mathrm{cell}}$ and $T'_{\varrho\varrho} > -1$, so by Lemma 5.3.51 (i) and since s preserves J_1, $\Gamma_{J_1}(\psi(T, (Z, s))) = Z^* \Gamma_{J_1}(Y^\vee(T'))Z = Z^* T' Z = T$. For $Z \in \Omega_{\mathrm{cell}}$ (so for μ_P-almost every point), $T \mapsto \psi(T, (Z, s))$ is continuous, and at $T = T_0$ one has $T' = -(Z^{-1})^* E_{\varrho\varrho} Z^{-1} = -\zeta^* \zeta$, so $T'_{\varrho\varrho} = -|\mathrm{ic}(Z)|^2 > -1$; the indicator is then 1 near T_0 and $T \mapsto w(T, (Z, s))$ is continuous at T_0. Finally, for Borel $K \geq 0$, by Tonelli's theorem, (5.61) and Step 1 (c),

$$\int_V \int_P w\, K(\psi)\, d\mu_P\, dT = \int_{\Omega_{\mathrm{cell}}} \int K(J_1 F Z + Rp)\, dp\, dZ \leq \int K(\Theta(Z, p))\, d(Z, p) = \int K\, dY.$$

Hence the image of $w(T_0, \cdot)\, \mu_P$ under $\psi(T_0, \cdot)$ is below the fibre measure dY/dT of Γ_{J_1} over $T_0 = \Gamma_{J_1}(F)$.

Step 4: the point and the density at T_0. Let $Z \in \Omega_{\mathrm{cell}}$. Then $\eta(Z)^2 = 1 - |\zeta_\varrho|^2 = 1 + T'_{\varrho\varrho}$ at $T = T_0$, and $\mathsf{g}_1(Z) = |\det Z|^2 (1 - |\mathrm{ic}(Z)|^2)$ (proof of Lemma 5.3.47 (i)); so

$$w(T_0, (Z, s)) = \frac{\pi^k}{2^\varrho (k-1)!} \big(|\det Z|^2 \eta(Z)^2\big)^{k-1} = \frac{2\pi^k}{(k-1)!\, 2^{\varrho+1}}\, \mathsf{g}_1(Z)^{k-1},$$

the density in the statement. Next, $Y^\vee(-\zeta^*\zeta) = F^\vee(Z)$: for $b < \varrho$, column b of $F\,\mathrm{Co}(Z) + F'\,\mathrm{dg}(Z)$ is $e^*_{b+1} + \sum_{a<\varrho}\mathrm{Co}(Z)_{ab}e_{a+1}$ with $\mathrm{Co}(Z)_{ab} = -\frac12\overline{\zeta_a}\zeta_b = \frac12(-\zeta^*\zeta)_{ab}$, and column ϱ is $-z + \sum_{a<\varrho}(-\overline{\zeta_a}\zeta_\varrho)e_{a+1} + \eta(Z)x_{k_0}$, with $\eta(Z) = \max(0, 1-|\zeta_\varrho|^2)^{1/2}$; these are the columns of $Y^\vee(-\zeta^*\zeta)$. Since the columns of F and F' are distinct standard basis vectors, $F^*F = 1$ and $F'^*F = 0$, and the formula for γ_Z gives $\gamma_Z F = F + (F^\vee(Z)Z - F) = F^\vee(Z)Z$. Hence $\psi(T_0,(Z,s)) = sF^\vee(Z)Z = s\gamma_Z F$ for $Z \in \Omega_{\mathrm{cell}}$.

Conclusion. The map $(Z,s)\mapsto s\gamma_Z$ is Borel by Lemma 5.3.47 (ii) and the continuity of multiplication, and λ is its image of $w(T_0,\cdot)\,\mu_P$ by Step 4; a measure with a Borel density with respect to an s-finite measure is s-finite, and so is its image, so λ is an s-finite Borel measure on G_1. The image of λ under $g\mapsto gF$ is the image of $w(T_0,\cdot)\,\mu_P$ under $(Z,s)\mapsto s\gamma_Z F$, which agrees μ_P-almost everywhere with $\psi(T_0,\cdot)$ (Step 4), so it is the measure of Step 3, below the fibre measure dY/dT of Γ_{J_1} over $\Gamma_{J_1}(F)$. By (BY2), λ is below the Gram fibre at F. □

Lemma 5.3.51. *Index the rows and columns of matrices in* $\mathrm{Herm}_{\varrho+1}$ *by* $0,\dots,\varrho$. *For* $T\in\mathrm{Herm}_{\varrho+1}$ *let* $Y^\vee(T)\in\mathrm{M}_{r\times(\varrho+1)}(\mathbb{C})$ *be the matrix whose columns are the coordinate vectors of*

$$e^*_{b+1} + \tfrac12\sum_{a<\varrho}T_{ab}\,e_{a+1}\quad(0\le b<\varrho),\qquad -z+\sum_{a<\varrho}T_{a\varrho}\,e_{a+1} + \max(0,1+T_{\varrho\varrho})^{1/2}\,x_{k_0}.$$

(i) $F^*J_1Y^\vee(T) = 1$, *and* $\Gamma_{J_1}(Y^\vee(T)) = T$ *if* $T_{\varrho\varrho}\ge -1$.

(ii) Give $\mathrm{M}_{(\varrho+k)\times(\varrho+1)}(\mathbb{C})$ *the Lebesgue measure* dp *of the real and imaginary parts of its entries. For every Borel function* $K\colon \mathrm{M}_{r\times(\varrho+1)}(\mathbb{C})\to[0,\infty]$,

$$\int K(J_1F+Rp)\,dp = \frac{\pi^k}{2^\varrho(k-1)!}\int_{\mathrm{Herm}_{\varrho+1}}\mathbf{1}_{\{T_{\varrho\varrho}>-1\}}\,(1+T_{\varrho\varrho})^{k-1}\int_{G_1}K\big(sY^\vee(T)\big)\,ds\,dT.$$

Proof. Write $T_1\in\mathrm{Herm}_\varrho$ for the upper left block of T, $c=(T_{a\varrho})_{a<\varrho}\in\mathbb{C}^\varrho$ and $\eta=\max(0,1+T_{\varrho\varrho})^{1/2}$. Then

$$Y^\vee(T) = \big(D + \tfrac12 XT_1 \;\big|\; -z + Xc + \eta\,x_{k_0}\big), \tag{5.62}$$

the first block having ϱ columns.

(i) For $a<\varrho$, $h(e_{a+1},y)$ is the coefficient of e^*_{a+1} in y, and $h(z,y)$ is minus the coefficient of z. So $h(f_a, Y^\vee(T)_b) = \delta_{ab}$ for all a,b, that is $F^*J_1Y^\vee(T) = 1$. The Gram matrix of the first ϱ columns is T_1 by Lemma 5.3.52 (i) (with $v=1$). The e_a are isotropic and orthogonal to z and X_0, $z\perp X_0$, and $h(e^*_{b+1},e_{a+1}) = \delta_{ab}$, $h(e^*_{b+1},z) = h(e^*_{b+1},x_{k_0}) = 0$; hence for $b<\varrho$ the product of column b with the last column is $c_b = T_{b\varrho}$, and the last column has h-square $h(z,z)+\eta^2h(x_{k_0},x_{k_0}) = -1+\eta^2$, which is $T_{\varrho\varrho}$ when $T_{\varrho\varrho}\ge -1$. As $\Gamma_{J_1}(Y^\vee(T))$ and T are hermitian, they agree.

The action of the frame fixer on a last column. Let $v = u(a,b)\in\mathsf{U}^0$ and $g\in H$, the latter acting by a unitary $k\times k$ matrix, also written g, on the coordinates of X_0 and trivially on e_l, z, e_l^*. From the formula for $u(a,b)$ and $W^*W=1$, $D^*W=0$, $vW = W+Xa$; also $vX=X$ and $vz=z$ ((5.66) and v fixes the frame). Hence, for $c\in\mathbb{C}^\varrho$ and $x\in\mathbb{C}^k$,

$$vg\,(-z+Xc+Wx) = -z + X(c+a\,gx) + W\,gx,\qquad vg\,(D+\tfrac12XT_1) = v(D+\tfrac12XT_1). \tag{5.63}$$

(ii) Write $p=(p'\mid q)$ with $p'\in\mathrm{M}_{(\varrho+k)\times\varrho}(\mathbb{C})$ and last column $q=\binom{c}{x}$, $c\in\mathbb{C}^\varrho$, $x\in\mathbb{C}^k$. The columns of J_1F are $e_1^*,\dots,e_\varrho^*,-z$, so $J_1F+Rp = (D+Rp'\mid -z+Xc+Wx)$. By Tonelli's theorem and Lemma 5.3.52 (ii) applied to the Borel function $L(Y') = \int K(Y'\mid -z+Xc+Wx)\,dc\,dx$,

$$\int K(J_1F+Rp)\,dp = \int L(D+Rp')\,dp' = 2^{-\varrho}\int_{\mathrm{Herm}_\varrho}\int_{\mathsf{U}^0}L\big(v(D+\tfrac12XT_1)\big)\,dv\,dT_1. \tag{5.64}$$

Fix T_1 and $v = u(a,b)$, and put $Y' = v(D + \frac{1}{2}XT_1)$. Translating c by ax for fixed x, $L(Y') = \int_{\mathbb{C}^k}\int_{\mathbb{C}^\varrho} K\big(Y' \mid -z + X(c+ax) + Wx\big)\,dc\,dx$. Polar coordinates in $\mathbb{C}^k$: Lebesgue measure is $\rho^{2k-1}d\rho\,d\sigma$, with σ the surface measure of the unit sphere, of total mass $2\pi^k/(k-1)!$; the normalised σ is the unique $\mathrm{U}(k)$-invariant Borel probability measure on the sphere, on which $\mathrm{U}(k)$ acts transitively, so it is the image of the Haar probability measure dg under $g \mapsto g\varepsilon_{k_0}$, ε_{k_0} the k_0-th unit vector; with $t = \rho^2$, so that $\rho^{2k-1}d\rho = \frac{1}{2}t^{k-1}dt$,

$$\int_{\mathbb{C}^k}\phi(x)\,dx = \frac{\pi^k}{(k-1)!}\int_0^\infty t^{k-1}\int_H \phi(\sqrt{t}\,g\varepsilon_{k_0})\,dg\,dt \qquad (\phi \geq 0 \text{ Borel}).$$

Apply it to the inner c-integral as a function of x, then substitute $t = 1+\tau$, and use (5.63) with $x = \sqrt{1+\tau}\,\varepsilon_{k_0}$ (so $Wx = \sqrt{1+\tau}\,x_{k_0}$) and Tonelli:

$$L(Y') = \frac{\pi^k}{(k-1)!}\int_{\mathbb{C}^\varrho}\int_{\mathbb{R}} \mathbf{1}_{\{\tau>-1\}}(1+\tau)^{k-1} \int_H K\Big(vg\big(D + \tfrac{1}{2}XT_1 \mid -z + Xc + \max(0,1+\tau)^{1/2}x_{k_0}\big)\Big)\,dg\,d\tau\,dc.$$

By (5.62) the argument of K is $vg\,Y^\vee(T)$, where $T \in \mathrm{Herm}_{\varrho+1}$ has upper left block T_1, entries $T_{a\varrho} = c_a$ above the corner and corner $T_{\varrho\varrho} = \tau$. The map $(T_1, c, \tau) \mapsto T$ is a bijection $\mathrm{Herm}_\varrho \times \mathbb{C}^\varrho \times \mathbb{R} \to \mathrm{Herm}_{\varrho+1}$ carrying $dT_1\,dc\,d\tau$ to dT, since the coordinates of dT (diagonal entries, real and imaginary parts of the entries above the diagonal) are those of T_1, c and τ. Inserting this into (5.64), using Tonelli's theorem once more and $\int_{\mathsf{U}^0}\int_H K(vgY)\,dg\,dv = \int_{G_1} K(sY)\,ds$ (definition of ds as the image of $dv \otimes dg$ under $(v,g) \mapsto vg$), we obtain (ii). □

Lemma 5.3.52. *Let $F \in \mathrm{M}_{r\times(\varrho+1)}(\mathbb{C})$ be the matrix whose columns are the coordinate vectors of $f_0, \dots, f_\varrho$, let $R = (X \mid W) \in \mathrm{M}_{r\times(\varrho+k)}(\mathbb{C})$ be the matrix with the columns of X followed by those of W, and give $\mathrm{M}_{(\varrho+k)\times\varrho}(\mathbb{C})$ the Lebesgue measure dp of the real and imaginary parts of its entries.*

(i) For $T \in \mathrm{Herm}_\varrho$ and $v \in \mathsf{U}^0$ the matrix $Y = v(D + \frac{1}{2}XT)$ satisfies $F^*J_1Y = F^*J_1D$ and $\Gamma_{J_1}(Y) = T$.

(ii) For every Borel function $K\colon \mathrm{M}_{r\times\varrho}(\mathbb{C}) \to [0,\infty]$,

$$\int_{\mathrm{M}_{(\varrho+k)\times\varrho}(\mathbb{C})} K(D+Rp)\,dp = 2^{-\varrho}\int_{\mathrm{Herm}_\varrho}\int_{\mathsf{U}^0} K\big(v(D+\tfrac{1}{2}XT)\big)\,dv\,dT.$$

Proof. The columns of X, W, D are distinct standard basis vectors, so $X^*X = W^*W = D^*D = 1$ and $X^*W = X^*D = W^*D = 0$. From the Gram matrix J_1 (e_a pairs with e_a^*, J_1 is the identity on X_0, $h(z,z) = -1$) we have $J_1X = D$, $J_1D = X$, $J_1W = W$, hence

$$X^*J_1X = D^*J_1D = X^*J_1W = 0, \qquad X^*J_1D = D^*J_1X = 1, \qquad F^*J_1X = 0, \tag{5.65}$$

the last because $h(e_a, e_b) = h(z, e_b) = 0$.

The action of U^0. Let $(a,b) \in \mathrm{M}_{\varrho\times k}(\mathbb{C}) \times \mathrm{M}_\varrho(\mathbb{R})$ and $u = u(a,b) = 1 + XaW^* - Wa^*D^* + X\big(\mathrm{sk}(b) - \frac{1}{2}aa^*\big)D^*$. Since $W^*X = D^*X = 0$, $uX = X$; since $W^*D = 0$ and $D^*D = 1$, $uD = D - Wa^* + X\big(\mathrm{sk}(b) - \frac{1}{2}aa^*\big)$. Hence for every $\alpha \in \mathrm{M}_\varrho(\mathbb{C})$

$$u(a,b)\,(D + X\alpha) = D + X\big(\mathrm{sk}(b) + \alpha - \tfrac{1}{2}aa^*\big) - Wa^*. \tag{5.66}$$

(i) An element $v \in \mathsf{U}^0$ fixes $f_0, \dots, f_\varrho$ and preserves h, so $h(f_a, vy) = h(v^{-1}f_a, y) = h(f_a, y)$ for all y; that is, $F^*J_1vY_0 = F^*J_1Y_0$ and $\Gamma_{J_1}(vY_0) = \Gamma_{J_1}(Y_0)$ for every $Y_0 \in \mathrm{M}_{r\times\varrho}(\mathbb{C})$. For $Y_0 = D + \frac{1}{2}XT$, (5.65) gives $F^*J_1Y_0 = F^*J_1D$ and, as $T^* = T$,

$$\Gamma_{J_1}(Y_0) = D^*J_1D + \tfrac{1}{2}D^*J_1XT + \tfrac{1}{2}T^*X^*J_1D + \tfrac{1}{4}T^*X^*J_1XT = \tfrac{1}{2}T + \tfrac{1}{2}T = T.$$

A linear change of variables. Let $\Phi\colon \mathrm{M}_\varrho(\mathbb{R}) \times \mathrm{Herm}_\varrho \to \mathrm{M}_\varrho(\mathbb{C})$, $\Phi(b,T) = \mathrm{sk}(b) + \frac{1}{2}T$. We claim that Φ is a real-linear bijection with $|\det\Phi| = 2^{-\varrho}$ for the coordinates of db (the entries of b), dT and the Lebesgue measure $d\alpha$ of $\mathrm{M}_\varrho(\mathbb{C})$. The map decomposes into blocks. For each l, $(b_{ll}, T_{ll}) \mapsto \Phi(b,T)_{ll} = \mathrm{i}b_{ll} + \frac{1}{2}T_{ll}$, with real part $\frac{1}{2}T_{ll}$ and imaginary part b_{ll}: determinant of absolute value $\frac{1}{2}$. For each pair $l < l'$, put $\xi = \mathrm{sk}(b)_{ll'} = \big((1+\mathrm{i})b_{ll'} - (1-\mathrm{i})b_{l'l}\big)/\sqrt{2}$; then $\mathrm{sk}(b)_{l'l} = -\bar{\xi}$, and since $(1+\mathrm{i})\overline{(1-\mathrm{i})} = 2\mathrm{i}$ is purely imaginary, $|\xi|^2 = b_{ll'}^2 + b_{l'l}^2$, so $(b_{ll'}, b_{l'l}) \mapsto \xi$ is a linear isometry $\mathbb{R}^2 \to \mathbb{C}$. With $\tau = T_{ll'}$ the block sends (ξ,τ) to $(\Phi_{ll'}, \overline{\Phi_{l'l}}) = (\xi + \frac{1}{2}\tau,\ -\xi + \frac{1}{2}\tau)$, a complex-linear map of $\mathbb{C}^2$ of determinant 1, hence of real determinant 1, followed by complex conjugation in the second coordinate, of real determinant -1. So each pair block has determinant of absolute value 1, and $|\det\Phi| = 2^{-\varrho}$. Consequently, for Borel $g\colon \mathrm{M}_\varrho(\mathbb{C}) \to [0,\infty]$,

$$\int_{\mathrm{M}_\varrho(\mathbb{C})} g(\alpha)\, d\alpha = 2^{-\varrho} \int_{\mathrm{Herm}_\varrho} \int_{\mathrm{M}_\varrho(\mathbb{R})} g\big(\mathrm{sk}(b) + \tfrac{1}{2}T\big)\, db\, dT. \tag{5.67}$$

(ii) Write $p = \binom{\alpha}{c}$ with $\alpha \in \mathrm{M}_\varrho(\mathbb{C})$ its first ϱ rows and $c \in \mathrm{M}_{k\times\varrho}(\mathbb{C})$ the others; then $Rp = X\alpha + Wc$ and $dp = d\alpha\, dc$. The map $a \mapsto -a^*$, $\mathrm{M}_{\varrho\times k}(\mathbb{C}) \to \mathrm{M}_{k\times\varrho}(\mathbb{C})$, permutes the real coordinates up to sign and so preserves Lebesgue measure. By Tonelli's theorem, the invariance of $d\alpha$ under the translation $\alpha \mapsto \alpha - \frac{1}{2}aa^*$ and (5.67),

$$\begin{aligned}\int K(D+Rp)\, dp &= \int_{\mathrm{M}_{\varrho\times k}(\mathbb{C})} \int_{\mathrm{M}_\varrho(\mathbb{C})} K\big(D + X\big(\alpha - \tfrac{1}{2}aa^*\big) - Wa^*\big)\, d\alpha\, da \\ &= 2^{-\varrho} \int_{\mathrm{Herm}_\varrho} \int_{\mathrm{M}_{\varrho\times k}(\mathbb{C})\times\mathrm{M}_\varrho(\mathbb{R})} K\big(D + X\big(\mathrm{sk}(b) + \tfrac{1}{2}T - \tfrac{1}{2}aa^*\big) - Wa^*\big)\, d(a,b)\, dT.\end{aligned}$$

By (5.66) with $\alpha = \frac{1}{2}T$ the integrand is $K\big(u(a,b)(D + \frac{1}{2}XT)\big)$, and as dv is the image of the Lebesgue measure $d(a,b)$ under u, the inner integral is $\int_{\mathsf{U}^0} K\big(v(D + \frac{1}{2}XT)\big)\, dv$. All integrands are compositions of K with continuous maps, hence Borel. □

Lemma 5.3.53. *Let $F \in \mathrm{M}_{r\times(\varrho+1)}(\mathbb{C})$ be the matrix whose columns are the coordinate vectors of $f_0, \dots, f_\varrho$, and let m be an s-finite Borel measure on G_1 that is below the Gram fibre at F (for $J = J_1$). Then for every Borel set $B \subseteq G_1$*

$$(m * ds)(B) \le \frac{\mathrm{vol}\,\mathrm{U}(r)}{\mathrm{vol}\,\mathrm{U}(k)\, 2^{\varrho+1}} \int_{G_1} \mathbf{1}_B(y)\, dy.$$

Proof. Let E^* be the matrix of the coordinate vectors of $e_1^*, \dots, e_\varrho^*$ and $\nu = 2^{-\varrho}\, dv$, a σ-finite Borel measure on G_1 carried by U^0.

Step 1: $m * \nu$ is below the Gram fibre at $(F\ E^*)$. Every $v \in \mathsf{U}^0$ fixes $f_0, \dots, f_\varrho$, so $gF = F$ for ν-almost every g; and the image of ν under $g \mapsto gE^*$ is below the fibre measure $dY/(dM \otimes dT)$ of $Y \mapsto (F^*J_1Y, \Gamma_{J_1}(Y))$ over the value at E^*, by Lemma 5.3.54. As m is below the Gram fibre at F, Lemma 5.5.12 (i) with $E_1 = F$, $E_2 = E^*$, $\lambda = m$, $\lambda' = \nu$ shows that $m * \nu$ is below the Gram fibre at the matrix $(F\ E^*)$ with the columns $e_1, \dots, e_\varrho, z, e_1^*, \dots, e_\varrho^*$.

Step 2: the definite complement. Reordering the columns to $e_1, e_1^*, \dots, e_\varrho, e_\varrho^*, z$ is right multiplication by a permutation matrix, so by Lemma 5.5.12 (ii) $m * \nu$ is below the Gram fibre

at the matrix E^{out} of Lemma 5.5.16. The measure $m * \nu$ is s-finite (the image of the s-finite measure $m \otimes \nu$), so Lemma 5.5.16 gives, with $\mu_H = dh$,

$$((m * \nu) * dh)(B) \le \frac{\operatorname{vol} \mathrm{U}(r)}{\operatorname{vol} \mathrm{U}(k)\, 2^{2\varrho+1}} \int_{G_1} \mathbf{1}_B \, dy \qquad (B \subseteq G_1 \text{ Borel}).$$

Step 3: conclusion. Convolution of s-finite measures is associative (Tonelli for the image of $m \otimes \nu \otimes dh$ under $(g, g', g'') \mapsto gg'g''$) and bilinear, so $(m*\nu)*dh = m*(\nu*dh) = 2^{-\varrho}\, m*(dv*dh) = 2^{-\varrho}\, m * ds$. Multiplying the display by 2^{ϱ} gives the claim, as $2^{\varrho}/2^{2\varrho+1} = 1/2^{\varrho+1}$. □

Lemma 5.3.54. *Let $F \in \mathrm{M}_{r\times(\varrho+1)}(\mathbb{C})$ and $E^* \in \mathrm{M}_{r\times\varrho}(\mathbb{C})$ be the matrices whose columns are the coordinate vectors of $f_0, \dots, f_\varrho$, respectively of $e_1^*, \dots, e_\varrho^*$, give $\mathrm{M}_{(\varrho+1)\times\varrho}(\mathbb{C})$ the Lebesgue measure dM of the real and imaginary parts of its entries, and let*

$$\pi \colon \mathrm{M}_{r\times\varrho}(\mathbb{C}) \to \mathrm{M}_{(\varrho+1)\times\varrho}(\mathbb{C}) \times \mathrm{Herm}_\varrho, \qquad \pi(Y) = \big(F^* J_1 Y,\ \Gamma_{J_1}(Y)\big).$$

Then the image of the measure $2^{-\varrho}\, dv$ under $\mathsf{U}^0 \to \mathrm{M}_{r\times\varrho}(\mathbb{C})$, $v \mapsto vE^*$, is below the fibre measure $dY/(dM \otimes dT)$ of π over $\pi(E^*)$.

Proof. Write $D = E^*$, $R = (X \mid W)$ and $M_0 = F^* J_1 D \in \mathrm{M}_{(\varrho+1)\times\varrho}(\mathbb{C})$; then $\pi(D) = (M_0, 0)$, since $D^* J_1 D = 0$ by (5.65). All spaces below are finite-dimensional real vector spaces, hence separable and metrizable, and all measures are Lebesgue measures or images of them, hence s-finite.

Products with the frame. The columns of F and of R are distinct standard basis vectors, so $F^*F = 1$ and $R^*R = 1$, and $F^*J_1R = 0$ because $h(f_a, e_b) = h(f_a, x_i) = 0$ for every a, b, i (the e_b are isotropic and orthogonal to z, and $X_0 \perp e_b, z$). The matrix J_1F has the columns $e_1^*, \dots, e_\varrho^*, -z$, and $(M_0)_{ab} = h(f_a, e_{b+1}^*)$ is δ_{ab} for $a < \varrho$ and 0 for $a = \varrho$; hence $J_1 F M_0 = D$. By Lemma 5.5.20 (with $J = J_1$, $N = r$, $E = F$, $n_1 = \varrho + 1$, $n_2 = \varrho + k$, so that $n_1 + n_2 = r$, $n = \varrho$, $M = M_0$), the measure μ_0, the image of the Lebesgue measure dp of $\mathrm{M}_{(\varrho+k)\times\varrho}(\mathbb{C})$ under $p \mapsto D + Rp$, is below the fibre measure dY/dM of $\pi_1 \colon Y \mapsto F^* J_1 Y$ over M_0.

Gram matrices. Apply Lemma 5.5.13 (i) with $X = \mathrm{M}_{r\times\varrho}(\mathbb{C})$, $\mu = \mu_0$, $B = V = \mathrm{Herm}_\varrho$, $\nu = dT$, $\beta = 0$, $P = \mathrm{M}_{\varrho\times k}(\mathbb{C}) \times \mathrm{M}_\varrho(\mathbb{R})$ with Lebesgue measure, $\psi(T, (a, b)) = u(a, b)(D + \frac{1}{2}XT)$ and $w \equiv 2^{-\varrho}$. Its hypotheses hold: dT is positive on nonempty open sets and finite on bounded ones; ψ and w are continuous; $\Gamma_{J_1}(\psi(T, p)) = T$ for all (T, p) by Lemma 5.3.52 (i); and for every Borel $K \ge 0$, by Lemma 5.3.52 (ii) and since dv is the image of the Lebesgue measure of P under u,

$$\int_V \int_P w\, K(\psi(T,p))\, dp\, dT = 2^{-\varrho} \int_{\mathrm{Herm}_\varrho} \int_{\mathsf{U}^0} K\big(v(D + \tfrac{1}{2}XT)\big)\, dv\, dT = \int K(D + Rp)\, dp = \int K\, d\mu_0.$$

Hence the image of $2^{-\varrho}$ times Lebesgue measure on P under $(a, b) \mapsto \psi(0, (a, b)) = u(a, b)D$, which is the image λ' of $2^{-\varrho} dv$ under $v \mapsto vD$, is below the fibre measure $d\mu_0/dT$ of Γ_{J_1} over 0.

Both together. The map Γ_{J_1} is continuous and dM, dT are s-finite. By Lemma 5.5.13 (iv), applied to $\lambda = \mu_0$ (below dY/dM of π_1 over M_0) and to λ' (below $d\mu_0/dT$ of Γ_{J_1} over 0), the measure λ' is below the fibre measure $dY/(dM \otimes dT)$ of $Y \mapsto (\pi_1(Y), \Gamma_{J_1}(Y)) = \pi(Y)$ over $(M_0, 0) = \pi(E^*)$. □

Lemma 5.3.55. *Let $\mathcal{D}$, L and I be finite sets, (Ω, σ) a σ-finite measure space, $0 < \varepsilon \le 1$, $\Lambda \ge 0$ and $K \in [0, \infty]$. For every word i (finite sequence) in the alphabet L let $f_i \colon \mathbb{R}^{\mathcal{D}} \times \Omega \to \mathbb{C}^I$ be measurable; li denotes the word with first letter l followed by i, $|i|$ the length of i, $\varnothing$ the empty word, $x[d \mapsto t]$ the point x with its coordinate d replaced by t, and $C = [0, \varepsilon]^{\mathcal{D}}$. Assume:*

(a) for σ-almost every ω, for every word i, every $d \in \mathcal{D}$, every $x \in \mathbb{R}^{\mathcal{D}}$ and every $t \in \mathbb{R}$ with $x[d \mapsto t] \in C$, the function $s \mapsto f_i(x[d \mapsto s], \omega)$ is differentiable at t, with derivative of norm at most $\Lambda \sum_{l \in L} \|f_{li}(x[d \mapsto t], \omega)\|$;

(b) $\int_C \int_\Omega \|f_i(x,\omega)\|^2 \, d\sigma(\omega)\, dx \le K$ for every word i with $|i| \le \#\mathcal{D}$.

Then

$$\int_\Omega \|f_\varnothing(0,\omega)\|^2 \, d\sigma(\omega) \le \Big(\frac{2(1+(\#L\,\Lambda)^2)}{\varepsilon}\Big)^{\#\mathcal{D}} K.$$

Proof. Norms are Euclidean; dx and dt are Lebesgue measures.

One variable. Let $g\colon \mathbb{R} \to \mathbb{C}^I$ be differentiable at every point of $[0,\varepsilon]$. We show

$$\|g(0)\|^2 \le \frac{2}{\varepsilon} \int_0^\varepsilon \big(\|g(t)\|^2 + \|g'(t)\|^2\big)\, dt. \tag{5.68}$$

The derivative g' is Borel on $[0,\varepsilon]$, as a pointwise limit of difference quotients of the continuous function g. Put $\varphi(t) = \|g(t)\|^2 (t-\varepsilon)/\varepsilon$; it is differentiable at every point of $[0,\varepsilon]$ with $\varphi'(t) = \big(2\operatorname{Re}\langle g(t), g'(t)\rangle (t-\varepsilon) + \|g(t)\|^2\big)/\varepsilon$. As $|t-\varepsilon| \le \varepsilon \le 1$ on $[0,\varepsilon]$, the Cauchy–Schwarz inequality gives

$$|\varphi'(t)| \le \frac{2\|g(t)\|\,\|g'(t)\| + \|g(t)\|^2}{\varepsilon} \le \frac{(\|g(t)\| + \|g'(t)\|)^2}{\varepsilon} \le \frac{2}{\varepsilon}\big(\|g(t)\|^2 + \|g'(t)\|^2\big).$$

If $\int_0^\varepsilon |\varphi'| = \infty$, (5.68) holds trivially. Otherwise φ' is integrable on $[0,\varepsilon]$ and φ is differentiable at every point, so $\varphi(\varepsilon) - \varphi(0) = \int_0^\varepsilon \varphi'$ (Rudin, *Real and Complex Analysis*, Theorem 7.21); as $\varphi(\varepsilon) = 0$ and $\varphi(0) = -\|g(0)\|^2$, $\|g(0)\|^2 \le \int_0^\varepsilon |\varphi'|$, and (5.68) follows.

One coordinate, integrated. Let ω lie in the set of full measure of (a), i a word, $d \in \mathcal{D}$ and $x \in C$ with $x_d = 0$. Then $g(s) = f_i(x[d \mapsto s], \omega)$ satisfies the hypothesis of (5.68), $g(0) = f_i(x,\omega)$, and $\|g'(t)\|^2 \le \#L\,\Lambda^2 \sum_l \|f_{li}(x[d \mapsto t], \omega)\|^2$ by (a) and the Cauchy–Schwarz inequality. Hence

$$\|f_i(x,\omega)\|^2 \le \frac{2}{\varepsilon} \int_0^\varepsilon \Big(\|f_i(x[d \mapsto t],\omega)\|^2 + \#L\,\Lambda^2 \sum_{l \in L} \|f_{li}(x[d \mapsto t],\omega)\|^2\Big) dt. \tag{5.69}$$

Induction over the coordinates. For $S \subseteq \mathcal{D}$ and $x \in [0,\varepsilon]^S$ let $\bar{x} \in \mathbb{R}^{\mathcal{D}}$ have the coordinates of x in S and 0 outside S, and put $N_i(S) = \int_{[0,\varepsilon]^S} \int_\Omega \|f_i(\bar{x},\omega)\|^2 \, d\sigma\, dx$ (measurable integrands; so $N_i(\varnothing) = \int_\Omega \|f_i(0,\omega)\|^2 d\sigma$ and $N_i(\mathcal{D})$ is the integral in (b)). Let $c = 2(1+(\#L\,\Lambda)^2)/\varepsilon$. We prove by induction on m: *if $\#S = m$, $M \in [0,\infty]$ and $N_i(S) \le M$ for all words i with $|i| \le m$, then $N_\varnothing(\varnothing) \le c^m M$.* For $m = 0$ this is the hypothesis for $i = \varnothing$. Let $\#S = m+1$, pick $d \in S$ and put $S_0 = S \setminus \{d\}$. For $x \in [0,\varepsilon]^{S_0}$ the point $\bar{x}$ (formed for S_0) lies in C and has $\bar{x}_d = 0$. Integrating (5.69) over ω (the exceptional set is null) and over $x \in [0,\varepsilon]^{S_0}$, and using Tonelli's theorem to combine the integrals over x and t into one over $[0,\varepsilon]^S$, we get for every word i with $|i| \le m$

$$N_i(S_0) \le \frac{2}{\varepsilon}\Big(N_i(S) + \#L\,\Lambda^2 \sum_{l \in L} N_{li}(S)\Big) \le \frac{2}{\varepsilon}\big(M + (\#L\,\Lambda)^2 M\big) = cM,$$

since $|i| \le m+1$ and $|li| \le m+1$. The induction hypothesis for S_0 and cM gives $N_\varnothing(\varnothing) \le c^m \cdot cM$. Applying the statement with $S = \mathcal{D}$ and $M = K$, which is allowed by (b), proves the lemma. □

Lemma 5.3.56. *Let Z be a complex $(\varrho+1) \times (\varrho+1)$ matrix.*

(i) If $M \ge n$, $|Z_{ab}| \le M^2$ for all a, b and $\mathfrak{g}_1(Z) \ge M^{-1}$, then Z is bounded in the cell by every $T \ge M^{8n}$.

(ii) If $T \ge 8$, $T \ge n$ and Z is bounded in the cell by T, then every Y with $\|Y - Z\| < T^{-6}$ is bounded in the cell by $2T$ and satisfies $\mathfrak{g}_1(Y) \ge \mathfrak{g}_1(Z)/2$.

(iii) If $M \ge 8n$, $|Z_{ab}| \le M^2$ for all a, b, $\mathfrak{g}_1(Z) \ge M^{-1}$ and $P \ge M^{9n}$, then every Y with $\|Y - Z\| < P^{-6}$ is bounded in the cell by P and satisfies $\mathfrak{g}_1(Y) \ge \mathfrak{g}_1(Z)/2$.

(iv) The map $Y \mapsto \gamma_Y$ is real differentiable on the open set Ω_{cell}. If $T \ge 4$ and Z is bounded in the cell by T, then $\|\gamma_Z\| \le T^{18}$ and the real derivative of $Y \mapsto \gamma_Y$ at Z has norm at most T^{25}.

Proof. **Step 0: $\mathfrak{g}_1(Y) = |\det Y|^2 \eta(Y)^2$ for invertible Y.** By Cramer's rule $\mathrm{ic}(Y) = (Y^{-1})_{\varrho\varrho} = D_\varrho(Y)/\det Y$, so $|D_\varrho(Y)|^2 = |\det Y|^2 |\mathrm{ic}(Y)|^2$. We use $\|A\| \le (\sum_{a,b} |A_{ab}|^2)^{1/2} \le l \max_{a,b} |A_{ab}|$ for an $l \times l$ matrix A, $|\det A| \le \|A\|^l$, $|A_{ab}| \le \|A\|$, and $\|F\|, \|F'\| \le 1$ (their columns are distinct vectors of an orthonormal basis).

Proof of (i). $M \ge n \ge 1$. Every square submatrix A of Z of size $l \le n$ has $\|A\| \le lM^2 \le M^3$, so $|\det A| \le M^{3l}$; in particular $\|Z\| \le M^3$. As $\mathfrak{g}_1(Z) \ge M^{-1} > 0$, Z is invertible and lies in Ω_{cell}, and by Step 0 $|\det Z|^2 \eta(Z)^2 \ge M^{-1} \ge M^{-2}$, so $|\det Z|\,\eta(Z) \ge M^{-1}$. Since $\eta(Z) \le 1$, $|\det Z|^{-1} \le M$; and $\eta(Z)^{-1} \le M |\det Z| \le M^{3n+1}$. The entries of the adjugate are minors of order ϱ, of modulus $\le M^{3\varrho}$, so $\|Z^{-1}\| = |\det Z|^{-1} \|\mathrm{adj}\, Z\| \le M \cdot nM^{3\varrho} \le M^{3\varrho+2}$. All four bounds are $\le M^{8n} \le T$.

Proof of (ii). Let $\|Y - Z\| < T^{-6}$. Then $\|Z^{-1}(Y - Z)\| \le T^{-5} \le \frac{1}{2}$, so $Y = Z(1 + Z^{-1}(Y - Z))$ is invertible; from $Y^{-1} - Z^{-1} = Y^{-1}(Z - Y)Z^{-1}$ we get $\|Y^{-1}\| \le T + \frac{1}{2}\|Y^{-1}\|$, so $\|Y^{-1}\| \le 2T$ and $\|Y^{-1} - Z^{-1}\| \le 2T \cdot T^{-6} \cdot T = 2T^{-4}$. Hence $|\mathrm{ic}(Y)| \le |\mathrm{ic}(Z)| + 2T^{-4}$ and, as $|\mathrm{ic}(Z)| < 1$, $|\mathrm{ic}(Y)|^2 \le |\mathrm{ic}(Z)|^2 + 8T^{-4}$. With $\eta(Z)^2 \ge T^{-2}$,

$$\eta(Y)^2 \ge \eta(Z)^2 - 8T^{-4} \ge (1 - 8T^{-2})\,\eta(Z)^2 \ge \tfrac{7}{8}\,\eta(Z)^2 \qquad (T \ge 8).$$

So $\eta(Y) > 0$, $Y \in \Omega_{\mathrm{cell}}$, $\eta(Y)^{-1} \le (8/7)^{1/2} T \le 2T$, and $\|Y\| \le T + T^{-6} \le 2T$: Y is bounded in the cell by $2T$. For the discriminant write $Z = (1 - (Y - Z)Y^{-1})Y$; as $\|(Y - Z)Y^{-1}\| \le 2T^{-5}$ and $n \le T$, $|\det Z| \le (1 + 2T^{-5})^n |\det Y| \le e^{2T^{-4}} |\det Y| \le \frac{9}{8} |\det Y|$. By Step 0,

$$\mathfrak{g}_1(Y) = |\det Y|^2 \eta(Y)^2 \ge \Big(\frac{8}{9}\Big)^2 |\det Z|^2 \cdot \frac{7}{8}\,\eta(Z)^2 = \frac{56}{81}\,\mathfrak{g}_1(Z) \ge \frac{1}{2}\,\mathfrak{g}_1(Z).$$

Proof of (iii). $M \ge 8n \ge 8$, so $M^{9n} \ge M \cdot M^{8n} \ge 2M^{8n}$ and $T = P/2 \ge M^{8n}$. By (i), Z is bounded in the cell by T; moreover $T \ge M \ge 8n$, so $T \ge 8$ and $T \ge n$. As $P^{-6} \le T^{-6}$, (ii) gives that Y is bounded in the cell by $2T = P$ and $\mathfrak{g}_1(Y) \ge \mathfrak{g}_1(Z)/2$.

Proof of (iv). On Ω_{cell} the maps $Y \mapsto Y^{-1}$, $Y \mapsto \mathrm{ic}(Y)$ and $Y \mapsto \eta(Y) = (1 - |\mathrm{ic}(Y)|^2)^{1/2}$ (with $1 - |\mathrm{ic}(Y)|^2 > 0$) are real differentiable, hence so are Co, Co′ (polynomials in the entries of the last row and column of Y^{-1} and their conjugates), dg, dg^{-1} and the formula for γ_Y of Definition 5.1.6, which is built from these by sums and products. Let Z be bounded in the cell by $T \ge 4$; write ζ, ζ' for the last row and the last column of Z^{-1} ($\|\zeta\|, \|\zeta'\| \le T$), and let H be a direction with $\|H\| \le 1$, ∂ the derivative at Z in the direction H. Then $\partial(Y^{-1}) = -Z^{-1} H Z^{-1}$ has norm $\le T^2$, so $\|\partial\zeta\|, \|\partial\zeta'\|, |\partial\,\mathrm{ic}| \le T^2$. Off its last row, $\mathrm{Co}(Z)$ is $-\bar{\zeta}^{\top}\zeta$ restricted to the rows $a < \varrho$, with column b multiplied by $c_b \in \{\frac{1}{2}, 1\}$; hence $\|\mathrm{Co}(Z)\| \le 1 + T^2$ and $\|\partial\mathrm{Co}\| \le 2T^3$, and likewise for Co′. Next $\partial\eta = -\mathrm{Re}(\overline{\mathrm{ic}}\,\partial\,\mathrm{ic})/\eta$, so $|\partial\eta| \le T^3$ and $|\partial(\eta^{-1})| = |\partial\eta|/\eta^2 \le T^5$; thus $\|\mathrm{dg}\| \le 1$, $\|\mathrm{dg}^{-1}\| \le T$, $\|\partial\,\mathrm{dg}\| \le T^3$, $\|\partial\,\mathrm{dg}^{-1}\| \le T^5$. For

$F^\vee = F\mathrm{Co} + F'\mathrm{dg}$: $\|F^\vee\| \le 2 + T^2 \le 2T^2$ and $\|\partial F^\vee\| \le 3T^3$. Put $Q = F(Z^{-1})^* - F^\vee Z\,\mathrm{Co}'$, so that $\gamma_Z = 1 + (F^\vee Z - F)F^* + (Q\,\mathrm{dg}^{-1} - F')F'^*$. Then, using $1 + T^2 \le 2T^2$ and $T \ge 4$,

$$\|Q\| \le T + 2T^2 \cdot T \cdot 2T^2 \le 5T^5, \qquad \|\partial Q\| \le T^2 + (3T^4 + 2T^2) \cdot 2T^2 + 2T^3 \cdot 2T^3 \le 13T^6.$$

Hence $\|\gamma_Z\| \le 1 + (2T^3 + 1) + (5T^6 + 1) \le 6T^6 \le T^{18}$, and

$$\|\partial\gamma\| \le \|\partial F^\vee\|\,\|Z\| + \|F^\vee\| + \|\partial Q\|\,\|\mathrm{dg}^{-1}\| + \|Q\|\,\|\partial\,\mathrm{dg}^{-1}\| \le 3T^4 + 2T^2 + 13T^7 + 5T^{10} \le 7T^{10} \le T^{25}.$$

□

Lemma 5.3.57. *Let $M \ge 8n$ and $T \ge M^{9n}$ be reals and Z an invertible complex $(\varrho+1)\times(\varrho+1)$ matrix with $\mathsf{g}_1(Z) \ge M^{-1}$ and $\|Z^{-1}\| \le T$. Let $s \in R$, $v \in \mathsf{U}^0$, $h \in H$ and $z \in \mathrm{Bx}(M)$ with $\ell(s\gamma_Z(vh)^{-1}z) \le M$. Then $\|v^{-1}z\| \le T^5$.*

Proof. Reduction. Put $z' = (vh)^{-1}z$. As vh fixes the frame, $z'^{-1}f_a = z^{-1}vhf_a = z^{-1}f_a$, so $z' \in \mathrm{Bx}(M)$. As R is a group, $\ell(qy) = \ell(y)$ for $q \in R$, so $\ell(\gamma_Z z') = \ell(s\gamma_Z z') \le M$. Finally $v^{-1}z = hz'$ and h is a unitary matrix, so $\|v^{-1}z\| = \|z'\|$. We show $\|z'\| \le T^5$.

A short point. As the infimum is $\le M < M + 1$, there is $q \in R$ with $\|q\gamma_Z z'\| \le M$. Write $q = uh'$ with $u \in \mathsf{U}$, $h' \in H$ (Lemma 5.5.30 (i)) and $w = h'^{-1}uh' \in \mathsf{U}$ (Lemma 5.5.29 (iii)); then $q = h'w$ and $y := w\gamma_Z z'$ satisfies $\|y\| = \|h'y\| = \|q\gamma_Z z'\| \le M$.

The Gram matrix at $w\gamma_Z$. By Lemma 5.3.47 (i), (ii), $Z \in \Omega_{\mathrm{cell}}$ and $Z(\gamma_Z) = Z$. Let $m = (F^*wF)^{-1}$, upper unitriangular by Lemma 5.3.41 (i), and $Z' = Z(w\gamma_Z)$. By Lemma 5.3.41 (ii), (iii), $Z' = m^*Z$ and $\mathsf{g}_1(Z') = \mathsf{g}_1(Z) \ge M^{-1}$. Since $y^{-1}w\gamma_Z = z'^{-1}$, Lemma 5.3.41 (iv) gives $|Z'_{ab}| \le \|y^{-1}f_a\|\,\|z'^{-1}f_b\| \le \|y\|M \le M^2$. By Lemma 5.3.56 (i) ($M \ge n$), Z' is bounded in the cell by every number $\ge M^{8n}$, in particular by T; so $\|Z'^{-1}\| \le T$.

The dual columns of z'^{-1}. As the columns of F and F' are distinct vectors of one orthonormal basis, $F^*F = F'^*F' = 1$ and $F^*F' = F'^*F = 0$; the formula for γ_Z gives $\gamma_Z F = F^\vee(Z)Z$ and $\gamma_Z F'\mathrm{dg}(Z) = F(Z^{-1})^* - \gamma_Z F\,\mathrm{Co}'(Z)$, so

$$F'\mathrm{dg}(Z) = \gamma_Z^{-1}F(Z^{-1})^* - F\,\mathrm{Co}'(Z), \qquad z'^{-1}F'\mathrm{dg}(Z) = y^{-1}wF(Z^{-1})^* - z'^{-1}F\,\mathrm{Co}'(Z),$$

using $(\gamma_Z z')^{-1} = y^{-1}w$. Now $wF = Fm^{-1}$ (Lemma 5.3.41 (i)) and $(Z^{-1})^* = (Z'^{-1}m^*)^* = m(Z'^{-1})^*$, so $wF(Z^{-1})^* = F(Z'^{-1})^*$. Column $a < \varrho$ of F' is e^*_{a+1} and $\mathrm{dg}(Z)_{aa} = 1$; hence

$$z'^{-1}e^*_{a+1} = \sum_{b=0}^{\varrho} \overline{(Z'^{-1})_{ab}}\,y^{-1}f_b + \sum_{b<\varrho} \tfrac{1}{2}(Z^{-1})_{b\varrho}\overline{(Z^{-1})_{a\varrho}}\,z'^{-1}f_b.$$

Entries are bounded by operator norms, $\|y^{-1}f_b\| \le \|y^{-1}\| = \|y\| \le M$ (Lemma 5.3.41 (iv)) and $\|z'^{-1}f_b\| \le M$, so with $M \le T$ and $\varrho + 1 = n \le M/8 \le T/8$,

$$\|z'^{-1}e^*_{a+1}\| \le (\varrho+1)TM + \tfrac{1}{2}\varrho T^2 M \le \tfrac{1}{8}T^3 + \tfrac{1}{16}T^4 \le T^4.$$

Conclusion. Also $\|z'^{-1}f_a\| \le M \le T^4$. By Lemma 5.3.58 with the bound $T^4 \ge 1$, $\|z'\| + 1 \le 4(\varrho+1)T^4 \le 8(\varrho+1)T^4 \le MT^4 \le T^5$. □

Lemma 5.3.58. *Let $M \ge 1$ and $y \in G_1$ with $\|y^{-1}f_a\| \le M$ for $0 \le a \le \varrho$ and $\|y^{-1}e^*_a\| \le M$ for $1 \le a \le \varrho$. Then $\|y\| + 1 \le 4(\varrho+1)M$.*

Proof. Let $A = y^{-1} \in G_1$. By Lemma 5.3.41 (iv), $\|A\| = \|y\| \geq 1$ and $A^{-1} = J_1 A^* J_1$, so $AJ_1A^* = J_1$ and

$$AA^* = AJ_1A^* + A(1-J_1)A^* = J_1 + A(1-J_1)A^*, \qquad \|A\|^2 = \|AA^*\| \leq 1 + \|A(1-J_1)\|\,\|A\|.$$

The matrix $1 - J_1$ sends $x_i \mapsto 0$, $z \mapsto 2z$, $e_a \mapsto e_a - e_a^*$ and $e_a^* \mapsto e_a^* - e_a$. For any matrix B, $\|B\| \leq \sum_q \|Bq\|$, the sum over the basis vectors q (as $B = \sum_q (Bq)q^*$). With $e_a = f_{a-1}$ and $z = f_\varrho$,

$$\|A(1-J_1)\| \leq 2\|Az\| + 2\sum_{a=1}^{\varrho}(\|Ae_a\| + \|Ae_a^*\|) \leq (4\varrho+2)M.$$

As $\|A\| \geq 1$, $\|A\|^2 \leq (1 + (4\varrho+2)M)\|A\|$, so $\|y\| = \|A\| \leq 1 + (4\varrho+2)M$ and $\|y\| + 1 \leq 2 + (4\varrho+2)M \leq (4\varrho+4)M = 4(\varrho+1)M$, using $M \geq 1$. □

Lemma 5.3.59. *Let Φ be a finite set. For $v \in \Phi$ let $(\mathcal{X}_v, m_v)$ be a probability space, $\mathcal{Y}_v$ a measurable space with finite measures μ_v, ν_v, I_v a finite set, and $k_i^v \colon \mathcal{X}_v \times \mathcal{Y}_v \to \mathbb{C}$ $(i \in I_v)$ bounded measurable functions forming an L^2 contraction from $(\mathcal{Y}_v, \mu_v)$ to $(\mathcal{X}_v, m_v)$ with bound ν_v. Then the kernels*

$$k_i(x,z) = \prod_{v\in\Phi} k_{i_v}^v(x_v, z_v) \qquad \Big(i \in \prod_v I_v\Big)$$

on $\prod_v \mathcal{X}_v \times \prod_v \mathcal{Y}_v$ form an L^2 contraction from $(\prod_v \mathcal{Y}_v, \bigotimes_v \mu_v)$ to $(\prod_v \mathcal{X}_v, \bigotimes_v m_v)$ with bound $\bigotimes_v \nu_v$.

Proof. By induction on $\#\Phi$; for $\Phi = \emptyset$ both sides are $|\phi|^2$ at the one point. For the step, write the factors as two: $(\mathcal{X}_1, m_1, \mathcal{Y}_1, \mu_1, \nu_1, I_1, k^1)$ for one place, and $(\mathcal{X}_2, m_2, \mathcal{Y}_2, \mu_2, \nu_2, I_2, k^2)$ for the product over the remaining places, which by the induction hypothesis is again a probability space, finite measures and bounded measurable kernels forming an L^2 contraction. All measures are finite, so Tonelli's and Fubini's theorems apply. Let ϕ be bounded measurable on $\mathcal{Y}_1 \times \mathcal{Y}_2$, $|\phi| \leq c$, and let $|k_i^2| \leq c_2$ for all i. For $x_2 \in \mathcal{X}_2$, $i_2 \in I_2$ and $z_1 \in \mathcal{Y}_1$ put

$$\psi_{x_2,i_2}(z_1) = \int_{\mathcal{Y}_2} \phi(z_1,z_2)\, k_{i_2}^2(x_2,z_2)\, d\mu_2(z_2);$$

it is jointly measurable in (x_2, z_1) and bounded by $c\, c_2\, \mu_2(\mathcal{Y}_2)$. By Fubini's theorem, for $i = (i_1, i_2)$,

$$\int_{\mathcal{Y}_1\times\mathcal{Y}_2} \phi\, k_i(x,\cdot)\, d(\mu_1\otimes\mu_2) = \int_{\mathcal{Y}_1} \psi_{x_2,i_2}(z_1)\, k_{i_1}^1(x_1,z_1)\, d\mu_1(z_1).$$

Hence, by Tonelli's theorem, the contraction property at the first factor applied to the bounded measurable ψ_{x_2,i_2}, Tonelli's theorem again, and the contraction property at the second factor applied to $\phi(z_1,\cdot)$,

$$\begin{aligned}
\int \sum_i \Big|\int \phi\, k_i(x,\cdot)\, d\mu\Big|^2 dm(x) &= \int_{\mathcal{X}_2} \sum_{i_2} \int_{\mathcal{X}_1} \sum_{i_1} \Big|\int_{\mathcal{Y}_1} \psi_{x_2,i_2} k_{i_1}^1(x_1,\cdot)\, d\mu_1\Big|^2 dm_1\, dm_2 \\
&\leq \int_{\mathcal{X}_2} \sum_{i_2} \int_{\mathcal{Y}_1} |\psi_{x_2,i_2}(z_1)|^2\, d\nu_1(z_1)\, dm_2(x_2) \\
&= \int_{\mathcal{Y}_1} \int_{\mathcal{X}_2} \sum_{i_2} \Big|\int_{\mathcal{Y}_2} \phi(z_1,\cdot)\, k_{i_2}^2(x_2,\cdot)\, d\mu_2\Big|^2 dm_2\, d\nu_1(z_1) \\
&\leq \int_{\mathcal{Y}_1}\int_{\mathcal{Y}_2} |\phi|^2\, d\nu_2\, d\nu_1.
\end{aligned}$$

The product kernel is bounded and measurable, which completes the induction. □

Lemma 5.3.60. *Let $\mathfrak{S}$ be admissible with Weil data, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, and $T' \subseteq G(E)$ stable. Let $\varphi\colon G(E) \times G_\infty \to [0,\infty]$ be such that $\varphi(\gamma,\cdot)$ is Borel for every γ and*

$$\sum_{(v,v') \in \mathsf{U}_c(M) \times \mathsf{U}_{c'}(M)} \varphi\big(v\gamma v'^{-1},\, v \cdot y\big) = 1$$

for every $y \in G_\infty$ and every $\gamma \in T'$ that is a term over (c,s,c'). Then

$$\sum_{\substack{\gamma \in T' \\ over\ (c,s,c')}} \int_{G_\infty} \varphi(\gamma,y) \left\| W^{\mathrm{full}}(y) \otimes \overline{W^{\mathrm{full}}(\gamma^{-1}y)} - W^{\mathrm{cut}}(y) \otimes \overline{W^{\mathrm{cut}}(\gamma^{-1}y)} \right\| dy \le \frac{\nu}{2\, b^{k^3 f}}.$$

Proof. Write $K^\sigma(\gamma,y) = W^\sigma(y) \otimes \overline{W^\sigma(\gamma^{-1}y)}$ ($\sigma \in \{\mathrm{full}, \mathrm{cut}\}$) and $D(\gamma,y) = \|K^{\mathrm{full}}(\gamma,y) - K^{\mathrm{cut}}(\gamma,y)\|$, a Borel function of y. Let X be the set of terms of T' over (c,s,c'), and let $Z = X \times G_\infty$, $\mu =$ (counting measure) $\otimes\, dy$, the group Γ_X, its countable subgroup $\Delta = \mathsf{U}_c(M) \times \mathsf{U}_{c'}(M)$ and $\beta_0(\gamma,y) = \beta_c(y)\beta_{c'}(\gamma^{-1}y)$ be as in (ii) of Lemma 5.2.36: Γ_X acts on Z by $(a,b)\cdot(\gamma,y) = (a\gamma b^{-1}, a \cdot y)$, by measurable maps that preserve integrals against μ, and $\sum_{\delta \in \Delta} \beta_0(\delta \cdot z) = 1$ for every $z \in Z$.

Step 1: exchange of the cutoff. D is Δ-invariant: for $\delta = (v,v') \in \Delta$ and $z = (\gamma,y)$, $W^\sigma(v \cdot y) = W^\sigma(y)$ by Lemma 5.2.42, and $(v\gamma v'^{-1})^{-1}(v \cdot y) = v' \cdot \gamma^{-1} y$ with $W^\sigma(v' \cdot x) = W^\sigma(x)$, so $K^\sigma(\delta \cdot z) = K^\sigma(z)$ and $D(\delta \cdot z) = D(z)$. By hypothesis $\sum_{\delta \in \Delta} \varphi(\delta \cdot z) = 1$ for every $z \in Z$, and φ is measurable on Z, as X is countable. By (i) of Lemma 5.2.45, applied to Γ_X, $\Lambda = \Delta$, the two cutoffs φ and β_0 and $H = D$,

$$\int_Z \varphi D \, d\mu = \int_Z \beta_0 D \, d\mu.$$

The left side is the left side of the claim. Adding the nonnegative terms of all classes d and all terms of $G(E)$ over (c,s,d),

$$\sum_{\gamma \in X} \int \varphi(\gamma,y) D(\gamma,y)\, dy \le \int_{G_\infty} \beta_c(y) \sum_{d \in \mathcal{C}} \sum_{\gamma \text{ over } (c,s,d)} \beta_d(\gamma^{-1}y)\, D(\gamma,y)\, dy. \tag{5.70}$$

Step 2: the bound. By Tonelli's theorem the right side of (5.70) is

$$\sum_{d \in \mathcal{C}} \sum_{\substack{\gamma \in G(E) \\ \text{over } (c,s,d)}} \int_{G_\infty} \beta_c(y)\, \beta_d(\gamma^{-1}y)\, \|K^{\mathrm{full}}(\gamma,y) - K^{\mathrm{cut}}(\gamma,y)\|\, dy,$$

which is the left side of (i) of Lemma 5.3.62 for the set $G(E)$ of terms; by that clause it is at most $\nu/(2b^{k^3 f})$. □

Lemma 5.3.61. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, with its fixed cutoff datum. For $z \in G_\infty$ put $m(z) = \prod_{v \in \Phi} \max(1, \ell(z_v)/b^{6n})$. Let $c \in \mathcal{C}$, $s \in \bar{G}$, $y \in G_\infty$ and let $i \ge 8nrf$ be an integer. Then*

$$\sum_{d \in \mathcal{C}} \sum_{\gamma \ over\ (c,s,d)} \beta_d(\gamma^{-1}y)\, m(\gamma^{-1}y)^{-i} \le 2\, b^{12n^3 rf}.$$

Proof. Let P_0 be the set of pairs (d,γ) with $d \in \mathcal{C}$ and γ a term over (c,s,d), and for $(d,\gamma) \in P_0$ put $w(d,\gamma) = \beta_d(\gamma^{-1}y) \in [0,1]$ and $m(d,\gamma) = m(\gamma^{-1}y) \geq 1$. Let $m_0 = 2nrf$ and $K = b^{6n^2}$.

Layers. Let $R \geq 1$. If $m(d,\gamma) \leq R$, every factor of $m(\gamma^{-1}y)$, being at least 1, is at most R, so $\ell((\gamma^{-1}y)_v) \leq b^{6n}R \leq b^{6n+2}R$ for every $v \in \Phi$. By Lemma 5.2.30,

$$\sum_{(d,\gamma)\in P_0,\ m(d,\gamma)\leq R} w(d,\gamma) \leq (KR^2)^{m_0}.$$

Summation. As $0 < m^{-i} \leq 1$, Tonelli's theorem for the counting measure on P_0 gives, with $R = t^{-1/i} \geq 1$ for $0 < t \leq 1$,

$$\begin{aligned}\sum_{P_0} w\, m^{-i} &= \int_0^1 \sum_{P_0} w\, \mathbf{1}[m^{-i} > t]\, dt \leq \int_0^1 \sum_{P_0} w\, \mathbf{1}[m \leq t^{-1/i}]\, dt \\ &\leq \int_0^1 K^{m_0} t^{-2m_0/i}\, dt = \frac{K^{m_0}}{1 - 2m_0/i} \leq 2K^{m_0},\end{aligned}$$

since $i \geq 8nrf = 4m_0$ gives $2m_0/i \leq \frac{1}{2}$. Finally $K^{m_0} = b^{12n^3rf}$. □

Lemma 5.3.62. *Let $\mathfrak{S}$ be admissible with Weil data, $T \subseteq G(E)$, $c \in \mathcal{C}$ and $s \in \bar{G}$. For $\gamma \in G(E)$ and $y \in G_\infty$ put $K^\sigma(\gamma,y) = W^\sigma(y) \otimes \overline{W^\sigma(\gamma^{-1}y)}$ ($\sigma \in \{\mathrm{full}, \mathrm{cut}\}$). Then:*

(i)

$$\sum_{d\in\mathcal{C}} \sum_{\substack{\gamma\in T \\ over\ (c,s,d)}} \int_{G_\infty} \beta_c(y)\, \beta_d(\gamma^{-1}y)\, \|K^{\mathrm{full}}(\gamma,y) - K^{\mathrm{cut}}(\gamma,y)\|\, dy \leq \frac{\nu}{2\, b^{k^3 f}};$$

(ii)

$$\sum_{c'\in\mathcal{C}} \|A_T^{\mathrm{full}}(c,s,c') - A_T^{\mathrm{cut}}(c,s,c')\| \leq \frac{\nu}{2\, b^{k^3 f}}.$$

Proof. Write $D(\gamma,y) = \|K^{\mathrm{full}}(\gamma,y) - K^{\mathrm{cut}}(\gamma,y)\|$, a Borel function of y (the functions of a Bessel system are continuous), and for $z \in G_\infty$ let $m(z) = \prod_v \max(1, \ell(z_v)/b^{6n}) \geq 1$. All sums over terms are countable, as $G(E)$ is. Since the summands of (i) are nonnegative, it suffices to prove (i) with T replaced by $G(E)$.

Step 1: a pointwise bound for the difference of the kernels. For $v \in \Phi$ let (A_v, a_v) be a decay majorant (BS3) of the cut pair $(W_v, W_v^\flat)$ of $\mathfrak{B}_v$: $A_v \colon G_1 \to [0,\infty]$ is measurable and left R-invariant, $A_v \leq a_v < \infty$, $\max(1, \ell(x)/b^{6n})^{3r^3 f}\|F(x)\| \leq A_v(x)$ for $F \in \{W_v, W_v^\flat\}$, and $a_v \int_{\mathsf{U}\setminus G_1} A_v \leq b^{400r^2} \# I_v$. Put $i = r^3 f$, $A(y) = \prod_v A_v(y_v)$ and $a = \prod_v a_v$. Taking the product over v of the bounds of (BS3),

$$\|W^\sigma(x)\| \leq m(x)^{-3i} A(x) \leq m(x)^{-3i} a \qquad (x \in G_\infty,\ \sigma \in \{\mathrm{full}, \mathrm{cut}\}).$$

Let $\gamma \in G(E)$, $y \in G_\infty$ and $z = \gamma^{-1}y$. If $D(\gamma,y) \neq 0$, then $W^{\mathrm{full}}(y) \neq W^{\mathrm{cut}}(y)$ or $W^{\mathrm{full}}(z) \neq W^{\mathrm{cut}}(z)$, so $W_v \neq W_v^\flat$ at y_v or at z_v for some v; by (BS2) that point has Bessel length $> b^{6n+2}/2$, so its factor in m exceeds $b^2/2 \geq b$, and as all factors are at least 1, $m(y)m(z) \geq b$. Since $\|K^\sigma(\gamma,y)\| = \|W^\sigma(y)\|\, \|W^\sigma(z)\| \leq m(y)^{-3i} A(y)\, m(z)^{-3i} a$, and $m(y)^{-3i} m(z)^{-3i} \leq (m(y)m(z))^{-2i} m(z)^{-i}$, we get in all cases

$$D(\gamma,y) \leq \|K^{\mathrm{full}}(\gamma,y)\| + \|K^{\mathrm{cut}}(\gamma,y)\| \leq 2\, b^{-2i}\, a\, A(y)\, m(\gamma^{-1}y)^{-i}.$$

Step 2: the sum over the terms. By (FG6), $k \geq 1000(2\varrho+2)^9 \geq 8n$, and $r \geq k$, so $i = r^3 f \geq 8nrf$. Hence Lemma 5.3.61 applies with this i and gives, for every $y \in G_\infty$,

$$\sum_{d\in\mathcal{C}} \sum_{\gamma \text{ over } (c,s,d)} \beta_d(\gamma^{-1}y)\, D(\gamma,y) \leq 2b^{-2i} a A(y) \sum_d \sum_\gamma \beta_d(\gamma^{-1}y)\, m(\gamma^{-1}y)^{-i} \leq 4\, b^{12n^3rf-2i}\, a\, A(y).$$

Step 3: unfolding along U_∞. For each v fix a Borel $\chi_v \colon G_1 \to [0,\infty]$ with $\int_{\mathsf{U}} \chi_v(ux)\, du = 1$ for every $x \in G_1$, so that $\int_{\mathsf{U}\backslash G_1} F = \int_{G_1} \chi_v F\, dx$ for every left U-invariant Borel $F \geq 0$ (Definition 5.1.6), and put $\chi(y) = \prod_v \chi_v(y_v)$; by Tonelli's theorem $\int_{\mathsf{U}_\infty} \chi(uy)\, du = 1$ for every y. A is left U_∞-invariant, as $\mathsf{U} \subseteq R$. Inserting this identity, substituting $y \mapsto u^{-1}y$ in the inner integral (the Cayley measures are left invariant, Lemma 5.2.41), interchanging the integrals (Tonelli), using that du is invariant under $u \mapsto u^{-1}$ (Lemma 5.2.34 (iv)) and then Lemma 5.2.33,

$$\begin{aligned}\int_{G_\infty} \beta_c A\, dy &= \int_{\mathsf{U}_\infty} \int_{G_\infty} \beta_c(u^{-1}y)\, \chi(y) A(y)\, dy\, du = \int_{G_\infty} \chi(y) A(y) \int_{\mathsf{U}_\infty} \beta_c(uy)\, du\, dy \\ &= \nu \int_{G_\infty} \chi A\, dy = \nu \prod_v \int_{\mathsf{U}\backslash G_1} A_v.\end{aligned}$$

Step 4: proof of (i). By Tonelli's theorem, Step 2 and Step 3, and then (BS3) and (FA7) ($\#I \leq b^{2kf}$),

$$\begin{aligned}\sum_d \sum_{\gamma \text{ over } (c,s,d)} \int \beta_c(y)\beta_d(\gamma^{-1}y) D(\gamma,y)\, dy &\leq 4\nu\, b^{12n^3rf-2i} \prod_v \Big(a_v \int_{\mathsf{U}\backslash G_1} A_v\Big) \\ &\leq 4\nu\, b^{12n^3rf+400r^2f-2r^3f}\, \#I \\ &\leq 4\nu\, b^{12n^3rf+400r^2f+2kf-2r^3f}.\end{aligned}$$

By (FG6), $k \geq 1000(2\varrho+2)^9 \geq 12n^3+500$ and $r \geq k+1 \geq 402$; so $12n^3r \leq r^2$, $2k+1 \leq r^2$, $402r^2 \leq r^3$ and $k^3 \leq r^3$, whence, with $f \geq 1$, $1 + (12n^3r + 400r^2 + 2k + k^3)f \leq (402r^2 + r^3)f \leq 2r^3 f$. As $8 \leq b$ (FG2), $8\, b^{12n^3rf+400r^2f+2kf+k^3f} \leq b^{2r^3f}$, and the right side above is at most $\nu/(2b^{k^3f})$. This proves (i).

Step 5: proof of (ii). Let $c' \in \mathcal{C}$ and $\sigma \in \{\mathrm{full}, \mathrm{cut}\}$. By Lemma 5.2.29 (ii), applied with $(F_v)_v = (W_v)_v$ and with $(F_v)_v = (W_v^\flat)_v$, the amplitude majorants $\int \beta_c(y)\beta_{c'}(\gamma^{-1}y)\|K^\sigma(\gamma,y)\|\, dy$ of the terms $\gamma \in T$ over (c,s,c') have a finite sum. So for each such γ the measurable function $y \mapsto \beta_c(y)\beta_{c'}(\gamma^{-1}y)K^\sigma(\gamma,y)$ is integrable, its Bochner integral is the amplitude $A^\sigma_\gamma(c,c')$ with $\|A^\sigma_\gamma(c,c')\|$ at most its majorant, and the series $A^\sigma_T(c,s,c') = \sum_\gamma A^\sigma_\gamma(c,c')$ converges absolutely. Subtracting the two absolutely convergent series term by term, and using linearity of the Bochner integral and $\|\int g\| \leq \int \|g\|$,

$$\begin{aligned}\|A^{\mathrm{full}}_T(c,s,c') - A^{\mathrm{cut}}_T(c,s,c')\| &= \Big\|\sum_\gamma \int \beta_c(y)\beta_{c'}(\gamma^{-1}y)(K^{\mathrm{full}} - K^{\mathrm{cut}})(\gamma,y)\, dy\Big\| \\ &\leq \sum_{\substack{\gamma\in T \\ \text{over } (c,s,c')}} \int \beta_c(y)\beta_{c'}(\gamma^{-1}y) D(\gamma,y)\, dy.\end{aligned}$$

Summing over $c' \in \mathcal{C}$ and applying (i) gives (ii). □

Lemma 5.3.63. *Let $\mathfrak{S}$ be an admissible filling datum and $\gamma \in G(E)$. Put $x = \prod_{v\in\Phi} |\mathsf{g}(\gamma)|_v$ and, for $x > 0$, $\mathrm{ob}(x) = \tau_{\mathrm{sz}}^2 \sqrt{\mathcal{D}_{\mathrm{main}}/(n_p(M^{2\varrho f}x)^k)}$.*

(i) If γ is a term over some (c,s,c') and $\mathsf{g}(\gamma) \neq 0$, then $x \geq 1$.

(ii) If E carries Weil data, γ is a near term and $x \geq 1$, then $b^{-k^3 f} \leq \mathrm{ob}(x)$.

(iii) If $x \geq 1$, then $\prod_{v\in\Phi} \mathrm{PB}(\gamma_v, \deg_v, b^{37n}, \#I_v) \leq \big(\nu\,\mathrm{ob}(x)/2\big)^2$.

Proof. Write $e_1 = 10^5 n^4$ and $g_v = v(\mathsf{g}(\gamma))$.

(i) Let γ be a term over (c, s, c'), $k_0 = h_c^{-1}\gamma h_{c'} \in K$. The frame vectors are lattice basis vectors fixed by h_c and $h_{c'}$, so $h(f_a, \gamma f_b) = h(h_c^{-1}f_a, k_0 h_{c'}^{-1} f_b) = h(f_a, k_0 f_b) \in h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24 (i), (ii). So the entries of $Z(\gamma)$ lie in $E \cap \hat{\mathcal{O}} = \mathcal{O}_E$, hence $D_{\varrho+1}(\gamma), D_\varrho(\gamma) \in \mathcal{O}_E$ and $\mathsf{g}(\gamma) \in \mathcal{O}_E$. If $\mathsf{g}(\gamma) \neq 0$, its norm is a nonzero rational integer, and since the embeddings of E are the $v \in \Phi$ and their conjugates, $x^2 = \prod_v |\mathsf{g}(\gamma)|_v^2 = |\mathrm{N}_{E/\mathbb{Q}}\mathsf{g}(\gamma)| \geq 1$.

(ii) As $x \geq 1$, $\mathsf{g}(\gamma) \neq 0$, so it is totally positive by Lemma 5.2.26 (ii): $0 < g_v = |v(D_{\varrho+1})|^2 - N^2|v(D_\varrho)|^2 \leq |D_{\varrho+1}(\gamma)|_v^2 \leq b^{270n^2}$ by Lemma 5.2.20. So $x \leq b^{270n^2 f}$. Next $n_p = \#\bar{R}_0 \#\mathcal{C}/N^{kf} \leq \#\bar{R}_0\#\mathcal{C}\#I = \mathcal{D}_{\mathrm{id}} \leq \mathcal{D}_{\mathrm{main}}$ by (FA6), and $\tau_{\mathrm{sz}} \geq 1$; with $M \leq b^{23}$ (FG6),

$$\mathrm{ob}(x) \geq (M^{2\varrho f} x)^{-k/2} \geq b^{-(46\varrho + 270n^2)fk/2} \geq b^{-k^3 f},$$

since $(46\varrho + 270n^2)k \leq 316n^2 k \leq 2k^3$ by $k \geq 1000(2\varrho+2)^9$ (FG6).

(iii) *The real Gram discriminant.* By Lemma 5.3.36 (ii),

$$\mathsf{g}_1(Z(\gamma_v)) = s_v^2\, g_v, \qquad s_v = \prod_{a=0}^{\varrho} \mathrm{fs}(v, a).$$

As $x \geq 1$, $\mathsf{g}(\gamma)$ is totally positive (Lemma 5.2.26 (ii)), so $g_v > 0$ and $\prod_v g_v = x$.

Splitting off x. With $\rho = b^{37n}$ and $d_v = \#I_v$, the definition of PB gives $\mathrm{PB}(\gamma_v, \deg_v, \rho, d_v) = C_v\, g_v^{-(e_1+k-1)}$ with

$$C_v = \Big(\frac{\rho^{9n}}{s_v^2}\Big)^{e_1} \frac{2^{k-1} d_v^2}{\deg_v c_G\, s_v^{2(k-1)}}.$$

Since $x \geq 1$ and $e_1 + k - 1 \geq k$, $\prod_v \mathrm{PB}(\gamma_v, \deg_v, \rho, d_v) \leq x^{-k} \prod_v C_v$.

Frame scales. By (FA4) and (FA5), $b^{-60n} \leq N^{-1} \leq \mathrm{fs}(v,a) \leq b^{46n}$, so $b^{-60n^2} \leq s_v \leq b^{46n^2}$ and $\mathrm{fs}(v,a)^{2(\varrho-a)} \leq b^{92n^2}$; hence $\Lambda_v = \prod_a \mathrm{fs}(v,a)^{k+2(\varrho-a)} \leq s_v^k b^{92n^3}$, and $\Lambda_{\mathrm{fr}} = \prod_v \Lambda_v$. Using $\rho^{9n}/s_v^2 \leq b^{453n^2}$, $s_v^{-2(k-1)} = s_v^2 s_v^{-2k} \leq b^{92n^2} b^{184n^3} \Lambda_v^{-2}$ and $2^{k-1} \leq 2^k$,

$$C_v \leq 2^k b^e \frac{d_v^2}{\deg_v c_G \Lambda_v^2}, \qquad e = 453n^2 e_1 + 92n^2 + 184n^3 \leq 10^5 n^9 \leq k/4,$$

the last two by $n \geq 10^5$ and $k \geq 1000(2n)^9$ (FG6). Multiplying over the f places, with $b^{ef} \leq b^{kf/4} = \tau_{\mathrm{sz}}$,

$$\prod_v C_v \leq 2^{kf} \tau_{\mathrm{sz}} \frac{\#I^2}{\deg\, c_G^f\, \Lambda_{\mathrm{fr}}^2} \leq 2^{kf} \tau_{\mathrm{sz}}\,(1 + b^{-9}) \frac{\mathcal{D}_{\mathrm{main}}\, \nu^2}{c_S^\sharp\, \mathrm{vol}(\hat{\mathcal{O}})^n},$$

the second inequality being (FA9) rearranged.

The Siegel constant. By the definitions, $c_S^\sharp = \#\bar{R}_0 M^{f\varrho(2k+2\varrho+1)} \#\mathcal{C}\, c_S$ and $n_p = \#\bar{R}_0\#\mathcal{C}/N^{kf}$, so, with $M \geq 1$, $\pi^k \geq 1$, $|\mathrm{disc}\, E| \geq 1$ and $\mathrm{vol}(\hat{\mathcal{O}}) = (2/\mathrm{rd}_E)^f \geq \mathrm{rd}_E^{-f}$,

$$\frac{c_S^\sharp\, \mathrm{vol}(\hat{\mathcal{O}})^n}{n_p M^{2\varrho fk}} \geq N^{kf} c_S\, \mathrm{vol}(\hat{\mathcal{O}})^n = \Big(\frac{\pi^k}{(k-1)!}\Big)^f |\mathrm{disc}\, E|^{1/4} \mathrm{vol}(\hat{\mathcal{O}})^{k+n} \geq \frac{1}{k^{kf}\, \mathrm{rd}_E^{f(k+n)}}.$$

Let $X = 200fk\,\mathrm{rd}_E$; then $2, k, \mathrm{rd}_E \leq X$ (as $\mathrm{rd}_E \geq 1$), $n \leq k$ and $X^{1000} \leq b$ (FG6), so $2^{kf} k^{kf} \mathrm{rd}_E^{f(k+n)} \leq X^{4kf} \leq b^{kf/4} = \tau_{\mathrm{sz}}$. Hence $2^{kf} n_p M^{2\varrho fk} \leq \tau_{\mathrm{sz}}\, c_S^\sharp \mathrm{vol}(\hat{\mathcal{O}})^n$.

Conclusion. Combining, $\prod_v \mathrm{PB}(\gamma_v, \deg_v, \rho, d_v) \le (1+b^{-9})\tau_{\mathrm{sz}}^2\nu^2\mathcal{D}_{\mathrm{main}}/(n_p M^{2\varrho fk}x^k)$, while $(\nu\,\mathrm{ob}(x)/2)^2 = \nu^2\tau_{\mathrm{sz}}^4\mathcal{D}_{\mathrm{main}}/(4n_pM^{2\varrho fk}x^k)$. As $\tau_{\mathrm{sz}} \ge b \ge 1000$ (FG2), $4(1+b^{-9}) \le \tau_{\mathrm{sz}}^2$, which proves (iii). □

Proposition 5.3.64. *Let $\mathfrak{S}$ be a filling datum with Weil data, $s \in \bar{G}$ agreeing, $x \in \mathbb{N}$ with $x \le$ the meet norm of s, and γ, γ' terms over (c, s, c') of cell ranks j, j'. Put $\epsilon = x$ if $\varrho < j$ and $c^+ = 0$, and $\epsilon = 1$ otherwise. Then*

$$\big(\mathrm{disc}(L_{12})\,\epsilon\big)^2 \le (2/M)^{2c^+f}\,\mathfrak{g}^*(j,c,c',\gamma)\,\mathfrak{g}^*(j',c,c',\gamma').$$

Proof. Write $k = h_c^{-1}\gamma h_{c'}$, $k' = h_c^{-1}\gamma' h_{c'}$, $m = \dim_E X_0(\gamma,\gamma')$, and let P, P' be the common parts of γ with γ' and of γ' with γ at c. The space $X_0(\gamma,\gamma')$, the link corank c^+ and the pair lattice L_{12} are symmetric in γ, γ'. Put $\epsilon = x$ if $\varrho < j$ and $c^+ = 0$, and $\epsilon = 1$ otherwise; then ϵ is at most the meet norm of s (which is a product of primes, hence ≥ 1).

Step 1 (splittings). By Proposition 5.3.5 for $(\gamma, \gamma', j, \epsilon)$: $\mathrm{ti}(k) \ge 1$, P is a lattice of rank m, and there are q, y, ϵ_1, σ as there with

$$\big(\mathrm{ti}(k)\,\mathrm{disc}_m(P)\,\epsilon\big)^2\,\mathrm{lkd}(y,\epsilon_1) \le \mathfrak{g}^*(j,c,c',\gamma)^2. \tag{5.71}$$

The same applies to $(\gamma', \gamma, j', \epsilon)$: if $\epsilon \ne 1$ then $\varrho < j$ and $c^+ = 0$, so $\mathfrak{g}(\gamma) \ne 0$ by the conditions of cell rank j and $\mathrm{link}\,\gamma = \mathrm{link}\,\gamma'$ by Lemma 5.3.13 (iv); then $\mathfrak{g}(\gamma') \ne 0$ by Lemma 5.3.13 (v), hence $\varrho < j'$. This gives $\mathrm{ti}(k') \ge 1$, P' a lattice of rank m, and $q', y', \epsilon_1', \sigma'$ with

$$\big(\mathrm{ti}(k')\,\mathrm{disc}_m(P')\,\epsilon\big)^2\,\mathrm{lkd}(y',\epsilon_1') \le \mathfrak{g}^*(j',c,c',\gamma')^2.$$

Step 2 (congruence). Let $w_l = \sum_\rho \sigma_{\rho l} q_\rho + \sum_a (\epsilon_1)_{al} y_a$ and w_l' likewise; they have integral lifts for (c,γ) and (c,γ'), so $M^{-1}\langle w_l, w_{l'}'\rangle_{\mathrm{lk}} \in \hat{\mathcal{O}}$ by Lemma 5.3.65 (i). The q_ρ, q_ρ' lie in both links, the y_a in $\mathrm{link}\,\gamma$ and the y_b' in $\mathrm{link}\,\gamma'$; as each link is isotropic for the link form (Lemma 5.2.28 (iv)), $\langle q_\rho, q_{\rho'}'\rangle_{\mathrm{lk}} = \langle q_\rho, y_b'\rangle_{\mathrm{lk}} = \langle y_a, q_{\rho'}'\rangle_{\mathrm{lk}} = 0$. Hence the matrix $(\langle w_l, w_{l'}'\rangle_{\mathrm{lk}})$ is $\epsilon_1^*\Lambda\epsilon_1'$ with $\Lambda = (\langle y_a, y_b'\rangle_{\mathrm{lk}})_{a,b<c^+}$, and $\epsilon_1^*(M^{-1}\Lambda)\epsilon_1'$ is integral. Moreover $\det\Lambda \ne 0$: if $\Lambda\tau = 0$, then $u = \sum_b \tau_b y_b' \in \mathrm{link}\,\gamma'$ is orthogonal for the link form to every y_a and to every $q_\rho \in \mathrm{link}\,\gamma'$, hence to $\mathrm{link}\,\gamma$, which q and y span; by Lemma 5.2.28 (iv) $u \in \mathrm{link}\,\gamma$, so $u \in \mathrm{link}\,\gamma \cap \mathrm{link}\,\gamma'$ and $\tau = 0$ by (i) of Proposition 5.3.5 for γ'. By Lemma 5.3.65 (ii) with $i = c^+$,

$$1 \le (2/M)^{4c^+f}\,\mathrm{lkd}(y,\epsilon_1)\,\mathrm{lkd}(y',\epsilon_1').$$

Step 3 (combination). With $d = \mathrm{ti}(k)\mathrm{disc}_m(P)\epsilon \ge 0$ and $d' = \mathrm{ti}(k')\mathrm{disc}_m(P')\epsilon \ge 0$, Steps 1 and 2 give

$$(dd')^2 \le (dd')^2(2/M)^{4c^+f}\mathrm{lkd}(y,\epsilon_1)\mathrm{lkd}(y',\epsilon_1') \le (2/M)^{4c^+f}\,\mathfrak{g}^*(j,c,c',\gamma)^2\,\mathfrak{g}^*(j',c,c',\gamma')^2,$$

so, both sides being squares of nonnegative numbers, $dd' \le (2/M)^{2c^+f}\mathfrak{g}^*(j,c,c',\gamma)\,\mathfrak{g}^*(j',c,c',\gamma')$.

Step 4 (index). By Lemma 5.3.4 (ii) for (γ,γ') and for (γ',γ) (the pair lattice is the same), $0 \le \mathrm{disc}(L_{12}) \le \mathrm{disc}_m(P)\,\mathrm{ti}(k')$ and $\mathrm{disc}(L_{12}) \le \mathrm{disc}_m(P')\,\mathrm{ti}(k)$. Multiplying, $(\mathrm{disc}(L_{12})\,\epsilon)^2 \le dd'$, and Step 3 gives the claim. □

Lemma 5.3.65. *Let $\mathfrak{S}$ be a filling datum, $c, c' \in \mathcal{C}$, $s \in \bar{G}$, and γ, γ' terms over (c, s, c').*

(i) If the family $w = (w_l)_{l\in\sigma}$ has integral lifts for (c,γ) and $w' = (w_{l'}')_{l'\in\sigma'}$ has integral lifts for (c,γ'), then $M^{-1}\langle w_l, w_{l'}'\rangle_{\mathrm{lk}} \in \hat{\mathcal{O}}$ for all l, l'.

(ii) Let $i \geq 0$, let $y = (y_l)_{l<i}$ be pairs in $\operatorname{link}\gamma$ and $y' = (y'_l)_{l<i}$ pairs in $\operatorname{link}\gamma'$, and $\epsilon, \epsilon' \in \mathrm{GL}_i(\mathbb{A}_f)$. Suppose that the matrix $\Lambda = (\langle y_l, y'_{l'}\rangle_{\mathrm{lk}})_{l,l'}$ has $\det\Lambda \neq 0$ and that $\epsilon^*(M^{-1}\Lambda)\epsilon'$ is integral. Then

$$1 \leq \Big(\frac{2}{M}\Big)^{4if} \operatorname{lkd}(y,\epsilon)\operatorname{lkd}(y',\epsilon').$$

Proof. (i). By (LK5) there are vectors $t_\rho \perp X + \gamma X$, $t'_{\rho'} \perp X + \gamma' X$ and adelic coefficients u, u' with $n_l = \sum_\rho u_{\rho l} t_\rho \in L_c$, $n'_{l'} = \sum_{\rho'} u'_{\rho' l'} t'_{\rho'} \in L_c$, $w_l = \sum_\rho u_{\rho l}([t_\rho],[\gamma^{-1}t_\rho])$ and similarly for w'. For vectors q, q' of V orthogonal to $X = \langle e_1, \dots, e_\varrho\rangle$ the e_a^*-coordinates vanish, and the e_a-coordinates pair only with them, so $h(q,q') = h([q],[q'])$. Applied to (t,t') and to $(\gamma^{-1}t, \gamma'^{-1}t')$ for $t \perp X + \gamma X$, $t' \perp X + \gamma' X$, and with $\delta = \gamma\gamma'^{-1}$,

$$\big\langle([t],[\gamma^{-1}t]),([t'],[\gamma'^{-1}t'])\big\rangle_{\mathrm{lk}} = h(t,t') - h(\gamma^{-1}t, \gamma'^{-1}t') = h(t,t') - h(t,\delta t').$$

By sesquilinearity, $\langle w_l, w'_{l'}\rangle_{\mathrm{lk}} = h(n_l, n'_{l'}) - h(n_l, \delta n'_{l'}) = -h\big(n_l, (\delta-1)n'_{l'}\big)$. Let $k = h_c^{-1}\gamma h_{c'}$, $k' = h_c^{-1}\gamma' h_{c'}$; they lie in K with $\operatorname{red}(k) = \operatorname{red}(k') = s$. By Lemma 5.2.24 (ii) K is a group, and red (entrywise reduction) is multiplicative, so $kk'^{-1} = h_c^{-1}\delta h_c \in K$ with reduction 1, i.e. $kk'^{-1} \in K(M)$. By Lemma 5.2.24 (iii), $(kk'^{-1}-1)L_0 \subseteq ML_0$, so $(\delta-1)L_c = h_c(kk'^{-1}-1)L_0 \subseteq ML_c$. Since h_c is an isometry, $h(L_c,L_c) = h(L_0,L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24 (i). Hence $\langle w_l, w'_{l'}\rangle_{\mathrm{lk}} \in h(L_c, ML_c) \subseteq M\hat{\mathcal{O}}$.

(ii), the pairing in the positive space. Put $a_l = y_l^{\mathrm{s}}$, $b_l = y_l'^{\mathrm{s}} \in V_0^+$, and $\tilde{b}_l = \Upsilon_\gamma^{-1}\Upsilon_{\gamma'} b_l$, with the link isometries of Lemma 5.2.28 (iii); so $y_l^{\mathrm{t}} = \Upsilon_\gamma a_l$ and $y_l'^{\mathrm{t}} = \Upsilon_{\gamma'} b_l = \Upsilon_\gamma \tilde{b}_l$. By Lemma 5.2.28 (iv) and since Υ_γ is an isometry,

$$\Lambda_{ll'} = \langle a_l, b_{l'}\rangle_+ - \langle \Upsilon_\gamma a_l, \Upsilon_\gamma \tilde{b}_{l'}\rangle_+ = \langle a_l,\, b_{l'} - \tilde{b}_{l'}\rangle_+.$$

For a family $x = (x_l)$ in V_0^+ write $G(x) = (\langle x_l, x_{l'}\rangle_+)$. By Lemma 5.2.28 (ii), $G(a)$ and $G(b)$ are the Gram matrices of y and y' for the link metric, so $\operatorname{lkd}(y,\epsilon) = |N\det G(a)|[\det\epsilon]^2$ and likewise for y' ($N = N_{E/\mathbb{Q}}$).

Liouville. In the basis of V_0^+ formed by the standard basis of X_0 and z^+, $\langle\cdot,\cdot\rangle_+$ has the matrix $\operatorname{diag}(1,\dots,1,N)$, positive definite at every infinite place. Apply Lemma 5.3.14 to the coordinate matrices of $(M^{-1}a_l)_l$ and $(b_l - \tilde{b}_l)_l$, with $v = \epsilon$, $v' = \epsilon'$ and $x = 1$: the pairing matrix is $M^{-1}\Lambda$ (M is real), with $\det(M^{-1}\Lambda) \neq 0$; and $\delta = \det(\epsilon^* M^{-1}\Lambda\,\epsilon')$ is a unit of $\mathbb{A}_f$ lying in $\hat{\mathcal{O}}$ by hypothesis, so $[\delta] = [\hat{\mathcal{O}} : \delta\hat{\mathcal{O}}] \geq 1$. Hence

$$1 \leq [\det\epsilon]^2\,\big|N\det(M^{-2}G(a))\big|\,\big|N\det G(b-\tilde{b})\big|\,[\det\epsilon']^2,$$
$$\big|N\det(M^{-2}G(a))\big| = M^{-4if}|N\det G(a)|.$$

The difference. $\Upsilon_\gamma^{-1}\Upsilon_{\gamma'}$ is an isometry, so $G(\tilde{b}) = G(b)$ and $G(b-\tilde{b}) + G(b+\tilde{b}) = 2G(b) + 2G(\tilde{b}) = 4G(b)$. At an infinite place w, $\Phi_w G(b+\tilde{b})$ is positive semidefinite, so $0 \leq \Phi_w G(b-\tilde{b}) \leq 4\,\Phi_w G(b)$ in the order of hermitian matrices, and the determinant is monotone on positive semidefinite matrices: $0 \leq \det\Phi_w G(b-\tilde{b}) \leq 4^i \det\Phi_w G(b)$. As $|N\alpha| = \prod_w |\Phi_w\alpha|^2$, $|N\det G(b-\tilde{b})| \leq 4^{2if}|N\det G(b)|$. Inserting,

$$1 \leq M^{-4if}\,4^{2if}\,|N\det G(a)|[\det\epsilon]^2\,|N\det G(b)|[\det\epsilon']^2 = \Big(\frac{2}{M}\Big)^{4if}\operatorname{lkd}(y,\epsilon)\operatorname{lkd}(y',\epsilon').$$

□

The third input of the pair bound is the count Proposition 5.3.66: weighted by $\operatorname{disc}(L_{12})^{-k}$, the pairs near over an agreeing block whose common definite part has dimension $k-l$ and whose pair discriminant is at most $b^{n^3 f}$ have total at most $\tau^{l+2} n_p$. The count has two steps. The first passes from pairs of terms to lattices: few near terms of one label contain a given lattice of bounded discriminant in their term lattice (Lemma 5.3.67), by the geometry of the frame-fixing moves and a count of algebraic integers in a box. The second sums inverse powers of the discriminant over the lattices of given corank in the definite class lattices (Lemma 5.3.78). After an averaging of the classes, the sum over subspaces is a height zeta sum, bounded by Siegel's lemma relative to a unimodular adelic lattice (Lemma 5.3.82) through an adelic form of Minkowski's second theorem [52] (Lemma 5.3.83), and the sum over sublattices of finite index is a sublattice zeta bound (Lemma 5.3.84). For the adelic form of Siegel's lemma and heights of subspaces see [32, 31]; zeta functions counting sublattices are a classical tool of integral representation theory [286], and the counting of subspaces of bounded height is in the tradition of Schmidt [252].

Proposition 5.3.66. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data. For $c, c' \in \mathcal{C}$ call a pair (γ, γ')* near over an agreeing block *for (c, c') if γ and γ' are near representatives for (c, c'), each satisfying the conditions of some cell rank, and both are terms over one (c, s, c') with s agreeing. Then for every integer $0 \le l \le n^3$,*

$$\sum_{c,c' \in \mathcal{C}} \sum_{(\gamma,\gamma')} \operatorname{disc}(L_{12})^{-k} \le \tau_{\mathrm{sz}}^{l+2}\, n_p,$$

the inner sum over the pairs near over an agreeing block for (c, c') with $\dim_E X_0(\gamma, \gamma') + l = k$ and $\operatorname{disc}(L_{12}) \le b^{n^3 f}$.

Proof. Fix $l \le n^3$. If $l > k$ no pair satisfies $\dim_E X_0(\gamma, \gamma') + l = k$ and the sum is 0; let $l \le k$ and $r = k - l$. Put $B = b^{n^3 f}$ and $Q = b^{2000 n^6 (l+1) f}$. Fix a representative of every left coset of $\bar{R}_0$ in $\bar{G}$, and labels as in Lemma 5.3.67.

Each pair gives a labelled lattice. Let (γ, γ') be near over the agreeing block (c, s, c'), of cell ranks j, j', with $\dim_E X_0(\gamma, \gamma') = r$ and $\operatorname{disc}(L_{12}) \le B$, and let t be the label of s. By Proposition 5.3.5 for (γ, γ') with $x = 1$, the common part P of γ with γ' at c is a lattice of rank r; by Proposition 5.3.5 for (γ', γ) with $x = 1$, $\operatorname{ti}(h_c^{-1} \gamma' h_{c'}) \ge 1$. By Lemma 5.3.4 (ii), L_{12} is a lattice of rank r and $\operatorname{disc}_r(L_{12}) = \operatorname{disc}(L_{12}) \ge 1$. By (LT4), $L_{12} \subseteq \operatorname{sat}_c(X_0(\gamma, \gamma')) \subseteq L_c \cap X_0(\mathbb{A}_f)$ and $L_{12} \subseteq L_c(\gamma) \cap L_c(\gamma')$. So L_{12} lies in the set $\mathcal{L}_c$ of lattices $L \subseteq L_c \cap X_0(\mathbb{A}_f)$ of rank r with $\operatorname{disc}_r(L) \le B$, and both (c', γ) and (c', γ') lie in the set $S(t, L_{12})$ of pairs counted in Lemma 5.3.67 for c, t and $L = L_{12}$.

Counting. Fix c. The map $(c', \gamma, \gamma') \mapsto (t, L_{12}, (c', \gamma), (c', \gamma'))$ is injective, and for fixed $(t, L) \in \bar{R}_0 \times \mathcal{L}_c$ the last two entries of an image lie in $S(t, L)$, which has at most Q elements by Lemma 5.3.67. Hence at most Q^2 triples have the image (t, L) in the first two entries, all with summand $\operatorname{disc}_r(L)^{-k}$, and

$$\sum_{c'} \sum_{(\gamma,\gamma')} \operatorname{disc}(L_{12})^{-k} \le \#\bar{R}_0\, Q^2 \sum_{L \in \mathcal{L}_c} \operatorname{disc}_r(L)^{-k}.$$

As $l + 1 \le 2n^3$, $Q^2 \le b^{8000 n^9 f}$, and by (FG6) $k \ge 1000(2\varrho + 2)^9 = 2^9 \cdot 1000\, n^9 \ge 32000\, n^9$, so $Q^2 \le b^{kf/4} = \tau_{\mathrm{sz}}$ ($b \ge 1$). Summing over c and applying Lemma 5.3.78,

$$\sum_{c,c'} \sum_{(\gamma,\gamma')} \operatorname{disc}(L_{12})^{-k} \le \#\bar{R}_0\, \tau_{\mathrm{sz}}\, \frac{\#\mathcal{C}}{N^{kf}}\, \tau_{\mathrm{sz}}^{l+1} = \tau_{\mathrm{sz}}^{l+2}\, n_p.$$

□

Lemma 5.3.67. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data. Fix a representative of every left coset of $\bar{R}_0$ in $\bar{G}$, and call* label *of $s \in \bar{G}$ the element $t \in \bar{R}_0$ with $s = r_0 t$, r_0 the representative of $s\bar{R}_0$. Let $c \in \mathcal{C}$, $t \in \bar{R}_0$, integers $r, l \geq 0$ with $r + l = k$, and $L \subseteq L_c \cap X_0(\mathbb{A}_f)$ a lattice of rank r with $\mathrm{disc}_r(L) \leq b^{n^3 f}$. Then at most $b^{2000n^6(l+1)f}$ pairs $(c', \gamma) \in \mathcal{C} \times G(E)$ have the following properties: γ is a near representative for (c, c') satisfying the conditions of some cell rank; γ is a term over (c, s, c') for some s of label t; and $L \subseteq L_c(\gamma)$.*

Proof. Let P be the set of pairs of the statement. For $(c', \gamma) \in P$ the cell rank $j(\gamma)$ of γ satisfies the conditions of cell rank $j(\gamma)$ (TA5), and γ is a near term. For $0 \leq j \leq \varrho + 1$ and a matrix Z let $P_{j,Z}$ be the set of $(c', \gamma) \in P$ with $j(\gamma) = j$ and $Z(\gamma) = Z$.

Each class is small. By Lemma 5.3.68 (all pairs of P have the label t), if $(c_1, \gamma_1), (c_2, \gamma_2) \in P$ and $u_1, u_2 \in \mathsf{U}_c^0(M)$ satisfy $u_1 \gamma_1 f_a = u_2 \gamma_2 f_a$ for all a, the pairs are equal. So each $P_{j,Z}$ satisfies the hypotheses of Lemma 5.3.70 for c, j, r, l and L, and

$$\#P_{j,Z} \leq b^{ef}, \qquad e = 366n^4 + 2n^3(\varrho + ln + n\varrho).$$

Few classes. There are $\varrho + 2$ values of j, and $\varrho + 2 \leq b + 1 \leq b^2 \leq b^{2f}$ as $\varrho + 1 \leq b$ (FG6) and $b \geq 2$. By Lemma 5.3.69 at most $b^{270n^3 f}$ matrices Z occur, since every γ is a near term over some (c, s, c'). Hence

$$\#P \leq b^{2f}\, b^{270n^3 f}\, b^{ef}.$$

As $\varrho < n$, $\varrho + ln + n\varrho \leq n^2(l+2)$, so $2n^3(\varrho + ln + n\varrho) \leq 4n^5(l+1)$, and $2 + 270n^3 + 366n^4 \leq 638n^4 \leq 638n^5(l+1)$. So the exponent is at most $642n^5(l+1)f \leq 2000n^6(l+1)f$, and $\#P \leq b^{2000n^6(l+1)f}$ as $b \geq 1$. □

Lemma 5.3.68. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, with a fixed representative of every left coset of $\bar{R}_0$ in $\bar{G}$, and let $c \in \mathcal{C}$, $t \in \bar{R}_0$. For $i = 1, 2$ let $(c_i, \gamma_i) \in \mathcal{C} \times G(E)$ be such that γ_i is a near representative for (c, c_i) satisfying the conditions of some cell rank, and a term over (c, s_i, c_i) for some s_i of label t. If $u_1, u_2 \in \mathsf{U}_c^0(M)$ satisfy $u_1 \gamma_1 f_a = u_2 \gamma_2 f_a$ for $0 \leq a \leq \varrho$, then $c_1 = c_2$ and $\gamma_1 = \gamma_2$.*

Proof. **Step 1: the moved elements are terms.** For $u \in \mathsf{U}_c^0(M)$, $h_c^{-1} u h_c \in \mathrm{K}(M) \subseteq K$ has reduction 1, so $h_c^{-1}(u\gamma_i)h_{c_i} = (h_c^{-1} u h_c)(h_c^{-1}\gamma_i h_{c_i}) \in K$ has reduction s_i: $u_i\gamma_i$ is a term over (c, s_i, c_i), $i = 1, 2$.

Step 2: equal reductions. As $u_1\gamma_1$ and $u_2\gamma_2$ have the same frame image, Lemma 5.2.32 (i) gives $s_2^{-1} s_1 \in \bar{R}_0$, so $s_1\bar{R}_0 = s_2\bar{R}_0$ and s_1, s_2 have the same coset representative r_0. Both have the label t, so $s_1 = r_0 t = s_2$.

Step 3: one class and one double coset. By Lemma 5.2.32 (ii) for $u_1\gamma_1$ and $u_2\gamma_2$, terms over (c, s_1, c_1) and (c, s_1, c_2) with the same frame image, $c_1 = c_2 =: c'$ and $\delta = (u_1\gamma_1)^{-1} u_2 \gamma_2 \in \mathsf{U}_{c'}^0(M)$. Hence $\gamma_2 = u_2^{-1} u_1 \gamma_1 \delta \in \mathsf{U}_c^0(M)\, \gamma_1\, \mathsf{U}_{c'}^0(M)$. Both γ_1 and γ_2 are near representatives for (c, c'), so both lie in $R_{c,c'}$, which contains exactly one element of each double coset $\mathsf{U}_c^0(M) \backslash G(E) / \mathsf{U}_{c'}^0(M)$. Therefore $\gamma_1 = \gamma_2$. □

Lemma 5.3.69. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, and $c \in \mathcal{C}$. The set of matrices $Z(\gamma)$, γ a near term that is a term over (c, s, c') for some $s \in \bar{G}$ and $c' \in \mathcal{C}$, has at most $b^{270n^3 f}$ elements.*

Proof. Let γ be a near term that is a term over (c, s, c'), and $0 \leq a, b' \leq \varrho$.

Integrality. With $k_0 = h_c^{-1}\gamma h_{c'} \in K$, and since the frame vectors are lattice basis vectors fixed by $h_c, h_{c'}$, $h(f_a, \gamma f_{b'}) = h(f_a, k_0 f_{b'}) \in h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24 (i), (ii); so $Z(\gamma)_{ab'} \in E \cap \hat{\mathcal{O}} = \mathcal{O}_E$.

Size. As γ is a near term, there is a boxed $y \in G_\infty$ (with $\gamma^{-1}y$ boxed), and Lemma 5.3.75 (iii), applied to y, gives $|v(Z(\gamma)_{ab'})| \le B := b^{73n}$ for every $v \in \Phi$.

Counting integers. By Lemma 5.3.77, at most $(1+2B)^{2f}$ elements $\alpha \in \mathcal{O}_E$ satisfy $|v(\alpha)| \le B$ for all $v \in \Phi$.

Conclusion. Each of the n^2 entries of $Z(\gamma)$ is one of at most $(1+2B)^{2f}$ integers, and $1 + 2b^{73n} \le 3b^{73n} \le b^{74n}$ ($b \ge 1000$, (FG2)). So at most $(b^{74n})^{2fn^2} = b^{148n^3 f} \le b^{270n^3 f}$ matrices occur. □

Lemma 5.3.70. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, $c \in \mathcal{C}$, $0 \le j \le \varrho + 1$, integers $r, l \ge 0$ with $r + l = k$, and $L \subseteq L_c \cap X_0(\mathbb{A}_f)$ a lattice of rank r with $\mathrm{disc}_r(L) \le b^{n^3 f}$. Let $B \subseteq \mathcal{C} \times G(E)$ be a set of pairs (c', γ) such that: every γ is a near term, a term over (c, s, c') for some s, and satisfies the conditions of cell rank j; all the matrices $Z(\gamma)$ are equal; $L \subseteq L_c(\gamma)$ for all; and whenever $(c_1, \gamma_1), (c_2, \gamma_2) \in B$ and $u_1, u_2 \in \mathsf{U}_c^0(M)$ satisfy $u_1\gamma_1 f_a = u_2\gamma_2 f_a$ for $0 \le a \le \varrho$, the two pairs are equal. Then*

$$\#B \le b^{(366n^4 + 2n^3(\varrho + ln + n\varrho))f}.$$

Proof. For $p = (c', \gamma) \in B$ write $\gamma_p = \gamma$, and let s_p be such that γ_p is a term over (c, s_p, c'). Let Z be the common matrix $Z(\gamma_p)$, $Z_<$ its first ϱ rows, and $D = D_j(Z)$, nonzero by (TA5). By Lemma 5.3.74 (iii), Z has entries in $\mathcal{O}_E$. Put $d = MD$ and $d' = MD\bar{D}$, nonzero elements of $\mathcal{O}_E$.

The three moduli. By (FG6), $M \le b^{23}$, and by Lemma 5.2.20 (each γ_p is a near term) $|v(D)|^2 \le b^{270n^2}$ for all $v \in \Phi$. Hence

$$[d] = \prod_v M^2 |v(D)|^2 \le b^{(46+270n^2)f} \quad \text{and} \quad [d'] = \prod_v M^2 |v(D)|^4 \le b^{(46+540n^2)f};$$

as $n \ge 10^5$, $46 + 540n^2 \le 2n^3$, so

$$[d] \le b^{2n^3 f}, \qquad [d'] \le b^{2n^3 f}, \qquad \mathrm{disc}_r(L)^2 \le b^{2n^3 f}.$$

First round: lifts of L. Write $L = ya\,\hat{\mathcal{O}}^r$ with $y \in \mathrm{M}_{k\times r}(E)$ of rank r and $a \in \mathrm{GL}_r(\mathbb{A}_f)$ (LT3). For each $p \in B$, as $L \subseteq L_c(\gamma_p)$, Lemma 5.3.71 (i) gives $w_p \in \mathrm{M}_{\varrho\times r}(E)$ with $w_p a$ integral and $Q_0(\gamma_p)^* y = -MZ_<^* w_p$. Colour p by the classes of the ϱ rows of $w_p a$ in $\hat{\mathcal{O}}^r / K_L$; by Lemma 5.3.71 (ii) there are at most $\mathrm{disc}_r(L)^{2\varrho}$ colours. Fix one colour class B_1 and $p_1 \in B_1$. For $p \in B_1$ the rows of $(w_{p_1} - w_p)a$ lie in K_L, so Lemma 5.3.71 (iii) gives $u_p \in \mathsf{U}_c^0(M)$ with

$$Q_0(u_p\gamma_p)^* y = Q_0(\gamma_p)^* y - MZ_<^*(w_{p_1} - w_p) = -MZ_<^* w_{p_1}.$$

Put $\gamma_p^{(1)} = u_p\gamma_p$. By Lemma 5.3.72 (i), $Z(\gamma_p^{(1)}) = Z$, and $\gamma_p^{(1)}$ satisfies the conditions of cell rank j and is a term over (c, s_p, c').

Second round: the definite parts. Let $W = \{t \in X_0 : y^* t = 0\}$, of dimension $k - r = l$, and $P = L_c \cap W(\mathbb{A}_f)$. For $p \in B_1$ let $\Delta_p = Q_0(\gamma_p^{(1)}) - Q_0(\gamma_{p_1}^{(1)})$. Its columns lie in P: first, $y^*\Delta_p = 0$ by the first round, so they lie in W. Second, for each b the vector $\gamma_p^{(1)} f_b - \gamma_{p_1}^{(1)} f_b$ lies in L_c, since a term γ over (c, s, c') satisfies $\gamma f_b = h_c(h_c^{-1}\gamma h_{c'}) f_b \in h_c L_0 = L_c$; its coordinates along z and along $e_1^*, \dots, e_\varrho^*$ are $-h(z, \cdot)/N$ and $h(e_a, \cdot)$, determined by Z, hence 0. As $L_c = \bigoplus_a \hat{\mathcal{O}} e_a \oplus h_c L_0^{\mathrm{m}} \oplus \bigoplus_a \hat{\mathcal{O}} e_a^*$, with L_0^{m} the span of the middle basis vectors in $(X_0 \oplus Ez)(\mathbb{A}_f)$ and h_c preserving $(X_0 \oplus Ez)(\mathbb{A}_f)$, the component of this vector in $X_0(\mathbb{A}_f)$, which is the column b of Δ_p, lies in $L_c \cap X_0(\mathbb{A}_f)$.

At each finite place w the $\mathcal{O}_w$-module $P_w = L_{c,w} \cap W_w$ is finitely generated and torsion-free, hence free, and it spans W_w, so it has rank l and $[P_w : dP_w] = |d|_w^{-l}$; as $P = \prod_w P_w$, $[P : dP] = [d]^l$. Colour $p \in B_1$ by the classes of the n columns of Δ_p in P/dP: at most $[d]^{ln}$ colours. Fix a colour class $B_2 \subseteq B_1$ and $p_2 \in B_2$. For $p \in B_2$, $Q_0(\gamma_p^{(1)}) - Q_0(\gamma_{p_2}^{(1)}) = \Delta_p - \Delta_{p_2} = MD\,T_p$ with a rational matrix T_p whose columns lie in $P \subseteq L_c \cap X_0(\mathbb{A}_f)$. By Lemma 5.3.73, applied to $\gamma_{p_2}^{(1)}$ and $\gamma_p^{(1)}$ (cell rank j, the same integral Z, $D_j = D$), there is $u'_p \in \mathsf{U}_c^0(M)$ with $Q_0(u'_p\gamma_p^{(1)}) = Q_0(\gamma_{p_2}^{(1)})$. Put $\gamma_p^{(2)} = u'_p\gamma_p^{(1)}$; by Lemma 5.3.72 (i), $Z(\gamma_p^{(2)}) = Z$ and $\gamma_p^{(2)}$ is a term over (c, s_p, c'), and all $\gamma_p^{(2)}$, $p \in B_2$, have the same matrix Q_0.

Third round: shared vectors and isotropic parts. By Lemma 5.3.74 (ii), $\mathrm{sh}_j(\gamma_p^{(2)}) = \mathrm{sh}_j(\gamma_p)$, and by Lemma 5.3.74 (iii), (iv) its ϱn entries are algebraic integers with $|v(\cdot)| \le b^{182n^2}$ for all $v \in \Phi$. By Lemma 5.3.77 each entry takes at most $(1 + 2b^{182n^2})^{2f} \le b^{366n^2 f}$ values ($b \ge 1000$), so $\mathrm{sh}_j(\gamma_p)$ takes at most $b^{366n^2 f\varrho n} \le b^{366n^4 f}$ values. Colour B_2 by $\mathrm{sh}_j(\gamma_p)$ and fix a colour class B_3. By Lemma 5.3.74 (iii), $Q_A(\gamma_p^{(2)}) \in \mathrm{M}_{\varrho\times n}(\mathcal{O}_E)$; colour B_3 by the class of $Q_A(\gamma_p^{(2)})$ modulo $d'\mathrm{M}_{\varrho\times n}(\mathcal{O}_E)$: at most $\#(\mathcal{O}_E/d'\mathcal{O}_E)^{\varrho n} = [d']^{n\varrho}$ colours. Let B_4 be a colour class and $p, q \in B_4$. Then $\gamma_p^{(2)}$ and $\gamma_q^{(2)}$ have the same integral Z with $D_j(Z) = D \ne 0$, the same shared-vector matrix, the same Q_0, and $Q_A(\gamma_q^{(2)}) - Q_A(\gamma_p^{(2)}) = MD\bar{D}\,\Psi$ with Ψ integral. By Lemma 5.3.76 there is $u'' \in \mathsf{U}_c^0(M)$ with $u''\gamma_p^{(2)} f_b = \gamma_q^{(2)} f_b$ for all b, that is,

$$(u''u'_pu_p)\,\gamma_p f_b = (u'_qu_q)\,\gamma_q f_b \qquad (0 \le b \le \varrho),$$

with both factors in the group $\mathsf{U}_c^0(M)$. By the separation hypothesis on B, $p = q$. So $\#B_4 \le 1$.

Count. Multiplying the numbers of colours of the four colourings,

$$\#B \le \mathrm{disc}_r(L)^{2\varrho}\,[d]^{ln}\,b^{366n^4 f}\,[d']^{n\varrho} \le b^{2n^3 f\varrho}\,b^{2n^3 fln}\,b^{366n^4 f}\,b^{2n^3 fn\varrho} = b^{(366n^4+2n^3(\varrho+ln+n\varrho))f}.$$

□

Lemma 5.3.71. *Let $\mathfrak{S}$ be a filling datum over a field E that carries Weil data, and $c \in \mathcal{C}$. Let $L \subseteq L_c \cap X_0(\mathbb{A}_f)$ be a lattice of rank r, $L = ya\,\hat{\mathcal{O}}^r$ with $y \in \mathrm{M}_{k\times r}(E)$ of rank r and $a \in \mathrm{GL}_r(\mathbb{A}_f)$. Conjugate transposes $(\cdot)^*$ are formed with the conjugation of E and of $\mathbb{A}_f$.*

(i) If $\gamma \in G(E)$ and $L \subseteq L_c(\gamma)$, there is $w \in \mathrm{M}_{\varrho\times r}(E)$ with $wa \in \mathrm{M}_{\varrho\times r}(\hat{\mathcal{O}})$ and $Q_0(\gamma)^*y + M\,Z_<(\gamma)^*w = 0$.

(ii) The Gram matrix $G_L = (ya)^*(ya)$ has entries in $\hat{\mathcal{O}}$, and the $\hat{\mathcal{O}}$-module $K_L \subseteq \hat{\mathcal{O}}^r$ of row vectors spanned by the rows of G_L has index $[\hat{\mathcal{O}}^r : K_L] = \mathrm{disc}_r(L)^2$.

(iii) If $w, w' \in \mathrm{M}_{\varrho\times r}(E)$ and every row of $(w' - w)a$ lies in K_L, there is $u \in \mathsf{U}_c^0(M)$ with

$$Q_0(u\gamma)^*y = Q_0(\gamma)^*y - M\,Z_<(\gamma)^*(w' - w) \qquad \text{for every } \gamma \in G(E).$$

Proof. Write $B = ya$, with columns $B_1, \dots, B_r \in L$.

(i) By (LT1), for each i there is $t_i = \sum_{a<\varrho} W_{ai}e_{a+1}$ with $W \in \mathrm{M}_{\varrho\times r}(\hat{\mathcal{O}})$ such that $h(\gamma f_b, B_i + Mt_i) = 0$ for $0 \le b \le \varrho$. The components of γf_b outside X_0 are orthogonal to X_0, and X_0 carries the unit form, so $h(\gamma f_b, B_i) = (Q_0(\gamma)^*B)_{bi}$; and $h(\gamma f_b, e_{a+1}) = \overline{h(e_{a+1}, \gamma f_b)} = \overline{Z_<(\gamma)_{ab}}$, so $h(\gamma f_b, Mt_i) = M(Z_<(\gamma)^*W)_{bi}$. Hence $S = Wa^{-1}$ solves the linear system

$$C\,s = d, \qquad C = M\,Z_<(\gamma)^* \in \mathrm{M}_{n\times\varrho}(E), \quad d = -Q_0(\gamma)^*y \in \mathrm{M}_{n\times r}(E),$$

over $\mathbb{A}_f$. Its component at one finite place solves it over a field containing E, so the system is consistent over E: there is $s_0 \in \mathrm{M}_{\varrho\times r}(E)$ with $Cs_0 = d$. Let $\kappa_1, \dots, \kappa_q$ be a basis of the E-space of $\kappa \in \mathrm{M}_{\varrho\times r}(E)$ with $C\kappa = 0$; as $\mathbb{A}_f$ is an E-vector space, the solutions over $\mathbb{A}_f$ are the $s_0 + \sum_m \lambda_m\kappa_m$ with $\lambda_m \in \mathbb{A}_f$, so $S = s_0 + \sum_m \lambda_m\kappa_m$ for some λ_m. The set $\mathcal{U} = \{s : sa \in \mathrm{M}_{\varrho\times r}(\hat{\mathcal{O}})\}$ is open in $\mathrm{M}_{\varrho\times r}(\mathbb{A}_f)$ and contains S. The field E is dense in $\mathbb{A}_f$: for $x \in \mathbb{A}_f$ and an integer $m \geq 1$, write $x/m = \alpha + o$ with $\alpha \in E$, $o \in \hat{\mathcal{O}}$; then $x - m\alpha \in m\hat{\mathcal{O}}$, and the $m\hat{\mathcal{O}}$ form a basis of neighbourhoods of 0. Choose $\lambda'_m \in E$ so close to λ_m that $w = s_0 + \sum_m \lambda'_m\kappa_m \in \mathcal{U}$. Then w is rational, wa is integral and $M\,Z_<(\gamma)^*w = -Q_0(\gamma)^*y$.

(ii) $(G_L)_{ii'} = h(B_i, B_{i'}) \in h(L_c, L_c) = h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24. Further $\det G_L = \overline{\det a}\,\det a\,\det(y^*y)$, and $\det(y^*y) \in E^\times$, as y has rank r and the unit form is definite; so $G_L \in \mathrm{GL}_r(\mathbb{A}_f)$, and G_L lies in $\mathrm{GL}_r(\mathcal{O}_w)$ at almost all finite places w. At each w, by the elementary divisor theorem over the principal ideal domain $\mathcal{O}_w$, $[\mathcal{O}_w^r : \mathcal{O}_w^r G_{L,w}] = |\det G_{L,w}|_w^{-1}$. As $\hat{\mathcal{O}} = \prod_w \mathcal{O}_w$, $K_L = \hat{\mathcal{O}}^r G_L = \prod_w \mathcal{O}_w^r G_{L,w}$ and

$$[\hat{\mathcal{O}}^r : K_L] = \prod_w |\det G_{L,w}|_w^{-1} = [\det(B^*B)] = \mathrm{disc}_r(L)^2$$

by (LT3).

(iii) Write $(w' - w)a = tG_L = t\,a^*y^*y\,a$ with $t \in \mathrm{M}_{\varrho\times r}(\hat{\mathcal{O}})$; then $w' - w = t\,a^*y^*y$. The matrix $y^*y \in \mathrm{GL}_r(E)$ is hermitian. Put $\eta = y\,(y^*y)^{-1}(w' - w)^* \in \mathrm{M}_{k\times\varrho}(E)$. Then $\eta^*y = (w' - w)(y^*y)^{-1}y^*y = w' - w$, and over $\mathbb{A}_f$, using $(w' - w)^* = y^*y\,a\,t^*$,

$$\eta = y\,(y^*y)^{-1}y^*y\,a\,t^* = ya\,t^*,$$

whose columns are $\hat{\mathcal{O}}$-combinations of the columns of ya (t^* is integral); so they lie in $L \subseteq L_c \cap X_0(\mathbb{A}_f)$. By Lemma 5.3.72 (ii) there is $u \in \mathsf{U}_c^0(M)$ with $Q_0(u\gamma) = Q_0(\gamma) - M\eta Z_<(\gamma)$ for every γ; then $Q_0(u\gamma)^*y = Q_0(\gamma)^*y - M\,Z_<(\gamma)^*\eta^*y = Q_0(\gamma)^*y - M\,Z_<(\gamma)^*(w' - w)$. □

Lemma 5.3.72. *Let $\mathfrak{S}$ be a filling datum over a field E that carries Weil data, and $c \in \mathcal{C}$.*

(i) If $u \in G(E)$ fixes $f_0, \dots, f_\varrho$, then $Z(u\gamma) = Z(\gamma)$ for every $\gamma \in G(E)$, and $u\gamma$ satisfies the conditions of cell rank j whenever γ does. If $u \in \mathsf{U}_c^0(M)$ and γ is a term over (c, s, c'), then $u\gamma$ is a term over (c, s, c').

(ii) Let $\eta \in \mathrm{M}_{k\times\varrho}(E)$ have its columns in $L_c \cap X_0(\mathbb{A}_f)$. There is $u \in \mathsf{U}_c^0(M)$ with $Q_0(u\gamma) = Q_0(\gamma) - M\,\eta\,Z_<(\gamma)$ for every $\gamma \in G(E)$.

(iii) Let $\sigma \in \mathrm{M}_\varrho(\mathcal{O}_E)$ with $\sigma^* = -\sigma$ (σ^* the conjugate transpose). There is $u \in \mathsf{U}_c^0(M)$ with

$$u\gamma f_b = \gamma f_b + M\sum_{a=0}^{\varrho-1}\big(\sigma Z_<(\gamma)\big)_{ab}\,e_{a+1} \qquad (\gamma \in G(E),\ 0 \leq b \leq \varrho);$$

in particular $Q_A(u\gamma) = Q_A(\gamma) + M\sigma Z_<(\gamma)$, and the other coordinates of the frame vectors $u\gamma f_b$ are those of γf_b.

Proof. **(i)** As u^{-1} fixes the frame, $Z(u\gamma)_{ab} = h(f_a, u\gamma f_b) = h(u^{-1}f_a, \gamma f_b) = Z(\gamma)_{ab}$. The conditions of cell rank j (TA5) are: the pairs (x, y) with $f \cdot x = \gamma f \cdot y$ and prescribed entries, $D_j(\gamma) \neq 0$, and $\varrho < j \iff \mathsf{g}(\gamma) \neq 0$. The last two depend on $Z(\gamma)$ only, and a pair for γ is a pair for $u\gamma$, as $u\gamma f \cdot y = u(f \cdot x) = f \cdot x$. If $u \in \mathsf{U}_c^0(M)$ and γ is a term over (c, s, c'), then $h_c^{-1}u\gamma h_{c'} = (h_c^{-1}uh_c)(h_c^{-1}\gamma h_{c'})$ with $h_c^{-1}uh_c \in \mathrm{K}(M) = \ker \mathrm{red} \subseteq K$, so it lies in K and has reduction s.

(ii) Fix μ as in Lemma 5.2.23 (ii), and for $1 \le a \le \varrho$ let $w_a \in X_0$ be the column of η of index $a-1$. Then $w_a \in V \cap L_c$ lies in X_0, so Lemma 5.2.23 (ii) with $s=0$ gives $E_a = E_a(w_a, 0) \in \mathsf{U}_c(M)$,

$$E_a x = x + M\,h(w_a, x)\,e_a - M\,h(e_a, x)\,w_a - M^2\mu\,h(w_a, w_a)\,h(e_a, x)\,e_a \qquad (x \in V),$$

and $E_a f_b = f_b + M\,h(w_a, f_b)\,e_a = f_b$, as X_0 is orthogonal to $e_1, \dots, e_\varrho, z$. So $E_a \in \mathsf{U}_c^0(M)$, and $u = E_1 E_2 \cdots E_\varrho \in \mathsf{U}_c^0(M)$, a group. Since the $e_{a'}$ are isotropic, mutually orthogonal and orthogonal to X_0, $h(e_{a'}, E_a x) = h(e_{a'}, x)$ for all a', and the coordinate vector of $E_a x$ along $x_1, \dots, x_k$ is that of x minus $M\,h(e_a, x)\,w_a$. By induction over the factors, the coordinate vector of ux along $x_1, \dots, x_k$ is that of x minus $M\sum_a h(e_a, x) w_a$. For $x = \gamma f_b$, $h(e_a, \gamma f_b) = Z_<(\gamma)_{a-1,b}$, so $Q_0(u\gamma) = Q_0(\gamma) - M\eta Z_<(\gamma)$.

(iii) Define $u\colon V \to V$ by $ux = x + M\sum_{a,a'=0}^{\varrho-1} \sigma_{aa'}\,h(e_{a'+1}, x)\,e_{a+1}$. As h is conjugate-linear in the first variable, the e_a are isotropic and mutually orthogonal, and $\overline{h(e_{a'+1}, x)} = h(x, e_{a'+1})$,

$$h(ux, ux') - h(x, x') = M\sum_{a,a'} (\overline{\sigma_{a'a}} + \sigma_{aa'}) h(x, e_{a+1})\,h(e_{a'+1}, x') = 0,$$

because $\sigma^* = -\sigma$. So u preserves h; it is invertible, since $(u-1)V \subseteq A$ and $(u-1)A = 0$ give $(u-1)^2 = 0$; hence $u \in G(E)$. It is the identity on $A^\perp$ (where all $h(e_{a'+1}, \cdot)$ vanish) and $(u-1)V \subseteq A \subseteq A^\perp$, so it preserves every member of the flag above and acts trivially on its successive quotients: $u \in \mathsf{U}(E)$. For $x \in L_c$ write $x = h_c x'$ with $x' \in L_0$; as h_c fixes $e_{a'+1}$ and is unitary, $h(e_{a'+1}, x) = h(e_{a'+1}, x') \in h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24, and $e_{a+1} = h_c e_{a+1} \in L_c$; with σ integral, $(u-1)L_c \subseteq ML_c$, so $u \in \mathsf{U}_c(M)$ by Lemma 5.2.23 (i). Since $h(e_{a'+1}, f_b) = 0$ for all a', b, u fixes the frame: $u \in \mathsf{U}_c^0(M)$. Finally $h(e_{a'+1}, \gamma f_b) = Z_<(\gamma)_{a'b}$, so $u\gamma f_b = \gamma f_b + M\sum_a (\sigma Z_<(\gamma))_{ab} e_{a+1}$, which changes only the coordinates along $e_1, \dots, e_\varrho$. □

Lemma 5.3.73. *Let $\mathfrak{S}$ be a filling datum over a field E that carries Weil data, $c \in \mathcal{C}$ and $0 \le j \le \varrho + 1$. Let $\gamma, \gamma' \in G(E)$ satisfy the conditions of cell rank j, with $Z(\gamma) = Z(\gamma')$ having entries in $\mathcal{O}_E$, and suppose that*

$$Q_0(\gamma') - Q_0(\gamma) = M\,D_j(\gamma)\,\Psi$$

for a matrix $\Psi \in \mathrm{M}_{k\times n}(E)$ whose columns lie in $L_c \cap X_0(\mathbb{A}_f)$. Then there is $u \in \mathsf{U}_c^0(M)$ with $Q_0(u\gamma') = Q_0(\gamma)$.

Proof. Write $Z = Z(\gamma)$, $D = D_j(\gamma)$, which is nonzero by (TA5), $Z_< = Z_<(\gamma)$ and $Z^{\mathrm{pd}} = Z_j^{\mathrm{pd}}(\gamma)$ ((TA14) of Definition 5.1.12); then $\det Z^{\mathrm{pd}} = D$ and Z^{pd}, $\mathrm{adj}(Z^{\mathrm{pd}})$ have entries in $\mathcal{O}_E$. Put $\Delta = Q_0(\gamma') - Q_0(\gamma)$ and

$$\eta' = \Delta\,(Z^{\mathrm{pd}})^{-1} = M\,\Psi\,\mathrm{adj}(Z^{\mathrm{pd}}).$$

The columns of $\Psi\,\mathrm{adj}(Z^{\mathrm{pd}})$ are $\mathcal{O}_E$-combinations of columns of Ψ, hence lie in the $\hat{\mathcal{O}}$-module $L_c \cap X_0(\mathbb{A}_f)$; so do those of η'.

The columns of η' of index $m \ge j$ vanish. The column m of $Q_0(\gamma)(Z^{\mathrm{pd}})^{-1}$ is D^{-1} times the column m of $Q_0(\gamma)\mathrm{adj}(Z^{\mathrm{pd}})$, which is 0 for $j \le m \le \varrho$ by Lemma 5.3.74 (i); the same holds for γ', which has the same Z^{pd}.

The column of η' of index ϱ vanishes. For $j \le \varrho$ this is the previous step; let $j = \varrho + 1$, so $Z^{\mathrm{pd}} = Z$. Let $t = Z^{-1}\varepsilon_\varrho$ and $q = \sum_l t_l \gamma f_l$. Then $h(f_i, q) = (Zt)_i = \delta_{i\varrho}$, so the coordinates of q along $e_1^*, \dots, e_\varrho^*$ (which are $h(e_a, q)$) vanish and its coordinate along z is $-h(z, q)/N = -1/N$: $q = q_A + q_0 - z/N$ with $q_A \in \langle e_1, \dots, e_\varrho\rangle$ and $q_0 \in X_0$ the column ϱ of $Q_0(\gamma)Z^{-1}$. As γ is an

isometry and in the frame only $h(z,z) = -N$ is nonzero, $h(q,q) = h(f\cdot t, f\cdot t) = -N\, t_\varrho \bar{t}_\varrho$; on the other hand $h(q,q) = h(q_0,q_0) - 1/N$. So for every $v \in \Phi$,

$$\sum_i |v(q_{0,i})|^2 = \frac{1}{N} - N|v(t_\varrho)|^2 \le \frac{1}{N}.$$

The same holds for the column q_0' of $Q_0(\gamma')Z^{-1}$, and the column $w = q_0' - q_0$ of η' satisfies $\sum_i |v(w_i)|^2 \le 2(\frac{1}{N} + \frac{1}{N}) = \frac{4}{N} < 1$ for all v, by (FG2). Now $w \in E^k$ lies in L_c, and $h(L_c, L_c) = h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24 ($L_c = h_c L_0$ with h_c unitary); so $h(w,w) \in E \cap \hat{\mathcal{O}} = \mathcal{O}_E$, with $|v(h(w,w))| < 1$ for all $v \in \Phi$. Then $|\mathrm{N}_{E/\mathbb{Q}}(h(w,w))| = \prod_v |v(h(w,w))|^2 < 1$, so $h(w,w) = 0$ and, the form being definite, $w = 0$.

The move. Let $\eta \in \mathrm{M}_{k\times\varrho}(E)$ be the matrix of the first ϱ columns of $\Psi \operatorname{adj}(Z^{\mathrm{pd}})$; its columns lie in $L_c \cap X_0(\mathbb{A}_f)$, and those of index $m \ge j$ vanish by the first step ($M \ne 0$). Since the columns of η' of index $\ge j$ and of index ϱ vanish, and the row of Z^{pd} of index $m < \min(j,\varrho)$ is the row m of $Z_<$,

$$\Delta = \eta' Z^{\mathrm{pd}} = \sum_{m<\min(j,\varrho)} \eta' \varepsilon_m \varepsilon_m^{\mathsf{T}} Z^{\mathrm{pd}} = M\,\eta\, Z_<.$$

By Lemma 5.3.72 (ii) there is $u \in \mathsf{U}_c^0(M)$ with $Q_0(u\gamma') = Q_0(\gamma') - M\eta Z_< = Q_0(\gamma') - \Delta = Q_0(\gamma)$, the first ϱ rows of $Z(\gamma')$ being those of Z. □

Lemma 5.3.74. *Let $\mathfrak{S}$ be a filling datum over E, $0 \le j \le \varrho+1$, and let $\gamma \in G(E)$ satisfy the conditions of cell rank j.*

(i) For $j \le m \le \varrho$ the vector $\sum_l \operatorname{adj}(Z_j^{\mathrm{pd}}(\gamma))_{lm}\, \gamma f_l$ lies in the E-span of $f_0,\dots,f_\varrho$; in particular the column of index m of $Q_0(\gamma)\operatorname{adj}(Z_j^{\mathrm{pd}}(\gamma))$ is 0.

(ii) If $u \in G(E)$ fixes $f_0,\dots,f_\varrho$, then $Z_j^{\mathrm{pd}}(u\gamma) = Z_j^{\mathrm{pd}}(\gamma)$ and $\mathrm{sh}_j(u\gamma) = \mathrm{sh}_j(\gamma)$.

(iii) If γ is a term over (c,s,c') for some $c,c' \in \mathcal{C}$ and s, then $Z(\gamma)$, $Q_A(\gamma)$, $Z_j^{\mathrm{pd}}(\gamma)$ and $\mathrm{sh}_j(\gamma)$ have entries in $\mathcal{O}_E$.

(iv) If $\mathfrak{S}$ is admissible, E carries Weil data and γ is a near term, then $|v(\mathrm{sh}_j(\gamma)_{am})| \le b^{182n^2}$ for all $v \in \Phi$, a and m.

Proof. Expanding along the rows of index $\ge j$, $\det Z^{\mathrm{pd}} = D_j(\gamma)$, which is nonzero by (TA5).

(i) We may assume $j \le \varrho$. For $j \le a \le \varrho$ let $(x^{(a)}, y^{(a)})$ be the pair of (TA5): $f\cdot x^{(a)} = \gamma f \cdot y^{(a)}$ with $y_a^{(a)} = 1$ and $y_b^{(a)} = 0$ for $b > a$. Then $(Z(\gamma)y^{(a)})_i = h(f_i, \gamma f\cdot y^{(a)}) = h(f_i, f\cdot x^{(a)})$, which vanishes for $i < \varrho$, because $f_i = e_{i+1}$ is isotropic and orthogonal to $e_1,\dots,e_\varrho,z$. The rows of Z^{pd} of index $i < j$ are rows of $Z(\gamma)$ with $i < \varrho$, so $Z^{\mathrm{pd}}y^{(a)} = \sum_{j\le i\le a} y_i^{(a)}\varepsilon_i$, with coefficient 1 at ε_a. Hence the vectors $Z^{\mathrm{pd}}y^{(a)}$, $j \le a \le \varrho$, span $\langle \varepsilon_m : m \ge j\rangle$, and for $m \ge j$ the vector $\operatorname{adj}(Z^{\mathrm{pd}})\varepsilon_m = D_j(\gamma)\,(Z^{\mathrm{pd}})^{-1}\varepsilon_m$ lies in the span of the $y^{(a)}$. So $\sum_l \operatorname{adj}(Z^{\mathrm{pd}})_{lm}\gamma f_l = \gamma f\cdot(\operatorname{adj}(Z^{\mathrm{pd}})\varepsilon_m)$ lies in the span of the $\gamma f\cdot y^{(a)} = f\cdot x^{(a)}$, hence in the span of the frame, whose vectors have no coordinates along $x_1,\dots,x_k$.

(ii) As u^{-1} fixes the frame, $Z(u\gamma)_{ab} = h(u^{-1}f_a, \gamma f_b) = Z(\gamma)_{ab}$, so $Z_j^{\mathrm{pd}}(u\gamma) = Z^{\mathrm{pd}}$. For $m \ge j$, by (i) the vector $t_m = \sum_l \operatorname{adj}(Z^{\mathrm{pd}})_{lm}\gamma f_l$ lies in the span of the frame, which u fixes; so $\sum_l \operatorname{adj}(Z^{\mathrm{pd}})_{lm} u\gamma f_l = ut_m = t_m$. The column of index m of sh_j consists of the coordinates of this vector along $e_1,\dots,e_\varrho$, for $u\gamma$ and for γ alike.

(iii) Let $k_0 = h_c^{-1}\gamma h_{c'} \in K$, so $k_0 L_0 = L_0$. As $h_{c'}$ fixes f_b, $\gamma f_b = h_c k_0 f_b$; as h_c is unitary and fixes f_a and e_a^*,

$$Z(\gamma)_{ab} = h(f_a, k_0 f_b), \qquad Q_A(\gamma)_{ab} = h(e_{a+1}^*, \gamma f_b) = h(e_{a+1}^*, k_0 f_b),$$

both in $h(L_0, L_0) \subseteq \hat{\mathcal{O}}$ by Lemma 5.2.24, and in E; so they lie in $E \cap \hat{\mathcal{O}} = \mathcal{O}_E$. The entries of Z^{pd} are entries of $Z(\gamma)$, 0 or 1, so Z^{pd} and $\mathrm{adj}(Z^{\mathrm{pd}})$ are integral, and so is $\mathrm{sh}_j(\gamma)$, whose nonzero columns are columns of $Q_A(\gamma)\mathrm{adj}(Z^{\mathrm{pd}})$.

(iv) Fix v, a and m; for $m < j$ there is nothing to prove, so let $m \geq j$. Put $\xi = \mathrm{adj}(Z^{\mathrm{pd}})\varepsilon_m \in E^n$. By (i), $\gamma f \cdot \xi = f \cdot w$ for some $w \in E^n$, and $\mathrm{sh}_j(\gamma)_{am} = w_a$ is its coordinate along $f_a = e_{a+1}$. Fix a boxed $y \in G_\infty$ such that $y' = \gamma^{-1} y$ is boxed; then $y_v^{-1}\gamma_v = y_v'^{-1}$. Let $B_v = \mathrm{diag}(\mathrm{bs}_v)$; by (RD1), $B_v^{-1} v(\gamma) = \gamma_v B_v^{-1}$ and $B_v^{-1} f_l = \mathrm{bs}_v(f_l)^{-1} f_l$. Applying $y_v^{-1} B_v^{-1} v$ to $f \cdot w = \gamma f \cdot \xi$ gives

$$\sum_l \frac{v(w_l)}{\mathrm{bs}_v(f_l)}\, y_v^{-1} f_l = \sum_l \frac{v(\xi_l)}{\mathrm{bs}_v(f_l)}\, y_v'^{-1} f_l.$$

By Lemma 5.3.75 (ii) at y and (i) at y',

$$\frac{|v(w_a)|}{|\mathrm{bs}_v(f_a)|} \leq b^{13n^2} \sum_l \frac{|v(\xi_l)|}{|\mathrm{bs}_v(f_l)|}\, b^{6n+29}.$$

By (RD1) and (FA4), $|\mathrm{bs}_v(f_a)|/|\mathrm{bs}_v(f_l)| = |\mathrm{rs}_v|^{l-a} \leq b^{23\varrho}$. The entries of $v(Z^{\mathrm{pd}})$ have modulus at most b^{73n} (Lemma 5.3.75 (iii) for the rows of index $< j$; the others are 0 or 1), so the entries $v(\xi_l)$ of $\mathrm{adj}(v(Z^{\mathrm{pd}}))$, minors of order ϱ up to sign, have modulus at most $\varrho!\, b^{73n\varrho} \leq b^{\varrho + 73n\varrho}$ ($\varrho + 1 \leq b$ by (FG6)). With $n \leq b$ and $\varrho < n$,

$$|v(w_a)| \leq b^{13n^2} \cdot n \cdot b^{\varrho + 73n\varrho} \cdot b^{23\varrho} \cdot b^{6n+29} \leq b^{87n^2 + 29n + 30} \leq b^{182n^2}.$$

□

Lemma 5.3.75. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, $y \in G_\infty$ a boxed point and $v \in \Phi$.*

(i) $\|y_v^{-1} f_a\| \leq b^{6n+29}$ *for* $0 \leq a \leq \varrho$.

(ii) For every $t \in \mathbb{C}^n$ *and* $0 \leq a \leq \varrho$,

$$|t_a| \leq b^{13n^2} \Big\| \sum_{l=0}^{\varrho} t_l\, y_v^{-1} f_l \Big\|.$$

(iii) If $\gamma \in G(E)$ *is a near term, then* $|v(Z(\gamma)_{ab})| \leq b^{73n}$ *for* $0 \leq a, b \leq \varrho$.

Proof. **(i)** The set $\mathcal{C}$ of classes is a quotient of $\mathrm{U}(X_0)(\mathbb{A}_f)$, hence non-empty; fix $c \in \mathcal{C}$. By Lemma 5.2.21 the indicator $\mathbf{1}_{\mathrm{red}}$ of the reduced points (for the residue domain of the fixed cutoff datum) is a box partition of unity for c. A boxed point is reduced, so $\mathbf{1}_{\mathrm{red}}(y) = 1 \neq 0$, and the first condition of (RD5) gives $y_v \in \mathrm{Bx}(b^{27}\ell(y_v))$. As y is boxed, $\ell(y_v) \leq b^{6n+2}$, so $\|y_v^{-1} f_a\| \leq b^{6n+29}$.

(ii) By the definition of $\ell(y_v)$ as an infimum over R and $\ell(y_v) \leq b^{6n+2}$, there is $s \in R$ with $\|s y_v\|_{\mathrm{op}} + 1 < b^{6n+2} + 1$; write $s = uh$ with $u \in \mathsf{U}$, $h \in H = \mathrm{U}(X_0)$. The element h acts trivially on $X_0^{\perp}$, which contains $f_0, \ldots, f_\varrho$, so $s f_b = u f_b$. The element u acts trivially on the successive quotients of the flag $\langle e_1 \rangle \subset \cdots \subset \langle e_1, \ldots, e_\varrho \rangle \subset \langle e_1, \ldots, e_\varrho \rangle^{\perp}$, and $z \in \langle e_1, \ldots, e_\varrho \rangle^{\perp}$; hence

$uf_b - f_b \in \langle f_0, \dots, f_{b-1}\rangle$ for $0 \le b \le \varrho$, that is, $uf_b = \sum_{a\le b} T_{ab} f_a$ with an upper unitriangular matrix $T \in \mathrm{M}_n(\mathbb{C})$. The frame vectors are standard basis vectors of $\mathbb{C}^r$, hence orthonormal for $\langle\cdot,\cdot\rangle$, so by (i)

$$|T_{ab}| = |\langle f_a, (sy_v)(y_v^{-1} f_b)\rangle| \le \|sy_v\|_{\mathrm{op}}\, \|y_v^{-1} f_b\| \le b^{6n+2}\, b^{6n+29} = b^{12n+31}.$$

Let $q = \sum_l t_l\, y_v^{-1} f_l$. Then $sy_v q = \sum_l t_l\, sf_l = \sum_a (Tt)_a f_a$, so $|(Tt)_a| \le \|sy_v q\| \le b^{6n+2}\|q\|$ for every a. As $\det T = 1$, $t = \mathrm{adj}(T)\,(Tt)$; the entries of $\mathrm{adj}(T)$ are minors of order ϱ of T up to sign, so they have modulus at most $\varrho!\,(b^{12n+31})^\varrho \le b^{(12n+32)\varrho}$, because $\varrho! \le \varrho^\varrho \le b^\varrho$ by $\varrho + 1 \le b$ (FG6). Hence, using $n \le b$,

$$|t_a| \le n\, b^{(12n+32)\varrho}\, b^{6n+2}\|q\| \le b^{(12n+32)(n-1)+6n+3}\|q\| = b^{12n^2+26n-29}\|q\| \le b^{13n^2}\|q\|,$$

since $26n \le n^2$ ($n \ge 10^5$ by (FG6)) and $b \ge 1$.

(iii) Fix a boxed $y' \in G_\infty$ such that $x = \gamma^{-1} y'$ is boxed; then $x_v = \gamma_v^{-1} y'_v$. By Lemma 5.3.36 (i), $Z(\gamma_v) = S\, v(Z(\gamma))\, S$ with $S = \mathrm{diag}(\mathrm{bs}_v(f_0), \dots, \mathrm{bs}_v(f_\varrho))$, so

$$v(Z(\gamma)_{ab}) = Z(\gamma_v)_{ab} / (\mathrm{bs}_v(f_a)\mathrm{bs}_v(f_b)),$$

and $|\mathrm{bs}_v(f_a)\mathrm{bs}_v(f_b)| = |\mathrm{rs}_v|^{2\varrho-a-b}/N \ge 1/N$ by (RD1) and (FA4). As $y'_v \in G_1$ preserves h_1 and $y_v'^{-1}\gamma_v = x_v^{-1}$,

$$Z(\gamma_v)_{ab} = h_1(f_a, \gamma_v f_b) = h_1(y_v'^{-1} f_a,\ x_v^{-1} f_b).$$

The matrix J_1 is a hermitian involution, hence unitary, so $|h_1(w, w')| = |\langle w, J_1 w'\rangle| \le \|w\|\,\|w'\|$. With (i) for the boxed points y' and x and with (FA5),

$$|v(Z(\gamma)_{ab})| \le N\, b^{6n+29}\, b^{6n+29} \le b^{60n+12n+58} \le b^{73n}.$$

□

Lemma 5.3.76. *Let $\mathfrak{S}$ be a filling datum over a field E that carries Weil data, $c \in \mathcal{C}$ and $0 \le j \le \varrho + 1$. Let $\gamma, \gamma' \in G(E)$ satisfy: $Z(\gamma) = Z(\gamma')$ with entries in $\mathcal{O}_E$; $D_j(\gamma) \ne 0$; $\mathrm{sh}_j(\gamma) = \mathrm{sh}_j(\gamma')$; $Q_0(\gamma) = Q_0(\gamma')$; and*

$$Q_A(\gamma') - Q_A(\gamma) = M\, D_j(\gamma)\, \overline{D_j(\gamma)}\, \Psi \qquad \text{for some } \Psi \in \mathrm{M}_{\varrho\times n}(\mathcal{O}_E).$$

Then there is $u \in \mathsf{U}_c^0(M)$ with $u\gamma f_b = \gamma' f_b$ for $0 \le b \le \varrho$.

Proof. Write $Z = Z(\gamma)$, $D = D_j(\gamma)$, $Z^{\mathrm{pd}} = Z_j^{\mathrm{pd}}(\gamma) = Z_j^{\mathrm{pd}}(\gamma')$, $Z_< = Z_<(\gamma) \in \mathrm{M}_{\varrho\times n}(\mathcal{O}_E)$ (the first ϱ rows of Z), $d = MD\bar{D}$ and $\xi = Q_A(\gamma') - Q_A(\gamma) = d\Psi$. Then $d \in \mathcal{O}_E$, $\bar{d} = d$ and $d \ne 0$; $\det Z^{\mathrm{pd}} = D$, and Z^{pd}, $\mathrm{adj}(Z^{\mathrm{pd}})$ have entries in $\mathcal{O}_E$.

The frames differ only along $e_1, \dots, e_\varrho$. For $x \in V$, the coordinate of x along z is $-h(z,x)/N$ and its coordinate along e_{a+1}^* is $h(e_{a+1}, x)$. For $x = \gamma f_b$ these are $-Z_{\varrho b}/N$ and Z_{ab}, the same for γ'; the coordinates along $x_1, \dots, x_k$ agree as $Q_0(\gamma) = Q_0(\gamma')$. Hence

$$\gamma' f_b = \gamma f_b + \sum_{a=0}^{\varrho-1} \xi_{ab}\, e_{a+1} \qquad (0 \le b \le \varrho).$$

$\Psi^* Z_<$ is skew. Both frames γf and $\gamma' f$ have the Gram matrix of f. Expanding $h(\gamma' f_b, \gamma' f_{b'})$ with the display, using that the e_{a+1} are isotropic and mutually orthogonal and that $h(e_{a+1}, \gamma f_{b'}) = (Z_<)_{ab'}$, the difference $h(\gamma' f_b, \gamma' f_{b'}) - h(\gamma f_b, \gamma f_{b'})$ is $(\xi^* Z_< + Z_<^* \xi)_{bb'}$. So $\xi^* Z_< = -Z_<^* \xi$, and dividing by the real number $d \ne 0$,

$$\Psi^* Z_< = -Z_<^* \Psi. \tag{1}$$

The columns of $\Psi\,\mathrm{adj}(Z^{\mathrm{pd}})$ of index $\geq j$ and of index ϱ vanish. For $m \geq j$, the column m of $\xi\,\mathrm{adj}(Z^{\mathrm{pd}}) = Q_A(\gamma')\mathrm{adj}(Z^{\mathrm{pd}}) - Q_A(\gamma)\mathrm{adj}(Z^{\mathrm{pd}})$ is $\mathrm{sh}_j(\gamma')\varepsilon_m - \mathrm{sh}_j(\gamma)\varepsilon_m = 0$; divide by d. If $j = \varrho+1$, then $Z^{\mathrm{pd}} = Z$; let α be the matrix of the first ϱ columns of $\mathrm{adj}(Z)$. From $Z\,\mathrm{adj}(Z) = D\cdot 1$, $Z_<\alpha = D\cdot 1_\varrho$ and $Z_<\mathrm{adj}(Z)\varepsilon_\varrho = 0$. By (1), $Z_<^*\Psi\,\mathrm{adj}(Z)\varepsilon_\varrho = -\Psi^* Z_<\mathrm{adj}(Z)\varepsilon_\varrho = 0$, and $\alpha^* Z_<^* = \bar{D}\cdot 1_\varrho$, so $\bar{D}\,\Psi\mathrm{adj}(Z)\varepsilon_\varrho = \alpha^* Z_<^*\Psi\mathrm{adj}(Z)\varepsilon_\varrho = 0$; as $D \neq 0$ the column ϱ vanishes.

A solution of $\Psi\alpha Z_< = D\Psi$. Let now, for every j, $\alpha \in \mathrm{M}_{n\times\varrho}(\mathcal{O}_E)$ be the matrix of the first ϱ columns of $\mathrm{adj}(Z^{\mathrm{pd}})$. As $\mathrm{adj}(Z^{\mathrm{pd}})Z^{\mathrm{pd}} = D\cdot 1$,

$$D\Psi = \Psi\,\mathrm{adj}(Z^{\mathrm{pd}})\,Z^{\mathrm{pd}} = \sum_{m=0}^{\varrho}\left(\Psi\mathrm{adj}(Z^{\mathrm{pd}})\varepsilon_m\right)\varepsilon_m^{\mathsf{T}} Z^{\mathrm{pd}} = \sum_{m<\min(j,\varrho)}\left(\Psi\mathrm{adj}(Z^{\mathrm{pd}})\varepsilon_m\right)\varepsilon_m^{\mathsf{T}} Z_< = \Psi\alpha Z_<, \tag{2}$$

because the terms with $m \geq j$ or $m = \varrho$ vanish, the row $m < j$ of Z^{pd} is the row m of Z, which for $m < \varrho$ is the row m of $Z_<$, and the terms with $j \leq m < \varrho$ added in the last step vanish.

The skew-hermitian matrix. Put

$$\sigma = \bar{D}\,\Psi\alpha - D\,(\Psi\alpha)^* - \alpha^* Z_<^*\Psi\alpha \;\in \mathrm{M}_\varrho(\mathcal{O}_E).$$

By (1), $\alpha^*\Psi^* Z_<\alpha = -\alpha^* Z_<^*\Psi\alpha$, so $\sigma^* = D\,(\Psi\alpha)^* - \bar{D}\,\Psi\alpha + \alpha^* Z_<^*\Psi\alpha = -\sigma$. By (2) and (1),

$$\sigma Z_< = \bar{D}\,\Psi\alpha Z_< - D\,\alpha^*\Psi^* Z_< - \alpha^* Z_<^*(\Psi\alpha Z_<) = D\bar{D}\,\Psi + D\,\alpha^* Z_<^*\Psi - D\,\alpha^* Z_<^*\Psi = D\bar{D}\,\Psi.$$

By Lemma 5.3.72 (iii) there is $u \in \mathsf{U}_c^0(M)$ with $u\gamma f_b = \gamma f_b + M\sum_a(\sigma Z_<)_{ab}e_{a+1} = \gamma f_b + \sum_a \xi_{ab}e_{a+1} = \gamma' f_b$. □

Lemma 5.3.77. *Let E be a totally complex number field of degree $2f$, $\mathcal{O}_E$ its ring of integers, and Φ a set of f embeddings $E \to \mathbb{C}$ containing exactly one of each pair of complex conjugate embeddings. For every real $B \geq 0$,*

$$\#\{\alpha \in \mathcal{O}_E :\ |v(\alpha)| \leq B \text{ for all } v \in \Phi\} \leq (1+2B)^{2f}.$$

Proof. Embed E in $\mathbb{C}^\Phi \cong \mathbb{R}^{2f}$ by $\alpha \mapsto (v(\alpha))_{v\in\Phi}$ and give $\mathbb{C}^\Phi$ the norm $\|w\| = \max_v |w_v|$. For distinct $\alpha, \beta \in \mathcal{O}_E$ we have $\|\alpha - \beta\| \geq 1$: otherwise the nonzero algebraic integer $\alpha - \beta$ would have $|\mathrm{N}_{E/\mathbb{Q}}(\alpha-\beta)| = \prod_{v\in\Phi}|v(\alpha-\beta)|^2 < 1$, while the norm of a nonzero algebraic integer is a nonzero rational integer. Hence the open balls of radius $\frac{1}{2}$ (for $\|\cdot\|$) about the points α of the set are pairwise disjoint, and they lie in the ball of radius $B + \frac{1}{2}$ about 0. The balls of $\|\cdot\|$ are products of f discs, so the ball of radius t has Lebesgue measure $(\pi t^2)^f$; comparing measures, the number of points is at most $((B+\frac{1}{2})/\frac{1}{2})^{2f} = (1+2B)^{2f}$. □

Lemma 5.3.78. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data, and $r, l \geq 0$ integers with $r + l = k$. Then*

$$\sum_{c\in\mathcal{C}}\sum_{L}\mathrm{disc}_r(L)^{-k} \leq \frac{\#\mathcal{C}}{N^{kf}}\,\tau_{\mathrm{sz}}^{l+1},$$

the inner sum over the lattices $L \subseteq L_c \cap X_0(\mathbb{A}_f)$ of rank r with $\mathrm{disc}_r(L) \leq b^{n^3 f}$.

Proof. Put $H = b^{n^3 f}$, $\mu = 2\varrho + 4$, $X = 200fk\,\mathrm{rd}_E$, $K_\circ = \mathrm{U}(X_0)(\hat{\mathcal{O}})$ and $K' = \mathrm{U}(X_0)(\mathbb{A}_f) \cap K$. For $c \in \mathcal{C}$ let

$$F(c) = \sum_L \mathrm{disc}_r(L)^{-k} \in [0,\infty],$$

the sum over the lattices $L \subseteq L_c \cap X_0(\mathbb{A}_f)$ of rank r with $\mathrm{disc}_r(L) \le H$; each term is finite, as $\det(B^*B)$ is a unit of $\mathbb{A}_f$ in (LT3). We show $\sum_c F(c) \le \#\mathcal{C}\, N^{-kf} \tau_{\mathrm{sz}}^{l+1}$.

Step 1: the cosets of K'. By Lemma 5.3.80 (ii), K' is a subgroup of $K_\circ$. By (FA1), $\mathrm{K}_X \subseteq \mathrm{K}(M) \subseteq K$, so $K' \supseteq \mathrm{K}_X$ is open in the compact group $K_\circ$, and $\mathcal{A} = K_\circ/K'$ is finite; by (FA8), $\#\mathcal{A} \ge (N^k/b)^f > 0$. Choose $y_\varphi \in \varphi$ for each $\varphi \in \mathcal{A}$. For $\varphi \ne \varphi'$ the k-th rows of y_φ^{-1} and $y_{\varphi'}^{-1}$ do not differ by an element of $\pi\hat{\mathcal{O}}^{1\times k}$: otherwise $y_\varphi^{-1} y_{\varphi'} \in K \cap \mathrm{U}(X_0)(\mathbb{A}_f) = K'$ by Lemma 5.3.80 (ii), that is, $\varphi = \varphi'$.

Step 2: the translates of one u. Fix $u \in \mathrm{U}(X_0)(\mathbb{A}_f)$ and let $\mathcal{L}$ be the set of lattices $L \subseteq u\hat{\mathcal{O}}^k$ of rank r with $\mathrm{disc}_r(L) \le H$. By Lemma 5.3.80 (iii) (with $y = y_\varphi$; $\Lambda(u, y_\varphi) \subseteq u\hat{\mathcal{O}}^k$), $F([uy_\varphi]) = \sum_{L\in\mathcal{L},\, L\subseteq\Lambda(u,y_\varphi)} \mathrm{disc}_r(L)^{-k}$. Summing over φ and exchanging the sums of nonnegative terms,

$$\sum_{\varphi\in\mathcal{A}} F([uy_\varphi]) = \sum_{L\in\mathcal{L}} n(L)\,\mathrm{disc}_r(L)^{-k}, \qquad n(L) = \#\{\varphi :\ L \subseteq \Lambda(u, y_\varphi)\}.$$

By Step 1 and Lemma 5.3.81 (iii), $n(L) \le i(L) N^{fl}$; by Lemma 5.3.81 (i), $\mathrm{disc}_r(L) = i(L)\, d(W_L)$ with $i(L) \ge 1$, $d(W_L) \ge 1$, and $i(L) d(W_L) \le H$.

Step 3: an elementary inequality. For reals $d, i \ge 1$ with $di \le H$,

$$i\,(di)^{-k} \le H^{\mu+2}\, d^{-(k+1)}\, i^{-(r+\mu)}\ :$$

the quotient of the right side by the left side is $H^{\mu+2} d^{-1} i^{\,l-\mu-1}$, and $d \le H$, $i^{\,l-\mu-1} \ge i^{-(\mu+1)} \ge H^{-(\mu+1)}$ (as $1 \le i \le H$ and $l \ge 0$), so the quotient is at least 1. With Step 2,

$$\sum_{\varphi} F([uy_\varphi]) \le N^{fl} H^{\mu+2} \sum_{L\in\mathcal{L}} d(W_L)^{-(k+1)}\, i(L)^{-(r+\mu)}.$$

Step 4: the sum over L, sorted by W_L. Each W_L is a subspace of E^k of dimension r, i.e. of codimension l (Lemma 5.3.81 (i)). Fix such a W that occurs, $W = W_{L_1}$. The $L \in \mathcal{L}$ with $W_L = W$ are lattices of rank r contained in $W(\mathbb{A}_f) \cap u\hat{\mathcal{O}}^k = \mathrm{sat}(L_1) = \mathrm{sat}(L)$, with $i(L) = [\mathrm{sat}(L_1) : L]$. By Lemma 5.3.81 (ii) and Lemma 5.3.84 (degree $m = 2f$, $s = r + \mu$, $t = \mu + 1 = 2\varrho + 5 \ge 3$),

$$\sum_{L\in\mathcal{L},\ W_L = W} i(L)^{-(r+\mu)} \le \sum_{M''} [\hat{\mathcal{O}}^r : M'']^{-(r+\mu)} \le \exp\bigl(2f \cdot 2^{-2\varrho-3}\bigr) \le e^{1/8} < 2,$$

the middle sum over the submodules of $\hat{\mathcal{O}}^r$ of finite index; here $2f \le (\varrho+1)[E:\mathbb{Q}] \le 2^{2\varrho}$ by (FG6), so $2f \cdot 2^{-2\varrho-3} \le \frac{1}{8}$. Hence, by Lemma 5.3.82 (ii) with $s = l$ and $\Lambda = u\hat{\mathcal{O}}^k$ ($u^*u = 1$),

$$\sum_{\varphi} F([uy_\varphi]) \le 2N^{fl} H^{\mu+2} \sum_{W} d(W)^{-(k+1)} \le 2N^{fl} H^{2\varrho+6} X^{f(k+1)l} =: \#\mathcal{A} \cdot \beta,$$

the sum over the subspaces W of codimension l.

Step 5: the classes. As u was arbitrary and $y_\varphi \in K_\circ$, Lemma 5.3.79 gives, with $\#\mathcal{A} \ge (N^k/b)^f$,

$$\sum_{c\in\mathcal{C}} F(c) \le \#\mathcal{C}\,\beta \le \#\mathcal{C}\, N^{-kf} \cdot \bigl(2b^f H^{2\varrho+6}\bigr) \cdot \bigl(N^f X^{f(k+1)}\bigr)^l.$$

Step 6: the constants. By (FG6), $k \ge 1000(2\varrho+2)^9 \ge 5\cdot 10^5 n^9$. First, $2 \le b^f$ and $n^3(2\varrho+6) = n^3(2n+4) \le 6n^4$, so $2b^f H^{2\varrho+6} \le b^{f(2+6n^4)} \le b^{kf/4} = \tau_{\mathrm{sz}}$. Second, $N \le b^{60n}$ by (FA5), and $1 \le X \le b^{1/1000}$ by (FG6), so $N^f X^{f(k+1)} \le b^{f(60n+(k+1)/1000)} \le b^{kf/4} = \tau_{\mathrm{sz}}$, since $60n \le k/8$ and $(k+1)/1000 \le k/8$. Hence $\sum_c F(c) \le \#\mathcal{C}\, N^{-kf} \tau_{\mathrm{sz}}^{l+1}$. □

Lemma 5.3.79. *Let $\mathfrak{S}$ be a filling datum, and for $g \in \mathrm{U}(X_0)(\mathbb{A}_f)$ let $[g] \in \mathcal{C}$ be its double coset. Let $\mathrm{U}(X_0)(\hat{\mathcal{O}}) = \mathrm{U}(X_0)(\mathbb{A}_f) \cap \mathrm{GL}_k(\hat{\mathcal{O}})$, matrices taken in the basis $x_1, \dots, x_k$. Let A be a finite nonempty set, $(a_\varphi)_{\varphi \in A}$ a family in $\mathrm{U}(X_0)(\hat{\mathcal{O}})$, $F \colon \mathcal{C} \to [0, \infty]$ and $\beta \in [0, \infty)$. If*

$$\sum_{\varphi \in A} F([u\, a_\varphi]) \le \#A \cdot \beta \qquad \text{for every } u \in \mathrm{U}(X_0)(\mathbb{A}_f),$$

then $\sum_{c \in \mathcal{C}} F(c) \le \#\mathcal{C} \cdot \beta$.

Proof. Write $\Gamma = \mathrm{U}(X_0)(E^+)$, $G_f = \mathrm{U}(X_0)(\mathbb{A}_f)$ and $K_\circ = \mathrm{U}(X_0)(\hat{\mathcal{O}})$. As $\mathrm{GL}_k(\hat{\mathcal{O}})$ is compact and open in $\mathrm{GL}_k(\mathbb{A}_f)$ and G_f is closed in it, $K_\circ$ is a compact open subgroup of G_f.

A small normal subgroup. For an integer $m \ge 1$ let $K_\circ(m) = \{g \in K_\circ : g \equiv 1 \bmod m\hat{\mathcal{O}}\}$, the kernel of reduction $K_\circ \to \mathrm{GL}_k(\hat{\mathcal{O}}/m\hat{\mathcal{O}})$; it is an open normal subgroup of $K_\circ$, and these groups form a basis of neighbourhoods of 1 in $K_\circ$. Since K_X is open, there is m with $K_1 := K_\circ(m) \subseteq \mathrm{K}_X \cap K_\circ$. As K_X is compact and K_1 is open in it, the index $e = [\mathrm{K}_X : K_1]$ is finite.

The finite set Y. Let $Y = \Gamma \backslash G_f / K_1$ and $p \colon Y \to \mathcal{C}$, $\Gamma g K_1 \mapsto [g]$, well defined as $K_1 \subseteq \mathrm{K}_X$. Fix $c \in \mathcal{C}$ with representative h_c. Every g with $[g] = c$ is $\gamma h_c k$ with $\gamma \in \Gamma$, $k \in \mathrm{K}_X$, so $kK_1 \mapsto \Gamma h_c k K_1$ is a surjection from the set K_X/K_1 of left cosets onto $p^{-1}(c)$. It is injective: if $\Gamma h_c k K_1 = \Gamma h_c k' K_1$, then $h_c k' = \gamma h_c k k_1$ with $\gamma \in \Gamma$, $k_1 \in K_1$, so $h_c^{-1} \gamma h_c = k' k_1^{-1} k^{-1} \in \mathrm{K}_X \cap h_c^{-1} \Gamma h_c = \{1\}$ by (FG4), whence $\gamma = 1$ and $k' \in kK_1$. Hence $\#p^{-1}(c) = e$ for every c, Y is finite, $\#Y = e\,\#\mathcal{C}$, and for every $G \colon \mathcal{C} \to [0, \infty]$

$$\sum_{y \in Y} G(p(y)) = e \sum_{c \in \mathcal{C}} G(c). \tag{5.72}$$

Right translation. For $a \in K_\circ$ the map $\Gamma g K_1 \mapsto \Gamma g a K_1$ is well defined, since $gK_1 a = gaK_1$ (K_1 is normal in $K_\circ$), and it is a bijection of Y, with inverse given by a^{-1}. Hence, for each $\varphi \in A$, $\sum_y F(p(y\, a_\varphi)) = \sum_y F(p(y))$, where $y\, a_\varphi$ denotes the translate.

Conclusion. For each $y \in Y$ choose $u_y \in G_f$ with $y = \Gamma u_y K_1$; then $p(y\, a_\varphi) = [u_y a_\varphi]$. Summing the translation identity over φ and applying the hypothesis with $u = u_y$,

$$\#A \sum_{y \in Y} F(p(y)) = \sum_{y \in Y} \sum_{\varphi \in A} F([u_y a_\varphi]) \le \#Y \cdot \#A \cdot \beta = e\,\#\mathcal{C}\,\#A\,\beta.$$

By (5.72) with $G = F$ the left side is $\#A \cdot e \sum_c F(c)$; all quantities lie in $[0, \infty]$ and the right side is finite, so dividing by $\#A \cdot e > 0$ gives $\sum_c F(c) \le \#\mathcal{C}\,\beta$. □

Lemma 5.3.80. *Let $\mathfrak{S}$ be a filling datum; $\mathrm{U}(X_0) \subseteq G$ acts trivially on $X_0^\perp$, vectors of $X_0(\mathbb{A}_f) = \mathbb{A}_f^k$ are columns in the basis $x_1, \dots, x_k$, and for $u \in \mathrm{U}(X_0)(\mathbb{A}_f)$, $y \in \mathrm{U}(X_0)(\hat{\mathcal{O}})$ put*

$$\Lambda(u, y) = \{v \in u\hat{\mathcal{O}}^k : \ (y^{-1}u^{-1}v)_k \in \pi\hat{\mathcal{O}}\}.$$

(i) $L_0 \cap X_0(\mathbb{A}_f) = \{v \in \hat{\mathcal{O}}^k : \ v_k \in \pi\hat{\mathcal{O}}\}$.

(ii) $\mathrm{U}(X_0)(\mathbb{A}_f) \cap K \subseteq \mathrm{U}(X_0)(\hat{\mathcal{O}})$. *If $y, y' \in \mathrm{U}(X_0)(\hat{\mathcal{O}})$ and the k-th rows of y^{-1} and y'^{-1} differ by an element of $\pi\hat{\mathcal{O}}^{1\times k}$, then $y^{-1}y' \in K$.*

(iii) Suppose (FA1). Let $u \in \mathrm{U}(X_0)(\mathbb{A}_f)$, $y \in \mathrm{U}(X_0)(\hat{\mathcal{O}})$ and $c = [uy]$. Then there is $\eta \in \mathrm{U}(X_0)(E^+)$ such that for every $r \ge 0$ the map $L \mapsto \eta^{-1}L$ is a bijection from the lattices of rank r contained in $L_c \cap X_0(\mathbb{A}_f)$ onto the lattices of rank r contained in $\Lambda(u, y)$, and $\mathrm{disc}_r(\eta^{-1}L) = \mathrm{disc}_r(L)$.

Proof. Write $L_0' = L_0 \cap X_0(\mathbb{A}_f)$ and $K_\circ = \mathrm{U}(X_0)(\hat{\mathcal{O}})$. As $\pi \in \hat{\mathcal{O}}$ and $\pi\bar{\pi} = N$ is a unit of $\mathbb{A}_f$, π and $\bar{\pi}$ are units of $\mathbb{A}_f$. By (FG2), at every finite place w one of π, $\bar{\pi}$ is a unit of $\mathcal{O}_w$ (if π is not, then π is a unit at $\bar{w}$, i.e. $\bar{\pi}$ is a unit at w); hence

$$\pi\hat{\mathcal{O}} \cap \bar{\pi}\hat{\mathcal{O}} = N\hat{\mathcal{O}}. \tag{5.73}$$

(i) Let $v \in L_0'$. In the lattice basis, $v = \sum_a(\alpha_a e_a + \alpha_a^* e_a^*) + \sum_{i<k} a_i x_i + a'x' + bz$ with all coefficients in $\hat{\mathcal{O}}$ and $x' = x_k/\bar{\pi} + z/N$. As $v \in X_0(\mathbb{A}_f)$, the α_a, α_a^* vanish and the coefficient $a'/N + b$ of z is 0; so $a' = -Nb$, $v_i = a_i \in \hat{\mathcal{O}}$ for $i < k$ and $v_k = a'/\bar{\pi} = -\pi b \in \pi\hat{\mathcal{O}}$. Conversely, if $v \in \hat{\mathcal{O}}^k$ and $v_k = \pi c$ with $c \in \hat{\mathcal{O}}$, then $v = \sum_{i<k} v_i x_i + Nc\,x' - c\,z \in L_0$.

(ii), first claim. Let $g \in \mathrm{U}(X_0)(\mathbb{A}_f) \cap K$. Then g preserves L_0 and $X_0(\mathbb{A}_f)$, hence L_0', and fixes z. For $i < k$, $x_i \in L_0'$ by (i), so $gx_i \in L_0' \subseteq \hat{\mathcal{O}}^k$. Further $gx' - x' = (gx_k - x_k)/\bar{\pi}$ lies in $L_0 \cap X_0(\mathbb{A}_f) = L_0' \subseteq \hat{\mathcal{O}}^k$, so $gx_k \in x_k + \bar{\pi}\hat{\mathcal{O}}^k \subseteq \hat{\mathcal{O}}^k$. Thus $g\hat{\mathcal{O}}^k \subseteq \hat{\mathcal{O}}^k$; the same holds for $g^{-1} \in K$, so $g \in \mathrm{GL}_k(\hat{\mathcal{O}})$.

(ii), second claim. Put $\kappa = y^{-1}y' \in K_\circ$. Then $e_k^T\kappa - e_k^T = (e_k^T y^{-1} - e_k^T y'^{-1})y' \in \pi\hat{\mathcal{O}}^{1\times k}$, as y' is integral. We show: every $\kappa \in K_\circ$ with $e_k^T(\kappa - 1) \in \pi\hat{\mathcal{O}}^{1\times k}$ satisfies $\kappa L_0 \subseteq L_0$. Write $e_k^T\kappa = e_k^T + \pi\rho$ with $\rho \in \hat{\mathcal{O}}^{1\times k}$. Since $\kappa^*\kappa = 1$, $\kappa^{-1} = \kappa^*$, so $e_k^T = (e_k^T + \pi\rho)\kappa^*$ and $e_k^T\kappa^* = e_k^T - \pi\rho\kappa^* \in e_k^T + \pi\hat{\mathcal{O}}^{1\times k}$. The entries of $e_k^T\kappa^*$ are $\overline{\kappa_{ik}}$, so $\kappa_{ik} - \delta_{ik} \in \bar{\pi}\hat{\mathcal{O}}$ for all i; in particular $\kappa_{kk} - 1 \in \pi\hat{\mathcal{O}} \cap \bar{\pi}\hat{\mathcal{O}} = N\hat{\mathcal{O}}$ by (5.73). Now κ fixes the e_a, e_a^* and z. For $i < k$, κx_i has integral coordinates with k-th coordinate $\kappa_{ki} \in \pi\hat{\mathcal{O}}$, so $\kappa x_i \in L_0$ by (i). Finally $\kappa x' - x' = (\kappa x_k - x_k)/\bar{\pi}$ has integral coordinates $(\kappa_{ik} - \delta_{ik})/\bar{\pi}$ and k-th coordinate $(\kappa_{kk} - 1)/\bar{\pi} \in (N/\bar{\pi})\hat{\mathcal{O}} = \pi\hat{\mathcal{O}}$, so it lies in L_0 by (i), and $\kappa x' \in L_0$. Hence $\kappa L_0 \subseteq L_0$. As $e_k^T(\kappa^{-1} - 1) = -e_k^T(\kappa - 1)\kappa^{-1} \in \pi\hat{\mathcal{O}}^{1\times k}$, also $\kappa^{-1}L_0 \subseteq L_0$, so $\kappa L_0 = L_0$ and $\kappa \in K$.

(iii) As $[uy] = c = [h_c]$, $h_c = \eta uyg$ with $\eta \in \mathrm{U}(X_0)(E^+)$ and $g \in \mathrm{K}_X$. By (FA1), $g \in \mathrm{K}(M) \subseteq K$, so g preserves L_0 and $X_0(\mathbb{A}_f)$, hence $gL_0' = L_0'$; and h_c preserves $X_0(\mathbb{A}_f)$. Therefore

$$L_c \cap X_0(\mathbb{A}_f) = h_c L_0 \cap h_c X_0(\mathbb{A}_f) = h_c L_0' = \eta\, uy\, L_0'.$$

By (i), $v \in uyL_0'$ if and only if $y^{-1}u^{-1}v \in \hat{\mathcal{O}}^k$ and $(y^{-1}u^{-1}v)_k \in \pi\hat{\mathcal{O}}$; as $y \in K_\circ$, the first condition is equivalent to $u^{-1}v \in \hat{\mathcal{O}}^k$, so $uyL_0' = \Lambda(u, y)$. Thus η^{-1} maps $L_c \cap X_0(\mathbb{A}_f)$ bijectively onto $\Lambda(u, y)$, and $L \mapsto \eta^{-1}L$ is a bijection between their $\hat{\mathcal{O}}$-submodules. If $L = B\hat{\mathcal{O}}^r$ with $B = xa$, $x \in \mathrm{M}_{k\times r}(E)$ of rank r and $a \in \mathrm{GL}_r(\mathbb{A}_f)$, then $\eta^{-1}L = (\eta^{-1}x)a\hat{\mathcal{O}}^r$ with $\eta^{-1}x \in \mathrm{M}_{k\times r}(E)$ of rank r, and conversely with η in place of η^{-1}; so lattices of rank r correspond. Since $\eta^*\eta = 1$, $(\eta^{-1})^*\eta^{-1} = \eta\eta^* = 1$ and $(\eta^{-1}B)^*(\eta^{-1}B) = B^*B$, so $\mathrm{disc}_r(\eta^{-1}L) = \mathrm{disc}_r(L)$. □

Lemma 5.3.81. *Let $\mathfrak{S}$ be a filling datum, $u \in \mathrm{U}(X_0)(\mathbb{A}_f)$, $0 \le r \le k$, $l = k - r$, and $L \subseteq u\hat{\mathcal{O}}^k$ a lattice of rank r. Let $W = E^k \cap \mathbb{A}_f L$, where $\mathbb{A}_f L$ is the $\mathbb{A}_f$-span of L, and* $\mathrm{sat}(L) = W(\mathbb{A}_f) \cap u\hat{\mathcal{O}}^k$.

(i) W is an E-subspace of dimension r; $\mathrm{sat}(L)$ *is a lattice of rank r containing L, the index $i(L) = [\mathrm{sat}(L) : L]$ is a positive integer, $d(W) := \mathrm{disc}_r(\mathrm{sat}(L)) \ge 1$, and* $\mathrm{disc}_r(L) = i(L)\,d(W)$.

(ii) If $\mathrm{sat}(L) = B_s\hat{\mathcal{O}}^r$ *with $B_s \in \mathrm{M}_{k\times r}(\mathbb{A}_f)$ as in (LT3), then $M \mapsto B_s^{-1}M$ is a bijection from the lattices of rank r contained in* $\mathrm{sat}(L)$ *onto the $\hat{\mathcal{O}}$-submodules of $\hat{\mathcal{O}}^r$ of finite index, with* $[\mathrm{sat}(L) : M] = [\hat{\mathcal{O}}^r : B_s^{-1}M]$*; every such M has $E^k \cap \mathbb{A}_f M = W$.*

(iii) Let $y_1, \dots, y_m \in \mathrm{U}(X_0)(\hat{\mathcal{O}})$ be such that the k-th rows of y_j^{-1} and $y_{j'}^{-1}$ do not differ by an element of $\pi\hat{\mathcal{O}}^{1\times k}$ for $j \ne j'$, and $L \subseteq \Lambda(u, y_j)$ for all j. Then $m \le i(L)\,N^{fl}$.

Proof. Write $\Lambda = u\hat{\mathcal{O}}^k$; as $u^*u = 1$, $u^{-1} = u^*$ and $(u^{-1})^*u^{-1} = 1$.

(i) Let $L = xa\hat{\mathcal{O}}^r$ as in (LT3), $x \in \mathrm{M}_{k\times r}(E)$ of rank r, with left inverse $x^+ \in \mathrm{M}_{r\times k}(E)$. Then $\mathbb{A}_f L = x\mathbb{A}_f^r$, and $xz \in E^k$ with $z \in \mathbb{A}_f^r$ forces $z = x^+xz \in E^r$; so $W = xE^r$ has dimension r and $W(\mathbb{A}_f) = x\mathbb{A}_f^r$. By the first assertion of Lemma 5.3.82 (for the subspace W and Λ), $\mathrm{sat}(L) = B_s\hat{\mathcal{O}}^r$ with $B_s = x_s a_s$, $x_s \in \mathrm{M}_{k\times r}(E)$ a basis of W and $a_s \in \mathrm{GL}_r(\mathbb{A}_f)$: a lattice of rank r, with $d(W)$ the quantity of that lemma. Clearly $L \subseteq \mathrm{sat}(L)$. As $x = x_s g$ for some $g \in \mathrm{GL}_r(E)$, $L = B_s A\hat{\mathcal{O}}^r$ with $A = a_s^{-1}ga \in \mathrm{GL}_r(\mathbb{A}_f)$, and $B_s\colon \mathbb{A}_f^r \to W(\mathbb{A}_f)$ is an isomorphism; so $L \subseteq \mathrm{sat}(L)$ gives $A\hat{\mathcal{O}}^r \subseteq \hat{\mathcal{O}}^r$, i.e. $A \in \mathrm{M}_r(\hat{\mathcal{O}})$. By elementary divisors at each place, $[\mathrm{sat}(L) : L] = [\hat{\mathcal{O}}^r : A\hat{\mathcal{O}}^r] = \prod_w |\det A_w|_w^{-1} = [\det A]$, a finite product of powers of residue cardinalities, hence a positive integer. Since $B^*B = A^*(B_s^*B_s)A$ for $B = B_sA$ and $[\overline{\det A}] = [\det A]$, $\mathrm{disc}_r(L) = [\det A]\,\mathrm{disc}_r(\mathrm{sat}(L)) = i(L)\,d(W)$. Finally $m_s = u^{-1}B_s$ has columns in $\hat{\mathcal{O}}^k$ and $B_s^*B_s = m_s^*m_s$; so $\delta = \det(B_s^*B_s)$ is integral, and a unit of $\mathbb{A}_f$ by (LT3), whence $d(W)^2 = [\delta] = \prod_w |\delta_w|_w^{-1} \geq 1$.

(ii) If $M \subseteq \mathrm{sat}(L)$ is a lattice of rank r, $M = x_M a_M \hat{\mathcal{O}}^r$, then $x_M E^r = E^k \cap \mathbb{A}_f M \subseteq E^k \cap W(\mathbb{A}_f) = W$, and both have dimension r, so $E^k \cap \mathbb{A}_f M = W$; as in (i), $M = B_s A_M \hat{\mathcal{O}}^r$ with $A_M \in \mathrm{M}_r(\hat{\mathcal{O}}) \cap \mathrm{GL}_r(\mathbb{A}_f)$, so $B_s^{-1}M = A_M\hat{\mathcal{O}}^r$ has finite index $[\det A_M] = [\mathrm{sat}(L) : M]$. Conversely, a submodule $M'' \subseteq \hat{\mathcal{O}}^r$ of finite index n contains $n\hat{\mathcal{O}}^r$, so it is open and compact, hence at each place a free $\mathcal{O}_w$-module of rank r equal to $\mathcal{O}_w^r$ for $w \nmid n$: $M'' = A\hat{\mathcal{O}}^r$ with $A \in \mathrm{GL}_r(\mathbb{A}_f)$, and $B_sM'' = x_s(a_sA)\hat{\mathcal{O}}^r$ is a lattice of rank r in $\mathrm{sat}(L)$. The two maps are inverse to each other, as B_s is injective.

(iii) Put $m_s = u^{-1}B_s \in \mathrm{M}_{k\times r}(\hat{\mathcal{O}})$. At each finite place w, $m_{s,w}\mathcal{O}_w^r = V_w \cap \mathcal{O}_w^k$ with $V_w = u_w^{-1}W(E_w)$ an E_w-subspace, so $\mathcal{O}_w^k/m_{s,w}\mathcal{O}_w^r$ embeds into E_w^k/V_w, is torsion-free, hence free, and the columns of $m_{s,w}$ extend to a basis of $\mathcal{O}_w^k$. This gives $U \in \mathrm{GL}_k(\hat{\mathcal{O}})$ whose first r columns are those of m_s. With A as in (i), $u^{-1}L = m_sA\hat{\mathcal{O}}^r$. Let $\rho_j = e_k^T y_j^{-1} \in \hat{\mathcal{O}}^{1\times k}$. Since $L \subseteq \Lambda$, the condition $L \subseteq \Lambda(u, y_j)$ says $\rho_j u^{-1}v \in \pi\hat{\mathcal{O}}$ for $v \in L$, i.e.

$$\rho_j m_s A \in \pi\hat{\mathcal{O}}^{1\times r}.$$

Write $\rho_j U = (s_j, t_j)$ with $s_j = \rho_j m_s \in \hat{\mathcal{O}}^{1\times r}$ and $t_j \in \hat{\mathcal{O}}^{1\times l}$, and put $W_j = \pi^{-1}s_jA \in \hat{\mathcal{O}}^{1\times r}$. Colour j by the class of W_j in $\hat{\mathcal{O}}^{1\times r}/\hat{\mathcal{O}}^{1\times r}A$ and the class of t_j in $\hat{\mathcal{O}}^{1\times l}/\pi\hat{\mathcal{O}}^{1\times l}$. If j, j' have the same colour, then $W_j - W_{j'} = zA$ with z integral, so $s_j - s_{j'} = \pi z$ (A is invertible), and $t_j - t_{j'} \in \pi\hat{\mathcal{O}}^{1\times l}$; hence $(\rho_j - \rho_{j'})U \in \pi\hat{\mathcal{O}}^{1\times k}$ and $\rho_j - \rho_{j'} \in \pi\hat{\mathcal{O}}^{1\times k}U^{-1} = \pi\hat{\mathcal{O}}^{1\times k}$, so $j = j'$. Therefore m is at most the number of colours,

$$m \leq [\hat{\mathcal{O}}^{1\times r} : \hat{\mathcal{O}}^{1\times r}A]\,[\hat{\mathcal{O}} : \pi\hat{\mathcal{O}}]^l = [\det A]\,[\pi]^l.$$

Finally $[\pi] = N^f$: $[\pi][\bar{\pi}] = [N] = |N_{E/\mathbb{Q}}(N)| = N^{2f}$ and $[\bar{\pi}] = [\pi]$. With $[\det A] = i(L)$ this is (iii). □

Lemma 5.3.82. *Let E be a CM field of degree $2f$ with root discriminant rd_E, Φ a set of f embeddings $E \to \mathbb{C}$ containing one of each pair of complex conjugate embeddings, $k \geq 1$, and $u \in \mathrm{GL}_k(\mathbb{A}_f)$ with $u^*u = 1$; put $\Lambda = u\hat{\mathcal{O}}^k$. For $x \in E^k$ let $\|x\| = (\sum_{v\in\Phi}\sum_i |v(x_i)|^2)^{1/2}$, and $h(x,t) = \sum_i \bar{x}_i t_i$. For an E-subspace $T \subseteq E^k$ of dimension m the $\hat{\mathcal{O}}$-module $T(\mathbb{A}_f) \cap \Lambda$ equals $B\hat{\mathcal{O}}^m$ for some $B = xa$ with $x \in \mathrm{M}_{k\times m}(E)$ of rank m and $a \in \mathrm{GL}_m(\mathbb{A}_f)$, and $d(T) = [\det(B^*B)]^{1/2}$ does not depend on B. Let $0 \leq s \leq k$.*

(i) For every subspace T of codimension s there are nonzero $X_1, \ldots, X_s \in E^k \cap \Lambda$ with $T = \{t \in E^k : h(X_l, t) = 0\ (1 \leq l \leq s)\}$ and

$$\Big(\prod_{l=1}^{s} \|X_l\|\Big)^{2f} \leq (fs\,\mathrm{rd}_E)^{fs}\,d(T).$$

(ii) $\sum_T d(T)^{-(k+1)} \le (200fk\,\mathrm{rd}_E)^{f(k+1)s}$, *the sum over all subspaces* $T \subseteq E^k$ *of codimension* s.

Proof. Write $\Lambda_E = E^k \cap \Lambda$. As u is unitary, $h(x,t)$, extended to $\mathbb{A}_f^k$, takes values in $\hat{\mathcal{O}}$ on Λ, so $h(x,x) \in \mathcal{O}_E$ for $x \in \Lambda_E$.

Bases and $d(T)$. Let T have dimension m and a basis matrix $x \in \mathrm{M}_{k\times m}(E)$. Then $T(\mathbb{A}_f) = x\mathbb{A}_f^m$ and $T(\mathbb{A}_f) \cap \Lambda = x\mathcal{M}$ with $\mathcal{M} = \{z \in \mathbb{A}_f^m : xz \in \Lambda\}$; Λ is open and compact and x is injective with a left inverse over E, so $\mathcal{M}$ is an open compact $\hat{\mathcal{O}}$-submodule of $\mathbb{A}_f^m$, at each place a finitely generated torsion-free $\mathcal{O}_w$-module of rank m, hence $\mathcal{M} = a\hat{\mathcal{O}}^m$ with $a \in \mathrm{GL}_m(\mathbb{A}_f)$. Two such B differ by an element of $\mathrm{GL}_m(\hat{\mathcal{O}})$ on the right, so $d(T)$ is well defined; and $d(T)^2 = [\det a]^2\,|\mathrm{N}_{E/\mathbb{Q}} \det(x^*x)|$, with $\det(x^*x) \in E^\times$ totally positive.

Duality: $d(T) = d(T^\perp)$, $T^\perp = \{t : h(x',t) = 0\ \forall x' \in T\}$. Let $B = xa$ and $B' = ya'$ be bases of $T(\mathbb{A}_f) \cap \Lambda$ and $T^\perp(\mathbb{A}_f) \cap \Lambda$ as above, $m' = k - m$, and put $F = u^{-1}B$, $P = u^{-1}B'$. As $uu^* = 1$, $F^*P = B^*B' = 0$, $F^*F = B^*B$ and $P^*P = B'^*B'$, both with unit determinant. The columns of P are an $\hat{\mathcal{O}}$-basis of $u^{-1}T^\perp(\mathbb{A}_f) \cap \hat{\mathcal{O}}^k$, a saturated submodule of $\hat{\mathcal{O}}^k$, hence locally a direct summand: P is primitive. Apply Lemma 5.3.8 with $J = 1$, $m_1 = m$, $m_2 = m'$, $m_3 = 0$ and $t = 1$: then $\mathcal{M} = F^*F$, $R = P^*P$, and $[\det(B^*B)] = i(F)^2[\det(B'^*B')]$. Here $Fz \in \hat{\mathcal{O}}^k$ means $xaz \in \Lambda$, that is $az \in a\hat{\mathcal{O}}^m$, so $i(F) = 1$, and $d(T) = d(T^\perp)$.

(i) Let $W = T^\perp$, of dimension s, and $B' = ya'$ a basis of $W(\mathbb{A}_f) \cap \Lambda$ ($y \in \mathrm{M}_{k\times s}(E)$ of rank s). For each $v \in \Phi$ the complex matrix $v(y)$ has rank s, so (Gram–Schmidt) there is $r_v \in \mathrm{GL}_s(\mathbb{C})$ with $(v(y)r_v)^*(v(y)r_v) = 1$; then $|\det r_v|^{-2} = \det(v(y)^*v(y)) = v(\det(y^*y))$. By Lemma 5.3.83 (ii) for (r, a') there is a basis $B_1, \dots, B_s$ of E^s with $a'^{-1}B_l$ integral and

$$\prod_v |\det r_v|^2\,[\det a']^{-1} \prod_l \|B_l\|_r^{2f} \le (fs\,\mathrm{rd}_E)^{fs}.$$

Put $X_l = yB_l \in E^k$. Then $u^{-1}X_l = (u^{-1}ya')(a'^{-1}B_l)$ is integral, so $X_l \in \Lambda_E$, and $X_l \ne 0$ as y is injective. The X_l span $yE^s = W$, so $T = W^\perp = \{t : h(X_l, t) = 0\ \forall l\}$. Since $v(y)r_v$ has orthonormal columns, $\|v(y)v(B_l)\| = \|r_v^{-1}v(B_l)\|$, so $\|X_l\| = \|B_l\|_r$. Finally $\prod_v v(\det(y^*y)) = |\mathrm{N}_{E/\mathbb{Q}} \det(y^*y)|^{1/2}$ ($\det(y^*y)$ lies in the totally real subfield and is totally positive), so by the first step and duality

$$\prod_v |\det r_v|^2 [\det a']^{-1} = \left([\det a']^2 |\mathrm{N}_{E/\mathbb{Q}} \det(y^*y)|\right)^{-1/2} = d(W)^{-1} = d(T)^{-1},$$

which gives (i).

Short vectors are separated. For $0 \ne x \in \Lambda_E$, $\alpha = h(x,x) \in \mathcal{O}_E$ is nonzero and totally positive, so $|\mathrm{N}_{E/\mathbb{Q}}\alpha| = \prod_v v(\alpha)^2 \ge 1$ and, by the inequality of arithmetic and geometric means, $\|x\|^2 = \sum_v v(\alpha) \ge f \ge 1$. Hence distinct points of Λ_E have distance at least 1 in $V_\infty = \prod_v \mathbb{C}^k \cong \mathbb{R}^{2fk}$, the open balls of radius $\frac{1}{2}$ about them are disjoint, and $\#\{x \in \Lambda_E : \|x\| \le R\} \le (1+2R)^{2fk} \le (3R)^{2fk}$ for $R \ge 1$. With $N = 2f(k+1)$ and $D = 2fk$, by partial summation (layer cake) over the nonzero x, all of norm ≥ 1,

$$\begin{aligned}\sum_{0\ne x\in\Lambda_E} \|x\|^{-N} &= \int_1^\infty NR^{-N-1}\#\{0 \ne x : \|x\| \le R\}\,dR \\ &\le N3^D \int_1^\infty R^{D-N-1}dR = \frac{N3^D}{N-D} = (k+1)\,3^{2fk} \le 5^{2f(k+1)},\end{aligned}$$

the last step as $k + 1 \le 1 + \frac{4}{3}fk \le (5/3)^{2fk}$.

(ii) For each T of codimension s fix a tuple $X(T)=(X_1,\dots,X_s)$ of nonzero vectors of Λ_E as in (i). As T is the orthogonal of its tuple, $T\mapsto X(T)$ is injective. Raising (i) to the power $k+1$,

$$d(T)^{-(k+1)}\le (fs\,\mathrm{rd}_E)^{f(k+1)s}\prod_{l=1}^{s}\|X_l\|^{-N}.$$

Summing over T and then over all s-tuples of nonzero vectors of Λ_E (all terms are nonnegative),

$$\sum_T d(T)^{-(k+1)}\le (fs\,\mathrm{rd}_E)^{f(k+1)s}\Big(\sum_{0\neq x\in\Lambda_E}\|x\|^{-N}\Big)^s\le (25fs\,\mathrm{rd}_E)^{f(k+1)s}\le (200fk\,\mathrm{rd}_E)^{f(k+1)s},$$

as $s\le k$. (For $s=0$ the tuple is empty, $T=E^k$ and $d(E^k)=[\det u^*u]^{1/2}=1$.) □

Lemma 5.3.83. *Let E be a CM field of degree $2f$ with discriminant d_E and root discriminant $\mathrm{rd}_E=|d_E|^{1/(2f)}$, and Φ a set of f embeddings $E\to\mathbb{C}$ containing one of each pair of complex conjugate embeddings. Let $s\ge 1$, $a\in\mathrm{GL}_s(\mathbb{A}_f)$ and $r=(r_v)_{v\in\Phi}$ with $r_v\in\mathrm{GL}_s(\mathbb{C})$. Put*

$$\Lambda=\{B\in E^s:\ a^{-1}B\in\hat{\mathcal{O}}^s\},\qquad \|B\|_r=\Big(\sum_{v\in\Phi}\|r_v^{-1}v(B)\|^2\Big)^{1/2},$$

where $v(B)\in\mathbb{C}^s$ is the entrywise image and $\|\cdot\|$ the standard hermitian norm of $\mathbb{C}^s$. Give $V_\infty=\prod_{v\in\Phi}\mathbb{C}^s$ the real inner product $\langle x,y\rangle=\mathrm{Re}\sum_v\sum_i\bar{x}_{v,i}y_{v,i}$ and its Lebesgue measure, and put $j(B)=(r_v^{-1}v(B))_{v\in\Phi}$ for $B\in E^s$. Then:

(i) $j(\Lambda)$ is a lattice in V_∞ of covolume $2^{-fs}|d_E|^{s/2}\,[\det a]\prod_{v\in\Phi}|\det r_v|^{-2}$;

(ii) there is a basis $B_1,\dots,B_s$ of E^s over E with $B_i\in\Lambda$ for all i and

$$\prod_{v\in\Phi}|\det r_v|^2\cdot[\det a]^{-1}\cdot\prod_{i=1}^{s}\|B_i\|_r^{2f}\le(fs\,\mathrm{rd}_E)^{fs}.$$

Proof. Let $V_\infty=\prod_{v\in\Phi}\mathbb{C}^s$ with the real inner product $\langle x,y\rangle=\mathrm{Re}\sum_v\sum_i\bar{x}_{v,i}y_{v,i}$, a euclidean space of dimension $2fs$ whose Lebesgue measure is the standard one, and $j\colon E^s\to V_\infty$, $j(B)=(r_v^{-1}v(B))_v$, so that $\|B\|_r=\|j(B)\|$. Put $L=a\hat{\mathcal{O}}^s$, so $\Lambda=E^s\cap L$.

(i): $j(\Lambda)$ is a lattice of covolume $2^{-fs}|d_E|^{s/2}[\det a]\prod_v|\det r_v|^{-2}$. The $\hat{\mathcal{O}}$-module L is open and compact in $\mathbb{A}_f^s$, so there are integers $m_1,m_2\ge1$ with $m_1\hat{\mathcal{O}}^s\subseteq L\subseteq m_2^{-1}\hat{\mathcal{O}}^s$, and intersecting with E^s ($E\cap\hat{\mathcal{O}}=\mathcal{O}_E$), $m_1\mathcal{O}_E^s\subseteq\Lambda\subseteq m_2^{-1}\mathcal{O}_E^s$. By Minkowski's theorem on $\mathcal{O}_E$ (applied coordinatewise), $j_1(\mathcal{O}_E^s)$ is a lattice of covolume $(2^{-f}|d_E|^{1/2})^s$ for $j_1=j$ with all $r_v=1$; hence $j_1(\Lambda)$ is a lattice, of covolume $(2^{-f}|d_E|^{1/2})^s\,[\mathcal{O}_E^s:\Lambda\cap\mathcal{O}_E^s]/[\Lambda:\Lambda\cap\mathcal{O}_E^s]$. The field E is dense in $\mathbb{A}_f$ ($\mathbb{A}_f=E+m\hat{\mathcal{O}}$ for every integer $m\ge1$, by $\mathbb{A}_f=E+\hat{\mathcal{O}}$ applied to x/m), and $L\cap\hat{\mathcal{O}}^s$ is open, so the injective maps $\Lambda/(\Lambda\cap\mathcal{O}_E^s)\to L/(L\cap\hat{\mathcal{O}}^s)$ and $\mathcal{O}_E^s/(\Lambda\cap\mathcal{O}_E^s)\to\hat{\mathcal{O}}^s/(L\cap\hat{\mathcal{O}}^s)$ are surjective: for $x\in L$ choose $B\in E^s$ with $B-x\in L\cap\hat{\mathcal{O}}^s$; then $B\in\Lambda$. So the quotient of the two indices is $[\hat{\mathcal{O}}^s:L\cap\hat{\mathcal{O}}^s]/[L:L\cap\hat{\mathcal{O}}^s]=\prod_w[\mathcal{O}_w^s:L_w\cap\mathcal{O}_w^s]/[L_w:L_w\cap\mathcal{O}_w^s]=\prod_w|\det a_w|_w^{-1}=[\det a]$, where at each finite place w the last equality follows from the elementary divisor theorem for a_w over the principal ideal domain $\mathcal{O}_w$ (write $a_w=k_1\mathrm{diag}(\varpi_w^{e_i})k_2$ with $k_1,k_2\in\mathrm{GL}_s(\mathcal{O}_w)$). Finally $j=(r_v^{-1})_v\circ j_1$, and the complex linear map r_v^{-1} of $\mathbb{C}^s$ has real determinant $|\det r_v|^{-2}$.

(ii), successive minima. By Theorem A.6.3 in $V_\infty\cong\mathbb{R}^{2fs}$, with $\mathrm{vol}(B_{2fs})=\pi^{fs}/(fs)!$, there are $\mathbb{R}$-linearly independent $y_1,\dots,y_{2fs}\in j(\Lambda)$ with $\|y_m\|=\lambda_m$, $\lambda_1\le\cdots\le\lambda_{2fs}$ the successive minima, and

$$\prod_{m=1}^{2fs}\lambda_m\le\frac{2^{2fs}(fs)!}{\pi^{fs}}\,2^{-fs}|d_E|^{s/2}[\det a]\prod_v|\det r_v|^{-2}.$$

An E-basis among the minima. Write $y_m = j(Y_m)$ with $Y_m \in \Lambda$ (j is injective). Choose indices $m_1 < m_2 < \dots$ greedily: $m_1 = 1$, and m_i is the least m such that Y_m is not in the E-span of $Y_{m_1}, \dots, Y_{m_{i-1}}$. An E-subspace of E^s of dimension d is mapped by j into a real subspace of dimension $2fd$; as the y_m are $\mathbb{R}$-independent, $y_1, \dots, y_{m_i-1}$, which lie in the image of an E-subspace of dimension $i-1$, number at most $2f(i-1)$, so $m_i \le 2f(i-1)+1$. The y_m span $V_\infty = j(E^s) \otimes \mathbb{R}$, so the Y_m span E^s and the choice produces s indices; put $B_i = Y_{m_i}$, a basis of E^s in Λ. As the minima increase, $\|B_i\|_r = \lambda_{m_i} \le \lambda_m$ for $2f(i-1) < m \le 2fi$, so

$$\prod_{i=1}^{s} \|B_i\|_r^{2f} \le \prod_{i=1}^{s} \prod_{m=2f(i-1)+1}^{2fi} \lambda_m = \prod_{m=1}^{2fs} \lambda_m.$$

The constant. With $|d_E|^{s/2} = \mathrm{rd}_E^{fs}$, $(fs)! \le (fs)^{fs}$ and $2/\pi < 1$,

$$\prod_v |\det r_v|^2 [\det a]^{-1} \prod_i \|B_i\|_r^{2f} \le \Big(\frac{2}{\pi}\Big)^{fs} (fs)! \, \mathrm{rd}_E^{fs} \le (fs \, \mathrm{rd}_E)^{fs}.$$

□

Lemma 5.3.84. *Let E be a number field of degree m, $\hat{\mathcal{O}}$ its ring of integral finite adeles, $r \ge 0$ an integer and s a real number with $t = s - r + 1 \ge 3$. Then*

$$\sum_M [\hat{\mathcal{O}}^r : M]^{-s} \le \exp\big(m \, 2^{2-t}\big),$$

the sum over all $\hat{\mathcal{O}}$-submodules $M \subseteq \hat{\mathcal{O}}^r$ of finite index.

Proof. For $r = 0$ the only module is $M = 0$, of index 1, and the bound holds. Let $r \ge 1$ and put $\sigma_i = s - r + i = t - 1 + i$ for $1 \le i \le r$; so $\sigma_i \ge t \ge 3$. Write $\mathcal{O} = \mathcal{O}_E$, embedded diagonally in $\hat{\mathcal{O}} = \prod_w \mathcal{O}_w$.

Adelic and global submodules. Let $n \ge 1$ be an integer. By the Chinese remainder theorem, $\mathcal{O}/n\mathcal{O} \cong \prod_{w|n} \mathcal{O}/\mathfrak{p}_w^{v_w(n)}$, and $\mathcal{O}/\mathfrak{p}_w^{v_w(n)} \to \mathcal{O}_w/n\mathcal{O}_w$ is an isomorphism for each finite place w with prime ideal $\mathfrak{p}_w$; as $\mathcal{O}_w/n\mathcal{O}_w = 0$ for $w \nmid n$, the diagonal map $\mathcal{O}/n\mathcal{O} \to \hat{\mathcal{O}}/n\hat{\mathcal{O}}$ is a ring isomorphism. Hence $\mathcal{O}^r/n\mathcal{O}^r \to \hat{\mathcal{O}}^r/n\hat{\mathcal{O}}^r$ is an isomorphism of $\mathcal{O}$-modules, and, since $\hat{\mathcal{O}}$ acts on $\hat{\mathcal{O}}^r/n\hat{\mathcal{O}}^r$ through $\hat{\mathcal{O}}/n\hat{\mathcal{O}}$, which is the image of $\mathcal{O}$, the $\mathcal{O}$-submodules and the $\hat{\mathcal{O}}$-submodules of $\hat{\mathcal{O}}^r/n\hat{\mathcal{O}}^r$ are the same. A submodule $M \subseteq \hat{\mathcal{O}}^r$ of index n contains $n\hat{\mathcal{O}}^r$ (the quotient is a group of order n, so it is killed by n), hence is the preimage of a submodule of index n of $\hat{\mathcal{O}}^r/n\hat{\mathcal{O}}^r$, and conversely; the same holds for submodules $L \subseteq \mathcal{O}^r$ of index n and $\mathcal{O}^r/n\mathcal{O}^r$. Composing these bijections with the isomorphism above gives, for each n, a bijection between the $\hat{\mathcal{O}}$-submodules of $\hat{\mathcal{O}}^r$ of index n and the $\mathcal{O}$-submodules of $\mathcal{O}^r$ of index n. All terms being nonnegative, the sums may be grouped by the index, and

$$\sum_M [\hat{\mathcal{O}}^r : M]^{-s} = \sum_L [\mathcal{O}^r : L]^{-s},$$

the second sum over the $\mathcal{O}$-submodules $L \subseteq \mathcal{O}^r$ of finite index.

Solomon's formula. Since $s = t + r - 1 > r$, Solomon's formula [286] gives

$$\sum_L [\mathcal{O}^r : L]^{-s} = \prod_{j=0}^{r-1} \zeta_E(s-j) = \prod_{i=1}^{r} \zeta_E(\sigma_i),$$

with $j = r - i$, each factor given by its absolutely convergent Euler product, as $\sigma_i > 1$.

The bound. Let q_w be the residue cardinality of the finite place w, so that $\zeta_E(\sigma) = \prod_w (1-q_w^{-\sigma})^{-1}$ for $\sigma > 1$. Above each rational prime p lie at most m places w, each with $q_w \geq p$, so $\zeta_E(\sigma) \leq \prod_p (1-p^{-\sigma})^{-m} = \zeta(\sigma)^m$ for $\sigma > 1$. For $\sigma \geq 3$, $\zeta(\sigma) - 1 \leq 2^{-\sigma} + \int_2^\infty x^{-\sigma} dx = 2^{-\sigma}(1 + \frac{2}{\sigma-1}) \leq 2^{1-\sigma}$. Hence, with $\log(1+x) \leq x$,

$$\log \prod_{i=1}^{r} \zeta_E(\sigma_i) \leq m \sum_{i=1}^{r} 2^{1-\sigma_i} = m\, 2^{2-t} \sum_{i=1}^{r} 2^{-i} \leq m\, 2^{2-t}.$$

□

5.4 The frames engine

The sieve of the main term needs, at every place, forms on pairs of heads that descend by integration over a head entry, decay in the frequency and have a controlled mass. This section proves these properties once, for an abstract place, in one theorem (Theorem 5.4.1). It is applied at the finite places of the main term and, in the next section, at the complex place; treating both kinds of place at once is the point of the abstraction. Every estimate is proved from the axioms of a place datum and a gauge (Definition 5.1.7). The objects are a frame with its flag of isotropic lines, the unipotent radical of the stabiliser of the flag, a tower of floor groups and the Bessel subgroup [96, 36, 42], and the floor forms obtained by pairing a cut function with its Weyl translates for two heads (Definition 5.2.4).

The core of the section is the gains. A character of the last frame product, or two different heads, makes the integrand oscillate along a floor or along a Heisenberg group, and Plancherel's inequality turns the oscillation into a decay factor (Proposition 5.4.34, Proposition 5.4.35); a deep vector after the head gives a further factor (Proposition 5.4.5). The shell sum adds the gains over dyadic shells of positions: a remote shell pays for its height with the deep-vector gain, because far positions have deep vectors (Proposition 5.4.38, Proposition 5.4.21). The descent is Fubini's theorem on the tower (Proposition 5.2.92, printed with the sieve system at the finite places, where it is first used). Plancherel's theorem for local fields is in Tate's thesis [294, 324], and harmonic analysis on Heisenberg groups goes back to the theorem of Stone and von Neumann [195].

Theorem 5.4.1. *Let Γ be a gauge of loss Λ for a place datum over a place A, with size filtration $(A_{(i)})_{i\geq 0}$; sizes refer to Γ unless another gauge is named. Put $r' = |\iota'|$, let $Z(\gamma)$ be the frame Gram matrix (5.3) of $\gamma \in G$, and let $W\colon G \to \mathbb{C}^I$ be cut. In (DN1)–(DN3) the group measure θ is a Haar measure of G.*

ro, orbital integrals. Let p, q be sequences of units of A.

(a) For $j \geq 0$ and $\omega\colon G \to \mathbb{C}$, $|\mathcal{F}_j(p,q;W,\omega)| \leq \mathrm{hdn}_j(p,q) \int_G \mathrm{FN}_j(p,q,W,x;\omega)\, d\theta(x)$; if $|\omega| \leq 1$ on G, then $\mathrm{FN}_j(p,q,W,x;\omega) \leq \mathrm{FM}_j(p,q,W,x)$ for every $x \in G$.

(b) For $0 \leq b \leq \varrho$, $\mathrm{FML}_b(\Lambda^{1287n} \operatorname{vol}(A_{(11)})^{r'}; 1)$.

(c) If

$$\int_G |\mathcal{K}_{W,0}(1,z)|^2\, d\theta(z) < \infty,$$

then $\mathcal{F}_0(p,q;W,1)$ equals this integral; otherwise $\mathcal{F}_0(p,q;W,1) = 0$.

(d) If $x \in \mathcal{P}_{\mathrm{pos}}$, $\sigma \in [0,\infty]$ and $(0,1,1,W)$ has a deep vector after the head of depth at least σ^{-1} at x, then $\mathrm{FM}_0(1,1,W,x)^2 \leq \sigma^{2s}\, \mathrm{WSP}_0(1,1,W,x)$.

(e) *If $l \geq 0$, $\gamma, y \in G$ and both y and $\gamma^{-1}y$ are near at l, then for $0 \leq i \leq \min(l,n)$ the leading principal minor of order i of $Z(\gamma)$ lies in $A_{(9n)}$.*

(f) *For a Borel measure μ on G and $\gamma \in G$ let $\mathrm{Orb}_\mu(\gamma) \in \mathbb{C}^{I\times I}$ be the Bessel orbital integral (5.13) of W. If $\mathrm{Orb}_\mu(\gamma) \neq 0$, then every leading principal minor of $Z(\gamma)$ lies in $A_{(9n)}$. If μ is left invariant, then $\mathrm{Orb}_\mu(u^{-1}\gamma u') = \overline{\psi(M^{-1}\sigma(u))}\,\psi(M^{-1}\sigma(u'))\,\mathrm{Orb}_\mu(\gamma)$ for all $u, u' \in \mathsf{U}$ and $\gamma \in G$. If μ is a Haar measure, W is continuous, p, q are heads of length ϱ and $x \in G^{(\varrho)}$, then every $y \in G$ with $W(y) \neq 0$ and $W((w_{\varrho,p}x)^{-1}y) \neq 0$ has size $60n^2$, and*

$$\langle \mathrm{Orb}_\mu(w_{\varrho,p}x), \mathrm{Orb}_\mu(w_{\varrho,q}x)\rangle = \int_{G\times G} \langle W(y), W(y')\rangle \overline{\langle W((w_{\varrho,p}x)^{-1}y), W((w_{\varrho,q}x)^{-1}y')\rangle}\, d(\mu\otimes\mu)(y,y').$$

(DN1) Descent. *For $a < \varrho$, $t \in \mathbb{C}$, $\eta \in A$ and heads p, q with $\int \mathrm{FM}_a(p,q,W,x)\,d\theta(x) < \infty$, the function $c \mapsto \psi(\eta c)\, t\,\mathcal{F}_{a+1}(p[a \mapsto u(c)], q[a \mapsto u(c)]; W, 1)$, where $u(c) = c$ if c is a unit and $u(c) = 1$ otherwise, is integrable on A and its integral is $t\,\mathcal{F}_a(p,q;W, x \mapsto \psi(\eta\, h(f_a, x f_a)))$.*

(DN2) Shells. *Let $j \leq \varrho$, p, q heads of length j, $V \geq 1$ with $\mathrm{FML}_j(V;1)$, $(S_i)_{i\geq 0}$ shells of heights 2^i for (j,p,q,W) covering the support of $\phi \geq 0$, $\phi \leq \mathrm{FM}_j(p,q,W,\cdot)$, $e \in [0,\infty]$ with $\phi(x)^2 \leq (Ve^s)^2 \mathrm{WSP}_j(p,q,W,x)$ for $x \in \mathcal{P}_{\mathrm{pos}}$ when $e < 1$, and an integer $t \geq 0$ with $9\cdot 10^7 n^4 + t \leq s$. Then*

$$\mathrm{hdn}_j(p,q) \int_G \phi\, d\theta \leq V \min(1,e)^t \Lambda^{4\cdot 10^8 n^4}\, \mathrm{SN}(W).$$

(DN3) Gains. *Let $j \leq \varrho$, p a head of length j, q a sequence of units and $x \in \mathcal{P}_{\mathrm{pos}}$.*

(a) *If ξ is a unit, $\eta \in A$ and $\psi(\eta z) = \psi(\xi z)$ for every $z \in A_{(200n^2)}$, then*

$$\mathrm{FN}_j(p,q,W,x; g \mapsto \psi(\eta\, h(f_j, g f_j)))^2 \leq (\mathrm{kb}_A/|\xi|)^{r'}\, \mathrm{WSP}_j(p,q,W,x).$$

(b) *If $j = i+1$ and $\xi = M^{-1}(p_i^{-1} - q_i^{-1})$ is a unit, then*

$$\mathrm{FN}_j(p,q,W,x;1)^2 \leq (\mathrm{kb}_A/|\xi|)^{r'}\, \mathrm{WSP}_j(p,q,W,x).$$

(c) *If $V \in [0,\infty]$ and $\mathrm{FML}_j(V;1)$, then $\mathrm{FM}_j(p,q,W,x)^2 \leq V^2\, \mathrm{WSP}_j(p,q,W,x)$; if moreover $V \geq 1$, $\sigma \in [0,\infty]$ and (j,p,q,W) has a deep vector after the head of depth at least σ^{-1} at x, then $\mathrm{FM}_j(p,q,W,x)^2 \leq \sigma^s V^2\, \mathrm{WSP}_j(p,q,W,x)$.*

Moreover, for $x \in \mathcal{P}_{\mathrm{pos}}$ and $a < \varrho$, $\mathrm{FML}_a(\Lambda^{10^4 n}; g \mapsto \mathrm{dp}_a(g,x)^s)$; and for $j \leq \varrho$, $d \in G$ and a pairing kernel $\mathcal{K}$ at floor j for d,

$$\int_{\{\text{positions of size } \Gamma\}} \mathrm{WSI}_j(\mathcal{K}, x)\, d\theta(x) \leq n\Big(\prod_{l<\varrho} c_{\mathfrak{fl}}(l)\Big) \int_G \int_G |\mathcal{K}(g,y)|^2\, d\theta_{\geq 0}(y)\, d\theta_{\geq 0}(g).$$

(DN4) Far means deep. *Let S be a second gauge for the same place datum, with size filtration $(A^S_{(i)})$, let $j \leq \varrho$ and let p, q be heads of length j for S; if $j \neq 0$, assume $M^{-1} \in A^S_{(1)}$ and $A^S_{(10n)} \subseteq A_{(1)}$. Let $x, y \in G$ and $u, v \in \mathsf{U}$ with $ux \in K$, $vxy \in K$ and $M^{-1}(vxy - ux)$ of size 2, and let $w^{-1}_{j,p}x$ and $w^{-1}_{j,q}xy$ be near at j. If for every a with $j \leq a < \varrho$ the set $\mathfrak{d}_a(x,y)$ contains a unit c with $c^{-1} \in A_{(1)}$, then $M^{-1}(y-1)$ has size $99n$.*

Proof. Each item is one of the following results, applied to the gauge Γ (and, in (DN4), the second gauge S), the cut function W and, in (DN1)–(DN3), the Haar measure θ.

- (DN0)(a): Lemma 5.4.2 (i) and (ii).
- (DN0)(b): Lemma 5.4.3 (ii).
- (DN0)(c): Lemma 5.2.89.
- (DN0)(d): Proposition 5.4.5 (iii).
- (DN0)(e): Lemma 5.4.13 (ii).
- (DN0)(f): Lemma 5.4.20: the minors by (ii); the equivariance by (i), as a cut function is a Bessel function of frequency M^{-1}; the size $60n^2$ by (iii); the product formula by (iv).
- (DN1): Proposition 5.2.92 (ii) with $\phi(c) = \psi(\eta c)$, which is measurable with $|\phi| = 1$; then $\phi \circ Z_a = (x \mapsto \psi(\eta\, h(f_a, x f_a)))$. (The heads are not needed.)
- (DN2): Proposition 5.4.21.
- (DN3)(a): Proposition 5.4.34; (DN3)(b): Proposition 5.4.35; (DN3)(c): Proposition 5.4.5 (i) and (ii).
- (DN3), the floor-mass bound of the depth: Lemma 5.4.19; the one-frame bound: Proposition 5.4.25.
- (DN4): Proposition 5.4.38.

In each case the hypotheses of the item are those of the cited result, or contain them. □

Lemma 5.4.2. *Let a place datum be given, $W\colon G \to \mathbb{C}^I$, $j \geq 0$, p, q sequences of units of A and $\omega\colon G \to \mathbb{C}$.*

(i) $|\mathcal{F}_j(p, q; W, \omega)| \leq \mathrm{hdn}_j(p, q) \int_G \mathrm{FN}_j(p, q, W, x; \omega)\, d\theta(x)$.

(ii) If W is cut and $|\omega| \leq 1$ on G, then $\mathrm{FN}_j(p, q, W, x; \omega) \leq \mathrm{FM}_j(p, q, W, x)$ for every $x \in G$.

Proof. **(i).** By (5.15), $\mathcal{F}_j(p, q; W, \omega)$ is either 0 or $\mathrm{hdn}_j(p, q) \int \mathrm{FI}_j(p, q, W, x; \omega)(g)\, d(\theta \otimes \mathfrak{m}_j)(x, g)$; in both cases its modulus is at most $\mathrm{hdn}_j(p, q) \int |\mathrm{FI}_j(p, q, W, x; \omega)(g)|\, d(\theta \otimes \mathfrak{m}_j)(x, g)$, which by Tonelli is $\mathrm{hdn}_j(p, q) \int \mathrm{FN}_j(p, q, W, x; \omega)\, d\theta(x)$.

(ii). Let $d = w_{j,q}^{-1} w_{j,p}$. By Lemma 5.2.57, (ii), $\mathcal{K}_W$ and $\mathcal{K}_W^d$ are pairing kernels at floor j, so by Lemma 5.2.64, (i), their partial correlations from floor $j+1$ are measurable. Fix x, g and put $u(\xi) = |\mathcal{K}_{W,j+1}(\xi g, \xi g x)|$ and $u'(\zeta) = |\mathcal{K}^d_{W,j+1}(\zeta w_{j,p}^{-1} g, \zeta w_{j,p}^{-1} g x)|$, measurable functions with $\int u\, d\theta_j = \mathrm{piv}_j(\mathcal{K}_W)(g, gx)$ and $\int u'\, d\theta_j = \mathrm{piv}_j(\mathcal{K}_W^d)(w_{j,p}^{-1} g, w_{j,p}^{-1} g x)$. Each of the two integrals in (5.14) is 0 or an integral, so its modulus is at most the integral of the modulus of its integrand; with $|\omega| \leq 1$ and Tonelli,

$$|\mathrm{FI}_j(p, q, W, x; \omega)(g)| \leq \int_G \int_G u(\xi)\, u'(\zeta)\, d\theta_j(\zeta)\, d\theta_j(\xi) = \mathrm{piv}_j(\mathcal{K}_W)(g, gx)\, \mathrm{piv}_j(\mathcal{K}_W^d)(w_{j,p}^{-1} g, w_{j,p}^{-1} g x).$$

Integrating over g against $\mathfrak{m}_j$ gives $\mathrm{FN}_j(p, q, W, x; \omega) \leq \mathrm{FM}_j(p, q, W, x)$. □

Lemma 5.4.3. *Let Γ be a gauge of loss Λ, with size filtration $(A_{(i)})_{i \geq 0}$, for a place datum of shape (ϱ, ι, m), and put $r' = |\iota'|$.*

(i) Let $i \geq 0$, let $g \in G$ have size i, let $0 \leq b \leq \varrho$, $\sigma \in G^{(b)}$, and let σg be near at $b+1$. Then $\sigma^{-1} f_b$ has size $i+6$.

(ii) For every $0 \leq b \leq \varrho$, $\mathrm{FML}_b(\Lambda^{1287n} \operatorname{vol}(A_{(11)})^{r'}; 1)$.

Proof. **Inverses and products.** By (SZ2) with one summand, $A_{(i)} \subseteq A_{(i+1)}$. If $g \in G$ has size i, then $g^{-1} = J^{-1}\bar{g}^{\mathsf{T}} J$ (from $\bar{g}^{\mathsf{T}} J g = J$) has size $i+4$: each entry of $J^{-1}\bar{g}^{\mathsf{T}}$ is a sum of at most r products of an entry of J^{-1} (size 1, (SZ5)) and the conjugate of an entry of g (size i, (SZ3)), hence lies in $A_{(i+2)}$ by (SZ1), (SZ2), and multiplying by J gives in the same way entries in $A_{(i+4)}$. Likewise the product of a matrix of size i and one of size i' has size $i+i'+1$. Elements of K have size 1 (GU2), so their inverses have size 5.

(i). As σg is near at $b+1$, there is $\xi \in R^{(b+1)}$ with $\kappa = \xi \sigma g \in K$. The column of f_b in ξ: the index f_b has floor $b < b+1$ and level $b < b+1$, so by the definition of $R^{(b+1)}$, $\xi_{i f_b} = \delta_{i f_b}$ for every index i of level at least b; the indices of level below b are the e_a with $a < b$. Hence $\xi f_b \in f_b + E_{<b}$, $E_{<b} = \operatorname{span}\{e_a : a < b\}$. In the same way $\xi e_a \in e_a + \operatorname{span}\{e_{a'} : a' < a\}$ for $a < b$, so ξ maps $E_{<b}$ bijectively onto itself, and therefore $\xi^{-1} f_b \in f_b + E_{<b}$. As $\sigma \in G^{(b)}$ fixes every e_a with $a < b$,

$$\sigma^{-1}\xi^{-1} f_b \in \sigma^{-1} f_b + E_{<b}.$$

Now $\sigma^{-1}\xi^{-1} = g\kappa^{-1}$ has size $i+5+1 = i+6$, so all coordinates of $\sigma^{-1}\xi^{-1} f_b$, a column of $g\kappa^{-1}$, lie in $A_{(i+6)}$; and the coordinates of floor at least b of $\sigma^{-1} f_b$ are those of $\sigma^{-1}\xi^{-1} f_b$, since $E_{<b}$ has none. The coordinates of floor below b of $\sigma^{-1} f_b$ vanish: the vectors v with $h(v, e_a) = h(v, e_a^*) = 0$ for all $a < b$ are those whose coordinates e_a^*, e_a ($a < b$) vanish, i.e. V_b; the vector f_b lies in V_b, and σ^{-1} preserves h and fixes the e_a, e_a^* with $a < b$, so $\sigma^{-1} f_b \in V_b$. As $0 \in A_{(i+6)}$ (SZ4), $\sigma^{-1} f_b$ has size $i+6$.

(ii). Let C_b and the projection P_b be as in Lemma 5.2.60. For $\kappa, \kappa' \in K$ the element $\kappa\kappa'^{-1}$ has size $1+5+1 = 7$, so the coordinates of $\kappa\kappa'^{-1} f_b$ lie in $A_{(7)}$, and P_b replaces some of them by 0; hence C_b lies in the set of vectors of V of size 7. By Lemma 5.2.60, (iii), $\mathrm{FML}_b(\mathrm{qv}_b(C_b); 1)$ holds, and by Lemma 5.4.4, (iv), with $\rho = \mathrm{qv}_b$, $j = 7$ and $\varphi = 1$,

$$\mathrm{qv}_b(C_b) \leq \mathrm{qv}_b(\{y \in V \text{ of size } 7\}) \leq \Lambda^{99n \cdot 13} \operatorname{vol}(A_{(11)}^{\iota'}) = \Lambda^{1287n} \operatorname{vol}(A_{(11)})^{r'}.$$

A floor-mass bound with a constant V holds with every larger constant, which gives (ii). □

Lemma 5.4.4. *Let Γ be a gauge of loss Λ, with size filtration $(A_{(i)})_{i \geq 0}$, for a place datum of shape (ϱ, ι, m), and let $0 \leq l \leq \varrho$. Write the points of $A \times A \times Y_l$ as $x = (c, t, Y)$ with $Y = (\zeta, w, \zeta')$, and for $\beta \in A^-$ let $\lambda_l(\beta)$ be the image of $\mathrm{vol} \otimes \mathrm{vol} \otimes \nu$ on $A \times Y_l \times A^-$ under $(t, Y, \alpha) \mapsto \big(t^{\dagger}\tau(\delta^{-1}\beta - h_l'(Y,Y)) + t\alpha,\, t,\, Y\big)$, so that $\mathrm{qv}_l(\beta)$ is the image of $\lambda_l(\beta)$ under B_l.*

(i) Let $B \subseteq \iota$ with $|B| = 2m+2$. Write $x = (x^\circ, z)$ with $z = (w_i)_{i \in B} \in A^B$ and $x^\circ \in X^\circ$ the other coordinates, put $q^\circ(x^\circ) = \bar{c}t + \bar{t}c + h_l'(Y,Y) - \bar{z}^{\mathsf{T}} z$ (a function of x°), and let $(\lambda_\gamma^B)_{\gamma \in A^-}$ be the kernel of (GU6) carried to A^B by a bijection $\{1, \dots, 2m+2\} \to B$. Then for every $\beta \in A^-$ and every measurable $f \colon A \times A \times Y_l \to [0, \infty]$,

$$\int f \, d\lambda_l(\beta) = \int_{X^\circ} \int_{A^B} f(x^\circ, z) \, d\lambda^B_{\beta - \delta q^\circ(x^\circ)}(z) \, dx^\circ,$$

and $\lambda^B_{\beta - \delta q^\circ(x^\circ)}(A^B_{(j)}) \leq \Lambda^{(2m+2)(j+1)}$ for all $x^\circ \in X^\circ$ and $j \geq 0$; moreover $\mathrm{vol}(A^B_{(j)}) \leq \Lambda^{(2m+2)(j+1)}$.

(ii) Let ρ_0 be vol *or $\lambda_l(\beta)$ for some $\beta \in A^-$. For every $j \geq 0$ and every measurable $G\colon A^{\iota'} \to [0,\infty]$,*

$$\int_{\{x:\ \text{all coordinates in } A_{(j)}\}} G((w_i)_{i\in\iota'})\, d\rho_0(x) \leq \Lambda^{99n(j+2)} \int_{A^{\iota'}_{(j)}} G\, d\mathrm{vol}.$$

(iii) For $x = (c,t,Y)$ and $x' = (c',t',Y')$ in $A \times A \times Y_l$, $h(B_l(x'), B_l(x)) = \bar{c}'t + \bar{t}'c + h'_l(Y',Y)$ and $h(o_i, B_l(x)) = w_i$ for $i \in \iota$; the image of vol *under B_l is vol_{V_l}; and if $B_l(x)$ has size j, then all coordinates of x lie in $A_{(j+4)}$.*

(iv) Let ρ be vol_{V_l} or $\mathrm{qv}_l(\beta)$ for some $\beta \in A^-$. For every $j \geq 0$ and every measurable $\varphi\colon A^{\iota'} \to [0,\infty]$,

$$\int_{\{y\in V \text{ of size } j\}} \varphi((h(o_i,y))_{i\in\iota'})\, d\rho(y) \leq \Lambda^{99n(j+6)} \int_{A^{\iota'}_{(j+4)}} \varphi\, d\mathrm{vol}.$$

Proof. Throughout, A and A^- are locally compact, second countable and metrisable; vol on a finite power of A is the product of copies of a σ-finite Haar measure; each $A_{(j)}$ is compact by (GU1), hence Borel. Recall from (SZ2) with one summand that $A_{(i)} \subseteq A_{(i+1)}$. For $r \in A$ put $\mathrm{sk}(r) = \tau\delta r - \overline{\tau\delta r} \in A^-$, a continuous map; if $\bar{r} = r$ then $\overline{\tau\delta r} = \bar{\tau}\bar{\delta}r = -\bar{\tau}\delta r$, so $\mathrm{sk}(r) = (\tau + \bar{\tau})\delta r = \delta r$. For $\gamma \in A^-$ the element $\delta^{-1}\gamma$ is hermitian ($\overline{\delta^{-1}\gamma} = (-\delta)^{-1}(-\gamma)$), so $\mathrm{sk}(\delta^{-1}\gamma) = \gamma$. The Haar measure ν of the abelian group A^- is invariant under $\gamma \mapsto \beta - \gamma$ (translation invariance, and invariance under the involutive automorphism $\gamma \mapsto -\gamma$, whose image of ν is $c\nu$ with $c^2 = 1$).

(i). Let $S^\circ = \mathcal{Q}_l \sqcup (\iota \setminus B) \sqcup \mathcal{Q}_l$, so that $X^\circ = A \times A \times A^{S^\circ}$, and let T° be the Gram matrix of the restriction h° of h'_l to the coordinates in S°. As the ι-part of h'_l is $\sum_{i\in\iota} \bar{w}_i w_i$, we have $h'_l(Y,Y) = h^\circ(Y^\circ,Y^\circ) + \bar{z}^{\mathsf{T}}z$, where Y° is Y without z; hence $q^\circ(x^\circ) = \bar{c}t + \bar{t}c + h^\circ(Y^\circ,Y^\circ)$ depends only on x° and is hermitian, so $\delta q^\circ(x^\circ) \in A^-$. For $\gamma \in A^-$ let λ°_γ be the image of $\mathrm{vol} \otimes \mathrm{vol} \otimes \nu$ on $A \times A^{S^\circ} \times A^-$ under $\mathrm{ch}^\circ_\gamma(t, Y^\circ, \alpha) = (t^\dagger\tau(\delta^{-1}\gamma - h^\circ(Y^\circ,Y^\circ)) + t\alpha, t, Y^\circ)$. By Lemma 5.2.52, (i), with $S = S^\circ$ and $T' = T^\circ$, the family (λ°_γ) is a disintegration of vol on X° along q°. The transported kernel (λ^B_γ) is an s-finite kernel and a disintegration of vol on A^B along $\bar{z}^{\mathsf{T}}z$ with $\lambda^B_\gamma(A^B_{(j)}) \leq \Lambda^{(2m+2)(j+1)}$ for all γ and j, because a permutation of coordinates preserves vol, the form $\bar{z}^{\mathsf{T}}z$ and the box $A^B_{(j)}$ (GU6). This gives the mass bound in (i); and $\mathrm{vol}(A^B_{(j)}) = \mathrm{vol}(A_{(j)})^{2m+2} \leq \Lambda^{(j+1)(2m+2)}$ by (GU5).

The chart splits. For $t \in A$, $\alpha \in A^-$ and $Y = (Y^\circ, z)$ the first coordinate of the chart of $\lambda_l(\beta)$ is $t^\dagger\tau(\delta^{-1}\beta - h^\circ(Y^\circ,Y^\circ) - \bar{z}^{\mathsf{T}}z) + t\alpha$, and $\delta^{-1}\beta - \bar{z}^{\mathsf{T}}z = \delta^{-1}(\beta - \delta\bar{z}^{\mathsf{T}}z)$ with $\beta - \delta\bar{z}^{\mathsf{T}}z \in A^-$. So the chart of $\lambda_l(\beta)$ at $(t,(Y^\circ,z),\alpha)$ is $(\mathrm{ch}^\circ_{\beta-\delta\bar{z}^{\mathsf{T}}z}(t,Y^\circ,\alpha), z)$, and by Tonelli (the measure vol on A^{S_l}, $S_l = \mathcal{Q}_l \sqcup \iota \sqcup \mathcal{Q}_l$, is the product of those on A^{S° and A^B)

$$\int f\, d\lambda_l(\beta) = \int_{A^B} \int_{X^\circ} f(x^\circ, z)\, d\lambda^\circ_{\beta-\delta\bar{z}^{\mathsf{T}}z}(x^\circ)\, dz. \tag{5.74}$$

Exchange of the two fibrations. Put

$$F(r,z) = \int f(x^\circ,z)\, d\lambda^\circ_{\beta-\mathrm{sk}(r)}(x^\circ) = \int f(\mathrm{ch}^\circ_{\beta-\mathrm{sk}(r)}(t,Y^\circ,\alpha), z)\, d(t,Y^\circ,\alpha)$$

for $(r,z) \in A \times A^B$, and $F'(r,x^\circ) = \int f(x^\circ,z)\, d\lambda^B_{\beta-\mathrm{sk}(r)}(z)$ for $(r,x^\circ) \in A \times X^\circ$. Both are measurable: $(\gamma,t,Y^\circ,\alpha) \mapsto \mathrm{ch}^\circ_\gamma(t,Y^\circ,\alpha)$ is Borel ($t \mapsto t^\dagger$ is Borel), so F is measurable by Tonelli, and F' is the integral of a measurable function against an s-finite kernel composed with the measurable map $(r,x^\circ) \mapsto \beta - \mathrm{sk}(r)$. Since $\bar{z}^{\mathsf{T}}z$ and $q^\circ(x^\circ)$ are hermitian, $F(\bar{z}^{\mathsf{T}}z, z)$ is the

inner integral of (5.74) and $F'(q^\circ(x^\circ),x^\circ)$ is the inner integral of the right side of (i). By (DJ2) for (λ^B_γ) and for (λ°_γ), using $\mathrm{sk}(\delta^{-1}\gamma)=\gamma$,

$$\int_{A^B} F(\bar z^{\mathsf T} z, z)\,dz = \int_{A^-}\int_{A^B}\int_{X^\circ} f\,d\lambda^\circ_{\beta-\gamma}\,d\lambda^B_\gamma\,d\nu(\gamma),$$
$$\int_{X^\circ} F'(q^\circ(x^\circ),x^\circ)\,dx^\circ = \int_{A^-}\int_{X^\circ}\int_{A^B} f\,d\lambda^B_{\beta-\gamma}\,d\lambda^\circ_\gamma\,d\nu(\gamma);$$

the outer integrands are measurable (Tonelli for the kernel λ^B and for the charts of λ°), so no lower integral occurs. In the second identity substitute $\gamma\mapsto\beta-\gamma$, which preserves ν; its inner double integral becomes $\int_{X^\circ}\int_{A^B} f\,d\lambda^B_\gamma\,d\lambda^\circ_{\beta-\gamma}$, which equals $\int_{A^B}\int_{X^\circ} f\,d\lambda^\circ_{\beta-\gamma}\,d\lambda^B_\gamma$ by Tonelli, as λ^B_γ is s-finite and $\lambda^\circ_{\beta-\gamma}$ is the image of a σ-finite measure. So the two right sides agree, and with (5.74) this is the identity of (i).

(ii). By (GU1), $|\iota|-|\iota'|=2(2m+2)$, so there is $B\subseteq\iota\setminus\iota'$ with $|B|=2m+2$; fix it. For $j\ge 0$ let $\mathbf{1}_j$ be the indicator of $A_{(j)}$ in each coordinate; the indicator of the box of $A\times A\times Y_l$ is $\mathbf{1}_j(x^\circ)\mathbf{1}_j(z)$, and the coordinates w_i, $i\in\iota'$, are coordinates of x°. By (i) (for $\rho_0=\mathrm{vol}$ by Tonelli and $\mathrm{vol}(A^B_{(j)})\le\Lambda^{(2m+2)(j+1)}$),

$$\begin{aligned}\int_{\mathrm{box}} G\big((w_i)_{i\in\iota'}\big)\,d\rho_0 &\le \Lambda^{(2m+2)(j+1)}\int_{X^\circ}\mathbf{1}_j(x^\circ)\,G\big((w_i)_{i\in\iota'}\big)\,dx^\circ\\ &= \Lambda^{(2m+2)(j+1)}\,\mathrm{vol}(A_{(j)})^d\int_{A^{\iota'}_{(j)}} G\,d\mathrm{vol},\end{aligned}$$

by Tonelli on $X^\circ=A^{\iota'}\times A^d$, where d is the number of coordinates of X° outside ι'. Here $d+2m+2=2+2|\mathcal{Q}_l|+|\iota|-|\iota'|=2+2(m+\varrho-l)+2(2m+2)\le 6m+6+2\varrho\le 62n\le 99n$, using $m\le 9n$ (GU1) and $n=\varrho+1\ge 1$. By (GU5) and $\Lambda\ge 2$, $\mathrm{vol}(A_{(j)})^d\Lambda^{(2m+2)(j+1)}\le\Lambda^{(d+2m+2)(j+1)}\le\Lambda^{99n(j+2)}$.

(iii). Let $S'_l=\{1,2\}\sqcup\mathcal{Q}_l\sqcup\iota\sqcup\mathcal{Q}_l$ index the coordinates $x=(c,t,Y)$, and regard B_l as the matrix X of the linear map $A^{S'_l}\to V$, $x\mapsto B_l(x)=cv_0+tv_0^*+\sum_{c'\in\mathcal{Q}_l}(\zeta_{c'}\epsilon_{c'}+\zeta'_{c'}\epsilon^*_{c'})+\sum_{i\in\iota}w_io_i$. Let J° be the hermitian matrix with $\bar x^{\mathsf T}J^\circ x'=\bar c t'+\bar t c'+h'_l(Y,Y')$; it is a permutation matrix of order two, $(J^\circ)^2=1$. From the relations of the hyperbolic basis, $h(e_a,e_b^*)=\delta_{ab}$, $h(e_a,e_b)=h(e_a^*,e_b^*)=0$ and the orthogonality of the e_a,e_a^* to the middle space, $\bar X^{\mathsf T}JX=J^\circ$, and $h(o_i,B_l(x))=w_i$ for $i\in\iota$.

The image of vol. The map X takes values in V_l and is the extension by zero of a square matrix X' from $A^{S'_l}$ to the coordinates of floor $\ge l$ (both index sets have $k+1+2(\varrho-l)$ elements). With J_l the restriction of J to these coordinates, $\bar X'^{\mathsf T}J_lX'=J^\circ$; taking determinants, $\overline{\det X'}\det J_l\det X'=\det J^\circ=\pm1$ and $\det J_l=\pm\det T$, so $\det X'$ is a unit and, by (PA2), (PE1) and multiplicativity, $|\det X'|^2=|\pm1|=1$ ($|-1|^2=|1|=1$), so $|\det X'|=1$. By (PA3), $X'_*\mathrm{vol}=\mathrm{vol}$, and extending by zero, $X_*\mathrm{vol}=\mathrm{vol}_{V_l}$.

Coordinates cost size 4. Since $(J^\circ)^2=1$, $x=J^\circ\bar X^{\mathsf T}J\,(Xx)$. The entries of X are 0, 1 or entries of the basis matrix, hence of size 1 by (GU2), (SZ4); those of J have size 1 (SZ5). By (SZ3) and (SZ1), each entry of $\bar X^{\mathsf T}J$ is a sum of at most r products of two elements of $A_{(1)}$, hence lies in $A_{(3)}$ by (SZ2); if Xx has size j, each entry of $\bar X^{\mathsf T}J(Xx)$ is a sum of at most r elements of $A_{(j+3)}$, hence lies in $A_{(j+4)}$; and J° permutes the entries. So if $B_l(x)$ has size j, then all coordinates of x lie in $A_{(j+4)}$.

(iv). The set of $y\in V$ of size j is Borel, and by (iii) and the definition of $\mathrm{qv}_l(\beta)$, $\rho=X_*\rho_0$

with $\rho_0 = \mathrm{vol}$ or $\rho_0 = \lambda_l(\beta)$. By (iii) and (ii) at $j+4$,

$$\begin{aligned}\int_{\{y \text{ of size } j\}} \varphi((h(o_i,y))_{i\in\iota'})\,d\rho(y) &= \int \mathbf{1}_{\{B_l(x) \text{ of size } j\}}\,\varphi((w_i)_{i\in\iota'})\,d\rho_0(x)\\ &\le \int_{\{x\text{: coordinates in } A_{(j+4)}\}} \varphi((w_i)_{i\in\iota'})\,d\rho_0(x)\\ &\le \Lambda^{99n(j+6)} \int_{A^{\iota'}_{(j+4)}} \varphi\,d\mathrm{vol}.\end{aligned}$$

□

Proposition 5.4.5. *Let Γ be a gauge of loss Λ for a place datum, let $W\colon G \to \mathbb{C}^I$ be cut and $x \in \mathcal{P}_{\mathrm{pos}}$; WSP_j is formed for Γ, and arithmetic is in $[0,\infty]$.*

(i) Suppose that the group measure θ is a Haar measure of G. Let $j \le \varrho$, p a head of length j, q a sequence of units, and $V \in [0,\infty]$ with $\mathrm{FML}_j(V;1)$. Then $\mathrm{FM}_j(p,q,W,x)^2 \le V^2\,\mathrm{WSP}_j(p,q,W,x)$.

(ii) If moreover $V \ge 1$, $\sigma \in [0,\infty]$ and (j,p,q,W) has a deep vector after the head of depth at least σ^{-1} at x, then $\mathrm{FM}_j(p,q,W,x)^2 \le \sigma^s V^2\,\mathrm{WSP}_j(p,q,W,x)$. The same conclusion holds under the hypotheses of (i) with $V \ge 1$ and $\sigma \in [0,\infty]$ such that, if $\sigma < 1$, (j,p,q,W) has a deep vector after the head of depth at least σ^{-1} at x.

(iii) If $\sigma \in [0,\infty]$ and $(0,1,1,W)$ has a deep vector after the head of depth at least σ^{-1} at x, then $\mathrm{FM}_0(1,1,W,x)^2 \le \sigma^{2s}\,\mathrm{WSP}_0(1,1,W,x)$.

Proof. Put $w_p = w_{j,p}$, $d = w_{j,q}^{-1}w_p$, $\mathcal{K}_1 = \mathcal{K}_W$, $\mathcal{K}_2 = \mathcal{K}_W^d$; by Lemma 5.2.57 (ii) these are pairing kernels at floor j (for 1 and for d). By definition $\mathrm{FM}_j(p,q,W,x) = \int f\,d\mathfrak{m}_j$ with

$$f(g) = \mathrm{piv}_j(\mathcal{K}_1)(g,gx)\,\mathrm{piv}_j(\mathcal{K}_2)(z,zx), \qquad z = w_p^{-1}g.$$

A bound for one pivot. Let $\mathcal{K}'$ be a pairing kernel at floor $j \le \varrho$ and $g' \in G$. By Lemma 5.4.16 (i) with $\mathrm{FML}_j(V;1)$, and (iv),

$$\mathrm{piv}_j(\mathcal{K}')(g',g'x)^2 \le V \int |\mathcal{K}'_{j+1}(\sigma'g',\sigma'g'x)|^2\,d\theta_j(\sigma') \le V\,\frac{\mathrm{WSS}_j(\mathcal{K}',x)(g')}{\mathrm{dpw}_j(g',x)}. \tag{5.75}$$

(i). By (5.75) for both pivots, and $c_{\mathrm{fls}} \ge 1$, $f(g)^2 \le V^2 c_{\mathrm{fls}} \frac{\mathrm{WSS}_j(\mathcal{K}_1,x)(g)}{\mathrm{dpw}_j(g,x)} \frac{\mathrm{WSS}_j(\mathcal{K}_2,x)(z)}{\mathrm{dpw}_j(z,x)}$ for every g, and Lemma 5.4.6 (ii) with $C = V^2$ gives the claim.

(ii). Let g with $f(g) \ne 0$. Then $\mathrm{piv}_j(\mathcal{K}_2)(z,zx) \ne 0$, so by Lemma 5.2.64 (iii) there is $\tau \in G^{(j)}$ with $\langle W(\tau z), W(d\tau zx)\rangle \ne 0$. As τ commutes with w_p and $w_{j,q}$ (Lemma 5.2.58 (ix)), $\tau z = w_p^{-1}\tau g$ and $d\tau zx = w_{j,q}^{-1}\tau gx$; so $W(w_p^{-1}\tau g) \ne 0$ and $W(w_{j,q}^{-1}\tau gx) \ne 0$, and both points are near at j by Lemma 5.2.57 (i). Let $\rho \in G^{(j)}$ with $\mathcal{K}_1(\rho g, \rho gx) \ne 0$. Then $w_p^{-1}\rho g = (\rho\tau^{-1})w_p^{-1}\tau g$ and $w_{j,q}^{-1}\rho gx = (\rho\tau^{-1})w_{j,q}^{-1}\tau gx$ with $\rho\tau^{-1} \in G^{(j)} \subseteq R^{(j)}$, so both are near at j; together with $\langle W(\rho g), W(\rho gx)\rangle \ne 0$ this says that ρg is active at x for (j,p,q,W), so some a with $j \le a < \varrho$ has $\mathrm{dp}_a(\rho g,x) \ge \sigma^{-1}$. By Lemma 5.4.17 (with $l = j$ and $\varepsilon_1 = \sigma$), $\mathrm{piv}_j(\mathcal{K}_1)(g,gx)^2 \le \sigma^s c_{\mathrm{fls}} \mathrm{WSS}_j(\mathcal{K}_1,x)(g)/\mathrm{dpw}_j(g,x)$. With (5.75) for the second pivot and $V \le V^2$,

$$f(g)^2 \le \sigma^s V^2\,c_{\mathrm{fls}}\,\frac{\mathrm{WSS}_j(\mathcal{K}_1,x)(g)}{\mathrm{dpw}_j(g,x)}\,\frac{\mathrm{WSS}_j(\mathcal{K}_2,x)(z)}{\mathrm{dpw}_j(z,x)},$$

and Lemma 5.4.6 (ii) with $C = \sigma^s V^2$ gives the first claim. For the second claim: if $\sigma < 1$ this is the first claim; if $\sigma \geq 1$, then $\sigma^s \geq 1$ and (i) suffices.

(iii). Here $j = 0$, $p = q = 1$, so $w_{0,1} = 1$, $d = 1$, $\mathfrak{m}_0 = \delta_1$, and $\mathrm{FM}_0(1,1,W,x) = \mathrm{piv}_0(\mathcal{K}_W)(1,x)^2$. The group $R^{(0)}$ is G (no index has floor below 0), so a point is near at 0 if and only if $K \neq \emptyset$. Let $\rho \in G = G^{(0)}$ with $\mathcal{K}_W(\rho, \rho x) = \langle W(\rho), W(\rho x)\rangle \neq 0$; then $W(\rho) \neq 0$, so ρ is near at 0 (Lemma 5.2.57 (i)), $K \neq \emptyset$, and ρ is active at x for $(0,1,1,W)$; the deep vector gives $a < \varrho$ with $\mathrm{dp}_a(\rho, x) \geq \sigma^{-1}$. By Lemma 5.4.17 with $l = 0$, $g = 1$ and $\mathrm{dpw}_0 = 1$, $\mathrm{piv}_0(\mathcal{K}_W)(1,x)^2 \leq \sigma^s c_{\mathrm{fls}} \mathrm{WSS}_0(\mathcal{K}_W, x)(1)$. Since the convolution in WSI_0 is δ_1, $\mathrm{WSP}_0(1,1,W,x) = c_{\mathrm{fls}}^3 \mathrm{WSS}_0(\mathcal{K}_W, x)(1)^2$, and therefore

$$\mathrm{FM}_0(1,1,W,x)^2 = \mathrm{piv}_0(\mathcal{K}_W)(1,x)^4 \leq \sigma^{2s} c_{\mathrm{fls}}^2 \mathrm{WSS}_0(\mathcal{K}_W, x)(1)^2 \leq \sigma^{2s} \mathrm{WSP}_0(1,1,W,x).$$

□

Lemma 5.4.6. *Let Γ be a gauge of loss Λ for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $j \leq \varrho$, p a head of length j, $w_p = w_{j,p}$, $x \in \mathcal{P}_{\mathrm{pos}}$, $C \in [0,\infty]$ and $\Theta = \theta_{j-1} * \cdots * \theta_0$ ($\Theta = \delta_1$ if $j = 0$); arithmetic is in $[0,\infty]$, the integral of a function that is not measurable is its lower Lebesgue integral, and c_{fls} and WSP_j are formed for Γ.*

(i) Let $B, B' \colon G \to [0,\infty]$ be measurable, with $B(\xi g) = B(g)$ and $B'(\xi g) = B'(g)$ for $\xi \in R^{(j)}$, $g \in G$, and $B(g) = B'(g) = 0$ unless g is near at j. Let $f \colon G \to [0,\infty]$ satisfy

$$f(g)^2 \leq C \, \frac{B(g)}{\mathrm{dpw}_j(g,x)} \, \frac{B'(w_p^{-1} g)}{\mathrm{dpw}_j(w_p^{-1} g, x)} \qquad \text{whenever } f(g) \neq 0.$$

Then

$$\Big(\int_G f \, d\mathfrak{m}_j\Big)^2 \leq C \Big(\Big(\prod_{a<j} \mathrm{fm}(a, p_a^{-1})\Big) c_{\mathrm{fls}}\Big)^2 \int_G B \, d\Theta \int_G B' \, d\Theta.$$

(ii) Let $W \colon G \to \mathbb{C}^I$ be cut, q a sequence of units, $d = w_{j,q}^{-1} w_p$, and let $f \colon G \to [0,\infty]$ satisfy

$$f(g)^2 \leq C \, c_{\mathrm{fls}} \, \frac{\mathrm{WSS}_j(\mathcal{K}_W, x)(g)}{\mathrm{dpw}_j(g,x)} \, \frac{\mathrm{WSS}_j(\mathcal{K}_W^d, x)(w_p^{-1} g)}{\mathrm{dpw}_j(w_p^{-1} g, x)} \qquad \text{whenever } f(g) \neq 0.$$

Then $\big(\int_G f \, d\mathfrak{m}_j\big)^2 \leq C \, \mathrm{WSP}_j(p,q,W,x)$.

Proof. Put $D = \big(\prod_{a<j} \mathrm{fm}(a, p_a^{-1})\big) c_{\mathrm{fls}}$.

(i). For $\Phi \in \{B, B'\}$ and every g, $\Phi(g)/\mathrm{dpw}_j(g,x) = \Phi(g)\,\mathrm{dpw}_{j,x}^-(g)$: both sides are 0 if g is not near at j, and $\mathrm{dpw}_{j,x}^-(g) = \mathrm{dpw}_j(g,x)^{-1}$ otherwise. Hence for every g (trivially where $f(g) = 0$)

$$f(g)^2 \leq \big[B'(w_p^{-1} g)\,\mathrm{dpw}_{j,x}^-(g)\big] \cdot C\big[B(g)\,\mathrm{dpw}_{j,x}^-(w_p^{-1} g)\big],$$

so f is bounded by the square root of the measurable function on the right, and by the Cauchy–Schwarz inequality for that function $(\int f \, d\mathfrak{m}_j)^2 \leq I_1 \cdot C I_2$ with $I_1 = \int B'(w_p^{-1} g) \mathrm{dpw}_{j,x}^-(g) \, d\mathfrak{m}_j(g)$ and $I_2 = \int B(g) \mathrm{dpw}_{j,x}^-(w_p^{-1} g) \, d\mathfrak{m}_j(g)$; the inverse depth weights are measurable by Lemma 5.4.8 (iii). By Lemma 5.2.59 (iv), $\mathfrak{m}_j = \eta_{<j} * \Theta$.

The first integral. Put $\Phi(g) = B'(g)\,\mathrm{dpw}_{j,x}^-(w_p g)$, so the integrand of I_1 is $\Phi(w_p^{-1} g)$. For $t \in G^{(j)} \subseteq R^{(j)}$, $B'(tg) = B'(g)$, and $w_p t = t w_p$ (Lemma 5.2.58 (ix)), so $\mathrm{dpw}_{j,x}^-(w_p t g) =$

$\mathrm{dpw}^-_{j,x}(tw_pg) = \mathrm{dpw}^-_{j,x}(w_pg)$ by Lemma 5.4.8 (iii); so Φ is invariant under left multiplication by $G^{(j)}$. By Lemma 5.4.15 (ii) and then Lemma 5.4.7 (iv) (with $b = j$, $\rho = \Theta$ and the function B'),

$$I_1 = \int \Phi \, d\mathfrak{m}_j = \int B'(g) \, \mathrm{dpw}^-_{j,x}(w_pg) \, d(\eta_{<j} * \Theta)(g) \le D \int B' \, d\Theta.$$

The second integral. $w_p^{-1} = w_{j,\bar{p}}$ with $\bar{p} = (\bar{p}_a)_a$: indeed $w_p^{-1}e_a = \bar{p}_a e_a^*$ and $w_p^{-1}e_a^* = p_a^{-1}e_a$ for $a < j$. The sequence $\bar{p}$ is a head of length j (conjugation preserves $A_{(1)}$, (SZ3)), and $\mathrm{fm}(a, \bar{p}_a^{-1}) = \mathrm{fm}(a, p_a^{-1})$ by (PA2). So Lemma 5.4.7 (iv) for the head $\bar{p}$ and the function B gives $I_2 \le D \int B \, d\Theta$. Hence $(\int f \, d\mathfrak{m}_j)^2 \le D \int B' \, d\Theta \cdot CD \int B \, d\Theta$.

(ii). By Lemma 5.2.57 (ii), $\mathcal{K}_W$ and $\mathcal{K}_W^d$ are pairing kernels at floor j (for 1 and for d). Put $B = \mathrm{WSS}_j(\mathcal{K}_W, x)$ and $B' = \mathrm{WSS}_j(\mathcal{K}_W^d, x)$; by Lemma 5.4.16 (ii), (iii) they are measurable, invariant under left multiplication by $R^{(j)}$ and zero off the points near at j. By (i) with Cc_{fls} in place of C, the definition $\mathrm{WSI}_j(\mathcal{K}, x) = \int \mathrm{WSS}_j(\mathcal{K}, x) \, d\Theta$ and Lemma 5.4.16 (vi) ($\mathrm{WSI}_j \le \mathrm{WSI}_0$, as $j \le n$),

$$\begin{aligned}\Big(\int f \, d\mathfrak{m}_j\Big)^2 &\le Cc_{\mathrm{fls}} D^2 \, \mathrm{WSI}_j(\mathcal{K}_W, x) \, \mathrm{WSI}_j(\mathcal{K}_W^d, x) \\ &\le C\Big(\prod_{a<j} \mathrm{fm}(a, p_a^{-1})\Big)^2 c_{\mathrm{fls}}^3 \, \mathrm{WSI}_0(\mathcal{K}_W, x) \, \mathrm{WSI}_j(\mathcal{K}_W^d, x),\end{aligned}$$

which is $C \, \mathrm{WSP}_j(p, q, W, x)$. □

Lemma 5.4.7. *Let Γ be a gauge of loss Λ for a place datum, and let $x \in \mathcal{P}_{\mathrm{pos}}$.*

(i) Let $a < \varrho$, p a head of length $a+1$, $y \in K$, $\nu \in N_{<a}$, and write $z(n) = w_{a+1,p} n \nu y$. Then

$$\int_G \mathbf{1}\{z(n) \text{ near at } a+1\} \, \mathrm{dp}_a(z(n), x)^s \, d\eta_a(n) \le \mathrm{fm}(a, p_a^{-1}) \, \Lambda^{10^6 n^2}.$$

(ii) Under the hypotheses of (i),

$$\int_G \mathrm{dpw}^-_{a+1,x}(z(n)) \, d\eta_a(n) \le \mathrm{dpw}^-_{a,x}(w_{a,p}\nu y) \, \mathrm{fm}(a, p_a^{-1}) \, \Lambda^{10^6 n^2}.$$

(iii) Let $j \le \varrho$, p a head of length j, and $g \in G$ near at j. Then

$$\int_G \mathrm{dpw}^-_{j,x}(w_{j,p}\nu g) \, d\eta_{<j}(\nu) \le \Big(\prod_{a<j} \mathrm{fm}(a, p_a^{-1})\Big) c_{\mathrm{fls}}.$$

(iv) Let $j \le b$ with $j \le \varrho$, p a head of length j, ρ an s-finite measure on G, and $\Phi \colon G \to [0, \infty]$ Borel with $\Phi(\xi g) = \Phi(g)$ for $\xi \in R^{(b)}$ and $\Phi(g) = 0$ unless g is near at b. Then

$$\int_G \Phi(g) \, \mathrm{dpw}^-_{j,x}(w_{j,p}g) \, d(\eta_{<j} * \rho)(g) \le \Big(\prod_{a<j} \mathrm{fm}(a, p_a^{-1})\Big) c_{\mathrm{fls}} \int_G \Phi \, d\rho.$$

Proof. The set of points near at l is closed (it is $R^{(l)}K$), and depth and inverse depth weights are measurable (Lemma 5.4.8), so all integrands are Borel.

(i). Let Q be the $\varrho \times \iota'$ matrix with $(Q\omega)_b = (\nu O\omega)_{e_b}$ for $b < \varrho$. By (GU7) (with $y \in K$, $x \in \mathcal{P}_{\mathrm{pos}}$) there is a common bound ϕ for $\mathcal{V}_{\mathrm{cm}}(y, x, Q)$ with loss Λ. Let n be a Heisenberg element of floor a and $\sigma = w_{a+1,p} n \nu$. For $\omega \in \mathcal{V}_{\mathrm{cm}}(y, x, Q)$ and $b < a$: $h(e_b, \sigma O\omega)$ is the e_b^*-coordinate of $\sigma O\omega$, which is p_b times the e_b-coordinate of $n\nu O\omega$ (as $w_{a+1,p}e_b = p_b e_b^*$), which equals

$(\nu O\omega)_{e_b} = (Q\omega)_b = 0$, since the rows of $n \in G^{(a)}$ at the e_b, $b < a$, are those of 1 (Lemma 5.2.58, (vii)). By Lemma 5.4.9, $\mathrm{dp}_a(z(n), x) \le \phi(\varsigma)$ with $\varsigma = (h(o_i, \sigma^{-1}e_a))_{i\in\iota'}$; by Lemma 5.4.10, (ii), $\sigma^{-1}e_a - \bar{p}_a n^{-1} e_a^* \in \mathrm{span}\{e_b : b < a\}$, and $h(o_i, e_b) = 0$, so $\varsigma = (h(o_i, \bar{p}_a n^{-1} e_a^*))_i$. Let $\Psi(w) = \mathbf{1}_{20n}(w)\, \phi((h(o_i, w))_i)^s$, with $\mathbf{1}_{20n}$ the indicator of the vectors of size $20n$. If $z(n)$ is near at $a+1$, then $\bar{p}_a n^{-1} e_a^*$ has size $20n$ (Lemma 5.4.10, (iii)); hence the integrand of (i) at n is at most $\Psi(\bar{p}_a n^{-1} e_a^*)$. As η_a is carried by the Heisenberg elements, with $c = \bar{p}_a$ and the section measure $\mathrm{Sec}_a(c)$ of (5.10) in Definition 5.2.1,

$$\int \mathbf{1}\{\dots\}\, \mathrm{dp}_a(z(n), x)^s\, d\eta_a(n) \le \int \Psi(cn^{-1}e_a^*)\, d\eta_a(n) = |c|^{-d_a} \int \Psi\, d\mathrm{Sec}_a(c).$$

By Lemma 5.4.10, (iv), with $j = 20n$, $\varphi = \phi^s$ and $B = \Lambda^{99n(20n+6)} \ge \int_{A^{\iota'}_{(20n+5)}} \phi^s$ (property of a common bound), $\int \Psi\, d\mathrm{Sec}_a(c) \le |c|^{-1/2} \Lambda^{20n+3} \Lambda^{99n(20n+7)} \Lambda^{99n(20n+6)}$. The exponent is $3960n^2 + 1307n + 3 \le 10^6 n^2$, and $|c| = |p_a|$ (PA2), so $|c|^{-d_a - 1/2} = \mathrm{fm}(a, p_a^{-1})$.

(ii). Let n be a Heisenberg element of floor a and $z = z(n)$. If z is not near at $a+1$, the integrand is 0. Otherwise z is near at a ($R^{(a+1)} \subseteq R^{(a)}$, Lemma 5.2.58, (i)), and by Lemma 5.4.8, (iii), $\mathrm{dpw}^-_{a+1,x}(z) = \mathrm{dpw}_a(z,x)^{-1}\mathrm{dp}_a(z,x)^s = \mathrm{dpw}^-_{a,x}(z)\, \mathrm{dp}_a(z,x)^s$. Now $w_{a+1,p} = w_{a,p}\, w_a(p_a)$, with $w_a(p_a), n \in G^{(a)}$, and $w_{a,p}$ commutes with $G^{(a)}$ (Lemma 5.2.58, (ix)); so $z = (w_a(p_a)n)\, w_{a,p}\nu y$, and as $\mathrm{dpw}^-_{a,x}$ is invariant under left translation by $R^{(a)} \supseteq G^{(a)}$ (Lemma 5.4.8, (iii)), $\mathrm{dpw}^-_{a,x}(z) = \mathrm{dpw}^-_{a,x}(w_{a,p}\nu y)$. Hence the integrand is at most $\mathrm{dpw}^-_{a,x}(w_{a,p}\nu y)\, \mathbf{1}\{z \text{ near at } a{+}1\}\, \mathrm{dp}_a(z,x)^s$, and (i) gives (ii).

(iii). Let $\xi \in R^{(j)}$ with $y_0 = \xi g \in K$; by Lemma 5.2.58, (v), $\xi = \gamma\nu_0$ with $\gamma \in G^{(j)}$, $\nu_0 \in N_{<j}$. Then $\nu g = \gamma^{-1}(\gamma\nu\nu_0^{-1}\gamma^{-1})y_0$, and since $w_{j,p}$ commutes with $\gamma^{-1} \in G^{(j)} \subseteq R^{(j)}$ and $\mathrm{dpw}^-_{j,x}$ is left $R^{(j)}$-invariant, $\mathrm{dpw}^-_{j,x}(w_{j,p}\nu g) = \mathrm{dpw}^-_{j,x}(w_{j,p}(\gamma\nu\nu_0^{-1}\gamma^{-1})y_0)$. By Lemma 5.4.14, (iii), $\eta_{<j}$ is invariant under $\nu \mapsto \nu\nu_0^{-1}$, and by Lemma 5.2.59, (iii), under $\nu \mapsto \gamma\nu\gamma^{-1}$; hence

$$I_j := \int \mathrm{dpw}^-_{j,x}(w_{j,p}\nu g)\, d\eta_{<j}(\nu) = \int \mathrm{dpw}^-_{j,x}(w_{j,p}\nu y_0)\, d\eta_{<j}(\nu).$$

We show by induction on $a \le j$ that $\int \mathrm{dpw}^-_{a,x}(w_{a,p}\nu y_0)\, d\eta_{<a}(\nu) \le \prod_{l<a} \mathrm{fm}(l, p_l^{-1}) \cdot \Lambda^{10^6 n^2 a}$ (p is a head of length a). For $a = 0$ the integral is $\mathrm{dpw}^-_{0,x}(y_0) \le 1$. For $a+1 \le j$ (so $a < \varrho$), by Lemma 5.4.14, (ii), $\eta_{<a+1} = \eta_a * \eta_{<a}$ with $\eta_{<a}$ carried by $N_{<a}$, so by Tonelli and (ii),

$$\begin{aligned}\int \mathrm{dpw}^-_{a+1,x}(w_{a+1,p}\nu' y_0)\, d\eta_{<a+1}(\nu') &= \iint \mathrm{dpw}^-_{a+1,x}(w_{a+1,p} n\nu y_0)\, d\eta_a(n)\, d\eta_{<a}(\nu) \\ &\le \mathrm{fm}(a, p_a^{-1}) \Lambda^{10^6 n^2} \int \mathrm{dpw}^-_{a,x}(w_{a,p}\nu y_0)\, d\eta_{<a}(\nu).\end{aligned}$$

At $a = j$: $I_j \le \prod_{a<j} \mathrm{fm}(a, p_a^{-1})\, \Lambda^{10^6 n^2 j} \le \prod_{a<j} \mathrm{fm}(a, p_a^{-1})\, c_{\mathrm{fls}}$, as $j < n$ and $\Lambda \ge 1$.

(iv). By Tonelli, the left side is $\iint \Phi(\nu y)\, \mathrm{dpw}^-_{j,x}(w_{j,p}\nu y)\, d\eta_{<j}(\nu)\, d\rho(y)$. For $\eta_{<j}$-almost every ν, $\nu \in N_{<j} \subseteq R^{(b)}$ (Lemma 5.4.14, (ii); Lemma 5.2.58, (i)), so $\Phi(\nu y) = \Phi(y)$. If y is near at b, it is near at j ($R^{(b)} \subseteq R^{(j)}$), and (iii) bounds the inner integral of $\mathrm{dpw}^-_{j,x}(w_{j,p}\nu y)$; otherwise $\Phi(y) = 0$. This gives (iv). □

Lemma 5.4.8. *Let a place datum be given and $0 \le a < \varrho$.*

(i) The set $\{(x, y, c) \in G \times G \times A : c \in \mathfrak{d}_a(x, y)\}$ is open. For all $x, y \in G$, $\mathfrak{d}_a(x, y)$ is open, contains 0 and has compact closure; hence $0 < \mathrm{vol}(\mathfrak{d}_a(x, y)) < \infty$, $0 < \mathrm{dp}_a(x, y) < \infty$, and $(x, y) \mapsto \mathrm{dp}_a(x, y)$ is measurable.

(ii) $\mathrm{dp}_a(\xi x, y) = \mathrm{dp}_a(x, y)$ for $\xi \in R^{(a+1)}$, and $\mathrm{dp}_a(x, x^{-1}\nu y) = \mathrm{dp}_a(x, x^{-1}y)$ for $\nu \in N_{<a}$, for all $x, y \in G$.

(iii) For $j \geq 0$: $\mathrm{dpw}_{a+1} = \mathrm{dpw}_a \cdot (\mathrm{dp}_a^{-1})^s$; $0 < \mathrm{dpw}_j(x,y) < \infty$; $\mathrm{dpw}_j(\xi x, y) = \mathrm{dpw}_j(x,y)$ for $\xi \in R^{(j)}$; dpw_j is measurable on $G \times G$; and for every x, $\mathrm{dpw}^-_{j,x}$ is measurable with $\mathrm{dpw}^-_{j,x}(\xi g) = \mathrm{dpw}^-_{j,x}(g)$ for $\xi \in R^{(j)}$.

Proof. Recall that $c \in \mathfrak{d}_a(x,y)$ means $c = h(e_a, \omega)$, the e_a^*-coordinate of some $\omega \in V$ with $h(e_b, \omega) = 0$ (the e_b^*-coordinate) for $b < a$, for which there is $\omega' \in \omega + \langle e_b : b < a\rangle$ with $(x^{-1}\omega, (xy)^{-1}\omega') \in \mathcal{P}_{\mathrm{cl}}$; call (ω, ω') a witness. Note that ω and ω' have the same e_b^*-coordinates for all b.

(i). *Openness.* Let (ω, ω') witness $c \in \mathfrak{d}_a(x,y)$. For $c_1 \in A$ let ω_{c_1}, ω'_{c_1} be ω, ω' with the e_a^*-coordinate replaced by c_1. Their e_b^*-coordinates for $b < a$ are unchanged, $\omega'_{c_1} - \omega_{c_1} = \omega' - \omega$, and $h(e_a, \omega_{c_1}) = c_1$. The map $(x_1, y_1, c_1) \mapsto (x_1^{-1}\omega_{c_1}, (x_1 y_1)^{-1}\omega'_{c_1})$ is continuous and sends (x,y,c) into the open set $\mathcal{P}_{\mathrm{cl}}$ (PE4); so a neighbourhood of (x,y,c) lies in the set of (i), each of its points being witnessed by $(\omega_{c_1}, \omega'_{c_1})$. Its sections $\mathfrak{d}_a(x,y)$ are open. $0 \in \mathfrak{d}_a(x,y)$, witnessed by $(0,0) \in \mathcal{P}_{\mathrm{cl}}$ (PE4). *Boundedness.* With $w_1 = x^{-1}\omega$, $c = (xw_1)_{e_a^*}$; so $\mathfrak{d}_a(x,y)$ lies in the image of the compact set $\overline{\mathcal{P}_{\mathrm{cl}}}$ (PE4) under the continuous map $(w_1, w_2) \mapsto (xw_1)_{e_a^*}$. A Haar measure is finite on compact sets and positive on non-empty open sets, so $0 < \mathrm{vol}(\mathfrak{d}_a(x,y)) < \infty$ (the outer measure of an open set is its measure), and $0 < \mathrm{dp}_a(x,y) < \infty$. *Measurability.* $\mathrm{vol}(\mathfrak{d}_a(x,y)) = \int_A \mathbf{1}_O(x,y,c)\,dc$ with O the open set above; it is measurable in (x,y) by Tonelli, and so is its inverse.

(ii). Let $\xi \in R^{(a+1)}$. For $b \leq a$ the column e_b of ξ and of ξ^{-1} has floor and level $b < a+1$, so its entries in rows of level at least b are those of 1: $\xi^{\pm 1} e_b \in e_b + \langle e_c : c < b\rangle$. Hence ξ preserves $\langle e_b : b < a\rangle$, and for ω with $h(e_b, \omega) = 0$ $(b < a)$: $h(e_b, \xi\omega) = h(\xi^{-1}e_b, \omega) = 0$ for $b < a$, and $h(e_a, \xi\omega) = h(\xi^{-1}e_a, \omega) = h(e_a, \omega)$. So if (ω, ω') witnesses $c \in \mathfrak{d}_a(x,y)$, then $(\xi\omega, \xi\omega')$ witnesses $c \in \mathfrak{d}_a(\xi x, y)$, as $((\xi x)^{-1}\xi\omega, (\xi xy)^{-1}\xi\omega') = (x^{-1}\omega, (xy)^{-1}\omega')$. Thus $\mathfrak{d}_a(x,y) \subseteq \mathfrak{d}_a(\xi x, y)$, and with ξ^{-1} equality holds; so $\mathrm{dp}_a(\xi x, y) = \mathrm{dp}_a(x,y)$.

Let $\nu \in N_{<a}$; the two points of $\mathfrak{d}_a(x, x^{-1}y)$ are x and y, those of $\mathfrak{d}_a(x, x^{-1}\nu y)$ are x and νy. Let ω' have e_b^*-coordinate 0 for $b < a$. The entries of $\nu - 1$ lie at (i,k) with $\mathrm{lev}_a(i) < \mathrm{lev}_a(k)$; if i has floor at least a, or $i = e_b^*$ with $b < a$, every such k is some e_c^* with $c < a$, where ω' vanishes. So $\nu\omega' - \omega' \in \langle e_b : b < a\rangle$. Hence if (ω, ω') witnesses c for (x,y), then $(\omega, \nu\omega')$ witnesses c for $(x, \nu y)$, as $(\nu y)^{-1}\nu\omega' = y^{-1}\omega'$; with ν^{-1} the converse holds, so the two sets of stable products are equal.

(iii). The recursion and $0 < \mathrm{dpw}_j < \infty$ follow from (5.16) and (i). If $\xi \in R^{(j)}$ and $a < \min(j, \varrho)$, then $\xi \in R^{(a+1)}$ (Lemma 5.2.58, (i)), so each factor of $\mathrm{dpw}_j(\xi x, y)$ equals that of $\mathrm{dpw}_j(x,y)$ by (ii). Measurability follows from (i). The set N_j of points near at j is $R^{(j)}K$ ($\xi g \in K$ means $g \in \xi^{-1}K$), the product of a closed subgroup and a compact set (PE4), hence closed, and $\xi N_j = N_j$ for $\xi \in R^{(j)}$. So $\mathrm{dpw}^-_{j,x} = \mathbf{1}_{N_j} \cdot \mathrm{dpw}_j(\cdot, x)^{-1}$ is measurable and left $R^{(j)}$-invariant. □

Lemma 5.4.9. *Let a place datum be given, $0 \leq a < \varrho$, $g, x, \sigma \in G$, Q a $\varrho \times \iota'$ matrix over A, and let ϕ be a common bound for $\mathcal{V}_{\mathrm{cm}}(g, x, Q)$ with some loss, for some size filtration. If $h(e_b, \sigma O\omega) = 0$ for all $\omega \in \mathcal{V}_{\mathrm{cm}}(g, x, Q)$ and $b < a$, then*

$$\mathrm{dp}_a(\sigma g, x) \leq \phi((h(o_i, \sigma^{-1}e_a))_{i \in \iota'}).$$

Proof. Put $\varsigma = (h(o_i, \sigma^{-1}e_a))_{i \in \iota'}$ and let $\omega \in \mathcal{V}_{\mathrm{cm}}(g, x, Q)$, $w = \sigma O\omega$. By hypothesis $h(e_b, w) = 0$ for $b < a$, and $((\sigma g)^{-1}w, (\sigma g x)^{-1}w) = (g^{-1}O\omega, (gx)^{-1}O\omega) \in \mathcal{P}_{\mathrm{cl}}$; taking $\omega' = w$ in the definition

of stable products, $h(e_a, w) \in \mathfrak{d}_a(\sigma g, x)$. As σ preserves h and h is hermitian,

$$h(e_a, \sigma O\omega) = h(\sigma^{-1}e_a, O\omega) = \sum_{i\in\iota'} h(\sigma^{-1}e_a, o_i)\,\omega_i = \sum_{i\in\iota'} \overline{h(o_i, \sigma^{-1}e_a)}\,\omega_i = \bar{\varsigma}^{\mathsf{T}}\omega.$$

Hence $\{\bar{\varsigma}^{\mathsf{T}}\omega : \omega \in \mathcal{V}_{\mathrm{cm}}(g, x, Q)\} \subseteq \mathfrak{d}_a(\sigma g, x)$, so by monotonicity of the outer measure and the first property of a common bound,

$$\mathrm{dp}_a(\sigma g, x) = \mathrm{vol}^*(\mathfrak{d}_a(\sigma g, x))^{-1} \le \mathrm{vol}^*\big(\{\bar{\varsigma}^{\mathsf{T}}\omega : \omega \in \mathcal{V}_{\mathrm{cm}}(g, x, Q)\}\big)^{-1} \le \phi(\varsigma).$$

□

Lemma 5.4.10. *Let a place datum be given, let $a < \varrho$ and $E_{<a} = \mathrm{span}\{e_b : b < a\}$. For $c \in A$ let $\mathrm{Sec}_a(c)$ be the section measure,* (5.10) *of Definition 5.2.1 ($|c|^{d_a}$ times the image of η_a under $n \mapsto c\,n^{-1}e_a^*$).*

(i) For every Borel $f\colon V \to [0,\infty]$, $\int_V f\,d\mathrm{qv}_a = \int_A \int_V f\,d\mathrm{Sec}_a(c)\,dc$.

(ii) For $v \in V_{a+1}$, $\beta \in A^-$ and $c \in A$, $c\,n_a(v,\beta)^{-1}e_a^* = c(e_a^* - v - (\beta + \bar{\tau}h(v,v))e_a)$. For $n \in G^{(a)}$ the coordinates of $n^{-1}e_a^*$ of floor below a vanish, and for $\nu \in N_{<a}$ and a sequence p of units, $(w_{a+1,p}n\nu)^{-1}e_a - \bar{p}_a\,n^{-1}e_a^* \in E_{<a}$.

Let now Γ be a gauge of loss Λ for the place datum, with size filtration $(A_{(i)})$.

(iii) Let p be a head of length $a+1$, $y \in K$, n a Heisenberg element of floor a and $\nu \in N_{<a}$. If $w_{a+1,p}n\nu y$ is near at $a+1$, then $\bar{p}_a\,n^{-1}e_a^*$ has size $20n$.

(iv) Let c be a unit, $j \ge 0$, $B \in [0,\infty]$ and $\varphi\colon A^{\iota'} \to [0,\infty]$ Borel with $\int_{A^{\iota'}_{(j+5)}} \varphi\,d\mathrm{vol} \le B$. Then

$$\int_{\{y\in V \text{ of size } j\}} \varphi((h(o_i,y))_{i\in\iota'})\,d\mathrm{Sec}_a(c)(y) \le |c|^{-1/2}\Lambda^{j+3}\Lambda^{99n(j+7)}B.$$

Proof. **(i).** By Lemma 5.2.63 with $b = a$ and $s = 1$, qv_a is the image of θ_a under $\sigma \mapsto \sigma^{-1}e_a$ ($f_a = e_a$). As $\theta_a = \mathrm{wl}_a * \eta_a$ and wl_a is the image of $|c|^{d_a}dc$ under $c \mapsto w_a(c)^{-1}$, Tonelli gives

$$\int f\,d\mathrm{qv}_a = \iint f((xn)^{-1}e_a)\,d\mathrm{wl}_a(x)\,d\eta_a(n) = \int_A |c|^{d_a} \int f(n^{-1}w_a(c)e_a)\,d\eta_a(n)\,dc.$$

For a unit c, $w_a(c)e_a = ce_a^*$ (5.7), so the inner integral is $\int f\,d\mathrm{Sec}_a(c)$ divided by $|c|^{d_a}$; almost every c is a unit (PA4).

(ii). The first formula is c times the second formula of Lemma 5.4.11, (i), plus ce_a^*. For $n \in G^{(a)}$, $n^{-1} \in G^{(a)}$, whose rows at the indices of floor below a are those of 1 (Lemma 5.2.58, (vii)); as e_a^* has floor a, these coordinates of $n^{-1}e_a^*$ vanish. The inverse of $w = w_{a+1,p}$ sends e_a to $\bar{p}_a e_a^*$, so $(wn\nu)^{-1}e_a = \bar{p}_a\,\nu^{-1}n^{-1}e_a^*$; by the last claim of Lemma 5.4.11, (i), applied to $n^{-1} \in G^{(a)}$ and $\nu^{-1} \in N_{<a}$, $\nu^{-1}n^{-1}e_a^* - n^{-1}e_a^* \in E_{<a}$.

(iii). The conjugate sequence $\bar{p}$ is a head of length $a+1$ (SZ3), and $w_{a+1,\bar{p}}^{-1} = w_{a+1,p}$ (both send $e_b \mapsto p_b e_b^*$ and $e_b^* \mapsto \bar{p}_b^{-1}e_b$ for $b \le a$). Put $g = n\nu y$ and $s = (n\nu)^{-1}$. By Lemma 5.2.58, (iii) and (i), $n \in N_{<a+1}$ and $\nu \in N_{<a}$ lie in $R^{(a+1)}$, so $s \in R^{(a+1)}$, $sg = y \in K$, and $w_{a+1,\bar{p}}^{-1}g = w_{a+1,p}n\nu y$ is near at $a+1$. By Lemma 5.4.12, (i), with $j = a+1$ and the head $\bar{p}$, both $\bar{p}_a$ and the entries of $se_a^* = \nu^{-1}n^{-1}e_a^*$ lie in $A_{(10n)}$, so $(w_{a+1,p}n\nu)^{-1}e_a = \bar{p}_a\,\nu^{-1}n^{-1}e_a^*$ has size $20n$ (SZ1). By (ii), $\bar{p}_a n^{-1}e_a^*$ has the same coordinates as this vector at all indices of level at least a (the

indices of $E_{<a}$ are the e_b, $b<a$, of level $b<a$), and its coordinates at the remaining indices, the e_b with $b<a$, vanish. Hence it has size $20n$ (SZ4).

(iv). Put $u=(-c)^{-1}$, so $u^{-1}=-c$ and $|u|=|c|^{-1}$ by (PA2). Let

$$\Phi(n)=\mathbf{1}_j(cn^{-1}e_a^*)\,\varphi((h(o_i,cn^{-1}e_a^*))_{i\in\iota'}),$$

with $\mathbf{1}_j$ the indicator of the vectors of size j, and $\Psi(v')=\varphi((h(o_i,v'))_{i\in\iota'})$; both are Borel, and the left side of (iv) is $|c|^{d_a}\int\Phi\,d\eta_a$. Let $n=n_a(v,\beta)$ with $\Phi(n)\neq 0$. As $h(o_i,e_a)=h(o_i,e_a^*)=0$, (ii) gives $h(o_i,cn^{-1}e_a^*)=h(o_i,-cv)$, so $\Phi(n)\leq\Psi(u^{-1}v)$. Moreover $cn^{-1}e_a^*$ has size j, and its e_a^*-coordinate is c by (ii) ($v\in V_{a+1}$ has no e_a^*-coordinate); so $w=(n^{-1}-1)e_a^*$ satisfies $u^{-1}w=ce_a^*-cn^{-1}e_a^*$, of size $j+1$ (SZ2, SZ3). By Lemma 5.4.4, (iv), with $l=a+1$, $\rho=\mathrm{vol}_{V_{a+1}}$ and $j+1$ in place of j, $\int_{\{v'\text{ of size }j+1\}}\Psi\,d\mathrm{vol}_{V_{a+1}}\leq\Lambda^{99n(j+7)}B$. Hence Lemma 5.4.11, (iii), with $C=1$, $j+1$ and $I=\Lambda^{99n(j+7)}B$ gives $\int\Phi\,d\eta_a\leq\mathrm{fm}(a,u)\Lambda^{j+3}\Lambda^{99n(j+7)}B$, with $\mathrm{fm}(a,u)=|u|^{d_a}|u|^{1/2}=|c|^{-d_a}|c|^{-1/2}$. Multiplying by $|c|^{d_a}$ ($0<|c|<\infty$ for a unit) gives (iv). □

Lemma 5.4.11. *Let a place datum be given, let $a<\varrho$, and write $E_{<a}=\mathrm{span}\{e_b:b<a\}$.*

(i) For $v\in V_{a+1}$ and $\beta\in A^-$: $(n_a(v,\beta)-1)e_a^*=v+(\beta-\tau h(v,v))e_a$ and $(n_a(v,\beta)^{-1}-1)e_a^*=-v-(\beta+\bar\tau h(v,v))e_a$. For $n\in G^{(a)}$ and $\nu\in N_{<a}$, $(\nu n-1)e_a^*-(n-1)e_a^*\in E_{<a}$.

Let now Γ be a gauge of loss Λ for the place datum, with size filtration $(A_{(i)})$.

(ii) Let u be a unit, $i\geq 0$, $v\in V_{a+1}$, $\beta\in A^-$, and let $w\in V$ with $w-(n_a(v,\beta)-1)e_a^*\in E_{<a}$ and $u^{-1}w$ of size i. Then $u^{-1}v$ has size i and $u^{-1}(\beta-\tau h(v,v))\in A_{(i)}$. The same holds with $n_a(v,\beta)^{-1}$ in place of $n_a(v,\beta)$ and $-u^{-1}(\beta+\bar\tau h(v,v))$ in place of $u^{-1}(\beta-\tau h(v,v))$.

(iii) Let u be a unit, $j\geq 0$, $C,I\in[0,\infty]$, let $\Psi\colon V\to[0,\infty]$ be Borel with $\int_{\{v'\text{ of size }j\}}\Psi\,d\mathrm{vol}_{V_{a+1}}\leq I$, and let $\Phi\colon G\to[0,\infty]$ be Borel. Suppose that for all $v\in V_{a+1}$ and $\beta\in A^-$ with $\Phi(n_a(v,\beta))\neq 0$ there is $w\in V$ with $w-(n_a(v,\beta)^{-1}-1)e_a^*\in E_{<a}$ and $u^{-1}w$ of size j, and $\Phi(n_a(v,\beta))\leq C\,\Psi(u^{-1}v)$. Then

$$\int_G\Phi\,d\eta_a\leq C\,\mathrm{fm}(a,u)\,\Lambda^{j+2}\,I.$$

Proof. **(i).** Write $n=n_a(v,\beta)$. In (5.8) take $w=e_a^*$: its e_a^*-coordinate is $h(e_a,e_a^*)=1$ and $h(v,e_a^*)=0$ as $v\in V_{a+1}$, so $ne_a^*=e_a^*+v+(\beta-\tau h(v,v))e_a$. By Lemma 5.2.58, (iii), $n_a(v,\beta)\,n_a(-v,\beta')=n_a(0,\beta+\beta'-\tau h(v,v)+\bar\tau h(v,v))$, and $n_a(0,0)=1$; so $n^{-1}=n_a(-v,\beta')$ with $\beta'=-\beta+(\tau-\bar\tau)h(v,v)\in A^-$, and the first formula gives $(n^{-1}-1)e_a^*=-v+(\beta'-\tau h(v,v))e_a=-v-(\beta+\bar\tau h(v,v))e_a$. For the last claim, $(\nu n-1)e_a^*-(n-1)e_a^*=(\nu-1)w_0$ with $w_0=ne_a^*$. For $b<a$, $h(e_b,w_0)=h(n^{-1}e_b,e_a^*)=h(e_b,e_a^*)=0$, so the e_b^*-coordinates of w_0 vanish ($h(e_b,w)$ is the e_b^*-coordinate of w). By the definition of $N_{<a}$, the columns of ν at the e_c ($c<a$) and at the indices of floor at least a are the coordinate columns plus elements of $E_{<a}$ (the indices of modified level below that of the column are among the e_b, $b<a$). Hence $(\nu-1)w_0\in E_{<a}$.

(ii). By (i), w and $v+(\beta-\tau h(v,v))e_a$ have the same coordinates outside the e_b, $b<a$. The coordinates of v at floors at most a vanish, so the coordinates of $u^{-1}v$ are 0 or coordinates of $u^{-1}w$, hence in $A_{(i)}$ (SZ4), and $u^{-1}(\beta-\tau h(v,v))$ is the e_a-coordinate of $u^{-1}w$. The second statement follows in the same way from the second formula of (i), using (SZ3) for the signs.

A bound for the skew measure. Let u be a unit and $S\subseteq A^-$ a Borel set with $u^{-1}(\beta-\beta')\in A_{(j+1)}$ for all $\beta,\beta'\in S$. Then $\nu(S)\leq|u|^{1/2}\Lambda^{j+2}$. Indeed, let $\Sigma(\alpha,\beta)=\tau\delta^{-1}\alpha+\beta$, which carries $\nu\otimes\nu$ to vol (PA1). For $p,p'\in S\times S$, $u^{-1}(\Sigma(p)-\Sigma(p'))=\tau\delta^{-1}\cdot u^{-1}(\alpha-\alpha')+u^{-1}(\beta-\beta')\in A_{(j+3)}$,

as $\tau\delta^{-1} \in A_{(1)}$ (GU2), by (SZ1), (SZ2). Fix $p_0 \in S\times S$ (if $S=\emptyset$ there is nothing to prove). Then $\Sigma(S\times S - p_0) \subseteq uA_{(j+3)}$, so by translation invariance and (PA1), $\nu(S)^2 \le \mathrm{vol}(uA_{(j+3)})$. By (PA3) for the 1×1 matrix (u^{-1}), $\mathrm{vol}(uC) = |u|\,\mathrm{vol}(C)$; with (GU5), $\nu(S)^2 \le |u|\Lambda^{j+4} \le (|u|^{1/2}\Lambda^{j+2})^2$.

(iii). By the definition of η_a and Tonelli, $\int \Phi\, d\eta_a = \int_{V_{a+1}} \int_{A^-} \Phi(n_a(v,\beta))\, d\nu(\beta)\, dv$. Fix v and let $S_v = \{\beta : \Phi(n_a(v,\beta)) \neq 0\}$, a Borel set. For $\beta \in S_v$, (ii) (second form, with $i=j$) gives that $u^{-1}v$ has size j and $u^{-1}(\beta + \bar\tau h(v,v)) \in A_{(j)}$; hence for $\beta,\beta' \in S_v$ the difference $u^{-1}(\beta-\beta')$ lies in $A_{(j+1)}$ (SZ2, SZ3), and by the bound for the skew measure,

$$\int_{A^-} \Phi(n_a(v,\beta))\, d\nu(\beta) \le \nu(S_v)\, C\, \Psi(u^{-1}v)\, \mathbf{1}_j(u^{-1}v) \le |u|^{1/2}\Lambda^{j+2}\, C\, \Psi(u^{-1}v)\, \mathbf{1}_j(u^{-1}v),$$

where $\mathbf{1}_j$ is the indicator of the vectors of size j (the left side is 0 if $S_v=\emptyset$). The space V_{a+1} has d_a coordinates, so by (PA3) for the diagonal matrix $u\cdot 1$ the image of $\mathrm{vol}_{V_{a+1}}$ under $v' \mapsto uv'$ is $|u|^{-d_a}\mathrm{vol}_{V_{a+1}}$, and

$$\int_{V_{a+1}} \Psi(u^{-1}v)\mathbf{1}_j(u^{-1}v)\, dv = |u|^{d_a} \int_{\{v' \text{ of size } j\}} \Psi\, d\mathrm{vol}_{V_{a+1}} \le |u|^{d_a} I.$$

Hence $\int \Phi\, d\eta_a \le C\,|u|^{d_a}|u|^{1/2}\Lambda^{j+2} I = C\,\mathrm{fm}(a,u)\,\Lambda^{j+2} I$. □

Lemma 5.4.12. *Let Γ be a gauge, with size filtration $(A_{(i)})_{i\ge 0}$, for a place datum; let $j \le \varrho$, let p be a head of length j, write $w_p = w_{j,p}$, and let $g \in G$.*

(i) Let $s \in R^{(j)}$ with $sg \in K$, and let $w_p^{-1}g$ be near at j. Then $p_0\cdots p_{l-1} \in A_{(9n)}$ for $0 \le l \le j$, and for every $a < j$: $p_0\cdots p_a\, s_{ke_a^*} \in A_{(8\varrho)}$ for every index k, the column se_a^* has size $8\varrho+1$, and p_a, p_a^{-1} and the entries of se_a^* lie in $A_{(10n)}$.

(ii) If moreover $s \in N_{<j}$, then g has size $60n^2$ and $w_p^{-1}g$ has size $99n^2$.

(iii) If g and $w_p^{-1}g$ are near at j, then there is $\sigma \in G^{(j)}$ such that σg has size $60n^2$ and $\sigma w_p^{-1}g$ has size $99n^2$.

Proof. We use the size rules of the proof of Lemma 5.4.13, which follow from (SZ1)–(SZ5): $A_{(i)} \subseteq A_{(i+1)}$; a product of matrices of sizes i and i' has size $i+i'+1$; the inverse of an element of G of size i has size $i+4$, so elements of K (size 1, (GU2)) have inverses of size 5; a determinant of order $i \le \varrho$ with entries in $A_{(7)}$ lies in $A_{(8i)}$. Recall also that for $t \in R^{(j)}$ and $d < j$ the column te_d is $e_d + \sum_{c\le d}(\cdot)\, e_c$ ((5.76) of Lemma 5.4.13, as $e_d = f_d$), and that $t^{-1} = J^{-1}\bar t^{\mathsf T} J$, which gives $t_{e_b^* e_c^*} = \overline{(t^{-1})_{e_c e_b}}$ for all $b,c < \varrho$, since the row e_b^* of J^{-1} and the column e_c^* of J are coordinate vectors at e_b and e_c.

(i). Let $\eta \in R^{(j)}$ with $\eta w_p^{-1} g \in K$. As $sg \in K$, g is near at j; so $y = g$ and $\gamma = w_p$ satisfy the hypothesis of Lemma 5.4.13, (ii), with $l = j$, and with (iii) there, $p_0\cdots p_{l-1} = D_l(w_p) \in A_{(9n)}$ for $l \le j$.

Cramer. Fix $a < j$ and an index k. The element $y = sw_p\eta^{-1} = (sg)(\eta w_p^{-1} g)^{-1}$ has size $1+5+1 = 7$. Let Z be the $(a+1)\times(a+1)$ matrix $Z_{bd} = y_{R_b e_d}$ $(b,d \le a)$ with rows $R_b = e_b^*$ for $b < a$ and $R_a = k$; its entries lie in $A_{(7)}$, so $\det Z \in A_{(8(a+1))} \subseteq A_{(8\varrho)}$. Since $\eta^{-1} \in R^{(j)}$ and $d \le a < j$, $\eta^{-1}e_d = \sum_{c\le d} C_{cd} e_c$ with C upper unitriangular; and $w_p e_c = p_c e_c^*$ for $c < j$. Hence $ye_d = \sum_{c\le d} C_{cd}\, p_c\, se_c^*$, that is $Z = LC$ with $L_{bc} = p_c\, s_{R_b e_c^*}$, and $\det Z = \det L$. For $b \le c < j$, $s_{e_b^* e_c^*} = \overline{(s^{-1})_{e_c e_b}} = \delta_{bc}$, because the column e_b of $s^{-1} \in R^{(j)}$ is e_b plus a combination of the $e_{c'}$ with $c' < b$. So the rows $b < a$ of L are p_b times the coordinate row at b on and to the right of the diagonal, L is lower triangular, and

$$\det Z = \det L = p_0\cdots p_{a-1}\cdot p_a\, s_{ke_a^*} \in A_{(8\varrho)}.$$

As p is a head of length j and $a+1 \le j$, $(p_0 \cdots p_a)^{-1} \in A_{(1)}$, so $s_{ke_a^*} \in A_{(8\varrho+1)} \subseteq A_{(10n)}$ by (SZ1). Finally $p_a = (p_0 \cdots p_{a-1})^{-1}(p_0 \cdots p_a)$ and $p_a^{-1} = (p_0 \cdots p_a)^{-1}(p_0 \cdots p_{a-1})$ lie in $A_{(9n+1)} \subseteq A_{(10n)}$.

(ii). Put $d = 10n$; by (i), every column se_b^*, $b < j$, has size d. We bound the other columns of s, using $s \in N_{<j}$ and that s preserves h. With lev_j as in the definition of $N_{<j}$, the e_c ($c < j$) have $\mathrm{lev}_j = c < \varrho$, the e_c^* ($c < j$) have $\mathrm{lev}_j = 2\varrho - c > \varrho$, and the indices of floor at least j have $\mathrm{lev}_j = \varrho$. Hence: $se_a = e_a + \sum_{c<a} u_{ca} e_c$ for $a < j$; $sv = v + \sum_{c<j} t_c(v) e_c$ for every coordinate vector v of floor at least j; and $s_{e_c^* e_b^*} = \delta_{cb}$ for $c \le b < j$. For $b, c < j$ put $N_{bc} = h(se_b^*, e_c) = \overline{s_{e_c^* e_b^*}}$ (the column e_c of J is the coordinate vector at e_c^*). Then $N_{bb} = 1$, $N_{bc} = 0$ for $c < b$, and $N_{bc} \in A_{(d)}$ (SZ3).

Columns of floor at least j. Let v be such a coordinate vector and $h_b = h(se_b^*, v)$, a sum of at most r products of the conjugate of an entry of se_b^* and an entry of J, so $h_b \in A_{(d+2)}$. Since $h(e_b^*, v) = v_{e_b} = 0$, preservation of h gives $0 = h(se_b^*, sv) = h_b + \sum_{c<j} N_{bc} t_c(v)$, that is $t_b(v) = -h_b - \sum_{b<c<j} N_{bc} t_c(v)$. By descending induction on b, each step being a sum of at most $j \le r+1$ terms, $t_b(v) \in A_{(d+2+(d+1)(j-1-b))} \subseteq A_{((d+1)j+1)}$.

Columns e_a. Put $u_{aa} = 1$ and $u_{ca} = 0$ for $c > a$. Since $h(e_b^*, e_a) = \delta_{ab}$, preservation of h gives $\delta_{ab} = h(se_b^*, se_a) = \sum_{c \le a} N_{bc} u_{ca}$; for $b < a$ this reads $u_{ba} = -\sum_{b<c\le a} N_{bc} u_{ca}$, and descending induction on b gives $u_{ba} \in A_{((d+1)(a-b))} \subseteq A_{((d+1)j+1)}$.

All other entries of s are 0 or 1. So s has size $D = (d+1)j + 1$ (for $j = 0$, $s = 1$), s^{-1} has size $D+4$, and $g = s^{-1}(sg)$ has size $D + 6 = (10n+1)j + 7 \le (10n+1)(n-1) + 7 \le 60n^2$. The inverse w_p^{-1} sends $e_a^* \mapsto p_a^{-1} e_a$ and $e_a \mapsto \bar{p}_a e_a^*$ for $a < j$ and fixes the other coordinate vectors, so by (i) and (SZ3), (SZ4) it has size $10n$; hence $w_p^{-1} g$ has size $10n + 60n^2 + 1 \le 99n^2$.

(iii). Let $\xi \in R^{(j)}$ with $\xi g \in K$ and $\zeta \in R^{(j)}$ with $\zeta w_p^{-1} g \in K$. By Lemma 5.2.58, (v), $\xi = \sigma\nu$ with $\sigma \in G^{(j)}$ and $\nu \in N_{<j}$. Put $g' = \sigma g$ and $s = \sigma\nu\sigma^{-1}$; by Lemma 5.2.58, (ii) and (i), $s \in N_{<j} \subseteq R^{(j)}$, and $sg' = \xi g \in K$. By Lemma 5.2.58, (ix), $w_p^{-1} g' = \sigma w_p^{-1} g$, and $(\zeta\sigma^{-1})(\sigma w_p^{-1} g) \in K$ with $\zeta\sigma^{-1} \in R^{(j)}$ (as $G^{(j)} \subseteq R^{(j)}$), so $w_p^{-1} g'$ is near at j. Now (ii) for g' and s gives the claim. □

Lemma 5.4.13. *Let a place datum be given. For $\gamma \in G$ let $Z(\gamma) = (h(f_a, \gamma f_b))_{0\le a,b\le\varrho}$, and for $0 \le i \le n$ let $D_i(\gamma)$ be the determinant of its upper left $i \times i$ block ($D_0(\gamma) = 1$).*

(i) For $l \ge 0$, $\xi, \xi' \in R^{(l)}$, $\gamma \in G$ and $0 \le i \le \min(l, n)$: $D_i(\xi^{-1}\gamma\xi') = D_i(\gamma)$.

(ii) Let Γ be a gauge for the place datum, with size filtration $(A_{(i)})$. If $l \ge 0$, $\gamma, y \in G$ and both y and $\gamma^{-1} y$ are near at l, then $D_i(\gamma) \in A_{(9n)}$ for $0 \le i \le \min(l, n)$.

(iii) For $j \le \varrho$, a sequence p of units of A and $0 \le i \le j$: $D_i(w_{j,p}) = p_0 p_1 \cdots p_{i-1}$.

Proof. **Frame columns of $R^{(l)}$.** Let $s \in R^{(l)}$ and $b < \min(l, n)$. The index f_b has level b; if $l \le \varrho + 1$ it has floor $b < l$ and level $b < l$, and if $l \ge \varrho + 2$ no condition on the column is needed. In both cases the definition of $R^{(l)}$ gives $s_{kf_b} = \delta_{kf_b}$ for every index k of level at least b. The indices of level below b are the $e_c = f_c$ with $c < b$ (the x_i and z have level $\varrho \ge b$, the e_c^* level $2\varrho - c \ge \varrho + 1$). Hence

$$sf_b = f_b + \sum_{c<b} t_{cb}(s)\, f_c \qquad (b < \min(l, n)) \tag{5.76}$$

for some $t_{cb}(s) \in A$.

(i). Fix $i \le \min(l, n)$, let $Z_i(\gamma)$ be the upper left $i \times i$ block of $Z(\gamma)$, and let $U_i(s)$ be the $i \times i$ matrix with entries $t_{cb}(s)$ for $c < b$, 1 on the diagonal and 0 below it; $\det U_i(s) = 1$. As h is linear in its second argument, (5.76) for ξ' gives $h(f_a, \gamma\xi' f_b) = \sum_{c\le b} h(f_a, \gamma f_c)\, t_{cb}(\xi')$ for $a, b < i$,

that is $Z_i(\gamma\xi') = Z_i(\gamma)U_i(\xi')$. As ξ preserves h, $h(f_a, \xi^{-1}w) = h(\xi f_a, w)$, and h is conjugate linear in its first argument, so (5.76) for ξ gives $Z_i(\xi^{-1}\gamma') = \overline{U_i(\xi)}^{\mathsf{T}} Z_i(\gamma')$. Taking determinants with $\gamma' = \gamma\xi'$ gives $D_i(\xi^{-1}\gamma\xi') = \overline{\det U_i(\xi)}\, D_i(\gamma) \det U_i(\xi') = D_i(\gamma)$.

Sizes of inverses, products and determinants. By (SZ2) with one summand, $A_{(i)} \subseteq A_{(i+1)}$. A product of matrices of sizes i and i' (of order at most r) has size $i + i' + 1$, by (SZ1), (SZ2). If $g \in G$ has size i, then $g^{-1} = J^{-1}\bar{g}^{\mathsf{T}}J$ has size $i + 4$, by (SZ3), (SZ5) and the rule for products. A square matrix of order $i \leq \varrho$ with entries in $A_{(7)}$ has determinant in $A_{(8i)}$: for $i = 0$ it is $1 \in A_{(0)}$ (SZ4), and by Laplace expansion along the first row the determinant of order $i \geq 1$ is a sum of $i \leq r + 1$ terms $\pm$(entry)(minor of order $i - 1$), each in $A_{(7+8(i-1))}$ by induction, (SZ1) and (SZ3), hence lies in $A_{(8i)}$ by (SZ2).

(ii). Let $\xi, \xi' \in R^{(l)}$ with $\xi y \in K$ and $\xi'\gamma^{-1}y \in K$, and put $x = (\xi y)(\xi'\gamma^{-1}y)^{-1} = \xi\gamma\xi'^{-1}$. Elements of K have size 1 (GU2), so x has size $1 + 5 + 1 = 7$, and $\gamma = \xi^{-1}x\xi'$, so $D_i(\gamma) = D_i(x)$ by (i). Since f_a is a coordinate vector, $Z(x)_{ab} = (Jx)_{f_a f_b}$. For $a < \varrho$ the row e_a of J is the coordinate row of e_a^*, so $Z(x)_{ab} = x_{e_a^* f_b} \in A_{(7)}$; the row $f_\varrho = z$ of Jx has entries in $A_{(9)}$ by the rule for products. If $i \leq \varrho$, $D_i(x)$ is a determinant of order i with entries in $A_{(7)}$, so $D_i(x) \in A_{(8i)} \subseteq A_{(9n)}$. If $i = n$ and $\varrho = 0$, $D_1(x) = Z(x)_{00} \in A_{(9)} = A_{(9n)}$. If $i = n$ and $\varrho \geq 1$, expanding along the last row, $D_n(x)$ is a sum of $n \leq r + 1$ terms $\pm$(entry of the row of z)(determinant of order ϱ with entries in $A_{(7)}$), each in $A_{(9+8\varrho)}$, so $D_n(x) \in A_{(8\varrho+10)} \subseteq A_{(9n)}$, as $8\varrho + 10 \leq 9\varrho + 9$.

(iii). For $b < i \leq j \leq \varrho$, $f_b = e_b$ and $w_{j,p}e_b = p_b e_b^*$, so $h(f_a, w_{j,p}f_b) = p_b\, h(e_a, e_b^*) = p_b\delta_{ab}$ for $a, b < i$. The block is the diagonal matrix with entries $p_0, \ldots, p_{i-1}$. □

Lemma 5.4.14. *Let a place datum be given and $j \geq 0$. Call $n_j(v, \beta)$ ($v \in V_{j+1}$, $\beta \in A^-$) the Heisenberg elements of floor j if $j < \varrho$, and 1 the only one if $j \geq \varrho$.*

(i) Every $s \in N_{<j+1}$ is a product $s = n\nu$ of a Heisenberg element n of floor j and some $\nu \in N_{<j}$.

(ii) $\eta_{<j+1} = \eta_j * \eta_{<j}$, and $\eta_{<j}$ is carried by $N_{<j}$.

(iii) $\eta_{<j} * \delta_s = \delta_s * \eta_{<j} = \eta_{<j}$ for every $s \in N_{<j}$.

Proof. **Two facts on $N_{<l}$.** The group $N_{<0}$ is $\{1\}$: for $l = 0$ every index has modified level ϱ, so every entry is that of 1. If $l \geq \varrho$, the modified level lev_{l+1} agrees with lev_l (the indices that change from level ϱ to their level have level ϱ already), so $N_{<l+1} = N_{<l}$.

(i). If $j \geq \varrho$, take $n = 1$, $\nu = s$. Let $j < \varrho$. By Lemma 5.2.58, (i), $s \in N_{<j+1} \subseteq R^{(j)}$, so by (v) there, $s = \gamma\nu$ with $\gamma \in G^{(j)}$ and $\nu \in N_{<j}$; then $\gamma = s\nu^{-1} \in N_{<j+1}$, as $N_{<j} \subseteq N_{<j+1}$ and $N_{<j+1}$ is a group. Since $N_{<j+1} \subseteq R^{(j+1)}$, $\gamma \in R^{(j+1)} \cap G^{(j)}$, and by Lemma 5.2.58, (iv), there is a Heisenberg element n of floor j with $\gamma' = n^{-1}\gamma \in G^{(j+1)}$; also $\gamma' \in N_{<j+1}$ (Heisenberg elements of floor j lie in $N_{<j+1}$, Lemma 5.2.58, (iii)). We show $\gamma' = 1$. It fixes the e_b, e_b^* with $b \leq j$. A coordinate vector w of floor at least $j + 1$ has $\mathrm{lev}_{j+1}(w) = \varrho$, and the indices of smaller modified level are the e_c, $c \leq j$; so $\gamma' w = w + \sum_{c \leq j} t_c e_c$; but the rows of $\gamma' \in G^{(j+1)}$ at the indices of floor below $j + 1$ are those of 1 (Lemma 5.2.58, (vii)), so all $t_c = 0$ and $\gamma' w = w$. Hence $\gamma' = 1$ and $s = n\nu$.

Commutation. If a measure μ is carried by a set of elements s with $\delta_s * \mu' = \mu' * \delta_s$, then $\mu * \mu' = \mu' * \mu$: for measurable $f \geq 0$, by Tonelli, $\int f\, d(\mu * \mu') = \iint f(sy)\, d\mu'(y)\, d\mu(s) = \iint f(ys)\, d\mu'(y)\, d\mu(s) = \int f\, d(\mu' * \mu)$.

(ii). By definition $\eta_{<j+1} = \eta_{<j} * \eta_j$. The measure η_j is carried by $G^{(j)}$ (Lemma 5.2.59, (ii)), and $\delta_s * \eta_{<j} = \eta_{<j} * \delta_s$ for $s \in G^{(j)}$ (Lemma 5.2.59, (iii)); by the commutation fact,

$\eta_{<j} * \eta_j = \eta_j * \eta_{<j}$. For the carrier, induct on j: $\eta_{<0} = \delta_1$ and $1 \in N_{<0}$; if $\eta_{<j}$ is carried by $N_{<j} \subseteq N_{<j+1}$, then as η_j is carried by the Heisenberg elements of floor j, which lie in $N_{<j+1}$ (for $j \geq \varrho$, $\eta_j = \delta_1$), the image $\eta_{<j} * \eta_j$ of $\eta_{<j} \otimes \eta_j$ under multiplication is carried by the group $N_{<j+1}$, which is closed (it is defined by equations on entries), hence Borel.

(iii). Induction on j. For $j = 0$, $N_{<0} = \{1\}$. Assume (iii) for j and let $s \in N_{<j+1}$; by (i), $s = n\nu$ with n a Heisenberg element of floor j and $\nu \in N_{<j}$, so $\delta_s = \delta_n * \delta_\nu$. By Lemma 5.2.61, (ii) (trivially if $j \geq \varrho$), $\eta_j * \delta_n = \delta_n * \eta_j = \eta_j$. Using (ii) and associativity of convolution,

$$\eta_{<j+1} * \delta_s = \eta_{<j} * (\eta_j * \delta_n) * \delta_\nu = (\eta_{<j} * \eta_j) * \delta_\nu = \eta_j * (\eta_{<j} * \delta_\nu) = \eta_j * \eta_{<j} = \eta_{<j+1},$$

$$\delta_s * \eta_{<j+1} = \delta_n * (\delta_\nu * \eta_{<j}) * \eta_j = \delta_n * \eta_{<j} * \eta_j = \delta_n * \eta_j * \eta_{<j} = (\delta_n * \eta_j) * \eta_{<j} = \eta_j * \eta_{<j} = \eta_{<j+1}.$$

□

Lemma 5.4.15. *Let a place datum of shape (ϱ, ι, m) be given, and let $p = (p_a)_{a\geq 0}$, $q = (q_a)_{a\geq 0}$ be sequences of units of A.*

(i) For $0 \leq j \leq \varrho$ and every measurable $\Phi\colon G \to [0,\infty]$,

$$\int \Phi(w_{j,q}^{-1} w_{j,p}\, x)\, d\theta_{\geq 0}(x) = \prod_{a<j} |p_a q_a^{-1}|^{k+2(\varrho-a)} \int \Phi\, d\theta_{\geq 0}.$$

(ii) Suppose that θ is a left Haar measure of G. For $0 \leq j \leq \varrho + 2$ and every measurable $\Phi\colon G \to [0,\infty]$ with $\Phi(tg) = \Phi(g)$ for all $t \in G^{(j)}$ and $g \in G$,

$$\int \Phi(w_{j,p}^{-1} g)\, d\mathfrak{m}_j(g) = \int \Phi\, d\mathfrak{m}_j.$$

Proof. All measures are s-finite; convolution is associative and $\int F\, d(\mu{*}\mu') = \iint F(xy)\, d\mu(x)\, d\mu'(y)$ for measurable $F \geq 0$.

(i). Put $R_j = w_{j,q}^{-1} w_{j,p}$. Since $w_{j,q} e_a = q_a e_a^*$ and $w_{j,q} e_a^* = \bar{q}_a^{-1} e_a$, we have $w_{j,q}^{-1} e_a^* = \overline{q_a p_a^{-1}}\, e_a^*$ and $w_{j,q}^{-1} e_a = \bar{q}_a e_a^*$ for $a < j$; hence R_j is diagonal, $R_j e_a = p_a q_a^{-1} e_a$ and $R_j e_a^* = \overline{q_a p_a^{-1}}\, e_a^*$ for $a < j$, and R_j fixes the other coordinate vectors. For $l < \varrho$ and a unit c, (5.7) gives $w_l(c)^{-1} e_l = \bar{c} e_l^*$ and $w_l(c)^{-1} e_l^* = c^{-1} e_l$.

We argue by induction on j; for $j = 0$, $R_0 = 1$. Let $j < \varrho$ and put $r = p_j q_j^{-1}$. Then $D = R_j^{-1} R_{j+1}$ scales e_j by r and e_j^* by $\bar{r}^{-1}$ and fixes the other coordinate vectors, and for every unit c

$$D\, w_j(rc)^{-1} = w_j(c)^{-1}, \qquad \text{so} \qquad R_{j+1}\, w_j(rc)^{-1} = R_j\, w_j(c)^{-1}, \tag{5.77}$$

as both sides of the first identity send $e_j \mapsto \overline{rc}\,\bar{r}^{-1} e_j^* = \bar{c} e_j^*$, $e_j^* \mapsto r(rc)^{-1} e_j = c^{-1} e_j$ and fix the other coordinate vectors. By Lemma 5.2.59, (i), applied repeatedly, $\theta_{\geq 0} = \theta_{\geq j} * \theta_{j-1} * \cdots * \theta_0$ and $\theta_{\geq j} = \mathrm{wl}_j * \theta_{\geq j+1} * \eta_j$; so $\theta_{\geq 0} = \mathrm{wl}_j * \mu$ with $\mu = \theta_{\geq j+1} * \eta_j * \theta_{j-1} * \cdots * \theta_0$, and by the definition of wl_j,

$$\int \Psi\, d\theta_{\geq 0} = \int_A |c|^{d_j} \int_G \Psi(w_j(c)^{-1} y)\, d\mu(y)\, dc \qquad (\Psi \geq 0 \text{ measurable}). \tag{5.78}$$

Apply (5.78) to $\Psi = \Phi(R_{j+1}\,\cdot)$ and put $F(c) = \int \Phi(R_{j+1} w_j(c)^{-1} y)\, d\mu(y)$. By (PA3) for the 1×1 matrix (r), $\int_A H(c)\, dc = |r| \int_A H(rc)\, dc$ for measurable $H \geq 0$; with $|rc|^{d_j} = |r|^{d_j} |c|^{d_j}$, the fact

that almost every c is a unit (PA4) and (5.77),

$$\begin{aligned}\int \Phi(R_{j+1}x)\,d\theta_{\geq 0} &= |r|^{d_j+1}\int_A |c|^{d_j} F(rc)\,dc \\ &= |r|^{d_j+1}\int_A |c|^{d_j}\int_G \Phi\big(R_j w_j(c)^{-1}y\big)\,d\mu(y)\,dc \\ &= |r|^{d_j+1}\int \Phi(R_j x)\,d\theta_{\geq 0},\end{aligned}$$

the last step by (5.78) for $\Psi = \Phi(R_j\,\cdot)$. As $d_j + 1 = k + 2(\varrho - j)$ for $j < \varrho$, the induction hypothesis gives (i) for $j+1$.

(ii). Let $w = w_{j,p}$, $s = w^{-1}$, $i = \varrho + 2 - j$ and $\rho = \mathfrak{m}_{j,i}$; by the definition of the partial group measures and associativity, $\theta = \mathfrak{m}_{0,\varrho+2} = \rho * \mathfrak{m}_j$.

Properties of ρ. It is carried by $G^{(j)}$ (Lemma 5.2.59, (ii)), satisfies $\rho * \delta_t = \rho$ for $t \in G^{(j)}$ (Lemma 5.2.61, (iii)), and $\rho \neq 0$ (Lemma 5.2.61, (iv)). Moreover $wt = tw$ for every $t \in G^{(j)}$: if $j \geq \varrho + 2$ then $t = 1$; otherwise $t \in G^{(\min(j,\varrho))}$, so by Lemma 5.2.58, (vii), the rows and columns of t at the indices of floor below $\min(j,\varrho)$ are those of 1, while w acts only on the span of the e_a, e_a^* with $a < \min(j,\varrho)$ and fixes the other coordinate vectors; both matrices are block diagonal for the same two blocks, t being the identity on the first and w on the second. Hence $\int F(sy)\,d\rho(y) = \int F(ys)\,d\rho(y)$ for measurable $F \geq 0$, that is, $\delta_s * \rho = \rho * \delta_s$.

Conclusion. The floor group $G^{(j)}$ is a closed subgroup of G, being cut out by the closed conditions of fixing the coordinate vectors of floor below j. Apply Lemma 5.4.33 to the s-finite measures ρ and $\mu = \mathfrak{m}_j$ (so that $\theta = \rho * \mathfrak{m}_j$), the closed subgroup $S = G^{(j)}$, by which ρ is carried and under whose right translations it is invariant, and the element $s = w^{-1}$, with $\delta_s * \rho = \rho * \delta_s$: for the left $G^{(j)}$-invariant Φ it gives $\int \Phi(w^{-1}g)\,d\mathfrak{m}_j(g) = \int \Phi\,d\mathfrak{m}_j$. □

Lemma 5.4.16. *Let a place datum be given, $j \geq 0$, $d \in G$, let $\mathcal{K}$ be a pairing kernel at floor j for d, and let $x \in G$; write* $\mathrm{WSq}_l = \mathrm{WSq}_l(\mathcal{K}, x)$ *and* $\mathrm{WSS}_l = \mathrm{WSS}_l(\mathcal{K}, x)$.

(i) Let $l \geq 0$, $g, y \in G$, $V \in [0,\infty]$, and let $u, v\colon G \to [0,\infty]$ be measurable with $\mathrm{FML}_l(V; u)$ *and $|\mathcal{K}_{l+1}(\sigma g, \sigma y)|^2 \leq u(\sigma)\,v(\sigma)$ for every $\sigma \in G^{(l)}$. Then* $\mathrm{piv}_l(\mathcal{K})(g,y)^2 \leq V\int_G v\,d\theta_l$. *In particular, if* $\mathrm{FML}_l(V;1)$, *then* $\mathrm{piv}_l(\mathcal{K})(g,y)^2 \leq V\int_G |\mathcal{K}_{l+1}(\sigma g, \sigma y)|^2\,d\theta_l(\sigma)$.

(ii) For every $l \geq 0$, $(x', g) \mapsto \mathrm{WSS}_l(\mathcal{K}, x')(g)$ is measurable on $G \times G$.

(iii) Let $l \geq j$. Then $\mathrm{WSq}_l(sg) = \mathrm{WSq}_l(g)$ for $s \in R^{(l+1)}$, and $\mathrm{WSq}_l(g) = 0$ if g is not near at $l+1$; and $\mathrm{WSS}_l(sg) = \mathrm{WSS}_l(g)$ for $s \in R^{(l)}$, and $\mathrm{WSS}_l(g) = 0$ if g is not near at l.

(iv) For $l \leq \varrho$ and $g \in G$, $\displaystyle\int_G |\mathcal{K}_{l+1}(\sigma g, \sigma g x)|^2\,d\theta_l(\sigma) \leq \mathrm{WSS}_l(g)/\mathrm{dpw}_l(g,x)$.

(v) For $l, i \geq 0$ with $l + i \leq \varrho$ and $g \in G$, $\displaystyle\int_G \mathrm{WSq}_{l+i}(\sigma g)\,d(\theta_{l+i} * \theta_{l+i-1} * \cdots * \theta_l)(\sigma) \leq \mathrm{WSS}_l(g)$.

(vi) For $l \leq \varrho$, $\mathrm{WSI}_l(\mathcal{K}, x) = \displaystyle\int_G \mathrm{WSq}_l\,d(\theta_l * \cdots * \theta_0) + \mathrm{WSI}_{l+1}(\mathcal{K}, x)$; hence $\mathrm{WSI}_l(\mathcal{K}, x) \leq \mathrm{WSI}_0(\mathcal{K}, x)$ for $l \leq n$.

Proof. The floor measures are s-finite (images and convolutions of s-finite measures: Haar measures of second countable locally compact groups, μ_{top}, μ_H), so Tonelli's theorem applies to all iterated integrals below. $R^{(l)}$ is a closed subgroup of G, and the set of points near at l is $R^{(l)}K$, closed (Lemma 5.4.8, proof of (iii)). By Lemma 5.2.64 (i), every $\mathcal{K}_l$ is measurable on $G \times G$,

and by Lemma 5.2.64 (iv), $\mathcal{K}$ is a pairing kernel at floor l for every $l \geq j$. By the definition of WSq, $\mathrm{WSq}_l(\sigma g) = \mathrm{dpw}_l(\sigma g, x)|\mathcal{K}_{l+1}(\sigma g, \sigma g x)|^2$.

(i). By Lemma 5.2.59 (ii), θ_l is carried by $G^{(l)}$, so $\mathrm{piv}_l(\mathcal{K})(g,y) = \int f\, d\theta_l$ with $f(\sigma) = \mathbf{1}_{G^{(l)}}(\sigma)|\mathcal{K}_{l+1}(\sigma g, \sigma y)|$, a measurable function. By (PK5) at $l+1$, f vanishes off the closed set $N = \{\sigma : \sigma g \text{ near at } l+1\}$, and $f(\sigma)^2 \leq u(\sigma g)v(\sigma)$ for all σ. By the Cauchy–Schwarz inequality and $\mathrm{FML}_l(V;u)$,

$$\mathrm{piv}_l(\mathcal{K})(g,y)^2 = \Big(\int_N f\, d\theta_l\Big)^2 \leq \int_N u(\sigma g)\, d\theta_l(\sigma) \int_N v\, d\theta_l \leq V \int_G v\, d\theta_l.$$

The second assertion is the case $u = 1$, $v(\sigma) = |\mathcal{K}_{l+1}(\sigma g, \sigma y)|^2$.

(ii). $(x', g) \mapsto \mathrm{WSq}_l(\mathcal{K}, x')(g)$ is measurable, as dpw_l is measurable (Lemma 5.4.8 (iii)) and $\mathcal{K}_{l+1}$ is. $\mathrm{WSS}_l = 0$ for $l \geq n$, and for $l < n$ the recursion $\mathrm{WSS}_l(\mathcal{K}, x')(g) = \int(\mathrm{WSq}_l(\mathcal{K}, x') + \mathrm{WSS}_{l+1}(\mathcal{K}, x'))(\xi g)\, d\theta_l(\xi)$ preserves joint measurability by Tonelli's theorem; descending induction on l.

(iii), the weighted squares. Let $l \geq j$ and $s \in R^{(l+1)} \subseteq R^{(l)}$ (Lemma 5.2.58 (i)). By Lemma 5.2.58 (v), $s = \gamma\nu$ with $\gamma \in G^{(l)}$, $\nu \in N_{<l}$; as $N_{<l} \subseteq R^{(l+1)}$ (Lemma 5.2.58 (i)), $\gamma = s\nu^{-1} \in R^{(l+1)} \cap G^{(l)}$. By Lemma 5.4.8 (iii), $\mathrm{dpw}_l(sg, x) = \mathrm{dpw}_l(g, x)$. By Lemma 5.2.64 (v) at floor $l+1$ (as $\gamma \in R^{(l+1)} \cap G^{(j)}$, since $G^{(l)} \subseteq G^{(j)}$), $\mathcal{K}_{l+1}(\gamma\nu g, \gamma\nu g x) = \mathcal{K}_{l+1}(\nu g, \nu g x)$, and by (PK2) with $n = n' = \nu \in N_{<l}$ this has the modulus of $\mathcal{K}_{l+1}(g, gx)$, as ψ takes values on the unit circle. So $\mathrm{WSq}_l(sg) = \mathrm{WSq}_l(g)$. If $\mathcal{K}_{l+1}(g, gx) \neq 0$, then g is near at $l+1$ by (PK5).

(iii), the sums. Descending induction on $l \geq j$; for $l \geq n$, $\mathrm{WSS}_l = 0$. Let $j \leq l \leq \varrho$, and let $F = \mathrm{WSq}_l + \mathrm{WSS}_{l+1}$, which by the first part and the induction hypothesis is measurable, invariant under left multiplication by $R^{(l+1)}$ and zero at the points that are not near at $l+1$. For $g \in G$, $f(\xi) = F(\xi g)$ satisfies $f(t\xi) = f(\xi)$ for $t \in R^{(l+1)}$, so Lemma 5.2.61 (i) with $S = G$ gives, for $s \in R^{(l)}$,

$$\mathrm{WSS}_l(sg) = \int F(\xi s g)\, d\theta_l(\xi) = \int f(\xi s)\, d\theta_l(\xi) = \int f\, d\theta_l = \mathrm{WSS}_l(g).$$

If g is not near at l and $\xi \in G^{(l)}$, then ξg is not near at $l+1$: otherwise $t\xi g \in K$ with $t \in R^{(l+1)}$, and $t\xi \in R^{(l)}$ as $G^{(l)} \subseteq R^{(l)}$; so $F(\xi g) = 0$ for $\xi \in G^{(l)}$, and $\mathrm{WSS}_l(g) = 0$ because θ_l is carried by $G^{(l)}$.

(iv). By Lemma 5.4.8 (iii), $0 < \mathrm{dpw}_l(g,x) < \infty$ and $\mathrm{dpw}_l(\sigma g, x) = \mathrm{dpw}_l(g,x)$ for $\sigma \in G^{(l)} \subseteq R^{(l)}$. As θ_l is carried by $G^{(l)}$ and $l < n$,

$$\begin{aligned}\mathrm{dpw}_l(g,x) \int |\mathcal{K}_{l+1}(\sigma g, \sigma g x)|^2\, d\theta_l(\sigma) &= \int \mathrm{WSq}_l(\sigma g)\, d\theta_l(\sigma) \\ &\leq \int (\mathrm{WSq}_l + \mathrm{WSS}_{l+1})(\sigma g)\, d\theta_l(\sigma) = \mathrm{WSS}_l(g).\end{aligned}$$

(v). Induction on i. For $i = 0$ the integral is $\int \mathrm{WSq}_l(\sigma g)\, d\theta_l(\sigma) \leq \mathrm{WSS}_l(g)$, as in (iv). For $i+1$ (with $l+i+1 \leq \varrho$) write $\theta_{l+i+1} * \cdots * \theta_l = (\theta_{l+i+1} * \cdots * \theta_{l+1}) * \theta_l$; by Tonelli's theorem and the induction hypothesis at $l+1$,

$$\begin{aligned}\int \mathrm{WSq}_{l+i+1}(\sigma g)\, d(\theta_{l+i+1} * \cdots * \theta_l)(\sigma) &= \iint \mathrm{WSq}_{(l+1)+i}(\sigma'\tau g)\, d(\theta_{l+i+1} * \cdots * \theta_{l+1})(\sigma')\, d\theta_l(\tau) \\ &\leq \int \mathrm{WSS}_{l+1}(\tau g)\, d\theta_l(\tau) \leq \mathrm{WSS}_l(g).\end{aligned}$$

(vi). For $l \leq \varrho$, by the recursion of WSS_l ($l < n$) and the definition of convolution,

$$\mathrm{WSI}_l(\mathcal{K}, x) = \iint (\mathrm{WSq}_l + \mathrm{WSS}_{l+1})(\xi g)\, d\theta_l(\xi)\, d(\theta_{l-1} * \cdots * \theta_0)(g) = \int (\mathrm{WSq}_l + \mathrm{WSS}_{l+1})\, d(\theta_l * \cdots * \theta_0),$$

which is the asserted sum, as $\int \mathrm{WSS}_{l+1}\, d(\theta_l * \cdots * \theta_0) = \mathrm{WSI}_{l+1}(\mathcal{K}, x)$. In particular $\mathrm{WSI}_{l+1} \le \mathrm{WSI}_l$ for $l \le \varrho$, and $\mathrm{WSI}_l \le \mathrm{WSI}_0$ for $l \le n$ by induction. $\square$

Lemma 5.4.17. *Let Γ be a gauge of loss Λ for a place datum, $x \in \mathcal{P}_{\mathrm{pos}}$, $j \ge 0$, $d \in G$, and let $\mathcal{K}$ be a pairing kernel at floor j for d. Let $l \ge 0$, $g \in G$ and $\varepsilon_1 \in [0, \infty]$, and suppose that for every $\sigma \in G^{(l)}$ with $\mathcal{K}(\sigma g, \sigma g x) \ne 0$ there is a with $l \le a < \varrho$ and $\mathrm{dp}_a(\sigma g, x) \ge \varepsilon_1^{-1}$. Then, with arithmetic in $[0, \infty]$,*

$$\mathrm{piv}_l(\mathcal{K})(g, gx)^2 \le \varepsilon_1^s\, c_{\mathrm{fls}}\, \frac{\mathrm{WSS}_l(\mathcal{K}, x)(g)}{\mathrm{dpw}_l(g, x)}.$$

Proof. Write $\Theta_{[l,i)} = \theta_{l+i-1} * \cdots * \theta_l$ ($\Theta_{[l,0)} = \delta_1$), $\mathrm{WSS}_l = \mathrm{WSS}_l(\mathcal{K}, x)$, $\mathrm{WSq}_a = \mathrm{WSq}_a(\mathcal{K}, x)$, and for $a < \varrho$, $D \in [0, \infty]$ and $y \in G$ let

$$\mathrm{DM}_{a,D}(y) = \mathbf{1}\{\mathrm{dp}_a(y, x) \ge D\}\, |\mathcal{K}_{a+1}(y, yx)|,$$

a measurable function (Lemma 5.4.8 (i), Lemma 5.2.64 (i)). The measures are s-finite and Tonelli's theorem is used freely.

Step 1: the cut. Let $D \in [0, \infty]$. We show, by descending induction on l, for all g: if for every $\sigma \in G^{(l)}$ with $\mathcal{K}(\sigma g, \sigma g x) \ne 0$ some a with $l \le a < \varrho$ has $\mathrm{dp}_a(\sigma g, x) \ge D$, then

$$\mathrm{piv}_l(\mathcal{K})(g, gx) \le \sum_{l \le a < \varrho} \int_G \mathrm{DM}_{a,D}(\sigma g)\, d\Theta_{[l,a-l+1)}(\sigma). \tag{5.79}$$

If $l \ge \varrho$, no a exists, so $\mathcal{K}(\sigma g, \sigma g x) = 0$ for all $\sigma \in G^{(l)}$, and $\mathrm{piv}_l(\mathcal{K})(g, gx) = 0$ by Lemma 5.2.64 (iii). Let $l < \varrho$. As θ_l is carried by $G^{(l)}$ (Lemma 5.2.59 (ii)), it suffices to bound $|\mathcal{K}_{l+1}(\sigma g, \sigma g x)|$ for $\sigma \in G^{(l)}$ by the sum over $l \le a < \varrho$ of $\mathrm{DM}_{l,D}(\sigma g)$ for $a = l$ and of $\int \mathrm{DM}_{a,D}(\tau \sigma g)\, d\Theta_{[l+1,a-l)}(\tau)$ for $a > l$: integrating over σ against θ_l then gives (5.79), since $\Theta_{[l,a-l+1)} = \Theta_{[l+1,a-l)} * \theta_l$. If $\mathrm{dp}_l(\sigma g, x) \ge D$, then $|\mathcal{K}_{l+1}(\sigma g, \sigma g x)| = \mathrm{DM}_{l,D}(\sigma g)$. Otherwise, let $\tau \in G^{(l+1)}$ with $\mathcal{K}(\tau \sigma g, \tau \sigma g x) \ne 0$. Since $\tau \sigma \in G^{(l)}$, some $a \ge l$ has $\mathrm{dp}_a(\tau \sigma g, x) \ge D$; and $\mathrm{dp}_l(\tau \sigma g, x) = \mathrm{dp}_l(\sigma g, x) < D$ by Lemma 5.4.8 (ii), as $\tau \in G^{(l+1)} \subseteq R^{(l+1)}$ (Lemma 5.2.58 (i)); so $a \ge l + 1$. The induction hypothesis at $l + 1$ and the point σg, with Lemma 5.2.64 (ii), gives

$$|\mathcal{K}_{l+1}(\sigma g, \sigma g x)| \le \mathrm{piv}_{l+1}(\mathcal{K})(\sigma g, \sigma g x) \le \sum_{l+1 \le a < \varrho} \int \mathrm{DM}_{a,D}(\tau \sigma g)\, d\Theta_{[l+1,a-l)}(\tau).$$

Step 2: one piece. Let $l \le a < \varrho$, write $a = l + i$, and let $D = \varepsilon_1^{-1}$. We show

$$\Big(\int \mathrm{DM}_{a,D}(\sigma g)\, d\Theta_{[l,i+1)}(\sigma) \Big)^2 \le \varepsilon_1^s (\Lambda^{10^4 n})^{\varrho}\, \frac{\mathrm{WSS}_l(g)}{\mathrm{dpw}_l(g, x)}. \tag{5.80}$$

First, for every y: $\mathrm{DM}_{a,D}(y)^2 \le \varepsilon_1^s\, \mathrm{dpw}^-_{a+1,x}(y)\, \mathrm{WSq}_a(y)$. Indeed, if $\mathrm{DM}_{a,D}(y) \ne 0$, then $\mathcal{K}_{a+1}(y, yx) \ne 0$, so y is near at $a + 1$ by (PK5) and $\mathrm{dpw}^-_{a+1,x}(y) = \mathrm{dpw}_{a+1}(y, x)^{-1}$; and $\mathrm{dp}_a(y, x) \ge \varepsilon_1^{-1}$ with $0 < \mathrm{dp}_a(y, x) < \infty$ (Lemma 5.4.8 (i)) gives $1 \le \varepsilon_1 \mathrm{dp}_a(y, x)$. Since $\mathrm{dpw}_{a+1} = \mathrm{dpw}_a \cdot \mathrm{dp}_a^{-s}$ (Lemma 5.4.8 (iii)),

$$\begin{aligned} \mathrm{DM}_{a,D}(y)^2 &\le (\varepsilon_1 \mathrm{dp}_a(y, x))^s |\mathcal{K}_{a+1}(y, yx)|^2 = \varepsilon_1^s\, \mathrm{dpw}_{a+1}(y, x)^{-1}\, \mathrm{dpw}_a(y, x)\, |\mathcal{K}_{a+1}(y, yx)|^2 \\ &= \varepsilon_1^s\, \mathrm{dpw}^-_{a+1,x}(y)\, \mathrm{WSq}_a(y). \end{aligned}$$

By the Cauchy–Schwarz inequality the left side of (5.80) is at most $\varepsilon_1^s \int \mathrm{dpw}^-_{a+1,x}(\sigma g)\, d\Theta_{[l,i+1)}(\sigma) \cdot \int \mathrm{WSq}_a(\sigma g)\, d\Theta_{[l,i+1)}(\sigma)$. By Lemma 5.4.18 (ii) (as $l + i + 1 = a + 1 \le \varrho$), the first integral is at most $(\Lambda^{10^4 n})^{i+1} \mathrm{dpw}^-_{l,x}(g) \le (\Lambda^{10^4 n})^{\varrho} \mathrm{dpw}_l(g, x)^{-1}$, using $i + 1 \le \varrho$, $\Lambda \ge 2$, and $\mathrm{dpw}^-_{l,x}(g) \le \mathrm{dpw}_l(g, x)^{-1}$. By Lemma 5.4.16 (v) (as $l + i \le \varrho$), the second is at most $\mathrm{WSS}_l(g)$.

Step 3: conclusion. Let B be the right side of (5.80). By the hypothesis, Step 1 with $D = \varepsilon_1^{-1}$ applies, and with Step 2, $\mathrm{piv}_l(\mathcal{K})(g,gx) \le \varrho B^{1/2}$. As $\varrho \le 2^\varrho \le \Lambda^\varrho$ and $2\varrho + 10^4 n\varrho \le 10^6 n^3$,

$$\mathrm{piv}_l(\mathcal{K})(g,gx)^2 \le \Lambda^{2\varrho} B = \varepsilon_1^s \Lambda^{2\varrho+10^4 n\varrho} \frac{\mathrm{WSS}_l(g)}{\mathrm{dpw}_l(g,x)} \le \varepsilon_1^s c_{\mathrm{fls}} \frac{\mathrm{WSS}_l(g)}{\mathrm{dpw}_l(g,x)}.$$

□

Lemma 5.4.18. *Let Γ be a gauge of loss Λ for a place datum and $x \in \mathcal{P}_{\mathrm{pos}}$.*

(i) For $a < \varrho$ and $g \in G$, $\int_G \mathrm{dpw}^-_{a+1,x}(\sigma g)\, d\theta_a(\sigma) \le \Lambda^{10^4 n}\, \mathrm{dpw}^-_{a,x}(g)$.

(ii) For $l, i \ge 0$ with $l + i \le \varrho$ and $g \in G$, with the descending convolution $\theta_{[l,i)}$ of (5.11) in Definition 5.2.1,

$$\int_G \mathrm{dpw}^-_{l+i,x}(\sigma g)\, d\theta_{[l,i)}(\sigma) \le \left(\Lambda^{10^4 n}\right)^i \mathrm{dpw}^-_{l,x}(g).$$

Proof. **(i).** The measure θ_a is carried by $G^{(a)}$ (Lemma 5.2.59, (ii)). Let $\sigma \in G^{(a)}$. If σg is not near at $a+1$, then $\mathrm{dpw}^-_{a+1,x}(\sigma g) = 0$. If $\xi\sigma g \in K$ with $\xi \in R^{(a+1)}$, then $\xi\sigma \in R^{(a)}$ (Lemma 5.2.58, (i): $R^{(a+1)} \subseteq R^{(a)}$ and $G^{(a)} \subseteq R^{(a)}$), so g is near at a; and by Lemma 5.4.8, (iii), $\mathrm{dpw}_{a+1} = \mathrm{dpw}_a \cdot (\mathrm{dp}_a^{-1})^s$ and $\mathrm{dpw}_a(\sigma g, x) = \mathrm{dpw}_a(g,x)$ (left invariance under $R^{(a)}$), all values in $(0,\infty)$. Hence

$$\mathrm{dpw}^-_{a+1,x}(\sigma g) = \mathbf{1}\{\sigma g \text{ near at } a+1\}\, \mathrm{dp}_a(\sigma g, x)^s\, \mathrm{dpw}^-_{a,x}(g) \qquad (\sigma \in G^{(a)}),$$

and by Lemma 5.4.19 (the floor-mass bound $\mathrm{FML}_a(\Lambda^{10^4 n}; g' \mapsto \mathrm{dp}_a(g',x)^s)$ at the point g), $\int \mathrm{dpw}^-_{a+1,x}(\sigma g)\, d\theta_a(\sigma) \le \Lambda^{10^4 n}\, \mathrm{dpw}^-_{a,x}(g)$.

(ii). Induction on i, for all l and g. For $i = 0$ both sides are $\mathrm{dpw}^-_{l,x}(g)$. Let $l + i + 1 \le \varrho$ and put $C = \Lambda^{10^4 n}$. As $\theta_{[l,i+1)} = \theta_{[l+1,i)} * \theta_l$, Tonelli, the induction hypothesis at $(l+1, i)$ and the point τg, and (i) with $a = l < \varrho$ give

$$\begin{aligned}\int \mathrm{dpw}^-_{l+i+1,x}(\sigma g)\, d\theta_{[l,i+1)}(\sigma) &= \iint \mathrm{dpw}^-_{(l+1)+i,x}(\sigma\tau g)\, d\theta_{[l+1,i)}(\sigma)\, d\theta_l(\tau) \\ &\le C^i \int \mathrm{dpw}^-_{l+1,x}(\tau g)\, d\theta_l(\tau) \le C^{i+1}\, \mathrm{dpw}^-_{l,x}(g).\end{aligned}$$

□

Lemma 5.4.19. *Let Γ be a gauge of loss Λ for a place datum, let $x \in \mathcal{P}_{\mathrm{pos}}$ and $0 \le a < \varrho$. Then*

$$\mathrm{FML}_a(\Lambda^{10^4 n};\ g \mapsto \mathrm{dp}_a(g,x)^s).$$

Proof. Put $f(g) = \mathrm{dp}_a(g,x)^s$. By Lemma 5.4.8, (i) and (ii), f is measurable and $f(\xi g) = f(g)$ for $\xi \in R^{(a+1)}$. We apply the chart criterion Lemma 5.2.60, (ii), with $b = a$ and its compact set $C_a = \{P_a(\kappa\kappa'^{-1} f_a) : \kappa, \kappa' \in K\}$.

Fix $g \in K$. By (GU7) with $y = x$ and $Q = 0$ there is a common bound ϕ for $\mathcal{V}_{\mathrm{cm}}(g,x,0)$ with loss Λ; it is measurable, and $\int_{\{\varsigma \text{ of size } 11\}} \phi^s \le \Lambda^{99n\cdot 12}$. Put $\Psi_g(v) = \phi\big((h(o_i, v))_{i\in\iota'}\big)^s$ for $v \in V$, a Borel function. For $\sigma \in G^{(a)}$ and $\omega \in A^{\iota'}$, the vector $O\omega$ lies in the middle space, so $h(e_b, \sigma O\omega) = h(\sigma^{-1} e_b, O\omega) = h(e_b, O\omega) = 0$ for $b < a$; by Lemma 5.4.9, $f(\sigma g) \le \Psi_g(\sigma^{-1} f_a)$.

It remains to bound $\int_{C_a} \Psi_g \, d\mathrm{qv}_a$. Elements of K have size 1 (GU2), their inverses size 5 (the inverse of an element of G of size i, $J^{-1}\bar{g}^{\mathsf{T}}J$, has size $i+4$ by (SZ1)–(SZ3), (SZ5)), and $\kappa\kappa'^{-1}$ has size 7; the projection P_a only replaces coordinates by 0 (SZ4). So C_a lies in the set of vectors of size 7, and by Lemma 5.4.4, (iv), with $\rho = \mathrm{qv}_a$ and $j = 7$,

$$\int_{C_a} \Psi_g \, d\mathrm{qv}_a \le \Lambda^{99n\cdot 13} \int_{A'_{(11)}} \phi^s \, d\mathrm{vol} \le \Lambda^{99n\cdot 13}\Lambda^{99n\cdot 12} = \Lambda^{2475n} \le \Lambda^{10^4 n},$$

as $\Lambda \ge 1$. The criterion gives the claim. □

Lemma 5.4.20. *Let a place datum be given, let $W\colon G \to \mathbb{C}^I$, and for a measure μ on G and $\gamma \in G$ let $\mathrm{Orb}_\mu(\gamma) \in \mathbb{C}^{I\times I}$ be the Bessel orbital integral of W,* (5.13) *of Definition 5.2.4, with the inner product of $\mathbb{C}^{I\times I}$ fixed there.*

(i) If W is a Bessel function of frequency η over the place and μ is left invariant, then $\mathrm{Orb}_\mu(u^{-1}\gamma u') = \overline{\psi(\eta\,\sigma(u))}\,\psi(\eta\,\sigma(u'))\,\mathrm{Orb}_\mu(\gamma)$ for all $u, u' \in \mathsf{U}$ and $\gamma \in G$.

Let now Γ be a gauge for the place datum, with size filtration $(A_{(i)})$, and let W be cut.

(ii) If $\mathrm{Orb}_\mu(\gamma) \ne 0$, then every leading principal minor of the frame Gram matrix $Z(\gamma)$, (5.3) *of Definition 5.1.7, lies in $A_{(9n)}$.*

(iii) If p is a head of length ϱ, $x \in G^{(\varrho)}$ and $y \in G$ satisfies $W(y) \ne 0$ and $W((w_{\varrho,p}x)^{-1}y) \ne 0$, then y has size $60n^2$.

(iv) If μ is a Haar measure of G, W is continuous, p, q are heads of length ϱ and $x \in G^{(\varrho)}$, then

$$\begin{aligned}&\langle \mathrm{Orb}_\mu(w_{\varrho,p}x), \mathrm{Orb}_\mu(w_{\varrho,q}x)\rangle\\ &\quad= \int_{G\times G} \langle W(y), W(y')\rangle\,\overline{\langle W((w_{\varrho,p}x)^{-1}y), W((w_{\varrho,q}x)^{-1}y')\rangle}\, d(\mu\otimes\mu)(y,y').\end{aligned}$$

Proof. **(i).** Put $\chi(v) = \psi(\eta\,\sigma(v))$ for $v \in \mathsf{U}$, a number of modulus 1. For $v \in \mathsf{U}$ and $y \in G$, $W(y) = W(v\cdot v^{-1}y) = \chi(v)W(v^{-1}y)$, so $W(v^{-1}y) = \overline{\chi(v)}\,W(y)$. As μ is left invariant, the map $y \mapsto u^{-1}y$ preserves μ, so it preserves integrability and Bochner integrals; with $(u^{-1}\gamma u')^{-1}u^{-1}y = u'^{-1}(\gamma^{-1}y)$,

$$\mathrm{Orb}_\mu(u^{-1}\gamma u')_{ii'} = \int W(u^{-1}y)_i\,\overline{W(u'^{-1}\gamma^{-1}y)_{i'}}\,d\mu(y) = \overline{\chi(u)}\,\chi(u')\int W(y)_i\,\overline{W(\gamma^{-1}y)_{i'}}\,d\mu(y),$$

where the integrand on the right is integrable exactly when the one on the left is (they differ by a constant of modulus 1), so the identity also holds when both entries are 0 by convention.

Near points of a cut function. If W is cut and $W(y) \ne 0$, then $uy \in K$ for some $u \in \mathsf{U}$, and $\mathsf{U} \subseteq R^{(l)}$ for every l (Lemma 5.2.58, (i)); so y is near at every l.

(ii). Some entry of $\mathrm{Orb}_\mu(\gamma)$ is a nonzero integral, so its integrand does not vanish identically: there is y with $W(y) \ne 0$ and $W(\gamma^{-1}y) \ne 0$. Then y and $\gamma^{-1}y$ are near at n, and Lemma 5.4.13, (ii), with $l = n$ gives $D_i(\gamma) \in A_{(9n)}$ for $i \le n$, where $D_i(\gamma)$ is the leading principal minor of order i of $(h(f_a, \gamma f_b))_{a,b}$.

(iii). Let $u \in \mathsf{U}$ with $uy \in K$. Since $W((w_{\varrho,p}x)^{-1}y) \ne 0$, the point $x^{-1}w_{\varrho,p}^{-1}y$ is near at ϱ: $\zeta x^{-1}w_{\varrho,p}^{-1}y \in K$ for some $\zeta \in R^{(\varrho)}$; as $x^{-1} \in G^{(\varrho)} \subseteq R^{(\varrho)}$ (Lemma 5.2.58, (i)), $w_{\varrho,p}^{-1}y$ is near at ϱ. For $l = \varrho$ the modified level lev_ϱ agrees with the level (the indices of floor at least ϱ are z and

the x_i, of level ϱ), so $N_{<\varrho} = \mathsf{U}$ and $u \in R^{(\varrho)} \cap N_{<\varrho}$. By Lemma 5.4.12, (ii), with $j = \varrho$, $s = u$ and $g = y$, y has size $60n^2$.

(iv). For a head r of length ϱ and $(i, i') \in I \times I$ put $F_{r,ii'}(y) = W(y)_i \overline{W((w_{\varrho,r}x)^{-1}y)_{i'}}$, so that $\mathrm{Orb}_\mu(w_{\varrho,r}x)_{ii'} = \int F_{r,ii'}\, d\mu$. The function $F_{r,ii'}$ is continuous, and by (iii) it vanishes off the set C of elements of G of size $60n^2$. As $A_{(60n^2)}$ is compact (GU1) and G is closed in the space of matrices, C is compact; a Haar measure is finite on compact sets, so $F_{r,ii'}$ is μ-integrable. The group G is second countable and μ is σ-finite, so by Fubini

$$\overline{\int F_{p,ii'}\, d\mu} \int F_{q,ii'}\, d\mu = \int_{G\times G} \overline{F_{p,ii'}(y)}\, F_{q,ii'}(y')\, d(\mu\otimes\mu)(y,y').$$

Summing over $(i, i') \in I \times I$, the left side becomes $\langle \mathrm{Orb}_\mu(w_{\varrho,p}x), \mathrm{Orb}_\mu(w_{\varrho,q}x)\rangle$, and the integrand on the right becomes

$$\begin{aligned}\sum_{i,i'} &\overline{W(y)_i}\, W(y')_i\; W((w_{\varrho,p}x)^{-1}y)_{i'}\, \overline{W((w_{\varrho,q}x)^{-1}y')_{i'}} \\ &= \langle W(y), W(y')\rangle\, \overline{\langle W((w_{\varrho,p}x)^{-1}y), W((w_{\varrho,q}x)^{-1}y')\rangle},\end{aligned}$$

which is the claim. □

Proposition 5.4.21. *Let Γ be a gauge of loss Λ for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $W\colon G \to \mathbb{C}^I$ be cut, $j \le \varrho$, p, q heads of length j for Γ, $V \ge 1$ with $\mathrm{FML}_j(V;1)$, and $(S_i)_{i\ge 0}$ shells of heights 2^i for (Γ, j, p, q, W) covering the support of $\phi\colon G \to [0,\infty]$, with $\phi \le \mathrm{FM}_j(p,q,W,\cdot)$. Let $e \in [0,\infty]$ with $\phi(x)^2 \le (Ve^s)^2\, \mathrm{WSP}_j(p,q,W,x)$ for $x \in \mathcal{P}_{\mathrm{pos}}$ when $e < 1$ (WSP_j formed for Γ), and let $t \ge 0$ be an integer with $9\cdot 10^7 n^4 + t \le s$. Then, $\int \phi\, d\theta$ being the lower integral if ϕ is not measurable,*

$$\mathrm{hdn}_j(p,q) \int_G \phi\, d\theta \le V \min(1,e)^t\, \Lambda^{4\cdot 10^8 n^4}\, \mathrm{SN}(W).$$

Proof. Arithmetic is in $[0,\infty]$. Put $e' = \min(1,e) \in [0,1]$ and $B = Ve'^t \Lambda^{3\cdot 10^8 n^4} \mathrm{SN}(W)$. Every S_i lies in $\mathcal{P}_{\mathrm{pos}}$, by (SH2).

One shell. Let $i \ge 0$ and $x \in S_i$. If $e < 1$, then $e' = e$ and $\phi(x)^2 \le (Ve'^s)^2 \mathrm{WSP}_j(p,q,W,x)$ by hypothesis. If $e \ge 1$, then $e' = 1$ and $\phi(x)^2 \le \mathrm{FM}_j(p,q,W,x)^2 \le V^2 \mathrm{WSP}_j(p,q,W,x)$ by Proposition 5.4.5 (i). So Lemma 5.4.22 applies to S_i (height $\Delta = 2^i$), e', t and ϕ, and gives a measurable $M_i\colon G \to [0,\infty]$ with $\phi \le M_i$ on S_i and $\mathrm{hdn}_j(p,q) \int M_i\, d\theta \le 2^{-i}B$.

The sum. $M = \sum_{i\ge 0} M_i$ is measurable, and $\phi \le M$ on G: off $\bigcup_i S_i$, $\phi = 0$; on S_i, $\phi \le M_i \le M$. By monotone convergence,

$$\mathrm{hdn}_j(p,q) \int_G \phi\, d\theta \le \mathrm{hdn}_j(p,q) \int_G M\, d\theta = \sum_{i\ge 0} \mathrm{hdn}_j(p,q) \int_G M_i\, d\theta \le \sum_{i\ge 0} 2^{-i} B = 2B \le \Lambda^{10^8 n^4} B,$$

as $\Lambda \ge 2$ (GU1). This is $V \min(1,e)^t \Lambda^{4\cdot 10^8 n^4} \mathrm{SN}(W)$. □

Lemma 5.4.22. *Let Γ be a gauge of loss Λ for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $W\colon G \to \mathbb{C}^I$ be cut, $j \le \varrho$, p, q heads of length j for Γ, S a shell of height Δ for (Γ, j, p, q, W), $V \ge 1$ with $\mathrm{FML}_j(V;1)$, $e \in [0,1]$, and $t \ge 0$ an integer with $9\cdot 10^7 n^4 + t \le s$. Let $f\colon G \to [0,\infty]$ with $f(x) \le \mathrm{FM}_j(p,q,W,x)$ and $f(x)^2 \le (Ve^s)^2\, \mathrm{WSP}_j(p,q,W,x)$ for every $x \in S$ (WSP_j formed for Γ). Then there is a measurable $M\colon G \to [0,\infty]$ with $f \le M$ on S and*

$$\mathrm{hdn}_j(p,q) \int_G M\, d\theta \le \Delta^{-1}\, V\, e^t\, \Lambda^{3\cdot 10^8 n^4}\, \mathrm{SN}(W).$$

Proof. Arithmetic is in $[0,\infty]$; put $N = 9\cdot 10^7 n^4$ and $c = \Lambda^{2\cdot 10^6 n^3}$. By (SH1), $1 \le \Delta < \infty$. For $g \in [0,1]$, $g^s \le g^N g^t$, as $s \ge N + t$. Note $2\cdot 10^6 n^3 + 29\cdot 10^7 n^4 \le 3\cdot 10^8 n^4$, so it suffices to find M with $f \le M$ on S and $\mathrm{hdn}_j(p,q)\int M\,d\theta \le \Delta^{-1} V e^t\, c\,\Lambda^{29\cdot 10^7 n^4}\mathrm{SN}(W)$.

Case $\Delta \le \Lambda^{2400n^2}$. By Lemma 5.4.23 with the gain Ve^s there is M with $f \le M$ on S and $\mathrm{hdn}_j(p,q)\int M \le Ve^s c\,\Delta^{10^5 n^2}\mathrm{SN}(W)$. Here $e^s \le e^t$ and $\Delta^{10^5 n^2} = \Delta^{-1}\Delta^{1+10^5 n^2} \le \Delta^{-1}\Lambda^{2400n^2(1+10^5 n^2)} \le \Delta^{-1}\Lambda^{29\cdot 10^7 n^4}$.

Case $\Delta > \Lambda^{2400n^2}$. Let $\tau \in (0,1)$ with $\tau^{800n^2} = \Delta^{-1}$ (as $\Delta > 1$). Since $800n^2\cdot 112500n^2 = N$, $1 + 10^5 n^2 \le 112500 n^2$ and $\Delta \ge 1$,

$$\tau^N \Delta^{1+10^5 n^2} \le \left(\tau^{800n^2}\Delta\right)^{112500n^2} = 1. \tag{5.81}$$

If $e \le \tau$: Lemma 5.4.23 with the gain Ve^s gives M with $f \le M$ on S and $\mathrm{hdn}_j(p,q)\int M \le Ve^t e^N c\,\Delta^{10^5 n^2}\mathrm{SN}(W) \le \Delta^{-1} Ve^t c\,\tau^N \Delta^{1+10^5 n^2}\mathrm{SN}(W) \le \Delta^{-1} Ve^t c\,\mathrm{SN}(W)$, by (5.81).

If $\tau < e$: let $x \in S$. Since $\Lambda^{2400n^2} < \Delta = \tau^{800n^2}\Delta^2$, we have $\Lambda^{1200n^2} \le \tau^{400n^2}\Delta$, and $\tau < 1$; so by (SH3) with $\varepsilon = \tau$, (j,p,q,W) has a deep vector after the head of depth at least $(\tau^2)^{-1}$ at x. By (SH2), x is a position of size some gauge, so $x \in \mathcal{P}_{\mathrm{pos}}$. By Proposition 5.4.5 (ii) with $\sigma = \tau^2$, $\mathrm{FM}_j(p,q,W,x)^2 \le \tau^{2s} V^2 \mathrm{WSP}_j(p,q,W,x) = (V\tau^s)^2 \mathrm{WSP}_j(p,q,W,x)$. Lemma 5.4.23 for the function $\mathrm{FM}_j(p,q,W,\cdot)$ with the gain $V\tau^s$ gives M with $\mathrm{FM}_j(p,q,W,\cdot) \le M$ on S, hence $f \le M$ on S, and, as $\tau^s \le \tau^N\tau^t \le \tau^N e^t$, $\mathrm{hdn}_j(p,q)\int M \le V\tau^N e^t c\,\Delta^{10^5 n^2}\mathrm{SN}(W) \le \Delta^{-1} Ve^t c\,\mathrm{SN}(W)$, by (5.81). □

Lemma 5.4.23. *Let Γ be a gauge of loss Λ for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $W\colon G \to \mathbb{C}^I$ be cut, $j \le \varrho$, p a sequence of units, q a head of length j for Γ, and S a shell of height Δ for (Γ, j, p, q, W). Let $e \in [0,\infty]$ and $f\colon G \to [0,\infty]$ with $f(x)^2 \le e^2\,\mathrm{WSP}_j(p,q,W,x)$ for every $x \in S$ (WSP_j formed for Γ). Then there is a measurable $M\colon G \to [0,\infty]$ with $f \le M$ on S and*

$$\mathrm{hdn}_j(p,q)\int_G M\,d\theta \le e\,\Lambda^{2\cdot 10^6 n^3}\,\Delta^{10^5 n^2}\,\mathrm{SN}(W);$$

in particular the lower integral of $f\mathbf{1}_S$ satisfies the same bound.

Proof. Arithmetic is in $[0,\infty]$. By (SH1), $1 \le \Delta < \infty$; by (SH2) there is a finite set $\mathcal{G}$ of gauges for the place datum with $\#\mathcal{G} \le 2\Delta^{9n}$, such that every $x \in S$ is a position of size Γ' for some $\Gamma' \in \mathcal{G}$, and the loss Λ' of every $\Gamma' \in \mathcal{G}$ satisfies $\Lambda' \le \Lambda\Delta^2$. Put $u = (e^2\,\mathrm{WSP}_j(p,q,W,\cdot))^{1/2}$, a measurable function (its factors WSI_0, WSI_j are measurable by Lemma 5.4.16 (ii) and Tonelli's theorem), and let $P_{\Gamma'}$ be the (measurable) set of positions of size Γ'. Put

$$M = \sum_{\Gamma' \in \mathcal{G}} u\,\mathbf{1}_{P_{\Gamma'}},$$

a measurable function with $f \le u \le M$ on S. For $\Gamma' \in \mathcal{G}$, Proposition 5.4.24 for the gauges Γ, Γ', the set $P_{\Gamma'}$ and the function u (for which $u^2 = e^2\mathrm{WSP}_j$) gives

$$\mathrm{hdn}_j(p,q)\int_{P_{\Gamma'}} u\,d\theta \le e\,\Lambda^{1500000n^3+1}\Lambda'^{25000n^2}\mathrm{SN}(W) \le e\,\Lambda^{1500000n^3+25000n^2+1}\Delta^{50000n^2}\mathrm{SN}(W).$$

Summing over $\mathcal{G}$ and using $2 \le \Lambda$ (GU1) and $\Delta \ge 1$,

$$\mathrm{hdn}_j(p,q)\int_G M\,d\theta \le 2\Delta^{9n}\,e\,\Lambda^{1500000n^3+25000n^2+1}\Delta^{50000n^2}\mathrm{SN}(W) \le e\,\Lambda^{2\cdot 10^6 n^3}\Delta^{10^5 n^2}\mathrm{SN}(W),$$

since $1500000n^3 + 25000n^2 + 2 \le 2\cdot 10^6 n^3$ and $9n + 50000n^2 \le 10^5 n^2$. The lower integral of $f\mathbf{1}_S$ is at most $\int M\,d\theta$, as $f\mathbf{1}_S \le M$ and M is measurable. □

Proposition 5.4.24. *Let Γ and Γ' be gauges of losses Λ and Λ' for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $W\colon G \to \mathbb{C}^I$ be cut, $j \le \varrho$, p a sequence of units and q a head of length j for Γ; let S be a set of positions of size Γ', $e \in [0,\infty]$, and $f\colon G \to [0,\infty]$ with $f(x)^2 \le e^2\,\mathrm{WSP}_j(p,q,W,x)$ for every $x \in S$, where WSP_j is formed for Γ. Then, with $\int_S f\,d\theta$ the lower integral of $f\mathbf{1}_S$,*

$$\mathrm{hdn}_j(p,q)\int_S f\,d\theta \le e\,\Lambda^{1500000n^3+1}\,\Lambda'^{25000n^2}\,\mathrm{SN}(W).$$

Proof. Arithmetic is in $[0,\infty]$ with $0\cdot\infty = 0$. Put $d = w_{j,q}^{-1}w_{j,p}$, $D = \big(\prod_{a<j}\mathrm{fm}(a,p_a^{-1})\big)^2$, $J = \prod_{a<j}|p_aq_a^{-1}|^{k+2(\varrho-a)}$, $V = \prod_{l<\varrho}c'_{\mathrm{fl}}(l)$ with $c'_{\mathrm{fl}}(l) = \mathrm{fm}(l)\mathrm{kb}_A^{|\iota'|}\Lambda'^{4900n}$ the floor constant of Γ', $N_1(x) = \mathrm{WSI}_0(\mathcal{K}_W,x)$, $N_2(x) = \mathrm{WSI}_j(\mathcal{K}_W^d,x)$, and let P' be the set of positions of size Γ'; so $\mathrm{WSP}_j(p,q,W,x) = D\,c_{\mathrm{fls}}^3N_1(x)N_2(x)$, with $c_{\mathrm{fls}} = \Lambda^{10^6n^3}$.

The head density. For $a < j \le \varrho$, $d_a = k + 2(\varrho-a) - 1$, and all moduli of units lie in $(0,\infty)$. So the a-th factor of $\mathrm{hdn}_j(p,q)^2DJ$ is

$$|p_aq_a|^{d_a}\,|p_a|^{-2d_a-1}\,|p_aq_a^{-1}|^{d_a+1} = |q_a|^{-1},$$

and $\mathrm{hdn}_j(p,q)^2DJ = |(q_0\cdots q_{j-1})^{-1}| \le \Lambda$ by (GU5), as q is a head for Γ, i.e. $(q_0\cdots q_{j-1})^{-1} \in A_{(1)}$.

Cauchy–Schwarz. By Lemma 5.2.57 (ii), $\mathcal{K}_W$ is a pairing kernel at floor 0 for 1 and $\mathcal{K}_W^d$ one at floor j for d; N_1, N_2 are measurable (Lemma 5.4.16 (ii) and Tonelli's theorem). Put $u = (e^2Dc_{\mathrm{fls}}^3N_1N_2)^{1/2}$, a measurable function with $f\mathbf{1}_S \le u\mathbf{1}_{P'}$. Hence, by the Cauchy–Schwarz inequality,

$$\Big(\int_S f\,d\theta\Big)^2 \le \Big(\int_{P'} u\,d\theta\Big)^2 \le e^2Dc_{\mathrm{fls}}^3\int_{P'}N_1\,d\theta\int_{P'}N_2\,d\theta.$$

One frame each. By Proposition 5.4.25 for the gauge Γ', with

$$\int\int|\mathcal{K}_W(g,y)|^2\,d\theta_{\ge0}(y)\,d\theta_{\ge0}(g) = \mathrm{PN}(W),$$

$\int_{P'}N_1\,d\theta \le nV\,\mathrm{PN}(W)$. For the second frame, Lemma 5.4.15 (i) applied for fixed g to $\Phi(y) = |\langle W(g),W(y)\rangle|^2$ (measurable) gives

$$\int|\langle W(g),W(dy)\rangle|^2\,d\theta_{\ge0}(y) = J\int|\langle W(g),W(y)\rangle|^2\,d\theta_{\ge0}(y);$$

integrating over g, the L^2 norm of $\mathcal{K}_W^d$ is $J\,\mathrm{PN}(W)$, and Proposition 5.4.25 gives $\int_{P'}N_2\,d\theta \le nVJ\,\mathrm{PN}(W)$.

Collecting constants. Combining,

$$\mathrm{hdn}_j(p,q)^2\Big(\int_S f\,d\theta\Big)^2 \le \big(\mathrm{hdn}_j(p,q)^2DJ\big)\,e^2c_{\mathrm{fls}}^3\,(nV)^2\,\mathrm{PN}(W)^2 \le \Lambda\,e^2\,\Lambda^{3\cdot10^6n^3}(nV)^2\,\mathrm{PN}(W)^2.$$

As $\Lambda' \ge 2$, $n \le 2^n \le \Lambda'^n$, and

$$nV \le \Lambda'^n\Big(\prod_{l<\varrho}\mathrm{fm}(l)\Big)\mathrm{kb}_A^{|\iota'|\varrho}\Lambda'^{4900n\varrho} \le \Big(\prod_{l<\varrho}\mathrm{fm}(l)\Big)\mathrm{kb}_A^{|\iota'|\varrho}\Lambda'^{25000n^2},$$

since $n + 4900n(n-1) \le 25000n^2$. Taking square roots, and using $\Lambda^{1/2} \le \Lambda$ and

$$\big(\prod_{l<\varrho}\mathrm{fm}(l)\big)\mathrm{kb}_A^{|\iota'|\varrho}\mathrm{PN}(W) = \mathrm{SN}(W),$$

$$\mathrm{hdn}_j(p,q)\int_S f\,d\theta \le e\,\Lambda^{1500000n^3+1}\Lambda'^{25000n^2}\,\mathrm{SN}(W).$$

□

Proposition 5.4.25. *Let Γ be a gauge for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $j \le \varrho$, $d \in G$, and let $\mathcal{K}$ be a pairing kernel at floor j for d. Then*

$$\int_{\{\text{positions of size }\Gamma\}} \mathrm{WSI}_j(\mathcal{K},x)\,d\theta(x) \le n\Big(\prod_{l<\varrho} c_{\mathrm{fl}}(l)\Big)\int_G\int_G |\mathcal{K}(g,y)|^2\,d\theta_{\ge 0}(y)\,d\theta_{\ge 0}(g).$$

Proof. Write P_Γ for the set of positions of size Γ (measurable, Lemma 5.4.27), $\mathbf{1}_\Gamma$ for its indicator, $\Theta_l = \theta_l * \theta_{l-1} * \cdots * \theta_0$, and $B = \big(\prod_{l<\varrho} c_{\mathrm{fl}}(l)\big)\int\int |\mathcal{K}(g,y)|^2\,d\theta_{\ge 0}(y)\,d\theta_{\ge 0}(g)$. Let clm_l, $\mathrm{csq}_l = \mathrm{csq}_l(\mathcal{K})$ and $c_{\mathrm{up}}(l)$ be as in Lemma 5.4.26, and $C_l = \prod_{a<l} c_{\mathrm{up}}(a)$; so $C_{\varrho+1} = \prod_{a<\varrho} c_{\mathrm{fl}}(a)$, and $C_l = \prod_{a<l} c_{\mathrm{fl}}(a)$ for $l \le \varrho$. All measures are s-finite, and Tonelli's theorem is used without comment; the functions integrated are measurable by Lemma 5.4.26 (i), Lemma 5.4.16 (ii) and Lemma 5.2.64 (i).

Step 1: factors of θ. We show by descending induction on l, for $j \le l \le \varrho+1$: there is an s-finite measure ρ_l with $\theta = \eta_{<l} * \rho_l$ and

$$C_l\int_G\int_G \mathrm{csq}_l(g,y)\,d\rho_l(y)\,d\Theta_l(g) \le B. \tag{5.82}$$

For $l = \varrho+1$: by Lemma 5.2.59 (iv), $\theta = \mathfrak{m}_{\varrho+2} = \eta_{<\varrho+2} * \Theta_{\varrho+1}$, and $\eta_{<\varrho+2} = \eta_{<\varrho+1}$ as $\eta_{\varrho+1} = \delta_1$; and $\Theta_{\varrho+1} = \theta_{\ge 0}$. Take $\rho_{\varrho+1} = \theta_{\ge 0}$. Since $\theta_{\ge\varrho+2} = \delta_1$, $\mathcal{K}_{\varrho+2} = \mathcal{K}$, so $\mathrm{csq}_{\varrho+1} \le |\mathcal{K}|^2$ and (5.82) holds.

Let $j \le l \le \varrho$ and let $\rho = \rho_{l+1}$ satisfy the claim at $l+1$. Put $\rho_l = \eta_l * \rho$; since $\eta_{<l+1} = \eta_{<l} * \eta_l$, $\theta = \eta_{<l} * \rho_l$. For $\sigma \in G^{(l+1)}$ and $g' \in G$, Lemma 5.4.33 applies to $\theta = \eta_{<l+1} * \rho$, $S = N_{<l+1}$ (closed; $\eta_{<l+1}$ is carried by S and $\eta_{<l+1} * \delta_t = \eta_{<l+1}$ for $t \in S$ by Lemma 5.4.14 (ii), (iii)), $s = \sigma$ ($\delta_\sigma * \eta_{<l+1} = \eta_{<l+1} * \delta_\sigma$ by Lemma 5.2.59 (iii)) and $\Phi = \mathrm{csq}_{l+1}(g',\cdot)$, which is invariant under left multiplication by $N_{<l+1}$ (Lemma 5.4.26 (i)); so

$$\int_G \mathrm{csq}_{l+1}(g',\sigma y)\,d\rho(y) = \int_G \mathrm{csq}_{l+1}(g',y)\,d\rho(y). \tag{5.83}$$

By Lemma 5.4.26 (ii) for each y, then (5.83) for θ_{l+1}-almost every σ (Lemma 5.2.59 (ii)), $\Theta_{l+1} = \theta_{l+1} * \Theta_l$, and the claim at $l+1$,

$$\begin{aligned}
C_l\iint \mathrm{csq}_l(g,y)\,d\rho_l(y)\,d\Theta_l(g) &= C_l\iiint \mathrm{csq}_l(g,ny)\,d\eta_l(n)\,d\rho(y)\,d\Theta_l(g)\\
&\le C_{l+1}\iiint \mathrm{csq}_{l+1}(\sigma g,\sigma y)\,d\rho(y)\,d\theta_{l+1}(\sigma)\,d\Theta_l(g)\\
&= C_{l+1}\iiint \mathrm{csq}_{l+1}(\sigma g,y)\,d\rho(y)\,d\theta_{l+1}(\sigma)\,d\Theta_l(g)\\
&= C_{l+1}\iint \mathrm{csq}_{l+1}(g,y)\,d\rho(y)\,d\Theta_{l+1}(g) \le B.
\end{aligned}$$

Step 2: one floor of weighted squares. Let $j \le l \le \varrho$. We show

$$\int_{P_\Gamma}\int_G \mathrm{WSq}_l(\mathcal{K},x)(g)\,d\Theta_l(g)\,d\theta(x) \le B. \tag{5.84}$$

Fix $g \in G$ and put $F(x) = \mathbf{1}_\Gamma(x)\,\mathrm{WSq}_l(\mathcal{K},x)(g) = \mathbf{1}_\Gamma(x)\,\mathrm{dpw}_l(g,x)\,|\mathcal{K}_{l+1}(g,gx)|^2$. As θ is left invariant and $\theta = \eta_{<l} * \rho_l$ (Step 1),

$$\int F\,d\theta = \int F(g^{-1}x)\,d\theta(x) = \iint F(g^{-1}\nu y)\,d\eta_{<l}(\nu)\,d\rho_l(y).$$

For $\nu \in N_{<l}$, $|\mathcal{K}_{l+1}(g,\nu y)| = |\mathcal{K}_{l+1}(g,y)|$ (Lemma 5.2.64 (vi)), and $\eta_{<l}$ is carried by $N_{<l}$, so the inner integral is $|\mathcal{K}_{l+1}(g,y)|^2 D(g,y)$ with $D(g,y) = \int \mathbf{1}_\Gamma(g^{-1}\nu y)\,\mathrm{dpw}_l(g,g^{-1}\nu y)\,d\eta_{<l}(\nu)$. We claim $|\mathcal{K}_{l+1}(g,y)|^2 D(g,y) \le C_l\,\mathrm{csq}_l(g,y)$. If $\mathcal{K}_{l+1}(g,y) = 0$ this is clear. If $\mathrm{clm}_l(g,y) = 0$, then $\mathbf{1}_\Gamma(g^{-1}\nu y) = 0$ for $\eta_{<l}$-almost every ν and $D(g,y) = 0$. Otherwise $\mathrm{csq}_l(g,y) = |\mathcal{K}_{l+1}(g,y)|^2$, and g is near at $l+1$ by (PK5) (Lemma 5.2.64 (iv): $\mathcal{K}$ is a pairing kernel at floor $l+1$), hence near at l as $R^{(l+1)} \subseteq R^{(l)}$ (Lemma 5.2.58 (i)); by Lemma 5.4.27 (ii), $D(g,y) \le \prod_{a<l} c_{\mathrm{fl}}(a) = C_l$. Integrating over y and then over g against Θ_l, and exchanging the integrals in x and g, the left side of (5.84) is at most $C_l \int\int \mathrm{csq}_l(g,y)\,d\rho_l(y)\,d\Theta_l(g) \le B$ by (5.82).

Step 3: summing the floors. By Lemma 5.4.16 (vi), $\mathrm{WSI}_l(\mathcal{K},x) = \int \mathrm{WSq}_l(\mathcal{K},x)\,d\Theta_l + \mathrm{WSI}_{l+1}(\mathcal{K},x)$ for $l \le \varrho$, and $\mathrm{WSI}_{\varrho+1}(\mathcal{K},x) = 0$ because $\mathrm{WSS}_n = 0$. Hence $\mathrm{WSI}_j(\mathcal{K},x) = \sum_{l=j}^{\varrho} \int \mathrm{WSq}_l(\mathcal{K},x)\,d\Theta_l$, and by (5.84) its integral over P_Γ is at most $(\varrho+1-j)B \le nB$. □

Lemma 5.4.26. *Let Γ be a gauge for a place datum and $\mathbf{1}_\Gamma$ the indicator function of the set of positions of size Γ. For $l \ge 0$, $g,y \in G$ and $\mathcal{K}\colon G \times G \to \mathbb{C}$ put*

$$\mathrm{clm}_l(g,y) = \int_G \mathbf{1}_\Gamma(g^{-1}\nu y)\,d\eta_{<l}(\nu), \qquad \mathrm{csq}_l(\mathcal{K})(g,y) = \begin{cases} |\mathcal{K}_{l+1}(g,y)|^2 & \text{if } \mathrm{clm}_l(g,y) > 0, \\ 0 & \text{if } \mathrm{clm}_l(g,y) = 0. \end{cases}$$

Let $j \ge 0$, $d \in G$ and let $\mathcal{K}$ be a pairing kernel at floor j for d.

(i) For every $l \ge 0$, clm_l and $\mathrm{csq}_l(\mathcal{K})$ are measurable on $G \times G$; $\mathrm{clm}_l(g,\nu y) = \mathrm{clm}_l(g,y)$ and $\mathrm{csq}_l(\mathcal{K})(g,\nu y) = \mathrm{csq}_l(\mathcal{K})(g,y)$ for $\nu \in N_{<l}$; and $\mathrm{clm}_l(\sigma g,\sigma y) = \mathrm{clm}_l(g,y)$ for $\sigma \in G^{(l)}$.

(ii) Let $j \le l \le \varrho$, and put $c_{\mathrm{up}}(l) = c_{\mathrm{fl}}(l)$ for $l < \varrho$ and $c_{\mathrm{up}}(\varrho) = 1$. Then for all $g,y \in G$

$$\int_G \mathrm{csq}_l(\mathcal{K})(g,ny)\,d\eta_l(n) \le c_{\mathrm{up}}(l) \int_G \mathrm{csq}_{l+1}(\mathcal{K})(\sigma g,\sigma y)\,d\theta_{l+1}(\sigma).$$

Proof. All measures are s-finite, so Tonelli's theorem applies; the set of positions of size Γ is measurable (Lemma 5.4.27, proof of (ii)), and $\mathcal{K}_l$ is measurable (Lemma 5.2.64 (i)).

(i). $(\nu,g,y) \mapsto \mathbf{1}_\Gamma(g^{-1}\nu y)$ is measurable, so clm_l is measurable by Tonelli's theorem, and $\mathrm{csq}_l(\mathcal{K}) = \mathbf{1}_{\{\mathrm{clm}_l>0\}}|\mathcal{K}_{l+1}|^2$ is measurable. For $\nu \in N_{<l}$, $\eta_{<l} * \delta_\nu = \eta_{<l}$ (Lemma 5.4.14 (iii)), so $\mathrm{clm}_l(g,\nu y) = \int \mathbf{1}_\Gamma(g^{-1}\nu' \nu y)\,d\eta_{<l}(\nu') = \mathrm{clm}_l(g,y)$; with $|\mathcal{K}_{l+1}(g,\nu y)| = |\mathcal{K}_{l+1}(g,y)|$ (Lemma 5.2.64 (vi)) this gives the invariance of $\mathrm{csq}_l(\mathcal{K})$. For $\sigma \in G^{(l)}$, $\delta_\sigma * \eta_{<l} = \eta_{<l} * \delta_\sigma$ (Lemma 5.2.59 (iii)), hence $\delta_{\sigma^{-1}} * \eta_{<l} * \delta_\sigma = \eta_{<l}$ and $\mathrm{clm}_l(\sigma g,\sigma y) = \int \mathbf{1}_\Gamma(g^{-1}\sigma^{-1}\nu\sigma y)\,d\eta_{<l}(\nu) = \mathrm{clm}_l(g,y)$.

(ii), the case $\mathrm{clm}_{l+1}(g,y) = 0$. As $\eta_{<l+1} = \eta_{<l} * \eta_l$, $0 = \mathrm{clm}_{l+1}(g,y) = \int \mathrm{clm}_l(g,ny)\,d\eta_l(n)$, so $\mathrm{clm}_l(g,ny) = 0$, hence $\mathrm{csq}_l(\mathcal{K})(g,ny) = 0$, for η_l-almost every n; the left side is 0.

(ii), the case $\mathrm{clm}_{l+1}(g,y) > 0$. By (i) and since θ_{l+1} is carried by $G^{(l+1)}$ (Lemma 5.2.59 (ii)), $\mathrm{clm}_{l+1}(\sigma g,\sigma y) > 0$ and so $\mathrm{csq}_{l+1}(\mathcal{K})(\sigma g,\sigma y) = |\mathcal{K}_{l+2}(\sigma g,\sigma y)|^2$ for θ_{l+1}-almost every σ. Since $\mathrm{csq}_l(\mathcal{K}) \le |\mathcal{K}_{l+1}|^2$, it suffices to show

$$\int_G \mathrm{csq}_l(\mathcal{K})(g,ny)\,d\eta_l(n) \le c_{\mathrm{up}}(l) \int_G |\mathcal{K}_{l+2}(\sigma g,\sigma y)|^2\,d\theta_{l+1}(\sigma). \tag{5.85}$$

The top floor $l = \varrho$. Here $\eta_\varrho = \delta_1$, and the left side of (5.85) is at most $|\mathcal{K}_{\varrho+1}(g,y)|^2 \le \mathrm{piv}_{\varrho+1}(\mathcal{K})(g,y)^2$ by Lemma 5.2.64 (ii). By the definition of $R^{(l)}$, $R^{(\varrho+2)} = \mathsf{U}$, so for every $g' \in G$ the set of ξ with $\xi g'$ near at $\varrho+2$ is $\{\xi : u\xi g' \in K \text{ for some } u \in \mathsf{U}\}$, of μ_H-measure at most 1 by (PE3); as $\theta_{\varrho+1} = \mu_H$, this is $\mathrm{FML}_{\varrho+1}(1;1)$. Lemma 5.4.16 (i) gives $\mathrm{piv}_{\varrho+1}(\mathcal{K})(g,y)^2 \le \int |\mathcal{K}_{\varrho+2}(\sigma g, \sigma y)|^2 \, d\theta_{\varrho+1}(\sigma)$, which is (5.85) with $c_{\mathrm{up}}(\varrho) = 1$.

A floor $l < \varrho$. We apply Proposition 5.4.28 with $a = l$, $\varepsilon_0 = 0$, $\xi = M^{-1}$, $u = M$, the points $x = g$ and y, $i = 1$, the size index 14 in place of its j, $C = 1$, the Borel function $\Phi(n) = \mathrm{csq}_l(\mathcal{K})(g, ny)$, and

$$S = \{n \text{ a Heisenberg element of floor } l : \ g \text{ is near at } l+1, \\ g^{-1}\nu_0 ny \text{ is a position of size } \Gamma \text{ for some } \nu_0 \in N_{<l}\}.$$

By Lemma 5.2.64 (iv), $\mathcal{K}$ is a pairing kernel at floor $l+1 \ge j$ for d. For a Heisenberg element s of floor l, $s \in G^{(l)} \subseteq G^{(j)}$, so $dsd^{-1} = s$ by (PK3), and $\sigma(s^0) = \sigma(1) = 0$; so $M^{-1}(\sigma(dsd^{-1}) - \sigma(s^0)) = \xi\,\sigma(s)$.

Hypothesis (a): if $\Phi(n) \ne 0$ for a Heisenberg element n, then $\mathrm{clm}_l(g, ny) > 0$, so, $\eta_{<l}$ being carried by $N_{<l}$ (Lemma 5.4.14 (ii)), $g^{-1}\nu_0 ny$ is a position of size Γ for some $\nu_0 \in N_{<l}$; and $\mathcal{K}_{l+1}(g, ny) \ne 0$, so g is near at $l+1$ by (PK5). Thus $n \in S$, and $\Phi(n) \le |\mathcal{K}_{l+1}(n^0 g, ny)|^2$.

Hypothesis (b): let $n_0 \in S$, with $\nu_0 \in N_{<l}$ such that $g^{-1}\nu_0 n_0 y$ is a position of size Γ, and let $\xi_0 g \in K$ with $\xi_0 \in R^{(l+1)} \subseteq R^{(l)}$. By Lemma 5.2.58 (v), $\xi_0 = t\nu'$ with $t \in G^{(l)}$, $\nu' \in N_{<l}$; as $N_{<l} \subseteq \mathsf{U} \subseteq R^{(l+1)}$ and $N_{<l} \subseteq N_{<l+1}$ (Lemma 5.2.58 (i)), $t \in R^{(l+1)} \cap G^{(l)}$, $\nu' \in N_{<l+1}$, and $t\nu' g = \xi_0 g \in K$ has size 1 (GU2). Let $n \in S$, with $\mu \in N_{<l}$ such that $g^{-1}\mu ny$ is a position of size Γ. Put $g' = t\nu' g \in K$, $Y_0 = t\nu'\nu_0 n_0 y$, $\delta = n n_0^{-1} \in G^{(l)}$, $n^* = tn(tn_0)^{-1} = t\delta t^{-1} \in G^{(l)}$ and

$$\kappa = t\,\nu'\mu\,\delta(\nu'\nu_0)^{-1}\delta^{-1}\,t^{-1}.$$

By Lemma 5.2.58 (ii) (conjugation by δ and by t, elements of $G^{(l)}$), $\kappa \in N_{<l}$. Now $g'^{-1}Y_0 = g^{-1}\nu_0 n_0 y$ is a position of size Γ, and $\kappa n^* Y_0 = t\nu'\mu\delta(\nu'\nu_0)^{-1}\delta^{-1}t^{-1} \cdot t\delta\nu'\nu_0 n_0 y = t\nu'\mu\, n n_0^{-1} n_0 y = t\nu'\mu n y$, so $g'^{-1}\kappa n^* Y_0 = g^{-1}\mu n y$ is a position of size Γ. By Lemma 5.4.27 (i) (with the box point g', the point Y_0, $n^* \in G^{(l)}$ and $\kappa \in N_{<l}$), $w = (n^{*-1}\kappa^{-1} - 1)e_l^*$ satisfies $w - (n^{*-1} - 1)e_l^* \in E_{<l}$ and $M^{-1}w$ has size 14; and $n^{*-1} = tn_0(tn)^{-1}$. This is (b) with $t_0 = t$ and $q = \nu'$.

Proposition 5.4.28 gives, as $|\xi u| = |1| = 1$,

$$\int_G \Phi \, d\eta_l \le \mathrm{kb}_A^{|\iota'|}\,\mathrm{fm}(l)\,\Lambda^{100n(1+14+31)} \int_G |\mathcal{K}_{l+2}(\sigma g, \sigma y)|^2 \, d\theta_{l+1}(\sigma),$$

and $\mathrm{kb}_A^{|\iota'|}\mathrm{fm}(l)\Lambda^{4600n} \le c_{\mathrm{fl}}(l)$ as $\Lambda \ge 2$. This is (5.85). □

Lemma 5.4.27. *Let Γ be a gauge of loss Λ for a place datum, with size filtration $(A_{(i)})_{i\ge 0}$; let $\mathbf{1}_\Gamma$ be the indicator function of the set of positions of size Γ, and write $E_{<a} = \mathrm{span}\{e_b : b < a\}$.*

(i) Let $a < \varrho$, $g \in K$, $y \in G$, $n \in G^{(a)}$ and $\nu_0 \in N_{<a}$, and let $g^{-1}y$ and $g^{-1}\nu_0 ny$ be positions of size Γ. Then $w = (n^{-1}\nu_0^{-1} - 1)e_a^*$ satisfies $w - (n^{-1} - 1)e_a^* \in E_{<a}$, and $M^{-1}w$ has size 14.

(ii) Let $j \le \varrho$ and let $g \in G$ be near at j. Then for every $y \in G$

$$\int_G \mathbf{1}_\Gamma(g^{-1}\nu y)\,\mathrm{dpw}_j(g, g^{-1}\nu y)\,d\eta_{<j}(\nu) \le \prod_{l<j} \mathrm{fm}(l)\,\Lambda^{4600n} \le \prod_{l<j} c_{\mathrm{fl}}(l).$$

Proof. Throughout, products and sums of matrices are formed in the coordinate basis, and we use: if X has size i and Y size i', then XY has size $i+i'+1$ (each entry is a sum of r elements of $A_{(i+i')}$, by (SZ1), (SZ2)); a sum $X+Y$ of two matrices of size i has size $i+1$ and $-X$, $\bar{X}$ have size i (SZ2), (SZ3); $A_{(i)} \subseteq A_{(i+1)}$ (a sum of one element, (SZ2)); for $x \in G$, $x^{-1} = J^{-1}\bar{x}^{\mathsf{T}}J$, so if x has size i then x^{-1} has size $i+4$ by (SZ5).

(i). Put $x = g^{-1}y$ and $x' = g^{-1}\nu_0 ny$. Since $M^{-1}(x'-1)$ has size 1 and $M \in A_{(1)}$ (GU2), the entries of $x' = M \cdot M^{-1}(x'-1)+1$ lie in $A_{(3)}$ by (SZ1), (SZ4), (SZ2); as $g \in K$ has size 1 (GU2), gx' has size 5 and $(gx')^{-1}$ size 9. The matrix $D = M^{-1}(x-1) - M^{-1}(x'-1)$ has size 2, so gD has size 4 and $gD(gx')^{-1}$ has size 14. Since M is a scalar,

$$\begin{aligned} gD(gx')^{-1} &= M^{-1}\, g(x-x')(gx')^{-1} = M^{-1}(gx(gx')^{-1} - 1) \\ &= M^{-1}(y(\nu_0 ny)^{-1} - 1) = M^{-1}(n^{-1}\nu_0^{-1} - 1). \end{aligned}$$

The vector $M^{-1}w$ is the column of this matrix at e_a^*, so it has size 14. Put $\mu = n^{-1}\nu_0^{-1}n$. As $n^{-1} \in G^{(a)}$ and $\nu_0^{-1} \in N_{<a}$, Lemma 5.2.58 (ii) gives $\mu \in N_{<a}$, and $n^{-1}\nu_0^{-1} = \mu n^{-1}$. By Lemma 5.4.11 (i), applied to $n^{-1} \in G^{(a)}$ and $\mu \in N_{<a}$, $w - (n^{-1}-1)e_a^* = (\mu n^{-1}-1)e_a^* - (n^{-1}-1)e_a^* \in E_{<a}$.

Inverse depth along the Heisenberg group of floor a. Let $a < \varrho$, $g \in K$ and $y \in G$ with $g^{-1}y \in \mathcal{P}_{\mathrm{pos}}$. By (GU7) with $Q = 0$ there is a common bound ϕ with loss Λ for $\mathcal{V} = \mathcal{V}_{\mathrm{cm}}(g, g^{-1}y, 0) = \{\omega \in A^{\iota'} : (g^{-1}O\omega, y^{-1}O\omega) \in \mathcal{P}_{\mathrm{cl}}\}$. We show: for $v \in V_{a+1}$, $\beta \in A^-$, $n = n_a(v,\beta)$ and $\varsigma(v) = (h(o_i, M^{-1}v))_{i\in\iota'}$,

$$\mathrm{dp}_a(g, g^{-1}ny)^{-1} \le \phi(\varsigma(v)). \tag{5.86}$$

By Lemma 5.4.8 (i), $\mathrm{dp}_a(g,g^{-1}ny)^{-1} = \mathrm{vol}^*(\mathfrak{d}_a(g,g^{-1}ny))$, and the second clause of a common bound bounds vol^* of $\{c \in A : \bar{c}\,\overline{\varsigma(v)}^{\mathsf{T}}\omega \in \mathcal{D}_{\mathrm{pr}} \text{ for all } \omega \in \mathcal{V}\}$ by $\phi(\varsigma(v))$; so it suffices that $\mathfrak{d}_a(g,g^{-1}ny)$ lies in this set. Let $c \in \mathfrak{d}_a(g,g^{-1}ny)$: $c = h(e_a,\zeta)$ with $h(e_b,\zeta) = 0$ for $b < a$, and $(g^{-1}\zeta, (ny)^{-1}\zeta') \in \mathcal{P}_{\mathrm{cl}}$ for some $\zeta' \in \zeta + E_{<a}$. Let $\omega \in \mathcal{V}$ and $o = O\omega$. As o lies in the middle space, $h(e_b,o) = 0$ for all $b < \varrho$; so (5.8) gives $no = o - h(v,o)e_a$, and since n is an isometry,

$$h(n^{-1}\zeta', o) = h(\zeta', no) = h(\zeta', o) - h(v,o)\,h(\zeta', e_a).$$

Here $h(\zeta',o) = h(\zeta,o)$, because $\zeta' - \zeta \in E_{<a}$ and $h(e_b,o) = 0$; and $h(\zeta',e_a) = \overline{h(e_a,\zeta')} = \overline{h(e_a,\zeta)} = \bar{c}$, because $h(e_a,e_b) = 0$. Hence $h(\zeta,o) - h(n^{-1}\zeta',o) = \bar{c}\,h(v,o)$. The pairs $(g^{-1}\zeta, (ny)^{-1}\zeta')$ and $(g^{-1}o, y^{-1}o)$ are close, and $h(g^{-1}\zeta, g^{-1}o) = h(\zeta,o)$, $h((ny)^{-1}\zeta', y^{-1}o) = h(n^{-1}\zeta', o)$; so $M^{-1}\bar{c}\,h(v,o) \in \mathcal{D}_{\mathrm{pr}}$. Finally, since $\bar{M} = M$ (PE1),

$$\overline{\varsigma(v)}^{\mathsf{T}}\omega = \sum_{i\in\iota'} M^{-1}h(v,o_i)\omega_i = M^{-1}h(v,o),$$

so $\bar{c}\,\overline{\varsigma(v)}^{\mathsf{T}}\omega = M^{-1}\bar{c}\,h(v,o) \in \mathcal{D}_{\mathrm{pr}}$. This proves (5.86).

Put $\Psi(v') = \phi((h(o_i,v'))_{i\in\iota'})^s$ for $v' \in V$; it is Borel, as ϕ is measurable and $v' \mapsto (h(o_i,v'))_i$ is continuous. By Lemma 5.4.4 (iv) with $l = a+1 \le \varrho$, $\rho = \mathrm{vol}_{V_{a+1}}$ and $j = 14$, and the integral clause of a common bound at size 18,

$$\int_{\{v' \text{ of size } 14\}} \Psi \, d\mathrm{vol}_{V_{a+1}} \le \Lambda^{99n\cdot 20} \int_{A^{\iota'}_{(18)}} \phi^s \, d\mathrm{vol} \le \Lambda^{99n\cdot 20}\Lambda^{99n\cdot 19} = \Lambda^{3861n}. \tag{5.87}$$

(ii) for g in the box. Fix $g \in K$. For $a \le \varrho$ put $F_a(x) = \mathbf{1}_\Gamma(x)\,\mathrm{dpw}_a(g,x)$, $I_a(z) = \int_G F_a(g^{-1}\nu z)\,d\eta_{<a}(\nu)$ and $C_a = \prod_{l<a}\mathrm{fm}(l)\Lambda^{4600n}$; $C_a < \infty$, as M is a unit (so $0 < |M| < \infty$)

and $\Lambda < \infty$ (GU1). The set of positions of size Γ is measurable: $\mathcal{P}_{\mathrm{pos}}$ is measurable (PE4), and $\{x : M^{-1}(x-1)$ has size $1\}$ is closed because $A_{(1)}$ is compact (GU1). With Lemma 5.4.8 (iii), F_a is Borel. The measures η_l are images of products of Haar measures of second countable locally compact groups, hence s-finite, and so are their convolutions; by Tonelli's theorem I_a is Borel and the iterated integrals below may be exchanged. We show $I_a \le C_a$ on G by induction on a. For $a = 0$, $\eta_{<0} = \delta_1$ and $\mathrm{dpw}_0 = 1$, so $I_0(z) = \mathbf{1}_\Gamma(g^{-1}z) \le 1$.

Let $a < \varrho$, assume $I_a \le C_a$, and let $z \in G$ with $I_{a+1}(z) \neq 0$. As $\eta_{<a+1}$ is carried by $N_{<a+1}$ (Lemma 5.4.14 (ii)), there is $\nu_1 \in N_{<a+1}$ with $F_{a+1}(g^{-1}\nu_1 z) \neq 0$; put $y = \nu_1 z$, so that $g^{-1}y$ is a position of size Γ. By Lemma 5.4.14 (iii), $\eta_{<a+1} * \delta_{\nu_1} = \eta_{<a+1}$, hence $I_{a+1}(z) = \int F_{a+1}(g^{-1}\nu\nu_1 z)\, d\eta_{<a+1}(\nu) = I_{a+1}(y)$. By associativity of convolution $\eta_{<a+1} = \eta_{<a} * \eta_a$, so

$$I_{a+1}(y) = \int_G J(n)\, d\eta_a(n), \qquad J(n) = \int_G F_{a+1}(g^{-1}\nu n y)\, d\eta_{<a}(\nu).$$

For $\nu \in N_{<a}$, Lemma 5.4.8 (iii) and (ii) give $F_{a+1}(g^{-1}\nu n y) = F_a(g^{-1}\nu n y)\,\mathrm{dp}_a(g, g^{-1}ny)^{-s}$. Since $\eta_{<a}$ is carried by $N_{<a}$, $J(n) = \mathrm{dp}_a(g, g^{-1}ny)^{-s} I_a(ny) \le C_a\,\mathrm{dp}_a(g, g^{-1}ny)^{-s}$, and $J(n) \neq 0$ implies $g^{-1}\nu_0 n y$ is a position of size Γ for some $\nu_0 \in N_{<a}$. We apply Lemma 5.4.11 (iii) with $u = M$, $j = 14$, Ψ, $I = \Lambda^{3861n}$ (5.87), $\Phi = J$ (Borel) and $C = C_a$. Its hypothesis: let $J(n_a(v,\beta)) \neq 0$ and $n = n_a(v,\beta) \in G^{(a)}$ (Lemma 5.2.58 (iii)); with ν_0 as above, (i) gives w with $w - (n^{-1} - 1)e_a^* \in E_{<a}$ and $M^{-1}w$ of size 14; and by (5.86), $J(n) \le C_a\,\phi(\varsigma(v))^s = C_a\Psi(M^{-1}v)$. Hence, as $\Lambda \ge 2$ and $16 + 3861n \le 4600n$,

$$I_{a+1}(z) = I_{a+1}(y) \le C_a\,\mathrm{fm}(a)\,\Lambda^{16}\Lambda^{3861n} \le C_a\,\mathrm{fm}(a)\Lambda^{4600n} = C_{a+1}.$$

(ii) in general. Let g be near at j: $\xi g \in K$ for some $\xi \in R^{(j)}$; by Lemma 5.2.58 (v), $\xi = \gamma\nu'$ with $\gamma \in G^{(j)}$ and $\nu' \in N_{<j}$. Put $g' = \xi g \in K$. By Lemma 5.4.8 (iii), $\mathrm{dpw}_j(g,x) = \mathrm{dpw}_j(g',x)$, and $g^{-1} = g'^{-1}\gamma\nu'$; let $F'(x) = \mathbf{1}_\Gamma(x)\mathrm{dpw}_j(g',x)$. Using $\delta_{\nu'} * \eta_{<j} = \eta_{<j}$ (Lemma 5.4.14 (iii)) and then $\delta_\gamma * \eta_{<j} = \eta_{<j} * \delta_\gamma$ (Lemma 5.2.59 (iii)),

$$\int F'(g'^{-1}\gamma\nu'\nu y)\, d\eta_{<j}(\nu) = \int F'(g'^{-1}\gamma\nu y)\, d\eta_{<j}(\nu) = \int F'(g'^{-1}\nu\gamma y)\, d\eta_{<j}(\nu),$$

which is at most $\prod_{l<j}\mathrm{fm}(l)\Lambda^{4600n}$ by the case of the box at g' and the point γy. The last inequality of (ii) holds termwise, as $\mathrm{kb}_A \ge 1$ (GU1) and $\Lambda \ge 2$, so $\mathrm{fm}(l)\Lambda^{4600n} \le \mathrm{fm}(l)\mathrm{kb}_A^{|\iota'|}\Lambda^{4900n} = c_{\mathfrak{fl}}(l)$. □

Proposition 5.4.28. *Let Γ be a gauge of loss Λ for a place datum, put $r' = |\iota'|$ and $E_{<a} = \mathrm{span}\{e_b : b < a\}$, let $a < \varrho$, $\varepsilon_0 \in \{0,1\}$, $d \in G$, let $\mathcal{K}$ be a pairing kernel at floor $a+1$ for d, and let ξ, u be units of A with $M^{-1}(\sigma(dsd^{-1}) - \sigma(s^{\varepsilon_0})) = \xi\,\sigma(s)$ for every Heisenberg element $s = n_a(v,\beta)$. Let $x, y \in G$, $i, j \ge 0$, $C \in [0,\infty]$, $S \subseteq G$, and let $\Phi\colon G \to [0,\infty]$ be Borel. Assume:*

(a) for every Heisenberg element $n = n_a(v,\beta)$ with $\Phi(n) \neq 0$: $n \in S$ and

$$\Phi(n) \le C\,|\mathcal{K}_{a+1}(n^{\varepsilon_0}x, ny)|^2;$$

(b) for every Heisenberg element $n_0 \in S$ there are $t_0 \in R^{(a+1)} \cap G^{(a)}$ and $q \in N_{<a+1}$ such that $t_0 q x$ has size i and, for every Heisenberg element $n \in S$, some $w \in V$ with $w - (t_0 n_0 (t_0 n)^{-1} - 1)e_a^* \in E_{<a}$ has $u^{-1}w$ of size j.

Then

$$\int_G \Phi\, d\eta_a \le C\Big(\frac{\mathrm{kb}_A}{|\xi u|}\Big)^{r'} \mathrm{fm}(a,u)\,\Lambda^{100n(i+j+31)} \int_G |\mathcal{K}_{a+2}(\varsigma x, \varsigma y)|^2\, d\theta_{a+1}(\varsigma).$$

Proof. If $\int \Phi\, d\eta_a = 0$ there is nothing to prove. Otherwise, as η_a is the image of a measure under $(v,\beta) \mapsto n_a(v,\beta)$, there is a Heisenberg element $n_0 = n_a(z,\gamma)$ with $\Phi(n_0) \neq 0$; by (a), $n_0 \in S$. Let t_0, q be as in (b) for n_0.

Splitting t_0. By Lemma 5.2.58, (iv), there is a Heisenberg element r' with $r'^{-1}t_0 \in G^{(a+1)}$; put $t = r'^{-1}t_0$ and $r = t^{-1}r't$. By Lemma 5.2.58, (iii), r is a Heisenberg element (conjugation by $t^{-1} \in G^{(a+1)}$ maps $n_a(v',\beta')$ to $n_a(t^{-1}v',\beta')$), and $t_0 = r't = tr$ with $t \in G^{(a+1)}$.

Substitution. For a Heisenberg element n put $N(n) = r^{-1}(t^{-1}nt)(rn_0)$, again a Heisenberg element by Lemma 5.2.58, (iii). By Lemma 5.2.61, (ii), η_a is invariant under left and right translation by Heisenberg elements and under $n \mapsto t^{-1}nt$; hence $\int \Phi\, d\eta_a = \int \Phi(N(n))\, d\eta_a(n)$. For $n = n_a(v,\beta)$, the product formula of Lemma 5.2.58, (iii), shows that $N(n)$ has vector part $t^{-1}v + z$, so by Lemma 5.4.29, (i), and since t preserves h,

$$\begin{aligned}\mathcal{K}_{a+1}(N(n)^{\varepsilon_0}x, N(n)y) &= \int_G \psi(-\xi\, h(t^{-1}v + z, \varsigma^{-1}f_{a+1}))\kappa(\varsigma)\, d\theta_{a+1}(\varsigma)\\ &= \int_G \psi(\xi'\, h(u^{-1}v + v_0, t\varsigma^{-1}f_{a+1}))\kappa(\varsigma)\, d\theta_{a+1}(\varsigma),\end{aligned}$$

where $\kappa(\varsigma) = \mathcal{K}_{a+2}(\varsigma x, \varsigma y)$, $\xi' = -\xi\bar{u}$ (a unit, with $|\xi'| = |\xi u|$ by (PA2)) and $v_0 = u^{-1}tz$; here $h(v + tz, \cdot) = \bar{u}\, h(u^{-1}v + u^{-1}tz, \cdot)$. Call the right side $T(u^{-1}v)$, and put $\Psi(v') = C|T(v')|^2$, a Borel function of $v' \in V$.

Plancherel one floor up. Put $q' = t_0 q = trq$. Then $t^{-1}q' = rq \in N_{<a+1}$ (Heisenberg elements of floor a lie in $N_{<a+1}$ by Lemma 5.2.58, (iii)), $q'x = t_0 qx$ has size i, $t \in G^{(a+1)}$, and $\mathcal{K}$ is a pairing kernel at floor $a+1$. By Lemma 5.4.30, (ii), with $b = a+1$, $\rho = \mathrm{vol}_{V_{a+1}}$, the frequency ξ', the shift v_0 and j in place of i,

$$\int_{\{v' \text{ of size } j\}} \Psi\, d\mathrm{vol}_{V_{a+1}} \leq C\, \Lambda^{99n(j+6)}\Lambda^{99n(i+12)}\Big(\frac{\mathrm{kb}_A}{|\xi u|}\Big)^{r'} \int_G |\kappa|^2\, d\theta_{a+1} =: I.$$

Integration over the Heisenberg group. Let $n = n_a(v,\beta)$ with $\Phi(N(n)) \neq 0$. By (a), $N(n) \in S$ and $\Phi(N(n)) \leq C|\mathcal{K}_{a+1}(N(n)^{\varepsilon_0}x, N(n)y)|^2 = \Psi(u^{-1}v)$. Moreover $t_0 N(n) = tr\, r^{-1}t^{-1}nt\, rn_0 = n\, t_0 n_0$, so $t_0 n_0 (t_0 N(n))^{-1} = n^{-1}$. By (b) applied to $N(n) \in S$, some $w \in V$ with $w - (n^{-1} - 1)e_a^* \in E_{<a}$ has $u^{-1}w$ of size j. So Lemma 5.4.11, (iii), applies to $\Phi \circ N$ with the constant 1, the function Ψ and the bound I:

$$\int \Phi\, d\eta_a = \int \Phi(N(n))\, d\eta_a(n) \leq \mathrm{fm}(a,u)\, \Lambda^{j+2}\, I.$$

Finally $j + 2 + 99n(j+6) + 99n(i+12) \leq 100n(i+j+31)$, as $n \geq 1$, and $\Lambda \geq 1$. □

Lemma 5.4.29. *Let a place datum be given, $a < \varrho$, $\varepsilon_0 \in \{0,1\}$, $d \in G$, $\xi \in A$, and let $\mathcal{K}$ be a pairing kernel (at some floor) for d.*

(i) Suppose that $M^{-1}(\sigma(dsd^{-1}) - \sigma(s^{\varepsilon_0})) = \xi\, \sigma(s)$ for every Heisenberg element $s = n_a(v,\beta)$. Then for all $v \in V_{a+1}$, $\beta \in A^-$ and $x, y \in G$,

$$\mathcal{K}_{a+1}(n_a(v,\beta)^{\varepsilon_0}x,\ n_a(v,\beta)\, y) = \int_G \psi(-\xi\, h(v, \varsigma^{-1}f_{a+1}))\, \mathcal{K}_{a+2}(\varsigma x, \varsigma y)\, d\theta_{a+1}(\varsigma).$$

(ii) If p, q are sequences of units, $j \leq a+1$ and $d = w_{j,q}^{-1}w_{j,p}$, the hypothesis of (i) holds with $\xi = M^{-1}(p_a q_a^{-1} - \varepsilon_0)$ if $a < j$, and with $\xi = M^{-1}(1 - \varepsilon_0)$ if $a \geq j$.

Proof. **The simple-root sum on the Heisenberg group.** Let $s = n_a(v,\beta)$. By (5.8), s fixes the coordinate vectors of floor at most a other than e_a^*, sends $w \in V_{a+1}$ to $w - h(v,w)e_a$, and $se_a^* - e_a^* \in \langle e_a\rangle + V_{a+1}$. Among the entries $s_{f_b f_{b+1}}$ ($b < \varrho$), only $b = a$ can be non-zero: for $b < a$ the column f_{b+1} has floor at most a and is not e_a^*, and for $b > a$ the column $f_{b+1} \in V_{a+1}$ has $sf_{b+1} - f_{b+1} \in \langle e_a\rangle$ with $e_a \neq f_b$. Hence

$$\sigma(n_a(v,\beta)) = s_{e_a f_{a+1}} = -h(v, f_{a+1}). \tag{5.88}$$

(i). Fix v, β, x, y and $n = n_a(v,\beta)$. By Lemma 5.2.64, (ii), at floor $a+1$,

$$\mathcal{K}_{a+1}(n^{\varepsilon_0}x, ny) = \int_G \mathcal{K}_{a+2}(\varsigma n^{\varepsilon_0}x, \varsigma ny)\, d\theta_{a+1}(\varsigma),$$

and θ_{a+1} is carried by $G^{(a+1)}$ (Lemma 5.2.59, (ii)). Let $\varsigma \in G^{(a+1)}$ and $s = \varsigma n \varsigma^{-1}$. By Lemma 5.2.58, (iii), $s = n_a(\varsigma v, \beta)$ is a Heisenberg element, so $s, s^{\varepsilon_0} \in N_{<a+1}$, and $\varsigma n^{\varepsilon_0} = s^{\varepsilon_0}\varsigma$, $\varsigma n = s\varsigma$. By (PK2) with $l = a+1$ and the hypothesis,

$$\mathcal{K}_{a+2}(s^{\varepsilon_0}\varsigma x, s\varsigma y) = \psi\big(M^{-1}(\sigma(dsd^{-1}) - \sigma(s^{\varepsilon_0}))\big)\mathcal{K}_{a+2}(\varsigma x, \varsigma y) = \psi(\xi\,\sigma(s))\,\mathcal{K}_{a+2}(\varsigma x, \varsigma y),$$

and by (5.88), $\sigma(s) = -h(\varsigma v, f_{a+1}) = -h(v, \varsigma^{-1}f_{a+1})$, ς being an isometry. Substituting gives (i).

(ii). By Lemma 5.2.58, (ix), d is diagonal with $d_{e_a e_a} = p_a q_a^{-1}$ if $a < j$ and $d_{e_a e_a} = 1$ otherwise, and $d_{f_{a+1} f_{a+1}} = 1$, as f_{a+1} is e_{a+1} with $a+1 \geq j$ or is z. By Lemma 5.2.58, (x), $(dsd^{-1})_{f_b f_{b+1}} = d_{f_b f_b} s_{f_b f_{b+1}} d^{-1}_{f_{b+1} f_{b+1}}$, and only $b = a$ contributes, so $\sigma(dsd^{-1}) = r\,\sigma(s)$ with $r = p_a q_a^{-1}$ if $a < j$ and $r = 1$ otherwise. Moreover $\sigma(s^{\varepsilon_0}) = \varepsilon_0\,\sigma(s)$, as $\sigma(1) = 0$. Hence $M^{-1}(\sigma(dsd^{-1}) - \sigma(s^{\varepsilon_0})) = M^{-1}(r - \varepsilon_0)\,\sigma(s)$. □

Lemma 5.4.30. *Let Γ be a gauge of loss Λ for a place datum, put $r' = |\iota'|$, let $0 \leq b \leq \varrho$, let $\mathcal{K}$ be a pairing kernel at floor b for some $d \in G$, let $t \in G^{(b)}$ and $q \in G$ with $t^{-1}q \in N_{<b}$, let $j \geq 0$ and let $x, y \in G$ with qx of size j.*

(i) For every $\sigma \in G^{(b)}$ with $\mathcal{K}_{b+1}(\sigma x, \sigma y) \neq 0$, the vector $t\sigma^{-1}f_b$ has size $j+6$.

(ii) For every unit ξ, every $v_0 \in V$, every $i \geq 0$ and $\rho = \mathrm{vol}_{V_b}$ or $\rho = \mathrm{qv}_b$,

$$\int_{\{v \in V \text{ of size } i\}} \Big| \int_G \psi(\xi\, h(v + v_0, t\sigma^{-1}f_b))\, \mathcal{K}_{b+1}(\sigma x, \sigma y)\, d\theta_b(\sigma)\Big|^2 d\rho(v)$$
$$\leq \Lambda^{99n(i+6)}\Lambda^{99n(j+12)}\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'} \int_G |\mathcal{K}_{b+1}(\sigma x, \sigma y)|^2\, d\theta_b(\sigma).$$

Proof. **(i).** By Lemma 5.2.64, (iv), $\mathcal{K}$ is a pairing kernel at floor $b+1$, so by (PK5) the point σx is near at $b+1$. Put $c = \sigma(t^{-1}q)\sigma^{-1}$; by Lemma 5.2.58, (ii) and (i), $c \in N_{<b} \subseteq R^{(b+1)}$, and $(\sigma t^{-1})(qx) = c\,\sigma x$. As $R^{(b+1)}$ is a group, $c\sigma x$ is near at $b+1$. Now $\sigma t^{-1} \in G^{(b)}$ and qx has size j, so Lemma 5.4.3, (i), gives that $(\sigma t^{-1})^{-1}f_b = t\sigma^{-1}f_b$ has size $j+6$.

(ii). Put $\kappa(\sigma) = \mathcal{K}_{b+1}(\sigma x, \sigma y)$. By Lemma 5.2.64, (i) and (ii), κ is measurable and θ_b-integrable, and by (v) there (with $l = b+1 \geq b$), $\kappa(s\sigma) = \kappa(\sigma)$ for $s \in R^{(b+1)} \cap G^{(b)}$. By Lemma 5.2.62 (with $Z = \mathbb{C}$) there is a Borel $f_0 \colon V \to \mathbb{C}$ with $\kappa(\sigma) = f_0(\sigma^{-1}f_b)$ for $\sigma \in G^{(b)}$. Let $f(w) = f_0(t^{-1}w)$ if w has size $j+6$ and $f(w) = 0$ otherwise, and $\phi(w) = \psi(\xi\, h(v_0, w))\, f(w)$; both are Borel, as the set of vectors of size $j+6$ is compact (GU1). For $\sigma \in G^{(b)}$: if $t\sigma^{-1}f_b$ has

size $j+6$, then $f(t\sigma^{-1}f_b) = f_0(\sigma^{-1}f_b) = \kappa(\sigma)$; otherwise $\kappa(\sigma) = 0 = f(t\sigma^{-1}f_b)$ by (i). As θ_b is carried by $G^{(b)}$ (Lemma 5.2.59, (ii)),

$$\kappa(\sigma) = f(t\sigma^{-1}f_b) \qquad \text{for } \theta_b\text{-almost every } \sigma.$$

By Lemma 5.2.63 with $s = t$, the map $\sigma \mapsto t\sigma^{-1}f_b$ carries θ_b to qv_b. Hence f and ϕ are qv_b-integrable, ϕ vanishes outside the vectors of size $j+6$, $\int |\phi|^2\,d\mathrm{qv}_b = \int |f|^2\,d\mathrm{qv}_b = \int |\kappa|^2\,d\theta_b$, and, as $h(v+v_0,w) = h(v,w) + h(v_0,w)$ and ψ is a character,

$$\int_G \psi(\xi\, h(v+v_0, t\sigma^{-1}f_b))\kappa(\sigma)\,d\theta_b(\sigma) = \int_V \psi(\xi\, h(v,w))\,\phi(w)\,d\mathrm{qv}_b(w) \qquad (v \in V).$$

Now Proposition 5.4.31 with $j+6$ in place of j gives the claim. □

Proposition 5.4.31. *Let Γ be a gauge of loss Λ for a place datum of shape (ϱ, ι, m), put $r' = |\iota'|$, let $0 \le b \le \varrho$, let ξ be a unit of A and let ρ be vol_{V_b} or qv_b. For $i, j \ge 0$ and every measurable $\phi\colon V \to \mathbb{C}$ that is qv_b-integrable and vanishes outside the vectors of size j,*

$$\int_{\{v\in V \text{ of size } i\}} \Big|\int_V \psi(\xi\, h(v,y))\,\phi(y)\,d\mathrm{qv}_b(y)\Big|^2 d\rho(v) \le \Lambda^{99n(i+6)}\,\Lambda^{99n(j+6)}\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'} \int_V |\phi|^2\,d\mathrm{qv}_b.$$

Proof. Arithmetic is in $[0,\infty]$. Let $x = (c,t,Y)$, $Y = (\zeta, w, \zeta')$, be the coordinates of $A \times A \times Y_b$, and $\lambda_b(\beta)$, B_b as in Lemma 5.4.4; put $\lambda = \lambda_b(\delta h(f_b,f_b))$, so that $\mathrm{qv}_b = (B_b)_*\lambda$, and let $\rho_0 = \mathrm{vol}$ if $\rho = \mathrm{vol}_{V_b}$ and $\rho_0 = \lambda$ if $\rho = \mathrm{qv}_b$, so that $\rho = (B_b)_*\rho_0$ (Lemma 5.4.4, (iii)). Put $\tilde\phi = \phi \circ B_b$, which is λ-integrable, and let $\square_l$ be the set of x with all coordinates in $A_{(l)}$, a compact set.

Two blocks. By (GU1), $|\iota \setminus \iota'| = 2(2m+2)$; choose disjoint $B, B' \subseteq \iota \setminus \iota'$ with $|B| = |B'| = 2m+2$. For the variable $y = B_b(x)$ write $x = (u, w_{\iota'}, z)$, with $z = (w_k)_{k\in B}$ the block, $w_{\iota'} = (w_k)_{k\in\iota'}$ the inner coordinates and $u \in A^U$ the other (outer) coordinates. For the variable $v = B_b(x')$ write likewise $x' = (u', w'_{\iota'}, z')$ with the block B' and outer coordinates $u' \in A^{U'}$. By Lemma 5.4.4, (i), there are s-finite kernels $(\zeta_{u,w})$ on A^B and $(\zeta'_{u',w'})$ on $A^{B'}$ with $\lambda = \mathrm{vol}\otimes\zeta$, $\rho_0 = \mathrm{vol}\otimes\zeta'$ in the sense of (i) there, and $\zeta_{u,w}(A^B_{(l)}) \le \Lambda^{(2m+2)(l+1)}$, $\zeta'_{u',w'}(A^{B'}_{(l)}) \le \Lambda^{(2m+2)(l+1)}$ for all l (for $\rho_0 = \mathrm{vol}$, $\zeta' = \mathrm{vol}$).

The phase. By Lemma 5.4.4, (iii), $h(B_b(x'), B_b(x)) = \bar c' t + \bar t' c + h'_b(Y', Y)$; in h'_b the coordinates indexed by ι are orthonormal and orthogonal to the others. As B' is disjoint from $\iota' \cup B$, the coordinates w_k, $k \in B'$, of x are outer coordinates, components of u; write $u_{B'}$ for them. Hence

$$h(B_b(x'), B_b(x)) = \overline{w'_{\iota'}}^{\mathsf T} w_{\iota'} + \overline{z'}^{\mathsf T} u_{B'} + a(u', x),$$

where $a(u',x)$ is the sum of the terms of $\bar c' t + \bar t' c + h'_b(Y', Y)$ that contain a coordinate of u'.

Cauchy–Schwarz in the outer coordinates of y. Fix x'. If $\tilde\phi(x) \ne 0$ then $B_b(x)$ has size j, so $x \in \square_{j+4}$ (Lemma 5.4.4, (iii)) and $u \in A^U_{(j+4)}$. The integrand $\psi(\xi h(B_b(x'), B_b(x)))\tilde\phi(x)$ is λ-integrable, so by Fubini for $\lambda = \mathrm{vol}\otimes\zeta$,

$$\int_V \psi(\xi h(v,y))\phi(y)\,d\mathrm{qv}_b(y) = \int_{A^U} \psi(\xi\,\overline{z'}^{\mathsf T} u_{B'})\,F_{u'}(w'_{\iota'}, u)\,du,$$

$$F_{u'}(w', u) = \int_{A^{\iota'}} \psi(\xi\,\overline{w'}^{\mathsf T} w)\,G_{u'}(u,w)\,dw,$$

with $G_{u'}(u,w) = \int_{A^B} \psi(\xi\, a(u', (u,w,z)))\,\tilde\phi(u,w,z)\,d\zeta_{u,w}(z)$, a measurable function that vanishes unless $u \in A^U_{(j+4)}$. As $|\psi| = 1$, Cauchy–Schwarz on $A^U_{(j+4)}$ gives, with $H(u',w') = \int_{A^U} |F_{u'}(w',u)|^2\,du$,

$$\Big|\int_V \psi(\xi h(B_b(x'), y))\phi(y)\,d\mathrm{qv}_b(y)\Big|^2 \le \mathrm{vol}(A_{(j+4)})^{|U|}\,H(u', w'_{\iota'}), \tag{5.89}$$

a bound that does not depend on z'.

Plancherel in the inner coordinates, Cauchy–Schwarz in the block of y. Fix u'. Since $\tilde\phi$ is λ-integrable, $(u,w)\mapsto\int|\tilde\phi(u,w,z)|\,d\zeta_{u,w}(z)$ is integrable, so for almost every u the function $w\mapsto G_{u'}(u,w)$ is integrable on $A^{\iota'}$. By Lemma 5.4.32 (its hypotheses (a)–(c) are (PA3) for 1×1 matrices, (PA4) and (PA5)) with $\eta=\xi$, for almost every u,

$$\int_{A^{\iota'}}|F_{u'}(w',u)|^2\,dw'\le\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'}\int_{A^{\iota'}}|G_{u'}(u,w)|^2\,dw.$$

By Cauchy–Schwarz in z, as $\tilde\phi(u,w,z)\neq0$ forces $z\in A^B_{(j+4)}$,

$$|G_{u'}(u,w)|^2\le\zeta_{u,w}(A^B_{(j+4)})\int|\tilde\phi(u,w,z)|^2\,d\zeta_{u,w}(z)\le\Lambda^{(2m+2)(j+5)}\int|\tilde\phi|^2\,d\zeta_{u,w}.$$

Integrating over u and using Tonelli,

$$\int_{A^{\iota'}}H(u',w')\,dw'\le\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'}\Lambda^{(2m+2)(j+5)}\int|\tilde\phi|^2\,d\lambda=\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'}\Lambda^{(2m+2)(j+5)}\int_V|\phi|^2\,d\mathrm{qv}_b.$$

Integration over v. If $v=B_b(x')$ has size i, then $x'\in\square_{i+4}$ (Lemma 5.4.4, (iii)). By (5.89) and $\rho_0=\mathrm{vol}\otimes\zeta'$,

$$\int_{\{v\text{ of size }i\}}\Big|\int\psi(\xi h(v,y))\phi(y)\,d\mathrm{qv}_b(y)\Big|^2d\rho(v)\le\mathrm{vol}(A_{(j+4)})^{|U|}\cdot\int_{A^{U'}_{(i+4)}}\int_{A^{\iota'}}H(u',w')\,\zeta'_{u',w'}(A^{B'}_{(i+4)})\,dw'\,du',$$

which, by the two bounds above, is at most $\mathrm{vol}(A_{(i+4)})^{|U'|}\Lambda^{(2m+2)(i+5)}\cdot\mathrm{vol}(A_{(j+4)})^{|U|}\Lambda^{(2m+2)(j+5)}\cdot(\mathrm{kb}_A/|\xi|)^{r'}\int|\phi|^2d\mathrm{qv}_b$. Counting coordinates, $|U|+2m+2=|U'|+2m+2=2+2(m+\varrho-b)+|\iota|-|\iota'|=6m+6+2(\varrho-b)\le62n\le99n$ by (GU1) ($m\le9n$, $|\iota|-|\iota'|=2(2m+2)$), $\mathrm{vol}(A_{(l)})\le\Lambda^{l+1}$ (GU5) and $\Lambda\ge2$, so $\mathrm{vol}(A_{(l+4)})^{|U|}\Lambda^{(2m+2)(l+5)}\le\Lambda^{99n(l+5)}\le\Lambda^{99n(l+6)}$ for $l=i,j$, which gives the claim. □

Lemma 5.4.32. *Let A be a commutative ring with an involution $x\mapsto\bar x$, carrying a locally compact Polish topology for which addition, multiplication and the involution are continuous, and let dx be a Haar measure of $(A,+)$. For a finite set ι give A^ι the product measure and write $v^*w=\sum_{i\in\iota}\bar v_iw_i$ for $v,w\in A^\iota$. Let ψ be a continuous homomorphism from $(A,+)$ to the unit circle, and $|\cdot|\colon A\to[0,\infty]$ a measurable map with $|1|=1$, $|xy|=|x|\,|y|$ and $|\bar x|=|x|$. Assume:*

(a) for every unit u of A the image of dx under $x\mapsto ux$ is $|u|^{-1}dx$;

(b) almost every element of A is a unit;

(c) there is a continuous integrable $G\colon A\to[0,\infty)$ with $G(0)=1$ and

$$\int_A\Big|\int_AG(v)\,\psi(\bar vz)\,dv\Big|\,dz\le\mathrm{kb}_A,\qquad\mathrm{kb}_A\in[0,\infty].$$

Then for every unit η of A and every integrable $f\colon A^\iota\to\mathbb{C}$,

$$\int_{A^\iota}\Big|\int_{A^\iota}\psi(\eta\,v^*w)\,f(w)\,dw\Big|^2dv\ \le\ \Big(\frac{\mathrm{kb}_A}{|\eta|}\Big)^{|\iota|}\int_{A^\iota}|f(w)|^2\,dw,$$

in $[0,\infty]$ with $0\cdot\infty=0$.

Proof. For a unit u we have $|u|\,|u^{-1}| = |1| = 1$, so $0 < |u| < \infty$. For $\xi \in A$ and $v \in A^\iota$ put $\mathcal{F}_\xi f(v) = \int_{A^\iota} \psi(\xi\, v^* w) f(w)\, dw$; the integrand is bounded by $|f|$, so $\mathcal{F}_\xi f$ is defined and, by dominated convergence, continuous in v. Let G be as in (c) and put $\widehat{G}_\xi(a) = \int_A G(v)\psi(\bar{v}\xi a)\, dv$ for $a \in A$.

Step 1: the damped inequality. For every $\xi \in A$,

$$\int_{A^\iota} |\mathcal{F}_\xi f(v)|^2 \prod_{i\in\iota} G(v_i)\, dv \le \Big(\int_A |\widehat{G}_\xi(a)|\, da\Big)^{|\iota|} \int_{A^\iota} |f|^2. \tag{5.90}$$

Put $g(v,w,w') = \psi(\xi\, v^*(w'-w)) \prod_i G(v_i)\, \overline{f(w)} f(w')$ on $(A^\iota)^3$. Since $|\psi| = 1$, $|g|$ is the product of $\prod_i G(v_i) \in L^1(A^\iota)$ and $|f(w)||f(w')| \in L^1(A^\iota \times A^\iota)$, so g is integrable. Writing $|\mathcal{F}_\xi f(v)|^2 = \overline{\mathcal{F}_\xi f(v)}\, \mathcal{F}_\xi f(v)$ and using $\overline{\psi(x)} = \psi(-x)$ and additivity of ψ,

$$\Phi(v) := |\mathcal{F}_\xi f(v)|^2 \prod_i G(v_i) = \iint g(v,w,w')\, dw\, dw' \ \ge 0.$$

By Fubini, Φ is integrable and $\int \Phi\, dv = \iint \big(\int g(v,w,w')\, dv\big) dw\, dw'$; as $\int \Phi \ge 0$ this gives $\int \Phi \le \iint \big|\int g(v,w,w')\, dv\big|\, dw\, dw'$. Since $\psi(\xi v^* z) = \prod_i \psi(\bar{v}_i \xi z_i)$, Fubini on the product A^ι gives

$$\int_{A^\iota} \psi(\xi v^* z) \prod_i G(v_i)\, dv = \prod_{i\in\iota} \widehat{G}_\xi(z_i), \qquad z \in A^\iota,$$

so $\big|\int g(v,w,w')\, dv\big| = \prod_i |\widehat{G}_\xi(w_i' - w_i)|\, |f(w)|\, |f(w')|$. The map $(w,z) \mapsto (w, w+z)$ preserves the Haar measure of $A^\iota \times A^\iota$, and by Cauchy–Schwarz and translation invariance $\int |f(w)||f(w+z)|\, dw \le \int |f|^2$ for every z. Hence, by Tonelli,

$$\int \Phi \le \int_{A^\iota} \prod_i |\widehat{G}_\xi(z_i)| \int_{A^\iota} |f(w)||f(w+z)|\, dw\, dz \le \Big(\int_A |\widehat{G}_\xi|\Big)^{|\iota|} \int |f|^2.$$

Step 2: the damped integral at a unit. For every unit u of A,

$$\int_{A^\iota} |\mathcal{F}_\eta f(v)|^2 \prod_i G(\bar{u} v_i)\, dv \le \Big(\frac{\mathrm{kb}_A}{|\eta|}\Big)^{|\iota|} \int |f|^2. \tag{5.91}$$

By (a) applied coordinatewise, the map $v' \mapsto \bar{u}^{-1} v'$ carries the measure of A^ι to $|\bar{u}^{-1}|^{-|\iota|} dv = |u|^{|\iota|} dv$. Since $(\bar{u}^{-1}v')^* w = u^{-1} v'^* w$, we get $\mathcal{F}_\eta f(\bar{u}^{-1}v') = \mathcal{F}_{\eta u^{-1}} f(v')$, and therefore the left side of (5.91) equals

$$|u|^{-|\iota|} \int_{A^\iota} |\mathcal{F}_{\eta u^{-1}} f(v')|^2 \prod_i G(v_i')\, dv' \le |u|^{-|\iota|} \Big(\int_A |\widehat{G}_{\eta u^{-1}}(a)|\, da\Big)^{|\iota|} \int |f|^2$$

by (5.90). Now $\widehat{G}_{\eta u^{-1}}(a) = \widehat{G}_1(\eta u^{-1} a)$, and by (a) for the unit ηu^{-1} and (c),

$$\int_A |\widehat{G}_1(\eta u^{-1} a)|\, da = |\eta u^{-1}|^{-1} \int_A |\widehat{G}_1(z)|\, dz \le |u|\, |\eta|^{-1} \mathrm{kb}_A.$$

Inserting this, the powers of $|u|$ cancel and (5.91) follows.

Step 3: removing the damping. By (b) the non-units form a null set; a Haar measure gives positive mass to every nonempty open set, so every neighbourhood of 0 contains a unit. As A is metrizable, there are units $u_k \to 0$. For each v, continuity of G, of the involution and of multiplication give $\prod_i G(\bar{u}_k v_i) \to G(0)^{|\iota|} = 1$, hence $|\mathcal{F}_\eta f(v)|^2 = \liminf_k |\mathcal{F}_\eta f(v)|^2 \prod_i G(\bar{u}_k v_i)$. The functions on the right are nonnegative and measurable, so Fatou's lemma and (5.91) give

$$\int_{A^\iota} |\mathcal{F}_\eta f|^2 \le \liminf_k \int_{A^\iota} |\mathcal{F}_\eta f(v)|^2 \prod_i G(\bar{u}_k v_i)\, dv \le \Big(\frac{\mathrm{kb}_A}{|\eta|}\Big)^{|\iota|} \int |f|^2.$$

□

Lemma 5.4.33. *Let a place datum be given and suppose that the group measure θ is a left Haar measure of G. Let ρ, μ be s-finite Borel measures on G with $\theta = \rho * \mu$, let S be a closed subgroup of G with $\rho(G \setminus S) = 0$ and $\rho * \delta_t = \rho$ for every $t \in S$, and let $s \in G$ with $\delta_s * \rho = \rho * \delta_s$. Then for every measurable $\Phi\colon G \to [0,\infty]$ with $\Phi(tg) = \Phi(g)$ for all $t \in S$ and $g \in G$,*

$$\int_G \Phi(sg)\, d\mu(g) = \int_G \Phi\, d\mu.$$

Proof. G is a closed subset of a finite product of copies of the locally compact Polish space A, hence a second countable locally compact group, and its Haar measure θ is σ-finite and not zero. Choose a measurable $f\colon G \to (0,\infty)$ with $\int f\, d\theta < \infty$, and put $\mathrm{av}(g) = \int f(yg)\, d\rho(y) \in [0,\infty]$, a measurable function by Tonelli's theorem.

Properties of av. For $t \in S$, $\mathrm{av}(tg) = \int f(ytg)\, d\rho(y) = \int f(yg)\, d(\rho * \delta_t)(y) = \mathrm{av}(g)$. Since $\theta = \rho * \mu \neq 0$, $\rho \neq 0$, and as $f > 0$, $\mathrm{av}(g) > 0$ for every g.

A formula for μ. Let μ' be any s-finite measure with $\theta = \rho * \mu'$. Then $\int \mathrm{av}\, d\mu' = \int f\, d\theta < \infty$, so $\mathrm{av} < \infty$ μ'-almost everywhere, and by Tonelli's theorem, using $\rho(G \setminus S) = 0$ and the S-invariance of Φ and av,

$$\int_G \frac{\Phi f}{\mathrm{av}}\, d\theta = \int_G \int_G \frac{\Phi(yg)\, f(yg)}{\mathrm{av}(yg)}\, d\rho(y)\, d\mu'(g) = \int_G \frac{\Phi(g)}{\mathrm{av}(g)}\, \mathrm{av}(g)\, d\mu'(g) = \int_G \Phi\, d\mu'.$$

The left side does not depend on μ'.

Conclusion. The measure $\delta_s * \mu$ is s-finite and, by associativity of convolution, $\rho * (\delta_s * \mu) = (\rho * \delta_s) * \mu = (\delta_s * \rho) * \mu = \delta_s * \theta = \theta$, the last equality by left invariance of θ. Applying the formula to $\mu' = \delta_s * \mu$ and to $\mu' = \mu$ gives $\int \Phi(sg)\, d\mu(g) = \int \Phi\, d(\delta_s * \mu) = \int \Phi\, d\mu$. □

Proposition 5.4.34. *Let Γ be a gauge of loss Λ for a place datum, with size filtration $(A_{(i)})$, and suppose that the group measure θ is a Haar measure of G; put $r' = |\iota'|$. Let $W\colon G \to \mathbb{C}^I$ be cut, $j \le \varrho$, p a head of length j, q a sequence of units and $x \in \mathcal{P}_{\mathrm{pos}}$. If ξ is a unit, $\eta \in A$ and $\psi(\eta z) = \psi(\xi z)$ for every $z \in A_{(200n^2)}$, then*

$$\mathrm{FN}_j(p,q,W,x;\, g \mapsto \psi(\eta\, h(f_j, gf_j)))^2 \le \Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'} \mathrm{WSP}_j(p,q,W,x),$$

with WSP_j *formed for* Γ.

Proof. Write $w_p = w_{j,p}$, $d = w_{j,q}^{-1} w_p$, $\omega(g) = \psi(\eta\, h(f_j, gf_j))$, $\mathcal{K}_1 = \mathcal{K}_W$, $\mathcal{K}_2 = \mathcal{K}_W^d$ (pairing kernels at floor j, Lemma 5.2.57 (ii), hence at floor $j+1$, Lemma 5.2.64 (iv)). By Lemma 5.4.6 (ii) with $C = (\mathrm{kb}_A/|\xi|)^{r'}$ and $f(g) = |\mathrm{FI}_j(p,q,W,x;\omega)(g)|$ (so that $\mathrm{FN}_j = \int f\, d\mathfrak{m}_j$), and by Lemma 5.4.16 (iv) at g and at $z = w_p^{-1} g$, it suffices to show for every g with $f(g) \neq 0$:

$$\begin{aligned} f(g)^2 &\le \Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'} c_{\mathrm{fls}} \int_G |F_1|^2\, d\theta_j \int_G |F_2|^2\, d\theta_j, \\ F_1(\sigma) &= \mathcal{K}_{1,j+1}(\sigma g, \sigma g x),\ F_2(\tau) = \mathcal{K}_{2,j+1}(\tau z, \tau z x). \end{aligned} \tag{5.92}$$

Fix such a g. Since σ, τ are isometries, $\omega(\sigma\tau^{-1}) = \psi(\eta\, h(\sigma^{-1} f_j, \tau^{-1} f_j))$, so by (5.14)

$$\mathrm{FI}_j(p,q,W,x;\omega)(g) = \int_G \int_G \psi(\eta\, h(\sigma^{-1} f_j, \tau^{-1} f_j))\, F_1(\sigma)\, \overline{F_2(\tau)}\, d\theta_j(\tau)\, d\theta_j(\sigma),$$

each integral being 0 where its integrand is not integrable.

A common translate of bounded size. As the double integral is not 0 and θ_j is carried by $G^{(j)}$ (Lemma 5.2.59 (ii)), there are $\sigma_0, \tau_0 \in G^{(j)}$ with $F_1(\sigma_0) \neq 0 \neq F_2(\tau_0)$. By (PK5) at $j+1$, $\sigma_0 g$ and $\tau_0 z$ are near at $j+1$, hence g and $z = w_p^{-1} g$ are near at j (as $\sigma_0, \tau_0 \in G^{(j)} \subseteq R^{(j)}$ and $R^{(j+1)} \subseteq R^{(j)}$, Lemma 5.2.58 (i)). By Lemma 5.4.12 (iii) there is $t \in G^{(j)}$ with tg of size $60n^2$ and tz of size $99n^2$.

Supports and the phase. By Lemma 5.4.30 (i) (floor $b = j$, $q = t$), for $\sigma, \tau \in G^{(j)}$: if $F_1(\sigma) \neq 0$ then $t\sigma^{-1} f_j$ has size $60n^2+6$, and if $F_2(\tau) \neq 0$ then $t\tau^{-1} f_j$ has size $99n^2+6$. For such σ, τ, $h(\sigma^{-1} f_j, \tau^{-1} f_j) = h(t\sigma^{-1} f_j, t\tau^{-1} f_j)$ has size $159n^2+15 \leq 200n^2$ (a pairing of vectors of sizes i, i' has size $i+i'+3$), so the hypothesis on η gives $\psi(\eta\, h(\sigma^{-1} f_j, \tau^{-1} f_j)) = \psi(\xi\, h(t\sigma^{-1} f_j, t\tau^{-1} f_j))$. Put, for $v \in V$,

$$G_2(v) = \int_G \psi(-\xi\, h(v, t\tau^{-1} f_j)) F_2(\tau)\, d\theta_j(\tau) \qquad \text{(0 if the integrand is not integrable).}$$

For θ_j-almost every σ with $F_1(\sigma) \neq 0$, the integrands of $\int \psi(\eta h(\sigma^{-1} f_j, \tau^{-1} f_j)) F_1(\sigma) \overline{F_2(\tau)}\, d\theta_j(\tau)$ and of $F_1(\sigma) \overline{G_2(t\sigma^{-1} f_j)}$ (as $\overline{\psi(a)} = \psi(-a)$) agree for θ_j-almost every τ and have the same modulus $|F_1(\sigma) F_2(\tau)|$; so the inner integral equals $F_1(\sigma) \overline{G_2(t\sigma^{-1} f_j)}$, and both vanish where $F_1(\sigma) = 0$. With $S = \{\sigma : t\sigma^{-1} f_j \text{ has size } 60n^2 + 6\}$, which contains almost every σ with $F_1(\sigma) \neq 0$, and the Cauchy–Schwarz inequality,

$$f(g)^2 \leq \Big(\int_S |F_1(\sigma)|\, |G_2(t\sigma^{-1} f_j)|\, d\theta_j(\sigma) \Big)^2 \leq \int_G |F_1|^2\, d\theta_j \cdot \int_S |G_2(t\sigma^{-1} f_j)|^2\, d\theta_j(\sigma).$$

Plancherel. By Lemma 5.2.63, the image of θ_j under $\sigma \mapsto t\sigma^{-1} f_j$ is qv_j, so the last integral is $\int_{\{v \text{ of size } 60n^2+6\}} |G_2|^2\, d\mathrm{qv}_j$. By Lemma 5.4.30 (ii) for the kernel $\mathcal{K}_2$ at floor j, t, $q = t$, the points z, zx (with tz of size $99n^2$), the unit $-\xi$ ($|-\xi| = |\xi|$ by (PA2)), $v_0 = 0$, $i = 60n^2 + 6$ and $\rho = \mathrm{qv}_j$, it is at most

$$\Lambda^{99n(60n^2+12)} \Lambda^{99n(99n^2+12)} \Big(\frac{\mathrm{kb}_A}{|\xi|} \Big)^{r'} \int_G |F_2|^2\, d\theta_j \leq c_{\mathrm{fls}} \Big(\frac{\mathrm{kb}_A}{|\xi|} \Big)^{r'} \int_G |F_2|^2\, d\theta_j,$$

since $99n(159n^2 + 24) \leq 10^6 n^3$. This proves (5.92). □

Proposition 5.4.35. *Let Γ be a gauge of loss Λ for a place datum, and suppose that the group measure θ is a Haar measure of G; put $r' = |\iota'|$. Let $W \colon G \to \mathbb{C}^I$ be cut, $j = i+1 \leq \varrho$, p a head of length j, q a sequence of units and $x \in \mathcal{P}_{\mathrm{pos}}$. If $\xi = M^{-1}(p_i^{-1} - q_i^{-1})$ is a unit, then*

$$\mathrm{FN}_j(p, q, W, x; 1)^2 \leq \Big(\frac{\mathrm{kb}_A}{|\xi|} \Big)^{r'} \mathrm{WSP}_j(p, q, W, x),$$

with WSP_j formed for Γ.

Proof. Put $w = w_{j,p}$, $d = w_{j,q}^{-1} w$, $\mathcal{K}_1 = \mathcal{K}_W$, $\mathcal{K}_2 = \mathcal{K}_W^d$ (pairing kernels at floor i and at floor j, Lemma 5.2.57 (ii)), $\Theta = \theta_i * \cdots * \theta_0$, $C = (\mathrm{kb}_A/|\xi|)^{r'}$, $\varphi_1(g) = |\mathcal{K}_{1,i+1}(g, gx)|$ and $\varphi_2(g) = |\mathcal{K}_{2,i+1}(g, gx)|$, measurable by Lemma 5.2.64 (i). By Lemma 5.2.57 (iii), $|\mathrm{FI}_j(p, q, W, x; 1)(g)| = \varphi_1(g) \varphi_2(w^{-1} g)$, so $\mathrm{FN}_j(p, q, W, x; 1) = \int \varphi_1(g) \varphi_2(w^{-1} g)\, d\mathfrak{m}_{i+1}(g)$. We apply Lemma 5.4.36 with $B = \mathrm{WSS}_{i+1}(\mathcal{K}_2, x)$.

Invariance and support. $\mathrm{dpw}_i(g, x) \varphi_1(g)^2 = \mathrm{WSq}_i(\mathcal{K}_1, x)(g)$ and B are invariant under left multiplication by $R^{(i+1)}$ and vanish off the points near at $i+1$, by Lemma 5.4.16 (iii) (at the floors i and $i+1$). For $\sigma \in G^{(i+1)} \subseteq R^{(i+1)} \cap G^{(j)}$, $\varphi_2(\sigma g) = \varphi_2(g)$ by Lemma 5.2.64 (v), and $\varphi_2(g) \neq 0$ forces g near at $i+1$ by (PK5). All three are measurable (Lemma 5.4.16 (ii)).

The section bound. For $g \in G$, Lemma 5.4.37 with $y = gx$, $C = 1$ and $\Phi(n) = \mathbf{1}\{wng \text{ near at } i+1\}\varphi_2(ng)^2$ (note $\varphi_2(ng) = |\mathcal{K}_{2,i+1}(ng, n(gx))|$), followed by Lemma 5.4.16 (iv) at $i+1 \le \varrho$, gives

$$\int_{\{n:\, wng \text{ near at } i+1\}} \varphi_2(ng)^2 \, d\eta_i(n) \le C \,\mathrm{fm}(i, p_i^{-1})\, c_{\mathrm{fls}} \int |\mathcal{K}_{2,i+2}(\sigma g, \sigma g x)|^2 \, d\theta_{i+1}(\sigma)$$
$$\le C \,\mathrm{fm}(i, p_i^{-1})\, c_{\mathrm{fls}} \frac{B(g)}{\mathrm{dpw}_{i+1}(g,x)}.$$

Conclusion. Lemma 5.4.36 gives

$$\mathrm{FN}_j(p,q,W,x;1)^2 \le C\Big(\prod_{a<j} \mathrm{fm}(a, p_a^{-1})\Big)^2 c_{\mathrm{fls}}^3 \int \mathrm{WSq}_i(\mathcal{K}_1, x)\, d\Theta \int \mathrm{WSS}_{i+1}(\mathcal{K}_2, x)\, d\Theta.$$

By Lemma 5.4.16 (vi),

$$\int \mathrm{WSq}_i(\mathcal{K}_1, x)\, d\Theta \le \mathrm{WSI}_i(\mathcal{K}_1, x) \le \mathrm{WSI}_0(\mathcal{K}_1, x),$$

and $\int \mathrm{WSS}_{i+1}(\mathcal{K}_2, x)\, d\Theta = \mathrm{WSI}_j(\mathcal{K}_2, x)$ by definition; so the right side is at most $C\,\mathrm{WSP}_j(p,q,W,x)$. □

Lemma 5.4.36. *Let Γ be a gauge of loss Λ for a place datum, and suppose that the group measure θ is a Haar measure of G. Let $x \in \mathcal{P}_{\mathrm{pos}}$, $i+1 \le \varrho$, p a head of length $i+1$, $w = w_{i+1,p}$, $\Theta = \theta_i * \cdots * \theta_0$, $C \in [0,\infty]$, and let $\varphi_1, \varphi_2, B \colon G \to [0,\infty]$ be measurable with:*

- *$g \mapsto \mathrm{dpw}_i(g,x)\varphi_1(g)^2$ and B are invariant under left multiplication by $R^{(i+1)}$, φ_2 is invariant under left multiplication by $G^{(i+1)}$, and all three vanish at the points that are not near at $i+1$;*
- *for every $g \in G$,*

$$\int_{\{n:\ wng \text{ near at } i+1\}} \varphi_2(ng)^2 \, d\eta_i(n) \le C \,\mathrm{fm}(i, p_i^{-1})\, c_{\mathrm{fls}} \, \frac{B(g)}{\mathrm{dpw}_{i+1}(g,x)}.$$

Then, with arithmetic in $[0,\infty]$,

$$\Big(\int_G \varphi_1(g)\, \varphi_2(w^{-1}g)\, d\mathfrak{m}_{i+1}(g)\Big)^2 \le C\Big(\prod_{a\le i} \mathrm{fm}(a, p_a^{-1})\Big)^2 c_{\mathrm{fls}}^3 \int_G \mathrm{dpw}_i(g,x)\varphi_1(g)^2\, d\Theta(g) \int_G B\, d\Theta.$$

Proof. Write $\mathrm{dpw}_l^- = \mathrm{dpw}_{l,x}^-$, $w' = w_{i,p}$ and N_l for the closed set of points near at l. All functions below are measurable (Lemma 5.4.8 (iii)), and the measures are s-finite.

Two facts on Weyl elements. (1) $w = w' w_i(p_i)$, where the floor Weyl element $w_i(p_i)$ fixes the coordinate vectors of floor below i; so $w'w^{-1} = w_i(p_i)^{-1} \in G^{(i)} \subseteq R^{(i)}$, and for $g \in N_{i+1} \subseteq N_i$, by Lemma 5.4.8 (iii), $\mathrm{dpw}_i^-(w'w^{-1}g) = \mathrm{dpw}_i^-(g) = \mathrm{dpw}_i(g,x)^{-1}$. (2) $w^{-1} = w_{i+1,\bar{p}}$ with $\bar{p} = (\bar{p}_a)_a$, a head of length $i+1$ with $\mathrm{fm}(a, \bar{p}_a^{-1}) = \mathrm{fm}(a, p_a^{-1})$ (SZ3), (PA2). Elements of $G^{(i+1)}$ (resp. $G^{(i)}$) commute with w (resp. w') by Lemma 5.2.58 (ix).

Crossing the weights. Put $r(g) = \mathrm{dpw}_{i+1}(g,x)\,\mathrm{dpw}_i^-(w'g)$ and $u = \mathbf{1}_{\{g:\, wg \in N_{i+1}\}}\, r\, \varphi_2^2$. We claim for every g

$$\big(\varphi_1(g)\varphi_2(w^{-1}g)\big)^2 \le \big[\mathrm{dpw}_i(g,x)\varphi_1(g)^2\, \mathrm{dpw}_{i+1}^-(w^{-1}g)\big] \cdot u(w^{-1}g).$$

If $g \notin N_{i+1}$, then $\mathrm{dpw}_i(g,x)\varphi_1(g)^2 = 0$ and $0 < \mathrm{dpw}_i < \infty$, so $\varphi_1(g) = 0$. If $w^{-1}g \notin N_{i+1}$, then $\varphi_2(w^{-1}g) = 0$. Otherwise $\mathrm{dpw}^-_{i+1}(w^{-1}g) = \mathrm{dpw}_{i+1}(w^{-1}g,x)^{-1}$, and by (1)

$$u(w^{-1}g) = \mathrm{dpw}_{i+1}(w^{-1}g,x)\,\mathrm{dpw}_i(g,x)^{-1}\varphi_2(w^{-1}g)^2;$$

the right side is then $\varphi_1(g)^2\varphi_2(w^{-1}g)^2$. By the Cauchy–Schwarz inequality the square of the integral is at most $I_1 I_2$, with

$$I_1 = \int \mathrm{dpw}_i(g,x)\varphi_1(g)^2 \mathrm{dpw}^-_{i+1}(w^{-1}g)\,d\mathfrak{m}_{i+1}(g) \quad \text{and} \quad I_2 = \int u(w^{-1}g)\,d\mathfrak{m}_{i+1}(g).$$

By Lemma 5.2.59 (iv) and Lemma 5.4.14 (ii), $\mathfrak{m}_{i+1} = \eta_{<i+1} * \Theta = \eta_i * \eta_{<i} * \Theta$.

The first integral. By (2) and Lemma 5.4.7 (iv) (length and b equal to $i+1$, head $\bar{p}$, $\rho = \Theta$, the function $\mathrm{dpw}_i(\cdot,x)\varphi_1^2$), $I_1 \le (\prod_{a\le i} \mathrm{fm}(a,p_a^{-1}))c_{\mathrm{fls}} \int \mathrm{dpw}_i(g,x)\varphi_1(g)^2\,d\Theta(g)$.

The second integral. u is invariant under left multiplication by $G^{(i+1)}$: for $\sigma \in G^{(i+1)} \subseteq R^{(i+1)}$, $w\sigma g = \sigma w g$ and N_{i+1} is $R^{(i+1)}$-invariant; $\mathrm{dpw}_{i+1}(\sigma g,x) = \mathrm{dpw}_{i+1}(g,x)$; $\mathrm{dpw}^-_i(w'\sigma g) = \mathrm{dpw}^-_i(\sigma w' g) = \mathrm{dpw}^-_i(w'g)$; and $\varphi_2(\sigma g) = \varphi_2(g)$. By Lemma 5.4.15 (ii) and the factorisation of $\mathfrak{m}_{i+1}$,

$$I_2 = \int u\,d\mathfrak{m}_{i+1} = \int_G \int_G u(ng)\,d\eta_i(n)\,d(\eta_{<i} * \Theta)(g).$$

η_i is carried by the Heisenberg elements n of floor i, which lie in $G^{(i)} \cap N_{<i+1}$ (Lemma 5.2.58 (iii)); for them $r(ng) = r(g)$ (as $n \in R^{(i+1)}$, and $w'n = nw'$ with $n \in R^{(i)}$). Hence, by the hypothesis on φ_2,

$$\int u(ng)\,d\eta_i(n) = r(g)\int_{\{n:\, wng \in N_{i+1}\}} \varphi_2(ng)^2\,d\eta_i(n) \le C\,\mathrm{fm}(i,p_i^{-1})\,c_{\mathrm{fls}}\,B(g)\,\mathrm{dpw}^-_i(w'g),$$

using $0 < \mathrm{dpw}_{i+1}(g,x) < \infty$. By Lemma 5.4.7 (iv) (length i, $b = i+1$, the head p of length i, $\rho = \Theta$, the function B),

$$I_2 \le C\,\mathrm{fm}(i,p_i^{-1})\,c_{\mathrm{fls}}\Big(\prod_{a<i} \mathrm{fm}(a,p_a^{-1})\Big)c_{\mathrm{fls}} \int B\,d\Theta.$$

Multiplying the bounds for I_1 and I_2 gives the claim. □

Lemma 5.4.37. *Let Γ be a gauge of loss Λ for a place datum, put $r' = |\iota'|$, let $W\colon G \to \mathbb{C}^I$ be cut, $i+1 \le \varrho$, p a head of length $i+1$, q a sequence of units, $w_p = w_{i+1,p}$, $d = w^{-1}_{i+1,q}w_p$, and let $\xi = M^{-1}(p_i^{-1} - q_i^{-1})$ be a unit. Let $g, y \in G$, $C \in [0,\infty]$ and $\Phi\colon G \to [0,\infty]$ Borel such that for every Heisenberg element n of floor i with $\Phi(n) \ne 0$, $w_p ng$ is near at $i+1$ and $\Phi(n) \le C\,|\mathcal{K}^d_{W,i+1}(ng,ny)|^2$. Then*

$$\int_G \Phi\,d\eta_i \le C\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'} \mathrm{fm}(i,p_i^{-1})\,c_{\mathrm{fls}} \int_G |\mathcal{K}^d_{W,i+2}(\sigma g,\sigma y)|^2\,d\theta_{i+1}(\sigma).$$

Proof. Write $\mathcal{K} = \mathcal{K}^d_W$, a pairing kernel at floor $i+1$ for d (Lemma 5.2.57 (ii)), and $E_{<i} = \mathrm{span}\{e_b : b < i\}$. We apply Proposition 5.4.28 with $a = i$, $\varepsilon_0 = 1$, the units $\xi' = -\xi p_i$ and $u = p_i^{-1}$, the points g, y, the size indices $99n^2$ (for i there) and $999n^2$ (for j there), the constant C, the function Φ, and

$$S = \{n \text{ a Heisenberg element of floor } i :\ w_p ng \text{ and } ng \text{ are near at } i+1\}.$$

The frequency. By Lemma 5.4.29 (ii) with $j = i+1$, $a = i < j$ and $\varepsilon_0 = 1$, the hypothesis of Proposition 5.4.28 holds with $M^{-1}(p_i q_i^{-1} - 1)$, and $M^{-1}(p_i q_i^{-1} - 1) = -M^{-1}(p_i^{-1} - q_i^{-1})p_i = \xi'$.

Hypothesis (a). If $\Phi(n) \neq 0$, then $\mathcal{K}_{i+1}(ng, ny) \neq 0$, so ng is near at $i+1$ by (PK5); with the hypothesis, $n \in S$, and $\Phi(n) \leq C|\mathcal{K}_{i+1}(n^1 g, ny)|^2$.

Sizes on S. Let $n \in S$. As $w_p ng$ and $w_p^{-1}(w_p ng) = ng$ are near at $i+1$, Lemma 5.4.12 (iii) (length $i+1$, head p, point $w_p ng$) gives $t_n \in G^{(i+1)}$ with $t_n ng$ of size $99n^2$, and Lemma 5.4.12 (i) gives $p_i \in A_{(10n)}$.

Hypothesis (b). Let $n_0 \in S$ and $t_0 = t_{n_0}$; then $t_0 \in G^{(i+1)} \subseteq R^{(i+1)} \cap G^{(i)}$, $n_0 \in N_{<i+1}$ (Lemma 5.2.58 (iii)), and $t_0 n_0 g$ has size $99n^2$. Let $n \in S$, $t = t_n$, and $v = (t_0 n_0 (t_0 n)^{-1} - 1)e_i^*$; we take $w = v$, so $w - v = 0 \in E_{<i}$. As t^{-1} and t_0^{-1} lie in $G^{(i+1)}$, they fix e_i^* (floor i), so

$$v = (t_0 n_0 n^{-1} t_0^{-1} - 1)e_i^* = (t_0 n_0 n^{-1} - 1)e_i^* = \big((t_0 n_0 g)(tng)^{-1} - 1\big)e_i^*.$$

The matrix $(t_0 n_0 g)(tng)^{-1} - 1$ has size $99n^2 + (99n^2 + 4) + 1 + 1$ (inverses of elements of G add 4, products add 1, a difference adds 1), so v has size $198n^2 + 6$ and $u^{-1}v = p_i v$ has size $10n + 198n^2 + 6 \leq 999n^2$.

Conclusion. Proposition 5.4.28 gives, with $|\xi' u| = |-\xi| = |\xi|$ (PA2),

$$\int_G \Phi \, d\eta_i \leq C\Big(\frac{\mathrm{kb}_A}{|\xi|}\Big)^{r'} \mathrm{fm}(i, p_i^{-1}) \Lambda^{100n(99n^2+999n^2+31)} \int_G |\mathcal{K}_{i+2}(\sigma g, \sigma y)|^2 \, d\theta_{i+1}(\sigma),$$

and $100n(1098n^2 + 31) \leq 10^6 n^3$. □

Proposition 5.4.38. *Let Γ and S be gauges for a place datum, with size filtrations $(A_{(i)})$ and $(A^S_{(i)})$; sizes refer to Γ unless S is named. Let $j \leq \varrho$ and let p, q be heads of length j for S; if $j \neq 0$, assume $M^{-1} \in A^S_{(1)}$ and $A^S_{(10n)} \subseteq A_{(1)}$. Let $x, y \in G$ and $u, v \in \mathsf{U}$ with $ux \in K$, $vxy \in K$ and $M^{-1}(vxy - ux)$ of size 2, and let $w_{j,p}^{-1}x$ and $w_{j,q}^{-1}xy$ be near at j. If for every a with $j \leq a < \varrho$ the set $\mathfrak{d}_a(x, y)$ contains a unit c with $c^{-1} \in A_{(1)}$, then $M^{-1}(y-1)$ has size $99n$.*

Proof. Write $E_{<l} = \mathrm{span}\{e_b : b < l\}$. We use the size rules of Lemma 5.4.39 (a matrix of size i maps vectors of size i' to vectors of size $i + i' + 1$; inverses of elements of G of size i have size $i + 4$), for either size filtration. Elements of K have size 1 for Γ and for S (GU2), so their inverses have size 5.

Step 1: every $\mathfrak{d}_a(x, y)$, $a < \varrho$, contains a unit c with $c^{-1} \in A_{(1)}$. For $a \geq j$ this is the hypothesis. Let $a < j$; then $j \neq 0$. Let (z, r, s) be (x, p, u) or (xy, q, v). By Lemma 5.2.58 (i), $\mathsf{U} \subseteq R^{(j)}$, so $s \in R^{(j)}$ with $sz \in K$, and $w_{j,r}^{-1}z$ is near at j; by Lemma 5.4.12 (i) for the gauge S and the head r, the column se_a^* has S-size $8\varrho + 1$. Hence $z^{-1}e_a^* = (sz)^{-1}(se_a^*)$ has S-size $8\varrho + 7$. As $M^{-1} \in A^S_{(1)}$, (GU4) for S gives a unit c with $c^{-1} \in A^S_{(8\varrho+9)}$ and $(c\omega_1, c\omega_2) \in \mathcal{P}_{\mathrm{cl}}$ for all ω_1, ω_2 of S-size $8\varrho + 7$. For $\omega = ce_a^*$ we get $(x^{-1}\omega, (xy)^{-1}\omega) \in \mathcal{P}_{\mathrm{cl}}$, $h(e_b, \omega) = 0$ for $b < a$ and $h(e_a, \omega) = c$; so $c \in \mathfrak{d}_a(x, y)$ (with $\omega' = \omega$). Finally $c^{-1} \in A^S_{(8\varrho+9)} \subseteq A^S_{(10n)} \subseteq A_{(1)}$.

Step 2: every e_a, $a < \varrho$, is 5-balanced for (x, xy) modulo M (in the sense of Lemma 5.4.39; $M \in A_{(1)}$ by (GU2)). *Lifts.* Put $f = u^{-1}e_a$ and $f' = v^{-1}e_a$. Since $u^{-1} \in \mathsf{U}$, its column at e_a agrees with that of 1 in every row of level at least a, and the indices of level below a are the e_b, $b < a$; so $f \in e_a + E_{<a}$, and likewise f'. Moreover $x^{-1}f = (ux)^{-1}e_a$ and $(xy)^{-1}f' = (vxy)^{-1}e_a$ are columns of inverses of elements of K, of size 5. *Dual.* By Step 1 take a unit $c \in \mathfrak{d}_a(x, y)$ with $c^{-1} \in A_{(1)}$: $c = h(e_a, \omega)$ with $h(e_b, \omega) = 0$ for $b < a$ and $(x^{-1}\omega, (xy)^{-1}\omega') \in \mathcal{P}_{\mathrm{cl}}$ for some $\omega' \in \omega + E_{<a}$. By (GU3), $x^{-1}\omega$ and $M^{-1}(x^{-1}\omega - (xy)^{-1}\omega')$

have size 1. Put $\zeta = c^{-1}\omega$ and $\zeta' = c^{-1}\omega' \in \zeta + E_{<a}$: then $h(e_b, \zeta) = 0$ for $b < a$, $h(e_a, \zeta) = 1$, and $x^{-1}\zeta$, $M^{-1}(x^{-1}\zeta - (xy)^{-1}\zeta')$ have size $2 \le 5$ (SZ1).

Step 3: the lengths at x and xy differ by at most 9 modulo M from ϱ on. Let $\omega \in V$ with $h(e_b, \omega) = 0$ for $b < \varrho$, and $x^{-1}\omega$ of size i. Put $\omega' = v^{-1}u\omega$. As $v^{-1}u \in \mathsf{U}$, the row of $v^{-1}u$ at an index k of level at least ϱ agrees with that of 1 except at columns of level above that of k, which are among the e_b^*; and the e_b^*-coordinate of ω is $h(e_b, \omega) = 0$. So ω' and ω agree at all indices of level at least ϱ, that is, $\omega' - \omega \in E_{<\varrho}$. Moreover

$$M^{-1}(x^{-1}\omega - (xy)^{-1}\omega') = (vxy)^{-1}\, M^{-1}(vxy - ux)\, x^{-1}\omega,$$

since $(vxy)^{-1}(vxy - ux)x^{-1}\omega = x^{-1}\omega - (vxy)^{-1}u\omega$ and $(vxy)^{-1}u = (xy)^{-1}v^{-1}u$. The matrix $(vxy)^{-1}M^{-1}(vxy - ux)$ has size $5 + 2 + 1 = 8$, so the vector has size $i + 9$.

Step 4: conclusion. By Lemma 5.4.39 (ii) with $g = x$, $g' = xy$, the index ϱ, $c = 5$ and $t = 9$ (Steps 2 and 3), the lengths at x and xy differ by at most $9 + 32\varrho$ modulo M from 0 on; by Lemma 5.4.39 (iii), $M^{-1}(y - 1)$ has size $13 + 32\varrho \le 99n$. □

Lemma 5.4.39. *Let a place datum be given, let $(A_{(i)})_{i\ge 0}$ be a size filtration, assume that the level unit M lies in $A_{(1)}$, and let $g, g' \in G$; write $E_{<l} = \operatorname{span}\{e_b : b < l\}$. For $0 \le l \le \varrho$ and $t \ge 0$ say that the* lengths at g and g' differ by at most t modulo M from l on *if for every $i \ge 0$ and every $\omega \in V$ with $h(e_b, \omega) = 0$ for all $b < l$ and $g^{-1}\omega$ of size i there is $\omega' \in \omega + E_{<l}$ such that $M^{-1}(g^{-1}\omega - g'^{-1}\omega')$ has size $i + t$. For $a < \varrho$ and $c \ge 0$ say that e_a is* c-balanced for (g, g') modulo M *if*

- *there are $f, f' \in e_a + E_{<a}$ such that $g^{-1}f$ and $g'^{-1}f'$ have size c, and*
- *there is $\zeta \in V$ with $h(e_b, \zeta) = 0$ for $b < a$, $h(e_a, \zeta) = 1$ and $g^{-1}\zeta$ of size c, and some $\zeta' \in \zeta + E_{<a}$ such that $M^{-1}(g^{-1}\zeta - g'^{-1}\zeta')$ has size c.*

(i) Let $a < \varrho$, $c, t \ge 0$, and let e_a be c-balanced for (g, g') modulo M. If the lengths at g and g' differ by at most t modulo M from $a + 1$ on, they differ by at most $t + 4c + 12$ modulo M from a on.

(ii) Let $j \le \varrho$, $c, t \ge 0$, and let e_a be c-balanced for (g, g') modulo M for every $a < j$. If the lengths at g and g' differ by at most t modulo M from j on, they differ by at most $t + (4c + 12)j$ modulo M from 0 on.

(iii) Let $x \in G$ and $t \ge 0$. If the lengths at g and gx differ by at most t modulo M from 0 on, then $M^{-1}(x - 1)$ has size $t + 4$.

Proof. We use the size rules: a product of entries of sizes i and i' has size $i + i'$ (SZ1); a sum of at most $r + 1$ elements of size i has size $i + 1$, so $A_{(i)} \subseteq A_{(i+1)}$, and negatives and conjugates keep the size (SZ2), (SZ3); hence a matrix of size i maps vectors of size i' to vectors of size $i + i' + 1$, and, as J has size 1 (SZ5), $h(v, w) = \bar{v}^{\mathsf{T}} J w$ has size $i + i' + 3$ when v has size i and w size i'. Since $J_{e_a e_b} = 0$ and $h(e_b, w)$ is the e_b^*-coordinate of w, we have: $h(\epsilon, w) = 0$ for $\epsilon \in E_{<l}$ whenever $h(e_b, w) = 0$ for all $b < l$, and $h(e_a, \epsilon) = 0$ for $\epsilon \in E_{<\varrho}$.

(i). Let f, f', ζ, ζ' be as in the definition of balance, let $i \ge 0$, and let $\omega \in V$ with $h(e_b, \omega) = 0$ for $b < a$ and $g^{-1}\omega$ of size i. Put $\alpha = h(e_a, \omega)$. As $f - e_a \in E_{<a}$, $\alpha = h(f, \omega) = h(g^{-1}f, g^{-1}\omega)$, so $\alpha \in A_{(c+i+3)}$. Put $\omega_0 = \omega - \alpha\zeta$. Then $h(e_b, \omega_0) = 0$ for $b < a$, and $h(e_a, \omega_0) = \alpha - \alpha h(e_a, \zeta) = 0$; and $g^{-1}\omega_0 = g^{-1}\omega - \alpha g^{-1}\zeta$ has size $2c + i + 4$. By hypothesis there is $\omega_0' \in \omega_0 + E_{<a+1}$ such that $M^{-1}(g^{-1}\omega_0 - g'^{-1}\omega_0')$ has size $m = 2c + i + 4 + t$. Write $\omega_0' - \omega_0 = \mu e_a + \epsilon$ with $\mu \in A$ and $\epsilon \in E_{<a}$.

The coefficient μ is small. We have $h(\zeta', e_a) = \overline{h(e_a, \zeta')} = \overline{h(e_a, \zeta)} = 1$, as $\zeta' - \zeta \in E_{<a}$; $h(\zeta', \epsilon) = 0$, as $h(e_b, \zeta') = h(e_b, \zeta) = 0$ for $b < a$; and $h(\zeta' - \zeta, \omega_0) = 0$, as $h(e_b, \omega_0) = 0$ for $b \le a$. Hence

$$\mu = h(\zeta', \omega_0') - h(\zeta, \omega_0) = h(v', w') - h(v, w), \qquad v = g^{-1}\zeta,\ v' = g'^{-1}\zeta',\ w = g^{-1}\omega_0,\ w' = g'^{-1}\omega_0',$$

since g, g' are isometries. Here v and $M^{-1}(v - v')$ have size c, w has size $2c + i + 4 \le m$ and $M^{-1}(w - w')$ has size m. As $\bar{M} = M$ (PE1), $h(M^{-1}u, u') = M^{-1}h(u, u')$, and

$$M^{-1}\big(h(v', w') - h(v, w)\big) = -h(v', M^{-1}(w - w')) - h(M^{-1}(v - v'), w).$$

Since $v' = v - M \cdot M^{-1}(v - v')$ has size $c + 2$ ($M \in A_{(1)}$), the two terms have sizes $c + m + 5$ and $c + m + 3$, so $M^{-1}\mu \in A_{(c+m+6)}$.

The lift. Put $\omega' = \alpha\zeta' + \omega_0' - \mu f'$. Then $\omega' - \omega = \alpha(\zeta' - \zeta) + \epsilon - \mu(f' - e_a) \in E_{<a}$, and

$$M^{-1}(g^{-1}\omega - g'^{-1}\omega') = M^{-1}(g^{-1}\omega_0 - g'^{-1}\omega_0') + \alpha\, M^{-1}(g^{-1}\zeta - g'^{-1}\zeta') + (M^{-1}\mu)\, g'^{-1} f'.$$

The three terms have sizes m, $2c + i + 3$ and $2c + m + 6$; the sum of the last two has size $2c + m + 7$, and the whole sum size $2c + m + 8 = i + t + 4c + 12$. So the lengths differ by at most $t + 4c + 12$ from a on.

(ii). By induction on j: for $j = 0$ there is nothing to show; for $j \ge 1$, (i) at $a = j - 1$ turns the bound t from j on into $t + 4c + 12$ from $j - 1$ on, and the induction hypothesis for $j - 1$ (balance holds for all $a < j - 1$) gives $t + 4c + 12 + (4c + 12)(j - 1) = t + (4c + 12)j$ from 0 on.

(iii). From 0 on there is no orthogonality condition and $E_{<0} = 0$, so the lift of ω is ω itself. For an index k take $\omega = ge_k$: $g^{-1}\omega = e_k$ has size 0 (SZ4), hence $M^{-1}(e_k - (gx)^{-1}ge_k) = -M^{-1}(x^{-1} - 1)e_k$ has size t. So $N = M^{-1}(x^{-1} - 1)$ has size t. As $x^{-1} \in G$, $x = (x^{-1})^{-1} = J^{-1}\overline{x^{-1}}^{\mathsf{T}} J$, and since $\bar{M} = M$,

$$M^{-1}(x - 1) = J^{-1}\bar{N}^{\mathsf{T}} J.$$

$\bar{N}^{\mathsf{T}} J$ has size $t + 2$ and $J^{-1}\bar{N}^{\mathsf{T}} J$ size $t + 4$, by (SZ5). □

5.5 Local bounds at the complex and finite places

At each infinite place the sieve of the main term needs band limits: a sieve system with mass bound $(1 + b^{-10})/\deg$ whose top form is the Gram matrix of the normalised orbital integrals of the cut Bessel function. The theorem of this section, Theorem 5.5.3, produces them for the group $G_1 = \mathrm{U}(V_1)$ of signature $(\varrho + k, \varrho + 1)$ at a real place, under an L^2 bound for the matrix coefficients and polynomial growth of balls. It is applied once, in the construction of the Bessel systems of the data (Proposition 5.7.3), with deg a product of formal degrees. The frames engine sees the real place through the field $\mathbb{C}$ with complex conjugation, and this is the complex place of the statements.

The idea is that the complex place is one more place for the frames engine. Its data form a place datum with a gauge (Lemma 5.5.5), so that the descent and the decay come from Section 5.4 (Lemma 5.5.4, Lemma 5.5.33). Two statements are particular to the archimedean place and carry the weight of the section. The mass bound on the bottom floor is where the L^2 hypothesis is used (Lemma 5.5.34); in our reading it is the orthogonality relation of the discrete series, with the formal degree in the role of deg, made effective. On the top floor the Gram form of the normalised orbital integrals does not depend on the frame-fixing element (Lemma 5.5.32). For the discrete series, their characters and formal degrees see [119, 250, 163, 315]; for Whittaker and Bessel functions on real groups see [316, 153].

The section closes with the corresponding statements at a finite place, for a large lattice datum, which feed the sieve system at T of the main term: the shell sum, the integrality of head products, the masses of the integral isometries and of congruence cosets, and the mass integral of the finite Bessel vector, whose main part comes from the congruence subgroup (Lemma 5.5.42).

Definition 5.5.1. Let $\varrho \geq 1$ and $k \geq 2$ be integers, $n = \varrho + 1$, $r = 2\varrho + k + 1$, and fix an index $k_0 \in \{1, \dots, k\}$. In this definition $|x|$ is the usual absolute value of $x \in \mathbb{C}$ and $\|\cdot\|$ the Euclidean norm of $\mathbb{C}^r$ (operator norm on matrices).

(RP1) The complex place. The **complex place** is $\mathbb{C}$ with complex conjugation and the tuple $(\mathrm{vol}, \tau, \delta, \nu, |\cdot|_{\mathbb{C}}, \psi, \mathrm{kb}_{\mathbb{C}})$: vol the Lebesgue measure of $\mathbb{C} = \mathbb{R}^2$ (coordinates Re, Im); $\tau = 1/2$; $\delta = \mathrm{i}/2$; ν the image of Lebesgue measure of $\mathbb{R}$ under $t \mapsto t\mathrm{i}$ on $\mathbb{C}^- = \mathrm{i}\mathbb{R}$; the modulus $|x|_{\mathbb{C}} = |x|^2$; the character $\psi =$ wave; and $\mathrm{kb}_{\mathbb{C}} = \pi^2$.

(RP2) Boosts and the top-floor chart. Let T be the Gram matrix of $X_0 \oplus \mathbb{C}z$ with $T = 1$ on $x_1, \dots, x_k$ and $h(z, z) = -1$. For $a \in \mathbb{C}$ with $|a| \geq 1$ and $s_a = \sqrt{|a|^2 - 1}$, the **boost** $\mathrm{bt}(a) \in G$ is

$$\mathrm{bt}(a)\, x_{k_0} = \bar{a}\, x_{k_0} - s_a\, z, \qquad \mathrm{bt}(a)\, z = s_a\, x_{k_0} - a\, z,$$

fixing every other coordinate vector. For $c \in \mathbb{C}^\times$ the **top-floor chart** is

$$\sigma_c = \mathrm{bt}(c/\min(1, |c|)).$$

(RP3) Real-place sizes. Real numbers ρ, b and an integer $s \geq 0$ are **real-place sizes** if $\rho = b^{6n+2}$, $8r \leq \rho$, $b \geq 2$, $k = s + 3n + 6$, $10^9 n^3 < s$, $n^7 \leq k$ and $10^8 \leq \varrho$.

(RP4) The place datum at the complex place. For $\rho > 0$, the **data at $\mathbb{C}$ with box radius** ρ are the following data of a place datum over $(\mathbb{C}, k, T)$ of shape $(\varrho, \{1, \dots, k\} \setminus \{k_0\}, 0)$: hyperbolic basis $v_0 = \frac{1+\mathrm{i}}{2}(x_{k_0} + z)$, $v_0^* = \frac{1+\mathrm{i}}{2}(x_{k_0} - z)$, $o_i = x_i$ $(i \neq k_0)$; μ_H the image of the Haar probability measure of $\mathrm{U}(k)$ under its embedding in G (acting on X_0, fixing e_a, e_a^*, z); μ_{top} the image of $\mu_{\mathrm{cell}} \otimes \mu_H$ under $(g, g') \mapsto gg'$, where μ_{cell} is the image under $c \mapsto \sigma_c^{-1}$ of the measure

$$\frac{2\pi^k}{(k-1)!}\big((|c|^2 - 1)_+\big)^{k-1}\, dc \qquad \text{on } \mathbb{C}^\times;$$

level unit $M = 1$; close pairs $\mathcal{P}_{\mathrm{cl}} = \{(\omega_1, \omega_2) : \|\omega_1\|^2 + \|\omega_2\|^2 < 1\}$; box $K = \{x \in G : \|x\| \leq \rho\}$; positions $\mathcal{P}_{\mathrm{pos}} = G$.

(RP5) Gauges of scale L. For $L \geq \rho$, the **size filtration of scale** L is $A_{(j)} = \{x \in \mathbb{C} : |x| \leq L^j\}$ $(j \geq 0)$, with loss $\Lambda = L^2$.

Definition 5.5.2. Let I be a finite set, $F\colon G_1 \to \mathbb{C}^I$ continuous, and $p = (p_a)_{a \geq 0}$ a sequence in $\mathbb{C}^\times$. The **normalised cell integral** of F at p is

$$\mathrm{Ci}_F(p) = N(\sigma_{p_\varrho}, F, p) \in \mathbb{C}^{I \times I},$$

the normalised orbital integral of F at the element $w_p \sigma_{p_\varrho}$; it depends only on $p_0, \dots, p_\varrho$.

Theorem 5.5.3. *Let $b \geq 2$, $f \geq 1$, $8r \leq b^{6n+2}$, $k = s + 3n + 6$ with an integer $10^9 n^3 < s$, $n^7 \leq k$ and $10^8 \leq \varrho$. Let $(W, W^\flat)$ be a cut pair for b, f of continuous Bessel functions whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$. Let $\deg > 0$ with*

$$\int_{G_1} \Big| \int_{\mathsf{U} \backslash G_1} \langle W(y), W(yx) \rangle dy \Big|^2 dx \leq \frac{(\#I)^2}{\deg}, \qquad \deg \cdot \Theta \leq b^{4r^2},$$

$\deg\cdot\mathrm{vol}\{g\in G_1:\|g\|_{\mathrm{op}}\le T\}\le T^{9r^2}b^{99r^2}$ *for all* $T\ge 1$, *and* $4000n\le f$. *Then* $W^\flat$ *has local bounds with degree* deg. *More precisely, let* $\mathcal{F}_i$ *be the floor forms and* λ *the Haar ratio of the data at* $\mathbb{C}$ *with box radius* b^{6n+2}, *and* $c_F=\mathrm{vol}\,\mathrm{U}(k)/\mathrm{vol}\,\mathrm{U}(r)/(\lambda\#I)^2$; *there is a form* $J_{\varrho+1}$ *such that the forms* $J_i=c_F\mathcal{F}_i(\cdot,\cdot;W^\flat,1)$ *(*$i\le\varrho$*) and* $J_{\varrho+1}$ *are local bounds for* $W^\flat$ *with degree* deg*; in particular* $J_{\varrho+1}(p,q)=\langle N(\sigma,W^\flat,p),N(\sigma,W^\flat,q)\rangle$ *for every* $\sigma\in G_1$ *that fixes* e_a *and* e_a^* *for* $1\le a\le\varrho$ *and all* p,q *with* $h(z,\sigma z)=p_\varrho=q_\varrho$, *and* $|c_F\mathcal{F}_0(p,q;W^\flat,1)|\le(1+b^{-10})/\deg$ *for all* p,q.

Proof. Put $\rho=b^{6n+2}$. The hypotheses say that ρ,b,s are real-place sizes; consider the data at $\mathbb{C}$ with box radius ρ, a place datum by Lemma 5.5.5, (i). Write $F=W^\flat$; it is cut for this place datum (Lemma 5.5.9). The type is irreducible, so $I\ne\emptyset$. By Lemma 5.5.10, $0<\lambda<\infty$, so $0<c_F<\infty$. Define the forms on pairs of sequences of nonzero complex numbers

$$J_i(p,q)=c_F\,\mathcal{F}_i(p,q;F,1)\quad(i\le\varrho),\qquad J_{\varrho+1}(p,q)=\langle\mathrm{Ci}_F(p),\mathrm{Ci}_F(q)\rangle,$$

and take the mass bound $E_0=(1+b^{-10})/\deg$, the weights $\Lambda_i=\Lambda_i^{R,K}$ with $R=b^{60n^2}$, $K=n^6$, and the decay $\beta(\xi)=\Theta\,b^{2000n^9}\ell_{k-n^7}(1/|\xi|)$, which is $\mathrm{Dec}(\xi)$ of Lemma 5.5.33. We check (SV1)–(SV6) for length ϱ and the top clause. Since $\#I\ge1$, the bounds of Lemma 5.5.33, (a) and (b), give the same bounds without the factor $\#I$.

(SV1). $\psi(0)=\exp(0)=1$.

(SV2) Descent. Let $i\le\varrho$, p,q sequences of nonzero numbers and $\xi\in\mathbb{C}$; put $\phi(c)=\mathrm{wave}(\xi c)$, a continuous function of modulus 1. We show that $c\mapsto\phi(c)J_{i+1}(p[i\mapsto u(c)],q[i\mapsto u(c)])$ is integrable with

$$\int_{\mathbb{C}}\phi(c)\,J_{i+1}(p[i\mapsto u(c)],q[i\mapsto u(c)])\,dc=c_F\,\mathcal{F}_i(p,q;F,\,x\mapsto\mathrm{wave}(\xi\,h(f_i,xf_i))).\tag{5.93}$$

If $i=\varrho$, this is Lemma 5.5.31 with this ϕ. Let $i<\varrho$. Choose $L\ge\rho$ with $|p_0\cdots p_{l-1}|^{-1}\le L$ and $|q_0\cdots q_{l-1}|^{-1}\le L$ for $l\le i$; then p,q are heads of length i for the gauge Γ_L, and Lemma 5.5.4, (ii), with $j=i$, $t=1$ and the majorant $\mathrm{FM}_i(p,q,F,\cdot)$ itself as the bounded function, gives $\#I\,c_F\,\mathrm{hdn}_i(p,q)\int\mathrm{FM}_i(p,q,F,x)\,d\theta(x)<\infty$; as $\#I\,c_F\,\mathrm{hdn}_i(p,q)>0$, the integral of the majorant is finite. So Proposition 5.2.92, (ii), applies with $a=i$, $t=c_F$ and this ϕ, and gives the integrability and (5.93), its weight being $\phi(h(f_i,xf_i))$. If $\xi=0$, the weight in (5.93) is 1 and the integral is $J_i(p,q)$. If $\xi\ne0$, Lemma 5.5.33, (a), with $\nu=\xi$, bounds the absolute value of (5.93) by $\beta(\xi)\Lambda_i(p)\Lambda_i(q)$.

(SV3) Positivity of the top form. For finitely many sequences $a_1,\dots,a_N$ and $x\in\mathbb{C}^N$, $\sum_{i,j}\bar{x}_ix_jJ_{\varrho+1}(a_i,a_j)=\|\sum_jx_j\mathrm{Ci}_F(a_j)\|^2\ge0$; so the matrix $(J_{\varrho+1}(a_i,a_j))_{i,j}$ is positive semidefinite (with or without a common last entry).

(SV4). $J_{\varrho+1}$ is jointly continuous by Lemma 5.5.32, (i), as F is continuous.

(SV5) Mass. $|J_0(p,q)|=|c_F\,\mathcal{F}_0(p,q;F,1)|\le(1+b^{-10})/\deg=E_0$ for all p,q, by Lemma 5.5.34, whose hypotheses are those of the theorem.

(SV6) Unequal heads. Let $i<\varrho$ with $\xi=\iota(p_i)-\iota(q_i)=p_i^{-1}-q_i^{-1}\ne0$. By Lemma 5.5.33, (b), with $\nu=\xi$, $|J_{i+1}(p,q)|\le\beta(\xi)\Lambda_{i+1}(p)\Lambda_{i+1}(q)$.

The top clause. Let $\sigma\in G_1$ fix e_a and e_a^* for $1\le a\le\varrho$ (the vectors of all ϱ hyperbolic planes), and let $h(z,\sigma z)=p_\varrho=q_\varrho$. By Lemma 5.5.32, (ii), $J_{\varrho+1}(p,q)=\langle\mathrm{Ci}_F(p),\mathrm{Ci}_F(q)\rangle=\langle N(\sigma,F,p),N(\sigma,F,q)\rangle$.

Hence the forms $J_0,\dots,J_{\varrho+1}$ with ψ, E_0, Λ_i and β form a sieve system of length ϱ on $\mathbb{C}$ with the data of a complex place, mass bound $(1+b^{-10})/\deg$, weights $\Lambda_i^{b^{60n^2},n^6}$ and decay $\Theta\,b^{2000n^9}\ell_{k-n^7}(1/|\xi|)$, and they satisfy the top clause: they are local bounds for $W^\flat$ with degree deg, and the mass clause of the statement is (SV5). □

Lemma 5.5.4. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, let λ be its Haar ratio, and put*

$$V = (\pi\rho^{24})^k \rho^{9999n}, \qquad c_F = \frac{\operatorname{vol} \mathrm{U}(k)}{\operatorname{vol} \mathrm{U}(r)\,(\lambda \#I)^2}.$$

(i) $V \geq 1$, and $\mathrm{FML}_j(V;1)$ holds for every $j \leq \varrho$.

(ii) Let $(W, W^\flat)$ be a cut pair for b, f whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. Let $L \geq \rho$, $j \leq \varrho$, p, q heads of length j for Γ_L, $t \geq 1$ real, and $\phi\colon G \to [0,\infty]$ with $\phi \leq \mathrm{FM}_j(p, q, W^\flat, \cdot)$ and, if $t > 1$, $\phi(x)^2 \leq (V/t^s)^2\,\mathrm{WSP}_j(p, q, W^\flat, x)$ for all $x \in G$. Then

$$\#I \cdot c_F\, \mathrm{hdn}_j(p,q) \int_G \phi\, d\theta \leq \Theta\, L^{10^9 n^4} \rho^{24k}\, \frac{t^{10^8 n^4}}{t^s}.$$

Proof. **Numbers.** $\rho \geq 8r \geq 8$. From $k = s + 3n + 6 \geq n^7$ and $n > \varrho \geq 10^8$: $s \geq n^7 - 3n - 6 \geq 10^{10} n^4$; so $s = 10^8 n^4 + r_0$ with an integer $r_0 \geq 0$, and $9 \cdot 10^7 n^4 + r_0 \leq s$.

(i). $V \geq 1$ as $\pi, \rho \geq 1$. By Lemma 5.5.5, (ii), Γ_ρ is a gauge of loss ρ^2, and by (GU5), $\operatorname{vol}(A_{(11)}) \leq (\rho^2)^{12}$. By (DN0)(b) of Theorem 5.4.1 for Γ_ρ, $\mathrm{FML}_j\big((\rho^2)^{1287n}\operatorname{vol}(A_{(11)})^{k-5}; 1\big)$ for $j \leq \varrho$, and $(\rho^2)^{1287n}(\rho^{24})^{k-5} \leq \rho^{9999n}(\pi\rho^{24})^k = V$; floor-mass bounds pass to larger constants.

(ii). By Lemma 5.5.9 ($\rho = b^{6n+2}$), $W^\flat$ is cut for the data at $\mathbb{C}$, and by Lemma 5.5.10 the group measure $\theta = \lambda\, dy$ ($\lambda > 0$) is a Haar measure. By Lemma 5.5.24 the dyadic shells D_i ($i \geq 0$) are shells of heights 2^i for $(\Gamma_L, j, p, q, W^\flat)$ and cover G, hence the support of ϕ. Put $e = t^{-1} \in (0,1]$; if $e < 1$ then $t > 1$ and $\phi(x)^2 \leq (Ve^s)^2 \mathrm{WSP}_j(p, q, W^\flat, x)$ for every $x \in \mathcal{P}_{\mathrm{pos}}$. With (i) and the integer r_0, (DN2) of Theorem 5.4.1 for Γ_L (loss L^2) gives

$$\mathrm{hdn}_j(p,q) \int_G \phi\, d\theta \leq V\, t^{-r_0}\, (L^2)^{4\cdot 10^8 n^4}\, \mathrm{SN}(W^\flat), \qquad \mathrm{SN}(W^\flat) = \pi^{2(k-5)\varrho}\, \mathrm{PN}(W^\flat) \leq \pi^{2(k-5)\varrho} \lambda^2 \#I$$

by Lemma 5.5.27. Multiplying by $\#I \cdot c_F$, the factors $\lambda^2(\#I)^2$ cancel, and with $t^{-r_0} = t^{10^8 n^4}/t^s$,

$$\#I\, c_F\, \mathrm{hdn}_j(p,q) \int_G \phi\, d\theta \leq \frac{\operatorname{vol} \mathrm{U}(k)}{\operatorname{vol} \mathrm{U}(r)}\, \pi^{k+2(k-5)\varrho} \rho^{24k} \rho^{9999n} L^{8\cdot 10^8 n^4}\, \frac{t^{10^8 n^4}}{t^s} \leq \Theta\, L^{10^9 n^4} \rho^{24k}\, \frac{t^{10^8 n^4}}{t^s},$$

since $\pi^{k+2(k-5)\varrho} \leq \pi^{(2\varrho+1)k}$, $\rho^{9999n} \leq L^{9999n}$ and $9999n + 8 \cdot 10^8 n^4 \leq 10^9 n^4$. □

Lemma 5.5.5. *(i) For every $\rho > 0$ and every enumeration of $\{1, \dots, k\} \setminus \{k_0\}$, the data at $\mathbb{C}$ with box radius ρ satisfy (PE1)–(PE4), so they form a place datum of shape $(\varrho, \{1, \dots, k\} \setminus \{k_0\}, 0)$ over $(\mathbb{C}, k, T)$.*

(ii) Let ρ, b, s be real-place sizes and $L \geq \rho$. Then the size filtration of scale L, with loss L^2, is a gauge for the data at $\mathbb{C}$ with box radius ρ. In (GU4) one may take $c = L^{-(i+2)}$, and in (GU6) a kernel with $\lambda_\beta(\{x \text{ of size } j\}) \leq 4\pi^2 L^{2j}$ for all β and j.

Proof. **(i) The hyperbolic basis and the shape.** $|\iota| + 2m + 2 = (k-1) + 0 + 2 = k + 1$. The vectors v_0, v_0^*, o_i lie in the middle space, and, h being conjugate-linear in the first variable, $h(x_{k_0} \pm z, x_{k_0} \pm z) = 1 - 1 = 0$ and $h(x_{k_0} + z, x_{k_0} - z) = 1 + 1 = 2$, so $h(v_0, v_0) = h(v_0^*, v_0^*) = 0$ and $h(v_0, v_0^*) = \left|\frac{1+\mathrm{i}}{2}\right|^2 \cdot 2 = 1$; for $i, i' \neq k_0$, $h(o_i, o_{i'}) = \delta_{ii'}$ and $h(v_0, o_i) = h(v_0^*, o_i) = 0$. The measures μ_H (finite) and μ_{top} (an image of the product of a σ-finite measure with density on $\mathbb{C}^\times$ and a finite measure) are s-finite Borel measures, and $M = 1$ is a unit.

(PE1). $|\det T| = |-1|^2 = 1$ and $\bar{M} = M = 1$.

(PE2) is Lemma 5.5.6.

(PE3). μ_H is a probability measure, so $\mu_H \neq 0$ and $\mu_H(E) \leq 1$ for every set E; in particular the last clause holds. The embedding ϵ of $\mathrm{U}(k)$ acts on $X_0 = \mathrm{span}\{x_i\}$ and fixes e_a, e_a^*, z, so it takes values in $H = G^{(\varrho+1)}$, the group of the $g \in G$ fixing the coordinate vectors of floor below $\varrho+1$, i.e. the e_a, e_a^* and z; hence $\mu_H(G \setminus H) = 0$. Conversely let $s \in H$. For $w \in X_0$ and $y \in \{e_a, e_a^*, z\}$, $h(sw, y) = h(sw, sy) = h(w, y) = 0$; as J is nondegenerate, the h-orthogonal complement of $\mathrm{span}\{e_a, e_a^*, z\}$ is X_0, so s preserves X_0, and its restriction preserves the standard form $h|_{X_0}$: $s = \epsilon(u)$ with $u \in \mathrm{U}(k)$. Right invariance of the Haar measure of $\mathrm{U}(k)$ gives that the image of μ_H under $g \mapsto gs$ is μ_H.

(PE4). $\mathcal{P}_{\mathrm{cl}}$ is the preimage of $[0,1)$ under the continuous map $(\omega_1, \omega_2) \mapsto \|\omega_1\|^2 + \|\omega_2\|^2$, hence open; it contains $(0,0)$; its closure lies in the compact set $\{\|\omega_1\|^2 + \|\omega_2\|^2 \leq 1\}$. G is closed in the matrices (defined by $\bar{g}^{\mathsf{T}} J g = J$, which forces invertibility), so K is closed and bounded, hence compact. $\mathcal{P}_{\mathrm{pos}} = G$ is measurable.

(ii) Numbers. From $\rho \geq 8r$: $L \geq 8r \geq 8$; so $r+1 \leq L$, $2r < L^4$, $\pi \leq L^2$ and $4\pi^2 \leq L^4$.

(SZ1)–(SZ5). If $|x| \leq L^i$ and $|y| \leq L^j$ then $|xy| \leq L^{i+j}$. A sum of at most $r+1$ elements of modulus at most L^i has modulus at most $(r+1)L^i \leq L^{i+1}$. The discs are invariant under $x \mapsto -x$ and $x \mapsto \bar{x}$, and contain 0 and 1 ($L \geq 1$). The entries of $J = J^{-1}$ have modulus at most $1 \leq L$.

(GU1). Each $A_{(j)}$ is a closed disc, hence compact; $2 \leq L^2 < \infty$; $m = 0 \leq 9n$; $2(2m+2) = 4 \leq k - 1 = |\iota|$; $\mathrm{kb}_{\mathbb{C}} = \pi^2 \geq 1$.

(GU2). $|M| = 1 \leq L$. The coordinates of v_0, v_0^* are 0 and $\pm\frac{1+\mathrm{i}}{2}$, of modulus at most $2^{-1/2}$, and those of the o_i are $0, 1$. $\tau\delta^{-1} = \frac{1}{2} \cdot \frac{2}{\mathrm{i}} = -\mathrm{i}$ has modulus 1. For $x \in K$ every entry satisfies $|x_{ij}| \leq \|x\| \leq \rho \leq L$.

(GU3). If $\|\omega_1\|^2 + \|\omega_2\|^2 < 1$, every entry of ω_1 and of ω_2 has modulus less than 1, so the entries of ω_1 and of $M^{-1}(\omega_1 - \omega_2) = \omega_1 - \omega_2$ have modulus at most $2 \leq L$.

(GU4). $M^{-1} = 1 \in A_{(1)}$. Let $i \geq 0$ and $c = L^{-(i+2)}$, a unit with $c^{-1} = L^{i+2} \in A_{(i+2)}$. If $\omega_1, \omega_2 \in V$ have size i, each has r entries of modulus at most L^i, so $\|c\omega_1\|^2 + \|c\omega_2\|^2 \leq 2rL^{2i}/L^{2i+4} = 2r/L^4 < 1$, and $(c\omega_1, c\omega_2) \in \mathcal{P}_{\mathrm{cl}}$.

(GU5). For a unit c with $|c| \leq L^j$, its modulus is $|c|^2 \leq (L^2)^j$. $\mathrm{vol}(A_{(j)}) = \pi L^{2j} \leq (L^2)^{j+1}$.

(GU6). Here $2m+2 = 2$. Let e be the first coordinate vector of $\mathbb{C}^2$, du the Haar probability measure of $\mathrm{U}(2)$, and for $\beta = t\mathrm{i} \in \mathrm{i}\mathbb{R}$ let λ_β be $2\pi^2(2t)_+$ times the image of du under $u \mapsto \sqrt{(2t)_+}\, ue$. For a Borel set B, $\beta \mapsto \lambda_\beta(B) = 2\pi^2(2t)_+ \int \mathbf{1}_B(\sqrt{(2t)_+}\, ue)\, du$ is measurable by Tonelli, so (λ_β) is a kernel; $\lambda_\beta(\mathbb{C}^2) = 4\pi^2 t_+$ is bounded on each set $\{N-1 \leq |t| < N\}$, so λ is the countable sum of the finite kernels $\mathbf{1}_{\{N-1\leq|t|<N\}}\lambda$ and is s-finite. (DJ1): for g continuous with compact support, $\int g\, d\lambda_{t\mathrm{i}} = 2\pi^2(2t)_+ \int g(\sqrt{(2t)_+}\, ue)\, du$ is finite and continuous in t, the integrand being continuous on $\mathbb{R} \times \mathrm{U}(2)$ and $\mathrm{U}(2)$ compact. (DJ2): by polar coordinates on $\mathbb{C}^2$ (Lebesgue measure is $\mathrm{U}(2)$-invariant, $\mathrm{U}(2)$ is transitive on spheres, and $\|x\|^2$ has density $\pi^2 r$ on $r > 0$), then $r = 2t$,

$$\begin{aligned}\int_{\mathbb{C}^2} f(\bar{x}^{\mathsf{T}}x, x)\, dx &= \int_0^\infty \pi^2 r \int f(r, \sqrt{r}\, ue)\, du\, dr = \int_{\mathbb{R}} 2\pi^2(2t)_+ \int f(2t, \sqrt{(2t)_+}\, ue)\, du\, dt \\ &= \int_{\mathrm{i}\mathbb{R}} \int f(\delta^{-1}\beta, x)\, d\lambda_\beta(x)\, d\nu(\beta),\end{aligned}$$

as $\delta^{-1}(t\mathrm{i}) = 2t$. Mass: if $\lambda_{t\mathrm{i}}$ charges $\{x : |x_1|, |x_2| \leq L^j\}$, then $t > 0$ and the sphere $\|x\|^2 = 2t$ meets this box, so $2t \leq 2L^{2j}$ and $\lambda_{t\mathrm{i}}(\{x \text{ of size } j\}) \leq \lambda_{t\mathrm{i}}(\mathbb{C}^2) = 2\pi^2 \cdot 2t \leq 4\pi^2 L^{2j} \leq L^4 L^{4j} = (L^2)^{(2m+2)(j+1)}$.

(GU7) is Lemma 5.5.8, applied to $g \in K \subseteq G$ and $y \in \mathcal{P}_{\mathrm{pos}} = G$. □

Lemma 5.5.6. *Let $\rho > 0$ and consider the data at $\mathbb{C}$ with box radius ρ. Put $\mathrm{sph}_k(r) = 2\pi^k r^{k-1}/(k-1)!$ for $r \geq 0$, and for $q \in \mathbb{R}$ let hy_q be the image of the measure $\mathrm{sph}_k((q+|c|^2)_+)\,dc\,du$ on $\mathbb{C}\times\mathrm{U}(k)$ under*

$$(c,u) \mapsto \sqrt{(q+|c|^2)_+}\,u\,x_{k_0} + c\,z \in V.$$

Then $\mathrm{qv}_\varrho(\beta) = \mathrm{hy}_{\delta^{-1}\beta}$ for every $\beta \in \mathrm{i}\mathbb{R}$ (note $\delta^{-1}\beta = 2\,\mathrm{Im}\,\beta$); in particular $\mathrm{qv}_\varrho = \mathrm{hy}_{-1}$. Moreover $\mu_{\mathrm{top}}(G \setminus G^{(\varrho)}) = 0$ and the image of μ_{top} under $g \mapsto g^{-1}z$ is qv_ϱ; that is, μ_{top} satisfies (PE2).

Proof. **Step 0: polar coordinates on $\mathbb{C}^k$.** For measurable $g\colon \mathbb{C}^k \to [0,\infty]$ and e the coordinate vector of index k_0,

$$\int_{\mathbb{C}^k} g(\omega)\,d\omega = \int_0^\infty \frac{\pi^k r^{k-1}}{(k-1)!}\int_{\mathrm{U}(k)} g(\sqrt{r}\,ue)\,du\,dr. \tag{5.94}$$

Indeed, Lebesgue measure is $\mathrm{U}(k)$-invariant, so by Tonelli $\int g = \int_{\mathbb{C}^k} G(\omega)\,d\omega$ with $G(\omega) = \int_{\mathrm{U}(k)} g(u\omega)\,du$. If $\|\omega\|^2 = r$, then $\omega = u_0\sqrt{r}\,e$ for some $u_0 \in \mathrm{U}(k)$, and right invariance of du gives $G(\omega) = \int g(\sqrt{r}\,ue)\,du$; so $G(\omega) = \Phi(\|\omega\|^2)$ for a measurable Φ. The law of $\|\omega\|^2$ under Lebesgue measure of $\mathbb{C}^k = \mathbb{R}^{2k}$ has density $\frac{d}{dr}\frac{\pi^k r^k}{k!} = \frac{\pi^k r^{k-1}}{(k-1)!}$ on $r > 0$ (volume of the ball of radius $\sqrt{r}$ in $\mathbb{R}^{2k}$), which gives (5.94).

Step 1: the quadric measures disintegrate vol_{V_ϱ}. At floor ϱ and $m = 0$ the index set $\mathcal{Q}_\varrho$ is empty, so $Y_\varrho = \mathbb{C}^\iota$, $h'_\varrho(w,w) = \sum_{i\in\iota}|w_i|^2$ and $B_\varrho(t_1,t_2,w) = t_1v_0 + t_2v_0^* + \sum_{i\in\iota} w_ix_i$. Let X be the matrix of B_ϱ, from $\mathbb{C}^{\{1,2\}\sqcup\iota}$ to V, and let J^{hyp} be the hermitian matrix with $\bar{x}^{\mathsf{T}}J^{\mathrm{hyp}}x = \bar{t}_1t_2 + \bar{t}_2t_1 + \sum_i |w_i|^2$ for $x = (t_1,t_2,w)$. From $h(v_0,v_0^*) = 1$, $h(v_0,v_0) = h(v_0^*,v_0^*) = 0$, $h(x_i,x_{i'}) = \delta_{ii'}$ and $h(v_0,x_i) = h(v_0^*,x_i) = 0$ $(i \neq k_0)$ we get $\bar{X}^{\mathsf{T}}JX = J^{\mathrm{hyp}}$; as $(J^{\mathrm{hyp}})^2 = 1$, $L = J^{\mathrm{hyp}}\bar{X}^{\mathsf{T}}J$ satisfies $LX = 1$. By definition (5.4), $\mathrm{qv}_\varrho(\beta)$ is the image under X of the measure λ^1_β of Lemma 5.2.52, (i), for $S = \iota$ and $T' = 1$; the complex place is a place (Lemma 5.5.7), so by Lemma 5.2.52, (i), $(\lambda^1_\beta)_\beta$ is a disintegration of vol on $\mathbb{C}^{\{1,2\}\sqcup\iota}$ along $\bar{x}^{\mathsf{T}}J^{\mathrm{hyp}}x$, and by Lemma 5.2.53, (ii), $(\mathrm{qv}_\varrho(\beta))_\beta$ is a disintegration of $X_*\mathrm{vol}$ along $h(v,v)$. Finally X is the extension by zero of the square matrix X' onto the coordinates $x_1,\dots,x_k,z$ of floor at least ϱ; X' is the identity on the x_i, $i \neq k_0$, and on $(t_1,t_2) \mapsto (x_{k_0},z)$-coordinates it is $\frac{1+\mathrm{i}}{2}\begin{pmatrix}1 & 1\\ 1 & -1\end{pmatrix}$, of determinant $-\frac{(1+\mathrm{i})^2}{2} = -\mathrm{i}$. So $|\det X'|_{\mathbb{C}} = 1$, (PA3) gives $X'_*\mathrm{vol} = \mathrm{vol}$, and $X_*\mathrm{vol} = \mathrm{vol}_{V_\varrho}$.

Step 2: the hyperboloid measures disintegrate vol_{V_ϱ}. Write

$$p_q(c,u) = \sqrt{(q+|c|^2)_+}\,ux_{k_0} + cz,$$

and for $\beta \in \mathrm{i}\mathbb{R}$ put $\lambda'_\beta = \mathrm{hy}_{\delta^{-1}\beta}$; for $\beta = t\mathrm{i}$, $\delta^{-1}\beta = 2t$.

(DJ2). Let $f\colon \mathbb{C}\times V \to [0,\infty]$ be measurable. A point of V_ϱ is $v = \omega + cz$ with $\omega \in X_0 = \mathbb{C}^k$, and $h(v,v) = \|\omega\|^2 - |c|^2$. By Tonelli and (5.94),

$$\int f(h(v,v),v)\,d\mathrm{vol}_{V_\varrho}(v) = \int_{\mathbb{C}}\int_0^\infty \frac{\pi^k r^{k-1}}{(k-1)!}\int_{\mathrm{U}(k)} f\big(r-|c|^2, \sqrt{r}\,ux_{k_0} + cz\big)\,du\,dr\,dc.$$

Substitute $r = 2t+|c|^2$ $(dr = 2\,dt)$: the range $r > 0$ becomes $2t+|c|^2 > 0$, the factor $2\pi^k r^{k-1}/(k-1)!$ is $\mathrm{sph}_k(r)$, and $\mathrm{sph}_k(0) = 0$ as $k \geq 2$, so the range may be extended to all $t \in \mathbb{R}$ with the density $\mathrm{sph}_k((2t+|c|^2)_+)$ and the point $p_{2t}(c,u)$. Exchanging the integrals over c and t (Tonelli),

$$\begin{aligned}\int f(h(v,v),v)\,d\mathrm{vol}_{V_\varrho} &= \int_{\mathbb{R}}\int_{\mathbb{C}\times\mathrm{U}(k)} f\big(2t, p_{2t}(c,u)\big)\,\mathrm{sph}_k\big((2t+|c|^2)_+\big)\,dc\,du\,dt\\ &= \int_{\mathrm{i}\mathbb{R}}\int f(\delta^{-1}\beta,v)\,d\lambda'_\beta(v)\,d\nu(\beta).\end{aligned}$$

(DJ1). Let $g\colon V \to [0,\infty)$ be continuous with compact support C_g, and let $C_z \subseteq \mathbb{C}$ be the (compact) set of z-coordinates of points of C_g. The z-coordinate of $p_q(c,u)$ is c, so

$$\int g\,d\mathrm{hy}_q = \int_{C_z\times \mathrm{U}(k)} \mathrm{sph}_k((q+|c|^2)_+)\, g(p_q(c,u))\,dc\,du.$$

The integrand is continuous in (q,c,u), so it is bounded on $[q_0-1,q_0+1]\times C_z\times \mathrm{U}(k)$, and $C_z\times \mathrm{U}(k)$ has finite measure; by dominated convergence $q\mapsto \int g\,d\mathrm{hy}_q$ is finite and continuous, and so is $\beta\mapsto \int g\,d\lambda'_\beta$.

Step 3: the identification. By Steps 1 and 2 and Lemma 5.2.53, (i), $\mathrm{qv}_\varrho(\beta) = \mathrm{hy}_{\delta^{-1}\beta}$ for every β. As $h(f_\varrho, f_\varrho) = h(z,z) = -1$, $\mathrm{qv}_\varrho = \mathrm{qv}_\varrho(-\delta) = \mathrm{hy}_{-1}$.

Step 4: (PE2). Write $\epsilon\colon \mathrm{U}(k)\to G$ for the embedding (acting on X_0, fixing the e_a, e_a^* and z). The boost $\mathrm{bt}(a)$ fixes every e_a, e_a^*, so $\sigma_c^{-1}\in G^{(\varrho)}$ for $c\neq 0$, and $\epsilon(u)\in G^{(\varrho)}$; as μ_{top} is the image of $\mu_{\mathrm{cell}}\otimes\mu_H$ under $(g,g')\mapsto gg'$, with μ_{cell} carried by $\{\sigma_c^{-1}\}$ and μ_H by $\epsilon(\mathrm{U}(k))$, it is carried by $G^{(\varrho)}$. For measurable $f\colon V\to[0,\infty]$, by the definitions of μ_{top}, μ_{cell}, μ_H,

$$\int f(g^{-1}z)\,d\mu_{\mathrm{top}}(g) = \int_{\mathbb{C}^\times} \mathrm{sph}_k((|c|^2-1)_+)\int_{\mathrm{U}(k)} f\big(\epsilon(u)^{-1}\sigma_c z\big)\,du\,dc,$$

since $(\sigma_c^{-1}\epsilon(u))^{-1} = \epsilon(u)^{-1}\sigma_c$ and the density of μ_{cell} is $\frac{2\pi^k}{(k-1)!}((|c|^2-1)_+)^{k-1} = \mathrm{sph}_k((|c|^2-1)_+)$. The density vanishes for $|c|\le 1$ ($k\ge 2$). For $|c|>1$, $\sigma_c = \mathrm{bt}(c)$ and $\mathrm{bt}(c)z = s_c x_{k_0} - cz$ with $s_c = \sqrt{|c|^2-1}$, so $\epsilon(u)^{-1}\sigma_c z = s_c\,u^{-1}x_{k_0} - cz$. The substitutions $u\mapsto u^{-1}$ (Haar measure of the compact group $\mathrm{U}(k)$ is invariant under inversion) and $c\mapsto -c$ (Lebesgue measure and the density are invariant) turn the integral into

$$\int_{\mathbb{C}} \mathrm{sph}_k((-1+|c|^2)_+)\int_{\mathrm{U}(k)} f\big(p_{-1}(c,u)\big)\,du\,dc = \int f\,d\mathrm{hy}_{-1},$$

where the set $\{|c|\le 1\}$, on which both densities vanish, has been added back. So the image of μ_{top} under $g\mapsto g^{-1}z$ is $\mathrm{hy}_{-1} = \mathrm{qv}_\varrho$ by Step 3. □

Lemma 5.5.7. *The complex place is a place. Moreover (PA5) holds with $\gamma(v) = e^{-|v|^2}$, for which*

$$\int_{\mathbb{C}} \gamma(v)\,\psi(\bar v y)\,dv = \pi e^{-|y|^2} \qquad (y\in\mathbb{C}),$$

and (PA6) holds with $\vartheta(u) = |u|^{-1}$ for $u\neq 0$ and $\vartheta(0)=0$.

Proof. **The structure.** $\mathbb{C}$ with complex conjugation is a commutative ring with an involution; its usual topology is that of $\mathbb{R}^2$, locally compact and Polish, and addition, multiplication and conjugation are continuous. Lebesgue measure is a Haar measure of $(\mathbb{C},+)$. $\tau+\bar\tau = \frac12+\frac12 = 1$; $\delta = \mathrm{i}/2$ is a unit with $\bar\delta = -\delta$. The skew elements form the closed subgroup $\mathrm{i}\mathbb{R}$, and $t\mapsto t\mathrm{i}$ is an isomorphism of topological groups $\mathbb{R}\to\mathrm{i}\mathbb{R}$, so ν is a Haar measure of $\mathrm{i}\mathbb{R}$. The modulus $x\mapsto|x|^2$ is continuous, hence measurable, with $|1|^2=1$ and $|xy|^2 = |x|^2|y|^2$. For $x = a+b\mathrm{i}$, $\psi(x) = \exp(x-\bar x) = e^{2b\mathrm{i}}$ is continuous, has modulus 1, and $\psi(x+x') = \psi(x)\psi(x')$. Finally $\mathrm{kb}_{\mathbb{C}} = \pi^2\in[0,\infty]$.

(PA1). For $\alpha = s\mathrm{i}$ and $\beta = t\mathrm{i}$ ($s,t\in\mathbb{R}$), $\tau\delta^{-1}\alpha+\beta = \frac12\cdot\frac{2}{\mathrm{i}}\cdot s\mathrm{i} + t\mathrm{i} = s+t\mathrm{i}$. Hence the map $(\alpha,\beta)\mapsto\tau\delta^{-1}\alpha+\beta$, composed with the parametrisation $(s,t)\mapsto(s\mathrm{i},t\mathrm{i})$ that carries Lebesgue measure of $\mathbb{R}^2$ to $\nu\otimes\nu$, is the identification $(s,t)\mapsto s+t\mathrm{i}$ of $\mathbb{R}^2$ with $\mathbb{C}$; it carries Lebesgue measure to vol, and so $\nu\otimes\nu$ is carried to vol.

(PA2). $|\bar x|^2 = |-x|^2 = |x|^2$.

(PA3). Let X be a complex $S \times S$ matrix with $\det X \neq 0$. Viewed as a real-linear map of $\mathbb{C}^S = \mathbb{R}^{2S}$, X has real determinant $|\det X|^2$ (classical: over $\mathbb{C}$ the real-linear map $x \mapsto Xx$ is conjugate to $\mathrm{diag}(X, \bar{X})$). By the change of variables formula for a linear automorphism of $\mathbb{R}^{2S}$, the image of Lebesgue measure under $x \mapsto Xx$ is $|\det X|^{-2}\mathrm{vol} = |\det X|_{\mathbb{C}}^{-1}\mathrm{vol}$.

(PA4). The non-units form the null set $\{0\}$.

(PA5). $\gamma(v) = e^{-|v|^2}$ is continuous, nonnegative, integrable (with integral π), and $\gamma(0) = 1$. Write $v = a + b\mathrm{i}$ and $y = c + d\mathrm{i}$. Then $\bar{v}y = (ac + bd) + (ad - bc)\mathrm{i}$, so $\psi(\bar{v}y) = e^{2\mathrm{i}(ad-bc)}$, and by Fubini and the Fourier transform of the Gaussian, $\int_{\mathbb{R}} e^{-a^2} e^{2\mathrm{i}au}\, da = \sqrt{\pi}\, e^{-u^2}$ $(u \in \mathbb{R})$,

$$\int_{\mathbb{C}} \gamma(v)\psi(\bar{v}y)\, dv = \int_{\mathbb{R}} e^{-a^2} e^{2\mathrm{i}ad}\, da \int_{\mathbb{R}} e^{-b^2} e^{-2\mathrm{i}bc}\, db = \sqrt{\pi} e^{-d^2} \cdot \sqrt{\pi} e^{-c^2} = \pi e^{-|y|^2}.$$

Hence $\int_{\mathbb{C}} \left| \int_{\mathbb{C}} \gamma(v)\psi(\bar{v}y)\, dv \right| dy = \pi \int_{\mathbb{C}} e^{-|y|^2}\, dy = \pi^2 = \mathrm{kb}_{\mathbb{C}}$.

(PA6). ϑ is Borel with values in $[0, \infty)$. For a unit u, $|u|_{\mathbb{C}}^{-1} = |u|^{-2} = \vartheta(u)^2$. A compact $C \subseteq \mathbb{C}$ lies in a disc $\{|u| \leq R\}$, and in polar coordinates $\int_{|u| \leq R} |u|^{-1}\, du = \int_0^{2\pi} \int_0^R r^{-1}\, r\, dr\, d\theta = 2\pi R < \infty$, so $\int_C \vartheta\, d\mathrm{vol} < \infty$. □

Lemma 5.5.8. *Let ρ, b, s be real-place sizes and consider the data at $\mathbb{C}$ with box radius ρ. Let $L \geq \rho$ and let sizes be those of the size filtration of scale L. Then for all $x, y \in G$ and every $\varrho \times \iota'$ matrix Q over $\mathbb{C}$ there is a common bound for $\mathcal{V}_{\mathrm{cm}}(x, y, Q)$ with loss L^2.*

Proof. **Step 0: numbers.** As $m = 0$, $|\iota| = k - 1$, $|\iota'| = k - 5$ and the volume exponent is $|\iota'| - (3n + 1) = k - 3n - 6 = s$; so $|\iota'| = s + 1 + 3n$. Also $r \geq 1$, so $L \geq \rho \geq 8r \geq 8$, and $|\iota'| \leq k \leq r \leq L$.

Step 1: a space of common vectors. Fix x, y, Q. Let N be the matrix of the n linear forms $u \mapsto u_{e_a} - u_{e_a^*}$ $(a < \varrho)$ and $u \mapsto u_z$ on V; if $Nu = 0$ then $Ju = u$. Let C be the matrix with the rows of Q, of $Nx^{-1}O$ and of $N(xy)^{-1}O$; it has $\varrho + 2n \leq 3n$ rows, so its kernel in $\mathbb{C}^{\iota'}$ has dimension at least $|\iota'| - 3n = s + 1$. Let Y be an $\iota' \times (s + 1)$ matrix whose columns are orthonormal and lie in $\ker C$, and complete them to a unitary matrix $U = (Y\ Y')$. For $t \in \mathbb{C}^{s+1}$ and $w = Yt$: $Qw = 0$, and for $g \in \{x^{-1}, (xy)^{-1}\}$, $JgOw = gOw$, so

$$\|gOw\|^2 = (gOw)^* J(gOw) = h(gOw, gOw) = h(Ow, Ow) = \|w\|^2 = \|t\|^2,$$

as g is an isometry of h and h is the standard form on the span of the x_i. Hence $Yt \in \mathcal{V}_{\mathrm{cm}}(x, y, Q)$ whenever $\|t\|^2 < 1/2$.

Step 2: product differences. For close pairs (ω_1, ω_2), (ω_1', ω_2'), as J is unitary, $|h(u, v)| \leq \|u\|\|v\| \leq (\|u\|^2 + \|v\|^2)/2$, so $|h(\omega_1, \omega_1') - h(\omega_2, \omega_2')| < 1$: $\mathcal{D}_{\mathrm{pr}}$ lies in the unit disc.

Step 3: the two inequalities. For $\varsigma \in \mathbb{C}^{\iota'}$ put $q(\varsigma) = \|Y^*\varsigma\|^2$ and $\phi(\varsigma) = 36/q(\varsigma)$ $(= \infty$ if $q(\varsigma) = 0)$, a Borel function; let $q = q(\varsigma) > 0$ (otherwise there is nothing to prove). For $c \in \mathbb{C}$ with $|c| \leq \sqrt{q}/2$ let $t = (c/q)Y^*\varsigma$; then $\|t\|^2 = |c|^2/q \leq 1/4$, so $w = Yt$ is a common vector, and $\bar{\varsigma}^{\mathsf{T}} w = (c/q)(Y^*\varsigma)^*(Y^*\varsigma) = c$. So $\{\bar{\varsigma}^{\mathsf{T}} w : w \in \mathcal{V}_{\mathrm{cm}}\}$ contains the disc of radius $\sqrt{q}/2$, of area $\pi q/4 \geq q/36$, which gives the first inequality. If $\bar{c}\,\bar{\varsigma}^{\mathsf{T}} w \in \mathcal{D}_{\mathrm{pr}}$ for all common vectors w, take w with $\bar{\varsigma}^{\mathsf{T}} w = \sqrt{q}/2$: Step 2 gives $|c|\sqrt{q}/2 \leq 1$, so these c lie in the disc of radius $2/\sqrt{q}$, of area $4\pi/q \leq 36/q$.

Step 4: the integral. Let $j \geq 0$ and let B_j be the set of ς with $|\varsigma_i| \leq L^j$ for all i. The unitary substitution $(p, p') = (Y^*\varsigma, Y'^*\varsigma) \in \mathbb{C}^{s+1} \times \mathbb{C}^{3n}$ preserves Lebesgue measure; on B_j each coordinate has modulus at most $|\iota'|L^j \leq L^{j+1}$, so $\|p\|^2 \leq (s+1)L^{2j+2} \leq R := L^{2j+3}$. Hence, by polar coordinates on $\mathbb{C}^{s+1}$,

$$\int_{B_j} \phi^s \leq \int_0^R \Big(\frac{36}{u}\Big)^s \frac{\pi^{s+1} u^s}{s!}\, du \cdot (\pi L^{2j+2})^{3n} = \pi \frac{(36\pi)^s}{s!}\, R\, (\pi L^{2j+2})^{3n} \leq 4e^{144} R\, (4L^{2j+2})^{3n},$$

using $\pi \le 4$ and $(144)^s/s! \le e^{144}$. With $4e^{144} \le 4 \cdot 3^{144} \le L^{145}$ and $4 \le L$, this is at most $L^{145+(2j+3)(3n+1)} \le L^{198n(j+1)} = (L^2)^{99n(j+1)}$, since $145 + (2j+3)(3n+1) \le 198n(j+1)$ for $n \ge 1$. So ϕ is a common bound with loss L^2. □

Lemma 5.5.9. *Let $b \ge 2$ and $f \ge 1$, and let $(W, W^\flat)$ be a cut pair for b, f (of any type). Then $W^\flat$ is cut for the data at $\mathbb{C}$ with box radius b^{6n+2}: it is a Bessel function of frequency $M^{-1} = 1$ over the place, and for every g with $W^\flat(g) \ne 0$ there is $u \in \mathsf{U}$ with $\|ug\|_{\mathrm{op}} < b^{6n+2}$.*

Proof. $W^\flat$ is a Bessel function of the type of the pair: bounded, measurable, $W^\flat(uy) = \mathrm{wave}(\sigma(u))W^\flat(y) = \psi(M^{-1}\sigma(u))W^\flat(y)$ for $u \in \mathsf{U}$. Let $W^\flat(g) \ne 0$; by (BS2), $\ell(g) \le b^{6n+2}$. Every $s \in R$ is $s = uh$ with $u \in \mathsf{U}$, $h \in H$; h is unitary for the Euclidean inner product of $\mathbb{C}^r$ (it acts unitarily on X_0 and fixes the other basis vectors), so $\|uhg\|_{\mathrm{op}} = \|h(h^{-1}uh)g\|_{\mathrm{op}} = \|u'g\|_{\mathrm{op}}$ with $u' = h^{-1}uh \in \mathsf{U}$ (H normalises U, as it preserves the span of the basis vectors of each level). Hence $\inf_{u \in \mathsf{U}} \|ug\|_{\mathrm{op}} = \ell(g) - 1 \le b^{6n+2} - 1 < b^{6n+2}$, and some $u \in \mathsf{U}$ has $\|ug\|_{\mathrm{op}} < b^{6n+2}$, so $ug \in K$. □

Lemma 5.5.10. *Let $\rho > 0$ and let θ, $\theta_{\ge 0}$ be the group measure and the tower measure from floor 0 of the data at $\mathbb{C}$ with box radius ρ. There is a unique real number λ (the* Haar ratio*) with $\theta(E) = \lambda \int_{G_1} \mathbf{1}_E \, dy$ for every Borel set $E \subseteq G_1$, and*

$$0 < \lambda \le \frac{\mathrm{vol}\,\mathrm{U}(r)}{\mathrm{vol}\,\mathrm{U}(k)}.$$

Moreover, for every Borel $f \colon G_1 \to [0, \infty]$ with $f(uy) = f(y)$ for all $u \in \mathsf{U}$ and $y \in G_1$,

$$\int_{G_1} f \, d\theta_{\ge 0} = \lambda \int_{\mathsf{U} \backslash G_1} f.$$

Proof. **Step 1: the Cayley measure is a nonzero Haar measure, invariant under inversion.** By Lemma 5.2.41, dy is invariant under left and right translations. The Cayley transform $g \mapsto (g-1)(g+1)^{-1}$ inverts κ ($\kappa(y) = (1 + \frac{1}{2}J_1S(y))(1 - \frac{1}{2}J_1S(y))^{-1}$, and $y \mapsto S(y)$ is a linear bijection onto the skew-hermitian matrices), so κ is a homeomorphism of Ω onto the open neighbourhood $\{g : \det(g+1) \ne 0\}$ of 1 in G_1. For a compact ball $B \subseteq \Omega$ around 0, $\kappa(B)$ is a neighbourhood of 1, and by injectivity of κ, $\int \mathbf{1}_{\kappa(B)} \, dy = \mathrm{vol}\,\mathrm{U}(r)^{-1} \int_B |\det D(y)|^{-2r} \, dy \in (0, \infty)$, the density being continuous and positive on B. By Lemma 5.5.17 (iii), applied to the hermitian involution J_1 with $\mathrm{U}(J_1) = G_1$, dy is finite on compact sets; it is a Radon measure on the locally compact, second countable group G_1, hence a left and right Haar measure, nonzero. Its image under $g \mapsto g^{-1}$ is again a left Haar measure, so equals $c\,dy$ with $c > 0$ by uniqueness of Haar measure; applying inversion twice gives $c^2 = 1$, so dy is invariant under inversion.

Step 2: $\theta = \lambda\, dy$ with $0 < \lambda < \infty$. By Lemma 5.2.61, (iii), θ is right invariant, and by (iv) there, $\theta \ne 0$. For compact C, C^{-1} is compact, and by Lemma 5.5.11 and Step 1, $\theta(C) = \theta^{-1}(C^{-1}) \le \frac{\mathrm{vol}\,\mathrm{U}(r)}{\mathrm{vol}\,\mathrm{U}(k)} \int \mathbf{1}_{C^{-1}} dy < \infty$. So θ is a right-invariant Radon measure on G_1, and by uniqueness of right Haar measure (Weil) there is $\lambda \in [0, \infty)$ with $\theta = \lambda\, dy$; λ is unique as $dy \ne 0$, and $\lambda > 0$ as $\theta \ne 0$.

Step 3: the bound. By Step 1, $\theta^{-1} = \lambda\, dy$. With $E = \kappa(B)$ of Step 1, Lemma 5.5.11 gives $\lambda \int \mathbf{1}_E \, dy \le \frac{\mathrm{vol}\,\mathrm{U}(r)}{\mathrm{vol}\,\mathrm{U}(k)} \int \mathbf{1}_E \, dy$ with $0 < \int \mathbf{1}_E \, dy < \infty$, so $\lambda \le \mathrm{vol}\,\mathrm{U}(r)/\mathrm{vol}\,\mathrm{U}(k)$.

Step 4: unfolding. By Lemma 5.2.59, (iv), with $j = \varrho + 2$, $\theta = \mathfrak{m}_{\varrho+2} = \eta_{<\varrho+2} * \theta_{[0,\varrho+2)}$; here $\eta_{<\varrho+2} = \eta_{<\varrho}$ since $\eta_\varrho = \eta_{\varrho+1} = \delta_1$, and $\theta_{[0,\varrho+2)} = \theta_{\varrho+1} * \cdots * \theta_0 = \theta_{\ge 0}$. By Lemma 5.5.23,

$\eta_{<\varrho}$ is du carried to G_1. Let f be Borel, $f \geq 0$, left U-invariant, and χ the cutoff. By Step 2 and Tonelli (both measures s-finite),

$$\lambda \int_{\mathsf{U}\backslash G_1} f = \lambda \int f\chi \, dy = \int f\chi \, d\theta = \int_{G_1} \int_{\mathsf{U}} f(ug)\chi(ug) \, du \, d\theta_{\geq 0}(g)$$
$$= \int_{G_1} f(g) \int_{\mathsf{U}} \chi(ug) \, du \, d\theta_{\geq 0}(g) = \int f \, d\theta_{\geq 0}.$$

□

Lemma 5.5.11. *Let $\rho > 0$ and let θ be the group measure of the data at $\mathbb{C}$ with box radius ρ. Then the image θ^{-1} of θ under $g \mapsto g^{-1}$ satisfies*

$$\theta^{-1}(B) \leq \frac{\operatorname{vol} \mathrm{U}(r)}{\operatorname{vol} \mathrm{U}(k)} \int_{G_1} \mathbf{1}_B(y) \, dy \qquad \text{for every Borel set } B \subseteq G_1.$$

Proof. All measures below are Borel measures on G. Each of η_l, θ_l, μ_{top}, μ_H is s-finite (images of σ-finite measures, and μ_{top} by Definition 5.1.7); images, finite multiples and convolutions of s-finite measures are s-finite, so all measures that occur are, and Tonelli's theorem applies to all iterated integrals. For a measure μ write μ^{-1} for its image under $g \mapsto g^{-1}$. For a single column $y \in \mathbb{C}^r$, $\Gamma_J(y) = y^*Jy = h(y,y)$, so $\mathrm{Herm}_1 = \mathbb{R}$ with dT the Lebesgue measure, and for a matrix E with columns $\varepsilon_1, \ldots, \varepsilon_n$ the entries of E^*Jy are $h(\varepsilon_j, y)$. For $0 \leq l \leq \varrho$ let $E_l \in \mathrm{M}_{r\times 2l}(\mathbb{C})$ have the columns $e_0, e_0^*, \ldots, e_{l-1}, e_{l-1}^*$, and for $a < \varrho$ let $E'_a = (E_a \; e_a)$; thus $E_{a+1} = (E'_a \; e_a^*)$ and $(E_\varrho \; z) = E^{\mathrm{out}}$ is the matrix of Lemma 5.5.16. The data at $\mathbb{C}$ form a place datum by Lemma 5.5.5, (i).

Step 1: rules for inversion. For s-finite μ, μ' and Borel $f \geq 0$, by Tonelli

$$\int f \, d(\mu * \mu')^{-1} = \iint f(y^{-1}x^{-1}) \, d\mu(x) \, d\mu'(y) = \int f \, d(\mu'^{-1} * \mu^{-1}),$$

so $(\mu * \mu')^{-1} = \mu'^{-1} * \mu^{-1}$; convolution is associative and $(c\mu) * \mu' = c(\mu * \mu') = \mu * (c\mu')$ for $c \in [0, \infty)$. Moreover $\eta_l^{-1} = \eta_l$ for every l: for $l \geq \varrho$, $\eta_l = \delta_1$; for $l < \varrho$, Lemma 5.2.58, (iii), with $\tau = \bar{\tau} = \frac{1}{2}$ gives $n_l(v,\beta)\, n_l(-v,-\beta) = n_l(0, -\frac{1}{2}h(v,v) + \frac{1}{2}h(v,v)) = n_l(0,0) = 1$ (by (5.8)), so $n_l(v,\beta)^{-1} = n_l(-v,-\beta)$, and $(v,\beta) \mapsto (-v,-\beta)$ preserves $dv \otimes \nu$. Finally $\mu_H^{-1} = \mu_H$, because μ_H is the image of the Haar probability measure of the compact group $\mathrm{U}(k)$, which is invariant under inversion, under a homomorphism.

Step 2: the inverse of the group measure. By definition $\mathfrak{m}_{0,0} = \delta_1$ and $\mathfrak{m}_{0,j+1} = (\eta_j * \theta_j) * \mathfrak{m}_{0,j}$, so by Step 1

$$\mathfrak{m}_{0,j+1}^{-1} = \mathfrak{m}_{0,j}^{-1} * \theta_j^{-1} * \eta_j \qquad (j \geq 0).$$

As $\eta_\varrho = \eta_{\varrho+1} = \delta_1$, $\theta_\varrho = \mu_{\mathrm{top}}$ and $\theta_{\varrho+1} = \mu_H$, this gives $\theta^{-1} = \mathfrak{m}_{0,\varrho+2}^{-1} = \mathfrak{m}_{0,\varrho}^{-1} * \mu_{\mathrm{top}}^{-1} * \mu_H$.

Step 3: adding the frame vector of a floor. Let $0 \leq b \leq \varrho$ and let λ be s-finite and below the Gram fibre at E_b. We show that $\lambda * \frac{1}{2}\theta_b^{-1}$ is below the Gram fibre at $(E_b \; f_b)$, by Lemma 5.5.12, (i), with $E_1 = E_b$, $E_2 = f_b$, $\lambda' = \frac{1}{2}\theta_b^{-1}$. By Lemma 5.2.59, (ii), θ_b is carried by the group $G^{(b)}$, hence so is θ_b^{-1}; elements of $G^{(b)}$ fix the coordinate vectors of floor below b, which are the columns of E_b, so $g'E_b = E_b$ for λ'-almost every g'. The image of θ_b^{-1} under $g' \mapsto g'f_b$ is the image of θ_b under $\sigma \mapsto \sigma^{-1}f_b$, which is qv_b by Lemma 5.2.63 with $s = 1$. So the image of λ' under $g' \mapsto g'f_b$ is $\frac{1}{2}\mathrm{qv}_b$, which by Lemma 5.5.14 is below the fibre measure of $y \mapsto (E_b^*Jy, h(y,y))$ over its value at f_b; this is the hypothesis of Lemma 5.5.12, (i), for $n_2 = 1$.

Step 4: adding the dual vector of a floor. Let $0 \le a < \varrho$ and let λ be s-finite and below the Gram fibre at E'_a. Then $\lambda * \frac{1}{2}\eta_a$ is below the Gram fibre at E_{a+1}, by Lemma 5.5.12, (i), with $E_1 = E'_a$, $E_2 = e_a^*$, $\lambda' = \frac{1}{2}\eta_a$: each $n_a(v,\beta)$ fixes e_b, e_b^* $(b < a)$ and e_a (Definition 5.2.1), so the closed set $\{g' : g'E'_a = E'_a\}$ contains the image of n_a and has η_a-null complement; and the image of λ' under $g' \mapsto g'e_a^*$ is below the fibre measure of $y \mapsto (E_a'^* J y, h(y,y))$ over its value at e_a^* by Lemma 5.5.15.

Step 5: induction over the floors. We show that $4^{-l}\mathfrak{m}_{0,l}^{-1}$ is below the Gram fibre at E_l for $0 \le l \le \varrho$. For $l = 0$, $E_0 \in \mathrm{M}_{r\times 0}(\mathbb{C})$ and Herm_0 are points carrying unit masses, and the image of δ_1 under $g \mapsto gE_0$ is the unit mass; if $K \ge 0$ and C satisfy the hypothesis of (BY1), then the open set $S = \mathrm{Herm}_0$ lies in every neighbourhood of $\Gamma_J(E_0)$ and gives $\int K\, d\delta_{E_0} = K(E_0) \le C$. For the step from $a < \varrho$ to $a+1$, Steps 1 and 2 give

$$4^{-(a+1)}\mathfrak{m}_{0,a+1}^{-1} = \left((4^{-a}\mathfrak{m}_{0,a}^{-1}) * \tfrac{1}{2}\theta_a^{-1}\right) * \tfrac{1}{2}\eta_a;$$

by the induction hypothesis and Step 3 with $b = a$ ($f_a = e_a$, so $(E_a\ f_a) = E'_a$) the inner convolution is below the Gram fibre at E'_a, and by Step 4 the whole is below the Gram fibre at E_{a+1}.

Step 6: the top floor and the definite complement. By Step 5 for $l = \varrho$ and Step 3 with $b = \varrho$ ($f_\varrho = z$, $\theta_\varrho = \mu_{\mathrm{top}}$), $\lambda_0 = (4^{-\varrho}\mathfrak{m}_{0,\varrho}^{-1}) * \frac{1}{2}\mu_{\mathrm{top}}^{-1}$ is below the Gram fibre at $(E_\varrho\ z) = E^{\mathrm{out}}$. By Steps 1 and 2, $\theta^{-1} = 2^{2\varrho+1}\,\lambda_0 * \mu_H$, and Lemma 5.5.16 gives, for every Borel set $B \subseteq G_1$,

$$\theta^{-1}(B) = 2^{2\varrho+1}(\lambda_0 * \mu_H)(B) \le 2^{2\varrho+1}\,\frac{\mathrm{vol}\,\mathrm{U}(r)}{\mathrm{vol}\,\mathrm{U}(k)\,2^{2\varrho+1}}\int_{G_1} \mathbf{1}_B\, dy = \frac{\mathrm{vol}\,\mathrm{U}(r)}{\mathrm{vol}\,\mathrm{U}(k)}\int_{G_1}\mathbf{1}_B\, dy.$$

□

Lemma 5.5.12. *Let $J \in \mathrm{M}_N(\mathbb{C})$ be a hermitian involution.*

(i) Let $n_1, n_2 \ge 0$, $E_1 \in \mathrm{M}_{N\times n_1}(\mathbb{C})$, $E_2 \in \mathrm{M}_{N\times n_2}(\mathbb{C})$, and let $E = (E_1\ E_2) \in \mathrm{M}_{N\times(n_1+n_2)}(\mathbb{C})$ have the columns of E_1 followed by those of E_2. Give $\mathrm{M}_{n_1\times n_2}(\mathbb{C})$ the Lebesgue measure dM of the real and imaginary parts of its entries, $\mathrm{M}_{N\times n_2}(\mathbb{C})$ the measure dY and Herm_{n_2} the measure dT, and let

$$\pi\colon \mathrm{M}_{N\times n_2}(\mathbb{C}) \to \mathrm{M}_{n_1\times n_2}(\mathbb{C}) \times \mathrm{Herm}_{n_2}, \qquad \pi(Y) = \big(E_1^* J Y,\ \Gamma_J(Y)\big).$$

Let λ, λ' be s-finite Borel measures on $\mathrm{U}(J)$ such that λ is below the Gram fibre at E_1, $g'E_1 = E_1$ for λ'-almost every g', and the image of λ' under $g' \mapsto g'E_2$ is below the fibre measure $dY/(dM \otimes dT)$ of π over $\pi(E_2)$. Then the convolution $\lambda * \lambda'$ is below the Gram fibre at E.

(ii) Let $m \ge 0$, $E \in \mathrm{M}_{N\times m}(\mathbb{C})$ and let P be an $m \times m$ permutation matrix. If a Borel measure λ on $\mathrm{U}(J)$ is below the Gram fibre at E, then it is below the Gram fibre at EP.

Proof. Throughout, Lebesgue measures on matrix spaces are those of the real and imaginary parts of the entries, dT_j is the measure dT of Herm_j, and for $g \in \mathrm{U}(J)$ we have $|\det g| = 1$ (from $g^*Jg = J$ and $|\det J| = 1$), so left multiplication by g, acting on each column, preserves Lebesgue measure on $\mathrm{M}_{N\times j}(\mathbb{C})$ (its real determinant is $|\det g|^{2j}$), and $\Gamma_J(gY) = \Gamma_J(Y)$.

(i), Step 1: the first block. Let $n = n_1 + n_2$ and write $Y \in \mathrm{M}_{N\times n}(\mathbb{C})$ as $Y = (Y_1\ Y_2)$ with Y_1 its first n_1 columns. Put $\pi_1(Y) = \Gamma_J(Y_1)$, $\pi_2(Y) = (Y_1^* J Y_2, \Gamma_J(Y_2))$ and $\mathrm{mv}(g,y) = (gE_1\ gy)$

for $g \in \mathrm{U}(J)$, $y \in \mathrm{M}_{N\times n_2}(\mathbb{C})$. Let ℓ_1 be the image of λ under $g \mapsto gE_1$, and κ the image of $\lambda \otimes dy$ under mv, dy the Lebesgue measure of $\mathrm{M}_{N\times n_2}(\mathbb{C})$. Substituting gy for y for fixed g (Tonelli),

$$\int f\,d\kappa = \iint f((gE_1\ gy))\,dy\,d\lambda(g) = \iint f((gE_1\ y))\,dy\,d\lambda(g) = \int f\,d\varphi_*(dy\otimes\ell_1)$$

for Borel $f \geq 0$, where $\varphi(y, Y_1) = (Y_1\ y)$. By hypothesis ℓ_1 is below the fibre measure dY_1/dT_{n_1} of Γ_J over $\Gamma_J(E_1)$. By Lemma 5.5.13, (v), with the parameter space $\mathrm{M}_{N\times n_2}(\mathbb{C})$ and dy, the continuous maps $Y_1 \mapsto \varphi(y, Y_1)$ and $\pi_0 = \pi_1$ (indeed $\pi_1(\varphi(y, Y_1)) = \Gamma_J(Y_1)$), the measure $\kappa = \varphi_*(dy \otimes \ell_1)$ is below the fibre measure of π_1 over $\Gamma_J(E_1)$ for $\varphi_*(dy \otimes dY_1)$ and dT_{n_1}; and $\varphi_*(dy \otimes dY_1)$ is the Lebesgue measure dY of $\mathrm{M}_{N\times n}(\mathbb{C})$, φ being a permutation of coordinates.

Step 2: the law of gE. Let ℓ_2 be the image of λ' under $g' \mapsto g'E_2$. As $g'E_1 = E_1$ for λ'-almost every g', $\mathrm{mv}(g, g'E_2) = (gg'E_1\ gg'E_2) = gg'E$ for $\lambda \otimes \lambda'$-almost every (g, g'), so the image of $\lambda \otimes \ell_2$ under mv is the image of $\lambda * \lambda'$ under $h \mapsto hE$; call it ℓ.

Step 3: the second block. By hypothesis ℓ_2 is below the fibre measure $dy/(dM \otimes dT_{n_2})$ of π over $\pi(E_2)$. For $g \in \mathrm{U}(J)$, $\pi_2(\mathrm{mv}(g, y)) = (E_1^* g^* Jgy, \Gamma_J(gy)) = \pi(y)$, and $y \mapsto \mathrm{mv}(g, y)$ is continuous. By Lemma 5.5.13, (v), with the parameter space $\mathrm{U}(J)$ and λ, $\ell = \mathrm{mv}_*(\lambda \otimes \ell_2)$ is below the fibre measure of π_2 over $\pi(E_2)$ for $\mathrm{mv}_*(\lambda \otimes dy) = \kappa$ and $dM \otimes dT_{n_2}$.

Step 4: composition and the blocks of the Gram matrix. As π_2 is continuous and the base measures are s-finite, Steps 1 and 3 and Lemma 5.5.13, (iv), show that ℓ is below the fibre measure $dY/(dT_{n_1} \otimes dM \otimes dT_{n_2})$ of $Y \mapsto (\pi_1(Y), \pi_2(Y))$ over $(\Gamma_J(E_1), \pi(E_2))$. Let $\mathrm{bl}\colon \mathrm{Herm}_n \to \mathrm{Herm}_{n_1} \times \mathrm{M}_{n_1\times n_2}(\mathbb{C}) \times \mathrm{Herm}_{n_2}$ send T to its blocks (T_{11}, T_{12}, T_{22}). It is a linear bijection ($T_{21} = T_{12}^*$), and it permutes coordinates: the diagonal entries of T are those of T_{11} and T_{22}, and the entries T_{ab} with $a < b$ are the entries above the diagonal of T_{11} or T_{22}, or, when $a \leq n_1 < b$, the entries of T_{12}. So bl is a homeomorphism carrying dT_n to $dT_{n_1} \otimes dM \otimes dT_{n_2}$. Since $\Gamma_J(Y) = \left(\begin{smallmatrix} Y_1^*JY_1 & Y_1^*JY_2 \\ Y_2^*JY_1 & Y_2^*JY_2 \end{smallmatrix}\right)$, $(\pi_1, \pi_2) = \mathrm{bl} \circ \Gamma_J$, and $(\Gamma_J(E_1), \pi(E_2)) = \mathrm{bl}(\Gamma_J(E))$. By Lemma 5.5.13, (iii), with the homeomorphism bl^{-1}, ℓ is below the fibre measure dY/dT_n of Γ_J over $\Gamma_J(E)$, that is, $\lambda * \lambda'$ is below the Gram fibre at E.

(ii). Let ℓ be the image of λ under $g \mapsto gE$, $r_P(Y) = YP$ on $\mathrm{M}_{N\times m}(\mathbb{C})$ and $c_P(T) = P^{\mathsf{T}}TP$ on Herm_m. The map r_P permutes columns, so it is continuous and preserves Lebesgue measure. If P sends the j-th standard basis vector to the $p(j)$-th, then $c_P(T)_{ab} = T_{p(a)p(b)}$: c_P permutes the diagonal entries, and sends each entry above the diagonal to an entry above the diagonal or to the conjugate of one; so c_P is a homeomorphism carrying dT to dT. As P is real, $\Gamma_J(YP) = c_P(\Gamma_J(Y))$. By Lemma 5.5.13, (iii), ℓ is below the fibre measure dY/dT of $c_P \circ \Gamma_J = \Gamma_J \circ r_P$ over $c_P(\Gamma_J(E)) = \Gamma_J(EP)$, and by Lemma 5.5.13, (vi), the image of ℓ under r_P, which is the image of λ under $g \mapsto gEP$, is below the fibre measure of Γ_J over $\Gamma_J(EP)$ for $(r_P)_* dY = dY$ and dT. □

Lemma 5.5.13. *In this lemma every topological space is separable and metrizable and carries its Borel σ-algebra; products carry the product topology, whose Borel σ-algebra is the product σ-algebra. Let $\pi\colon X \to B$ be Borel, μ a Borel measure on X, ν a Borel measure on B and $\beta \in B$; "below $d\mu/d\nu$" means below the fibre measure $d\mu/d\nu$ of π over β when π, β are clear.*

(i) (Parametrisations.) Suppose $\nu(O) > 0$ for every nonempty open $O \subseteq B$ and every point of B has a neighbourhood of finite ν-measure. Let V be a neighbourhood of β, P a space with an s-finite Borel measure μ_P, and $\psi\colon B \times P \to X$, $w\colon B \times P \to [0, \infty]$ Borel maps such that: for every $t \in V$, $\pi(\psi(t, p)) = t$ for μ_P-almost every p with $w(t, p) \neq 0$; for μ_P-almost every p the maps $t \mapsto \psi(t, p)$ and $t \mapsto w(t, p)$ are continuous at β; and

$$\int_V \int_P w(t,p)\,K(\psi(t,p))\,d\mu_P(p)\,d\nu(t) \leq \int_X K\,d\mu \qquad \text{for every Borel } K\colon X \to [0,\infty].$$

Then the image of the measure $w(\beta,p)\,d\mu_P(p)$ under $p\mapsto\psi(\beta,p)$ is below the fibre measure $d\mu/d\nu$ of π over β.

(ii) (Measure-preserving parametrisations.) Suppose ν is as in (i), μ_P is an s-finite Borel measure on a space P, and $\varphi\colon B\times P\to X$ is a Borel map carrying $\nu\otimes\mu_P$ to μ, with $\pi(\varphi(t,p))=t$ for all (t,p) and $t\mapsto\varphi(t,p)$ continuous at β for every p. Then the image of μ_P under $p\mapsto\varphi(\beta,p)$ is below the fibre measure $d\mu/d\nu$ of π over β.

(iii) (Change of base.) Let $e\colon B\to B'$ be a homeomorphism carrying ν to a measure ν'. If λ is below the fibre measure $d\mu/d\nu$ of π over β, then λ is below the fibre measure $d\mu/d\nu'$ of $e\circ\pi$ over $e(\beta)$.

(iv) (Two steps.) Let ν, ν' be s-finite, ν' a Borel measure on B', $\pi_2\colon X\to B'$ continuous and $\beta'\in B'$. If λ is below the fibre measure $d\mu/d\nu$ of π over β and λ' is below the fibre measure $d\lambda/d\nu'$ of π_2 over β', then λ' is below the fibre measure $d\mu/(\nu\otimes\nu')$ of $x\mapsto(\pi(x),\pi_2(x))$ over (β,β').

(v) (Families.) Let μ and λ be s-finite, μ_P an s-finite Borel measure on a space P, $\varphi\colon P\times X\to X'$ a Borel map with $x\mapsto\varphi(p,x)$ continuous for every p, and $\pi_0\colon X'\to B$ Borel with $\pi_0(\varphi(p,x))=\pi(x)$ for all (p,x). If λ is below the fibre measure $d\mu/d\nu$ of π over β, then the image of $\mu_P\otimes\lambda$ under φ is below the fibre measure of π_0 over β for the image of $\mu_P\otimes\mu$ under φ and ν.

(vi) (Images.) Let $\varphi\colon X\to X'$ be continuous and $\pi_0\colon X'\to B$ Borel. If λ is below the fibre measure $d\mu/d\nu$ of $\pi_0\circ\varphi$ over β, then the image of λ under φ is below the fibre measure of π_0 over β for the image of μ under φ and ν.

Proof. All functions below take values in $[0,\infty]$, with $0\cdot\infty=0$; Tonelli's theorem is used for s-finite measures, and jointly Borel integrands, on products of the spaces above. A function A is lower semicontinuous at x_0 if for every $c<A(x_0)$ the set $\{A>c\}$ is a neighbourhood of x_0; in a metrizable space this is equivalent to $A(x_0)\le\liminf A(x_j)$ for every sequence $x_j\to x_0$.

Two auxiliary facts. (A) Let μ_P be a measure on P and $F\colon X\times P\to[0,\infty]$ with $F(x,\cdot)$ Borel for every x and $x\mapsto F(x,p)$ lower semicontinuous at x_0 for μ_P-almost every p. Then $x\mapsto\int F(x,p)\,d\mu_P(p)$ is lower semicontinuous at x_0: for $x_j\to x_0$, Fatou's lemma gives $\int F(x_0,p)\,d\mu_P\le\int\liminf_j F(x_j,p)\,d\mu_P\le\liminf_j\int F(x_j,p)\,d\mu_P$. (B) Let ν be as in (i), let $A\colon B\to[0,\infty]$ be lower semicontinuous at β and Borel, $C\in[0,\infty]$, and U a neighbourhood of β with $\int_S A\,d\nu\le C\,\nu(S)$ for every open $S\subseteq U$. Then $A(\beta)\le C$: for $c<A(\beta)$ there is an open $S\ni\beta$ inside U, inside $\{A>c\}$ and of finite measure; then $0<\nu(S)<\infty$ and $c\,\nu(S)\le\int_S A\,d\nu\le C\,\nu(S)$, so $c\le C$.

(i). Let $K\colon X\to[0,\infty]$ be lower semicontinuous, $C\in[0,\infty]$ and U a neighbourhood of β with $\int_{\pi^{-1}(S)}K\,d\mu\le C\nu(S)$ for open $S\subseteq U$. Put $A(t)=\int_P w(t,p)K(\psi(t,p))\,d\mu_P(p)$, a Borel function of t by Tonelli; the integral of K against the image measure of (i) is $A(\beta)$. For almost every p, $t\mapsto K(\psi(t,p))$ is lower semicontinuous at β and $t\mapsto w(t,p)$ is continuous there, so their product is lower semicontinuous at β (for $t_j\to\beta$, $w(\beta,p)K(\psi(\beta,p))\le\lim_j w(t_j,p)\cdot\liminf_j K(\psi(t_j,p))\le\liminf_j w(t_j,p)K(\psi(t_j,p))$, where the second inequality holds as the middle product is 0 if a factor is 0, and otherwise, for finite $0<a'<\lim_j w(t_j,p)$ and $0<b'<\liminf_j K(\psi(t_j,p))$, the products $w(t_j,p)K(\psi(t_j,p))$ eventually exceed $a'b'$); by (A), A is lower semicontinuous at β. Let $S\subseteq U\cap V$ be open. For $t\in S$ and almost every p, either $w(t,p)=0$ or $\psi(t,p)\in\pi^{-1}(S)$, so $w(t,p)K(\psi(t,p))=w(t,p)(\mathbf{1}_{\pi^{-1}(S)}K)(\psi(t,p))$; hence,

applying the hypothesis to the Borel function $\mathbf{1}_{\pi^{-1}(S)}K$,

$$\int_S A\,d\nu \le \int_V \int_P w(t,p)\,(\mathbf{1}_{\pi^{-1}(S)}K)(\psi(t,p))\,d\mu_P\,d\nu \le \int_{\pi^{-1}(S)} K\,d\mu \le C\,\nu(S).$$

By (B) with the neighbourhood $U\cap V$, $A(\beta)\le C$.

(ii). The measure ν is σ-finite: B is Lindelöf and covered by open sets of finite measure. Apply (i) with $V=B$, $\psi=\varphi$ and $w\equiv 1$: the fibre and continuity conditions hold for all t, p, and for Borel K, by Tonelli and as φ carries $\nu\otimes\mu_P$ to μ, $\int_B\int_P K(\varphi(t,p))\,d\mu_P\,d\nu = \int K\circ\varphi\,d(\nu\otimes\mu_P) = \int K\,d\mu$.

(iii). Let K, C and a neighbourhood U' of $e(\beta)$ be such that $\int_{(e\circ\pi)^{-1}(S')} K\,d\mu \le C\nu'(S')$ for open $S'\subseteq U'$. Then $e^{-1}(U')$ is a neighbourhood of β, and for open $S\subseteq e^{-1}(U')$ the set $S'=e(S)$ is open in U', $(e\circ\pi)^{-1}(S') = \pi^{-1}(S)$ and $\nu'(S') = \nu(e^{-1}(S')) = \nu(S)$. So the hypothesis of (BY1) for λ, π, β holds, and $\int K\,d\lambda\le C$.

(iv). Let K be lower semicontinuous, $C\in[0,\infty]$, and U a neighbourhood of (β,β') with $\int_{(\pi,\pi_2)^{-1}(S)} K\,d\mu \le C\,(\nu\otimes\nu')(S)$ for open $S\subseteq U$. Choose open $W\ni\beta$, $W'\ni\beta'$ with $W\times W'\subseteq U$, and let $S'\subseteq W'$ be open. The function $K'=\mathbf{1}_{\pi_2^{-1}(S')}K$ is lower semicontinuous ($\pi_2^{-1}(S')$ is open), and for open $S\subseteq W$

$$\int_{\pi^{-1}(S)} K'\,d\mu = \int_{(\pi,\pi_2)^{-1}(S\times S')} K\,d\mu \le C\,\nu(S)\,\nu'(S') = \big(C\nu'(S')\big)\,\nu(S),$$

as $S\times S'\subseteq U$ is open. Since λ is below $d\mu/d\nu$, $\int_{\pi_2^{-1}(S')} K\,d\lambda = \int K'\,d\lambda \le C\nu'(S')$ for every open $S'\subseteq W'$, and since λ' is below $d\lambda/d\nu'$, $\int K\,d\lambda'\le C$.

(v). Let $K\colon X'\to[0,\infty]$ be lower semicontinuous, C and U as in (BY1) for π_0 and the image $\varphi_*(\mu_P\otimes\mu)$. Put $K'(x)=\int_P K(\varphi(p,x))\,d\mu_P(p)$. For each p, $x\mapsto K(\varphi(p,x))$ is lower semicontinuous, so K' is lower semicontinuous by (A), and $\int K\,d\varphi_*(\mu_P\otimes\lambda) = \int K'\,d\lambda$ by Tonelli. For open $S\subseteq U$, as $\mathbf{1}_{\pi^{-1}(S)}(x) = \mathbf{1}_{\pi_0^{-1}(S)}(\varphi(p,x))$,

$$\int_{\pi^{-1}(S)} K'\,d\mu = \int \mathbf{1}_{\pi_0^{-1}(S)}(\varphi(p,x))\,K(\varphi(p,x))\,d(\mu_P\otimes\mu)(p,x) = \int_{\pi_0^{-1}(S)} K\,d\varphi_*(\mu_P\otimes\mu) \le C\,\nu(S),$$

so $\int K'\,d\lambda\le C$.

(vi). For lower semicontinuous K on X', $K\circ\varphi$ is lower semicontinuous, $\int_{(\pi_0\circ\varphi)^{-1}(S)} K\circ\varphi\,d\mu = \int_{\pi_0^{-1}(S)} K\,d\varphi_*\mu$, and $\int K\circ\varphi\,d\lambda = \int K\,d\varphi_*\lambda$; so the hypothesis of (BY1) for $\varphi_*\lambda$ is the hypothesis for λ, and the conclusion follows. □

Lemma 5.5.14. *Let $\rho>0$, consider the data at $\mathbb{C}$ with box radius ρ, and let $0\le b\le \varrho$. Let $E_b\in \mathrm{M}_{r\times 2b}(\mathbb{C})$ be the matrix with the columns $e_0, e_0^*, \dots, e_{b-1}, e_{b-1}^*$, and*

$$\pi_b\colon V\to\mathbb{C}^{2b}\times\mathbb{R},\qquad \pi_b(y) = \big(E_b^*Jy,\ h(y,y)\big),$$

so that the entries of E_b^*Jy are the products $h(e_a,y)$, $h(e_a^*,y)$, $a<b$. Give V the Lebesgue measure dy of the real and imaginary parts of the coordinates, and $\mathbb{C}^{2b}\times\mathbb{R}$ the Lebesgue measure $dc\otimes dt$. Then $\frac12\mathrm{qv}_b$ is below the fibre measure $dy/(dc\otimes dt)$ of π_b over $\pi_b(f_b)=(0,h(f_b,f_b))$.

Proof. For $a<\varrho$, $Je_a=e_a^*$ and $Je_a^*=e_a$, so $h(e_a,y)$ and $h(e_a^*,y)$ are the coordinates of y at e_a^* and at e_a. In particular $E_b^*Jf_b=0$, as $f_b\in\{e_b,z\}$ has no coordinate of floor below b, and $\pi_b(f_b)=(0,h(f_b,f_b))$. Put $t_0=h(f_b,f_b)$.

Step 1: the products with the lower basis vectors. Let I_b be the set of indices of floor below b and I_b' its complement, so $V=\mathbb{C}^{I_b}\times\mathbb{C}^{I_b'}$ and dy is the product of the Lebesgue

measures. For $c \in \mathbb{C}^{2b}$ and $v \in \mathbb{C}^{I'_b}$ let $\phi(c,v) \in V$ have the coordinates c_{2a+1} at e_a^* and c_{2a+2} at e_a ($a < b$) and v at the indices in I'_b. Then ϕ is a permutation of coordinates, so it carries $dc \otimes dv$ to dy; $E_b^* J \phi(c,v) = c$; and ϕ is continuous. By Lemma 5.5.13, (ii), at the base point 0 of $\mathbb{C}^{2b}$, the image of dv under $v \mapsto \phi(0,v)$, which is vol_{V_b} (as I'_b is the set of indices of floor at least b), is below the fibre measure dy/dc of $y \mapsto E_b^* J y$ over 0.

Step 2: the norm. We show that $\frac{1}{2}\mathrm{qv}_b$ is below the fibre measure $d\mathrm{vol}_{V_b}/dt$ of $y \mapsto h(y,y)$ over t_0, by Lemma 5.5.13, (i), with the space V and its measure vol_{V_b}, the base space $\mathbb{R}$ with the measure dt, the base point t_0 and its neighbourhood $\mathbb{R}$, $P = \mathbb{C} \times Y_b \times \mathrm{i}\mathbb{R}$ with $\mu_P = \mathrm{vol} \otimes \mathrm{vol} \otimes \nu$, $w \equiv \frac{1}{2}$, and

$$\psi(t,(s,Y,\alpha)) = B_b(s^\dagger \tfrac{1}{2}(t - h'_b(Y,Y)) + s\alpha,\ s,\ Y),$$

the flat chart (5.4) with parameter δt (as $\tau\delta^{-1} \cdot \delta t = t/2$); ψ is Borel and affine in t, and the image of $\frac{1}{2}\mu_P$ under $\psi(t_0,\cdot)$ is $\frac{1}{2}\mathrm{qv}_b(\delta t_0) = \frac{1}{2}\mathrm{qv}_b$. Fibres: for $s \neq 0$, so for μ_P-almost every p, $h(\psi(t,p),\psi(t,p)) = t$.

Bound: for Borel $K \geq 0$, by Tonelli, then the substitution $\beta = \delta t = \mathrm{i}t/2$, which carries $\frac{1}{2}dt$ to ν, and the disintegration (DJ2) of vol_{V_b} along $h(y,y)$ by $(\mathrm{qv}_b(\beta))_\beta$ (Lemma 5.2.52, (ii), for the place $\mathbb{C}$ of Lemma 5.5.7 and the place datum of Lemma 5.5.5, (i)) applied to $f(c,y) = K(y)$,

$$\int_{\mathbb{R}} \int_P \tfrac{1}{2} K(\psi(t,p))\, d\mu_P\, dt = \int_{\mathbb{R}} \int K\, d\mathrm{qv}_b(\delta t)\, \tfrac{1}{2} dt = \int_{\mathrm{i}\mathbb{R}} \int K\, d\mathrm{qv}_b(\beta)\, d\nu(\beta) = \int K\, d\mathrm{vol}_{V_b}$$

(the function $\beta \mapsto \int K\, d\mathrm{qv}_b(\beta)$ is Borel by Tonelli, so the outer integral in (DJ2) is the ordinary one). Lebesgue measure on $\mathbb{R}$ is positive on nonempty open sets and locally finite, so Lemma 5.5.13, (i), applies.

Step 3: composition. As $y \mapsto h(y,y)$ is continuous, Steps 1 and 2 and Lemma 5.5.13, (iv), show that $\frac{1}{2}\mathrm{qv}_b$ is below the fibre measure $dy/(dc \otimes dt)$ of π_b over $(0,t_0) = \pi_b(f_b)$. □

Lemma 5.5.15. *Let $\rho > 0$, consider the data at $\mathbb{C}$ with box radius ρ, and let $0 \leq a < \varrho$. Let $E'_a \in \mathrm{M}_{r \times (2a+1)}(\mathbb{C})$ be the matrix with the columns $e_0, e_0^*, \dots, e_{a-1}, e_{a-1}^*, e_a$, and*

$$\pi'_a \colon V \to \mathbb{C}^{2a+1} \times \mathbb{R}, \qquad \pi'_a(y) = (E_a'^* J y,\ h(y,y)).$$

Give V the Lebesgue measure dy of the real and imaginary parts of the coordinates, and $\mathbb{C}^{2a+1} \times \mathbb{R}$ the Lebesgue measure $dc \otimes dt$. Then one half of the image of η_a under $G \to V$, $u \mapsto ue_a^*$, is below the fibre measure $dy/(dc \otimes dt)$ of π'_a over $\pi'_a(e_a^*) = (\epsilon, 0)$, where $\epsilon \in \mathbb{C}^{2a+1}$ has last entry $h(e_a, e_a^*) = 1$ and all other entries 0.

Proof. For $b < \varrho$, $h(e_b, y)$ and $h(e_b^*, y)$ are the coordinates of y at e_b^* and e_b ($Je_b = e_b^*$, $Je_b^* = e_b$). So the entries of $E_a'^* J y$ are the coordinates of y at $e_0^*, e_0, \dots, e_{a-1}^*, e_{a-1}, e_a^*$, and $E_a'^* J e_a^* = \epsilon$; also $h(e_a^*, e_a^*) = 0$, so $\pi'_a(e_a^*) = (\epsilon, 0)$.

Step 1: the products. The indices not listed above are e_a and the indices of floor at least $a+1$. For $c \in \mathbb{C}^{2a+1}$, $\mu' \in \mathbb{C}$ and $v \in V_{a+1}$ let $\phi(c,(\mu',v)) \in V$ have the coordinates c_{2b+1} at e_b^*, c_{2b+2} at e_b ($b < a$), c_{2a+1} at e_a^*, μ' at e_a, and the coordinates of v at the indices of floor at least $a+1$. It is a permutation of coordinates, hence carries $dc \otimes d\mu' \otimes dv$ to dy, it is continuous, and $E_a'^* J \phi(c,(\mu',v)) = c$. By Lemma 5.5.13, (ii), at the base point ϵ, the image λ_a of $d\mu' \otimes dv$ under $(\mu',v) \mapsto \phi(\epsilon,(\mu',v)) = e_a^* + v + \mu' e_a$ is below the fibre measure dy/dc of $y \mapsto E_a'^* J y$ over ϵ.

Step 2: the norm. For $\mu' \in \mathbb{C}$ and $v \in V_{a+1}$, as e_a, e_a^* are isotropic with $h(e_a, e_a^*) = 1$ and orthogonal to V_{a+1},

$$h(e_a^* + v + \mu' e_a,\ e_a^* + v + \mu' e_a) = 2\,\mathrm{Re}\,\mu' + h(v,v).$$

Apply Lemma 5.5.13, (i), with the space V and the measure λ_a, the map $y \mapsto h(y,y)$, the base space $\mathbb{R}$ with dt, the base point 0 and its neighbourhood $\mathbb{R}$, the parameter space $V_{a+1} \times \mathrm{i}\mathbb{R}$ with $dv \otimes \nu$, $w \equiv \frac{1}{2}$ and

$$\psi(t,(v,\beta)) = e_a^* + v + (\tfrac{t}{2} + \beta - \tfrac{1}{2}h(v,v))e_a.$$

Since $\operatorname{Re}\beta = 0$ and $h(v,v)$ is real, $h(\psi(t,(v,\beta)),\psi(t,(v,\beta))) = t$ for all t, v, β; ψ is continuous; and $\psi(0,(v,\beta)) = n_a(v,\beta)e_a^*$, so the image of $\frac{1}{2}dv \otimes \nu$ under $\psi(0,\cdot)$ is one half of the image of η_a under $u \mapsto ue_a^*$. For Borel $K \geq 0$, by Tonelli, then because $(t,\beta) \mapsto \frac{t}{2} + \beta$ carries $\frac{1}{2}dt \otimes \nu$ to Lebesgue measure $d\mu'$ of $\mathbb{C}$ (real part $t/2$, imaginary part the coordinate of β), and by the translation invariance of $d\mu'$,

$$\int_{\mathbb{R}} \iint \tfrac{1}{2}K(\psi(t,(v,\beta)))\,d\nu(\beta)\,dv\,dt = \int_{V_{a+1}} \int_{\mathbb{C}} K(e_a^* + v + (\mu' - \tfrac{1}{2}h(v,v))e_a)\,d\mu'\,dv = \int K\,d\lambda_a.$$

So one half of the image of η_a under $u \mapsto ue_a^*$ is below the fibre measure $d\lambda_a/dt$ of $y \mapsto h(y,y)$ over 0.

Step 3: composition. As $y \mapsto h(y,y)$ is continuous, Steps 1 and 2 and Lemma 5.5.13, (iv), give the claim over $(\epsilon, 0) = \pi'_a(e_a^*)$. □

Lemma 5.5.16. *Let $E^{\mathrm{out}} \in \mathrm{M}_{r\times(2\varrho+1)}(\mathbb{C})$ be the matrix with the columns $e_0, e_0^*, \dots, e_{\varrho-1}, e_{\varrho-1}^*, z$. If λ is an s-finite Borel measure on G_1 below the Gram fibre at E^{out} (for $J = J_1$), then*

$$(\lambda * \mu_H)(B) \leq \frac{\operatorname{vol}\mathrm{U}(r)}{\operatorname{vol}\mathrm{U}(k)\,2^{2\varrho+1}} \int_{G_1} \mathbf{1}_B(y)\,dy \qquad \text{for every Borel set } B \subseteq G_1.$$

Proof. Write $J = J_1$, let $X \in \mathrm{M}_{r\times k}(\mathbb{C})$ have the columns $x_1, \dots, x_k$, let $c = \operatorname{vol}\mathrm{U}(k)/2^k$, and let $\iota\colon \mathrm{U}(k) \to G_1$ be the embedding of (RP4), $\iota(h)x_j = \sum_i h_{ij}x_i$, $\iota(h)$ fixing e_a, e_a^*, z; so $\iota(h)X = Xh$ and $\iota(h)E^{\mathrm{out}} = E^{\mathrm{out}}$. Matrix spaces carry the Lebesgue measures of the real and imaginary parts of the entries, Herm_k the measure dT_k. As $T = 1$ on the x_i and the x_i are orthogonal to the other coordinate vectors, $JX = X$; and $X^*X = 1$, $E^{\mathrm{out}*}E^{\mathrm{out}} = 1$, $E^{\mathrm{out}*}X = 0$, the columns being distinct standard basis vectors.

Step 1: bases of X_0. The Cayley measure dh of $\mathrm{U}(1_k) = \mathrm{U}(k)$ is invariant under left translations (Lemma 5.2.41), has total mass 1 (Lemma 5.5.21) and is finite on compact sets and outer regular (Lemma 5.5.17, (iii)); by uniqueness of Haar measure it is the Haar probability measure of $\mathrm{U}(k)$, so μ_H is the image of dh under ι. By Lemma 5.5.17, (ii), with $N = k$ and $J = 1_k$, the measure $c\,dh$, viewed on $\mathrm{M}_k(\mathbb{C})$, is below the fibre measure dx/dT_k of $x \mapsto x^*x$ over 1_k. Let $\varphi(x) = Xx$; then $\Gamma_J(\varphi(x)) = x^*X^*JXx = x^*x$. By Lemma 5.5.13, (vi), the image of $c\,dh$ under $h \mapsto Xh = \iota(h)X$, which is the image of $c\mu_H$ under $g \mapsto gX$, is below the fibre measure of Γ_J over $1_k = \Gamma_J(X)$ for $\varphi_* dx$ and dT_k.

Step 2: the products with E^{out}. By Lemma 5.5.20 with $E = E^{\mathrm{out}}$, $R = X$, $n_1 = 2\varrho + 1$, $n_2 = n = k$ and $M = 0$, $\varphi_* dx$ is below the fibre measure dy/dM of $y \mapsto E^{\mathrm{out}*}Jy$ on $\mathrm{M}_{r\times k}(\mathbb{C})$ over $0 = E^{\mathrm{out}*}JX$. As Γ_J is continuous, Lemma 5.5.13, (iv), and Step 1 show that the image of $c\mu_H$ under $g \mapsto gX$ is below the fibre measure $dy/(dM \otimes dT_k)$ of $y \mapsto (E^{\mathrm{out}*}Jy, \Gamma_J(y))$ over $(E^{\mathrm{out}*}JX, \Gamma_J(X))$.

Step 3: the full basis. Every element of the image of ι fixes E^{out}, so $gE^{\mathrm{out}} = E^{\mathrm{out}}$ for μ_H-almost every g. By Step 2 and Lemma 5.5.12, (i), with $E_1 = E^{\mathrm{out}}$, $E_2 = X$ and the s-finite measures λ, $c\mu_H$, the convolution $\lambda * c\mu_H$ is below the Gram fibre at $P_0 = (E^{\mathrm{out}}\ X)$. The columns of P_0 are the r coordinate vectors, each once, so P_0 is a permutation matrix, and by

Lemma 5.5.12, (ii), with $P = P_0^{-1}$, $\lambda * c\mu_H$ is below the Gram fibre at 1_r. By Lemma 5.5.17, (i), for $J = J_1$, for every Borel $B \subseteq G_1$

$$c\,(\lambda * \mu_H)(B) = (\lambda * c\mu_H)(B) \leq \frac{\operatorname{vol} \mathrm{U}(r)}{2^r} \int \mathbf{1}_B \, dy,$$

and as $r - k = 2\varrho + 1$, $(\lambda * \mu_H)(B) \leq \frac{\operatorname{vol} \mathrm{U}(r)}{\operatorname{vol} \mathrm{U}(k)\, 2^{2\varrho+1}} \int \mathbf{1}_B \, dy$. □

Lemma 5.5.17. *Let $J \in \mathrm{M}_N(\mathbb{C})$ be a hermitian involution, dg the Cayley measure of $\mathrm{U}(J)$ and $c_N = \operatorname{vol} \mathrm{U}(N)/2^N$.*

(i) If a Borel measure λ on $\mathrm{U}(J)$ is below the Gram fibre at the identity matrix 1_N, then $\lambda(B) \leq c_N \int \mathbf{1}_B \, dg$ for every Borel set $B \subseteq \mathrm{U}(J)$.

(ii) The measure $c_N \, dg$ is below the Gram fibre at 1_N.

(iii) dg is finite on compact subsets of $\mathrm{U}(J)$, and $\int \mathbf{1}_B \, dg = \inf\{\int \mathbf{1}_O \, dg : O \supseteq B \text{ open}\}$ for every Borel set $B \subseteq \mathrm{U}(J)$.

Proof. **(iii).** By Lemma 5.5.19, (i), γ is a continuous injection of the open set $\mathcal{D}_J \ni 0$ onto the open subset $\mathrm{U}^\circ(J) = \{g : \det(1+g) \neq 0\}$ of $\mathrm{U}(J)$, with continuous inverse $g \mapsto S^{-1}(2J(g-1)(g+1)^{-1})$: if $g = \gamma(y) = 2D(y)^{-1} - 1$, then $1 - \frac{1}{2}JS(y) = D(y) = 2(g+1)^{-1}$, so $S(y) = 2J(1 - 2(g+1)^{-1}) = 2J(g-1)(g+1)^{-1}$ as $J^2 = 1$. Let $\bar{\Delta} \subseteq \mathcal{D}_J$ be a closed ball around 0. Then $\gamma(\bar{\Delta})$ is compact, contains the open neighbourhood $\gamma(\bar{\Delta}^\circ)$ of $\gamma(0) = 1$, and by injectivity $dg(\gamma(\bar{\Delta})) = \operatorname{vol} \mathrm{U}(N)^{-1} \int_{\bar{\Delta}} |\det D(y)|^{-2N} dy < \infty$, the density being continuous on the compact $\bar{\Delta}$. A compact $C \subseteq \mathrm{U}(J)$ is covered by finitely many open sets $g\gamma(\bar{\Delta}^\circ)$, each of measure at most $dg(\gamma(\bar{\Delta}))$ by Lemma 5.2.41; so $dg(C) < \infty$. As $\mathrm{U}(J)$ is closed in $\mathrm{M}_N(\mathbb{C})$, it is locally compact, separable and metrizable, and a Borel measure on such a space that is finite on compact sets is outer regular (Rudin, Real and Complex Analysis, Theorem 2.18). In particular dg is σ-finite.

(ii). Let $\Omega \ni J$ and φ be as in Lemma 5.5.18, (i). Apply Lemma 5.5.13, (i), with the space $\mathrm{M}_N(\mathbb{C})$ and dY, the base space Herm_N and dT (Lebesgue measure: positive on nonempty open sets, locally finite), the map Γ_J, the base point J and its neighbourhood Ω, the parameter space $\mathrm{U}(J)$ with dg, $w \equiv c_N$, and $\psi(T, g) = g\varphi(T)$ for $T \in \Omega$, $\psi(T, g) = g$ otherwise (Borel, as Ω is open and φ continuous). For $T \in \Omega$, $\Gamma_J(g\varphi(T)) = \varphi(T)^* g^* J g \varphi(T) = \Gamma_J(\varphi(T)) = T$; $T \mapsto g\varphi(T)$ is continuous at J; and for Borel $K \geq 0$, by Lemma 5.5.18, (ii),

$$\int_\Omega \int_{\mathrm{U}(J)} c_N \, K(g\varphi(T)) \, dg \, dT = \int_{\Gamma_J^{-1}(\Omega)} K \, dY \leq \int K \, dY.$$

So the image of $c_N \, dg$ under $g \mapsto g\varphi(J) = g$ is below the fibre measure dY/dT of Γ_J over J, which is (ii).

(i). Let $O \subseteq \mathrm{U}(J)$ be open, $O = O' \cap \mathrm{U}(J)$ with O' open in $\mathrm{M}_N(\mathbb{C})$, and Ω, φ as in (ii). The map $Y \mapsto Y\varphi(\Gamma_J(Y))^{-1}$ is continuous on the open set $\Gamma_J^{-1}(\Omega)$ (φ is continuous with invertible values), so

$$W = \{Y \in \Gamma_J^{-1}(\Omega) : Y\varphi(\Gamma_J(Y))^{-1} \in O'\}$$

is open and $K = \mathbf{1}_W$ is lower semicontinuous. For $T \in \Omega$ and $g \in \mathrm{U}(J)$, $\Gamma_J(g\varphi(T)) = T$ and $g\varphi(T)\varphi(T)^{-1} = g$, so $g\varphi(T) \in W$ if and only if $g \in O$; hence $\int K(g\varphi(T)) \, d\mu'(g) = \mu'(O)$ for every measure μ' on $\mathrm{U}(J)$. For an open $S \subseteq \Omega$, Lemma 5.5.18, (ii), applied to S and $\varphi|_S$, gives

$$\int_{\Gamma_J^{-1}(S)} K \, dY = c_N \int_S \int_{\mathrm{U}(J)} K(g\varphi(T)) \, dg \, dT = \big(c_N \, dg(O)\big) \, dT(S).$$

As λ is below the Gram fibre at 1_N and Ω is a neighbourhood of $J = \Gamma_J(1_N)$,

$$\lambda(O) = \int K(g\varphi(J))\, d\lambda(g) = \int K\, d\lambda \le c_N\, dg(O).$$

By (iii), for Borel B,

$$\lambda(B) \le \inf_{O \supseteq B} \lambda(O) \le c_N \inf_{O \supseteq B} dg(O) = c_N\, dg(B).$$

□

Lemma 5.5.18. *Let $J \in \mathrm{M}_N(\mathbb{C})$ be a hermitian involution, $\Gamma_J(Y) = Y^*JY$ for $Y \in \mathrm{M}_N(\mathbb{C})$ its Gram map, and dY on $\mathrm{M}_N(\mathbb{C})$ and dT on Herm_N the measures of (BY2), in the case $m = N$.*

(i) There are an open neighbourhood Ω of J in Herm_N and a continuously differentiable map $\varphi\colon \Omega \to \mathrm{GL}_N(\mathbb{C})$ with $\varphi(J) = 1$ and $\Gamma_J(\varphi(T)) = T$ for $T \in \Omega$.

(ii) Let $\Omega \subseteq \mathrm{Herm}_N$ be open and $\varphi\colon \Omega \to \mathrm{GL}_N(\mathbb{C})$ differentiable with $\Gamma_J(\varphi(T)) = T$ for $T \in \Omega$. Then for every Borel $f\colon \mathrm{M}_N(\mathbb{C}) \to [0,\infty]$

$$\int_{\Gamma_J^{-1}(\Omega)} f(Y)\, dY = \frac{\mathrm{vol}\,\mathrm{U}(N)}{2^N} \int_\Omega \int_{\mathrm{U}(J)} f(g\varphi(T))\, dg\, dT.$$

Proof. Throughout, $|\det h| = 1$ for $h \in \mathrm{U}(J)$ (from $h^*Jh = J$ and $|\det J| = 1$, as $J^2 = 1$), so $Y \mapsto hY$ preserves dY (its real determinant is $|\det h|^{2N}$) and $\Gamma_J(hY) = \Gamma_J(Y)$. The Cayley measure is σ-finite and nonzero: it is the image under the injective chart γ of the measure $\mathrm{vol}\,\mathrm{U}(N)^{-1}|\det D(y)|^{-2N}dy$ on the open set $\mathcal{D}_J \ni 0$, whose density is continuous and positive.

(i). The map $Q(X) = \Gamma_J(1 + \frac{1}{2}JX)$ of Herm_N into itself is polynomial, $Q(0) = J$, and $dQ_0(X) = (\frac{1}{2}JX)^*J + J(\frac{1}{2}JX) = \frac{1}{2}XJ^2 + \frac{1}{2}J^2X = X$. By the inverse function theorem there is an open neighbourhood U_0 of 0 such that $Q(U_0)$ is an open neighbourhood of J and $Q\colon U_0 \to Q(U_0)$ is a diffeomorphism of class C^1. Put $\varphi(T) = 1 + \frac{1}{2}JQ^{-1}(T)$; it is C^1, $\varphi(J) = 1$ and $\Gamma_J(\varphi(T)) = Q(Q^{-1}(T)) = T$. As φ is continuous and $\varphi(J)$ invertible, $\Omega = \{T \in Q(U_0) : \det\varphi(T) \ne 0\}$ is an open neighbourhood of J.

(ii), Step 1: a parametrisation up to a null set. Let $\Phi(T,y) = \gamma(y)\varphi(T)$ on the open set $\Omega \times \mathcal{D}_J \subseteq \mathrm{Herm}_N \times \mathrm{M}_N(\mathbb{R})$; Φ is continuous (φ is differentiable, hence continuous). As $\gamma(y) \in \mathrm{U}(J)$, $\Gamma_J(\Phi(T,y)) = T$, so Φ maps into $\Gamma_J^{-1}(\Omega)$, and Φ is injective: equal values have equal T, then equal $\gamma(y)$, then equal y (Lemma 5.5.19, (i)). Let $Y \in \Gamma_J^{-1}(\Omega)$, $T = \Gamma_J(Y)$ and $g_Y = Y\varphi(T)^{-1}$; then $g_Y^*Jg_Y = \varphi(T)^{-*}T\varphi(T)^{-1} = J$, so $g_Y \in \mathrm{U}(J)$ and $Y = g_Y\varphi(T)$. Since $Y + \varphi(T) = (g_Y + 1)\varphi(T)$, Lemma 5.5.19, (i), shows that Y lies in the image of Φ if and only if $Y \notin B$, where

$$B = \{Y \in \Gamma_J^{-1}(\Omega) : \det(Y + \varphi(\Gamma_J(Y))) = 0\},$$

a Borel set. We show $dY(B) = 0$. Fix $Y \in \mathrm{M}_N(\mathbb{C})$. If $\Gamma_J(Y) \notin \Omega$, then $hY \notin B$ for all $h \in \mathrm{U}(J)$. Otherwise $hY \in B$ if and only if $\det((hg_Y + 1)\varphi(T)) = 0$, that is $hg_Y \notin \mathrm{U}^\circ(J)$, that is $h \in (\mathrm{U}(J) \setminus \mathrm{U}^\circ(J))g_Y^{-1}$, a null set by Lemma 5.5.19, (i), and the right invariance of dg (Lemma 5.2.41). So $dg\{h : hY \in B\} = 0$ for every Y, and by Tonelli on $\mathrm{U}(J) \times \mathrm{M}_N(\mathbb{C})$ (the set $\{(h,Y) : hY \in B\}$ is Borel)

$$0 = \iint \mathbf{1}_B(hY)\, dg(h)\, dY = \int_{\mathrm{U}(J)} dY(h^{-1}B)\, dg(h) = dY(B) \cdot dg(\mathrm{U}(J)),$$

and $dg(\mathrm{U}(J)) > 0$. Hence $\Gamma_J^{-1}(\Omega)$ and $\Phi(\Omega \times \mathcal{D}_J)$ differ by the null set B.

Step 2: the Jacobian. Let $(T,y)\in\Omega\times\mathcal{D}_J$, $\gamma=\gamma(y)$, $\varphi=\varphi(T)$, $P=(\gamma\varphi)^*J$. Then Φ is differentiable at (T,y) with $d\Phi(T',y')=\gamma\,d\varphi_T(T')+d\gamma_y(y')\,\varphi$, and, by $\gamma^*J\gamma=J$,

$$P\,d\Phi(T',y')=\varphi^*J\,d\varphi_T(T')+\varphi^*W_y(y')\varphi.$$

Let Skew_N carry the measure dS, the image of Lebesgue measure under $y\mapsto S(y)$; it is the Lebesgue measure of the coordinates $\operatorname{Im}S_{aa}$ and $\operatorname{Re}S_{ab}$, $\operatorname{Im}S_{ab}$ $(a<b)$, since the pair $(y_{ab},y_{ba})\mapsto S(y)_{ab}$ has the real matrix $\frac{1}{\sqrt2}\left(\begin{smallmatrix}1&-1\\1&1\end{smallmatrix}\right)$ of determinant 1. Let $\kappa_0(Z)=(Z+Z^*,\frac12(Z-Z^*))$, a real-linear bijection $\mathrm{M}_N(\mathbb{C})\to\mathrm{Herm}_N\times\mathrm{Skew}_N$ with inverse $(H,S)\mapsto\frac12H+S$. For the measures dY and $dT\otimes dS$ its determinant has absolute value 2^N: on a diagonal entry it is $(\operatorname{Re}Z_{aa},\operatorname{Im}Z_{aa})\mapsto(2\operatorname{Re}Z_{aa},\operatorname{Im}Z_{aa})$; on a pair $a<b$ it is $(Z_{ab},Z_{ba})\mapsto(Z_{ab}+\overline{Z_{ba}},\frac12(Z_{ab}-\overline{Z_{ba}}))$, the conjugation of Z_{ba} (determinant -1) followed by a complex-linear map of $\mathbb{C}^2$ of complex determinant -1, hence of real determinant 1.

The first component of $\kappa_0(P\,d\Phi(T',y'))$ is $\varphi^*J\,d\varphi_T(T')+d\varphi_T(T')^*J\varphi$, the term $\varphi^*(W_y+W_y^*)\varphi$ vanishing as $W_y(y')$ is skew-hermitian (Lemma 5.5.19, (ii)); it is the derivative of $\Gamma_J\circ\varphi$ at T in the direction T', which is T' because $\Gamma_J\circ\varphi$ is the identity of the open set Ω. So $\kappa_0\circ P\,d\Phi$ is block triangular,

$$(T',y')\longmapsto\big(T',\ s(T')+\varphi^*W_y(y')\varphi\big)$$

for a linear s, and its determinant, for $dT\otimes dy$ and $dT\otimes dS$, has absolute value $|\det(X\mapsto\varphi^*X\varphi)|\cdot|\det(S^{-1}\circ W_y)|$. The map $X\mapsto\varphi^*X\varphi$ is the restriction to the real form Skew_N of $\mathrm{M}_N(\mathbb{C})=\mathrm{Skew}_N\oplus\mathrm{i}\,\mathrm{Skew}_N$ of a complex-linear map of complex determinant $\det(\varphi^*)^N\det(\varphi)^N=|\det\varphi|^{2N}$, so its determinant on Skew_N is $|\det\varphi|^{2N}$; and $|\det(S^{-1}\circ W_y)|=|\det D(y)|^{-2N}$ by Lemma 5.5.19, (ii). Left multiplication by P on $\mathrm{M}_N(\mathbb{C})$ is complex-linear of complex determinant $\det(P)^N$, so its real determinant has absolute value $|\det P|^{2N}=|\det\varphi|^{2N}$ ($|\det\gamma|=|\det J|=1$). Writing $d\Phi=P^{-1}\circ\kappa_0^{-1}\circ(\kappa_0\circ P\,d\Phi)$, the Jacobian of Φ for $dT\otimes dy$ and dY is

$$|\det d\Phi_{(T,y)}|=|\det\varphi|^{-2N}\cdot2^{-N}\cdot|\det\varphi|^{2N}|\det D(y)|^{-2N}=2^{-N}|\det D(y)|^{-2N}.$$

Step 3: change of variables. Φ is continuous and injective on the open set $\Omega\times\mathcal{D}_J$ and differentiable at each of its points, so, by the change of variables formula for such maps (Rudin, Real and Complex Analysis, Theorem 7.26), $\Phi(\Omega\times\mathcal{D}_J)$ is Borel and, with Step 1 and Step 2,

$$\int_{\Gamma_J^{-1}(\Omega)}f\,dY=\int_{\Phi(\Omega\times\mathcal{D}_J)}f\,dY=2^{-N}\int_\Omega\int_{\mathcal{D}_J}f(\gamma(y)\varphi(T))\,|\det D(y)|^{-2N}\,dy\,dT$$

(Tonelli). By the definition of the Cayley measure the inner integral is $\operatorname{vol}\mathrm{U}(N)\int_{\mathrm{U}(J)}f(g\varphi(T))\,dg$, which gives the formula. □

Lemma 5.5.19. *Let $J\in\mathrm{M}_N(\mathbb{C})$ be a hermitian involution, $\mathcal{D}_J=\{y\in\mathrm{M}_N(\mathbb{R}):\det D(y)\neq0\}$, $\gamma(y)=2D(y)^{-1}-1$ for $y\in\mathcal{D}_J$, and Skew_N the real vector space of skew-hermitian $N\times N$ matrices; $y\mapsto S(y)$ is a real-linear bijection $\mathrm{M}_N(\mathbb{R})\to\mathrm{Skew}_N$.*

(i) $\mathcal{D}_J$ is open, γ is a smooth injective map $\mathcal{D}_J\to\mathrm{U}(J)$ with image $\mathrm{U}^\circ(J)=\{g\in\mathrm{U}(J):\det(1+g)\neq0\}$, and $\mathrm{U}(J)\setminus\mathrm{U}^\circ(J)$ is a null set of the Cayley measure.

(ii) For $y\in\mathcal{D}_J$ and $y'\in\mathrm{M}_N(\mathbb{R})$ the matrix $W_y(y')=\gamma(y)^*J\,d\gamma_y(y')$ is skew-hermitian, and the real-linear map $y'\mapsto S^{-1}(W_y(y'))$ of $\mathrm{M}_N(\mathbb{R})$ has determinant of absolute value $|\det D(y)|^{-2N}$.

Proof. **The chart in the coordinates Y.** Put $\mathfrak{l}_J = \{Y \in \mathrm{M}_N(\mathbb{C}) : Y^*J + JY = 0\}$. As $J^* = J$ and $J^2 = 1$, $Y \in \mathfrak{l}_J$ if and only if JY is skew-hermitian, so $X \mapsto JX$ maps Skew_N bijectively onto $\mathfrak{l}_J$, and $\Psi(y) = JS(y)$ is a real-linear bijection $\mathrm{M}_N(\mathbb{R}) \to \mathfrak{l}_J$ with inverse $S^{-1}(J\,\cdot)$. (S is a bijection onto Skew_N: the diagonal entry $\mathrm{i}y_{aa}$ runs over $\mathrm{i}\mathbb{R}$, and for $a < b$ the entry $S(y)_{ab}$, which determines $S(y)_{ba} = -\overline{S(y)_{ab}}$, is the image of (y_{ab}, y_{ba}) under the real-linear bijection with matrix $\frac{1}{\sqrt{2}}\left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ in the coordinates Re, Im.) For $Y \in \mathfrak{l}_J$ write $A_\pm = 1 \pm \frac{1}{2}Y$; they commute, and $D(y) = A_-$ for $Y = \Psi(y)$.

(a) For $Y \in \mathfrak{l}_J$, $A_+^* = 1 - \frac{1}{2}JYJ = JA_-J$, so $\overline{\det A_+} = \det A_-$ and $|\det A_+| = |\det A_-|$.

(i). $\mathcal{D}_J$ is open as $y \mapsto \det D(y)$ is continuous, and γ is smooth there (a rational map with nonvanishing denominator). Let $y \in \mathcal{D}_J$, $Y = \Psi(y)$; then $\gamma(y) = 2A_-^{-1} - 1 = A_+A_-^{-1}$. From $A_+^*J = JA_-$ and $A_-^*J = JA_+$ (by (a)) we get $\gamma(y)^*J\gamma(y) = (A_-^*)^{-1}JA_-A_+A_-^{-1} = (A_-^*)^{-1}JA_+ = J$, so $\gamma(y) \in \mathrm{U}(J)$, and $\gamma(y)+1 = 2A_-^{-1}$ is invertible, so $\gamma(y) \in \mathrm{U}^\circ(J)$. Conversely, for $g \in \mathrm{U}^\circ(J)$ put $Y = 2(g-1)(g+1)^{-1}$; then $1 - \frac{1}{2}Y = 2(g+1)^{-1}$ is invertible, $1 + \frac{1}{2}Y = 2g(g+1)^{-1}$, so $A_+A_-^{-1} = g$, and from $g^* = Jg^{-1}J$, $Y^* = 2J(g^{-1}+1)^{-1}(g^{-1}-1)J = 2J(1+g)^{-1}(1-g)J = -JYJ$, so $Y \in \mathfrak{l}_J$ and $g = \gamma(\Psi^{-1}(Y))$. As $\gamma(y)$ determines $A_-^{-1} = \frac{1}{2}(\gamma(y)+1)$, hence Y, hence y, γ is injective. The Cayley measure is the image under γ of a measure on $\mathcal{D}_J$ (Definition 3.2.1), and $\gamma(\mathcal{D}_J) = \mathrm{U}^\circ(J)$, so the complement of $\mathrm{U}^\circ(J)$ is null.

(ii). Differentiating $\gamma = 2A_-^{-1} - 1$ with $A_- = 1 - \frac{1}{2}\Psi(y)$ gives $d\gamma_y(y') = A_-^{-1}Y'A_-^{-1}$ with $Y' = \Psi(y') \in \mathfrak{l}_J$. As $\gamma \in \mathrm{U}(J)$, $\gamma^*J = J\gamma^{-1}$ and $\gamma^{-1} = A_-A_+^{-1}$, so, $A_\pm^{-1}$ commuting with A_-,

$$W_y(y') = J\gamma^{-1}d\gamma_y(y') = J\,L_Y(Y'), \qquad L_Y(Y') = A_+^{-1}Y'A_-^{-1}.$$

Differentiating $\gamma^*J\gamma = J$ gives $d\gamma^*J\gamma + \gamma^*Jd\gamma = 0$, so $W_y(y')^* = -W_y(y')$. The map L_Y preserves $\mathfrak{l}_J$: by (a), $(A_+^*)^{-1} = JA_-^{-1}J$ and $(A_-^*)^{-1} = JA_+^{-1}J$, so for $Y' \in \mathfrak{l}_J$, $L_Y(Y')^* = JA_-^{-1}J(-JY'J)JA_+^{-1}J = -J\,L_Y(Y')\,J$. Hence $S^{-1}(W_y(\cdot)) = S^{-1}(J\,L_Y(\Psi(\cdot))) = \Psi^{-1} \circ L_Y|_{\mathfrak{l}_J} \circ \Psi$, whose determinant is $\det(L_Y|_{\mathfrak{l}_J})$. Now $\mathfrak{l}_J$ is a real form of $\mathrm{M}_N(\mathbb{C})$: if Y' and $\mathrm{i}Y'$ lie in $\mathfrak{l}_J$ then JY' and $\mathrm{i}JY'$ are skew-hermitian, so $Y' = 0$, and $\dim_{\mathbb{R}} \mathfrak{l}_J = N^2$. So a real basis of $\mathfrak{l}_J$ is a complex basis of $\mathrm{M}_N(\mathbb{C})$, in which the complex-linear map $Y' \mapsto A_+^{-1}Y'A_-^{-1}$ of $\mathrm{M}_N(\mathbb{C})$ has the same matrix as $L_Y|_{\mathfrak{l}_J}$. Its complex determinant is $\det(A_+)^{-N}\det(A_-)^{-N}$ (a Kronecker product), so by (a), $|\det(L_Y|_{\mathfrak{l}_J})| = |\det A_-|^{-2N} = |\det D(y)|^{-2N}$. □

Lemma 5.5.20. *Let $J \in \mathrm{M}_N(\mathbb{C})$ be a hermitian involution, $n_1, n_2, n \geq 0$ integers with $n_1+n_2 = N$, and $E \in \mathrm{M}_{N\times n_1}(\mathbb{C})$, $R \in \mathrm{M}_{N\times n_2}(\mathbb{C})$ with $E^*E = 1$, $R^*R = 1$ and $E^*JR = 0$. Give each space $\mathrm{M}_{a\times b}(\mathbb{C})$ the Lebesgue measure of the real and imaginary parts of its entries. Then for every $M \in \mathrm{M}_{n_1\times n}(\mathbb{C})$ the image of Lebesgue measure on $\mathrm{M}_{n_2\times n}(\mathbb{C})$ under $x \mapsto JEM + Rx$ is below the fibre measure of $\mathrm{M}_{N\times n}(\mathbb{C}) \to \mathrm{M}_{n_1\times n}(\mathbb{C})$, $y \mapsto E^*Jy$, over M.*

Proof. Let $U = (JE\ R) \in \mathrm{M}_N(\mathbb{C})$. As $J^* = J$ and $J^2 = 1$,

$$U^*U = \begin{pmatrix} E^*E & E^*JR \\ R^*JE & R^*R \end{pmatrix} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix},$$

using $R^*JE = (E^*JR)^* = 0$; so U is unitary. The map $\Phi(M', x) = JEM' + Rx = U\left(\begin{smallmatrix} M' \\ x \end{smallmatrix}\right)$ from $\mathrm{M}_{n_1\times n}(\mathbb{C}) \times \mathrm{M}_{n_2\times n}(\mathbb{C})$ to $\mathrm{M}_{N\times n}(\mathbb{C})$ is the identification of a pair with the stacked matrix, which preserves Lebesgue measure, followed by left multiplication by U, which acts on each column by the unitary map U of $\mathbb{C}^N = \mathbb{R}^{2N}$, a Euclidean isometry; so Φ carries the product of the Lebesgue measures to Lebesgue measure. Moreover $E^*J\Phi(M', x) = E^*J^2EM' + E^*JRx = M'$, and $M' \mapsto \Phi(M', x)$ is continuous. By Lemma 5.5.13, (ii), with $B = \mathrm{M}_{n_1\times n}(\mathbb{C})$ (Lebesgue measure is positive on nonempty open sets and locally finite), $\beta = M$, $P = \mathrm{M}_{n_2\times n}(\mathbb{C})$ and $\varphi = \Phi$, the image of Lebesgue measure under $x \mapsto \Phi(M, x)$ is below the fibre measure of $y \mapsto E^*Jy$ over M. □

Lemma 5.5.21. *Let $N \geq 1$. The Cayley measure of $\mathrm{U}(1_N) = \{g \in \mathrm{GL}_N(\mathbb{C}) : g^*g = 1\}$ has total mass 1.*

Proof. Write μ for the Cayley measure of $\mathrm{U}(N) = \mathrm{U}(1_N)$ and $|y|$ for the euclidean norm of $y \in \mathrm{M}_N(\mathbb{R}) = \mathbb{R}^{N\times N}$. Give $\mathrm{M}_N(\mathbb{C})$ the inner product $\langle Y, Z\rangle = \mathrm{Re}\,\mathrm{tr}(YZ^*)$ and let ν be the Riemannian volume of the induced bi-invariant metric on $\mathrm{U}(N)$: the Haar measure of Lemma 5.5.22, of total mass

$$\nu(\mathrm{U}(N)) = \frac{(2\pi)^{N(N+1)/2}}{\prod_{j=1}^{N-1} j!}.$$

The chart. For $y \in \mathrm{M}_N(\mathbb{R})$ the matrix $S(y)$ is skew-hermitian, so its eigenvalues lie in $\mathrm{i}\mathbb{R}$ and $D(y) = 1 - \frac{1}{2}S(y)$ is invertible. Hence μ is the image of $\mathrm{vol}\,\mathrm{U}(N)^{-1}|\det D(y)|^{-2N}dy$ on all of $\mathrm{M}_N(\mathbb{R})$ under $\psi(y) = 2D(y)^{-1} - 1$. The map ψ is smooth and injective: $y \mapsto S(y)$ is injective and linear, and $\psi(y)$ determines $D(y)^{-1}$, hence $S(y)$. From $\psi(y) = 2(1 - \frac{1}{2}S(y))^{-1} - 1$ we get $d\psi_0 = S$. The squared norm of $S(y)$ is

$$\mathrm{tr}\big(S(y)S(y)^*\big) = \sum_a y_{aa}^2 + 2\sum_{a<b} |S(y)_{ab}|^2 = \sum_a y_{aa}^2 + 2\sum_{a\neq b} y_{ab}^2,$$

since $S(y)_{ba} = -\overline{S(y)_{ab}}$ and $|(1+\mathrm{i})y_{ab} - (1-\mathrm{i})y_{ba}|^2 = 2y_{ab}^2 + 2y_{ba}^2$ (the cross term is $-2y_{ab}y_{ba}\,\mathrm{Re}((1+\mathrm{i})\overline{(1-\mathrm{i})}) = -2y_{ab}y_{ba}\,\mathrm{Re}(2\mathrm{i}) = 0$). So S is injective, $\dim_{\mathbb{R}} \mathrm{U}(N) = N^2$, and the Gram matrix of S in the standard basis of $\mathbb{R}^{N\times N}$ is diagonal with N entries 1 and $N(N-1)$ entries 2. By the inverse function theorem there is $r > 0$ such that ψ maps the ball $B_r = \{|y| < r\}$ diffeomorphically onto an open neighbourhood W of 1 in $\mathrm{U}(N)$. In this chart the Riemannian volume has a continuous density: $\nu(\psi(A)) = \int_A \rho(y)\,dy$ for Borel $A \subseteq B_r$, where $\rho(y)$ is the square root of the Gram determinant of $d\psi_y$, and

$$\rho(0) = \big(\det \mathrm{Gram}(S)\big)^{1/2} = 2^{N(N-1)/2}.$$

Since ψ is injective on $\mathrm{M}_N(\mathbb{R})$, also $\mu(\psi(A)) = \mathrm{vol}\,\mathrm{U}(N)^{-1}\int_A |\det D(y)|^{-2N}dy$ for Borel $A \subseteq B_r$.

μ is a finite Haar measure. Since $\psi^{-1}(W) = B_r$,

$$\mu(W) \leq \mathrm{vol}\,\mathrm{U}(N)^{-1}\int_{\overline{B_r}} |\det D(y)|^{-2N}dy < \infty,$$

the integrand being continuous. By compactness $\mathrm{U}(N) = \bigcup_{i=1}^k a_i W$ for some $a_1, \ldots, a_k \in \mathrm{U}(N)$, and $\mu(a_iW) = \mu(W)$ by Lemma 5.2.41 applied to the indicator of a_iW (whose composite with $y \mapsto a_i y$ is the indicator of W). Hence μ is a finite, nonzero, left-invariant Borel measure on the compact metrisable group $\mathrm{U}(N)$; it is regular, being finite on a compact metric space, and by the uniqueness of Haar measure $\mu = c\,\nu$ for some $c > 0$.

The constant. For Borel $A \subseteq B_r$ the two descriptions above give

$$\int_A \big(\mathrm{vol}\,\mathrm{U}(N)^{-1}|\det D(y)|^{-2N} - c\rho(y)\big)dy = 0.$$

The integrand is continuous on B_r, so it vanishes identically there; at $y = 0$, where $D(0) = 1$,

$$\mathrm{vol}\,\mathrm{U}(N)^{-1} = c\,2^{N(N-1)/2}.$$

The mass. Since $0! = 1$, $\mathrm{vol}\,\mathrm{U}(N) = \prod_{i=0}^{N-1} 2\pi^{i+1}/i! = 2^N\pi^{N(N+1)/2}/\prod_{j=1}^{N-1} j!$, and therefore

$$\mu(\mathrm{U}(N)) = c\,\nu(\mathrm{U}(N)) = \frac{(2\pi)^{N(N+1)/2}}{2^{N(N-1)/2}\,2^N\,\pi^{N(N+1)/2}} = 2^{N(N+1)/2 - N(N-1)/2 - N} = 1.$$

□

Lemma 5.5.22. *All symbols introduced here are local to this statement and to the results that cite it. Equip* $\mathrm{M}_n(\mathbb{C})$ *with the euclidean inner product* $\langle Y, Z\rangle = \operatorname{Re}\operatorname{tr}(YZ^*)$*, and give the compact groups* $\mathrm{U}(n)$ *and* $\mathrm{SU}(n)$ *the Haar measures whose density at* 1*, with respect to the Lebesgue measure of the restriction of this inner product to their Lie algebras* $\mathfrak{u}(n)$*,* $\mathfrak{su}(n)$*, equals* 1*. Then for every integer* $n \geq 1$

$$\operatorname{vol}\mathrm{U}(n) = \frac{(2\pi)^{n(n+1)/2}}{\prod_{j=1}^{n-1} j!}, \qquad \operatorname{vol}\mathrm{SU}(n) = \frac{\sqrt{n}\,(2\pi)^{n(n+1)/2-1}}{\prod_{j=1}^{n-1} j!} \quad (n \geq 2).$$

In particular $\operatorname{vol}\mathrm{SU}(n) \cdot \prod_{j=1}^{n-1} \dfrac{j!}{(2\pi)^{j+1}} = \sqrt{n}$ *for* $n \geq 2$.

Proof. **Haar measure as Riemannian volume.** The inner product is invariant under left and right multiplication by unitary matrices ($\operatorname{tr}(gYZ^*g^*) = \operatorname{tr}(YZ^*)$ for g unitary, and similarly on the right). Hence the euclidean metric of $\mathrm{M}_n(\mathbb{C}) \cong \mathbb{R}^{2n^2}$ restricted to the submanifolds $\mathrm{U}(n)$, $\mathrm{SU}(n)$ is a bi-invariant Riemannian metric, its Riemannian volume is a Haar measure, and its density at 1 with respect to the Lebesgue measure of the inner product on the Lie algebra is 1. So the measures of the statement are the Riemannian volumes of these submanifolds. We use the coarea formula for a smooth submersion $\pi\colon M \to N$ of compact Riemannian manifolds: $\int_M J\pi \, d\mathrm{vol}_M = \int_N \operatorname{vol}(\pi^{-1}(y))\, d\mathrm{vol}_N(y)$, where $J\pi(x)$ is the absolute value of the determinant of $d\pi_x$ restricted to $(\ker d\pi_x)^\perp$, computed in orthonormal bases.

The unitary group. For $n = 1$, $\mathrm{U}(1) = \{e^{i\theta}\}$ is the unit circle of $\mathbb{C}$, of length 2π, which is the formula. Let $n \geq 2$ and $\pi\colon \mathrm{U}(n) \to S^{2n-1} \subseteq \mathbb{C}^n$, $\pi(g) = ge_1$, where $\mathbb{C}^n$ carries the euclidean metric $\operatorname{Re}(y^*x)$. It is a surjective submersion, equivariant for left multiplication by $h \in \mathrm{U}(n)$, which is an isometry of $\mathrm{U}(n)$ and of S^{2n-1}; hence $J\pi$ is constant, equal to $J\pi(1)$. The fibre $\pi^{-1}(ge_1) = g\,\mathrm{U}(n-1)$, with $\mathrm{U}(n-1)$ embedded as the stabiliser of e_1 (lower right block), is isometric to $\mathrm{U}(n-1)$ by left translation. At 1: $\ker d\pi_1 = \{X \in \mathfrak{u}(n) : Xe_1 = 0\}$ consists of the skew-hermitian matrices with vanishing first column, hence vanishing first row; its orthogonal complement in $\mathfrak{u}(n)$ consists of the matrices

$$X(a,b) = \begin{pmatrix} ia & -b^* \\ b & 0 \end{pmatrix}, \qquad a \in \mathbb{R},\ b \in \mathbb{C}^{n-1}, \qquad |X(a,b)|^2 = a^2 + 2|b|^2,$$

and $d\pi_1 X(a,b) = X(a,b)e_1 = (ia, b)$, of squared length $a^2 + |b|^2$. In the orthonormal basis $X(1,0)$, $X(0, e_k/\sqrt{2})$, $X(0, ie_k/\sqrt{2})$ $(1 \leq k \leq n-1)$ the images are pairwise orthogonal of lengths 1 and $2(n-1)$ times $1/\sqrt{2}$, so $J\pi = 2^{-(n-1)}$. The coarea formula and $\operatorname{vol}(S^{2n-1}) = 2\pi^n/(n-1)!$ give

$$\operatorname{vol}\mathrm{U}(n) = 2^{n-1}\,\frac{2\pi^n}{(n-1)!}\operatorname{vol}\mathrm{U}(n-1) = \frac{(2\pi)^n}{(n-1)!}\operatorname{vol}\mathrm{U}(n-1),$$

and by induction $\operatorname{vol}\mathrm{U}(n) = \prod_{k=1}^{n}(2\pi)^k/(k-1)! = (2\pi)^{n(n+1)/2}/\prod_{j=1}^{n-1} j!$.

The special unitary group. Let $n \geq 2$ and $\det\colon \mathrm{U}(n) \to \mathrm{U}(1)$, a surjective submersion with fibres $\det^{-1}(\det g) = g\,\mathrm{SU}(n)$, isometric to $\mathrm{SU}(n)$. Since $\det(hg) = \det h \det g$ and multiplication by $\det h$ is an isometry of the circle, $J\det$ is constant. At 1, $d\det_1(X) = \operatorname{tr} X$, $\ker d\det_1 = \mathfrak{su}(n)$, whose orthogonal complement in $\mathfrak{u}(n)$ is $i\mathbb{R}\,I_n$ (as $\operatorname{Re}\operatorname{tr}(Y(itI_n)^*) = \operatorname{Re}(-it\operatorname{tr} Y) = 0$ for $\operatorname{tr} Y = 0$); the unit vector $iI_n/\sqrt{n}$ is mapped to $i\sqrt{n}$, so $J\det = \sqrt{n}$. The coarea formula gives $\sqrt{n}\operatorname{vol}\mathrm{U}(n) = 2\pi \operatorname{vol}\mathrm{SU}(n)$, which is the second formula.

The product. Since $\sum_{j=1}^{n-1}(j+1) = n(n+1)/2 - 1$,

$$\operatorname{vol}\mathrm{SU}(n) \prod_{j=1}^{n-1} \frac{j!}{(2\pi)^{j+1}} = \sqrt{n}\,(2\pi)^{n(n+1)/2-1-\sum_{j=1}^{n-1}(j+1)} = \sqrt{n}.$$

□

Lemma 5.5.23. *Let $\rho > 0$ and consider the data at $\mathbb{C}$ with box radius ρ. Then $\eta_{<\varrho} = \eta_0 * \eta_1 * \cdots * \eta_{\varrho-1}$ is the image of the Haar measure du of U under the inclusion $\mathsf{U} \subseteq G$.*

Proof. Write g_{ij} for the entries of $g \in G$ in the coordinate basis and, for $0 \le l \le \varrho$ and $g \in G$,

$$\mathcal{G}_l(g) = \exp\Big(-\pi \sum_{b<l} \Big(\sum_{i:\,\mathrm{floor}(i)>b} |g_{i\,e_b^*}|^2 + (\operatorname{Im} g_{e_b\,e_b^*})^2 \Big)\Big),$$

a continuous function with values in $(0,1]$; $\mathcal{G}_0 = 1$.

Step 1: $N_{<\varrho} = \mathsf{U}$. For $l = \varrho$ the indices of floor below ϱ are the e_a, e_a^*, and the others (x_i, z) have level ϱ; so lev_ϱ is the level, and the definitions of $N_{<\varrho}$ and U coincide.

Step 2: $\int \mathcal{G}_\varrho \, d\eta_{<\varrho} = 1$. We show $\int \mathcal{G}_a \, d\eta_{<a} = 1$ for $0 \le a \le \varrho$ by induction; for $a = 0$ both sides are 1. Let $a < \varrho$, $\nu' \in N_{<a}$ and $n = n_a(v,\beta)$ with $v \in V_{a+1}$, $\beta = t\mathrm{i}$. For $b < a$, n fixes e_b^*, so column e_b^* of $\nu' n$ is that of ν'. Column e_a^* of $\nu' n$ is $\nu' w$ with $w = e_a^* + v + (\beta - \tau h(v,v)) e_a$. Let i have floor $\ge a$; then $\mathrm{lev}_a(i) = \varrho$, so $\nu'_{ij} = \delta_{ij}$ unless $\mathrm{lev}_a(j) > \varrho$, i.e. unless $j = e_c^*$ with $c < a$; as w has no e_c^*-coordinate for $c < a$, $(\nu' w)_i = w_i$. Hence the entries of column e_a^* of $\nu' n$ in the rows of floor $> a$ are the coordinates of v, and its (e_a, e_a^*) entry is $\beta - \frac{1}{2} h(v,v)$, of imaginary part t ($h(v,v)$ is real). So

$$\mathcal{G}_{a+1}(\nu' n_a(v, t\mathrm{i})) = e^{-\pi(\|v\|^2 + t^2)} \, \mathcal{G}_a(\nu') \qquad (\nu' \in N_{<a}).$$

By Lemma 5.4.14, (ii), $\eta_{<a}$ is carried by $N_{<a}$, and $\eta_{<a+1} = \eta_{<a} * \eta_a$ by definition of the convolution. By Tonelli,

$$\int \mathcal{G}_{a+1} \, d\eta_{<a+1} = \iint e^{-\pi(\|v\|^2 + t^2)} \, dv \, dt \cdot \int \mathcal{G}_a \, d\eta_{<a} = 1 \cdot 1,$$

since $\int_{\mathbb{R}} e^{-\pi x^2} dx = 1$ in each real coordinate.

Step 3: $\int \mathcal{G}_\varrho(y^{-1}) \, du(y) = 1$. For $y \in G$, $\bar{y}^{\mathsf{T}} J y = J$ and $J^2 = 1$ give $y^{-1} = J \bar{y}^{\mathsf{T}} J$. As J exchanges e_c and e_c^*, fixes the x_j and sends z to $-z$, the entry of y^{-1} in row i and column e_b^* is $\pm\overline{y_{e_b\,i'}}$, where i' is the image of i under the exchange $e_c \leftrightarrow e_c^*$ (and $i' = i$ for $i = x_j, z$); for $i = e_b$ the sign is $+$. The indices of floor $> b$ are exchanged among themselves, and they are the set J_{b+1} of Lemma 5.2.34 in its numbering. Hence $\mathcal{G}_\varrho(y^{-1}) = \exp(-\pi \|\mathrm{rw}(y)\|^2)$ for $y \in \mathsf{U}$, and by Lemma 5.2.34, (iii), the image of du under rw is Lebesgue measure of $\mathcal{C}_\mathsf{U}$, so $\int \mathcal{G}_\varrho(y^{-1}) \, du(y) = \int_{\mathcal{C}_\mathsf{U}} e^{-\pi\|c\|^2} \, dc = 1$.

Step 4: uniqueness. Write $\eta = \eta_{<\varrho}$ and $\mathcal{G} = \mathcal{G}_\varrho$. By Step 1 and Lemma 5.4.14, (ii) and (iii), η is carried by U and $\int f(xs) \, d\eta(x) = \int f(sx) \, d\eta(x) = \int f \, d\eta$ for measurable $f \ge 0$ and $s \in \mathsf{U}$; by Lemma 5.2.34, (iv), du is left invariant. Both are s-finite, so Tonelli applies. For measurable $f \colon G \to [0,\infty]$, using Step 3, right invariance of η, Tonelli, then for η-almost every $x \in \mathsf{U}$ the substitution $y \mapsto x^{-1} y$ in du, Tonelli again, left invariance of η and Step 2:

$$\begin{aligned} \int f \, d\eta &= \int_\mathsf{U} \mathcal{G}(y^{-1}) \int f(xy) \, d\eta(x) \, du(y) = \int \int_\mathsf{U} \mathcal{G}(y^{-1}x) f(y) \, du(y) \, d\eta(x) \\ &= \int_\mathsf{U} f(y) \int \mathcal{G}(y^{-1}x) \, d\eta(x) \, du(y) = \int_\mathsf{U} f \, du. \end{aligned}$$

So η is the image of du under the inclusion. □

Lemma 5.5.24. *For $i \ge 0$ let the* dyadic shell *D_i be the set of $x \in G$ such that 2^i is the least of the numbers $1, 2, 4, \ldots$ with $|(x-1)_{ac}| \le 2^i$ for all indices a, c. Then the D_i are Borel sets and*

G is their disjoint union. Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, let $W\colon G \to \mathbb{C}^I$ be cut, $L \geq \rho$, $j \leq \varrho$, and let p, q be heads of length j for the size filtration Γ_L of scale L. Then for every $i \geq 0$, D_i is a shell of height 2^i for (Γ_L, j, p, q, W).

Proof. **The dyadic shells.** Let $m(x) = \max_{a,c} |(x-1)_{ac}|$, a continuous function. Then $D_0 = \{m \leq 1\}$ and $D_i = \{m \leq 2^i\} \setminus \{m \leq 2^{i-1}\}$ for $i \geq 1$, Borel sets; as $m(x) < \infty$ there is a least i with $m(x) \leq 2^i$, so every x lies in exactly one D_i.

Fix i and put $\Delta = 2^i$. As $\rho \geq 8r \geq 8$, $L \geq 8$.

(SH1). $1 \leq \Delta < \infty$.

(SH2). Let $L' = L\Delta \geq \rho$; by Lemma 5.5.5, (ii), the size filtration Γ' of scale L' is a gauge for the same place datum, with loss $L'^2 = L^2\Delta^2$, the loss of Γ_L times Δ^2. Take $\mathcal{G} = \{\Gamma'\}$; $\#\mathcal{G} = 1 \leq 2\Delta^{9n}$. For $x \in D_i$ every entry of $M^{-1}(x-1) = x - 1$ has modulus at most $\Delta \leq L'$, so x is a position of size Γ'.

(SH3). Let $x \in D_i$ and $\varepsilon \in [0, 1)$ with $(L^2)^{1200n^2} \leq \varepsilon^{400n^2}\Delta$. The left side is positive, so $\varepsilon > 0$. Put $T = L^{11n+1}/\varepsilon$. Then $T \geq L^{11n+1} \geq L^{11n}$, and $T^{-1} = \varepsilon/L^{11n+1} \leq \varepsilon/2$. Moreover $2T^{99n} \leq \Delta$: as $\varepsilon \leq 1$, $400n^2 \geq 99n$ and $2 \leq L$,

$$\varepsilon^{400n^2} \cdot 2T^{99n} \leq \varepsilon^{99n} L\Big(\frac{L^{11n+1}}{\varepsilon}\Big)^{99n} = L^{(11n+1)99n+1} \leq L^{2400n^2} \leq \varepsilon^{400n^2}\Delta,$$

using $(11n+1)99n + 1 = 1089n^2 + 99n + 1 \leq 2400n^2$ for $n \geq 1$; divide by $\varepsilon^{400n^2} > 0$. Now some entry of $x - 1$ has modulus above T^{99n}: if $i = 0$, then $2T^{99n} \leq 1$ contradicts $T \geq 1$, so this case does not occur; if $i \geq 1$ and all entries had modulus at most $T^{99n} \leq \Delta/2 = 2^{i-1}$, then $x \notin D_i$. By Lemma 5.5.25, (ii), with $\tau = \varepsilon$, (j, p, q, W) has a deep vector after the head of depth at least $\varepsilon^{-2} = (\varepsilon^2)^{-1}$ at x. □

Lemma 5.5.25. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, let $W\colon G \to \mathbb{C}^I$ be cut, $L \geq \rho$, $j \leq \varrho$, and let p, q be heads of length j for the size filtration of scale L. Let $T \geq L^{11n}$ and let $x \in G$ have an entry with $|(x-1)_{ac}| > T^{99n}$. Then:*

(i) every point y active at x for (j, p, q, W) has some a with $j \leq a < \varrho$ and $d_a(y, x) \geq T^2$, hence $\mathrm{dp}_a(y, x) \geq T^2/\pi$;

(ii) for every $\tau > 0$ with $T^{-1} \leq \tau/2$, (j, p, q, W) has a deep vector after the head of depth at least τ^{-2} at x.

Proof. **(i).** As $\rho \geq 8r \geq 8$, $L \geq 8$ and $T \geq L^{11n} \geq L$. By Lemma 5.5.5, (ii), the size filtrations of scales L and T (losses L^2, T^2) are gauges S and Γ for the data at $\mathbb{C}$, which form a place datum by Lemma 5.5.5, (i). Let y be active at x and suppose, for a contradiction, that $d_a(y, x) < T^2$ for every a with $j \leq a < \varrho$. We check the hypotheses of (DN4) of Theorem 5.4.1 for the gauge Γ, the second gauge S, the points y and x (in the roles of x and y there), and the heads p, q.

- p, q are heads of length j for S. If $j \neq 0$: $M^{-1} = 1$ has modulus $1 \leq L$, so $M^{-1} \in A^S_{(1)}$; and a number of modulus at most L^{10n} has modulus at most T, so $A^S_{(10n)} \subseteq A^\Gamma_{(1)}$.
- By (AC1), $W(y) \neq 0$ and $W(yx) \neq 0$; as W is cut there are $u, v \in \mathsf{U}$ with $uy \in K$ and $vyx \in K$. Every entry of an element of K has modulus at most $\rho \leq T$, so every entry of $M^{-1}(vyx - uy)$ has modulus at most $2\rho \leq T^2$: it has size 2 for Γ.
- By (AC2) and (AC3), $w_{j,p}^{-1}y$ and $w_{j,q}^{-1}yx$ are near at j.

- For $j \le a < \varrho$ let $c = T^{-1}$, a unit with $c^{-1} = T$ of size 1 for Γ. By Lemma 5.5.26, $\mathfrak{d}_a(y,x) = \{c' : |c'|^2 d_a(y,x) < 1\}$, and $|c|^2 d_a(y,x) = d_a(y,x)/T^2 < 1$, so $c \in \mathfrak{d}_a(y,x)$.

By (DN4), $M^{-1}(x-1) = x - 1$ has size $99n$ for Γ: every entry has modulus at most T^{99n}, against the hypothesis on x. So some a with $j \le a < \varrho$ has $d_a(y,x) \ge T^2$, and $\mathrm{dp}_a(y,x) = d_a(y,x)/\pi \ge T^2/\pi$ by Lemma 5.5.26.

(ii). If $T^{-1} \le \tau/2$ then $T^2 \ge 4\tau^{-2} \ge \pi\tau^{-2}$, so the a of (i) has $\mathrm{dp}_a(y,x) \ge T^2/\pi \ge \tau^{-2}$ for every active y; this is a deep vector after the head of depth at least τ^{-2} at x. □

Lemma 5.5.26. *Consider the data at $\mathbb{C}$ with box radius $\rho > 0$. For $a < \varrho$ and $x, y \in G$ let $d_a(x,y) \in [0,\infty)$ be the infimum of $\|x^{-1}\zeta\|^2 + \|(xy)^{-1}\zeta'\|^2$ over the pairs (ζ,ζ') of vectors with $h(e_b,\zeta) = 0$ for $b < a$, $h(e_a,\zeta) = 1$ and $\zeta' - \zeta \in \mathrm{span}\{e_b : b < a\}$. Then*

$$\mathfrak{d}_a(x,y) = \{c \in \mathbb{C} : |c|^2 d_a(x,y) < 1\}, \qquad \mathrm{dp}_a(x,y) = d_a(x,y)/\pi.$$

Proof. Write $d = d_a(x,y)$; it is finite, as $\zeta = \zeta' = e_a^*$ is admissible. Call (ω,ω') admissible for c if $h(e_b,\omega) = 0$ for $b < a$, $h(e_a,\omega) = c$ and $\omega' - \omega \in \mathrm{span}\{e_b : b < a\}$; all these conditions are linear, so (ω,ω') is admissible for $c \ne 0$ exactly when $(c^{-1}\omega, c^{-1}\omega')$ is admissible for 1.

The set. For $c = 0$ the pair $(0,0)$ is admissible and close, so $0 \in \mathfrak{d}_a(x,y)$, and $|0|^2 d < 1$. Let $c \ne 0$. Then $c \in \mathfrak{d}_a(x,y)$ if and only if some pair (ζ,ζ') admissible for 1 has $|c|^2(\|x^{-1}\zeta\|^2 + \|(xy)^{-1}\zeta'\|^2) < 1$, i.e. $\|x^{-1}\zeta\|^2 + \|(xy)^{-1}\zeta'\|^2 < |c|^{-2}$; such a pair exists if and only if the infimum d is below $|c|^{-2}$, that is $|c|^2 d < 1$.

The depth. If $d = 0$, then $\mathfrak{d}_a(x,y) = \mathbb{C}$ has infinite area and $\mathrm{dp}_a(x,y) = 0 = d/\pi$. If $d > 0$, $\mathfrak{d}_a(x,y)$ is the open disc of radius $d^{-1/2}$, of area π/d, so $\mathrm{dp}_a(x,y) = d/\pi$. □

Lemma 5.5.27. *Let $\rho > 0$, consider the data at $\mathbb{C}$ with box radius ρ, and let λ be its Haar ratio. Let $(W, W^\flat)$ be a cut pair whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. Then*

$$\mathrm{PN}(W^\flat) = \int_{G_1}\int_{G_1} |\langle W^\flat(x), W^\flat(y)\rangle|^2 \, d\theta_{\ge 0}(x)\, d\theta_{\ge 0}(y) \le \lambda^2 \, \#I.$$

Proof. Fix $x \in G_1$. The function $y \mapsto |\langle W^\flat(x), W^\flat(y)\rangle|^2$ is Borel, nonnegative and left U-invariant, since $|\mathrm{wave}| = 1$. By the unfolding identity of Lemma 5.5.10 and by Lemma 5.5.28 with $v = W^\flat(x)$,

$$\int_{G_1} |\langle W^\flat(x), W^\flat(y)\rangle|^2 \, d\theta_{\ge 0}(y) = \lambda \int_{\mathsf{U}\backslash G_1} |\langle W^\flat(x), W^\flat\rangle|^2 \le \lambda \, \|W^\flat(x)\|^2.$$

The function $\|W^\flat\|^2$ is also Borel and left U-invariant, so integrating over x (Tonelli) and unfolding once more,

$$\mathrm{PN}(W^\flat) \le \lambda \int_{G_1} \|W^\flat(x)\|^2 \, d\theta_{\ge 0}(x) = \lambda^2 \int_{\mathsf{U}\backslash G_1} \|W^\flat\|^2 \le \lambda^2 \, \#I,$$

by (BS1). □

Lemma 5.5.28. *Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be an irreducible unitary representation on $\mathbb{C}^I$, I finite and nonempty, and let F be a Bessel function of type ρ with $\int_{\mathsf{U}\backslash G_1} \|F\| < \infty$. Then for all $i, i' \in I$ and $v \in \mathbb{C}^I$*

$$\int_{\mathsf{U}\backslash G_1} F_i\,\overline{F_{i'}} = \frac{\delta_{ii'}}{\#I}\int_{\mathsf{U}\backslash G_1}\|F\|^2, \qquad \int_{\mathsf{U}\backslash G_1}|\langle v, F\rangle|^2 = \frac{\|v\|^2}{\#I}\int_{\mathsf{U}\backslash G_1}\|F\|^2.$$

In particular, if $(W, W^\flat)$ is a cut pair of type ρ, then $\int_{\mathsf{U}\backslash G_1}|\langle v, W^\flat\rangle|^2 \le \|v\|^2$ for every $v \in \mathbb{C}^I$.

Proof. **Step 1: the matrix of integrals is scalar.** For $i, i' \in I$ the function $\phi_{ii'} = F_i\overline{F_{i'}}$ is Borel and left U-invariant ($|\text{wave}| = 1$), and $|\phi_{ii'}| \le \|F\|_\infty\|F\|$, so it is integrable over $\mathsf{U}\backslash G_1$. Let $P = (\int_{\mathsf{U}\backslash G_1}\phi_{ii'})_{i,i'}$. For $h \in H$, $F(hy)F(hy)^* = \rho(h)F(y)F(y)^*\rho(h)^*$, so Lemma 5.5.29, (iii), gives $\rho(h)P\rho(h)^* = P$; as $\rho(h)$ is unitary, P commutes with $\rho(\mathrm{U}(k))$, and by Schur's lemma for the irreducible representation ρ, $P = c\cdot 1$. Taking traces, $c\,\#I = \int_{\mathsf{U}\backslash G_1}\|F\|^2$. This is the first identity.

Step 2: the second identity. $|\langle v, F\rangle|^2 = \sum_{i,i'} v_i\bar{v}_{i'}\overline{F_i}F_{i'}$; integrating term by term, $\int_{\mathsf{U}\backslash G_1}|\langle v, F\rangle|^2 = \sum_{i,i'} v_i\bar{v}_{i'}\overline{P_{ii'}} = c\|v\|^2$.

Step 3: cut pairs. Let $(W, W^\flat)$ be a cut pair of type ρ and take A, a of (BS3). If $a = 0$ then $A = 0$ and $W^\flat = 0$. Otherwise $\|W^\flat\| \le A$ and $\int_{\mathsf{U}\backslash G_1} A \le a^{-1}b^{400r^2}\#I < \infty$, so $\int_{\mathsf{U}\backslash G_1}\|W^\flat\| < \infty$; and $\int_{\mathsf{U}\backslash G_1}\|W^\flat\|^2 \le \#I$ by (BS1). The second identity for $F = W^\flat$ gives $\int_{\mathsf{U}\backslash G_1}|\langle v, W^\flat\rangle|^2 \le \|v\|^2$. □

Lemma 5.5.29. *Call a Borel function $\chi\colon G_1 \to [0,\infty]$ with $\int_{\mathsf{U}}\chi(uy)\,du = 1$ for every $y \in G_1$ a* cutoff. *Let $\phi\colon G_1 \to [0,\infty]$ be Borel with $\phi(uy) = \phi(y)$ for all $u \in \mathsf{U}$, $y \in G_1$. Then:*

(i) $\int_{G_1}\phi\chi\,dy = \int_{G_1}\phi\chi'\,dy$ for any two cutoffs χ, χ'; this common value is $\int_{\mathsf{U}\backslash G_1}\phi$;

(ii) $\int_{\mathsf{U}\backslash G_1}\phi(yz)\,dy = \int_{\mathsf{U}\backslash G_1}\phi$ for every $z \in G_1$;

(iii) $h\mathsf{U}h^{-1} = \mathsf{U}$ and $\int_{\mathsf{U}\backslash G_1}\phi(hy)\,dy = \int_{\mathsf{U}\backslash G_1}\phi$ for every $h \in H$.

The same identities hold for complex Borel ϕ, left U-invariant, with $\int_{\mathsf{U}\backslash G_1}|\phi| < \infty$.

Proof. **(i).** By Tonelli, the left invariance of dy (Lemma 5.2.41) applied to $y \mapsto uy$ for fixed u, and the U-invariance of ϕ,

$$\begin{aligned}\int\phi\chi\,dy &= \int_{\mathsf{U}}\int\phi(y)\chi(y)\chi'(uy)\,dy\,du = \int_{\mathsf{U}}\int\phi(y)\chi(u^{-1}y)\chi'(y)\,dy\,du\\ &= \int\phi(y)\chi'(y)\int_{\mathsf{U}}\chi(u^{-1}y)\,du\,dy = \int\phi\chi'\,dy,\end{aligned}$$

as du is invariant under $u \mapsto u^{-1}$ (Lemma 5.2.34, (iv)), so $\int_{\mathsf{U}}\chi(u^{-1}y)\,du = 1$.

(ii). $y \mapsto \phi(yz)$ is again U-invariant, and $\chi_z(y) = \chi(yz^{-1})$ is a cutoff. By right invariance of dy (Lemma 5.2.41) and (i), $\int\phi(yz)\chi(y)\,dy = \int\phi(y)\chi(yz^{-1})\,dy = \int\phi\chi\,dy$.

(iii). h fixes the e_a, e_a^*, z and preserves X_0, so it preserves the span of the basis vectors of each level; as $u \in \mathsf{U}$ means that $u - 1$ maps each basis vector into the span of basis vectors of lower level, so does $h(u-1)h^{-1} = huh^{-1} - 1$, and $h\mathsf{U}h^{-1} = \mathsf{U}$. Conjugation by h preserves du (Lemma 5.5.30, (vi)), so $\chi_h(y) = \chi(h^{-1}y)$ is a cutoff: $\int_{\mathsf{U}}\chi(h^{-1}uy)\,du = \int_{\mathsf{U}}\chi(u'h^{-1}y)\,du' = 1$. The function $y \mapsto \phi(hy)$ is U-invariant, and by left invariance of dy and (i), $\int\phi(hy)\chi(y)\,dy = \int\phi\chi_h\,dy = \int\phi\chi\,dy$.

For complex ϕ with $\int|\phi|\chi\,dy < \infty$, apply the above to the positive and negative parts of $\operatorname{Re}\phi$ and $\operatorname{Im}\phi$, which are Borel, nonnegative and U-invariant. □

Lemma 5.5.30. *Fix the setting of Definition 5.1.6. For a complex $r \times r$ matrix g and basis vectors i, j of V_1 write g_{ij} for the i-coordinate of gj. Give the basis vectors* levels*: e_b has level b, the x_i and z level $\varrho+1$, e_b^* level $2\varrho+2-b$. Let dh be the Haar probability measure of H, and ds the image of $du \otimes dh$ under $(u,h) \mapsto uh$.*

(i) R is the set of $g \in G_1$ with $gf_b - f_b \in \langle f_a : a < b\rangle$ for $0 \le b \le \varrho$; it is a closed subgroup of G_1. Every $s \in R$ is uniquely $s = uh$ with $u \in \mathsf{U}$, $h \in H$; writing $h_s = h$, the matrix of h_s in $\mathrm{U}(k)$ is $(s_{x_i x_j})_{1\le i,j\le k}$, the map $s \mapsto h_s$ is a continuous homomorphism $R \to H$, and $s \mapsto (sh_s^{-1}, h_s)$ is a homeomorphism $R \to \mathsf{U} \times H$.

(ii) For $s \in R$ put $\sigma(s) = \sigma(sh_s^{-1})$. Then $\sigma(s) = \sum_{a<\varrho} s_{f_a f_{a+1}}$, $\sigma(st) = \sigma(s) + \sigma(t)$ and $\sigma(s^{-1}) = -\sigma(s)$ for $s, t \in R$, and $\sigma = 0$ on H.

(iii) If Z is a complex $r \times r$ matrix with $Z_{ij} = 0$ whenever the level of i exceeds the level of j, then $\mathrm{tr}\big(Z(s-h_s)\big) = 0$ for every $s \in R$. In particular $\mathrm{tr}(s-1) = \mathrm{tr}(h_s - 1)$, the right side computed in $\mathrm{U}(k)$.

(iv) Let C be the chain matrix*: $Ce_b = f_b$ $(1 \le b \le \varrho)$, $Cz = -e_\varrho^*$, $Ce_b^* = e_{b-1}^*$ $(2 \le b \le \varrho)$, $Ce_1^* = 0$ and $Cx_i = 0$ $(1 \le i \le k)$. Then $\mathrm{tr}\big(C(s-1)\big) = \sigma(s) - \overline{\sigma(s)}$ for every $s \in R$.*

(v) With the topology of G_1 on R, left and right translations of R are continuous, and ds is a right-invariant Borel measure on R that is finite on compact sets.

(vi) Conjugation by every $h \in H$ preserves du, and for every Borel $f\colon G_1 \to [0,\infty]$, with dy the Cayley measure of G_1,

$$\int_{\mathsf{U}\backslash G_1} \int_R f(sy)\, ds\, dy = \int_{G_1} f(g)\, dg.$$

Proof. Here $h(v,w) = v^* J_1 w$, linear in w, and J_1 exchanges e_b and e_b^*, fixes the x_i and sends z to $-z$. Hence the coordinates of $w \in V_1$ are $w_{e_b^*} = h(e_b, w)$, $w_{e_b} = h(e_b^*, w)$, $w_{x_i} = h(x_i, w)$ and $w_z = -h(z,w)$. Write $F_c = \langle e_1, \dots, e_c\rangle$ $(0 \le c \le \varrho)$, $F = F_\varrho$, and $\perp$ for the orthogonal for h. Then $F_c^\perp$ is spanned by the e_b, the x_i, z and the e_b^* with $b > c$, and the span of the basis vectors of level at most m is F_m for $m \le \varrho$ and $F_{2\varrho+1-m}^\perp$ for $\varrho+1 \le m \le 2\varrho+1$. So the refined flag

$$0 = F_0 \subset F_1 \subset \cdots \subset F_\varrho \subset F_\varrho^\perp \subset F_{\varrho-1}^\perp \subset \cdots \subset F_0^\perp = V_1$$

is the flag of the level spans. The stabiliser P of $F_1 \subset \cdots \subset F_\varrho$ in G_1 stabilises the refined flag, and its unipotent radical U consists of the elements of G_1 that act trivially on each of its successive quotients (the standard description of the unipotent radical of a parabolic subgroup of a unitary group, [36]). Equivalently: $(u-1)j$ lies in the span of the basis vectors of level smaller than that of j, for every basis vector j; that is, $u_{ij} = \delta_{ij}$ whenever the level of i is at least the level of j. The group H fixes F pointwise and preserves X_0, so $H \subseteq P$; and P normalises U.

(i). Let Q be the set of $g \in G_1$ with $gf_b - f_b \in \langle f_a : a < b\rangle$ for all b. On the span $W = \langle f_0, \dots, f_\varrho\rangle$ such a g acts by an upper unitriangular matrix, so Q is a subgroup; the conditions say that finitely many coordinates of gf_b are 0 or 1, so Q is closed. Every $u \in \mathsf{U}$ lies in Q: $ue_b - e_b \in F_{b-1}$ because u is trivial on F_b/F_{b-1}, and $uz - z \in F$ because u is trivial on $F^\perp/F$ and $z \in F^\perp$. Every $h \in H$ fixes the frame. Hence $R = \mathsf{U}H \subseteq Q$.

Conversely let $g \in Q$. Then $gF_c = F_c$ for every c, hence $gF^\perp = F^\perp$. For $1 \le j \le k$ write $gx_j = w_j + \sum_i m_{ij} x_i + \lambda_j z$ with $w_j \in F$. Since $g^{-1} \in Q$, $g^{-1}z \in z + F$, so $-\lambda_j = h(z, gx_j) = h(g^{-1}z, x_j) = h(z, x_j) = 0$, as $F \perp X_0$. As F is isotropic and orthogonal to X_0,

$\delta_{jj'} = h(gx_j, gx_{j'}) = \sum_i \overline{m_{ij}} m_{ij'}$, so (m_{ij}) is unitary; let $h \in H$ be the element with this matrix. Put $u = gh^{-1}$; then $u \in G_1$, $ue_b = ge_b \in e_b + F_{b-1}$, $uz = gz \in z + F$, and $ux_j = g(h^{-1}x_j) \in x_j + F$ by the decomposition of $gx_{j'}$. So u preserves the flag $F_1 \subset \cdots \subset F_\varrho$, acts trivially on F_c/F_{c-1} and on $F^\perp/F = \langle x_i, z\rangle + F$. It also acts trivially on $F_{c-1}^\perp/F_c^\perp$ $(1 \le c \le \varrho)$: for $w \in F_{c-1}^\perp$, $uw - w \in F_{c-1}^\perp$ and $h(e_c, uw - w) = h(u^{-1}e_c - e_c, w) = 0$ because $u^{-1}e_c - e_c \in F_{c-1}$; so $uw - w \in F_c^\perp$. Hence $u \in \mathsf{U}$ and $g = uh \in R$. Thus $R = Q$, a closed subgroup.

Uniqueness: if $h \in H \cap \mathsf{U}$, then h preserves X_0 and acts trivially on $F^\perp/F$, so $hx_i \in (x_i + F) \cap X_0 = \{x_i\}$ and $h = 1$; hence $uh = u'h'$ forces $u'^{-1}u = h'h^{-1} = 1$. For $s = uh$ and $1 \le j \le k$, $sx_j = u(hx_j) \in hx_j + F$, so $s_{x_i x_j}$ is the (i,j) entry of the matrix of h; thus $s \mapsto h_s$ is the restriction of a linear map, hence continuous. For $s = uh$, $t = u'h'$ in R, $st = (u \cdot hu'h^{-1})(hh')$ with $hu'h^{-1} \in \mathsf{U}$, so $h_{st} = h_s h_t$. The map $s \mapsto (sh_s^{-1}, h_s)$ is continuous with continuous inverse $(u,h) \mapsto uh$.

(ii). By (i), each $s \in R$ acts on W by an upper unitriangular matrix $[s] = (s_{f_a f_b})_{a,b \le \varrho}$, and $[st] = [s][t]$. For unitriangular matrices $([s][t])_{a,a+1} = [s]_{a,a+1} + [t]_{a,a+1}$, so $\tau(s) = \sum_{a<\varrho} s_{f_a f_{a+1}}$ is additive on R, $\tau(1) = 0$ and $\tau(s^{-1}) = -\tau(s)$. Elements of H fix W, so $\tau = 0$ on H, and $\tau(s) = \tau(sh_s^{-1}) + \tau(h_s) = \tau(sh_s^{-1}) = \sigma(sh_s^{-1})$, the last equality being the definition of σ on U. So $\sigma = \tau$ on R, which gives (ii).

(iii). Let $s = uh$ with $h = h_s$; then $s - h = (u-1)h$ and $\operatorname{tr}(Z(s-h)) = \operatorname{tr}(hZ(u-1))$. The element h maps the level-$(\varrho+1)$ span to itself and fixes the other basis vectors, so $Y = hZ$ again satisfies $Y_{ij} = 0$ when the level of i exceeds that of j. By the description of U, $(u-1)_{ji} \ne 0$ only if the level of j is smaller than that of i. Hence every term of $\operatorname{tr}(Y(u-1)) = \sum_{i,j} Y_{ij}(u-1)_{ji}$ vanishes. For $Z = 1$ this gives $\operatorname{tr}(s-1) = \operatorname{tr}(h_s - 1)$; as $h_s - 1$ vanishes outside X_0, its trace is that of its matrix in $\mathrm{U}(k)$.

(iv). Let $g \in G_1$. Computing $\operatorname{tr}(Cg) = \operatorname{tr}(gC)$ in the basis,

$$\operatorname{tr}(gC) = \sum_{b=1}^{\varrho} g_{e_b f_b} - g_{z,e_\varrho^*} + \sum_{b=2}^{\varrho} g_{e_b^*, e_{b-1}^*}.$$

By the coordinate formulas and $h(gv, w) = h(v, g^{-1}w)$: $g_{e_b^*, e_{b-1}^*} = h(e_b, ge_{b-1}^*) = \overline{h(e_{b-1}^*, g^{-1}e_b)} = \overline{(g^{-1})_{e_{b-1} f_{b-1}}}$, and $-g_{z,e_\varrho^*} = h(z, ge_\varrho^*) = \overline{h(e_\varrho^*, g^{-1}z)} = \overline{(g^{-1})_{e_\varrho f_\varrho}}$. Since $f_a = e_{a+1}$ for $a < \varrho$, the first sum is $\sum_{a<\varrho} g_{f_a f_{a+1}}$ and the last two terms together are $\overline{\sum_{a<\varrho}(g^{-1})_{f_a f_{a+1}}}$. For $g = s \in R$ and $g = 1$, (ii) gives $\operatorname{tr}(Cs) = \sigma(s) + \overline{\sigma(s^{-1})} = \sigma(s) - \overline{\sigma(s)}$ and $\operatorname{tr}(C) = 0$, whence (iv).

(v). Translations are restrictions of matrix multiplication, hence continuous. By (i), $m\colon (u,h) \mapsto uh$ is a homeomorphism $\mathsf{U} \times H \to R$, so $ds = m_*(du \otimes dh)$ is a Borel measure on R, and for compact $C \subseteq R$, $ds(C) = (du \otimes dh)(m^{-1}C) < \infty$, because $m^{-1}C$ is compact, dh is finite and du is finite on compact sets (by Lemma 5.2.34 (i), (iii), a compact set of U has compact image under the row-coordinate map, of finite Lebesgue measure). Let $t = u'h' \in R$ and $\phi \ge 0$ Borel on R. For $s = uh$, $st = u\, c_h\, hh'$ with $c_h = hu'h^{-1} \in \mathsf{U}$. By Tonelli's theorem, the right invariance of du (Lemma 5.2.34 (iv)) applied for fixed h to c_h, and then the right invariance of dh applied for fixed u to h',

$$\int_R \phi(st)\, ds = \int_H \int_{\mathsf{U}} \phi(u\, c_h\, hh')\, du\, dh = \int_H \int_{\mathsf{U}} \phi(u\, hh')\, du\, dh = \int_{\mathsf{U}} \int_H \phi(uh)\, dh\, du = \int_R \phi\, ds.$$

(vi). Let $h \in H$, and write $\mathrm{rw}\colon \mathsf{U} \to \mathcal{C}_{\mathsf{U}}$ for the row-coordinate map of Lemma 5.2.34. Since h and h^{-1} fix the e_b, e_b^* and z and preserve X_0, the e_a-coordinate of hw is that of w for every w; hence $(huh^{-1})_{e_a j} = u_{e_a, h^{-1}j}$, which is $u_{e_a j}$ for $j \in \{e_b, e_b^*, z\}$ and $\sum_{i'} u_{e_a x_{i'}} (h^{-1})_{x_{i'} x_i}$ for $j = x_i$. So $\mathrm{rw}(huh^{-1}) = \Theta_h(\mathrm{rw}(u))$, where Θ_h is the linear map of $\mathcal{C}_{\mathsf{U}}$ that multiplies each block $(u_{e_a x_i})_{1 \le i \le k}$ by the unitary matrix h^{-1} and fixes the other coordinates; it preserves Lebesgue

measure. Let $A \subseteq \mathsf{U}$ be Borel. As rw is continuous and injective on the closed subgroup U of G_1 (Lemma 5.2.34 (i)), $B = \mathrm{rw}(A)$ is Borel (Lusin–Souslin) and $A = \mathrm{rw}^{-1}(B)$. By Lemma 5.2.34 (iii), $du(\{u : huh^{-1} \in A\}) = du(\mathrm{rw}^{-1}(\Theta_h^{-1}B)) = \mathrm{Leb}(\Theta_h^{-1}B) = \mathrm{Leb}(B) = du(A)$; so conjugation by h preserves du.

For the unfolding, recall that $\int_{\mathsf{U}\backslash G_1} \Phi = \int_{G_1} \Phi(y)\chi(y)\,dy$ for left U-invariant Borel $\Phi \geq 0$, where $\chi \geq 0$ is a Borel cutoff with $\int_{\mathsf{U}} \chi(uy)\,du = 1$ for every y (Definition 5.1.6). Put $\Phi(y) = \int_R f(sy)\,ds$; by (v) it is left R-invariant, in particular left U-invariant. By Tonelli's theorem and the left invariance of dy (Lemma 5.2.41), substituting $g = uhy$,

$$\int_{\mathsf{U}\backslash G_1} \Phi = \int_H \int_{\mathsf{U}} \int_{G_1} \chi(y) f(uhy)\,dy\,du\,dh = \int_{G_1} f(g) \int_H \int_{\mathsf{U}} \chi(h^{-1}u^{-1}g)\,du\,dh\,dg.$$

Here $h^{-1}u^{-1} = (h^{-1}u^{-1}h)h^{-1}$, and $u \mapsto h^{-1}u^{-1}h$ preserves du (inversion by Lemma 5.2.34 (iv), conjugation by the first part); so the inner integral over U is $\int_{\mathsf{U}} \chi(u'h^{-1}g)\,du' = 1$, and $\int_H dh = 1$ gives the claim. □

Lemma 5.5.31. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, let λ be its Haar ratio and $c_F = \mathrm{vol}\,\mathrm{U}(k)/(\mathrm{vol}\,\mathrm{U}(r)(\lambda\#I)^2)$, and let $(W, W^\flat)$ be a cut pair for b, f whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. Let p, q be sequences of nonzero complex numbers and $\phi\colon \mathbb{C} \to \mathbb{C}$ measurable with $|\phi| \leq 1$. For $c \in \mathbb{C}$ let $u(c) = c$ if $c \neq 0$ and $u(c) = 1$ if $c = 0$, let p_c, q_c be p, q with the entry of index ϱ replaced by $u(c)$, and*

$$\Phi(c) = \phi(c)\,\langle \mathrm{Ci}_{W^\flat}(p_c), \mathrm{Ci}_{W^\flat}(q_c)\rangle.$$

Then Φ is Lebesgue integrable on $\mathbb{C}$ and

$$\int_{\mathbb{C}} \Phi(c)\,dc = c_F\,\mathcal{F}_\varrho(p, q; W^\flat,\ x \mapsto \phi(h(f_\varrho, xf_\varrho))).$$

Proof. Write $F = W^\flat$, $\mathrm{dn}(c) = \frac{2\pi^k}{(k-1)!}((|c|^2 - 1)_+)^{k-1}$ for $c \in \mathbb{C}$, and $Z_\varrho(x) = h(f_\varrho, xf_\varrho)$. Since $k = s + 3n + 6 \geq 2$, $\mathrm{dn}(c) = 0$ for $|c| \leq 1$.

Step 1: the setting of the descent. By Lemma 5.5.5, (i), the data at $\mathbb{C}$ with box radius $\rho = b^{6n+2}$ form a place datum, and by Lemma 5.5.9 F is cut for it. Choose $L \geq \rho$ with $|p_0 \cdots p_{l-1}|^{-1} \leq L$ and $|q_0 \cdots q_{l-1}|^{-1} \leq L$ for all $l \leq \varrho$; then p, q are heads of length ϱ for the gauge Γ_L (Lemma 5.5.5, (ii)), whose size filtration is $A_{(j)} = \{|x| \leq L^j\}$. By Lemma 5.5.4, (ii), with $j = \varrho$, $t = 1$ and the majorant $\mathrm{FM}_\varrho(p, q, F, \cdot)$ itself as the function bounded there (Θ as in Definition 5.1.6),

$$\#I\,c_F\,\mathrm{hdn}_\varrho(p, q) \int_G \mathrm{FM}_\varrho(p, q, F, x)\,d\theta(x) \leq \Theta\,L^{10^9 n^4}\rho^{24k} < \infty;$$

as $0 < \lambda < \infty$ (Lemma 5.5.10) and the p_a, q_a are nonzero, $\#I\,c_F\,\mathrm{hdn}_\varrho(p, q) > 0$, so

$$\int \mathrm{FM}_\varrho(p, q, F, x)\,d\theta(x) < \infty.$$

Put $\zeta = \mu_H$, $v(c) = \sigma_c$ for $c \neq 0$ and $v(0) = 1$; v is measurable (continuous on $\mathbb{C}^\times$ by the formula (RP2)). By (RP4), $\theta_\varrho = \mu_{\mathrm{top}}$ is the image of $\mu_{\mathrm{cell}} \otimes \mu_H$ under $(g, g') \mapsto gg'$, and μ_{cell} is the image of $\mathrm{dn}(c)\,dc$ under $c \mapsto v(c)^{-1}$ (the point $c = 0$ is Lebesgue-null); so θ_ϱ is the convolution of that image with ζ. The density dn is measurable and finite. The finite measure ζ

is carried by $H = G^{(\varrho+1)}$, and $G^{(\varrho+1)} \subseteq G^{(\varrho)} \cap R^{(\varrho+1)}$ (Lemma 5.2.58, (i)). So Proposition 5.2.92, (i), applies with $b = \varrho$, the weight ϕ, $t = c_F$, the density dn and the maps v: the function

$$\Psi(c) = c_F \,\mathrm{hdn}_\varrho(p,q)\,\mathrm{dn}(c)\,\phi(Z_\varrho(v(c)))\int_{G\times G} \mathcal{K}_{F,\varrho+1}(g,gx)\,\overline{\mathcal{K}^d_{F,\varrho+1}(w_c^{-1}g, w_c^{-1}gx)}\,d\nu(x,g),$$

with $w_c = w_{\varrho,p}v(c)$, $d = w_{\varrho,q}^{-1}w_{\varrho,p}$ and $\nu = \theta\otimes((\mu_H * \theta_\varrho) * \mathfrak{m}_\varrho)$, is integrable on $\mathbb{C}$ with $\int\Psi = c_F\,\mathcal{F}_\varrho(p,q;F,\phi\circ Z_\varrho)$. It remains to show $\Phi(c) = \Psi(c)$ for every $c \neq 0$.

Step 2: the measures and the kernels above the top floor. By Definition 5.2.1, $\eta_l = \delta_1$ for $l \geq \varrho$, so $\theta = \mathfrak{m}_{0,\varrho+2} = \mu_H * \mu_{\mathrm{top}} * \mathfrak{m}_\varrho$ (convolution of s-finite measures is associative, by Tonelli), that is $(\mu_H * \theta_\varrho) * \mathfrak{m}_\varrho = \theta$, and $\nu = \theta\otimes\theta = \lambda^2\,dy\otimes dy$ by Lemma 5.5.10. The tower measure from floor $\varrho+1$ is $\theta_{\geq\varrho+1} = \mu_H$, the image of the Haar probability measure of $\mathrm{U}(k)$. Let $\mathrm{em}(h) \in H$ be the image of $h \in \mathrm{U}(k)$. For $g, y \in G$: $F(\mathrm{em}(h)g)$ is the image of $F(g)$ under the unitary operator by which h acts in the type of F, so $\langle F(\mathrm{em}(h)g), F(\mathrm{em}(h)y)\rangle = \langle F(g), F(y)\rangle$; and d commutes with $\mathrm{em}(h) \in G^{(\varrho)}$ (Lemma 5.2.58, (ix)), so $\langle F(\mathrm{em}(h)g), F(d\mathrm{em}(h)y)\rangle = \langle F(g), F(dy)\rangle$. The integrands being bounded and μ_H a probability measure,

$$\mathcal{K}_{F,\varrho+1}(g,y) = \langle F(g), F(y)\rangle, \qquad \mathcal{K}^d_{F,\varrho+1}(g,y) = \langle F(g), F(dy)\rangle.$$

Step 3: the inner integral is a Gram product of orbital integrals. Let $c \neq 0$ and put $\gamma_p = w_{\varrho,p}\sigma_c$, $\gamma_q = w_{\varrho,q}\sigma_c$. As $\sigma_c \in G^{(\varrho)}$ (the boosts fix every e_a, e_a^*) and $w_{\varrho,p}$ commutes with $G^{(\varrho)}$ (Lemma 5.2.58, (ix)), $dw_c^{-1} = w_{\varrho,q}^{-1}w_{\varrho,p}\sigma_c^{-1}w_{\varrho,p}^{-1} = \gamma_q^{-1}$, while $w_c^{-1} = \gamma_p^{-1}$. By Step 2 the integrand of $\Psi(c)$ is

$$\Pi(x,g) = \langle F(g), F(gx)\rangle\,\overline{\langle F(\gamma_p^{-1}g), F(\gamma_q^{-1}gx)\rangle}.$$

The map $(x,g) \mapsto (y,y') = (g,gx)$ is a homeomorphism of $G\times G$ carrying $dy\otimes dy$ to itself (for fixed g, $x \mapsto gx$ preserves dy, Lemma 5.2.41; then Tonelli), and turns Π into $\Pi'(y,y') = \langle F(y), F(y')\rangle\,\overline{\langle F(\gamma_p^{-1}y), F(\gamma_q^{-1}y')\rangle}$. By Lemma 5.4.20, (iii), for Γ_L and $x = \sigma_c \in G^{(\varrho)}$: if $F(y) \neq 0$ and $F(\gamma_p^{-1}y) \neq 0$ then y lies in the set C_0 of elements of size $60n^2$, and likewise for y' with q. The set C_0 is compact ($A_{(60n^2)}$ is compact by (GU1), and G is closed), and $dy(C_0) < \infty$: a compact neighbourhood of 1 contained in the image of a compact neighbourhood of 0 under the Cayley chart (a homeomorphism onto an open neighbourhood of 1 with continuous density) has finite measure, and finitely many of its left translates cover C_0 (Lemma 5.2.41). Since F is bounded and measurable, Π' is integrable for $dy\otimes dy$, vanishing outside $C_0\times C_0$, so Π is ν-integrable, and by Fubini, expanding $\langle u,u'\rangle = \sum_i \bar{u}_i u'_i$,

$$\int\Pi\,d\nu = \lambda^2\sum_{i,j\in I}\overline{\int_G F_i(y)\overline{F_j(\gamma_p^{-1}y)}\,dy}\int_G F_i(y')\overline{F_j(\gamma_q^{-1}y')}\,dy' = \lambda^2\langle \mathrm{Orb}_{dy}(\gamma_p), \mathrm{Orb}_{dy}(\gamma_q)\rangle,$$

each single integral being absolutely convergent for the same reason.

Step 4: comparison of the constants. If $0 < |c| \leq 1$, then $\mathrm{dn}(c) = 0$, so $\Psi(c) = 0$; and the factor $\sqrt{(|c|^2-1)_+}^{k-1}$ of both normalised orbital integrals vanishes ($k \geq 2$), so $\Phi(c) = 0$. Let $|c| > 1$. Then $u(c) = c$, $\sigma_c = \mathrm{bt}(c)$ and $\mathrm{bt}(c)z = s_c x_{k_0} - cz$, so $Z_\varrho(v(c)) = h(z, s_c x_{k_0} - cz) = -c\,h(z,z) = c$ and the weight in $\Psi(c)$ is $\phi(c)$. The Weyl element w_{p_c} depends only on the entries of index below ϱ, so $w_{p_c} = w_{\varrho,p}$ and, by Definition 5.5.2 and the definition of N,

$$\mathrm{Ci}_F(p_c) = \frac{\sqrt{c_G}}{\#I}\,(|c|^2-1)^{(k-1)/2}\prod_{a<\varrho}|p_a|^{d_a}\,\mathrm{Orb}_{dy}(\gamma_p),$$

and likewise for q_c with γ_q. The scalar factors are real, so

$$\Phi(c) = \phi(c)\,\frac{c_G}{(\#I)^2}\,(|c|^2-1)^{k-1}\,\mathrm{hdn}_\varrho(p,q)\,\langle \mathrm{Orb}_{dy}(\gamma_p), \mathrm{Orb}_{dy}(\gamma_q)\rangle,$$

using $\prod_{a<\varrho}(|p_a||q_a|)^{d_a} = \mathrm{hdn}_\varrho(p,q)$. By Step 3,

$$\Psi(c) = c_F\,\lambda^2\,\mathrm{dn}(c)\,\mathrm{hdn}_\varrho(p,q)\,\phi(c)\,\langle \mathrm{Orb}_{dy}(\gamma_p), \mathrm{Orb}_{dy}(\gamma_q)\rangle,$$

and

$$c_F\,\lambda^2\,\mathrm{dn}(c) = \frac{\mathrm{vol}\,\mathrm{U}(k)}{\mathrm{vol}\,\mathrm{U}(r)\,(\#I)^2}\cdot\frac{2\pi^k}{(k-1)!}(|c|^2-1)^{k-1} = \frac{c_G}{(\#I)^2}(|c|^2-1)^{k-1},$$

since $c_G = \mathrm{vol}\,\mathrm{U}(k)/\mathrm{vol}\,\mathrm{U}(r)\cdot 2\pi^k/(k-1)!$. So $\Phi(c) = \Psi(c)$.

Conclusion. $\Phi = \Psi$ outside the null set $\{0\}$, so Φ is integrable and $\int\Phi = \int\Psi = c_F\,\mathcal{F}_\varrho(p,q;F,\phi\circ Z_\varrho)$. □

Lemma 5.5.32. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, and let $(W, W^\flat)$ be a cut pair for b, f whose type is a unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. Give the set $\mathcal{S}$ of sequences $(p_a)_{a\geq 0}$ in $\mathbb{C}^\times$ the product topology.*

(i) If $W^\flat$ is continuous, then $p \mapsto \mathrm{Ci}_{W^\flat}(p)$ is continuous on $\mathcal{S}$; hence $(p,q) \mapsto \langle \mathrm{Ci}_{W^\flat}(p), \mathrm{Ci}_{W^\flat}(q)\rangle$ is continuous on $\mathcal{S}\times\mathcal{S}$.

(ii) Let $\sigma \in G_1$ fix every e_a and e_a^* $(a<\varrho)$, and let $p, q \in \mathcal{S}$ with $p_\varrho = q_\varrho = h(z, \sigma z)$. Then

$$\langle N(\sigma, W^\flat, p), N(\sigma, W^\flat, q)\rangle = \langle \mathrm{Ci}_{W^\flat}(p), \mathrm{Ci}_{W^\flat}(q)\rangle.$$

Proof. Write $F = W^\flat$ and $\mathrm{em}(u) \in G_1$ for the image of $u \in \mathrm{U}(k)$ (acting on X_0 through the orthonormal coordinates $x_1, \dots, x_k$, fixing every e_a, e_a^* and z); $F(\mathrm{em}(u)y) = \Pi(u)F(y)$, where $\Pi(u)$ is the unitary matrix by which u acts in the type of F. For $p \in \mathcal{S}$ put

$$s(p) = \frac{\sqrt{c_G}}{\#I}\left((|p_\varrho|^2-1)_+\right)^{(k-1)/2}\prod_{a<\varrho}|p_a|^{d_a},$$

so that $N(\sigma, F, p) = s(p)\,\mathrm{Orb}_{dy}(w_p\sigma)$ for every $\sigma \in G_1$, and $\mathrm{Ci}_F(p) = s(p)\,\mathrm{Orb}_{dy}(w_p\sigma_{p_\varrho})$ (Definition 5.1.6, Definition 5.5.2).

Step 0: compact support. By Lemma 5.5.5, (i), and Lemma 5.5.9, F is cut for the place datum at $\mathbb{C}$ with box radius $\rho = b^{6n+2}$. Let $L \geq \rho$, let $p \in \mathcal{S}$ be a head of length ϱ for Γ_L and $x \in G^{(\varrho)}$. By Lemma 5.4.20, (iii), the function $y \mapsto F_i(y)\overline{F_j((w_px)^{-1}y)}$ vanishes outside the set C_L of the elements of G_1 of size $60n^2$ for Γ_L. The set C_L is compact ((GU1) and G_1 closed), and $dy(C_L) < \infty$: a compact neighbourhood of 1 contained in the image of a compact neighbourhood of 0 under the Cayley chart (a homeomorphism onto an open neighbourhood of 1, with continuous density) has finite measure, and finitely many of its left translates cover C_L (Lemma 5.2.41). As F is bounded and measurable, every entry of $\mathrm{Orb}_{dy}(w_px)$ is an absolutely convergent integral over C_L. Every $p \in \mathcal{S}$ is a head of length ϱ for Γ_L as soon as $L \geq \rho$ and $L \geq |p_0\cdots p_{l-1}|^{-1}$ for $l \leq \varrho$.

(i). Fix $p \in \mathcal{S}$ and choose $L \geq \rho$ with $|p_0\cdots p_{l-1}|^{-1} < L$ for all $l \leq \varrho$. The set $\mathcal{S}_L$ of the $p' \in \mathcal{S}$ with $|p'_0\cdots p'_{l-1}|^{-1} < L$ for all $l \leq \varrho$ is open (it is defined by finitely many continuous coordinate conditions), contains p, and consists of heads of length ϱ for Γ_L. On $\mathcal{S}$, s is continuous (it depends continuously on $p_0, \dots, p_\varrho$). The map $c \mapsto \sigma_c = \mathrm{bt}(c/\min(1,|c|))$ is continuous on $\mathbb{C}^\times$: $c \mapsto c/\min(1,|c|)$ is continuous with values in $\{|a| \geq 1\}$, where the matrix entries $\bar a$, $\pm a$, $\sqrt{|a|^2-1}$ of $\mathrm{bt}(a)$ are continuous. The entries p'_a, $\bar p'^{-1}_a$ of $w_{p'}$ are continuous in p', and inversion and multiplication are continuous on G_1. Hence, F being continuous, $(p', y) \mapsto F_i(y)\overline{F_j((w_{p'}\sigma_{p'_\varrho})^{-1}y)}$ is continuous on $\mathcal{S}_L \times G_1$; by Step 0 (with $x = \sigma_{p'_\varrho} \in G^{(\varrho)}$, the

boosts fixing every e_a, e_a^*) it vanishes outside $\mathcal{S}_L \times C_L$, and it is bounded by $(\sup\|F\|)^2$. The space $\mathcal{S}$ is metrizable (a countable product of metric spaces), so continuity at p is sequential continuity, and dominated convergence with the integrable majorant $(\sup\|F\|)^2\mathbf{1}_{C_L}$ shows that $p' \mapsto \mathrm{Orb}_{dy}(w_{p'}\sigma_{p'_\varrho})$ is continuous at p. So $\mathrm{Ci}_F = s \cdot \mathrm{Orb}_{dy}(w.\sigma_{._\varrho})$ is continuous at p, and the Gram form is continuous as the composite with the continuous inner product.

(ii). Put $c = h(z, \sigma z)$; the normalising factors of both sides are $s(p)s(q)$, real. If $|c| \le 1$, then $s(p) = s(q) = 0$ (as $k \ge 2$), and both sides vanish. Let $|c| > 1$ and $s_c = \sqrt{|c|^2 - 1}$.

Cartan decomposition: $\sigma = \mathrm{em}(u_1)\,\mathrm{bt}(c)\,\mathrm{em}(u_2)$ for some $u_1, u_2 \in \mathrm{U}(k)$. As σ is an isometry fixing the vectors of the hyperbolic planes, it preserves their h-orthogonal complement $X_0 \oplus \mathbb{C}z$. Write $\sigma z = \omega + c'z$ with $\omega \in X_0$. Then $c = h(z, \sigma z) = c'h(z, z) = -c'$, and $-1 = h(\sigma z, \sigma z) = \|\omega\|^2 - |c|^2$, so $\|\omega\| = s_c > 0$. As $\mathrm{U}(k)$ acts transitively on the sphere of radius s_c in $X_0 = \mathbb{C}^k$, there is u_1 with $u_1(s_c x_{k_0}) = \omega$; then $\mathrm{em}(u_1)\mathrm{bt}(c)z = \mathrm{em}(u_1)(s_c x_{k_0} - cz) = \omega - cz = \sigma z$. So $\tau = (\mathrm{em}(u_1)\mathrm{bt}(c))^{-1}\sigma \in G_1$ fixes z and every e_a, e_a^*; it preserves their orthogonal complement X_0, on which h is the standard positive form, so $\tau = \mathrm{em}(u_2)$ with $u_2 = \tau|_{X_0} \in \mathrm{U}(k)$. Since $\sigma_c = \mathrm{bt}(c)$ for $|c| \ge 1$, $\sigma = \mathrm{em}(u_1)\sigma_c\mathrm{em}(u_2)$.

Transport of the orbital integrals. The elements $\mathrm{em}(u_1)$, σ and σ_c lie in $G^{(\varrho)}$, which commutes with w_p and w_q (Lemma 5.2.58, (ix)); so $w_p\sigma = \mathrm{em}(u_1)\,\gamma_p\,\mathrm{em}(u_2)$ with $\gamma_p = w_p\sigma_c$, and likewise for q. Take L so large that p, q are heads of length ϱ for Γ_L; by Step 0 all entries of $\mathrm{Orb}_{dy}(w_p\sigma)$ and $\mathrm{Orb}_{dy}(\gamma_p)$ (and those for q) are absolutely convergent. Substituting $y = \mathrm{em}(u_1)y''$, which preserves dy (Lemma 5.2.41), and writing $U = \Pi(u_1)$, $V = \Pi(u_2)^{-1}$,

$$\mathrm{Orb}_{dy}(w_p\sigma)_{ij} = \int_{G_1} F_i(\mathrm{em}(u_1)y'')\,\overline{F_j(\mathrm{em}(u_2)^{-1}\gamma_p^{-1}y'')}\,dy'' = \sum_{a,b\in I} U_{ia}\,\mathrm{Orb}_{dy}(\gamma_p)_{ab}\,\overline{V_{jb}},$$

that is $\mathrm{Orb}_{dy}(w_p\sigma) = U\,\mathrm{Orb}_{dy}(\gamma_p)\,V^*$, and the same with q and the same unitary U, V. The inner product of $\mathbb{C}^{I\times I}$ is $\langle A, B\rangle = \mathrm{tr}(A^*B)$, so $\langle UAV^*, UBV^*\rangle = \mathrm{tr}(VA^*BV^*) = \langle A, B\rangle$. Therefore

$$\langle N(\sigma, F, p), N(\sigma, F, q)\rangle = s(p)s(q)\langle \mathrm{Orb}_{dy}(\gamma_p), \mathrm{Orb}_{dy}(\gamma_q)\rangle = \langle \mathrm{Ci}_F(p), \mathrm{Ci}_F(q)\rangle,$$

the last equality because $p_\varrho = q_\varrho = c$, so $\gamma_p = w_p\sigma_{p_\varrho}$ and $\gamma_q = w_q\sigma_{q_\varrho}$. □

Lemma 5.5.33. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, and let $(W, W^\flat)$ be a cut pair for b, f whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. Put $R = b^{60n^2}$, $K = n^6$ and $\mathrm{Dec}(\nu) = \Theta\, b^{2000n^9}\ell_{k-n^7}(|\nu|^{-1})$ for $\nu \in \mathbb{C}^\times$. Let p, q be sequences of nonzero complex numbers.*

(a) For $i \le \varrho$ and $\nu \in \mathbb{C}^\times$,

$$\#I \cdot |c_F\,\mathcal{F}_i(p, q; W^\flat, x \mapsto \psi(\nu\, h(f_i, xf_i)))| \le \mathrm{Dec}(\nu)\,\Lambda_i^{R,K}(p)\,\Lambda_i^{R,K}(q).$$

(b) For $i + 1 \le \varrho$ with $\nu = p_i^{-1} - q_i^{-1} \ne 0$,

$$\#I \cdot |c_F\,\mathcal{F}_{i+1}(p, q; W^\flat, 1)| \le \mathrm{Dec}(\nu)\,\Lambda_{i+1}^{R,K}(p)\,\Lambda_{i+1}^{R,K}(q).$$

Proof. Treat (a) and (b) together: let $j = i$ and $\omega(x) = \psi(\nu h(f_i, xf_i))$ in case (a), $j = i + 1$ and $\omega = 1$ in case (b); in both cases $|\omega| \le 1$ and $j \le \varrho$. Write $H = \Lambda_j^{R,K}(p)\Lambda_j^{R,K}(q)$. By Lemma 5.5.9, $W^\flat$ is cut, and by Lemma 5.5.10, θ is a Haar measure. By (DN0)(a) of Theorem 5.4.1 and $c_F > 0$,

$$|c_F\,\mathcal{F}_j(p, q; W^\flat, \omega)| \le c_F\,\mathrm{hdn}_j(p, q)\int_G \mathrm{FN}_j(p, q, W^\flat, x; \omega)\,d\theta(x), \qquad \mathrm{FN}_j(\cdot;\omega) \le \mathrm{FM}_j. \quad (5.95)$$

Step 1: large head products give the form 0. As $n \ge 3$, $\rho^{9n} = b^{(6n+2)9n} \le b^{60n^2} = R$. Suppose some $l \le j$ has $|\delta_{l-1}(p)| > R$ or $|\delta_{l-1}(q)| > R$ (with $l \ge 1$). Let y be active at some x for $(j,p,q,W^\flat)$. By (AC1), $W^\flat(y) \ne 0$ and $W^\flat(yx) \ne 0$, so $uy \in K$ and $vyx \in K$ for some $u, v \in \mathsf{U}$; as $\mathsf{U} \subseteq R^{(j)}$, y and yx are near at j. By (AC2), (AC3), $w_{j,p}^{-1}y$ and $w_{j,q}^{-1}yx$ are near at j. The frame Gram matrix of $w_{j,p}$ is diagonal in its first j rows with entries $p_0, \dots, p_{j-1}$ ($h(e_a, w_{j,p}e_a) = p_a$), so its leading principal minor of order l is $\delta_{l-1}(p)$; by (DN0)(e) of Theorem 5.4.1 for the gauge Γ_ρ, $|\delta_{l-1}(p)| \le \rho^{9n} \le R$, and likewise for q. This contradicts the assumption, so no point is active at any x: $(j,p,q,W^\flat)$ has a deep vector after the head of depth at least $\infty = \sigma^{-1}$, $\sigma = 0$, at every x. With $V \ge 1$ and $\mathrm{FML}_j(V;1)$ from Lemma 5.5.4, (i), and p a head of length j for Γ_L with $L = \max(\rho, \max_{l \le j} |\delta_{l-1}(p)|^{-1})$, (DN3)(c) gives $\mathrm{FM}_j(p,q,W^\flat,x)^2 \le 0^s V^2 \mathrm{WSP}_j = 0$ ($s > 0$). By (5.95) the form is 0, and the claim holds.

Step 2: a gauge for both heads. Assume now $|\delta_l(p)|, |\delta_l(q)| \le R$ for $l < j$. Let

$$L = \max\bigl(\rho, \max_{l \le j} |\delta_{l-1}(p)|^{-1}, \max_{l \le j} |\delta_{l-1}(q)|^{-1}\bigr)$$

(empty products = 1). Then $L \ge \rho$ and p, q are heads of length j for Γ_L. Each term of the maximum is at most

$$\rho \prod_{l<j} \max(1, |\delta_l(p)|^{-1}) \prod_{l<j} \max(1, |\delta_l(q)|^{-1}),$$

as every factor is ≥ 1 and $\rho \ge 1$; raising to the power K and using the definition of the head weights,

$$L^K \le \rho^K H.$$

Step 3: the local gain. Let $x \in G$. In case (a), (DN3)(a) of Theorem 5.4.1 with $\xi = \eta = \nu$ gives $\mathrm{FN}_j(p,q,W^\flat,x;\omega)^2 \le (\pi^2/|\nu|^2)^{k-5} \mathrm{WSP}_j(p,q,W^\flat,x)$ for Γ_L; in case (b), (DN3)(b) with $\xi = M^{-1}(p_i^{-1} - q_i^{-1}) = \nu$ gives the same. Put $t = \max(1, \rho^{24}|\nu|)$ and V as in Lemma 5.5.4. If $t > 1$, then $t = \rho^{24}|\nu|$, and since $\pi\rho^{24} \ge 1$, $\rho^{24}|\nu| \ge 1$ and $s \le k - 5 \le k$,

$$\Bigl(\frac{\pi^2}{|\nu|^2}\Bigr)^{k-5} = \Bigl(\frac{(\pi\rho^{24})^{k-5}}{(\rho^{24}|\nu|)^{k-5}}\Bigr)^2 \le \Bigl(\frac{(\pi\rho^{24})^k \rho^{9999n}}{(\rho^{24}|\nu|)^s}\Bigr)^2 = \Bigl(\frac{V}{t^s}\Bigr)^2.$$

So $\phi = \mathrm{FN}_j(p,q,W^\flat,\cdot;\omega)$ satisfies the hypotheses of Lemma 5.5.4, (ii), and with (5.95),

$$\#I\, |c_F\, \mathcal{F}_j(p,q;W^\flat,\omega)| \le \Theta\, L^{10^9 n^4} \rho^{24k}\, \frac{t^{10^8 n^4}}{t^s}.$$

Step 4: the damped power. Write $k = n^7 + K'$ ($K' = k - n^7 \ge 0$). As $n > 10^8$: $10^9 n^4 \le n^6 = K$, and $s = k - 3n - 6 \ge 10^8 n^4 + K' + 6$. As $L, t \ge 1$, Step 2 gives $L^{10^9 n^4} \le L^K \le \rho^K H$, and $t^{10^8 n^4}/t^s \le t^{-K'-6}$. Moreover $\rho^{24}/t \le |\nu|^{-1}$ and $t^{-1} \le \min(1, |\nu|^{-1})$ (as $t \ge 1$ and $t \ge \rho^{24}|\nu| \ge |\nu|$). Hence

$$\begin{aligned} L^{10^9 n^4} \rho^{24k} \frac{t^{10^8 n^4}}{t^s} &\le \rho^{n^6} \rho^{24n^7} \Bigl(\frac{\rho^{24}}{t}\Bigr)^{K'} t^{-6} H \\ &\le \rho^{n^6 + 24n^7}\, |\nu|^{-K'} \min(1, |\nu|^{-1})^6\, H = \rho^{n^6+24n^7}\, \ell_{K'}(|\nu|^{-1})\, H, \end{aligned}$$

and $\rho^{n^6+24n^7} = b^{(6n+2)(n^6+24n^7)} \le b^{2000n^9}$. With Step 3 this is the claim. □

Lemma 5.5.34. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, and let $(W, W^\flat)$ be a cut pair for b, f whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. Let* $\deg > 0$ *with*

$$\int_{G_1} \Bigl| \int_{\mathsf{U} \setminus G_1} \langle W(y), W(yx) \rangle\, dy \Bigr|^2 dx \le \frac{(\#I)^2}{\deg}, \qquad \deg \cdot \Theta \le b^{4r^2},$$

$\deg\cdot\mathrm{vol}\{g\in G_1:\|g\|_{\mathrm{op}}\le T\}\le T^{9r^2}b^{99r^2}$ *for all* $T\ge 1$, *and* $4000n\le f$. *Then for all sequences* p,q *of nonzero complex numbers*

$$|c_F\,\mathcal{F}_0(p,q;W^\flat,1)|\le\frac{1+b^{-10}}{\deg}.$$

Proof. **Step 0: numbers.** $n\ge 3$, so $\rho=b^{6n+2}\le b^{7n}$; $r=s+5n+5$; $s>10^9n^3$, and $s\ge 10^{10}n^4$ (from $k=s+3n+6\ge n^7$, $n>10^8$). Put $\varepsilon=b^{-r^3f}$.

Step 1: the matrix coefficients. For $A,B\in\{W,W^\flat,W^\flat-W\}$ (Bessel functions of the type of the pair) and $x\in G_1$, the function $y\mapsto\langle A(y),B(yx)\rangle$ is left U-invariant ($|\text{wave}|=1$), and by Cauchy–Schwarz and Lemma 5.5.29, (ii), applied to the U-invariant $\|B\|^2$,

$$\int_{\mathsf{U}\backslash G_1}|\langle A(y),B(yx)\rangle|\,dy\le\Big(\int_{\mathsf{U}\backslash G_1}\|A\|^2\Big)^{1/2}\Big(\int_{\mathsf{U}\backslash G_1}\|B\|^2\Big)^{1/2}.$$

Put $Q(x)=\int_{\mathsf{U}\backslash G_1}\langle W(y),W(yx)\rangle\,dy$ and $Q^\flat(x)=\int_{\mathsf{U}\backslash G_1}\langle W^\flat(y),W^\flat(yx)\rangle\,dy$, both finite and Borel in x (Fubini). Since $\langle W^\flat(y),W^\flat(yx)\rangle-\langle W(y),W(yx)\rangle=\langle(W^\flat-W)(y),W^\flat(yx)\rangle+\langle W(y),(W^\flat-W)(yx)\rangle$, (BS1) and (BS2) give $|Q^\flat(x)-Q(x)|\le 2\varepsilon\#I$ for every x.

Step 2: $\mathrm{FN}_0(p,q,W^\flat,x;1)=\lambda^2|Q^\flat(x)|^2$**.** Fix x and put $g_x(y)=\langle W^\flat(y),W^\flat(yx)\rangle=\mathcal{K}_{W^\flat}(y,yx)$. By the unfolding identity of Lemma 5.5.10, applied to $|g_x|$ and to the positive and negative parts of $\mathrm{Re}\,g_x$, $\mathrm{Im}\,g_x$ (all Borel, ≥ 0, U-invariant), g_x is $\theta_{\ge 0}$-integrable with $\int g_x\,d\theta_{\ge 0}=\lambda Q^\flat(x)$. As $\theta_{\ge 0}=\theta_{\ge 1}*\theta_0$ (Lemma 5.2.59, (i)), Fubini gives: for θ_0-almost every ξ, $y'\mapsto g_x(y'\xi)$ is $\theta_{\ge 1}$-integrable, so $A(\xi):=\mathcal{K}_{W^\flat,1}(\xi,\xi x)=\int g_x(y'\xi)\,d\theta_{\ge 1}(y')$, and $\int A\,d\theta_0=\lambda Q^\flat(x)$. At floor 0 the Weyl elements are 1, so $d=1$ and $\mathcal{K}^d_{W^\flat}=\mathcal{K}_{W^\flat}$, and by definition

$$\mathrm{FI}_0(p,q,W^\flat,x;1)(1)=\iint A(\xi)\,\overline{A(\zeta)}\,d\theta_0(\zeta)\,d\theta_0(\xi)=\Big|\int A\,d\theta_0\Big|^2=\lambda^2|Q^\flat(x)|^2;$$

as $\mathfrak{m}_0=\delta_1$, $\mathrm{FN}_0(p,q,W^\flat,x;1)=|\mathrm{FI}_0(p,q,W^\flat,x;1)(1)|=\lambda^2|Q^\flat(x)|^2$.

Step 3: positions near 1. Let $T_0=b^{6r}\rho^{11n}$ and $C=\{x:|(x-1)_{ac}|\le T_0^{99n}\ \forall a,c\}$, a closed set. For $x\in C$, $\|x-1\|_{\mathrm{op}}\le rT_0^{99n}$, so $\|x\|_{\mathrm{op}}\le(r+1)T_0^{99n}\le\rho^2T_0^{99n}\le b^{14n+594nr+7623n^3}\le b^{700nr}=:T$, as $14n+7623n^3\le 106nr$ ($r>10^9n^3$). By hypothesis $\mathrm{vol}(C)\le T^{9r^2}b^{99r^2}/\deg$. By Step 1 and Minkowski's inequality in $L^2(C,dx)$,

$$\Big(\int_C|Q^\flat|^2dx\Big)^{1/2}\le\frac{\#I}{\sqrt{\deg}}+2\varepsilon\#I\Big(\frac{T^{9r^2}b^{99r^2}}{\deg}\Big)^{1/2}\le(1+b^{-12})\frac{\#I}{\sqrt{\deg}},$$

since $(2\varepsilon)^2T^{9r^2}b^{99r^2}\le b^{2+6300nr^3+99r^2-2r^3f}\le b^{-24}$, using $2r^3f\ge 8000nr^3\ge 6300nr^3+99r^2+26$. By Step 2, $\theta=\lambda\,dx$ and Lemma 5.5.10 ($\lambda\,\mathrm{vol}\,\mathrm{U}(k)/\mathrm{vol}\,\mathrm{U}(r)\le 1$),

$$c_F\int_C\mathrm{FN}_0(p,q,W^\flat,x;1)\,d\theta=c_F\lambda^3\int_C|Q^\flat|^2dx\le\frac{\mathrm{vol}\,\mathrm{U}(k)}{\mathrm{vol}\,\mathrm{U}(r)}\,\lambda\,\frac{(1+b^{-12})^2}{\deg}\le\frac{(1+b^{-12})^2}{\deg}.$$

Step 4: remote positions. With $L=\rho$ and $t=b^{6r}\ge 1$, $C=B(tL^{11n})$ in the notation of Lemma 5.5.35; every sequence is a head of length 0. By Lemma 5.5.9, $W^\flat$ is cut, so (DN0)(a) of Theorem 5.4.1 gives $\mathrm{FN}_0(\cdot;1)\le\mathrm{FM}_0$, and Lemma 5.5.35 with $j=0$ gives

$$c_F\int_{G\backslash C}\mathrm{FN}_0\,d\theta\le\Theta\,\rho^{10^9n^4}\rho^{24k}\frac{t^{10^8n^4}}{t^s}\le\frac{b^E}{\deg\,b^{6rs}},\qquad E=4r^2+7\cdot10^9n^5+168nk+6\cdot10^8n^4r,$$

by $\Theta \le b^{4r^2}/\deg$ and $\rho \le b^{7n}$. Here $E+12 \le 6rs$: as $s \ge 20n+20$, $6rs-4r^2 = r(2s-20n-20) \ge s^2$, and with $r,k \le 2s$ and $s \ge 10^{10}n^4$, $7\cdot 10^9 n^5 + 168nk + 6\cdot 10^8 n^4 r + 12 \le 7\cdot 10^9 n^5 + 336ns + 12\cdot 10^8 n^4 s + 12 \le s^2$. So this part is at most $b^{-12}/\deg$.

Step 5. By (DN0)(a), $\kappa_0 = 1$, Steps 3 and 4, and with $x = b^{-12}$, $(1+x)^2 + x = 1 + (3+x)b^{-2}b^{-10} \le 1 + b^{-10}$ (as $b \ge 2$),

$$|c_F \mathcal{F}_0(p,q;W^\flat,1)| \le c_F \int_G \mathrm{FN}_0\, d\theta \le \frac{(1+b^{-12})^2 + b^{-12}}{\deg} \le \frac{1+b^{-10}}{\deg}.$$

□

Lemma 5.5.35. *Let ρ, b, s be real-place sizes, consider the data at $\mathbb{C}$ with box radius ρ, and let $(W, W^\flat)$ be a cut pair for b, f whose type is an irreducible unitary representation of $\mathrm{U}(k)$ on $\mathbb{C}^I$, I nonempty. For $T > 0$ let $B(T) = \{x \in G : |(x-1)_{ac}| \le T^{99n} \text{ for all } a, c\}$. Let $L \ge \rho$, $j \le \varrho$, p, q heads of length j for Γ_L and $t \ge 1$. Then*

$$c_F \,\mathrm{hdn}_j(p,q) \int_{G\setminus B(tL^{11n})} \mathrm{FM}_j(p,q,W^\flat,x)\, d\theta(x) \le \Theta\, L^{10^9 n^4} \rho^{24k}\, \frac{t^{10^8 n^4}}{t^s}.$$

Proof. Put $T = tL^{11n}$; $B(T)$ is closed, hence Borel. Let $\phi = \mathbf{1}_{G\setminus B(T)} \mathrm{FM}_j(p,q,W^\flat,\cdot)$, so $\phi \le \mathrm{FM}_j(p,q,W^\flat,\cdot)$. Let V be as in Lemma 5.5.4; by (i) there, $V \ge 1$ and $\mathrm{FML}_j(V;1)$. Suppose $t > 1$ and let $x \in G$. If $x \in B(T)$, $\phi(x) = 0$. Otherwise some entry of $x-1$ has modulus above T^{99n}, with $T \ge L^{11n}$ and $T^{-1} = t^{-1}L^{-11n} \le t^{-1}/2$ (as $L \ge \rho \ge 8$). By Lemma 5.5.9, $W^\flat$ is cut for the data at $\mathbb{C}$, so Lemma 5.5.25, (ii), with $\tau = t^{-1}$ shows that $(j,p,q,W^\flat)$ has a deep vector after the head of depth at least $t^2 = \sigma^{-1}$ at x, $\sigma = t^{-2}$. By (DN3)(c) of Theorem 5.4.1 (for Γ_L; $x \in \mathcal{P}_{\mathrm{pos}}$, p a head of length j, $V \ge 1$),

$$\phi(x)^2 = \mathrm{FM}_j(p,q,W^\flat,x)^2 \le \sigma^s V^2 \,\mathrm{WSP}_j(p,q,W^\flat,x) = (V/t^s)^2 \,\mathrm{WSP}_j(p,q,W^\flat,x).$$

So ϕ satisfies the hypotheses of Lemma 5.5.4, (ii), which gives

$$\#I\, c_F \,\mathrm{hdn}_j(p,q) \int \phi\, d\theta \le \Theta L^{10^9 n^4} \rho^{24k} t^{10^8 n^4}/t^s;$$

as $\#I \ge 1$ the claim follows. □

Lemma 5.5.36. *Let F be a large lattice datum over a finite place A with level unit M, ϱ pairs, $n = \varrho + 1$ and middle coordinates x_i, $i \in \{1,\dots,k\}$; let Z be an intermediate group, $j \le \varrho$, and $r \ge 0$ an integer with $r + 10^8 n^4 \le k$. Let α be a unit of A with $\alpha \in \mathcal{O}_A$ and $\bar\alpha = \alpha$, Γ the gauge of scale α and $\Lambda = 2/|\alpha|$ its loss. Let p, q be heads of length j for Γ, and if $j \ne 0$ let M^{-1} have size 1 for Γ. Let $f\colon G \to [0,\infty]$ satisfy $f \le \mathrm{FM}_j(p,q,W_Z,\cdot)$, and let $e \in [0,\infty]$ be such that, if $e < 1$, then $f(x)^2 \le (e^s)^2 \,\mathrm{WSP}_j(p,q,W_Z,x)$ for every $x \in \mathcal{P}_{\mathrm{pos}}$ (with WSP_j formed for Γ). Then*

$$\mathrm{hdn}_j(p,q) \int_G f\, d\theta \le \min(1,e)^r \,\mathrm{mr}(Z)\, \Lambda^{10^9 n^4}.$$

Proof. Write $W = W_Z$. As $\alpha \in \mathcal{O}_A$, $\Lambda = 2/|\alpha| \ge 2$.

Step 1: the rank condition. From the shape, $s = k - 7m - 3n - 13 \ge k - 66n - 6$, as $m \le 9n-1$; with $k \ge r + 10^8 n^4$ this gives $s \ge r + 9\cdot 10^7 n^4$, since $10^7 n^4 \ge 66n + 6$. In particular $s \ge 1$.

Step 2: support and shells. If $f(x) \neq 0$, then $\mathrm{FM}_j(p,q,W,x) \neq 0$, so x is a position by Lemma 5.5.40. By Lemma 5.5.37 the sets S_t ($t \geq 0$) of that lemma cover the positions, hence the support of f, and each S_t is a shell of height 2^t for (Γ, j, p, q, W).

Step 3: the floor mass. The sizes of scale 1 form a gauge of loss 2 with $A_{(11)} = \mathcal{O}_A$ of volume 1 (Lemma 5.2.51), so by Lemma 5.4.3 (ii) the bound $\mathrm{FML}_j(V;1)$ holds with $V = 2^{1287n} \geq 1$ (this bound reads no gauge).

Step 4: the shell sum. If $e = 0$, the hypothesis gives $f(x)^2 \leq 0$ on the positions ($s \geq 1$), so $f = 0$ by Step 2 and the claim holds. Let $e > 0$. If $e < 1$, then for every position x, $f(x)^2 \leq (e^s)^2 \mathrm{WSP}_j(p,q,W,x) \leq (Ve^s)^2 \mathrm{WSP}_j(p,q,W,x)$. The group measure θ is a Haar measure of G (Lemma 5.5.41 (1)). So (DN2) of Theorem 5.4.1, for the gauge Γ, the heads p, q of length j, the cut function W, the shells S_t of Step 2, $\phi = f \leq \mathrm{FM}_j(p,q,W,\cdot)$, V, e and the integer r with $9 \cdot 10^7 n^4 + r \leq s$ (Step 1), gives

$$\mathrm{hdn}_j(p,q) \int_G f \, d\theta \leq V \min(1,e)^r \, \Lambda^{4 \cdot 10^8 n^4} \, \mathrm{SN}(W).$$

Step 5. By Lemma 5.5.39, $\mathrm{SN}(W) \leq \mathrm{mr}(Z)$, and $V = 2^{1287n} \leq \Lambda^{1287n}$. As $1287n + 4 \cdot 10^8 n^4 \leq 10^9 n^4$ and $\Lambda \geq 1$,

$$\mathrm{hdn}_j(p,q) \int_G f \, d\theta \leq \min(1,e)^r \, \mathrm{mr}(Z) \, \Lambda^{10^9 n^4}.$$

□

Lemma 5.5.37. *Let F be a large lattice datum over a finite place A with level unit M, ϱ pairs and $n = \varrho + 1$, and let Z be an intermediate group. For $x \in G$ the set $I(x) = \{\varepsilon \in \mathcal{O}_A : \varepsilon M^{-1}(x-1)$ has entries in $\mathcal{O}_A\}$ is an ideal of finite index of $\mathcal{O}_A$; for $t \geq 0$ let S_t be the set of positions x for which t is the least integer $t' \geq 0$ with $[\mathcal{O}_A : I(x)] \leq 2^{t'}$. Let $\alpha \in \mathcal{O}_A$ be a unit with $\bar{\alpha} = \alpha$, Γ the gauge of scale α, $j \leq \varrho$, p, q heads of length j for Γ, and if $j \neq 0$ let M^{-1} have size 1 for Γ. Then the sets S_t ($t \geq 0$) cover $\mathcal{P}_{\mathrm{pos}}$, and each S_t is a shell of height 2^t for (Γ, j, p, q, W_Z).*

Proof. Let $\Lambda = 2/|\alpha| \geq 2$ be the loss of Γ. Componentwise, $I(x)$ is the set of ε with $v_i(\varepsilon_i) \geq \max(0, -\min v_i(\mathrm{entries}_i))$, so $I(x) = c_x \mathcal{O}_A$ for a unit $c_x \in \mathcal{O}_A$, of index $|c_x|^{-1} < \infty$. Hence each position lies in exactly one S_t. Fix t and put $\Delta = 2^t$; (SH1) holds. For $x \in S_t$, $[\mathcal{O}_A : I(x)] \leq \Delta \leq 2[\mathcal{O}_A : I(x)]$ (if $t \geq 1$, minimality gives $[\mathcal{O}_A : I(x)] > 2^{t-1}$; if $t = 0$, $\Delta = 1$).

(SH2). As $\zeta_{\mathcal{O}_A}(m) \geq 1$ and $\zeta_{\mathcal{O}_A}(m)^n \leq 2$, $\zeta_{\mathcal{O}_A}(m) \leq 2$; each ideal I with $[\mathcal{O}_A : I] \leq \Delta$ contributes at least Δ^{-m} to $\zeta_{\mathcal{O}_A}(m)$, so there are at most $2\Delta^m \leq 2\Delta^{9n}$ of them. For each such $I = c\mathcal{O}_A$ ($c \in \mathcal{O}_A$ a unit) let Γ_I be the gauge of scale $\bar{c}c$ (Lemma 5.2.51), of loss $2/|\bar{c}c| = 2[\mathcal{O}_A : I]^2 \leq \Lambda\Delta^2$. If $x \in S_t$ and $I = I(x)$, then $c \in I(x)$, so $cM^{-1}(x-1)$ is integral and $\bar{c}c\, M^{-1}(x-1)$ is integral: x is a position of size Γ_I. So S_t is covered by the positions of size Γ_I for the at most $2\Delta^{9n}$ ideals I of index at most Δ.

(SH3). Let $x \in S_t$ and $\sigma \in [0,1)$ with $\Lambda^{1200n^2} \leq \sigma^{400n^2}\Delta$. The unit $c = c_x$ satisfies the hypothesis of Lemma 5.5.38 (iii): if $\varepsilon \in \mathcal{O}_A$ and $\varepsilon M^{-1}(x-1)$ is integral, then $\varepsilon \in c\mathcal{O}_A$. Moreover, with $\Delta \leq 2|c|^{-1}$ and $\Lambda^{210n^2} \geq 2$,

$$|c| \, \Lambda^{990n^2} \leq \tfrac{1}{2}|c| \, \Lambda^{1200n^2} \leq \tfrac{1}{2}|c| \, \sigma^{400n^2}\Delta \leq \sigma^{400n^2}.$$

So by Lemma 5.5.38 (iii), (j, p, q, W_Z) has a deep vector after the head of depth at least $(\sigma^2)^{-1}$ at x. □

Lemma 5.5.38. *Let F be a large lattice datum over a finite place A with level unit M, ϱ pairs and $n = \varrho + 1$, and let Z be an intermediate group.*

(i) *For $x, y \in G$ and $a < \varrho$ there is a unit c of A with $\mathfrak{d}_a(x,y) = c\mathcal{O}_A$. If x is near at $a+1$, then $c \in \mathcal{O}_A$ and $\mathrm{dp}_a(x,y) = [\mathcal{O}_A : c\mathcal{O}_A] = |c|^{-1}$.*

(ii) *If $x, z \in G$ and $\langle W_Z(x), W_Z(z)\rangle \neq 0$, there are $u, v \in \mathsf{U}$ with $ux \in \mathrm{K}(1)$ and $(ux)^{-1}vz \in \mathrm{K}(M)$; in particular x and z are near at every $l \leq \varrho$.*

(iii) *Let $\alpha \in \mathcal{O}_A$ be a unit with $\bar{\alpha} = \alpha$, Γ the gauge of scale α, $\Lambda = 2/|\alpha|$, $j \leq \varrho$, p, q heads of length j for Γ, and if $j \neq 0$ let M^{-1} have size 1 for Γ. Let $x \in G$ and let $c \in \mathcal{O}_A$ be a unit such that $c^{-1}\varepsilon \in \mathcal{O}_A$ for every $\varepsilon \in \mathcal{O}_A$ for which $\varepsilon M^{-1}(x-1)$ has entries in $\mathcal{O}_A$. If $\sigma \in [0,1)$ and $|c|\,\Lambda^{990n^2} \leq \sigma^{400n^2}$, then (j,p,q,W_Z) has a deep vector after the head of depth at least σ^{-2} at x.*

(iv) *Let $e \in [0,\infty]$ satisfy $|c| \leq e$ for every unit $c \in \mathcal{O}_A$ with $c^{-1} \notin \mathcal{O}_A$. If $x \in G \setminus \mathrm{K}(M)$, then $(0,1,1,W_Z)$ has a deep vector after the head of depth at least e^{-1} at x.*

Proof. **(i).** Let L be the set of the pairs $(\omega, d) \in V \times \mathrm{span}\{e_b : b < a\}$ with $h(e_b, \omega) = 0$ for $b < a$, $x^{-1}\omega$ integral and $M^{-1}(x^{-1}\omega - (xy)^{-1}(\omega + d))$ integral. As h is linear in its second argument, L is an $\mathcal{O}_A$-module, and $\mathfrak{d}_a(x,y)$ is its image under the $\mathcal{O}_A$-linear map $(\omega, d) \mapsto h(e_a, \omega)$; so $\mathfrak{d}_a(x,y)$ is an $\mathcal{O}_A$-submodule of A. Choose units $c_0 \in \mathcal{O}_A$ and c_1 such that $c_0 x^{-1}$ and $c_0 M^{-1}(x^{-1} - (xy)^{-1})$ are integral and the entries of x lie in $c_1\mathcal{O}_A$. For $t \in c_0\mathcal{O}_A$ the pair $(te_a^*, 0)$ lies in L, so $c_0\mathcal{O}_A \subseteq \mathfrak{d}_a(x,y)$; for $(\omega, d) \in L$, $\omega = x(x^{-1}\omega)$ has entries in $c_1\mathcal{O}_A$, so $\mathfrak{d}_a(x,y) \subseteq c_1\mathcal{O}_A$. An $\mathcal{O}_A$-submodule N of A is the product of the $\mathcal{O}_{K_i}$-submodules $\epsilon_i N$ (ϵ_i the idempotents), and an $\mathcal{O}_{K_i}$-submodule of K_i between two nonzero fractional ideals is a fractional ideal, the discrete valuation ring $\mathcal{O}_{K_i}$ having totally ordered ideals. Hence $\mathfrak{d}_a(x,y) = c\mathcal{O}_A$ for a unit c.

Let x be near at $a+1$: $\xi x \in K = \mathrm{K}(1)$ for some $\xi \in R^{(a+1)}$. For $(\omega, d) \in L$, $\xi\omega = (\xi x)(x^{-1}\omega)$ is integral, so $h(e_a, \xi\omega) \in \mathcal{O}_A$. As ξ is an isometry, $h(e_a, \xi\omega) = h(\xi^{-1}e_a, \omega)$, and $\xi^{-1} \in R^{(a+1)}$ gives $\xi^{-1}e_a - e_a \in \mathrm{span}\{e_b : b < a\}$, orthogonal to ω; so $h(e_a, \omega) = h(e_a, \xi\omega) \in \mathcal{O}_A$. Thus $c\mathcal{O}_A \subseteq \mathcal{O}_A$, $c \in \mathcal{O}_A$, and $\mathrm{dp}_a(x,y) = \mathrm{vol}(c\mathcal{O}_A)^{-1} = |c|^{-1} = [c] = [\mathcal{O}_A : c\mathcal{O}_A]$.

(ii). $\langle W_Z(x), W_Z(z)\rangle = \sum_c \overline{\chi_M(xc^{-1})}\chi_M(zc^{-1})$ over the chosen representatives c of $\mathrm{Cos}(Z)$, so for some c both $\chi_M(xc^{-1})$ and $\chi_M(zc^{-1})$ are nonzero: there are $u', v' \in \mathsf{U}$ with $k_1 = u'^{-1}xc^{-1}$ and $k_2 = v'^{-1}zc^{-1}$ in $\mathrm{K}(M)$. Put $u = u'^{-1}$, $v = v'^{-1}$. Then $ux = k_1 c \in \mathrm{K}(1)$, as $c \in Z \leq \mathrm{K}(1)$ and $\mathrm{K}(M) \leq \mathrm{K}(1)$, and $(ux)^{-1}vz = c^{-1}k_1^{-1}k_2 c \in \mathrm{K}(M)$, as $\mathrm{K}(1)$ normalises $\mathrm{K}(M)$ (Lemma 5.5.44 (a)). Then $vz = ux \cdot (ux)^{-1}vz \in \mathrm{K}(1)$. For $l \leq \varrho$ and $b < l$, an element of U maps e_b to e_b plus coordinate vectors of level below b, i.e. the e_c, $c < b$; so $\mathsf{U} \subseteq R^{(l)}$, and x, z are near at l.

(iii). Suppose y is active at x for (j,p,q,W_Z) and $\mathrm{dp}_a(y,x) < \sigma^{-2}$ for every a with $j \leq a < \varrho$; we derive a contradiction. By (AC1) and (ii), y is near at every $a+1 \leq \varrho$, so by (i) $\mathfrak{d}_a(y,x) = d_a\mathcal{O}_A$ with units $d_a \in \mathcal{O}_A$ and $|d_a| = \mathrm{dp}_a(y,x)^{-1} > \sigma^2$. Put $C = \prod_{j \leq a < \varrho} d_a\bar{d}_a$, a unit in $\mathcal{O}_A$ with $\bar{C} = C$, $Cd_a^{-1} \in \mathcal{O}_A$ and, by (PA2), $|C| = \prod_a |d_a|^2 \geq \sigma^{4(\varrho - j)} \geq \sigma^{4n}$. Let Γ' be the gauge of scale $\alpha' = \alpha^{10n}C$ (Lemma 5.2.51). Then the elements of size $10n$ for Γ have size 1 for Γ' ($\alpha^{10n}b \in \mathcal{O}_A$ implies $\alpha' b \in \mathcal{O}_A$), and d_a^{-1} has size 1 for Γ' ($\alpha' d_a^{-1} = \alpha^{10n}Cd_a^{-1}$). By (ii) applied to $\langle W_Z(y), W_Z(yx)\rangle \neq 0$ there are $u, v \in \mathsf{U}$ with $uy \in K$ and $(uy)^{-1}vyx \in \mathrm{K}(M)$, so $vyx \in K$ and $M^{-1}(vyx - uy) = uy \cdot M^{-1}((uy)^{-1}vyx - 1)$ is integral, hence of size 2 for Γ'. By (AC2), (AC3), $w_{j,p}^{-1}y$ and $w_{j,q}^{-1}yx$ are near at j. Hence (DN4) of Theorem 5.4.1, for the gauge Γ' with second gauge $S = \Gamma$, the point y and the element x, shows that $M^{-1}(x-1)$ has size $99n$ for Γ': $\varepsilon = \alpha'^{99n} \in \mathcal{O}_A$ has $\varepsilon M^{-1}(x-1)$ integral. By hypothesis $c^{-1}\alpha'^{99n} \in \mathcal{O}_A$, so $|\alpha|^{990n^2}|C|^{99n} \leq |c|$. With $|\alpha| = 2/\Lambda \geq \Lambda^{-1}$ and $|C| \geq \sigma^{4n}$,

$$\Lambda^{-990n^2}\sigma^{396n^2} \leq |c| \leq \sigma^{400n^2}\Lambda^{-990n^2}.$$

Here $\sigma > 0$, since $|c| > 0$; so $\sigma^{396n^2} \le \sigma^{400n^2}$ contradicts $0 < \sigma < 1$.

(iv). Let y be active at x for $(0, 1, 1, W_Z)$ and suppose $\mathrm{dp}_a(y, x) < e^{-1}$ for every $a < \varrho$. As in (iii), $\mathfrak{d}_a(y, x) = d_a \mathcal{O}_A$ with units $d_a \in \mathcal{O}_A$ and $|d_a| = \mathrm{dp}_a(y, x)^{-1} > e$; by the hypothesis on e, $d_a^{-1} \in \mathcal{O}_A$. Let Γ_1 be the gauge of scale 1 (all sizes mean integral). The constant sequence 1 is a head of length 0, and d_a^{-1} has size 1. With u, v from (ii) as in (iii), (DN4) of Theorem 5.4.1 with $j = 0$ and $\Gamma = S = \Gamma_1$ gives that $M^{-1}(x - 1)$ is integral. Then $x = 1 + M \cdot M^{-1}(x - 1)$ is integral, and so is $x^{-1} = J^{-1} \bar{x}^{\mathsf{T}} J$; hence $x \in \mathrm{K}(M)$, a contradiction. So every active point has $a < \varrho$ with $\mathrm{dp}_a(y, x) \ge e^{-1}$. □

Lemma 5.5.39. *Let F be a large lattice datum over a finite place A and Z an intermediate group. Then $\mathrm{SN}(W_Z) \le \mathrm{mr}(Z)$.*

Proof. Write $W = W_Z$, $\eta = \eta_0 * \cdots * \eta_{\varrho+1}$, and recall $0 < \mathrm{fl} < \infty$. By Lemma 5.2.59 (iv) with $j = \varrho + 2$, $\theta = \eta * \theta_{\ge 0}$. By Lemma 5.5.41 (1) θ is a Haar measure of G; as G is unimodular, θ is also right invariant.

Step 1: $\mathrm{fl}\,\|W(y)\|^2 = \eta(\{u : uy \in Z\}) \le 1$ for $y \in G$. By Lemma 5.5.44 (c), Z is the finite disjoint union of the cosets $\mathrm{K}(M)c$, c the chosen representatives. For each c, Lemma 5.5.43 (level M, $\theta' = \delta_1$, $w = yc^{-1}$) gives $\eta(\{u : uyc^{-1} \in \mathrm{K}(M)\}) = \mathrm{fl}$ if $u' yc^{-1} \in \mathrm{K}(M)$ for some $u' \in \mathsf{U}$, and 0 otherwise; the first case is exactly $\chi_M(yc^{-1}) \ne 0$, i.e. $|\chi_M(yc^{-1})|^2 = 1$. Summing over c gives the identity. Since $Z \le \mathrm{K}(1)$, $\eta(\{u : uy \in Z\}) \le \eta(\{u : uy \in \mathrm{K}(1)\}) \le 1$ by Lemma 5.5.43 at level 1 (with $\theta' = \delta_1$, $w = y$).

Step 2: $\mathrm{fl} \int \|W\|^2 \, d\theta_{\ge 0} = \theta(Z)$. By Step 1 and Tonelli,

$$\mathrm{fl} \int \|W(x)\|^2 \, d\theta_{\ge 0}(x) = \int \eta(\{u : ux \in Z\}) \, d\theta_{\ge 0}(x) = (\eta * \theta_{\ge 0})(Z) = \theta(Z).$$

Step 3: the inner integral. Let $x \in G$ with $W(x) \ne 0$. By Lemma 5.5.44 (c) there is $u_0 \in \mathsf{U}$ with $u_0 x \in \mathrm{K}(1)$; put $w = (u_0 x)^{-1}$ and $S = \{y : vyw \in \mathrm{K}(M) \text{ for some } v \in \mathsf{U}\}$, an open set. If $\langle W(x), W(y) \rangle \ne 0$, then by Lemma 5.5.38 (ii) there are $u, v \in \mathsf{U}$ with $ux \in \mathrm{K}(1)$ and $k = (ux)^{-1} vy \in \mathrm{K}(M)$, and

$$u_0 u^{-1} v \, y \, w = u_0 u^{-1} (ux) k \, (u_0 x)^{-1} = (u_0 x) \, k \, (u_0 x)^{-1} \in \mathrm{K}(M),$$

as $\mathrm{K}(1)$ normalises $\mathrm{K}(M)$ (Lemma 5.5.44 (a)); so $y \in S$. By Cauchy–Schwarz and Step 1, $|\langle W(x), W(y) \rangle|^2 \le \|W(x)\|^2 \|W(y)\|^2 \le \|W(x)\|^2 \mathrm{fl}^{-1}$. By Lemma 5.5.43 (level M, $\theta' = \theta_{\ge 0}$, the element w) and right invariance,

$$\mathrm{fl}\, \theta_{\ge 0}(S) = (\eta * \theta_{\ge 0})(\{y : yw \in \mathrm{K}(M)\}) = \theta(\mathrm{K}(M) w^{-1}) = \theta(\mathrm{K}(M)).$$

Hence $\int |\langle W(x), W(y) \rangle|^2 \, d\theta_{\ge 0}(y) \le \|W(x)\|^2 \mathrm{fl}^{-1} \theta_{\ge 0}(S) = \|W(x)\|^2 \mathrm{fl}^{-2} \theta(\mathrm{K}(M))$; for $W(x) = 0$ both sides vanish.

Step 4. Integrating Step 3 over x and using Step 2,

$$\mathrm{SN}(W) = \mathrm{fl}\, \mathrm{PN}(W) \le \mathrm{fl} \cdot \mathrm{fl}^{-2} \theta(\mathrm{K}(M)) \int \|W\|^2 \, d\theta_{\ge 0} = \theta(Z) \, \theta(\mathrm{K}(M)) \, \mathrm{fl}^{-2} = \mathrm{mr}(Z).$$

□

Lemma 5.5.40. *Let F be a large lattice datum over a finite place A with level unit M and ϱ pairs, Z an intermediate group, $j \le \varrho$, $K \ge 0$ an integer, and p, q sequences of units of A. For a sequence r of units put $\mathrm{hw}_{K,j}(r) = \prod_{l<j} [r_0 \cdots r_l]^{K/2}$ if $r_0 \cdots r_l \in \mathcal{O}_A$ for every $l < j$, and $\mathrm{hw}_{K,j}(r) = 0$ otherwise. Suppose $\mathrm{FM}_j(p, q, W_Z, x) \ne 0$ for some $x \in G$. Then x is a position, $p_0 \cdots p_{l-1}$ and $q_0 \cdots q_{l-1}$ lie in $\mathcal{O}_A$ for every $l \le j$, and there is a unit α of A with $\alpha \in \mathcal{O}_A$ and $\bar{\alpha} = \alpha$ such that, for the gauge Γ of scale α and its loss $\Lambda = 2/|\alpha|$:*

(i) p and q are heads of length j for Γ;

(ii) if $j \neq 0$, M^{-1} has size 1; and $p_i^{-1} - q_i^{-1}$ has size 1 for every $i < j$;

(iii) $\Lambda^E \leq (2/|M|)^K \operatorname{hw}_{K,j}(p) \operatorname{hw}_{K,j}(q)$ for every integer $E \geq 0$ with $4E \leq K$.

Proof. Write $W = W_Z$, $w_p = w_{j,p}$, $w_q = w_{j,q}$ and $d = w_q^{-1} w_p$.

Step 1: support of the measures, and d commutes with $G^{(j)}$. The floor measure θ_l is concentrated on $G^{(l)}$: for $l < \varrho$ it is an image of a measure under $(c, v, \beta) \mapsto w_l(c)^{-1} n_l(v, \beta)$, and both factors fix the coordinate vectors e_b, e_b^* ($b < l$) of floor below l; for $l = \varrho$ by (PE2); for $l = \varrho + 1$ by (PE3); for $l \geq \varrho + 2$ it is δ_1. As the $G^{(l)}$ decrease in l, $\theta_{\geq j+1}$ is concentrated on $G^{(j+1)} \subseteq G^{(j)}$. The element d maps $e_a \mapsto p_a q_a^{-1} e_a$ and $e_a^* \mapsto \bar{p}_a^{-1} \bar{q}_a e_a^*$ for $a < j$ and fixes the other coordinate vectors. An element $\sigma \in G^{(j)}$ fixes the e_a, e_a^* ($a < j$) and hence preserves their orthogonal complement, the span of the coordinate vectors of floor at least j, on which d is the identity; so $d\sigma = \sigma d$.

Step 2: four near points. Let $x \in G$ with $\mathrm{FM}_j(p, q, W, x) \neq 0$. The integrand of FM_j is nonnegative, so there is $g \in G$ with $\mathrm{piv}_j(\mathcal{K}_W)(g, gx) \neq 0$ and $\mathrm{piv}_j(\mathcal{K}_W^d)(w_p^{-1} g, w_p^{-1} gx) \neq 0$. If $\mathrm{piv}_j(\mathcal{K})(g', y') = \int |\mathcal{K}_{j+1}(\xi g', \xi y')| \, d\theta_j(\xi) \neq 0$, then by Step 1 there is $\xi \in G^{(j)}$ with $\mathcal{K}_{j+1}(\xi g', \xi y') = \int \mathcal{K}(x' \xi g', x' \xi y') \, d\theta_{\geq j+1}(x') \neq 0$, and then $x' \in G^{(j)}$ with $\mathcal{K}(x' \xi g', x' \xi y') \neq 0$. So there are $\sigma, \sigma' \in G^{(j)}$ with

$$\langle W(\sigma g), W(\sigma g x) \rangle \neq 0, \qquad \langle W(\sigma' w_p^{-1} g), W(d \sigma' w_p^{-1} g x) \rangle \neq 0,$$

and $d\sigma' w_p^{-1} = \sigma' w_q^{-1}$ by Step 1. Hence W does not vanish at σg, $\sigma g x$, $\sigma' w_p^{-1} g$ and $\sigma' w_q^{-1} g x$. As W is cut (Lemma 5.5.44 (c)), for each of these points $z = \rho z_0$ ($\rho \in \{\sigma, \sigma'\}$) there is $u \in \mathsf{U}$ with $u \rho z_0 \in K$. Now $u\rho \in R^{(j)}$: for $b < j$, $\rho e_b = e_b$ and $u e_b - e_b$ is a combination of coordinate vectors of level below b, i.e. of the e_a, $a < b$, which is the defining condition of $R^{(j)}$ on the columns e_b, $b < j$. So g, gx, $w_p^{-1} g$ and $w_q^{-1} gx$ are near at j. Moreover, by Lemma 5.5.38 (ii) for $\langle W(\sigma g), W(\sigma g x) \rangle \neq 0$ there are $u_1, v_1 \in \mathsf{U}$ with $u_1 \sigma g \in \mathrm{K}(1)$ and $k_1 = (u_1 \sigma g)^{-1} v_1 \sigma g x \in \mathrm{K}(M)$; with $y_1 = \sigma g$ this reads $x = y_1^{-1} (v_1^{-1} u_1) y_1 \, k_1$, so x is a position (Definition 5.2.2).

Step 3: the head products are integral. The sizes of scale 1 ($A_{(i)} = \mathcal{O}_A$ for all i) form a gauge of F (Lemma 5.2.51 with $\alpha = 1$). By Lemma 5.4.13 (ii) for this gauge, applied to $\gamma = w_p$, $y = g$ and to $\gamma = w_q$, $y = gx$, and by Lemma 5.4.13 (iii),

$$p_0 \cdots p_{l-1} = D_l(w_p) \in \mathcal{O}_A, \qquad q_0 \cdots q_{l-1} = D_l(w_q) \in \mathcal{O}_A \qquad (0 \leq l \leq j),$$

as $j \leq \min(j, n)$. This is the first assertion.

Step 4: the scale. Put $P_l = p_0 \cdots p_{l-1}$, $P_l' = q_0 \cdots q_{l-1}$, $\beta = \prod_{l=1}^{j} P_l$, $\gamma = \prod_{l=1}^{j} P_l'$ and $\alpha = M \, \overline{\beta\gamma} \, \beta\gamma$. These are units in $\mathcal{O}_A$ (Step 3, and $\mathcal{O}_A$ is stable under the involution), and $\bar{\alpha} = \alpha$ as $\bar{M} = M$. Let Γ be the gauge of scale α (Lemma 5.2.51); size 1 means $\alpha x \in \mathcal{O}_A$.

(i) For $1 \leq l \leq j$, $\alpha P_l^{-1} = M \, \overline{\beta\gamma} \, \gamma \prod_{l' \neq l} P_{l'} \in \mathcal{O}_A$, so P_l^{-1} has size 1; $P_0 = 1$ has size 1. Hence p is a head of length j, and likewise q.

(ii) $\alpha M^{-1} = \overline{\beta\gamma} \, \beta\gamma \in \mathcal{O}_A$, so M^{-1} has size 1. For $i < j$, $p_i^{-1} = P_i P_{i+1}^{-1}$, so $\alpha p_i^{-1} = (\alpha P_{i+1}^{-1}) P_i \in \mathcal{O}_A$ by (i) and Step 3; likewise $\alpha q_i^{-1} \in \mathcal{O}_A$, and $\alpha(p_i^{-1} - q_i^{-1}) \in \mathcal{O}_A$.

(iii) By (PA2) and multiplicativity, $|\alpha| = |M| \, (|\beta||\gamma|)^2$, and $|\beta|, |\gamma|, |M| \leq 1$. Since all P_l are integral, $\operatorname{hw}_{K,j}(p) = \prod_{l<j} [P_{l+1}]^{K/2} = [\beta]^{K/2} = |\beta|^{-K/2}$, and $\operatorname{hw}_{K,j}(q) = |\gamma|^{-K/2}$. For $4E \leq K$, using $2/|M| \geq 1$ and $(|\beta||\gamma|)^{-1} \geq 1$,

$$\Lambda^E = \Big(\frac{2}{|M|}\Big)^E (|\beta||\gamma|)^{-2E} \leq \Big(\frac{2}{|M|}\Big)^K (|\beta||\gamma|)^{-K/2} = \Big(\frac{2}{|M|}\Big)^K \operatorname{hw}_{K,j}(p) \operatorname{hw}_{K,j}(q).$$

□

Lemma 5.5.41. *Let F be a large lattice datum over a finite place A, with group measure θ on the unitary group G.*

1. *θ is a Haar measure on G.*
2. *$\theta(\mathrm{K}(1)) \le 1 + 2^{-n}$.*

Proof. Let the shape be $(\varrho, \iota, m+1)$, so that $k+1 = |\iota| + 2m + 4 \ge 2m+4$.

Step 1: floor masses. Let $0 \le b \le \varrho$ and let S_b be the set of coordinate indices of floor at least b; identify V_b with A^{S_b}, so that vol_{V_b} is the Haar measure of A^{S_b} and $h(v,v) = \bar{v}^{\mathsf{T}} J_b v$ with J_b the $S_b \times S_b$ block of J. Since J pairs e_a with e_a^* (both of floor a) and the middle indices among themselves, J is block diagonal for S_b and its complement, so J_b and $J_b^{-1} = (J^{-1})_b$ are integral and hermitian. By Lemma 5.2.52 (ii), $(\mathrm{qv}_b(\beta))_\beta$ is a disintegration of vol_{V_b} along h, and $|S_b| \ge k+1 \ge 2m+1$; so Lemma 5.2.54 with $\mu = m$, $g = 1$, $x_0 = 0$ and $\beta = \delta h(f_b, f_b)$ gives $\mathrm{qv}_b(\mathcal{O}_A^{S_b}) \le \zeta_{\mathcal{O}_A}(m)$. The compact set $C_b = \{P_b(\kappa\kappa'^{-1} f_b) : \kappa, \kappa' \in K\}$ of Lemma 5.2.60 consists of integral vectors of V_b, as $\kappa\kappa'^{-1} \in \mathrm{K}(1)$ has integral entries. Hence, by Lemma 5.2.60 (iii), $\mathrm{FML}_b(\zeta_{\mathcal{O}_A}(m); 1)$ for every $b \le \varrho$.

Step 2: (2). By Lemma 5.2.59 (iv) with $j = \varrho+2$, $\theta = \eta_{<\varrho+2} * \theta_{\ge 0}$ with $\eta_{<\varrho+2} = \eta_0 * \cdots * \eta_{\varrho+1}$. By Lemma 5.5.43 at level 1 (factor 1), with $\theta' = \theta_{\ge 0}$ and $w = 1$,

$$\theta(\mathrm{K}(1)) = \theta_{\ge 0}\big(\{y \in G : uy \in \mathrm{K}(1) \text{ for some } u \in \mathsf{U}\}\big).$$

For $l = \varrho + 2$ the defining condition of $R^{(l)}$ is that of U, so $R^{(\varrho+2)} = \mathsf{U}$ and this is the set of the y near at $\varrho + 2$. By Step 1 and Lemma 5.2.60 (iv) with $l = 0$, $c = 1$,

$$\theta(\mathrm{K}(1)) \le \zeta_{\mathcal{O}_A}(m)^{\varrho+1} = \zeta_{\mathcal{O}_A}(m)^n \le 1 + 2^{-n}.$$

Step 3: (1). $\mathrm{K}(1)$ is an open subgroup of G (integral matrices form an open set and inversion is continuous) and compact (a closed set of integral matrices). By Lemma 5.2.61 (iii), (iv), θ is right invariant and nonzero. A compact subset of G is covered by finitely many right cosets $\mathrm{K}(1)g$, each of θ-measure $\theta(\mathrm{K}(1)) < \infty$ by Step 2 and right invariance; so θ is finite on compact sets. As G is a second countable locally compact group, θ is then a right Haar measure, and by uniqueness $\theta = d\,\nu$ for the left Haar measure ν that is right invariant (unimodularity) and some $d \in (0, \infty)$, $d \ne 0$ because $\theta \ne 0$. Hence θ is a Haar measure of G. □

Lemma 5.5.42. *Let F be a large lattice datum over a finite place A, with level unit M and group measure* vol*, and let Z be an intermediate group. Let $Q \ge 2$ be a real number with $|c| \le Q^{-1}$ for every unit c of A such that $c \in \mathcal{O}_A$ and $c^{-1} \notin \mathcal{O}_A$, and let $t \ge 0$ be an integer with $t + 2 \cdot 10^9 n^4 \le k$. Then*

$$\mathrm{mi}(Z) \le \mathrm{vol}(Z)\,\mathrm{vol}(\mathrm{K}(M))\,\big(\mathrm{vol}(Z) + Q^{-t}\big).$$

Proof. Write $W = W_Z$ and, for $x \in G$, $I(x) = \int_Z \chi_M(yxy^{-1})\,d\mathrm{vol}(y)$, so that $\mathrm{mi}(Z) = \int_G |I|^2\,d\mathrm{vol}$. As $\mathrm{K}(M)$ is open (Lemma 5.5.44 (a)),

$$\mathrm{mi}(Z) = \int_{\mathrm{K}(M)} |I|^2\,d\mathrm{vol} + \int_{G \setminus \mathrm{K}(M)} |I|^2\,d\mathrm{vol},$$

and the first term is $\mathrm{vol}(Z)^2 \mathrm{vol}(\mathrm{K}(M))$ by Lemma 5.5.44 (e).

The integrand off $\mathrm{K}(M)$**.** By Lemma 5.2.90, $|I(x)| = |\mathcal{K}_{W,0}(1,x)|\,\mathrm{fl}$. If $x' \mapsto \mathcal{K}_W(x', x'x)$ is $\theta_{\geq 0}$-integrable, then, as $\theta_{\geq 0} = \theta_{\geq 1} * \theta_0$ (Lemma 5.2.59 (i)), Fubini's theorem for the s-finite measures $\theta_{\geq 1}$, θ_0 gives, for θ_0-almost every ξ, the integrability of $x'' \mapsto \mathcal{K}_W(x''\xi, x''\xi x)$, whose integral is $\mathcal{K}_{W,1}(\xi, \xi x)$, and

$$\mathcal{K}_{W,0}(1,x) = \int_G \mathcal{K}_{W,1}(\xi,\xi x)\,d\theta_0(\xi), \qquad |\mathcal{K}_{W,0}(1,x)| \leq \int_G |\mathcal{K}_{W,1}(\xi,\xi x)|\,d\theta_0(\xi) = \mathrm{piv}_0(\mathcal{K}_W)(1,x);$$

otherwise $\mathcal{K}_{W,0}(1,x) = 0$. For $j = 0$ and $p = q = 1$ one has $w_{0,1} = 1$, $d = 1$ and $\mathfrak{m}_0 = \delta_1$, so $\mathrm{FM}_0(1,1,W,x) = \mathrm{piv}_0(\mathcal{K}_W)(1,x)^2$. Hence $|I(x)|^2 \leq \mathrm{fl}^2\,\mathrm{FM}_0(1,1,W,x)$ for every x.

Conclusion. By Lemma 5.5.45,

$$\int_{G\backslash \mathrm{K}(M)} |I|^2\,d\mathrm{vol} \leq \mathrm{fl}^2 \int_{G\backslash \mathrm{K}(M)} \mathrm{FM}_0(1,1,W,x)\,d\mathrm{vol}(x) \leq \mathrm{fl}^2 Q^{-t}\,\mathrm{mr}(Z) = Q^{-t}\,\mathrm{vol}(Z)\,\mathrm{vol}(\mathrm{K}(M)).$$

Adding the two terms, $\mathrm{mi}(Z) \leq \mathrm{vol}(Z)\,\mathrm{vol}(\mathrm{K}(M))\,(\mathrm{vol}(Z) + Q^{-t})$. □

Lemma 5.5.43. *Let F be a large lattice datum over a finite place A, with level unit M, and put $\eta_{<\varrho+2} = \eta_0 * \eta_1 * \cdots * \eta_{\varrho+1}$. Let $c \in \mathcal{O}_A$ be a unit with $\bar{c} = c$. Then for every s-finite Borel measure θ' on G and every $w \in G$,*

$$(\eta_{<\varrho+2} * \theta')(\{y \in G : yw \in \mathrm{K}(c)\}) = \Big(\prod_{l<\varrho} \mathrm{fm}(l,c)\Big) \cdot \theta'(\{y \in G : uyw \in \mathrm{K}(c) \text{ for some } u \in \mathsf{U}\}).$$

For $c = M$ the factor is fl*; for $c = 1$ it is* 1*.*

Proof. Fix c. $\mathrm{K}(c)$ is an open subgroup of G: for $x, y \in \mathrm{K}(c)$, $c^{-1}(xy-1) = c^{-1}(x-1)y + c^{-1}(y-1)$ and $c^{-1}(x^{-1}-1) = -x^{-1}c^{-1}(x-1)$ are integral, and integrality of matrices is an open condition. For a subgroup S of G and $w \in G$ the set $\{y : uyw \in \mathrm{K}(c) \text{ for some } u \in S\} = S\,\mathrm{K}(c)w^{-1}$ is open.

Step 1: unfolding. Let $j \geq 0$, θ' s-finite and $w \in G$. Then

$$(\eta_{<j} * \theta')(\{y : yw \in \mathrm{K}(c)\}) = \eta_{<j}(\mathrm{K}(c)) \cdot \theta'(\{y : uyw \in \mathrm{K}(c) \text{ for some } u \in N_{<j}\}). \tag{1}$$

By Tonelli the left side is $\int \eta_{<j}(\{x : xyw \in \mathrm{K}(c)\})\,d\theta'(y)$. If $uyw \in \mathrm{K}(c)$ for some $u \in N_{<j}$, then $\{x : xyw \in \mathrm{K}(c)\} = \{x : xu^{-1} \in \mathrm{K}(c)\}$, whose $\eta_{<j}$-measure is $(\eta_{<j} * \delta_{u^{-1}})(\mathrm{K}(c)) = \eta_{<j}(\mathrm{K}(c))$ by Lemma 5.4.14 (iii). Otherwise $xyw \notin \mathrm{K}(c)$ for every $x \in N_{<j}$, and $\eta_{<j}$ is carried by $N_{<j}$ (Lemma 5.4.14 (ii)), so the integrand vanishes. This gives (1).

Step 2: one floor. Let $l < \varrho$ and let $S \leq N_{<l}$ be a subgroup. For $v \in V_{l+1}$ and $\beta \in A^-$, some $u \in S$ has $un_l(v,\beta) \in \mathrm{K}(c)$ if and only if $c^{-1}v$ and $c^{-1}\beta$ are integral. Suppose $u \in S$ and $un \in \mathrm{K}(c)$, $n = n_l(v,\beta)$. As $u \in N_{<l}$, u maps e_l^*, e_l and every vector of V_{l+1} to itself plus a combination of the e_a, $a < l$ (their modified level is ϱ, and only indices of modified level below ϱ, the e_a with $a < l$, can occur). Hence $une_l^* - e_l^*$ equals $v + (\beta - \tau h(v,v))e_l$ plus a combination of the e_a, $a < l$, and integrality of $c^{-1}(un-1)$ gives $c^{-1}v$ and $c^{-1}(\beta - \tau h(v,v))$ integral. With $v_0 = c^{-1}v$, $h(v,v) = c^2 h(v_0,v_0)$ ($\bar{c} = c$), and $c^{-1}\tau h(v,v) = \tau c\,h(v_0,v_0) \in \mathcal{O}_A$ as J is integral; so $c^{-1}\beta$ is integral. Conversely, if $v = cv_0$ and $\beta = c\beta_0$ with v_0, β_0 integral, then $\beta - \tau h(v,v) = c\,t$ with $t = \beta_0 - \tau c h(v_0,v_0) \in \mathcal{O}_A$, and

$$(n-1)w = c\big(w_l^* v_0 + (tw_l^* - h(v_0,w))e_l\big),$$

where $w \mapsto w_l^* = h(e_l, w)$ and $w \mapsto h(v_0, w)$ have integral matrices. So $c^{-1}(n-1)$ is integral, $n = 1 + c \cdot c^{-1}(n-1)$ is integral, $n^{-1} = J^{-1}\bar{n}^{\mathsf{T}}J$ is integral, and $u = 1$ works. By the definition

of η_l, (PA3) and Lemma 5.2.55 (the skew ball of c^{-1}),

$$\begin{aligned}\eta_l(\{y : uy \in \mathrm{K}(c) \text{ for some } u \in S\}) &= \mathrm{vol}(\{v \in V_{l+1} : c^{-1}v \text{ integral}\}) \cdot \nu(\{\beta : c^{-1}\beta \in \mathcal{O}_A\}) \\ &= |c|^{\dim V_{l+1}}|c|^{1/2} = \mathrm{fm}(l,c),\end{aligned}$$

as $\dim V_{l+1} = k + 1 + 2(\varrho - l - 1) = d_l$.

Step 3: the congruence subgroup. For $j \le \varrho$, $\eta_{<j}(\mathrm{K}(c)) = \prod_{l<j} \mathrm{fm}(l,c)$, by induction on j: for $j = 0$, $\eta_{<0} = \delta_1$; for $j < \varrho$, $\eta_{<j+1} = \eta_{<j} * \eta_j$, and (1) with $\theta' = \eta_j$, $w = 1$, followed by Step 2 with $S = N_{<j}$, gives $\eta_{<j+1}(\mathrm{K}(c)) = \eta_{<j}(\mathrm{K}(c))\,\mathrm{fm}(j,c)$.

Step 4. As $\eta_l = \delta_1$ for $l \ge \varrho$, $\eta_{<\varrho+2} = \eta_{<\varrho}$; and $N_{<\varrho} = \mathsf{U}$, since for $l = \varrho$ the modified level of every index is its level. By (1) with $j = \varrho$ and Step 3,

$$(\eta_{<\varrho+2} * \theta')(\{y : yw \in \mathrm{K}(c)\}) = \Big(\prod_{l<\varrho} \mathrm{fm}(l,c)\Big)\theta'(\{y : uyw \in \mathrm{K}(c) \text{ for some } u \in \mathsf{U}\}).$$

For $c = M$ the factor is fl, and for $c = 1$ it is 1, as $|1| = 1$. □

Lemma 5.5.44. *Let F be a large lattice datum over a finite place A, with level unit M and group measure* vol.

(a) For every unit c of A, $\mathrm{K}(c)$ is a compact open subgroup of G, and $y\mathrm{K}(c)y^{-1} = \mathrm{K}(c)$ for $y \in \mathrm{K}(1)$; $\mathrm{K}(M) \le \mathrm{K}(1)$.

(b) The value $\chi_M(y)$ does not depend on the chosen u; $|\chi_M| \le 1$; $\chi_M(uy) = \psi(M^{-1}\sigma(u))\chi_M(y)$ for $u \in \mathsf{U}$; $\chi_M(yk) = \chi_M(y)$ for $k \in \mathrm{K}(M)$; $\chi_M = 1$ on $\mathrm{K}(M)$; and χ_M is continuous.

(c) For an intermediate group Z, the set $\mathrm{Cos}(Z)$ is finite and nonempty; W_Z is continuous and bounded, $W_Z(uy) = \psi(M^{-1}\sigma(u))W_Z(y)$ for $u \in \mathsf{U}$, and $W_Z(y) \ne 0$ implies $uy \in \mathrm{K}(1)$ for some $u \in \mathsf{U}$. In particular W_Z is cut.

(d) $0 < \mathrm{vol}(Z) < \infty$, $0 < \mathrm{vol}(\mathrm{K}(M)) < \infty$ and $0 < \mathrm{mr}(Z) < \infty$.

(e)

$$\int_{\mathrm{K}(M)} \Big| \int_Z \chi_M(yxy^{-1})\, d\mathrm{vol}(y) \Big|^2 d\mathrm{vol}(x) = \mathrm{vol}(Z)^2\, \mathrm{vol}(\mathrm{K}(M));$$

in particular $\mathrm{mi}(Z) \ge \mathrm{vol}(Z)^2\mathrm{vol}(\mathrm{K}(M))$.

Proof. **(a).** For $x \in G$ we have $x^{-1} = J^{-1}\bar{x}^{\mathsf{T}}J$, so x^{-1} is integral as soon as x is; hence $\mathrm{K}(1) = G \cap \mathrm{M}_r(\mathcal{O}_A)$ and $\mathrm{K}(c) = \mathrm{K}(1) \cap (1 + c\mathrm{M}_r(\mathcal{O}_A))$. Since $\mathcal{O}_A$ is compact and open in A and multiplication by the unit c is a homeomorphism of A, the sets $\mathrm{M}_r(\mathcal{O}_A)$ and $1 + c\mathrm{M}_r(\mathcal{O}_A)$ are compact and open in $\mathrm{M}_r(A)$; as G is closed in $\mathrm{M}_r(A)$, $\mathrm{K}(1)$ and $\mathrm{K}(c)$ are compact and open in G. If $x, y \in \mathrm{K}(c)$, then xy and x^{-1} lie in $\mathrm{K}(1)$, $c^{-1}(xy - 1) = c^{-1}(x - 1)y + c^{-1}(y - 1)$ and $c^{-1}(x^{-1} - 1) = -x^{-1}c^{-1}(x - 1)$ are integral; so $\mathrm{K}(c)$ is a subgroup. For $y \in \mathrm{K}(1)$ and $x \in \mathrm{K}(c)$, $yxy^{-1} \in \mathrm{K}(1)$ and $c^{-1}(yxy^{-1} - 1) = y\,c^{-1}(x - 1)\,y^{-1}$ is integral, so $y\mathrm{K}(c)y^{-1} \subseteq \mathrm{K}(c)$, and equality follows by applying this to y^{-1}. By definition $\mathrm{K}(M) \subseteq \mathrm{K}(1)$.

The simple-root sum. U acts trivially on the successive quotients of the flag $F_a = \langle e_0, \dots, e_a\rangle$ $(a < \varrho)$ and on $F_{\varrho-1}^{\perp}/F_{\varrho-1}$, which contains the image of z. Hence for $u \in \mathsf{U}$, $ue_{a+1} \in e_{a+1} + u_{a,a+1}e_a + F_{a-1}$ $(a + 1 < \varrho)$ and $uz \in z + u_{\varrho-1,z}e_{\varrho-1} + F_{\varrho-2}$, and $\sigma(u)$ is the sum of these coefficients $u_{a,a+1}$ and $u_{\varrho-1,z}$, which are matrix entries of u. Applying u to $ve_{a+1} \in e_{a+1} + v_{a,a+1}e_a + F_{a-1}$ gives $(uv)_{a,a+1} = u_{a,a+1} + v_{a,a+1}$, and likewise at z; so

$\sigma(uv) = \sigma(u) + \sigma(v)$ on U. If moreover $v \in \mathrm{K}(M)$, the off-diagonal entries of v are those of $v - 1$, so $M^{-1}\sigma(v) \in \mathcal{O}_A$, and $\psi(M^{-1}\sigma(v)) = 1$ by self-duality of $\mathcal{O}_A$ (take $r = 1$).

(b). Let $u, u' \in \mathsf{U}$ with $u^{-1}y, u'^{-1}y \in \mathrm{K}(M)$. Then $v = u^{-1}u' = (u^{-1}y)(u'^{-1}y)^{-1} \in \mathsf{U} \cap \mathrm{K}(M)$, $\sigma(u') = \sigma(u) + \sigma(v)$ and $\psi(M^{-1}\sigma(u')) = \psi(M^{-1}\sigma(u))\psi(M^{-1}\sigma(v)) = \psi(M^{-1}\sigma(u))$; so the value is independent of u. $|\chi_M| \leq 1$ as ψ is unitary. If $y \in v\mathrm{K}(M)$ with $v \in \mathsf{U}$, then $uy \in (uv)\mathrm{K}(M)$ and $\chi_M(uy) = \psi(M^{-1}\sigma(u))\psi(M^{-1}\sigma(v))$; if $y \notin \mathsf{U}\mathrm{K}(M)$ then $uy \notin \mathsf{U}\mathrm{K}(M)$ and both sides vanish. Right translation by $k \in \mathrm{K}(M)$ preserves $\mathsf{U}\mathrm{K}(M)$ and the admissible u, so $\chi_M(yk) = \chi_M(y)$; for $y \in \mathrm{K}(M)$ one may take $u = 1$, so $\chi_M(y) = \psi(0) = 1$. Being invariant under right translation by the open subgroup $\mathrm{K}(M)$, χ_M is locally constant, hence continuous.

(c). Z is a union of cosets of the open group $\mathrm{K}(M)$, hence open and closed in G; as $Z \subseteq \mathrm{K}(1)$, Z is compact, and the disjoint open cover of Z by its right cosets of $\mathrm{K}(M)$ is finite. It contains $\mathrm{K}(M)$, so $\mathrm{Cos}(Z) \neq \emptyset$. Each coordinate $y \mapsto \chi_M(yc^{-1})$ of W_Z is continuous with absolute value at most 1 by (b), so W_Z is continuous and $\|W_Z\| \leq (\#\mathrm{Cos}(Z))^{1/2}$; and $\chi_M(uyc^{-1}) = \psi(M^{-1}\sigma(u))\chi_M(yc^{-1})$ gives the transformation law. If $W_Z(y) \neq 0$, some $\chi_M(yc^{-1}) \neq 0$ with $c \in Z$, so $yc^{-1} \in v\mathrm{K}(M)$ for some $v \in \mathsf{U}$, and $v^{-1}y \in \mathrm{K}(M)c \subseteq \mathrm{K}(1)$. These are the properties of a cut function of frequency M^{-1} supported in $\mathsf{U}\mathrm{K}(1)$, the box being $\mathrm{K}(1)$.

(d). By Lemma 5.5.41 (1), vol is a Haar measure on G, so it is positive on the nonempty open sets $Z, \mathrm{K}(M)$ and finite on these compact sets. Since M is a unit of A, $|M| = \mathrm{vol}(M\mathcal{O}_A) \in (0, \infty)$ (a Haar measure of the compact open set $M\mathcal{O}_A$), so $\mathrm{fm}(l)$ and fl lie in $(0, \infty)$, and so does $\mathrm{mr}(Z) = \mathrm{vol}(Z)\mathrm{vol}(\mathrm{K}(M))\mathrm{fl}^{-2}$.

(e). Let $x \in \mathrm{K}(M)$. For $y \in Z \subseteq \mathrm{K}(1)$, $yxy^{-1} \in \mathrm{K}(M)$ by (a), so $\chi_M(yxy^{-1}) = 1$ by (b), and $\int_Z \chi_M(yxy^{-1})\, d\mathrm{vol}(y) = \mathrm{vol}(Z)$, finite by (d). Hence the integrand equals the constant $\mathrm{vol}(Z)^2$ on $\mathrm{K}(M)$, and its integral over $\mathrm{K}(M)$ is $\mathrm{vol}(Z)^2\mathrm{vol}(\mathrm{K}(M))$. The integrand of $\mathrm{mi}(Z)$ is nonnegative (and measurable: $x \mapsto \int_Z \chi_M(yxy^{-1})\, d\mathrm{vol}(y)$ is continuous by dominated convergence, χ_M being continuous and bounded and $\mathrm{vol}(Z)$ finite), so $\mathrm{mi}(Z)$ is at least its integral over $\mathrm{K}(M)$. □

Lemma 5.5.45. *Let F be a large lattice datum over a finite place A with level unit M, and let Z be an intermediate group. Let $Q \geq 2$ be a real number with $|c| \leq Q^{-1}$ for every unit $c \in \mathcal{O}_A$ with $c^{-1} \notin \mathcal{O}_A$, and let $t \geq 0$ be an integer with $t + 2 \cdot 10^9 n^4 \leq k$. Then*

$$\int_{G \backslash \mathrm{K}(M)} \mathrm{FM}_0(1, 1, W_Z, x)\, d\theta(x) \leq Q^{-t}\, \mathrm{mr}(Z).$$

Proof. Write $W = W_Z$, $N = 10^9 n^4$, and let Γ_1 be the gauge of scale 1 (Lemma 5.2.51 with $\alpha = 1$), of loss 2; the constant sequence 1 is a head of length 0 for Γ_1. Let $f = \mathbf{1}_{G \backslash \mathrm{K}(M)}\, \mathrm{FM}_0(1, 1, W, \cdot)$ and $e = Q^{-1} < 1$.

The gain. Let x be a position. If $x \in \mathrm{K}(M)$, $f(x) = 0$. If $x \notin \mathrm{K}(M)$, then by Lemma 5.5.38 (iv) (with $e = Q^{-1}$, admissible by the hypothesis on Q) $(0, 1, 1, W)$ has a deep vector after the head of depth at least Q at x, and (DN0)(d) of Theorem 5.4.1, for Γ_1 and $\sigma = Q^{-1}$, gives $f(x)^2 \leq (e^s)^2\, \mathrm{WSP}_0(1, 1, W, x)$, with WSP_0 formed for Γ_1.

The shell sum. Apply Lemma 5.5.36 with $\alpha = 1$, $j = 0$, $p = q = 1$, the integer $r = t + N$ (so $r + 10^8 n^4 \leq t + 2 \cdot 10^9 n^4 \leq k$), the function $f \leq \mathrm{FM}_0(1, 1, W, \cdot)$ and e:

$$\begin{aligned} \int_{G \backslash \mathrm{K}(M)} \mathrm{FM}_0(1, 1, W, x)\, d\theta(x) &= \int_G f\, d\theta \leq Q^{-(t+N)}\, \mathrm{mr}(Z)\, 2^N \\ &= Q^{-t}\, (2Q^{-1})^N\, \mathrm{mr}(Z) \leq Q^{-t}\, \mathrm{mr}(Z), \end{aligned}$$

as $Q \geq 2$. □

5.6 Filling data, unfolding and moments near the Bessel subgroup

This section connects the abstract filling datum, for which the two moments of Proposition 5.6.48 are proved, to the data. The data give an admissible filling datum that fits Y_0, whose classes and Bessel coordinates are coordinates on the source forms, $\mathcal{S} \cong \mathbb{C}^{\mathcal{C}\times I}$ (Proposition 5.6.4). The scaled Poincaré map has amplitude blocks (Proposition 5.6.16), which carries the second moment through Theorem 5.1.13. Near the Bessel subgroup the moments are those of the Bessel translates (Lemma 5.6.33, Proposition 5.6.41, Proposition 5.6.42), which together with the rarity of bad types carries the near-isometry. The classes are those of the definite group $\mathrm{U}(X_0)$, so that the coordinates are values of algebraic modular forms at class representatives [110] (Lemma 5.6.14), and the class number is controlled by a mass of hermitian lattices [97, 303]. The arrangement follows [259]; for another reading see [223].

Definition 5.6.1. Let $G_f = G_f(\{1,\dots,r\})$ and $\mathrm{K}_f = \mathbf{K}_0(\{1,\dots,r\})$ be the groups of (VP1) of Definition 3.2.2 (those of (FT1) of Definition 3.2.4 for $N = r$); $G_f = \mathrm{U}_r(\mathbb{A}_{E^+,f})$ for the unitary group U_r over E^+ of the standard form $\sum_i \bar{z}_i z'_i$ on E^r. For a chosen place w and $g \in G_f$ write $g_w \in \mathrm{GL}_r(E_w)$ for its component at w.

(HO1) Framed spaces. Here framed spaces are those of rank r of (FT1) of Definition 3.2.4, that is, framed hermitian spaces with signs $s\colon \{1,\dots,r\} \to \{\pm 1\}$ in the sense of (VP3) of Definition 3.2.2: signs the same at every $v \in \Phi$, a frame of $V \otimes_{E,v} \mathbb{C}$ with form $\mathrm{diag}(s)$ at each $v \in \Phi$, and the finite frame x_V. Through x_V, $\mathrm{U}(V)(\mathbb{A}_{E^+,f}) = G_f$ as in (VP3); the integral elements are K_f, the principal level is $\mathrm{K}_M = \{k \in \mathrm{K}_f :\ k_w \equiv 1 \bmod w \text{ for every chosen place } w\}$, and $\bar{G} = \mathrm{K}_f/\mathrm{K}_M$ by reduction at the chosen places. For a framed space, $\mathcal{A}_M(V)$ and the action of $\bar{G}$ of Definition 3.2.16 are taken in these frames: the archimedean type at v is the discrete series with Harish-Chandra parameter $\varsigma(v)$ relative to the signs s, and G_f acts on $\mathcal{A}_M(V)$-type forms by right translation ρ_V. The spaces $Y_0, W_1, \dots, W_m$ are framed spaces with the signs and frames fixed in Definition 3.2.13, Definition 3.2.15 and below; for W_j the signs are $+1$ at the first $k+j-1$ indices and -1 at the others.

(HO2) Gap. For a framed space V with signs s, ς **has gap Δ for** V if for every $v \in \Phi$ the entries $\varsigma(v)_1, \dots, \varsigma(v)_r$ are pairwise distinct and $|\varsigma(v)_i - \varsigma(v)_j| \geq \Delta$ whenever $s(i) \neq s(j)$.

(HO3) Hecke operators away from M. Let

$$G^M = \{g \in G_f :\ g_w = 1 \text{ for every chosen place } w\}.$$

The **spherical algebra away from** M is the set $\mathcal{H}^M$ of finitely supported $a = \sum_g a_g\, g \in \mathbb{C}[G^M]$ such that for every representation π of G_f on a complex vector space X and every $x \in X$ fixed by K_M, the vector $\pi(a)x = \sum_g a_g \pi(g)x$ is fixed by K_M. For $a \in \mathcal{H}^M$ and a framed space V let $T_a(V) = \rho_V(a)|_{\mathcal{A}_M(V)}$; the family $T_a = (T_a(V))_V$ is the **spherical Hecke operator away from** M given by a.

(HO4) Eigenparts. A finite place w of E is **split off the level** if $w \neq \bar{w}$ and neither w nor $\bar{w}$ is a chosen place; then G_f has the factor $\mathrm{GL}_r(E_w)$ at the place of E^+ below w, and for $1 \leq i \leq r$ let $a_{w,i} \in \mathcal{H}^M$ be the sum of the coset representatives of $\mathrm{GL}_r(\mathcal{O}_w)\,\mathrm{diag}(\varpi_w 1_i, 1_{r-i})\,\mathrm{GL}_r(\mathcal{O}_w)/\mathrm{GL}_r(\mathcal{O}_w)$, placed at w (and 1 elsewhere), with ϖ_w a uniformiser, and $T_{w,i} = T_{a_{w,i}}$. An **eigensystem** is a function q from the pairs (w,i) to $\mathbb{C}$; its **eigenpart** on a framed space V is

$$\mathcal{A}_M(V)[q] = \{y \in \mathcal{A}_M(V) :\ T_{w,i}(V)\, y = q(w,i)\, y \text{ for all } (w,i)\}.$$

The frame of Y_0 is its fixed frame, (XF1) of Definition 3.2.15, the frames of W_j those of its standard lattice $\mathcal{O}_E^r$ in (HP4), and the entries of $\varsigma(v)$ are attached to the basis by the numbering num of (HP2) of Definition 3.2.13, as in Definition 3.2.16.

Definition 5.6.2. Let E be a CM field, let Φ be its set of infinite places (all complex, $f = \#\Phi = [E^+ : \mathbb{Q}]$), let $N \geq 1$ and $s \in \{\pm 1\}^N$.

(EK1) Real group and size. $G_\infty = \prod_{v\in\Phi} \mathrm{U}(\operatorname{diag} s)$ is the real group of the signs s as in (FT1) of Definition 3.2.4, $\mathrm{U}(\operatorname{diag} s) = \{g \in \mathrm{GL}_N(\mathbb{C}) : \ \bar{g}^{\mathsf{T}} \operatorname{diag}(s)\, g = \operatorname{diag}(s)\}$, with a fixed Haar measure dg_v on each factor and the product measure dx on G_∞. The **archimedean size** of $x = (x_v)_v \in G_\infty$ is

$$\|x\|_\infty = \prod_{v\in\Phi} \|x_v\|,$$

$\|x_v\|$ the operator norm of x_v for the standard hermitian norm on $\mathbb{C}^N$.

(EK2) Real convolution. For a group $G = G_\infty \times G'$ (G' any group), a function α on G_∞ and a function F on G, the **real convolution** is

$$R(\alpha)F(g) = \int_{G_\infty} \alpha(h)\, F\big(g\,(h,1)\big)\, dh$$

at every g at which the integral converges absolutely.

(EK3) Idempotent kernel. A function $e\colon G_\infty \to \mathbb{C}$ is an **idempotent kernel** if it is continuous and integrable, $e(x^{-1}) = \overline{e(x)}$ for all x, $e(1) \neq 0$, and

$$\int_{G_\infty} e(z)\, e(x^{-1}z^{-1}y)\, dz = \frac{e(x^{-1})\, e(y)}{e(1)} \qquad (x, y \in G_\infty).$$

(EK4) Cusp kernel. For an integer $B \geq 0$, an idempotent kernel e is a **cusp kernel of order** B if

(a) $x \mapsto |e(x)|\, \|x\|_\infty^{B+1}$ is integrable on G_∞;

(b) $\sup_{x\in G_\infty} |e(x)|\, \|x\|_\infty^{B} < \infty$;

(c) there is a continuous compactly supported $\beta\colon G_\infty \to \mathbb{C}$ with $\int_{G_\infty} \beta(x)\, e(x^{-1}y)\, dx = e(y)$ for all $y \in G_\infty$.

Definition 5.6.3. Let D be admissible data and let V be a hermitian space over E of rank $n \geq 1$ with a frame and signs $s \in \{\pm 1\}^n$, the same at every $v \in \Phi$; with its frame V is a framed hermitian space with signs s on $\{1, \dots, n\}$ in the sense of (VP3) of Definition 3.2.2, that is, a framed space of rank n with signs s in the sense of (FT1) of Definition 3.2.4. Through the frame $\mathrm{U}(V)(\mathbb{A})$ is written as $\mathrm{G}(s) = G_\infty \times G_f$, $G_\infty = G_\infty(s)$, as in (VP3), and $u \in V$ has the coordinate vector $c(u) = c_V(u) \in \mathbb{A}_E^n$ of (VP3); $\|\cdot\|$ is the euclidean norm on $\prod_{v\in\Phi} \mathbb{C}^n$ of (VP4), and $\|g\|$ is the operator norm of a complex matrix g.

(DZ1) Gap. For $s \in \{\pm 1\}^n$ and $h, A \in \mathbb{N}$, an integer vector $l \in \mathbb{Z}^n$ has gap h, or large gap A, for s in the sense of (WM8) of Definition 3.2.19, on the index set $\{1, \dots, n\}$: its entries are distinct and congruent to $n-1$ modulo 2, and $|l_i - l_j| \geq 2h$ whenever $s_i \neq s_j$, respectively with $h = 500n^3 + A$. Then $\frac{1}{2}l$ is a Harish-Chandra parameter for $\mathrm{U}(\operatorname{diag} s)$.

(DZ2) Forms of a given type and level. For a family $\lambda = (\lambda(v))_{v\in\Phi}$ of Harish-Chandra parameters for $\mathrm{U}(\operatorname{diag} s)$, forms of type λ on V means the forms of parameter λ of (FT3) of Definition 3.2.4: the forms of type e_λ in the sense of (FT2), e_λ the type kernel built from Flensted-Jensen's functions $c_{\lambda(v)}$ of Definition 3.2.3 and the formal degrees $d_{\lambda(v)}$. For $0 \neq a \in \mathcal{O}_E$ the **principal level** $\mathrm{K}(a) \subseteq G_f$ consists of the elements whose matrix in the frame and whose inverse have entries in $\hat{\mathcal{O}}_E$ and which are congruent to 1 modulo a; a form **has level** $\mathrm{K}(a)$ if it is right invariant under $\mathrm{K}(a)$.

(DZ4) Cusp constant. $c_{\mathrm{cs}}(n) = 8fn\,\mathrm{rd}_E + 48n^6f^2q_1d + 1$.

(DZ5) Deep-level sizes. Integers $A, L, a_{\mathrm{p}} \geq 0$ and reals $\beta, R > 0$ satisfy the **deep-level size conditions for rank** n if

$$8(n+1)^2 < A, \quad a_{\mathrm{p}} < A, \quad 2f(n+1)+2 \leq A,$$
$$M\,c_{\mathrm{cs}}(n)^2 \leq \beta, \quad 2000(n+L+1)^6 \leq \beta, \quad f \leq \beta,$$
$$\beta^{20A(f+1)} \leq R, \qquad R^{3n+2} \leq M^{b/2}.$$

The last condition says $R^{3n+2} \leq |\pi_M^b|_v$ at every $v \in \Phi$, since $|\pi_M|_v^2 = \pi_M\bar{\pi}_M = M$. The **cusp threshold** is $\theta_{\mathrm{cs}} = \left(R^{-2}/(M\,c_{\mathrm{cs}}(n)^2)\right)^n$.

Proposition 5.6.4. *Let D be admissible data. There is a filling datum $\mathfrak{S}_D$ over E of shape (ϱ, k), $\varrho = (r-k-1)/2$, with level N, $\pi = \pi_N$ (as an idele), primes p_0, p_1, chosen places those of Definition 2.3.4 above p_0 and p_1, size b, source level the level K_0 of the source forms, and Bessel systems those of Proposition 5.7.3, such that:*

(i) $\mathfrak{S}_D$ is admissible, and E carries Weil data;

(ii) the level group of $\mathfrak{S}_D$ is $\bar{G}$, and $\mathfrak{S}_D$ fits Y_0: the space V of $\mathfrak{S}_D$ is Y_0 (the same basis vectors and hermitian form), so $\mathrm{U}(Y_0) = G$ with the same rational points; with $\iota\colon \mathrm{U}(X_0) \to G$ the inclusion, u_0 the central idele of (HP5) of Definition 3.2.13 and $\eta = \iota(u_0^{-1}1_{X_0}) \in G(\mathbb{A}_f)$, the element η commutes with $\iota(\mathrm{U}(X_0)(\mathbb{A}_f))$, the finite frame of Y_0 is $u_0\,\eta\,B\,k$ with B the lattice basis of (FG3) and $k \in \mathrm{GL}_r(\hat{\mathcal{O}})$ reducing to 1 at every chosen place, the principal level of Y_0 (as a group of operators on $Y_0 \otimes \mathbb{A}_f$) is $\mathrm{K}_M = \eta\,\mathrm{K}(M)\,\eta^{-1}$, and every $g \in G(\mathbb{A}_f)$ integral in the finite frame of Y_0 satisfies $\eta^{-1}g\eta \in K$, with $\mathrm{red}(\eta^{-1}g\eta)$ the family of reductions of g at the chosen places;

(iii) there is a linear isomorphism $\mathcal{S} \cong \mathbb{C}^{\mathcal{C}\times I}$ (the isomorphism θ: translation by the central idele u_0, evaluation at the class representatives, and a $\mathrm{U}(k)$-equivariant change of coordinates on the Weyl module), so $\dim \mathcal{S} = D_X = \#\mathcal{C}\cdot\#I \geq 1$;

(iv) $\#\bar{H}\cdot\#\mathcal{C}\cdot\prod_v \mathrm{fr}_v\,\#I_v^2/\deg_v \leq (1+b^{-9})\mathcal{D}_{\mathrm{main}}$ for the frame masses fr_v, and $\#I \leq b^{2kf}$.

Proof. The datum. Let $\mathfrak{S}_D$ have shape (ϱ, k), with $X_0 = E^k$ through the basis of X_0, numbered $x_1, \ldots, x_k$ (so $r = 2\varrho + k + 1$ and $n = \varrho + 1$), the CM field $E = E_s$, the prime N and the idele $\pi = \pi_N$, the primes p_0, p_1 with S_i the chosen places of D above p_i, the generator ϖ of the different of Lemma 3.2.35, the size b, the source level $K_X = K_0$, and at each $v \in \Phi$ the Bessel system $\mathfrak{B}_v$ of Proposition 5.7.3 (for (ϱ, k, b, f)). We check the clauses of Definition 5.1.9.

(FG1) and (FG3) are constructions. (FG2): N is prime by (AD6), $N \geq 5$ and $p_i < N$ by (S1) of Lemma 5.2.12; $\pi \in \hat{\mathcal{O}}$ and $\pi\bar{\pi} = N$ by (AD6). By Lemma 5.2.11 (a), (b), at a finite place w either π is a unit at w, or $w \in T_N$, in which case $q_w = N$ and $\bar{w} \notin T_N$, so π is a unit at $\bar{w}$; this

is the level clause of (FG2). By Lemma 5.2.11 (c), (d), $\#S_i = f$, $q_w = p_i$ for $w \in S_i$, $S_0 \cap S_1 = \emptyset$, no conjugate of a chosen place is chosen, and $M \mid x$ in $\hat{\mathcal{O}}$ if and only if $x \equiv \bar{x} \equiv 0$ modulo every chosen w. By Lemma 3.2.35 (i), $\bar{\varpi} = -\varpi$ and ϖ generates the different. $b \geq 2000$ by (S4) of Lemma 5.2.12. (FG4): K_0 is the subgroup of the compact group K^{st} of Lemma 5.6.5 cut out by congruences at the finitely many places of T_N and the chosen places, hence open and compact; it meets every conjugate of $\mathrm{U}(X_0)(E^+)$ trivially by Lemma 5.6.6. (FG5) is Proposition 5.7.3. (FG6): $b^{10} \leq p_i \leq b^{11}$ is (AD5); the other size fields are those of (S1) of Lemma 5.2.12, using $[E : \mathbb{Q}] = 2f$ (so $(\varrho+1)[E:\mathbb{Q}] \leq 2^{2\varrho}$ is $2f(\varrho+1) \leq 2^{2\varrho}$) and $2^{-\varrho} \leq b^{-6}$ from $b^{10} \leq 2^{\varrho}$.

Weil data. $5040 = 2^4 \cdot 3^2 \cdot 5 \cdot 7$ divides $q_1(s) = q_0 \cdot 3\, l_0(s) \cdot 2^s$, because $2^4 \cdot 3 \cdot 5 \cdot 7 \mid q_0$ and $3 \mid 3\, l_0(s)$. So $E = K(\zeta_{q_1})$ contains a primitive 5040-th root of unity.

Admissibility, (i). (FA1): $K_X = K_0 = \{h : \iota(h) \in K(M)\}$ by Lemma 5.6.5 (b). (FA2): let $s = (s_w) \in \bar{G}$. For a chosen w, π and N are units at w (Lemma 5.2.11), so the lattice of (FG3) at w is the standard lattice $\mathcal{O}_{E_w}^r$, whose Gram matrix (hyperbolic planes, 1 on X_0, $-N$ at z) lies in $\mathrm{GL}_r(\mathcal{O}_{E_w})$. Let u be the place of E^+ below w; it splits ($\bar{w} \neq w$), $g \mapsto g_w$ identifies $G(E_u^+)$ with $\mathrm{GL}_r(E_w)$, and, the lattice being self-dual, the factor K_u of K with $\mathrm{GL}_r(\mathcal{O}_{E_w})$, which reduces onto $\mathrm{GL}_r(k_w)$. Distinct chosen places lie above distinct places of E^+ (Lemma 5.2.11 (c)). Choosing at each such u a lift of s_w in K_u and 1 at the other places gives $g \in K$ with $\mathrm{red}(g) = s$. (FA3) and (FA4): ϖ is purely imaginary, so $|\mathrm{rs}_v| = |\mathrm{Re}(Mv(\varpi)/2\pi i)| = M|\varpi|_v/2\pi$; by (S2) of Lemma 5.2.12, $|\varpi|_v \leq b$ and $1 \leq M|\varpi|_v/2\pi \leq b^{23}$. (FA5): by (S2), $\log N \leq 30(2\varrho+2)\log b = 60n \log b$. (FA6): the quantities $D_X = \#\mathcal{C} \cdot \#I$, $\mathcal{D}_{\mathrm{id}}$, $\mathcal{D}_{\mathrm{main}}$ of $\mathfrak{S}_D$ are those of Lemma 5.6.9, whose (iii) is (FA6). (FA7) is Lemma 5.6.8 (a). (FA8): by Lemma 5.6.5 (a), (c), the group $\{h : \iota(h) \in K\} = K^\pi$ has index $(N^k-1)^f$ in the standard level K^{st}, and $N^k - 1 \geq N^k/2 \geq N^k/b$. (FA9) is Lemma 5.6.12 (ii), whose quantities are those of $\mathfrak{S}_D$.

(ii). The level group of $\mathfrak{S}_D$ is $\prod_{w \in S_0 \cup S_1} \mathrm{GL}_r(k_w) = \bar{G}$. By (HP2), Y_0 has the basis $e_1, \dots, e_\varrho$, the basis of X_0, z, $e_\varrho^*, \dots, e_1^*$ (in the order of the string $v_1, \dots, v_{2\varrho+1} = e_1, \dots, e_\varrho, z, e_\varrho^*, \dots, e_1^*$) with the Gram matrix of (FG1); so $\mathrm{U}(Y_0) = G$ with the same rational points. As $s_0 = 2\varrho + 1$ is odd, the graded basis L_0 of (HP5) keeps the basis vectors of X_0 other than x_k and replaces $x_k, v_1, \dots, v_{2\varrho+1}$ by $\bar{\pi}^{-1}x_k + u_0 N^{-1} z$ and $u_0 v_1, \dots, u_0 v_{2\varrho+1}$, where $u_0 \bar{u}_0 = 1$. Let B be the lattice basis of (FG3) and $\eta = \iota(u_0^{-1} 1_{X_0}) \in \iota(\mathrm{U}(X_0)(\mathbb{A}_f))$, central there. Applying the scalar u_0 after η to B: the string vectors become $u_0 v_i$; x_j ($j < k$) becomes $u_0 u_0^{-1} x_j = x_j$; and $x_k/\bar{\pi} + z/N$ becomes $u_0(u_0^{-1}x_k/\bar{\pi} + z/N) = \bar{\pi}^{-1}x_k + u_0 N^{-1} z$. So $L_0 = u_0\, \eta\, B$, and the frame of Y_0 is $F = u_0 \eta B k$ with $k \in \mathrm{GL}_r(\hat{\mathcal{O}})$ reducing to 1 at every chosen place (HP5). Now $\mathcal{A}_M(Y_0)$ consists of the forms right invariant under $K_M = \{g : F^{-1} g F \in \mathrm{GL}_r(\hat{\mathcal{O}}),\ F^{-1} g F \equiv 1 \text{ at the chosen places}\}$. Since u_0 is a central scalar and conjugation by k preserves integrality and the congruence $\equiv 1$ at the chosen places, $g \in K_M$ if and only if $B^{-1}\eta^{-1} g \eta B$ is integral and $\equiv 1$ there, that is, $\eta^{-1} g \eta \in K(M)$; so $K_M = \eta K(M) \eta^{-1}$. Hence $\varphi \mapsto \varphi(\,\cdot\,\eta^{-1})$ is a linear isomorphism from $\mathcal{A}_M(Y_0)$ onto the space of forms on $G(\mathbb{A})$ of archimedean type ς (read in the frame of Y_0 at the infinite places, which is not changed) that are right invariant under $K(M)$, the forms of principal level of $\mathfrak{S}_D$: right translation by a finite element preserves left invariance, boundedness, continuity and the archimedean type, and $\varphi(gm\eta^{-1}) = \varphi(g\eta^{-1} \cdot \eta m \eta^{-1})$ with $\eta m \eta^{-1} \in K_M$ for $m \in K(M)$. It intertwines the actions of $\bar{G}$: if g is integral in the frame with reductions s, then $\eta^{-1} g \eta \in K$ has reduction s (again because $k \equiv 1$ at the chosen places), and $\varphi(h\eta^{-1}g) = \varphi(h(\eta^{-1}g\eta)\eta^{-1})$.

(iii) is Lemma 5.6.14 (b), with $D_X = \#\mathcal{C} \cdot \#I$. *(iv)* is Lemma 5.6.12 (i), and $\#I \leq b^{2kf}$ is (FA7). □

Lemma 5.6.5. *Let D be admissible data, and for $h \in \mathrm{U}(X_0)(\mathbb{A}_f)$ write $\iota(h) \in G(\mathbb{A}_f)$ for the element acting as h on X_0 and trivially on the hyperbolic planes and on z. Let $K^{\mathrm{st}} = \mathrm{U}(X_0)(\mathbb{A}_f) \cap \mathrm{GL}_k(\hat{\mathcal{O}})$ and let $K^\pi \subseteq K^{\mathrm{st}}$ be the subgroup of the h whose last row is $\equiv (0, \dots, 0, 1)$ (mod π_N). Then:*

(a) $\iota(h) \in K$ *if and only if* $h \in K^\pi$*;*

(b) $\iota(h) \in K(M)$ *if and only if* $h \in K_0$*;*

(c) $[K^{\mathrm{st}} : K^\pi] = (N^k - 1)^f$ *and* $[K^\pi : K_0] = \#\bar{H}$*, where* $\bar{H} = \mathrm{red}(\iota(\mathrm{U}(X_0)(\mathbb{A}_f)) \cap K)$*.*

Proof. Write $\pi = \pi_N$. Let $e_1, \dots, e_k$ be the basis of X_0, so that the lattice basis of (FG3) is the basis of V with e_k replaced by $e'_k = e_k/\bar{\pi} + z/N$, and L is its $\widehat{\mathcal{O}}$-span; K is the stabiliser of L in $G(\mathbb{A}_f)$. By Lemma 5.2.11 (b), π is a uniformiser at the f places of T_N and a unit elsewhere, $\bar{\pi}$ is a uniformiser exactly at the places of $\overline{T_N}$, $T_N \cap \overline{T_N} = \emptyset$, and $\pi\bar{\pi} = N$; hence $\pi\widehat{\mathcal{O}} + \bar{\pi}\widehat{\mathcal{O}} = \widehat{\mathcal{O}}$ and $\pi\widehat{\mathcal{O}} \cap \bar{\pi}\widehat{\mathcal{O}} = N\widehat{\mathcal{O}}$, and $\bar{\pi}/N = \pi^{-1}$.

(a). Let $h = (h_{ij}) \in \mathrm{U}(X_0)(\mathbb{A}_f)$; then $h^{-1} = h^*$, $(h^*)_{ij} = \overline{h_{ji}}$. The basis vectors outside $X_0 \oplus Ez$ and z are fixed by $\iota(h)$. For $j < k$, using $e_k = \bar{\pi}e'_k - \pi^{-1}z$,

$$\iota(h)e_j = \sum_{i<k} h_{ij}e_i + h_{kj}\bar{\pi}\, e'_k - h_{kj}\pi^{-1}z, \qquad \iota(h)e'_k = \sum_{i<k} \frac{h_{ik}}{\bar{\pi}}e_i + h_{kk}e'_k + \frac{1 - h_{kk}}{N}z.$$

As $\pi, \bar{\pi} \in \widehat{\mathcal{O}}$, $\iota(h)L \subseteq L$ holds if and only if

$$\text{(R)} \qquad h_{ij} \in \widehat{\mathcal{O}}\ (i,j<k), \quad h_{kj} \in \pi\widehat{\mathcal{O}}\ (j<k), \quad h_{ik} \in \bar{\pi}\widehat{\mathcal{O}}\ (i<k), \quad h_{kk} - 1 \in N\widehat{\mathcal{O}}.$$

Applying complex conjugation, condition (R) for $h^{-1} = h^*$ is again (R) for h. So $\iota(h) \in K$, i.e. $\iota(h)L \subseteq L$ and $\iota(h)^{-1}L \subseteq L$, if and only if (R) holds. If (R) holds, h and h^{-1} are integral and the last row of h is $\equiv (0, \dots, 0, 1) \pmod{\pi}$ because $N\widehat{\mathcal{O}} \subseteq \pi\widehat{\mathcal{O}}$; so $h \in K^\pi$. Conversely let $h \in K^\pi$. The entries of $hh^* = 1$ in column k read $\sum_j h_{ij}\overline{h_{kj}} = \delta_{ik}$. Conjugating $h_{kj} \equiv \delta_{kj} \pmod{\pi}$ gives $\overline{h_{kj}} \equiv \delta_{kj} \pmod{\bar{\pi}}$, and the h_{ij} are integral, so $h_{ik} \equiv \delta_{ik} \pmod{\bar{\pi}}$. Thus $h_{ik} \in \bar{\pi}\widehat{\mathcal{O}}$ for $i < k$, and $h_{kk} - 1 \in \pi\widehat{\mathcal{O}} \cap \bar{\pi}\widehat{\mathcal{O}} = N\widehat{\mathcal{O}}$; with $h_{kj} \in \pi\widehat{\mathcal{O}}$ $(j < k)$ this is (R).

(b). $K(M)$ is the set of $g \in K$ whose matrix in the lattice basis reduces to 1 at every chosen place w. A chosen place lies above p_0 or $p_1 \neq N$, so π and N are units at w, and the matrix B_w of the lattice basis in the standard basis lies in $\mathrm{GL}_r(\widehat{\mathcal{O}}_{E,w})$. The matrix of g in the lattice basis at w is $B_w^{-1}g_wB_w$; conjugation by an element of $\mathrm{GL}_r(\widehat{\mathcal{O}}_{E,w})$ preserves the congruence $\equiv 1 \pmod{w}$, so it reduces to 1 if and only if $g_w \equiv 1 \pmod{w}$. For $g = \iota(h)$ with $h \in K^\pi$ this says $h_w \equiv 1 \pmod{w}$. By (a), $\iota(h) \in K(M)$ if and only if $h \in K^\pi$ and $h_w \equiv 1 \pmod{w}$ at every chosen place w, which is the definition of K_0.

(c). The conditions defining K^π inside K^{st} concern only the components at the places of T_N, where π is not a unit. Let $w \in T_N$ and u the place of E^+ below it. By Lemma 5.2.11 (b), $\bar{w} \neq w$, so u splits in E, $h \mapsto h_w$ is an isomorphism $\mathrm{U}(X_0)(E_u^+) \to \mathrm{GL}_k(E_w)$ (the component at $\bar{w}$ is determined by $h_{\bar{w}} = \overline{(h_w^{\mathsf{T}})^{-1}}$, the bar applied entrywise through $E_w \cong E_{\bar{w}}$, so it is integral if and only if h_w is), and it carries the factor of K^{st} at u onto $\mathrm{GL}_k(\mathcal{O}_{E_w})$; distinct places of T_N lie above distinct places of E^+, again because $\overline{T_N} \cap T_N = \emptyset$. So $[K^{\mathrm{st}} : K^\pi] = \prod_{w \in T_N}[\mathrm{GL}_k(\mathcal{O}_{E_w}) : \Gamma_w]$, where Γ_w is the subgroup of the g whose last row is $\equiv (0, \dots, 0, 1) \pmod{w}$. As $q_w = N$ (Lemma 5.2.11 (a)), Γ_w is the preimage under the surjective reduction $\mathrm{GL}_k(\mathcal{O}_{E_w}) \to \mathrm{GL}_k(\mathbb{F}_N)$ of the stabiliser of the row vector $(0, \dots, 0, 1)$ for the right action $x \mapsto xg$; this action is transitive on the $N^k - 1$ nonzero row vectors, so the index is $N^k - 1$. With $\#T_N = f$ this gives $[K^{\mathrm{st}} : K^\pi] = (N^k - 1)^f$. Finally, by (a) $\iota(\mathrm{U}(X_0)(\mathbb{A}_f)) \cap K = \iota(K^\pi)$, so $\mathrm{red} \circ \iota \colon K^\pi \to \bar{G}$ has image $\bar{H}$, and by (b) its kernel is K_0; hence $[K^\pi : K_0] = \#\bar{H}$. □

Lemma 5.6.6. *Let D be admissible data and $\mathcal{C} = \mathrm{U}(X_0)(E^+)\backslash\mathrm{U}(X_0)(\mathbb{A}_f)/K_0$. Then $\mathcal{C}$ is finite, $\mathrm{U}(X_0)(E^+) \cap gK_0g^{-1} = \{1\}$ for every $g \in \mathrm{U}(X_0)(\mathbb{A}_f)$, and*

$$\#\mathcal{C} = \#\bar{H} \cdot (N^k - 1)^f \cdot \mathrm{mass}(I_k).$$

Proof. Put $\Gamma = \mathrm{U}(X_0)(E^+)$, $G_f = \mathrm{U}(X_0)(\mathbb{A}_f)$ and let $K^{\mathrm{st}} \supseteq K^\pi \supseteq K_0$ be as in Lemma 5.6.5; K^{st} is the stabiliser of $\widehat{\mathcal{O}}_E^k$ in G_f.

Freeness. K_0 is an open subgroup of K^{st}, and each element of K_0 reduces to 1 at every chosen place w, hence acts trivially on $\mathcal{O}_{E,w}^k / w\mathcal{O}_{E,w}^k$. By Lemma 4.6.2 (c), applied to the definite space X_0 with the lattice $\mathcal{O}_E^k$, $\Gamma \cap gK_0g^{-1} = \{1\}$ for every $g \in G_f$.

The count. By (2) of Lemma 3.2.9, E satisfies (Um). The space X_0 is E^k with $h(x,y) = \sum_i \bar{x}_i y_i$ and the lattice $\mathcal{O}_E^k$, and K_0 is an open subgroup of K^{st} with $\Gamma \cap gK_0g^{-1} = \{1\}$ for every $g \in G_f$ (Freeness). So Lemma 5.6.7 with $n = k$ and the level K_0 shows that $\mathcal{C}$ is finite and $\#\mathcal{C} = [K^{\mathrm{st}} : K_0] \cdot \mathrm{mass}(I_k)$.

The index. By Lemma 5.6.5 (c), $[K^{\mathrm{st}} : K_0] = [K^{\mathrm{st}} : K^\pi]\,[K^\pi : K_0] = (N^k - 1)^f \cdot \#\bar{H}$, which gives the formula. □

Lemma 5.6.7. *Let E be a CM field with (Um), E^+ its maximal totally real subfield, $n \geq 1$, $V = E^n$ with $h(x,y) = \sum_i \bar{x}_i y_i$ and $L = \mathcal{O}_E^n$. Put $\Gamma = \mathrm{U}(V)(E^+)$, $G_f = \mathrm{U}(V)(\mathbb{A}_{E^+,f})$ and let K^{st} be the stabiliser of $\widehat{L}$ in G_f. Let $\mathrm{K} \subseteq \mathrm{K}^{\mathrm{st}}$ be an open subgroup with $\Gamma \cap g\mathrm{K}g^{-1} = \{1\}$ for every $g \in G_f$. Then $\Gamma\backslash G_f/\mathrm{K}$ is finite and*

$$\#(\Gamma\backslash G_f/\mathrm{K}) = [\mathrm{K}^{\mathrm{st}} : \mathrm{K}] \cdot \mathrm{mass}(I_n).$$

Proof. **Step 1: classes of K^{st} and lattices of the genus.** For $g \in G_f$ put $L_g = V \cap g\widehat{L}$. Since $g_{\mathfrak{p}} \in \mathrm{U}(V)(E_{\mathfrak{p}}^+)$ fixes $\widehat{L}_{\mathfrak{p}}$ for almost all $\mathfrak{p}$, L_g is a lattice in V with completions $(\widehat{L_g})_{\mathfrak{p}} = g_{\mathfrak{p}}\widehat{L}_{\mathfrak{p}}$ (a lattice is the intersection of V with its completions, and every family of local lattices that agrees with $\widehat{L}_{\mathfrak{p}}$ for almost all $\mathfrak{p}$ arises so); hence L_g lies in the genus of L. Conversely, if M' lies in the genus of L, choose isometries $g_{\mathfrak{p}}$ with $g_{\mathfrak{p}}\widehat{L}_{\mathfrak{p}} = \widehat{M}'_{\mathfrak{p}}$, and $g_{\mathfrak{p}} = 1$ at the almost all $\mathfrak{p}$ where $\widehat{M}'_{\mathfrak{p}} = \widehat{L}_{\mathfrak{p}}$; then $g = (g_{\mathfrak{p}}) \in G_f$ and $M' = L_g$. For $g, g' \in G_f$ and $\gamma \in \Gamma$, $\gamma L_{g'} = L_{\gamma g'}$, and $L_{\gamma g'} = L_g$ if and only if $\gamma g'\widehat{L} = g\widehat{L}$, that is $g \in \gamma g'\mathrm{K}^{\mathrm{st}}$. So $g \mapsto L_g$ induces a bijection from $\Gamma\backslash G_f/\mathrm{K}^{\mathrm{st}}$ onto the set of $\mathrm{U}(V)$-orbits of lattices in the genus of L (here $\mathrm{U}(V) = \Gamma$), and $\Gamma_g := \Gamma \cap g\mathrm{K}^{\mathrm{st}}g^{-1}$ is the stabiliser $\mathrm{Aut}(L_g)$, a finite group. The genus of L consists of finitely many orbits (finiteness of the class number, [33]), so $\Gamma\backslash G_f/\mathrm{K}^{\mathrm{st}}$ is finite.

Step 2: the fibres. K is open in the compact group K^{st}, so $[\mathrm{K}^{\mathrm{st}} : \mathrm{K}] < \infty$. The fibre of the projection $\Gamma\backslash G_f/\mathrm{K} \to \Gamma\backslash G_f/\mathrm{K}^{\mathrm{st}}$ over $\Gamma g\mathrm{K}^{\mathrm{st}}$ consists of the double cosets $\Gamma gk\mathrm{K}$, $k \in \mathrm{K}^{\mathrm{st}}$. Two of them coincide, $\Gamma gk'\mathrm{K} = \Gamma gk\mathrm{K}$, if and only if $gk'\mathrm{K} = \gamma gk\mathrm{K}$ for some $\gamma \in \Gamma$, and such a γ lies in $g\mathrm{K}^{\mathrm{st}}g^{-1}$, hence in Γ_g. So the fibre is the orbit set of Γ_g acting by left multiplication on $g\mathrm{K}^{\mathrm{st}}/\mathrm{K}$, a set of $[\mathrm{K}^{\mathrm{st}} : \mathrm{K}]$ elements. The action is free: $\gamma gk\mathrm{K} = gk\mathrm{K}$ means $\gamma \in \Gamma \cap (gk)\mathrm{K}(gk)^{-1} = \{1\}$. Hence the fibre has $[\mathrm{K}^{\mathrm{st}} : \mathrm{K}]/\#\Gamma_g$ elements, $\Gamma\backslash G_f/\mathrm{K}$ is finite, and

$$\#(\Gamma\backslash G_f/\mathrm{K}) = [\mathrm{K}^{\mathrm{st}} : \mathrm{K}] \sum_{\Gamma g\mathrm{K}^{\mathrm{st}}} \frac{1}{\#\Gamma_g}.$$

Step 3: the mass. By Step 1 the sum runs over representatives L_g of the $\mathrm{U}(V)$-orbits in the genus of L, with $\#\Gamma_g = |\mathrm{Aut}(L_g)|$; by Definition 3.2.5 it is $\mathrm{mass}(I_n)$. □

Lemma 5.6.8. *Let D be admissible data, $I = \prod_{v \in \Phi} I_v$ and $\deg = \prod_{v \in \Phi} \deg_v$. Then:*

(a) $\#I \leq b^{2kf}$ and $\#I \cdot ((k-1)!)^f \leq b^{5kf/4}$;

(b) with the sums over $v \in \Phi$,

$$\sum_v m(k-1)\log\kappa(v) \;\le\; \log\deg + f\sum_{l=k-1}^{r-1}\log l! \;\le\; \sum_v mr\Big(\log\kappa(v)+\frac{1}{x}\Big).$$

Proof. Sizes. By (AD2), $k \le r \le 3x^5$ and $m \le 2\sqrt{x}$; by (AD4), $\kappa(v) \ge xb/x_1$; $a = xb$. By Proposition 2.3.5, $x \ge (\log b)^{100}$ is large, $x_1 \ge x^{10^6}$ and $b \ge x_1^{10^6}$. Hence

$$(2m+1)r^8 \le (4\sqrt{x}+1)3^8x^{40} \le x^{42}, \qquad (k+a)k \le (3x^5+xb)\,3x^5 \le 6x^6b \le b^{5/4}, \qquad k+a \le b^2,$$

and $(2m+1)r^8/\kappa(v) \le x^{42}x_1/(xb) \le x_1^2/(xb) \le 1/x$.

(a). By Proposition 5.7.3 (ii), $\#I_v$ is the dimension of the irreducible representation of $\mathrm{U}(k)$ of the column count of v; this Schur module of GL_k is formed from the columns of height $t < k$, and $\mathrm{cols}_v(t) = 0$ for $1 < t < k$ (Definition 2.3.4), so it is that of the one-row weight λ_v: the representation $\mathrm{Sym}^{d_v}(\mathbb{C}^k)$ with $d_v = a$ for $v \in \Phi_a$ and $d_v = 0$ otherwise. So $\#I_v = \binom{k-1+d_v}{d_v} \le \binom{k+d_v}{k} \le (k+a)^k$. Multiplying over the f places and using $(k-1)! \le k^k$,

$$\#I \le (k+a)^{kf} \le b^{2kf}, \qquad \#I\cdot((k-1)!)^f \le \big((k+a)k\big)^{kf} \le b^{5kf/4}.$$

The parameter. Fix v and number the entries of $\varsigma = \varsigma(v)$ from 0 to $r-1$: $\varsigma_i = k/2-1-i$ for $i < k-1$ and $\varsigma_l = \Delta/2 - \kappa_{l+2-k}(v)$ for $k-1 \le l < r$, where $1 \le l+2-k \le m$ ($r-(k-1) = m$). Recall $\kappa_j(v) = \kappa(v) + (2j+1)\Delta/2$. For $i < l$:

- if $l < k-1$: $\varsigma_i - \varsigma_l = l - i$;
- if $i < k-1 \le l$: $\varsigma_i - \varsigma_l = k/2-1-i+\kappa(v)+2(l+2-k)\Delta/2$; as $|k/2-1-i| \le k \le r \le \Delta/2$, this lies between $\kappa(v)$ and $\kappa_{l+2-k}(v)$;
- if $k-1 \le i < l$: $\varsigma_i - \varsigma_l = 2(l-i)\Delta/2$, which lies between 1 and $\kappa_{l+2-k}(v)$, since $2(l-i) \le 2(l+2-k)$.

In all cases $1 \le \varsigma_i - \varsigma_l \le \kappa_{l+2-k}(v)$ when $l \ge k-1$.

(b). By Proposition 5.7.3 (i), $\deg_v = \mathrm{d}(\varsigma(v))$. As $\prod_{0\le i<l<r}(l-i) = \prod_{l<r} l!$ and, for $l < k-1$, $\prod_{i<l}(\varsigma_i - \varsigma_l) = l!$,

$$\log\deg_v = \sum_{l=k-1}^{r-1}\Big(\sum_{i<l}\log(\varsigma_i-\varsigma_l) - \log l!\Big).$$

All logarithms are ≥ 0. Lower bound: for each of the m values of $l \ge k-1$ keep the $k-1$ terms $i < k-1$, each $\ge \log\kappa(v)$; so $\log\deg_v + \sum_{l=k-1}^{r-1}\log l! \ge m(k-1)\log\kappa(v)$. Upper bound: each of the $l < r$ terms is at most $\log\kappa_{l+2-k}(v)$, and

$$\log\kappa_j(v) = \log\kappa(v) + \log\Big(1+\frac{(2j+1)\Delta/2}{\kappa(v)}\Big) \le \log\kappa(v) + \frac{(2m+1)r^8}{\kappa(v)} \le \log\kappa(v)+\frac{1}{x} \qquad (j \le m),$$

so the inner sum is at most $r(\log\kappa(v)+1/x)$ and $\log\deg_v + \sum_{l=k-1}^{r-1}\log l! \le mr(\log\kappa(v)+1/x)$. Summing over the f places v gives (b). □

Lemma 5.6.9. *Let D be admissible data, $D_X = \#\mathcal{C}\cdot\#I$, $\mathcal{D}_{\mathrm{id}} = \#\bar{R}_0\cdot D_X$ and $\mathcal{D}_{\mathrm{main}} = D_X^2/(\deg\cdot\mathrm{mass}(I_r))$. Then*

(i) $\dfrac{\mathcal{D}_{\mathrm{main}}}{\mathcal{D}_{\mathrm{id}}} = \dfrac{\#I\,(N^k-1)^f\,\mathrm{mass}(I_k)}{\deg\cdot\mathrm{mass}(I_r)\cdot M^{f\varrho(2k+2\varrho+1)}}$;

(ii) $\Big|\log\dfrac{\mathcal{D}_{\mathrm{main}}}{\mathcal{D}_{\mathrm{id}}} - fk\Big(\log M - \dfrac{15}{2}\log b\Big) - \log\big(\#I\,((k-1)!)^f\big)\Big| \le \dfrac{fk\log b}{4}$;

(iii) $b^{11kf}\,\mathcal{D}_{\mathrm{id}} \le \mathcal{D}_{\mathrm{main}} \le (M/b^6)^{kf}\,\mathcal{D}_{\mathrm{id}}$.

Proof. (i). $\mathcal{D}_{\mathrm{main}}/\mathcal{D}_{\mathrm{id}} = D_X/(\deg\cdot\mathrm{mass}(I_r)\cdot\#\bar R_0)$. By Lemma 5.6.6, $D_X = \#\bar H(N^k-1)^f\mathrm{mass}(I_k)\cdot\#I$, and by Lemma 5.2.67, $\#\bar R_0 = \#\bar H\cdot M^{f\varrho(2k+2\varrho+1)}$; $\#\bar H$ cancels.

Logarithm of the masses. By (S3) of Lemma 5.2.12, $8f \le 2^\varrho$ and $4\varrho+12 \le k$, so Lemma 5.6.10 applies with $u=\varrho$ to every j with $k \le j < r$. Summing over these $r-k = 2\varrho+1$ values,

$$\log\mathrm{mass}(I_r) - \log\mathrm{mass}(I_k) = f\sum_{i=k}^{r-1}\Big((i+\tfrac12)\log\mathrm{rd}_E + \log i! - (i+1)\log(2\pi)\Big) + e_1,$$
$$|e_1| \le (r-k)2^{1-\varrho}.$$

With $\sum_{i=k}^{r-1}(i+\frac12) = (2\varrho+1)(k+\varrho+\frac12)$ and $\sum_{i=k}^{r-1}(i+1) = (2\varrho+1)(k+\varrho+1)$.

Logarithm of the degree. By Lemma 5.6.8 (b),

$$\log\deg = -f\sum_{l=k-1}^{r-1}\log l! + (k-1)m\sum_v\log\kappa(v) + \theta'$$

with $0 \le \theta' \le m\big(m\sum_v\log\kappa(v) + fr/x\big)$, since $r-(k-1) = m$; note $\kappa(v)\ge 1$.

The level. By (AD6), $\log N = \lambda + e_3$ with $0 \le e_3 \le \sqrt{\log b}$ and $\lambda = \frac{m}{f}\sum_v\log\kappa(v) + (m-1)\log\frac{M\mathrm{rd}_E}{2\pi} - \frac{15}{2}\log b$. Also $f\log(N^k-1) = fk\log N - e_2$ with $0 \le e_2 = f\log\frac{N^k}{N^k-1} \le 2f/N$, since $N^k - 1 \ge N/2$ gives $\log\frac{N^k}{N^k-1} \le \frac{1}{N^k-1} \le \frac{2}{N}$.

Assembly. Insert these into the logarithm of (i), $\log\#I + f\log(N^k-1) + \log\mathrm{mass}(I_k) - \log\deg - \log\mathrm{mass}(I_r) - f\varrho(2k+2\varrho+1)\log M$. The factorials give $f\sum_{l=k-1}^{r-1}\log l! - f\sum_{i=k}^{r-1}\log i! = f\log(k-1)!$. Collecting the coefficients of $\log M$, $\log\mathrm{rd}_E$ and $\log 2\pi$, with $m-1 = 2\varrho+1$:

$$fk(m-1) - f\varrho(2k+2\varrho+1) = fk - f\varrho(2\varrho+1), \qquad fk(m-1) - f(2\varrho+1)(k+\varrho+\tfrac12) = -f(2\varrho+1)(\varrho+\tfrac12),$$

and $-fk(m-1) + f(2\varrho+1)(k+\varrho+1) = f(2\varrho+1)(\varrho+1)$. Hence, with

$$A = f(m-1)\Big(\varrho\log\frac{M\mathrm{rd}_E}{2\pi} + \log\frac{\sqrt{\mathrm{rd}_E}}{2\pi}\Big), \qquad B = m\sum_v\log\kappa(v),$$

we get

$$\log\frac{\mathcal{D}_{\mathrm{main}}}{\mathcal{D}_{\mathrm{id}}} - fk\Big(\log M - \frac{15}{2}\log b\Big) - \log\big(\#I((k-1)!)^f\big) = fk\,e_3 + (B-A) - \theta' - e_1 - e_2,$$

the κ-terms being $km\sum_v\log\kappa(v) - (k-1)m\sum_v\log\kappa(v) - \theta' = B - \theta'$. By (S3) of Lemma 5.2.12, $|e_1| + e_2 \le (r-k)2^{1-\varrho} + 2f/N \le \frac{2b^{-9}}{b^{-9}+2} \le \log(1+b^{-9})$, the middle step being the first clause of (S3) (with $2f/N \le 4f/N$) and the last the inequality $\log(1+t) \ge 2t/(t+2)$ for $t \ge 0$. So the right side lies between $-(|A-B| + \log(1+b^{-9}) + m(m\sum_v\log\kappa(v) + fr/x))$ and $fk\sqrt{\log b} + |A-B|$, and both bounds are at most $fk\log b/4$ in absolute value by the error clause of (S2) of Lemma 5.2.12. This is (ii).

(iii). By Lemma 5.6.8 (a) and $\#I \geq 1$, $0 \leq \log(\#I((k-1)!)^f) \leq \frac{5}{4} fk \log b$. By (AD5), $M \geq b^{20}$, so $\log M \geq 19 \log b$. From (ii),

$$\log \frac{\mathcal{D}_{\mathrm{main}}}{\mathcal{D}_{\mathrm{id}}} \geq fk\Big(19 - \frac{15}{2} - \frac{1}{4}\Big) \log b \geq 11 fk \log b,$$
$$\log \frac{\mathcal{D}_{\mathrm{main}}}{\mathcal{D}_{\mathrm{id}}} \leq fk\Big(\log M - \frac{15}{2} \log b + \frac{5}{4} \log b + \frac{1}{4} \log b\Big) = fk \log \frac{M}{b^6}.$$

□

Lemma 5.6.10. *Let P be a parameter pair, $s \geq 0$, $E = E_s$, and let $j, u \geq 0$ be integers with $8f \leq 2^u$ and $j \geq 4u + 12$. Then*

$$\Big|\log \mathrm{mass}(I_{j+1}) - \log \mathrm{mass}(I_j) - f\Big((j + \tfrac{1}{2}) \log \mathrm{rd}_E + \log j! - (j+1) \log(2\pi)\Big)\Big| \leq \frac{2}{2^u}.$$

Proof. By Lemma 3.2.9 (2), $E = E_s$ satisfies (Um), and E/F is unramified at every finite place, $F = E^+$. Here $[E : \mathbb{Q}] = 2f$ and $\mathrm{rd}_E = |d_E|^{1/(2f)}$, so the number $v = |d_E|^{1/(2f)}/2$ of Proposition 5.6.11 is $\mathrm{rd}_E/2$. Put $m = j + 1 \geq 4u + 13 \geq 3$. By Proposition 5.6.11 with $M = m$,

$$\begin{aligned} \log \frac{\mathrm{mass}(I_{j+1})}{\mathrm{mass}(I_j)} &= f\Big(\log j! + (j+1) \log \frac{\mathrm{rd}_E}{2\pi}\Big) - \frac{f}{2} \log \mathrm{rd}_E + \log L_E(m) \\ &= f\Big((j + \tfrac{1}{2}) \log \mathrm{rd}_E + \log j! - (j+1) \log(2\pi)\Big) + \log L_E(m), \end{aligned}$$

so it suffices to show $|\log L_E(m)| \leq 2/2^u$. Group the factors of $L_E(m)$ by the maximal ideals $\mathfrak{p}$ of $\mathcal{O}_F$, with $q = |\mathcal{O}_F/\mathfrak{p}|$ (the product converges absolutely). As $\mathfrak{p}$ is unramified in E, either it is inert, with one $\mathfrak{P} = \bar{\mathfrak{P}}$ of norm q^2 and factor $(1 - (-1)^m q^{-m})^{-1}$, or it splits into $\mathfrak{P} \neq \bar{\mathfrak{P}}$ of norm q with joint factor $(1 - q^{-m})^{-1}$. In both cases the factor lies between $(1 + q^{-m})^{-1}$ and $(1 - q^{-m})^{-1}$, so its logarithm has absolute value at most $-\log(1 - q^{-m})$. For a rational prime ℓ, the $\mathfrak{p} \mid \ell$ have $q = \ell^{a_\mathfrak{p}}$ with $\sum_{\mathfrak{p}|\ell} a_\mathfrak{p} \leq f$, and $-\log(1 - t^a) \leq -a \log(1-t)$ for $0 < t < 1$, $a \geq 1$ (as $(1-t)^a + t^a \leq 1$). Hence

$$|\log L_E(m)| \leq f \sum_\ell -\log(1 - \ell^{-m}) = f \log \zeta(m) \leq f(\zeta(m) - 1) \leq f\Big(2^{-m} + \int_2^\infty t^{-m}\, dt\Big) \leq 2f\, 2^{-m},$$

using $\log x \leq x - 1$ and $2^{1-m}/(m-1) \leq 2^{-m}$ for $m \geq 3$. With $f \leq 2^{u-3}$ and $m \geq 4u + 13$ this is at most $2^{u-2} 2^{-4u-13} \leq 2/2^u$. □

Proposition 5.6.11. *All symbols introduced here are local to this statement and to the results that cite it. Let E be a CM field with (Um), $f = [E : \mathbb{Q}]/2$, d_E its discriminant and $v = |d_E|^{1/(2f)}/2$. For an integer $M \geq 3$ and a maximal ideal $\mathfrak{P}$ of $\mathcal{O}_E$ with norm $N\mathfrak{P}$ put*

$$\epsilon_M(\mathfrak{P}) = \begin{cases} \big(1 - (-1)^M (N\mathfrak{P})^{-M/2}\big)^{-1} & \text{if } \bar{\mathfrak{P}} = \mathfrak{P}, \\ \big(1 - (N\mathfrak{P})^{-M}\big)^{-1/2} & \text{if } \bar{\mathfrak{P}} \neq \mathfrak{P}, \end{cases} \qquad L_E(M) = \prod_{\mathfrak{P}} \epsilon_M(\mathfrak{P}),$$

the product over all maximal ideals, absolutely convergent. Then for every integer $M \geq 3$

$$\frac{\mathrm{mass}(I_M)}{\mathrm{mass}(I_{M-1})} = \Big((M-1)! \Big(\frac{v}{\pi}\Big)^M\Big)^f (2v)^{-f/2}\, L_E(M).$$

Proof. Let F be the maximal totally real subfield of E, $d=[F:\mathbb{Q}]=f$, $d_F>0$ the discriminant of F (positive as F is totally real), χ the quadratic character of E/F and $q_{\mathfrak{p}}=|\mathcal{O}_F/\mathfrak{p}|$. By (Um), E/F is unramified at every finite place.

The ratio of two explicit masses. For $j\geq 1$ the lattice $\mathcal{O}_E^j$ with $h(x,y)=\sum_i \bar{x}_i y_i$ is unimodular: its Gram matrix in the standard basis is the identity, so $x\in(\mathcal{O}_E^j)^\vee$ if and only if all coordinates of x lie in $\mathcal{O}_E$. By the explicit mass formula for unimodular lattices of Gan–Yu in the form of Terakado–Yu [303] (Theorem 2.3.4 and its formula (2.6); hypotheses: E CM, E/F unramified at every finite place, the space definite and the lattice unimodular),

$$\operatorname{mass}(I_j)=2\,d_F^{j^2/2}\prod_{i=1}^{j}\Big(\frac{(i-1)!}{(2\pi)^i}\Big)^d L_F(i,\chi^i),$$

and these numbers are positive. For $M\geq 3$ the factors with $i\leq M-1$ cancel in the quotient, and $M^2-(M-1)^2=2M-1$:

$$\frac{\operatorname{mass}(I_M)}{\operatorname{mass}(I_{M-1})}=d_F^{M-\frac12}\Big(\frac{(M-1)!}{(2\pi)^M}\Big)^f L_F(M,\chi^M).$$

The discriminant. By the transitivity of discriminants, $|d_E|=d_F^{[E:F]}N_{F/\mathbb{Q}}(\mathfrak{d}_{E/F})$, and $\mathfrak{d}_{E/F}=\mathcal{O}_F$ because E/F is unramified at every finite place; so $|d_E|=d_F^2$ and $v=|d_E|^{1/(2f)}/2=d_F^{1/f}/2$. Hence

$$\Big((M-1)!\Big(\frac{v}{\pi}\Big)^M\Big)^f(2v)^{-f/2}=\big((M-1)!\big)^f\frac{d_F^M}{(2\pi)^{Mf}}\,d_F^{-1/2}=d_F^{M-\frac12}\Big(\frac{(M-1)!}{(2\pi)^M}\Big)^f.$$

The Euler product. Group the maximal ideals $\mathfrak{P}$ of $\mathcal{O}_E$ by $\mathfrak{p}=\mathfrak{P}\cap\mathcal{O}_F$; this is allowed since $M\geq 3$ makes both products absolutely convergent ($N\mathfrak{P}\geq q_{\mathfrak{p}}$ and at most two $\mathfrak{P}$ lie over $\mathfrak{p}$). As $\mathfrak{p}$ is unramified in E, either $\mathfrak{p}$ is inert, with the single prime $\mathfrak{P}=\mathfrak{p}\mathcal{O}_E=\bar{\mathfrak{P}}$ of norm $q_{\mathfrak{p}}^2$ and $\chi(\mathfrak{p})=-1$, so that

$$\epsilon_M(\mathfrak{P})=\big(1-(-1)^M q_{\mathfrak{p}}^{-M}\big)^{-1}=\big(1-\chi^M(\mathfrak{p})q_{\mathfrak{p}}^{-M}\big)^{-1}$$

($\chi^M(\mathfrak{p})=(-1)^M$ in both parities); or $\mathfrak{p}$ splits as $\mathfrak{P}\bar{\mathfrak{P}}$ with $\mathfrak{P}\neq\bar{\mathfrak{P}}$, both of norm $q_{\mathfrak{p}}$, $\chi(\mathfrak{p})=1$, and $\epsilon_M(\mathfrak{P})\epsilon_M(\bar{\mathfrak{P}})=(1-q_{\mathfrak{p}}^{-M})^{-1}=(1-\chi^M(\mathfrak{p})q_{\mathfrak{p}}^{-M})^{-1}$. Hence $L_E(M)=\prod_{\mathfrak{p}}(1-\chi^M(\mathfrak{p})q_{\mathfrak{p}}^{-M})^{-1}=L_F(M,\chi^M)$.

The three displays give the assertion. □

Lemma 5.6.12. *Let D be admissible data. Then*

(i) $\#\bar{H}\cdot\#\mathcal{C}\cdot\displaystyle\prod_{v\in\Phi}\frac{\mathrm{fr}_v\,(\#I_v)^2}{\deg_v}\leq(1+b^{-9})\,\mathcal{D}_{\mathrm{main}}$;

(ii) $c_S^\sharp\leq(1+b^{-9})\,\mathcal{D}_{\mathrm{main}}\,\deg c_G^f\,\mathrm{vol}(\hat{\mathcal{O}})^{-n}\,(\nu\Lambda_{\mathrm{fr}}/\#I)^2$.

Proof. Write $m_j=\operatorname{mass}(I_j)$ and $F=\prod_v\mathrm{fr}_v$; note $\prod_v\mathrm{fr}_v(\#I_v)^2/\deg_v=F\,(\#I)^2/\deg$.

(i). By Lemma 5.6.6, $\#\mathcal{C}=\#\bar{H}(N^k-1)^f m_k$, and $\mathcal{D}_{\mathrm{main}}=(\#\mathcal{C})^2(\#I)^2/(\deg\cdot m_r)$. Dividing both sides of (i) by the positive number $\#\mathcal{C}\,(\#I)^2/\deg$, (i) is equivalent to $\#\bar{H}\,F\,m_r\leq(1+b^{-9})\#\mathcal{C}$, that is, to $F\,m_r\leq(1+b^{-9})(N^k-1)^f m_k$. By Lemma 5.6.13, $F\,m_r\leq(1+b^{-9})N^{kf}m_k\big((N^k-1)/N^k\big)^{2f}$, and $N^{kf}\big((N^k-1)/N^k\big)^{2f}=(N^k-1)^f\big((N^k-1)/N^k\big)^f\leq(N^k-1)^f$.

An identity of constants. By Lemma 3.2.35 (iii), $\prod_v \mathrm{sph}_{i+1}(v) = (2\pi)^{(i+1)f}\mathrm{rd}_E^{-f(i+1/2)}(i!)^{-f}$, so $F = N^{kf}\prod_{i=k}^{r-1}(2\pi)^{(i+1)f}\mathrm{rd}_E^{-f(i+1/2)}(i!)^{-f}$. By the definitions of c_G and $\mathrm{vol}\,\mathrm{U}(j)$, $c_G = \frac{2\pi^k}{(k-1)!}\prod_{i=k}^{r-1}\frac{i!}{2\pi^{i+1}}$. Hence, using $\sum_{i=k}^{r-1} i = (2\varrho+1)(k+\varrho)$ and $\sum_{i=k}^{r-1}(i+\frac{1}{2}) = (2\varrho+1)(k+\varrho+\frac{1}{2})$,

$$F\,c_G^f = N^{kf}\Big(\frac{2\pi^k}{(k-1)!}\Big)^f 2^{f(2\varrho+1)(k+\varrho)}\,\mathrm{rd}_E^{-f(2\varrho+1)(k+\varrho+1/2)}.$$

As $|\mathrm{disc}\,E| = \mathrm{rd}_E^{2f}$, $c_S = \big(\pi^k/((k-1)!N^k)\big)^f \mathrm{rd}_E^{f/2}(2/\mathrm{rd}_E)^{fk}$. Comparing the exponents of 2, rd_E, N, π and $(k-1)!$,

$$F\,c_G^f = c_S\,N^{2kf}\,\mathrm{vol}(\hat{\mathcal{O}})^{n+2d}\,|\mathrm{disc}\,E|^{-\varrho/2}.$$

(ii). By the definition of ν, $\nu\Lambda_{\mathrm{fr}} = M^{(2d+\varrho)f}N^{-kf}\mathrm{vol}(\hat{\mathcal{O}})^{-d}|\mathrm{disc}\,E|^{\varrho/4}$ ($\Lambda_{\mathrm{fr}} > 0$ since $\mathrm{rs}_v \neq 0$: $|\mathrm{rs}_v| = M|\varpi|_v/2\pi > 0$), and $2d+\varrho = \varrho(2k+2\varrho+1)$, so $M^{(2d+\varrho)f} = \#\bar{\mathsf{U}}$ by Lemma 5.2.67 (a). Hence, by the identity,

$$c_G^f\,\mathrm{vol}(\hat{\mathcal{O}})^{-n}(\nu\Lambda_{\mathrm{fr}})^2 = (\#\bar{\mathsf{U}})^2N^{-2kf}\mathrm{vol}(\hat{\mathcal{O}})^{-n-2d}|\mathrm{disc}\,E|^{\varrho/2}c_G^f = \frac{(\#\bar{\mathsf{U}})^2c_S}{F},$$

and the right side of (ii) is $(1+b^{-9})\mathcal{D}_{\mathrm{main}}\deg(\#\bar{\mathsf{U}})^2c_S/((\#I)^2F)$. By Lemma 5.2.67 (b), $c_S^\sharp = \#\bar{R}_0\cdot\#\bar{\mathsf{U}}\cdot\#\mathcal{C}\cdot c_S = \#\bar{H}(\#\bar{\mathsf{U}})^2\#\mathcal{C}\,c_S$. Dividing by the positive number $(\#\bar{\mathsf{U}})^2c_S$ and multiplying by $F(\#I)^2/\deg$, (ii) becomes $\#\bar{H}\,\#\mathcal{C}\,F(\#I)^2/\deg \le (1+b^{-9})\mathcal{D}_{\mathrm{main}}$, which is (i). □

Lemma 5.6.13. *Let D be admissible data. For $v \in \Phi$ and $l \ge 1$ put*

$$\mathrm{sph}_l(v) = \frac{(2\pi)^l}{|\varpi|_v^{l-1/2}\,(l-1)!}, \qquad \mathrm{fr}_v = N^k\prod_{i=k}^{r-1}\mathrm{sph}_{i+1}(v)$$

*(the **sphere masses** and the **frame masses**). Then*

$$\Big(\prod_{v\in\Phi}\mathrm{fr}_v\Big)\,\mathrm{mass}(I_r)\Big(\frac{N^k}{N^k-1}\Big)^{2f} \le (1+b^{-9})\,N^{kf}\,\mathrm{mass}(I_k).$$

Proof. One rank. Fix i with $k \le i < r$. By Lemma 3.2.35 (iii), $\prod_v|\varpi|_v = \mathrm{rd}_E^f$, so

$$\log\prod_{v\in\Phi}\mathrm{sph}_{i+1}(v) = -f\Big((i+\tfrac{1}{2})\log\mathrm{rd}_E + \log i! - (i+1)\log(2\pi)\Big).$$

By (S3) of Lemma 5.2.12, $8f \le 2^\varrho$ and $4\varrho+12 \le k \le i$. Hence Lemma 5.6.10, with $j = i$ and $u = \varrho$, gives

$$\Big|\log\prod_v\mathrm{sph}_{i+1}(v) - \big(\log\mathrm{mass}(I_i) - \log\mathrm{mass}(I_{i+1})\big)\Big| \le \frac{2}{2^\varrho}.$$

Telescoping. Summing over the $r-k$ values of i, the masses telescope:

$$\log\prod_{i=k}^{r-1}\prod_v\mathrm{sph}_{i+1}(v) + \log\mathrm{mass}(I_r) - \log\mathrm{mass}(I_k) \le (r-k)\,2^{1-\varrho}.$$

Since $N \ge 2$ and $k \ge 1$, $N^k - 1 \ge N/2$, so $\log\frac{N^k}{N^k-1} \le \frac{N^k}{N^k-1} - 1 = \frac{1}{N^k-1} \le \frac{2}{N}$. As $\prod_v\mathrm{fr}_v = N^{kf}\prod_i\prod_v\mathrm{sph}_{i+1}(v)$, the logarithm of the left side of the claim minus $\log\big(N^{kf}\mathrm{mass}(I_k)\big)$ is at most

$$(r-k)\,2^{1-\varrho} + 2f\cdot\frac{2}{N} \le \frac{2b^{-9}}{b^{-9}+2} \le \log(1+b^{-9}),$$

by the first clause of (S3) of Lemma 5.2.12 and the elementary inequality $\log(1+t) \geq 2t/(t+2)$ for $t \geq 0$ (both sides vanish at $t = 0$, and the derivatives are $1/(1+t) \geq 4/(t+2)^2$). Exponentiating gives the claim. □

Lemma 5.6.14. *Let D be admissible data and fix representatives h_c of the classes $c \in \mathcal{C}$.*

(a) For each $v \in \Phi$ there is a linear isomorphism $A_v \colon W_{\lambda_v} \to \mathbb{C}^{I_v}$ with $A_v(\rho_{\lambda_v}(h^{\mathsf{T}})x) = A_v(x)\,\rho_v(h)$ for all $h \in \mathrm{U}(k)$ and $x \in W_{\lambda_v}$; put $A = \bigotimes_v A_v \colon W_\lambda \to \mathbb{C}^I$.

(b) The map $\theta \colon \mathcal{S} \to \mathbb{C}^{\mathcal{C}\times I}$, $\theta(\varphi)_{(c,\cdot)} = A\big(\varphi(h_c u_0)\big)$, where u_0 acts on X_0 as a scalar, is a linear isomorphism. In particular $\dim \mathcal{S} = \#\mathcal{C} \cdot \#I \geq 1$.

Proof. (a). By Proposition 5.7.3 (ii), ρ_v is isomorphic to the transpose of the Schur functor of the column count of v; the Schur module of GL_k is formed from the columns of height $t < k$, and $\mathrm{cols}_v(t) = 0$ for $1 < t < k$ (Definition 2.3.4), so its diagram is one row of length $\mathrm{cols}_v(1)$, the one-row weight λ_v (as in Lemma 5.6.8): there is an invertible matrix B_v, with rows indexed by the Weyl coordinates and columns by I_v, such that $B_v\rho_v(h) = \rho_{\lambda_v}(h^{\mathsf{T}})^{\mathsf{T}}B_v$ for all $h \in \mathrm{U}(k)$. Put $A_v(x) = x^{\mathsf{T}}B_v$ for a coordinate column vector x. Then $A_v(\rho_{\lambda_v}(h^{\mathsf{T}})x) = x^{\mathsf{T}}\rho_{\lambda_v}(h^{\mathsf{T}})^{\mathsf{T}}B_v = x^{\mathsf{T}}B_v\rho_v(h) = A_v(x)\rho_v(h)$, and A_v is bijective because B_v is invertible.

Translation by u_0. The idele $u_0 = (a/\bar{a})^{\lceil m/2\rceil}$ satisfies $u_0\bar{u}_0 = 1$, so the scalar matrix $u_0 \cdot 1_k$ lies in $\mathrm{U}(X_0)(\mathbb{A}_f)$ and is central there. Hence $R(u_0)\varphi = \varphi(\,\cdot\, u_0)$ maps $\mathcal{S}$ to itself: for $\gamma \in \mathrm{U}(X_0)(E^+)$ and $\omega \in K_0$, $\varphi(\gamma g\omega u_0) = \varphi(\gamma g u_0 \omega) = \gamma \cdot \varphi(g u_0)$. It is invertible, with inverse $R(u_0^{-1})$.

Evaluation at the classes. Put $\Gamma = \mathrm{U}(X_0)(E^+)$ and $G_f = \mathrm{U}(X_0)(\mathbb{A}_f)$. The map $\mathrm{ev} \colon \mathcal{S} \to W_\lambda^{\mathcal{C}}$, $\varphi \mapsto (\varphi(h_c))_c$, is linear. It is injective: every $g \in G_f$ is $\gamma h_c \omega$ with $\gamma \in \Gamma$, $\omega \in K_0$, and then $\varphi(g) = \gamma \cdot \varphi(h_c)$. It is surjective: given $(w_c)_c$, define $\varphi(\gamma h_c \omega) = \gamma \cdot w_c$; if $\gamma h_c \omega = \gamma' h_c \omega'$ then $\gamma'^{-1}\gamma = h_c\omega'\omega^{-1}h_c^{-1} \in \Gamma \cap h_c K_0 h_c^{-1} = \{1\}$ by Lemma 5.6.6, so φ is well defined, and it satisfies $\varphi(\gamma'' g \omega'') = \gamma'' \cdot \varphi(g)$ by construction.

(b). $\theta = (A^{\mathcal{C}}) \circ \mathrm{ev} \circ R(u_0)$ followed by the identification $(\mathbb{C}^I)^{\mathcal{C}} = \mathbb{C}^{\mathcal{C}\times I}$, a composition of linear isomorphisms. So $\dim \mathcal{S} = \#\mathcal{C} \cdot \#I$; $\mathcal{C}$ is nonempty and finite by Lemma 5.6.6, and each I_v is nonempty (a Bessel system has a nonempty index set), so $\dim \mathcal{S} \geq 1$. □

Definition 5.6.15. Let D be admissible data, $\mathfrak{S}$ a filling datum over E whose space V is Y_0 (the same basis vectors and hermitian form, so that $\mathrm{U}(Y_0) = G$ with the same rational points), with its classes $\mathcal{C}$, representatives h_c, Bessel coordinates I, Bessel functions W^{full} and the cutoff datum fixed with it, and let $\eta \in G(\mathbb{A}_f)$; the objects below depend on $(\mathfrak{S}, \eta)$, which is not written. Regard $\mathrm{U}(Y_0)(\mathbb{A}) = G(\mathbb{A}) = G(F_\infty) \times G(\mathbb{A}_f)$ as a group of operators, $G(F_\infty) = \prod_{v\in\Phi} \mathrm{U}(Y_0 \otimes_{E,v} \mathbb{C})$, matrices being taken in the basis of Y_0. Let s be the signs of Y_0, read on the basis $e_1, \dots, e_\varrho$, the basis of X_0, z, $e_1^*, \dots, e_\varrho^*$, and let p be a sign frame for s. For $v \in \Phi$ let B_v be the diagonal matrix of the basis scales bs_v and P_v the matrix of the frame of Y_0 at v.

Class coordinates. The **class coordinates** of $x \in G(\mathbb{A})$ for p are

$$\mathbf{y}_p(x) = \big(B_v^{-1} x_v P_v p^{-1}\big)_{v\in\Phi}. \tag{5.96}$$

Class-cut Bessel functions. For $a = (c, i) \in \mathcal{C} \times I$ the **class-cut Bessel function** is the function on $G(\mathbb{A})$

$$f_{a,p}(x) = \beta_c(\mathbf{y}_p(x))\, W_i^{\mathrm{full}}(\mathbf{y}_p(x))\, \mathbf{1}\big[x_f \in \eta^{-1} h_c \mathrm{K}_M\big]$$

when $\mathbf{y}_p(x) \in G_\infty$, and $f_{a,p}(x) = 0$ otherwise.

Class Poincaré series. The **class Poincaré series** of a is $\Pi_{a,p}(x) = \sum_{\gamma\in G(E)} f_{a,p}(\gamma x)$ for those $x \in G(\mathbb{A})$ at which the sum converges absolutely, and $\Pi_{a,p}(x) = 0$ at the other x.

Where p is fixed by the statement, it is not written: $\mathbf{y}$, f_a, Π_a.

Let D be admissible data. From here on, the class coordinates $\mathbf{y}_p$, the class-cut Bessel functions $f_{a,p}$ and the class Poincaré series $\Pi_{a,p}$ of D are those of the pair $(\mathfrak{S}_D, \eta)$, where $\mathfrak{S}_D$ is the filling datum and $\eta = \iota(u_0^{-1} 1_{X_0}) \in G(\mathbb{A}_f)$ the element of Proposition 5.6.4, (ii); its space is Y_0, as that statement says.

The scaled Poincaré map has amplitude blocks (Proposition 5.6.16), by the classical unfolding of a Poincaré series [234]. The Poincaré map represents Bessel periods [96, 153, 2], and in the coordinates of Proposition 5.6.4 it is described by class Poincaré series, sums over the rational points of a Bessel function at the infinite places (Lemma 5.6.18). The Petersson product of a translate of one such series with another unfolds into a sum of amplitudes over terms: the rational points that are integral between the two class representatives and reduce to the given level element, each weighted by an integral over G_∞ of one Bessel function against a translate of the other. From here on the second moment is a statement about sums of amplitudes over terms. For the convergence of Poincaré series on semisimple groups see [120, 38]; the same unfolding underlies the Rankin–Selberg method [148].

Proposition 5.6.16. *Let D be admissible data, and let Π_a ($a \in \mathcal{C} \times I$) be the class Poincaré series of Lemma 5.6.18, formed with the sign frame p of the Bessel systems of $\mathfrak{S}_D$, and suppose that $\mathcal{P}\varphi = \sum_{a \in \mathcal{C}\times I} \theta(\varphi)_a \, \Pi_a$ for every $\varphi \in \mathcal{S}$. Fix a Haar measure dg_f on G_f and put $V_M = \mathrm{vol}(\mathrm{K}_M)$; let dg_∞ be the Haar measure on $G_\infty^{Y_0}$ whose image under $g \mapsto \mathbf{y}((P_v g_v P_v^{-1})_v)$ is dy, and let the Petersson product on $\mathcal{A}_M(Y_0)$ be formed with the quotient of $dg_\infty \otimes dg_f$ by the counting measure on Γ_{Y_0}. Let ρ be the action of $\bar{G}$ on $\mathcal{A}_M(Y_0)$, which is unitary, and $c_{\mathcal{P}} = (V_M \nu)^{-1/2}$. Then:*

(i) (Petersson unfolding) for $k \in \mathrm{K}_f$ with reductions $s \in \bar{G}$ at the chosen places and $a = (c, i)$, $a' = (c', i') \in \mathcal{C} \times I$, the series defining $A^{\mathrm{full}}_{G(E)}(c, s, c')$ converges absolutely and

$$\langle \rho(k)\Pi_{a'}, \Pi_a \rangle = V_M \, A^{\mathrm{full}}_{G(E)}(c, s, c')_{i,i'};$$

(ii) the scaled Poincaré map $L = c_{\mathcal{P}}\, \mathcal{P} \circ \theta^{-1} \colon \mathbb{C}^{\mathcal{C}\times I} \to \mathcal{A}_M(Y_0)$ has amplitude blocks for ρ (TA6): $\langle \rho(s) L e_y, L e_x \rangle = \nu^{-1} A^{\mathrm{full}}_{G(E)}(c_x, s, c_y)_{i_x, i_y}$ for all $s \in \bar{G}$ and $x = (c_x, i_x)$, $y = (c_y, i_y)$; equivalently the (c, c') block of $L^* \rho(s) L$ is $\nu^{-1} \overline{A^{\mathrm{full}}_{G(E)}(c, s, c')}$.

Proof. The measure dg_∞ exists and is unique: $g \mapsto \mathbf{y}((P_v g_v P_v^{-1})_v) = t \cdot (p g_v p^{-1})_v$ with $t = (B_v^{-1} P_v p^{-1})_v \in G_\infty$ is a group isomorphism $g \mapsto (p g_v p^{-1})_v$ followed by a left translation, so it carries Haar measures to Haar measures. Work on $G(\mathbb{A}) = G(F_\infty) \times G(\mathbb{A}_f)$ (operators), with $\Gamma = G(E)$ and the Haar measure $\mu = \mu_\infty \otimes \mu_f$ that corresponds through the frames to $dg_\infty \otimes dg_f$; then $\mu_f(\mathrm{K}_M) = V_M$ (conjugation by the finite frame carries the principal level of (HO1) onto the operator group K_M), and $\int_{G(F_\infty)} \phi(\mathbf{y}(x))\, d\mu_\infty(x) = \int_{G_\infty} \phi \, dy$ for $\phi \geq 0$ measurable, by the choice of dg_∞. Γ is a discrete subgroup of the second countable locally compact group $G(\mathbb{A})$ (as E is discrete in $\mathbb{A}_E$), so by Lemma 5.6.20 it has a Borel fundamental set F_Γ, and the Petersson product is $\langle F, F' \rangle = \int_{F_\Gamma} \overline{F} F' \, d\mu$.

Step 1: the finite condition. Let k be as in (i), $\tilde{k} = \eta^{-1} k \eta$ (operators), so $\tilde{k} \in K$ and $\mathrm{red}(\tilde{k}) = s$ by Proposition 5.6.4 (ii). Let $x_f \in \Omega_c$ and $\gamma \in \Gamma$. Then $\gamma^{-1} x_f k \in \Omega_{c'}$ if and only if γ is a term over (c, s, c'). Indeed, $\mathrm{K}_M = \eta \mathrm{K}(M) \eta^{-1}$ and η commutes with $h_c \in \iota(\mathrm{U}(X_0)(\mathbb{A}_f))$ (Proposition 5.6.4 (ii)), so $\Omega_c = \eta^{-1} h_c \eta \mathrm{K}(M) \eta^{-1} = h_c \mathrm{K}(M) \eta^{-1}$ and $x_f = h_c m \eta^{-1}$ with $m \in \mathrm{K}(M)$, and with $t = h_c^{-1} \gamma h_{c'}$,

$$\gamma^{-1} x_f k \in h_{c'} \mathrm{K}(M) \eta^{-1} \iff t^{-1} m \tilde{k} \in \mathrm{K}(M) \iff t \in m \tilde{k}\, \mathrm{K}(M) = \{t' \in K : \mathrm{red}(t') = s\},$$

the last equality because $\mathrm{K}(M)$ is the kernel of $\mathrm{red} \colon K \to \bar{G}$ and $\mathrm{red}(m\tilde{k}) = s$.

Step 2: the series at the class point. Let $x \in G(F_\infty)$. Since $B_v^{-1}\gamma^{-1}B_v = (\gamma^{-1})_v$ by (5.5), $\mathbf{y}(\gamma^{-1}x) = \gamma^{-1}\mathbf{y}(x)$, and right translation by k does not change the archimedean part. As $\eta^{-1}h_c \in \Omega_c$, Step 1 says that the finite factor $\mathbf{1}[\gamma^{-1}\eta^{-1}h_c k \in \Omega_{c'}]$ of $f_{a'}(\gamma^{-1}(x,\eta^{-1}h_c)k)$ is 1 if γ is a term over (c,s,c') and 0 otherwise. Summing over $\gamma^{-1} \in \Gamma$ (the series converges absolutely by Lemma 5.6.18 (i)),

$$\Pi_{a'}((x,\eta^{-1}h_c)k) = \sum_{\gamma \text{ over } (c,s,c')} \beta_{c'}(\gamma^{-1}\mathbf{y}(x))\, W_{i'}^{\mathrm{full}}(\gamma^{-1}\mathbf{y}(x)).$$

Step 3: folding, proof of (i). The function $z(x) = \overline{\Pi_{a'}(xk)} = \overline{(\rho(k)\Pi_{a'})(x)}$ on $G(\mathbb{A})$ is bounded and Borel by Lemma 5.6.18 (i), left Γ-invariant, and right K_M-invariant: K_M is the kernel of the reduction $\mathrm{K}_f \to \bar{G}$ ((HO1)), hence normalised by k, and for $k' \in \mathrm{K}_M$, $\Pi_{a'}(xk'k) = \Pi_{a'}(xk\,(k^{-1}k'k)) = \Pi_{a'}(xk)$ by the right K_M-invariance of $\Pi_{a'}$ (Lemma 5.6.18 (ii)). By Lemma 5.6.17 (ii) for z and a, Step 2, the transport of μ_∞ to dy and the reality of the cutoffs,

$$\langle \rho(k)\Pi_{a'}, \Pi_a\rangle = \int_{F_\Gamma} z\,\Pi_a\, d\mu = V_M \int_{G_\infty} \sum_{\gamma \text{ over } (c,s,c')} \beta_c(y)\beta_{c'}(\gamma^{-1}y)\, W_i^{\mathrm{full}}(y)\, \overline{W_{i'}^{\mathrm{full}}(\gamma^{-1}y)}\, dy.$$

The integral over G_∞ of the absolute value of the term of γ is at most the amplitude majorant $M_\gamma(c,c')$ of (TA2) (an entry of $W(y) \otimes \overline{W(\gamma^{-1}y)}$ is at most its Hilbert–Schmidt norm), and $\sum_{\gamma \text{ over } (c,s,c')} M_\gamma(c,c') < \infty$ by Lemma 5.2.29 (ii) (with $T = G(E)$, $F_v = W_v$). So the series $\sum_\gamma A_\gamma(c,c')$ over the terms over (c,s,c') converges absolutely, $A^{\mathrm{full}}_{G(E)}(c,s,c')$ is defined, and by Fubini's theorem for the product of counting measure and dy the right side is $V_M \sum_\gamma A_\gamma(c,c')_{i,i'} = V_M\, A^{\mathrm{full}}_{G(E)}(c,s,c')_{i,i'}$.

Step 4: proof of (ii). By Proposition 5.8.4 (with $V = V' = Y_0$, using its (iii)) $\mathcal{A}_M(Y_0)$ is finite-dimensional; the Petersson product is positive definite on it, since a continuous F with $\int_{F_\Gamma} |F|^2 d\mu = 0$ vanishes μ-almost everywhere on $\Gamma F_\Gamma = G(\mathbb{A})$, hence everywhere; and ρ is unitary: for $k \in G(\mathbb{A}_f)$, $F_\Gamma k$ is again a Borel fundamental set and μ is right invariant ($G(\mathbb{A})$ is unimodular), so $\langle \rho(k)F, \rho(k)F'\rangle = \int_{F_\Gamma k} \overline{F}F'\, d\mu$; and for two Borel fundamental sets F_1, F_2 and an integrable Γ-invariant φ on them, $F_1 = \bigsqcup_{\gamma\in\Gamma}(F_1 \cap \gamma F_2)$ and $F_2 = \bigsqcup_\gamma(\gamma^{-1}F_1 \cap F_2)$ (left multiplication is free), so $\int_{F_1} \varphi\, d\mu = \sum_\gamma \int_{\gamma^{-1}F_1 \cap F_2} \varphi\, d\mu = \int_{F_2} \varphi\, d\mu$ by left invariance of μ. Since θ is a linear isomorphism (Proposition 5.6.4 (iii)), the hypothesis on $\mathcal{P}$ gives $\mathcal{P}\theta^{-1}e_a = \sum_{b\in\mathcal{C}\times I}(e_a)_b\,\Pi_b = \Pi_a$ for $a \in \mathcal{C}\times I$, so $Le_a = c_{\mathcal{P}}\Pi_a$, where $V_M > 0$ and $\nu > 0$ ($|\mathrm{rs}_v| \geq 1$ by (FA4), so $\Lambda_{\mathrm{fr}} > 0$). For $s \in \bar{G}$ choose $k \in \mathrm{K}_f$ with reductions s (reduction $\mathrm{K}_f \to \bar{G}$ is onto by (HO1)); then $\rho(s) = \rho(k)$ and by (i)

$$\langle \rho(s)Le_y, Le_x\rangle = c_{\mathcal{P}}^2\,\langle \rho(k)\Pi_y, \Pi_x\rangle = \frac{V_M}{V_M\nu} A^{\mathrm{full}}_{G(E)}(c_x, s, c_y)_{i_x,i_y},$$

which is (TA6). Finally $(L^*\rho(s)L)_{x,y} = \langle Le_x, \rho(s)Le_y\rangle = \overline{\langle \rho(s)Le_y, Le_x\rangle}$ gives the block form. □

Lemma 5.6.17. *Let D be admissible data, $G = \mathrm{U}(Y_0)$, $G(\mathbb{A}) = G(F_\infty) \times G(\mathbb{A}_f)$ as a group of operators, $\Gamma = G(E)$, and let p be a matrix with the properties required of it in Lemma 5.6.18, with f_a, Π_a formed for it. Let $\mu = \mu_\infty \otimes \mu_f$ be a left Haar measure of $G(\mathbb{A})$ with μ_∞, μ_f left Haar measures of $G(F_\infty)$, $G(\mathbb{A}_f)$, put $V_M = \mu_f(\mathrm{K}_M)$, and let $F_\Gamma \subseteq G(\mathbb{A})$ be a Borel set meeting every orbit Γx in exactly one point. Let $z\colon G(\mathbb{A}) \to \mathbb{C}$ be a bounded Borel function with $z(\gamma x) = z(x)$ and $z(xk) = z(x)$ for $\gamma \in \Gamma$, $k \in \mathrm{K}_M$, $x \in G(\mathbb{A})$. Then for every $a = (c,i) \in \mathcal{C}\times I$:*

(i) *f_a is integrable on $G(\mathbb{A})$, $z\,\Pi_a$ is integrable on F_Γ, and the function*

$$x \mapsto \beta_c(\mathbf{y}(x))\, W_i^{\mathrm{full}}(\mathbf{y}(x))\, z(x, \eta^{-1} h_c)$$

is integrable on $G(F_\infty)$, where $(x, \eta^{-1}h_c)$ is the element with archimedean component x and finite component $\eta^{-1}h_c$;

(ii)

$$\int_{F_\Gamma} z\,\Pi_a\, d\mu = \int_{G(\mathbb{A})} z\, f_a\, d\mu = V_M \int_{G(F_\infty)} \beta_c(\mathbf{y}(x))\, W_i^{\mathrm{full}}(\mathbf{y}(x))\, z(x, \eta^{-1}h_c)\, d\mu_\infty(x).$$

Proof. Write $\Omega_c = \eta^{-1} h_c \mathrm{K}_M$, an open subset of $G(\mathbb{A}_f)$, so that

$$f_a(x) = \beta_c(\mathbf{y}(x))\, W_i^{\mathrm{full}}(\mathbf{y}(x))\, \mathbf{1}_{\Omega_c}(x_f)$$

for $x = (x_\infty, x_f)$, with $\mathbf{y}(x)$ depending only on x_∞ (Definition 5.6.15); f_a is Borel, as β_c is Borel, W_i^{full} and $\mathbf{y}$ are continuous and Ω_c is open. By Lemma 5.6.18 (i) there is a constant C with $\sum_{\gamma\in\Gamma} |f_a(\gamma x)| \le C$ for every $x \in G(\mathbb{A})$; in particular $\Pi_a(x) = \sum_{\gamma\in\Gamma} f_a(\gamma x)$ converges absolutely at every x, and Π_a is Borel as a pointwise limit of finite sums of Borel functions (Γ is countable).

Step 1: the fundamental set. Γ is discrete in $G(\mathbb{A})$, because E is discrete in $\mathbb{A}_E$, and it acts freely by left multiplication; as F_Γ meets every orbit in exactly one point, $G(\mathbb{A}) = \bigsqcup_{\gamma\in\Gamma} \gamma F_\Gamma$. By left invariance of μ, $\mu(F_\Gamma)$ is the volume of $\Gamma\backslash G(\mathbb{A})$ for the quotient of μ by counting measure, which is finite by [37], for the hermitian space Y_0 over the CM extension E/E^+. Hence, for every Borel $\phi \ge 0$ on $G(\mathbb{A})$, by left invariance and monotone convergence,

$$\int_{G(\mathbb{A})} \phi\, d\mu = \sum_{\gamma\in\Gamma} \int_{F_\Gamma} \phi(\gamma x)\, d\mu(x) = \int_{F_\Gamma} \sum_{\gamma\in\Gamma} \phi(\gamma x)\, d\mu(x). \tag{5.97}$$

Step 2: integrability. With $\phi = |f_a|$, (5.97) gives $\int_{G(\mathbb{A})} |f_a|\, d\mu \le C\mu(F_\Gamma) < \infty$. Let $\|z\|_\infty$ be a bound of $|z|$. Then $|z\Pi_a| \le \|z\|_\infty C$ on F_Γ, which has finite measure, so $z\Pi_a$ is integrable on F_Γ; and $|z f_a| \le \|z\|_\infty |f_a|$ is integrable on $G(\mathbb{A})$.

Step 3: unfolding. By the invariance of z, $z(x)\Pi_a(x) = \sum_\gamma z(\gamma x) f_a(\gamma x)$ for every x, and $\sum_\gamma |z(\gamma x) f_a(\gamma x)| \le \|z\|_\infty C$. By the dominated convergence theorem on F_Γ (the partial sums are dominated by the constant $\|z\|_\infty C$), then left invariance and the disjoint decomposition of Step 1 (that is, (5.97) applied to the positive and negative parts of the real and imaginary parts of the integrable function $z f_a$),

$$\int_{F_\Gamma} z\,\Pi_a\, d\mu = \sum_{\gamma\in\Gamma} \int_{F_\Gamma} z(\gamma x) f_a(\gamma x)\, d\mu(x) = \sum_{\gamma\in\Gamma} \int_{\gamma F_\Gamma} z\, f_a\, d\mu = \int_{G(\mathbb{A})} z\, f_a\, d\mu,$$

the last series converging absolutely by (5.97) for $\phi = |z f_a|$.

Step 4: the finite variable. If $x_f \in \Omega_c$, then $x_f = \eta^{-1} h_c k$ with $k \in \mathrm{K}_M$, so $z(x_\infty, x_f) = z((x_\infty, \eta^{-1}h_c)k) = z(x_\infty, \eta^{-1}h_c)$. Hence $z(x) f_a(x) = A(x_\infty)\, \mathbf{1}_{\Omega_c}(x_f)$ with

$$A(x_\infty) = \beta_c(\mathbf{y}(x_\infty))\, W_i^{\mathrm{full}}(\mathbf{y}(x_\infty))\, z(x_\infty, \eta^{-1}h_c),$$

a Borel function on $G(F_\infty)$ (a section of the Borel function z is Borel). By left invariance $\mu_f(\Omega_c) = \mu_f(\mathrm{K}_M) = V_M$, and $0 < V_M < \infty$ as K_M is open and compact. By Tonelli's theorem for $\mu_\infty \otimes \mu_f$, $\int |z f_a|\, d\mu = V_M \int_{G(F_\infty)} |A|\, d\mu_\infty$, which is finite by Step 2, so A is integrable; and by Fubini's theorem $\int_{G(\mathbb{A})} z f_a\, d\mu = V_M \int_{G(F_\infty)} A\, d\mu_\infty$. With Step 3 this proves (ii), and (i) is Steps 2 and 4. □

Lemma 5.6.18. *Let D be admissible data and $\mathfrak{S}_D$ the filling datum of Proposition 5.6.4, with its fixed cutoff datum. Let s be the signs of Y_0 and p a sign frame for s such that for every $v \in \Phi$ and $y \in G_1$*

$$\int_{\mathrm{U}(\mathrm{diag}\, s)} d_{\varsigma(v)}\, \overline{c_{\varsigma(v)}(g)}\, W_v(y\, pgp^{-1})\, dg = W_v(y), \tag{5.98}$$

the formal degree being taken for the Haar measure dg. Write $\mathbf{y} = \mathbf{y}_p$, $f_a = f_{a,p}$ and $\Pi_a = \Pi_{a,p}$ for $a \in \mathcal{C} \times I$. Then $\mathbf{y}(x) \in G_\infty$ for every $x \in G(\mathbb{A})$, so that for $a = (c, i)$

$$f_a(x) = \beta_c(\mathbf{y}(x))\, W_i^{\mathrm{full}}(\mathbf{y}(x))\, \mathbf{1}[x_f \in \eta^{-1} h_c \mathrm{K}_M] \qquad (x \in G(\mathbb{A})),$$

and:

(i) for every $x \in G(\mathbb{A})$,

$$\sum_{\gamma \in G(E)} |f_a(\gamma x)| \le 2\, b^{12n^3 rf} \prod_{v \in \Phi} a_v;$$

in particular $\Pi_a(x) = \sum_{\gamma \in G(E)} f_a(\gamma x)$, the series converging absolutely, for every x;

(ii) the class Poincaré series Π_a, read on $G_\infty^{Y_0} \times G_f$ through the frames of Y_0 ($G_\infty^{Y_0} = \prod_v \mathrm{U}(\mathrm{diag}\, s)$), lies in $\mathcal{A}_M(Y_0)$.

Proof. By Proposition 5.6.4 (i), $\mathfrak{S}_D$ is admissible and E carries Weil data. Write $\Omega_c = \eta^{-1} h_c \mathrm{K}_M \subseteq G(\mathbb{A}_f)$, an open set.

Step 1: properties of $\mathbf{y}$ *and* Ω_c. Let H_v be the Gram matrix of $Y_0 \otimes_{E,v} \mathbb{C}$. By (RD1), $B_v^* H_v B_v = J_1$; by the frame condition of (VP3) of Definition 3.2.2 (as in (FT1)), $P_v^* H_v P_v = \mathrm{diag}(s)$; and $p^{-*}\mathrm{diag}(s) p^{-1} = J_1$. Hence for $x_v \in \mathrm{U}(H_v)$ the matrix $z = B_v^{-1} x_v P_v p^{-1}$ satisfies $z^* J_1 z = p^{-*} P_v^* x_v^* H_v x_v P_v p^{-1} = J_1$, so $\mathbf{y}(x) \in G_\infty$; and $\mathbf{y}$ is a homeomorphism $G(F_\infty) \to G_\infty$, being a product of left and right multiplications by fixed invertible matrices. Moreover:

(a) $\mathbf{y}(\gamma x) = \gamma_\infty \mathbf{y}(x)$ for $\gamma \in G(E)$, since $B_v^{-1} \gamma x_v P_v p^{-1} = (B_v^{-1} \gamma B_v)(B_v^{-1} x_v P_v p^{-1})$ and $B_v^{-1} \gamma B_v = \gamma_v$ by (5.5);

(b) $\mathbf{y}(x\,(P_v g_v P_v^{-1})_v) = \big(\mathbf{y}(x)_v\, pg_v p^{-1}\big)_v$ for $(g_v) \in \prod_v \mathrm{U}(\mathrm{diag}\, s)$;

(c) if $\gamma, \delta \in G(E)$ and $\gamma x_f, \delta x_f \in \Omega_c$, then $\delta\gamma^{-1}$ is a term over $(c, 1, c)$: writing $\gamma x_f = \eta^{-1} h_c k_1$, $\delta x_f = \eta^{-1} h_c k_2$ with $k_2 k_1^{-1} = \eta m \eta^{-1}$, $m \in \mathrm{K}(M)$ (Proposition 5.6.4 (ii): $\mathrm{K}_M = \eta \mathrm{K}(M) \eta^{-1}$), and since η commutes with h_c, which lies in $\iota(\mathrm{U}(X_0)(\mathbb{A}_f))$, we get $\delta\gamma^{-1} = \eta^{-1} h_c \eta m \eta^{-1} h_c^{-1} \eta = h_c m h_c^{-1}$, so $h_c^{-1}(\delta\gamma^{-1}) h_c = m \in \mathrm{K}(M) \subseteq K$ has reduction 1;

(d) $u\,\Omega_c = \Omega_c$ for $u \in \mathsf{U}_c(M)$: as above $\Omega_c = h_c \mathrm{K}(M) \eta^{-1}$, and $u h_c \mathrm{K}(M) = h_c (h_c^{-1} u h_c) \mathrm{K}(M) = h_c \mathrm{K}(M)$;

(e) $\Omega_c k = \Omega_c$ for $k \in \mathrm{K}_M$.

Since $\mathbf{y}(x) \in G_\infty$ for every x, the case $\mathbf{y}_p(x) \notin G_\infty$ of the definition of $f_{a,p}$ does not occur, and f_a is given by the displayed formula of the statement. The function f_a is Borel: β_c is Borel, W_i^{full} and $\mathbf{y}$ are continuous, Ω_c is open.

Step 2: proof of (i). Fix x. If no $\delta \in G(E)$ has $\delta x_f \in \Omega_c$, every term vanishes. Otherwise fix such a δ and put $y_0 = \mathbf{y}(\delta x)$. If $f_a(\gamma x) \neq 0$ then $\gamma x_f \in \Omega_c$, so $\tau = \delta\gamma^{-1}$ is a term over $(c, 1, c)$ by (c), and $\gamma = \tau^{-1}\delta$; the map $\gamma \mapsto \tau$ is injective. By (a), $\mathbf{y}(\gamma x) = \tau^{-1} y_0$, and $|W_i^{\mathrm{full}}(z)| = \prod_v |W_{v,i_v}(z_v)| \le \prod_v \|W_v(z_v)\|$. Hence

$$\sum_\gamma |f_a(\gamma x)| \le \sum_{\tau \text{ over } (c,1,c)} \beta_c(\tau^{-1} y_0) \prod_v \|W_v((\tau^{-1} y_0)_v)\|,$$

which is at most $2b^{12n^3rf}\prod_v a_v$ by Lemma 5.2.29 (i) with $s=1$, $T=G(E)$ and $F_v=W_v$ (the right side is the part $d=c$ of its sum). So the series $\sum_\gamma f_a(\gamma x)$ converges absolutely at every x, and by the definition of $\Pi_{a,p}$ its value is $\Pi_a(x)$.

Step 3: coset sums. Let $u\in \mathsf{U}_c(M)$ and $x\in G(\mathbb{A})$. By (a), (d) and Lemma 5.2.42,

$$f_a(ux)=\beta_c(u\cdot \mathbf{y}(x))\,W_i^{\mathrm{full}}(\mathbf{y}(x))\,\mathbf{1}[x_f\in\Omega_c].$$

By (RD6) the weights $a(u)=\beta_c^0(u\cdot z)$ ($z\in G_\infty$) have sum 1 over every right coset $\mathsf{U}_c^0(M)u'$, so by Lemma 5.2.21 and (RD5) $\sum_{u\in\mathsf{U}_c(M)}\beta_c(u\cdot z)=\sum_u a(u)\mathbf{1}_{\mathrm{red}}(u\cdot z)=1$. Let $D\subseteq G(E)$ contain one element of every right coset $\mathsf{U}_c(M)\delta$. By (i) the series $\Pi_a(x)$ converges absolutely, so it may be summed coset by coset:

$$\Pi_a(x)=\sum_{\delta\in D}F_\delta(x),\qquad F_\delta(x)=\sum_{u\in\mathsf{U}_c(M)}f_a(u\delta x)=W_i^{\mathrm{full}}(\mathbf{y}(\delta x))\,\mathbf{1}[\delta x_f\in\Omega_c],\tag{5.99}$$

and $\sum_{\delta\in D}|F_\delta(x)|\le\sum_\gamma|f_a(\gamma x)|$ is bounded by the constant C of (i).

Step 4: the type kernel is integrable. By Proposition 5.8.4 (iii), ς has gap Δ for Y_0 in the sense of (HO2). The entries of $\varsigma(v)$ are integers, so $l=2\varsigma(v)$ has even entries, which are congruent to $r-1$ modulo 2 because r is odd (Definition 2.3.4: $r=3^{e'+1}$); they are distinct, and $|l_i-l_j|\ge 2\Delta$ whenever $s_i\ne s_j$. As $\Delta=2r^8\ge 500r^3$, l has gap $500r^3$ for s in the sense of (DZ1). By Lemma 5.6.21 with $N=r$, $B=0$, the type kernel $e=e_\varsigma$, $e(g)=\prod_v e_v(g_v)$ with $e_v=d_{\varsigma(v)}\overline{c_{\varsigma(v)}}$, is a cusp kernel of order 0, in particular continuous and integrable with $e(1)\ne 0$. Then each e_v is continuous with $e_v(1)\ne 0$, so $0<\int|e_v|$, and $\prod_v\int|e_v|=\int|e|<\infty$ gives $e_v\in L^1$.

Step 5: proof of (ii). Read through the frames (the coordinate map of (VP3) of Definition 3.2.2), x corresponds to (g_∞,g_f) with $x_v=P_vg_vP_v^{-1}$, $x_f=Fg_fF^{-1}$ (F the finite frame), Γ_{Y_0} to $G(E)$, right translation by $(g,1)$ to $x\mapsto x(P_vg_vP_v^{-1})_v$, and K_M of (HO1) to the operator group K_M. *Invariance and bound.* For $\gamma'\in G(E)$, $\Pi_a(\gamma' x)=\sum_\gamma f_a(\gamma\gamma' x)=\Pi_a(x)$ by reindexing the absolutely convergent series; $f_a(xk)=f_a(x)$ for $k\in\mathrm{K}_M$ by (e), so Π_a is right K_M-invariant; $|\Pi_a|\le C$ by (i); and Π_a is Borel as a pointwise limit of Borel partial sums. *Type.* For $\delta\in D$ and $g=(g_v)_v$, by (b) the finite part is unchanged and

$$F_\delta(x(P_vg_vP_v^{-1})_v)=\mathbf{1}[\delta x_f\in\Omega_c]\prod_v W_{v,i_v}(\mathbf{y}(\delta x)_v\,pg_vp^{-1}).$$

The functions W_v are bounded and each e_v is integrable, so by Fubini's theorem and (5.98) at each place, $\int_{G_\infty^{Y_0}}e(g)F_\delta(x(P_vg_vP_v^{-1})_v)\,dg=F_\delta(x)$. As $\sum_\delta|F_\delta|\le C$ everywhere (Step 3) and e is integrable, dominated convergence and (5.99) give

$$\int_{G_\infty^{Y_0}}e(g)\,\Pi_a(x(P_vg_vP_v^{-1})_v)\,dg=\sum_{\delta\in D}F_\delta(x)=\Pi_a(x).$$

Continuity. In frame coordinates this reads

$$\Pi_a(h,g_f)=\int e(g)\Pi_a(hg,g_f)\,dg=\int e(h^{-1}g')\,\Pi_a(g',g_f)\,dg'$$

for $h\in G_\infty^{Y_0}$, by left invariance of dg. Since $e\in L^1$, $h\mapsto e(h^{-1}\cdot)$ is continuous into $L^1(G_\infty^{Y_0})$ (continuity of translation in L^1 of a locally compact group), and $|\Pi_a|\le C$, so $h\mapsto\Pi_a(h,g_f)$ is continuous for each g_f. As Π_a is right invariant under the open subgroup K_M, it is constant in g_f on the open sets $g_f\mathrm{K}_M$, hence continuous on $G_\infty^{Y_0}\times G_f$. Thus Π_a is continuous, bounded, left Γ_{Y_0}-invariant, right K_M-invariant and of type e_ς ((FT2) with e_ς integrable): $\Pi_a\in\mathcal{A}_M(Y_0)$. □

Lemma 5.6.19. *Let $\mathfrak{S}$ be an admissible filling datum. Then:*

(i) a residue domain exists;

(ii) for every class c the map $u \mapsto u_\infty$ is an injective homomorphism of $\mathsf{U}_c^0(M)$ onto a discrete subgroup of G_∞, and there is a Borel set $F_c \subseteq G_\infty$ such that $\beta_c^0 = \mathbf{1}_{F_c}$ satisfies $\sum_{u \in \mathsf{U}_c^0(M)} \beta_c^0(u \cdot y) = 1$ for every $y \in G_\infty$;

(iii) in particular $\mathfrak{S}$ has a cutoff datum.

Proof. Write $\mathbf{v}(x) = (v(x))_{v \in \Phi} \in \mathbb{C}^\Phi$ for $x \in E$, and give $\mathbb{C}^\Phi$ the real inner product $\langle a, a' \rangle = \mathrm{Re} \sum_{v \in \Phi} \bar{a}_v a'_v$, of real dimension $2f$. Since Φ contains exactly one embedding from each pair of complex conjugate embeddings of the CM field E, $\mathbf{v}$ extends to an isomorphism $E \otimes_{\mathbb{Q}} \mathbb{R} \to \mathbb{C}^\Phi$, so $\Gamma = \mathbf{v}(\mathcal{O}_E)$ is a lattice in $\mathbb{C}^\Phi$; moreover $v(\bar{x}) = \overline{v(x)}$, hence for $x, \eta \in E$

$$\langle \mathbf{v}(x), \mathbf{v}(\eta) \rangle = \mathrm{Re} \sum_{v \in \Phi} v(\bar{x}\eta) = \tfrac{1}{2} \mathrm{Tr}_{E/\mathbb{Q}}(\bar{x}\eta). \tag{5.100}$$

Step 1: covering radius of Γ. Let $\mathcal{O}_E^\vee = \{\eta \in E : \mathrm{Tr}_{E/\mathbb{Q}}(x\eta) \in \mathbb{Z} \text{ for all } x \in \mathcal{O}_E\}$, the inverse different; it is stable under complex conjugation, as $\mathcal{O}_E$ is. By (5.100) (extended by linearity to $E \otimes \mathbb{R}$; a point of $E \otimes \mathbb{R}$ pairing integrally with the $\mathbb{Q}$-basis $\mathcal{O}_E$ of E lies in E) the dual lattice is $\Gamma^* = \mathbf{v}(2\mathcal{O}_E^\vee)$. Let $0 \neq \eta \in \mathcal{O}_E^\vee$. By (FG2) ϖ generates the different $(\mathcal{O}_E^\vee)^{-1}$, so $\varpi\eta$ is a nonzero element of $\mathcal{O}_E$ and $\prod_{v \in \Phi} |v(\varpi\eta)|^2 = |N_{E/\mathbb{Q}}(\varpi\eta)| \geq 1$. Hence $|v(\varpi\eta)| \geq 1$ for some v, and by (FA3) $|v(\eta)| \geq 1/|\varpi|_v \geq 1/b$. So every nonzero $u = \mathbf{v}(2\eta) \in \Gamma^*$ has $\|u\| \geq 2|v(\eta)| \geq 2/b$. Banaszczyk's transference theorem [12] gives: for every $t \in \mathbb{C}^\Phi$ there is $x \in \mathcal{O}_E$ with $\|t - \mathbf{v}(x)\| \leq 2f/(2 \cdot 2/b) = fb/2$, in particular $|t_v - v(x)| \leq fb/2$ for every v.

Step 2: (i). Let $B = \{w \in \mathbb{C}^\Phi : |w_v| \leq b^{26} \ (v \in \Phi)\}$, a compact set, and $L = \mathbf{v}(M\mathcal{O}_E)$, a lattice acting on $\mathbb{C}^\Phi$ by translation. For $w \in \mathbb{C}^\Phi$ apply Step 1 to $t = -w/M$: some $x \in \mathcal{O}_E$ has $|v(x) + w_v/M| \leq fb/2$, so by (FG6) ($M \leq b^{23}$, $f \leq b/1000$)

$$|v(Mx) + w_v| \leq \tfrac{Mfb}{2} \leq \tfrac{b^{25}}{2000} \leq b^{26} \qquad (v \in \Phi),$$

that is, $(w + L) \cap B \neq \emptyset$. As L is discrete and B compact, $(w + L) \cap B$ is finite. Identify $\mathbb{C}^\Phi$ with $\mathbb{R}^{2f}$ by real and imaginary parts in a fixed order and let $\leq_{\mathrm{lex}}$ be the lexicographic order; the set $\{(a, a') : a \leq_{\mathrm{lex}} a'\}$ is a finite Boolean combination of the sets $\{a_i < a'_i\}$, $\{a_i = a'_i\}$, hence Borel. Put

$$D_{\mathrm{res}} = \bigcap_{l \in L} \{w \in B : \ w + l \notin B \text{ or } w \leq_{\mathrm{lex}} w + l\},$$

a countable intersection of Borel sets. For each w, the finite nonempty set $(w + L) \cap B$ has a unique $\leq_{\mathrm{lex}}$-least element, and the points of $D_{\mathrm{res}} \cap (w + L)$ are exactly the least elements of $(w + L) \cap B$; so D_{res} meets $w + L$ in exactly one point. Since $x \mapsto \mathbf{v}(Mx)$ is injective, there is exactly one $x \in \mathcal{O}_E$ with $(v(Mx) + w_v)_v \in D_{\mathrm{res}}$, and $D_{\mathrm{res}} \subseteq B$. So D_{res} is a residue domain (RD3).

Step 3: (ii). By (RD1) $\gamma \mapsto \gamma_\infty$ is a homomorphism, and it is injective since every v is injective and the basis scales are nonzero. Let $u \in \mathsf{U}_c^0(M)$. Then $h_c^{-1} u h_c \in \mathrm{K}(M) \subseteq K$, so u preserves the $\hat{\mathcal{O}}$-lattice $h_c L_0$ of (FG3), hence the $\mathcal{O}_E$-lattice $\Lambda_c = V \cap h_c L_0$ of $V = E^r$. Choose nonzero integers d_1, d_2 with $d_1 \mathcal{O}_E^r \subseteq \Lambda_c \subseteq d_2^{-1} \mathcal{O}_E^r$; then $u e_j \in d_1^{-1} u \Lambda_c = d_1^{-1} \Lambda_c \subseteq (d_1 d_2)^{-1} \mathcal{O}_E^r$ for every standard basis vector e_j, so all matrix entries of u lie in $(d_1 d_2)^{-1} \mathcal{O}_E$. By (5.5) the entries of u_v are $v(u_{ij})$ times nonzero constants depending only on (v, i, j). If u_∞ lies in a compact set $C \subseteq G_\infty$, every $|v(u_{ij})|$ is bounded by a constant depending on C, and since $\mathbf{v}((d_1 d_2)^{-1} \mathcal{O}_E)$ is discrete, only finitely many u qualify. So the image Γ_c of $\mathsf{U}_c^0(M)$ meets every compact set in a finite set, and is a discrete subgroup of $G_\infty = \prod_v G_1$, a closed subgroup of

$\prod_v \mathrm{GL}_r(\mathbb{C})$ whose topology has a countable base. By Lemma 5.6.20 there is a Borel $F_c \subseteq G_\infty$ meeting every orbit $\Gamma_c y$ in exactly one point. For $y \in G_\infty$, $u \mapsto u_\infty y$ is injective on $\mathsf{U}_c^0(M)$, so $\sum_{u \in \mathsf{U}_c^0(M)} \mathbf{1}_{F_c}(u_\infty y) = \#(F_c \cap \Gamma_c y) = 1$; and $\mathbf{1}_{F_c}$ is measurable with values in $[0,1]$.

Step 4: (iii). $G(E)$ is countable; choosing one element of every double coset $\mathsf{U}_c^0(M)\gamma\,\mathsf{U}_{c'}^0(M)$ gives sets $R_{c,c'}$ of representatives. With the residue domain of (i) and the β_c^0 of (ii),

$$(D_{\mathrm{res}}, (\beta_c^0)_c, (R_{c,c'})_{c,c'})$$

is a cutoff datum (RD6). □

Lemma 5.6.20. *Let G be a topological group whose topology has a countable base, and let $\Gamma \leq G$ be a discrete subgroup. Then there is a Borel set $F \subseteq G$ that meets every orbit Γx ($x \in G$) in exactly one point.*

Proof. Since Γ is discrete, there is an open neighbourhood W of 1 in G with $W \cap \Gamma = \{1\}$. By continuity of $(x,y) \mapsto xy^{-1}$ at $(1,1)$ there is an open neighbourhood V of 1 with $VV^{-1} \subseteq W$. The open sets Vg ($g \in G$) cover G; as G has a countable base, it is Lindelöf, so there are $g_1, g_2, \cdots \in G$ (a finite or infinite sequence) with $G = \bigcup_i Vg_i$.

Each orbit meets each Vg_i in at most one point. If $\gamma x = vg_i$ and $\gamma' x = v'g_i$ with $\gamma, \gamma' \in \Gamma$, $v, v' \in V$, then $\gamma'\gamma^{-1} = v'g_i x^{-1} \cdot x g_i^{-1} v^{-1} = v'v^{-1} \in VV^{-1} \cap \Gamma \subseteq W \cap \Gamma = \{1\}$, so $\gamma x = \gamma' x$.

The set. Put

$$F_i = Vg_i \setminus \bigcup_{j<i} \Gamma V g_j, \qquad F = \bigcup_i F_i.$$

Each $\Gamma V g_j = \bigcup_{\gamma \in \Gamma} \gamma V g_j$ is open, so every F_i is Borel, and so is the countable union F.

F meets every orbit exactly once. Let $O = \Gamma x$ and let i be the least index with $O \cap Vg_i \neq \emptyset$ (it exists since the Vg_i cover G); by the previous paragraph $O \cap Vg_i = \{p\}$ for one point p. For $j < i$ we have $O \cap \Gamma V g_j = \emptyset$, because O is Γ-stable and $O \cap Vg_j = \emptyset$; hence $p \in F_i$, and $F_j \cap O \subseteq Vg_j \cap O = \emptyset$. For $j > i$ we have $O = \Gamma p \subseteq \Gamma V g_i$, so $F_j \cap O = \emptyset$. Finally $F_i \cap O \subseteq Vg_i \cap O = \{p\}$. Thus $F \cap O = \{p\}$. □

Lemma 5.6.21. *Let E be a CM field with set of infinite places Φ, let $N \geq 1$, $s \in \{\pm 1\}^N$ and $B \geq 0$ an integer, and let $\lambda = (\lambda_v)_{v \in \Phi}$ be such that $2\lambda_v \in \mathbb{Z}^N$ has gap $500N^3 + B$ for s for every $v \in \Phi$. With the formal degrees taken for the Haar measures dg_v of $G_\infty = \prod_{v \in \Phi} \mathrm{U}(\mathrm{diag}\, s)$, the function*

$$e_\lambda(x) = \prod_{v \in \Phi} d_{\lambda_v}\, \overline{c_{\lambda_v}(x_v)} \qquad (x \in G_\infty)$$

is a cusp kernel of order B on G_∞.

Proof. Write $e_v(g) = d_{\lambda_v} \overline{c_{\lambda_v}(g)}$ on $G_v = \mathrm{U}(\mathrm{diag}\, s)$, so $e_\lambda(x) = \prod_v e_v(x_v)$, and put $h = 500N^3 + B$. A vector with gap h has gap h' for every $h' \leq h$, by the definition (DZ1).

Local facts. By Lemma 5.6.22 (gap $500N^3 \leq h$), each e_v is continuous and integrable on G_v, $e_v(g^{-1}) = \overline{e_v(g)}$, $e_v(1) \neq 0$, $\int e_v(z) e_v(x^{-1}z^{-1}y)\, dz = e_v(x^{-1}) e_v(y)/e_v(1)$, and there is a continuous compactly supported β_v on G_v with $\int \beta_v(x) e_v(x^{-1}g)\, dx = e_v(g)$. By Lemma 5.7.38(1) (gap h), $|c_{\lambda_v}(g)| \leq 1$ and $|c_{\lambda_v}(g)| \leq (2/\|g\|)^c$ for every integer $0 \leq c \leq h$; and $d_{\lambda_v} > 0$, as the inverse of the positive finite number $\int |c_{\lambda_v}|^2$.

e_λ is an idempotent kernel. It is continuous as a finite product of continuous functions of the coordinates, and integrable on the product G_∞ by Tonelli's theorem, $|e_\lambda(x)| = \prod_v |e_v(x_v)|$ being a product of integrable functions of distinct coordinates. Since $x^{-1} = (x_v^{-1})_v$, $e_\lambda(x^{-1}) = \prod_v \overline{e_v(x_v)} = \overline{e_\lambda(x)}$, and $e_\lambda(1) = \prod_v e_v(1) \neq 0$. For $x, y \in G_\infty$ the function $z \mapsto e_\lambda(z) e_\lambda(x^{-1}z^{-1}y)$

is the product over v of $z_v \mapsto e_v(z_v)e_v(x_v^{-1}z_v^{-1}y_v)$, each integrable on G_v (integrable times bounded, $|e_v| \le d_{\lambda_v}$); by Fubini's theorem and the local identity,

$$\int_{G_\infty} e_\lambda(z)e_\lambda(x^{-1}z^{-1}y)\,dz = \prod_v \frac{e_v(x_v^{-1})e_v(y_v)}{e_v(1)} = \frac{e_\lambda(x^{-1})e_\lambda(y)}{e_\lambda(1)}.$$

Decay (EK4)(b). With $c = B \le h$: $|e_\lambda(x)|\,\|x\|_\infty^B = \prod_v d_{\lambda_v}|c_{\lambda_v}(x_v)|\,\|x_v\|^B \le \prod_v d_{\lambda_v} 2^B$.

Moment (EK4)(a). Put $c' = h - B - 1 = 500N^3 - 1$, an integer with $c' > 8N^2$ (as $500N^3 \ge 500N^2 > 8N^2 + 1$). With $c = h$,

$$d_{\lambda_v}|c_{\lambda_v}(g)|\,\|g\|^{B+1} \le d_{\lambda_v}\Big(\frac{2}{\|g\|}\Big)^h \|g\|^{B+1} = 2^{B+1} d_{\lambda_v}\Big(\frac{2}{\|g\|}\Big)^{c'},$$

and $g \mapsto d_{\lambda_v}(2/\|g\|)^{c'}$ is integrable on G_v by Lemma 5.7.38(3), applied with large gap B (that is, gap $500N^3+B$) and $L = \max_i |2\lambda_{v,i}|$. So $|e_\lambda(x)|\,\|x\|_\infty^{B+1} = \prod_v d_{\lambda_v}|c_{\lambda_v}(x_v)|\,\|x_v\|^{B+1}$ is dominated by a product of nonnegative integrable functions of distinct coordinates, hence integrable by Tonelli's theorem.

Bump (EK4)(c). $\beta(x) = \prod_v \beta_v(x_v)$ is continuous with compact support $\prod_v \operatorname{supp}\beta_v$, and for $y \in G_\infty$, by Fubini's theorem (the integrand is bounded with compact support),

$$\int_{G_\infty} \beta(x)e_\lambda(x^{-1}y)\,dx = \prod_v \int_{G_v} \beta_v(x_v)e_v(x_v^{-1}y_v)\,dx_v = \prod_v e_v(y_v) = e_\lambda(y).$$

□

Lemma 5.6.22. *Let $n \ge 1$, $s \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have gap $500n^3$ for s; put $\lambda = \frac{1}{2}l$. Fix a Haar measure dg on $\mathrm{U}(\operatorname{diag} s)$, let d_λ be the formal degree for it, and put $e_\lambda(g) = d_\lambda\,\overline{c_\lambda(g)}$. Then:*

(i) e_λ is continuous and integrable, $e_\lambda(g^{-1}) = \overline{e_\lambda(g)}$, $e_\lambda(1) \ne 0$, and for all $x, y \in \mathrm{U}(\operatorname{diag} s)$

$$\int_{\mathrm{U}(\operatorname{diag} s)} e_\lambda(z)\,e_\lambda(x^{-1}z^{-1}y)\,dz = \frac{e_\lambda(x^{-1})\,e_\lambda(y)}{e_\lambda(1)};$$

(ii) there is a continuous compactly supported function β on $\mathrm{U}(\operatorname{diag} s)$ with $\int \beta(x)\,e_\lambda(x^{-1}g)\,dx = e_\lambda(g)$ for all g.

Proof. Write $G = \mathrm{U}(\operatorname{diag} s)$ and $c = c_\lambda$. Since $n \ge 1$, $500n^3 > 8n^2$, so Lemma 5.6.23 applies to l and dg; its $d_\lambda = (\int_G |c|^2 dg)^{-1}$ is the formal degree for dg, a positive real number. By Lemma 5.7.40, $c(g^{-1}) = \overline{c(g)}$.

(i). By Lemma 5.6.23 (i), c is continuous and integrable, hence so is $e_\lambda = d_\lambda \bar{c}$. As d_λ is real, $e_\lambda(g^{-1}) = d_\lambda \overline{c(g^{-1})} = d_\lambda c(g) = \overline{e_\lambda(g)}$, and $e_\lambda(1) = d_\lambda c(1) = d_\lambda \ne 0$, since $c(1) = \|m_{\mu_l}\|^{-2} \int_{K_s} |m_{\mu_l}|^2 dk = 1$ by (3.2), as $\mathrm{bd}_s(1) = 1$ and $m_w(1) = 1$. For $x, y \in G$, using $\overline{c(u)} = c(u^{-1})$ for $u = x^{-1}z^{-1}y$ and Lemma 5.6.23 (ii) with (x, a) replaced by (y^{-1}, x),

$$\int_G e_\lambda(z)\,e_\lambda(x^{-1}z^{-1}y)\,dz = d_\lambda \cdot d_\lambda \int_G c(y^{-1}zx)\,\overline{c(z)}\,dz = d_\lambda\,c(y^{-1})\,c(x) = d_\lambda\,\overline{c(y)}\,\overline{c(x^{-1})},$$

and the right side equals $e_\lambda(x^{-1})e_\lambda(y)/e_\lambda(1) = d_\lambda\overline{c(x^{-1})} \cdot d_\lambda\overline{c(y)}/d_\lambda$.

(ii). Let β be the smooth compactly supported function of Lemma 5.6.23 (iii), so

$$\int_G \beta(x)c(hx)\,dx = c(h) \quad \text{for all } h;$$

it is continuous. For $g \in G$, $e_\lambda(x^{-1}g) = d_\lambda \overline{c(x^{-1}g)} = d_\lambda c(g^{-1}x)$, so

$$\int_G \beta(x)\, e_\lambda(x^{-1}g)\, dx = d_\lambda \int_G \beta(x)\, c(g^{-1}x)\, dx = d_\lambda\, c(g^{-1}) = d_\lambda \overline{c(g)} = e_\lambda(g).$$

□

Lemma 5.6.23. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $h > 8(\#n)^2$ an integer, $l \in \mathbb{Z}^n$ a vector with gap h for ε, $\lambda = \frac{1}{2}l$, and dg a Haar measure on $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$.*

(i) c_λ is continuous, integrable and square integrable on G, and $d_\lambda = \left(\int_G |c_\lambda|^2 dg\right)^{-1}$ is a positive real number.

(ii) For all $x, a \in G$,

$$d_\lambda \int_G c_\lambda(xya)\, \overline{c_\lambda(y)}\, dy = c_\lambda(x)\, c_\lambda(a).$$

(iii) There is a smooth compactly supported function $\beta\colon G \to \mathbb{C}$ with $\int_G \beta(y)\, c_\lambda(gy)\, dy = c_\lambda(g)$ for every $g \in G$.

Proof. Write $c = c_\lambda$, $\mu = \mu_l$, $K = K_\varepsilon$ with its Haar probability measure dk, $J = \mathrm{diag}(\varepsilon)$, $\mathfrak{u}(J) = \{Y : Y^*J + JY = 0\}$, and $\|\cdot\|$ for the operator norm; m_μ and $\|m_\mu\|^2 > 0$ are as in Definition 3.2.3.

Unimodularity. The real bilinear form $B(X,Y) = \mathrm{Re}\,\mathrm{tr}(XY)$ on $\mathfrak{u}(J)$ is invariant under $\mathrm{Ad}(g)X = gXg^{-1}$ ($g \in G$) and nondegenerate: for $0 \neq X \in \mathfrak{u}(J)$ also $X^* \in \mathfrak{u}(J)$ and $B(X, X^*) = \mathrm{tr}(XX^*) > 0$.

Hence $|\det \mathrm{Ad}(g)| = 1$, the modular function of G is 1, and dg is invariant under left and right translations and under $g \mapsto g^{-1}$.

(i). By Lemma 5.6.24 (ii), c is locally the restriction of a holomorphic function, in particular continuous (indeed smooth) on G. By Lemma 5.7.40, $|c| \leq 1$ and $|c(g)| \leq (2/\|g\|)^h$; as $h > 8(\#n)^2$, the right side is integrable by Lemma 5.6.32 (ii) (with $S = G$, the right-invariant measure dg, finite on compact sets, the proper homomorphism $j = \mathrm{id}$ and $y = 1$). So c is integrable, and $|c|^2 \leq |c|$ is integrable. Since $\mathrm{bd}_\varepsilon(1) = 1$ and $m_w(1) = 1$, (3.2) gives $c(1) = \|m_\mu\|^{-2} \int_K |m_\mu|^2 dk = 1$; by continuity $|c| \geq \frac{1}{2}$ on a neighbourhood of 1, which has positive Haar measure. Hence $0 < \int_G |c|^2 < \infty$.

A translate identity. Let $w\colon G \to \mathbb{C}$ be integrable with

$$\int_K \overline{m_\mu(k)}\, w(k^{-1}g)\, dk = \|m_\mu\|^2\, w(g) \qquad (g \in G). \tag{5.101}$$

Then

$$\int_G w(g)\, c(xga)\, dg = c(x) \int_G w(g)\, c(ga)\, dg$$

for all $x, a \in G$. Indeed, the function $(k,g) \mapsto \overline{m_\mu(k)}\, w(g)\, c(xkga)$ is integrable on $K \times G$, being bounded by $\sup_K |m_\mu| \cdot |w(g)|$. Integrating first over k and using Lemma 5.6.31 (i) with $b = ga$, its integral is $\|m_\mu\|^2 c(x) \int_G w(g) c(ga)\, dg$. Integrating first over g, after the substitution $g \mapsto k^{-1}g$ (left invariance) the inner integral is $\int_G w(k^{-1}g) c(xga)\, dg$, and by Fubini's theorem and (5.101) the double integral is $\|m_\mu\|^2 \int_G w(g) c(xga)\, dg$. Divide by $\|m_\mu\|^2$.

(ii). Take $w(g) = c(g^{-1}) = \overline{c(g)}$ (Lemma 5.7.40), integrable by (i). It satisfies (5.101): $w(k^{-1}g) = c(g^{-1}k)$ and Lemma 5.6.31 (i) with $x = g^{-1}$, $b = 1$ gives $\int_K \overline{m_\mu(k)}\, c(g^{-1}k)\, dk = \|m_\mu\|^2 c(g^{-1}) c(1) = \|m_\mu\|^2 w(g)$. Hence

$$\int_G \overline{c(g)}\, c(xga)\, dg = c(x) \int_G \overline{c(g)}\, c(ga)\, dg.$$

The substitution $g \mapsto a^{-1}g^{-1}$, which preserves dg, carries $\overline{c(g)}\,c(ag) = c(g^{-1})\,c(ag)$ to $c(ga)\,c(g^{-1})$; so $\int_G \overline{c(g)}c(ga)\,dg = \int_G \overline{c(g)}c(ag)\,dg$, and the displayed identity with (x,a) replaced by $(a,1)$ evaluates the latter as $c(a)\int_G |c|^2 = c(a)/d_\lambda$. Together, $d_\lambda \int_G c(xga)\,\overline{c(g)}\,dg = c(x)c(a)$.

(iii). Let $\psi\colon \mathbb{R} \to [0,1]$ be smooth with $\psi = 1$ on $[-1,1]$ and $\psi = 0$ outside $[-2,2]$, and $\chi(g) = \psi(\|gg^* - 1\|_{\mathrm{HS}}^2)$. Then χ is smooth on G, $\chi(1) = 1$, $\chi(gk) = \chi(g)$ for $k \in K$, and χ has compact support: $\chi(g) \neq 0$ forces $\|g\|^2 = \|gg^*\| \leq 1 + \sqrt{2}$, and $\{g \in G : \|g\| \leq R\}$ is compact as G is closed in $\mathrm{M}_n(\mathbb{C})$. Put $w(g) = \chi(g^{-1})\,c(g^{-1})$, a continuous compactly supported function. It satisfies (5.101): $w(k^{-1}g) = \chi(g^{-1}k)c(g^{-1}k) = \chi(g^{-1})c(g^{-1}k)$, and Lemma 5.6.31 (i) (with $x = g^{-1}$, $b = 1$) gives $\int_K \overline{m_\mu(k)}c(g^{-1}k)\,dk = \|m_\mu\|^2 c(g^{-1})$. The translate identity with $a = 1$ gives $\int_G w(y)c(gy)\,dy = \kappa_0\,c(g)$, where

$$\kappa_0 = \int_G w(y)c(y)\,dy = \int_G \chi(y^{-1})\,|c(y)|^2\,dy > 0,$$

because $c(y^{-1}) = \overline{c(y)}$ and the integrand is continuous, nonnegative and equal to 1 at $y = 1$. Then $\beta = w/\kappa_0$ is smooth (as χ, c and inversion are smooth on G) and compactly supported, and $\int_G \beta(y)c(gy)\,dy = c(g)$. □

Lemma 5.6.24. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $J = \mathrm{diag}(\varepsilon)$, $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, $\mathfrak{u}(J) = \{Y \in \mathrm{M}_n(\mathbb{C}) : Y^*J + JY = 0\}$, and let E_{ab} $(a,b \in n)$ be the matrix units. Call a function $f\colon G \to \mathbb{C}$* locally holomorphic *if every $g \in G$ has an open neighbourhood W in $\mathrm{GL}_n(\mathbb{C})$ with a holomorphic $F\colon W \to \mathbb{C}$ such that $f = F$ on $W \cap G$; for such (W,F) and $X \in \mathrm{M}_n(\mathbb{C})$ put $(Xf)(g) = F'(g)[gX]$ $(g \in W \cap G)$, the complex derivative of F at g in the direction gX.*

- *(i) For locally holomorphic f and $X \in \mathrm{M}_n(\mathbb{C})$ the function Xf does not depend on the choice of the pairs (W,F) and is locally holomorphic; $(Yf)(g) = \frac{d}{dt}|_{t=0} f(ge^{tY})$ for $Y \in \mathfrak{u}(J)$; $X \mapsto Xf$ is complex linear; and $X(X'f) - X'(Xf) = (XX' - X'X)f$ for all $X, X' \in \mathrm{M}_n(\mathbb{C})$.*
- *(ii) Let $l \in \mathbb{Z}^n$ have gap 0 for ε, $\lambda = \frac{1}{2}l$ and $\mu = \mu_l$. Then c_λ is locally holomorphic: for $g_0 \in G$ and $a = \mathrm{bd}_\varepsilon(g_0)$ one may take $W = \{y \in \mathrm{GL}_n(\mathbb{C}) : a^{-1}y$ accretive$\}$ and $F(y) = \mathrm{FJ}_l(a, a^{-1}y)$.*
- *(iii) In the situation of (ii), $E_{aa}c_\lambda = \mu_a\,c_\lambda$ for every $a \in n$, and $E_{ab}c_\lambda = 0$ whenever $a \neq b$, $\varepsilon_a = \varepsilon_b$ and $l_a > l_b$.*
- *(iv) In the situation of (ii),*

$$\sum_{a,b \in n} E_{ab}(E_{ba}c_\lambda) = \kappa_l\,c_\lambda, \qquad \kappa_l = \frac{1}{4}\sum_{a \in n}(l_a^2 - (2\rho_l(a))^2).$$

Proof. For $X \in \mathrm{M}_n(\mathbb{C})$ and a holomorphic function F on an open set $W \subseteq \mathrm{GL}_n(\mathbb{C})$ write $(D_XF)(y) = F'(y)[yX] = \frac{d}{ds}|_{s=0} F(y(1+sX))$ $(y \in W)$; D_XF is holomorphic on W and $X \mapsto D_XF$ is complex linear. Write $K = K_\varepsilon$ with its Haar probability measure dk.

(i). Let (W,F) be a pair for f and $g \in W \cap G$. For $Y \in \mathfrak{u}(J)$ the curve $t \mapsto ge^{tY}$ lies in G, in W for small $|t|$, and has derivative gY at 0; so $F'(g)[gY] = \frac{d}{dt}|_{t=0} F(ge^{tY}) = \frac{d}{dt}|_{t=0} f(ge^{tY})$, which depends only on f. Every $X \in \mathrm{M}_n(\mathbb{C})$ is $X = Y_1 + iY_2$ with

$$Y_1 = \tfrac{1}{2}(X - JX^*J), \qquad Y_2 = \tfrac{1}{2i}(X + JX^*J) \in \mathfrak{u}(J),$$

and $F'(g)$ is complex linear, so $F'(g)[gX] = (Y_1f)(g) + i(Y_2f)(g)$ depends only on f. On $W \cap G$ the function Xf is the restriction of the holomorphic D_XF, so Xf is locally holomorphic,

and complex linearity in X is clear. For the commutator, differentiate $y \mapsto F'(y)[yX']$ in the direction yX: $(D_X D_{X'}F)(y) = F''(y)[yX, yX'] + F'(y)[yXX']$; as $F''(y)$ is symmetric, $D_X D_{X'}F - D_{X'}D_X F = D_{XX'-X'X}F$. Restricting to $W \cap G$, where $X'f = D_{X'}F$ and hence $X(X'f) = D_X D_{X'}F$, gives the last claim.

(ii). By Lemma 5.6.25 (i), $a = \mathrm{bd}_\varepsilon(g_0)$ is invertible and $a^{-1}g_0$ is accretive; accretivity ($z+z^*$ positive definite) is an open condition, so W is an open neighbourhood of g_0. For $y \in W$ and $k \in K$ the matrix $k^*a^{-1}yk$ is accretive (Lemma 5.6.25 (ii)), so its determinant and principal minors do not vanish (Lemma 5.6.25 (ii)), and

$$\Phi_k(y) = \frac{m_\mu(ak)\,\overline{m_\mu(k)}}{m_{-l^\rho}(k^*a^{-1}yk)}$$

is continuous in $(y,k) \in W \times K$ and, for fixed k, holomorphic in y: by (3.1), $m_{-l^\rho}(Z)$ is an integer power of $\det Z$ times a product of principal minors of Z, and these are polynomials in the entries of y. Hence $F = \|m_\mu\|^{-2}\int_K \Phi_k\,dk$ is holomorphic on W (differentiation under the integral sign over the compact K, the y-derivatives of Φ_k being continuous on $W \times K$ by Cauchy's integral formula). For $y \in W \cap G$, $F(y) = c_\lambda(y)$ by Lemma 5.6.26 (i), a being block-diagonal with $a^{-1}y$ accretive.

(iii). Let $g_0 \in G$, $a' = \mathrm{bd}_\varepsilon(g_0^{-1})$, $W' = \{y \in \mathrm{GL}_n(\mathbb{C}) : a'^{-1}y^{-1}$ accretive$\}$ and $\tilde F(y) = \mathrm{FJ}_{-l}(a', a'^{-1}y^{-1})$. The vector $-l$ has gap 0, so, as in (ii) composed with the holomorphic map $y \mapsto y^{-1}$, W' is an open neighbourhood of g_0 and $\tilde F$ is holomorphic on it. For $y \in W' \cap G$: $\tilde F(y) = c_{-l/2}(y^{-1})$ by Lemma 5.6.26 (i), $= \overline{c_{l/2}(y^{-1})}$ by Lemma 5.6.29 (ii), $= c_{l/2}(y)$ by Lemma 5.7.40. So $(W', \tilde F)$ is a pair for c_λ at g_0.

Let B_l be as in Lemma 5.6.27 (invertible x with $x_{ij} = 0$ unless $\varepsilon_i = \varepsilon_j$ and $l_i \geq l_j$), and let $x \in \mathrm{B}_l$ and $y \in W'$ with $yx \in W'$. We show $\tilde F(yx) = x^\mu \tilde F(y)$, $x^\mu = \prod_i x_{ii}^{\mu_i}$. Put $g = (yx)^{-1} = x^{-1}y^{-1}$. The matrices a' and $x^{-1}a'$ are block-diagonal and invertible, $a'^{-1}g = a'^{-1}(yx)^{-1}$ is accretive as $yx \in W'$, and $(x^{-1}a')^{-1}g = a'^{-1}y^{-1}$ is accretive as $y \in W'$; so Lemma 5.6.26 (i) for $-l$ gives $\tilde F(yx) = \mathrm{FJ}_{-l}(a', a'^{-1}g) = \mathrm{FJ}_{-l}(x^{-1}a', a'^{-1}y^{-1})$. By Lemma 5.6.27 (iii), $\mu_{-l} = -\mu$ and $(-l)^\rho = -l^\rho$, so in the integrand (3.2) of $\mathrm{FJ}_{-l}(x^{-1}a', \cdot)$ only the factor $m_{-\mu}(x^{-1}a'k)$ involves x, and

$$m_{-\mu}(x^{-1}a'k) = m_\mu(k^{-1}a'^{-1}x) = x^\mu\, m_\mu(k^{-1}a'^{-1}) = x^\mu\, m_{-\mu}(a'k)$$

by Lemma 5.6.27 (i) (twice) and (ii) (with the left factor $1 \in \mathrm{B}_l$; μ satisfies its hypothesis by (iii) there). Hence $\tilde F(yx) = x^\mu\,\mathrm{FJ}_{-l}(a', a'^{-1}y^{-1}) = x^\mu \tilde F(y)$.

Now let $y \in W' \cap G$. If $a \neq b$, $\varepsilon_a = \varepsilon_b$ and $l_a > l_b$, then $x_t = 1 + tE_{ab} \in \mathrm{B}_l$ with $x_t^\mu = 1$ for every $t \in \mathbb{C}$, and $yx_t \in W'$ for small $|t|$; so $\tilde F(y(1+tE_{ab})) = \tilde F(y)$ and $(E_{ab}c_\lambda)(y) = (D_{E_{ab}}\tilde F)(y) = 0$. For $a = b$, $x_t = 1 + tE_{aa} \in \mathrm{B}_l$ for $t \neq -1$ with $x_t^\mu = (1+t)^{\mu_a}$, so $(E_{aa}c_\lambda)(y) = \frac{d}{dt}|_{t=0}(1+t)^{\mu_a}\tilde F(y) = \mu_a\, c_\lambda(y)$. As g_0 was arbitrary, (iii) holds on G.

(iv). Let g_0, a, W, F and Φ_k be as in (ii), and $\Omega = \sum_{a,b} D_{E_{ab}}D_{E_{ba}}$. The y-derivatives of order at most 2 of $\Phi_k(y)$ are continuous on $W \times K$, so $\Omega F = \|m_\mu\|^{-2}\int_K \Omega\Phi_k\,dk$. We show $\Omega\Phi_k = \kappa_l\Phi_k$ on W for each $k \in K$.

Change of basis. Put $X_{ab} = kE_{ab}k^{-1}$. Then $\sum_{a,b} X_{ab} \otimes X_{ba} = \sum_{c,d} E_{cd} \otimes E_{dc}$ in $\mathrm{M}_n(\mathbb{C}) \otimes \mathrm{M}_n(\mathbb{C})$,

and since $(X, X') \mapsto D_X D_{X'}$ is bilinear, $\Omega = \sum_{a,b} D_{X_{ab}}D_{X_{ba}}$.

Weights of Φ_k. Let B' be the set of invertible $t \in \mathrm{M}_n(\mathbb{C})$ with $t_{ij} = 0$ unless $l_i \leq l_j$. Lemma 5.6.27 (ii), applied to the signs $(1, \ldots, 1)$ and the vector $-l$ (for which the group of that lemma is B') and to the weight $-l^\rho$, which is admissible because $l_i^\rho \leq l_j^\rho$ whenever $l_i < l_j$ (Lemma 5.6.27 (iii)), gives $m_{-l^\rho}(Zt) = t^{-l^\rho} m_{-l^\rho}(Z)$ for invertible Z and $t \in \mathrm{B}'$. If y and $yktk^{-1}$ lie in W, then $k^*a^{-1}(yktk^{-1})k = (k^*a^{-1}yk)\,t$, so $\Phi_k(yktk^{-1}) = t^{l^\rho}\Phi_k(y)$. Taking $t = 1 + sE_{ij}$

with $i \neq j$ and $l_i < l_j$ (so $t^{l^\rho} = 1$), and $t = 1 + sE_{ii}$ (so $t^{l^\rho} = (1+s)^{l_i^\rho}$), and noting $yktk^{-1} = y(1 + sX_{ij})$, we get

$$D_{X_{ij}}\Phi_k = 0 \quad (i \neq j,\ l_i < l_j), \qquad D_{X_{ii}}\Phi_k = l_i^\rho\,\Phi_k.$$

Evaluation. By the commutator identity of (i) for the D's and $X_{ab}X_{ba} - X_{ba}X_{ab} = X_{aa} - X_{bb}$: for $l_a < l_b$, $D_{X_{ab}}D_{X_{ba}}\Phi_k = D_{X_{ba}}D_{X_{ab}}\Phi_k + D_{X_{aa}-X_{bb}}\Phi_k = (l_a^\rho - l_b^\rho)\Phi_k$; for $l_a > l_b$, $D_{X_{ba}}\Phi_k = 0$, so the term vanishes; for $a = b$ it is $(l_a^\rho)^2\Phi_k$. The entries of l are distinct, so

$$\Omega\Phi_k = \Big(\sum_a (l_a^\rho)^2 + \sum_{l_a<l_b} (l_a^\rho - l_b^\rho)\Big)\Phi_k = \sum_a l_a^\rho(l_a^\rho - 2\rho_l(a))\,\Phi_k,$$

since $\sum_{l_a<l_b}(l_a^\rho - l_b^\rho) = \sum_a l_a^\rho(\#\{b : l_b > l_a\} - \#\{b : l_b < l_a\}) = -\sum_a l_a^\rho\, 2\rho_l(a)$. The entries of l are congruent to $\#n - 1$ modulo 2, so $2l^\rho = l + 2\rho_l$ (Lemma 5.6.27 (iii)) and $l_a^\rho(l_a^\rho - 2\rho_l(a)) = \frac{1}{4}(l_a + 2\rho_l(a))(l_a - 2\rho_l(a))$; the sum is κ_l. Hence $\Omega F = \kappa_l F$ on W, and by (i), $\sum_{a,b} E_{ab}(E_{ba}c_\lambda) = (\Omega F)|_{W\cap G} = \kappa_l\, c_\lambda$ on $W \cap G$. As g_0 was arbitrary, (iv) holds on G. □

Lemma 5.6.25. *Let n be a nonempty finite set and $\varepsilon \in \{\pm 1\}^n$.*

1. *For every $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ the matrix $\mathrm{bd}_\varepsilon(g)$ is invertible and $\mathrm{bd}_\varepsilon(g)^{-1}g$ is accretive.*
2. *If z is accretive and k is invertible, then k^*zk is accretive, and $\Delta_P(y) \neq 0$ for every accretive y and every $P \subseteq n$.*

Proof. (ii) For $x \neq 0$, $x^*(k^*zk + k^*z^*k)x = (kx)^*(z + z^*)(kx) > 0$ as $kx \neq 0$. If y is accretive and $P \neq \emptyset$, let y_P be its submatrix on $P \times P$; for $0 \neq x \in \mathbb{C}^P$, extended by 0 to $\tilde{x} \in \mathbb{C}^n$, $x^*(y_P + y_P^*)x = \tilde{x}^*(y + y^*)\tilde{x} > 0$. If $y_P x = 0$ then $x^*(y_P + y_P^*)x = 2\,\mathrm{Re}\, x^*y_P x = 0$, so $x = 0$; hence y_P is invertible and $\Delta_P(y) \neq 0$. For $P = \emptyset$, $\Delta_\emptyset = 1$.

(i) Number n so that the indices with $\varepsilon_i = 1$ come first and write $g = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ and $J = \mathrm{diag}(\varepsilon) = \mathrm{diag}(1, -1)$ in the corresponding blocks; if one block is empty, $\mathrm{bd}_\varepsilon(g) = g$ and $\mathrm{bd}_\varepsilon(g)^{-1}g = 1$, and there is nothing to prove. From $g^*Jg = J$ we get $g^{-1} = Jg^*J$, hence $gJg^* = J$, whose blocks read

$$AA^* - BB^* = 1, \qquad DD^* - CC^* = 1, \qquad AC^* = BD^*.$$

So $AA^* \geq 1$ and $DD^* \geq 1$, A and D are invertible, and $\mathrm{bd}_\varepsilon(g) = \mathrm{diag}(A, D)$ is invertible. Put $X = A^{-1}B$. Then $z = \mathrm{bd}_\varepsilon(g)^{-1}g = \begin{pmatrix} 1 & X \\ D^{-1}C & 1 \end{pmatrix}$, and $C^* = A^{-1}BD^*$ gives $(D^{-1}C)^* = C^*D^{-*} = X$, so

$$\tfrac{1}{2}(z + z^*) = \begin{pmatrix} 1 & X \\ X^* & 1 \end{pmatrix}.$$

Moreover $XX^* = A^{-1}(AA^* - 1)A^{-*} = 1 - (A^*A)^{-1}$, and $(A^*A)^{-1}$ is positive definite, so $\|X\|_{\mathrm{op}} < 1$. For $(u, v) \neq 0$, $|2\,\mathrm{Re}\, u^*Xv| \leq 2\|X\|_{\mathrm{op}}\|u\|\|v\| \leq \|X\|_{\mathrm{op}}(\|u\|^2 + \|v\|^2) < \|u\|^2 + \|v\|^2$, hence $(u, v)^*\frac{1}{2}(z + z^*)(u, v) = \|u\|^2 + \|v\|^2 + 2\,\mathrm{Re}\, u^*Xv > 0$, and z is accretive. □

Lemma 5.6.26. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$ and $l \in \mathbb{Z}^n$ a vector with gap 0 for ε; write $\mu = \mu_l$. Call a complex $n \times n$ matrix x block-diagonal if $x_{ij} = 0$ whenever $\varepsilon_i \neq \varepsilon_j$.*

1. *If g is a complex $n \times n$ matrix and a, a' are block-diagonal matrices such that $a^{-1}g$ and $a'^{-1}g$ are accretive, then $\mathrm{FJ}_l(a, a^{-1}g) = \mathrm{FJ}_l(a', a'^{-1}g)$. In particular $c_{l/2}(g) = \mathrm{FJ}_l(a, a^{-1}g)$ for every $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ and every block-diagonal a with $a^{-1}g$ accretive.*

2. *If $g = pzq^*$ with p, q invertible block-diagonal and z accretive, then $a = pq^{-1}$ is block-diagonal with $a^{-1}g$ accretive, and*

$$\mathrm{FJ}_l(a, a^{-1}g) = \frac{1}{\|m_\mu\|^2} \int_{K_\varepsilon} \frac{m_\mu(pk)\,\overline{m_\mu(qk)}}{m_{-l^\rho}(k^* z k)}\, dk.$$

3. *Let b, c be invertible block-diagonal matrices with $b_{ij} = c_{ij} = 0$ whenever $l_i < l_j$. If y and $c^* y b$ are accretive, then*

$$\mathrm{FJ}_l(1, c^* y b) = \overline{c^\mu}\, b^\mu\, \mathrm{FJ}_l(1, y), \qquad b^\mu = \prod_{i \in n} b_{ii}^{\mu_i}.$$

Proof. Write $K = K_\varepsilon$, let $K_\mathbb{C}$ be the group of invertible block-diagonal matrices and $\mathrm{B}_l \subseteq K_\mathbb{C}$ the subgroup of the b with $b_{ij} = 0$ whenever $l_i < l_j$, as in Lemma 5.6.27 and Lemma 5.6.28. Gap 0 means: distinct entries, all congruent to $\#n - 1$ modulo 2. By Lemma 5.6.27 (iii) the weights μ and l^ρ both satisfy the hypothesis of (ii) there ($w_i \geq w_j$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$). The inverse of an accretive y is accretive, since $y^{-1} + y^{-*} = y^{-1}(y + y^*)y^{-*}$; an accretive matrix is invertible, and $k^* y k$ is accretive for invertible k (Lemma 5.6.25, (ii)).

Step 1: the integral I. Fix an invertible g. For invertible p, r with $rg^{-1}p$ accretive put

$$I(p, r) = \int_K \frac{m_\mu(pk)\, m_\mu(k^* r)}{m_{l^\rho}(k^* r g^{-1} p k)}\, dk.$$

The denominator is a product of powers of the determinant and of principal minors of the accretive matrix $k^*(rg^{-1}p)k$, all nonzero by Lemma 5.6.25 (ii); the integrand is continuous on the compact group K. If a is block-diagonal and $a^{-1}g$ is accretive, then $g^{-1}a = (a^{-1}g)^{-1}$ is accretive, and for $k \in K$ (so $k^{-1} = k^*$), Lemma 5.6.27 (i) gives $\overline{m_\mu(k)} = m_\mu(k^*)$ and $m_{-l^\rho}(k^* a^{-1} g k) = m_{l^\rho}(k^* g^{-1} a k)$. Comparing with (3.2),

$$\mathrm{FJ}_l(a, a^{-1}g) = \|m_\mu\|^{-2}\, I(a, 1). \tag{5.102}$$

Step 2: invariance. Let $rg^{-1}p$ be accretive and $x \in K_\mathbb{C}$. Then $(x^* r)g^{-1}(px) = x^*(rg^{-1}p)x$ is accretive and $I(px, x^* r) = I(p, r)$. Indeed, put

$$F(y) = \frac{m_\mu(py)\, m_\mu(y^* r)}{m_{l^\rho}(y^* r g^{-1} p y)} \qquad (y \in K_\mathbb{C});$$

F is continuous (principal minors are polynomials, the denominator does not vanish as above), and $F(xk)$ is the integrand of $I(px, x^* r)$ at k, $F(k)$ that of $I(p, r)$. For $b \in \mathrm{B}_l$, Lemma 5.6.27 (ii) (with the second factor 1 or the first factor 1) gives $m_\mu(pyb) = b^\mu m_\mu(py)$, $m_\mu(b^* y^* r) = \overline{b^\mu}\, m_\mu(y^* r)$ and $m_{l^\rho}(b^* Y b) = \overline{b^{l^\rho}}\, b^{l^\rho} m_{l^\rho}(Y)$ for $Y = y^* r g^{-1} p y$. As $\mu = l^\rho - 2\rho_l^{\mathrm{c}}$ by definition,

$$F(yb) = \frac{|b^\mu|^2}{|b^{l^\rho}|^2} F(y) = \left|b^{-2\rho_l^{\mathrm{c}}}\right|^2 F(y),$$

and Lemma 5.6.28 gives $\int_K F(xk)\, dk = \int_K F(k)\, dk$.

Step 3: the first variable alone. Let p be block-diagonal with $g^{-1}p$ accretive and Y block-diagonal. There is $\delta > 0$ such that for $|s|, |u| < \delta$ the matrices $1 + sY$, $1 + uY^*$ are invertible and $(1 + uY^*)g^{-1}p(1 + sY)$ is accretive (accretive matrices form an open set). On this bidisc put $\psi(s, u) = I\big(p(1 + sY), 1 + uY^*\big)$. The integrand is a continuous function of (s, u, k) and, for fixed k, a quotient of polynomials in (s, u) whose denominator (powers of determinants of invertible

matrices and principal minors of accretive matrices) does not vanish; hence ψ is holomorphic (continuity of parameter integrals over a compact space, Morera's theorem in each variable with Fubini, and Osgood's lemma). For complex t with $|t| < \delta$, $x = 1 + tY \in K_{\mathbb{C}}$ and $x^* = 1 + \bar{t}Y^*$, so Step 2 gives $\psi(t, \bar{t}) = \psi(0,0)$. Expand $\psi(s,u) - \psi(0,0) = \sum_{\alpha,\beta \geq 0} e_{\alpha\beta} s^\alpha u^\beta$, absolutely convergent for $|s|, |u| < \delta'$ with some $0 < \delta' \leq \delta$. With $t = \tau e^{i\theta}$, $0 \leq \tau < \delta'$,

$$0 = \sum_{\alpha,\beta} e_{\alpha\beta} \tau^{\alpha+\beta} e^{i(\alpha-\beta)\theta} \quad \text{for all } \theta,$$

so for each integer m the Fourier coefficient $\sum_{\beta \geq \max(0,-m)} e_{\beta+m,\beta}\, \tau^{2\beta+m}$ vanishes for all $0 \leq \tau < \delta'$; the exponents $2\beta + m$ are distinct, so every $e_{\beta+m,\beta} = 0$. Hence $\psi \equiv \psi(0,0)$ on the smaller bidisc, and in particular

$$I(p + sp\,Y, 1) = I(p, 1) \qquad (|s| < \delta'). \tag{5.103}$$

Step 4: proof of (i). The matrices a, a', g are invertible, and $g^{-1}a$, $g^{-1}a'$ are accretive. For $t \in [0,1]$ put $p_t = (1-t)a + ta'$: it is block-diagonal and $g^{-1}p_t = (1-t)g^{-1}a + tg^{-1}a'$ is accretive, a convex combination of accretive matrices; so p_t is invertible. Let $\phi(t) = I(p_t, 1)$. At $t_0 \in [0,1]$ apply (5.103) with $p = p_{t_0}$ and $Y = p_{t_0}^{-1}(a' - a)$, which is block-diagonal: $p_{t_0} + sp_{t_0}Y = p_{t_0+s}$, so ϕ is constant on a neighbourhood of t_0 in $[0,1]$. As $[0,1]$ is connected, $\phi(0) = \phi(1)$, that is $I(a,1) = I(a',1)$, and (i) follows from (5.102). For $g \in \mathrm{U}(\operatorname{diag}\varepsilon)$ the block-diagonal matrix $a_0 = \mathrm{bd}_\varepsilon(g)$ is invertible with $a_0^{-1}g$ accretive (Lemma 5.6.25, (i)), and $c_{l/2}(g) = \mathrm{FJ}_l(a_0, a_0^{-1}g)$ by definition; the second sentence follows.

Step 5: proof of (ii). The matrix $a = pq^{-1}$ is block-diagonal and $a^{-1}g = qzq^* = (q^*)^* z\, q^*$ is accretive. By (5.102) and Step 2 (applied to $(p,r) = (a,1)$, for which $g^{-1}a$ is accretive, and $x = q$),

$$\|m_\mu\|^2\, \mathrm{FJ}_l(a, a^{-1}g) = I(a,1) = I(aq, q^*) = I(p, q^*).$$

Here $q^*g^{-1}p = q^*q^{-*}z^{-1}p^{-1}p = z^{-1}$, $m_\mu(k^*q^*) = m_\mu((qk)^*) = \overline{m_\mu(qk)}$ and $m_{l^\rho}(k^*z^{-1}k) = m_{l^\rho}((k^*zk)^{-1}) = m_{-l^\rho}(k^*zk)$ by Lemma 5.6.27 (i); this is the asserted integral.

Step 6: proof of (iii). The hypotheses say $b, c \in \mathrm{B}_l$. The factor 1 is admissible for y and for c^*yb. Apply (ii) and (i) to $c^*yb = c^*\, y\, (b^*)^*$ (so $p = c^*$, $q = b^*$, $z = y$) and to $y = 1 \cdot y \cdot 1^*$:

$$\mathrm{FJ}_l(1, c^*yb) = \frac{1}{\|m_\mu\|^2} \int_K \frac{m_\mu(c^*k)\, \overline{m_\mu(b^*k)}}{m_{-l^\rho}(k^*yk)}\, dk, \qquad \mathrm{FJ}_l(1,y) = \frac{1}{\|m_\mu\|^2} \int_K \frac{m_\mu(k)\, \overline{m_\mu(k)}}{m_{-l^\rho}(k^*yk)}\, dk.$$

By Lemma 5.6.27 (ii), $m_\mu(c^*k) = \overline{c^\mu}\, m_\mu(k)$ and $m_\mu(b^*k) = \overline{b^\mu}\, m_\mu(k)$, which gives (iii). □

Lemma 5.6.27. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$ and $l \in \mathbb{Z}^n$ with distinct entries. Let B_l be the set of invertible complex $n \times n$ matrices b with $b_{ij} = 0$ unless $\varepsilon_i = \varepsilon_j$ and $l_i \geq l_j$, and for $w \in \mathbb{Z}^n$ and $b \in \mathrm{B}_l$ put $b^w = \prod_{i \in n} b_{ii}^{w_i}$.*

1. *For every invertible complex $n \times n$ matrix z and every $w \in \mathbb{Z}^n$, $m_w(z^*) = \overline{m_w(z)}$ and $m_{-w}(z) = m_w(z^{-1})$.*

2. *Let $w \in \mathbb{Z}^n$ satisfy $w_i \geq w_j$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$. Then every $b \in \mathrm{B}_l$ has nonzero diagonal entries, and*

$$m_w(c^*z\, b) = \overline{c^w}\, b^w\, m_w(z)$$

for every invertible complex $n \times n$ matrix z and all $b, c \in \mathrm{B}_l$.

3. *$2\rho_l(i) \geq 2\rho_l(j) + 2$ and $l_i^\rho \geq l_j^\rho$ whenever $l_i > l_j$. If moreover every entry of l is congruent to $\#n - 1$ modulo 2, then $2l^\rho = l + 2\rho_l$, $(-l)^\rho = -l^\rho$, $\mu_{-l} = -\mu_l$, and $\mu_l(i) \geq \mu_l(j)$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$.*

Proof. Throughout, z_{PQ} denotes the submatrix of a matrix z with rows in P and columns in Q, so that $\Delta_P(z) = \det z_{PP}$.

(i). $(z^*)_{PP} = (z_{PP})^*$, so $\Delta_P(z^*) = \overline{\Delta_P(z)}$ for every $P \subseteq n$ (including $P = n$, the determinant), and $m_w(z^*) = \overline{m_w(z)}$ by (3.1). For the second identity we use Jacobi's complementary minor formula $\Delta_P(z^{-1}) = \Delta_{n\smallsetminus P}(z)/\det z$ for invertible z and $P \subseteq n$ ([133], 0.8.4; for $P = \emptyset$ and $P = n$ it reads $1 = 1$). Put $w_- = \min_i w_i$ and $w_+ = \max_i w_i$. The minimum and maximum of $-w$ are $-w_+$ and $-w_-$, so by (3.1)

$$m_{-w}(z) = (\det z)^{-w_+} \prod_{-w_+ < t \le -w_-} \Delta_{\{i:\, -w_i \ge t\}}(z).$$

Substitute $t = 1 - s$: the integers t with $-w_+ < t \le -w_-$ are those with $w_- < s \le w_+$, and $\{i : -w_i \ge 1 - s\} = \{i : w_i < s\} = n \smallsetminus \{i : w_i \ge s\}$. By Jacobi's formula each factor is $\det z \cdot \Delta_{\{i:\, w_i \ge s\}}(z^{-1})$, and there are $w_+ - w_-$ factors, so

$$m_{-w}(z) = (\det z)^{-w_-} \prod_{w_- < s \le w_+} \Delta_{\{i:\, w_i \ge s\}}(z^{-1}) = (\det z^{-1})^{w_-} \prod_{w_- < s \le w_+} \Delta_{\{i:\, w_i \ge s\}}(z^{-1}) = m_w(z^{-1}).$$

(ii). Order n by decreasing l (possible as the entries are distinct). In this order every $b \in \mathrm{B}_l$ is upper triangular, since $b_{kj} \ne 0$ forces $l_k \ge l_j$; hence $\det b = \prod_i b_{ii}$, and the diagonal entries are nonzero because b is invertible. Call $P \subseteq n$ *closed* if $j \in P$, $\varepsilon_k = \varepsilon_j$ and $l_k > l_j$ imply $k \in P$. Every set $P_t = \{i : w_i \ge t\}$ is closed: if $j \in P_t$, $\varepsilon_k = \varepsilon_j$ and $l_k > l_j$, then $w_k \ge w_j \ge t$ by the hypothesis on w. The set n is closed as well.

Let P be closed, y any matrix and $b, c \in \mathrm{B}_l$. For $i, j \in P$, $(yb)_{ij} = \sum_k y_{ik} b_{kj}$, and $b_{kj} \ne 0$ forces $k = j$ or ($\varepsilon_k = \varepsilon_j$ and $l_k > l_j$), hence $k \in P$; so $(yb)_{PP} = y_{PP} b_{PP}$. Likewise $(c^* y)_{ij} = \sum_k \overline{c_{ki}}\, y_{kj}$, and $c_{ki} \ne 0$ forces $k \in P$; so $(c^* y)_{PP} = (c_{PP})^* y_{PP}$. The matrices b_{PP}, c_{PP} are upper triangular in the order by decreasing l, so

$$\Delta_P(c^* z b) = \Big(\prod_{i \in P} \overline{c_{ii}}\, b_{ii}\Big) \Delta_P(z) \qquad (P \text{ closed}).$$

Put $d_i = \overline{c_{ii}}\, b_{ii} \ne 0$. Applying this to $P = n$ and to the sets P_t in (3.1),

$$m_w(c^* z b) = m_w(z) \prod_{i \in n} d_i^{e_i}, \qquad e_i = w_- + \#\{t \in \mathbb{Z} :\, w_- < t \le w_+,\, t \le w_i\} = w_- + (w_i - w_-) = w_i,$$

and $\prod_i d_i^{w_i} = \overline{c^w}\, b^w$.

(iii). Let $l_i > l_j$. Every k with $l_k < l_j$ satisfies $l_k < l_i$, and j itself satisfies $l_j < l_i$; every k with $l_k > l_i$ satisfies $l_k > l_j$, and i itself satisfies $l_i > l_j$. Hence $2\rho_l(i) \ge 2\rho_l(j) + 2$, so $l_i + 2\rho_l(i) > l_j + 2\rho_l(j)$, and taking integer parts of halves, $l_i^\rho \ge l_j^\rho$.

Now assume the parity condition. For each i, $\#\{k : l_k < l_i\} + \#\{k : l_k > l_i\} = \#n - 1$ because the entries are distinct, so $2\rho_l(i) \equiv \#n - 1 \equiv l_i \pmod 2$; thus $l_i + 2\rho_l(i)$ is even and $2l_i^\rho = l_i + 2\rho_l(i)$. Replacing l by $-l$ exchanges the two counts in $2\rho_l$ and in $2\rho_l^{\mathrm{c}}$, so $2\rho_{-l} = -2\rho_l$ and $2\rho_{-l}^{\mathrm{c}} = -2\rho_l^{\mathrm{c}}$; as $-l$ satisfies the same parity condition, $2(-l)^\rho = -l - 2\rho_l = -2l^\rho$, and $\mu_{-l} = (-l)^\rho - 2\rho_{-l}^{\mathrm{c}} = -\mu_l$.

Finally let $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$. Write $\sigma(x) \in \{-1, 0, 1\}$ for the sign of an integer x, and $\tau_k = 1$ if $\varepsilon_k \ne \varepsilon_i$, $\tau_k = -1$ if $\varepsilon_k = \varepsilon_i$ (the same for j). By definition $2\rho_l(i) = \sum_k \sigma(l_i - l_k)$ and $2\rho_l^{\mathrm{c}}(i) = \sum_{k:\, \varepsilon_k = \varepsilon_i} \sigma(l_i - l_k)$, hence

$$2\mu_l(i) = l_i + 2\rho_l(i) - 2 \cdot 2\rho_l^{\mathrm{c}}(i) = l_i + \sum_k \tau_k\, \sigma(l_i - l_k),$$

and the same with j (with the same τ_k, since $\varepsilon_i = \varepsilon_j$). Therefore

$$2\mu_l(i) - 2\mu_l(j) = (l_i - l_j) + \sum_k \tau_k(\sigma(l_i - l_k) - \sigma(l_j - l_k)).$$

The bracket lies in $\{0, 1, 2\}$; it vanishes unless $l_j \le l_k \le l_i$, equals 1 for $k \in \{i, j\}$ (where $\tau_k = -1$), and equals 2 when $l_j < l_k < l_i$. The entries of l are distinct and congruent modulo 2, so the number N of k with $l_j < l_k < l_i$ is at most $\frac{1}{2}(l_i - l_j) - 1$. Hence the sum is at least $-2 - 2N \ge -(l_i - l_j)$, and $2\mu_l(i) - 2\mu_l(j) \ge 0$. □

Lemma 5.6.28. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$ and $l \in \mathbb{Z}^n$ with distinct entries. Let $K_{\mathbb{C}}$ be the group of invertible complex $n \times n$ matrices x with $x_{ij} = 0$ whenever $\varepsilon_i \ne \varepsilon_j$, let $\mathrm{B}_l \subseteq K_{\mathbb{C}}$ be the subgroup of the b with $b_{ij} = 0$ unless $\varepsilon_i = \varepsilon_j$ and $l_i \ge l_j$, and for $w \in \mathbb{Z}^n$ put $b^w = \prod_i b_{ii}^{w_i}$. Let $F\colon K_{\mathbb{C}} \to \mathbb{C}$ be continuous with*

$$F(yb) = \left|b^{-2\rho_l^c}\right|^2 F(y) \qquad (y \in K_{\mathbb{C}},\ b \in \mathrm{B}_l).$$

Then $\int_{K_\varepsilon} F(xk)\,dk = \int_{K_\varepsilon} F(k)\,dk$ for every $x \in K_{\mathbb{C}}$.

Proof. Write $n_\pm = \{i : \varepsilon_i = \pm 1\}$, so that $K_{\mathbb{C}} = \mathrm{GL}(\mathbb{C}^{n_+}) \times \mathrm{GL}(\mathbb{C}^{n_-})$ and $K_\varepsilon = \mathrm{U}(n_+) \times \mathrm{U}(n_-)$, the blocks being the restrictions to $n_\pm$ (a factor with empty index set is the trivial group). The diagonal entries of every $b \in \mathrm{B}_l$ are nonzero (Lemma 5.6.27, (ii)), so b^w is defined.

Block scalars are invisible. For nonzero complex numbers c_+, c_- let s_c be the diagonal matrix with entry $c_\pm$ at the indices in $n_\pm$; it is central in $K_{\mathbb{C}}$ and lies in B_l. For each sign e, $\sum_{i \in n_e} 2\rho_l^c(i) = \sum_{i,k \in n_e} \sigma(l_i - l_k) = 0$, where σ is the sign function, because the summand is antisymmetric in (i, k). Hence $|s_c^{-2\rho_l^c}| = |c_+|^{-\sum_{n_+} 2\rho_l^c} |c_-|^{-\sum_{n_-} 2\rho_l^c} = 1$ and

$$F(ys_c) = F(y) \qquad (y \in K_{\mathbb{C}}). \tag{5.104}$$

Reduction to the special linear group. Let G be the subgroup of $K_{\mathbb{C}}$ of the x whose blocks have determinant 1, and $K' = G \cap K_\varepsilon = \mathrm{SU}(n_+) \times \mathrm{SU}(n_-)$. Every $x \in K_{\mathbb{C}}$ is $x's_c$ with $x' \in G$: choose c_e with $c_e^{\#n_e} = \det x_e$ for each nonempty block x_e of x. Likewise every $k \in K_\varepsilon$ is $k's_u$ with $k' \in K'$ and $|u_\pm| = 1$. The map $K' \times \mathrm{U}(1)^2 \to K_\varepsilon$, $(k', u) \mapsto k's_u$, is a continuous surjective homomorphism (s_u is central), so the image of the product of the Haar probability measures is a left-invariant probability measure on K_ε, that is, its Haar probability measure. With (5.104) and the centrality of s_c this gives

$$\int_{K_\varepsilon} F(xk)\,dk = \int_{K'} \int_{\mathrm{U}(1)^2} F(x'k's_cs_u)\,du\,dk' = \int_{K'} F(x'k')\,dk',$$

and for $x = 1$, $\int_{K_\varepsilon} F(k)\,dk = \int_{K'} F(k')\,dk'$. It remains to show $\int_{K'} F(x'k')\,dk' = \int_{K'} F(k')\,dk'$ for $x' \in G$. Factors of G with one index are trivial and may be omitted; if G is trivial there is nothing to prove.

Iwasawa decomposition of G. G is a product of groups $\mathrm{SL}_m(\mathbb{C})$, $m \ge 2$, hence a connected semisimple Lie group with finite centre, and K' is a maximal compact subgroup. Let $A \subseteq G$ be the group of diagonal matrices with positive entries and $N \subseteq G$ the group of the y with $y_{ii} = 1$ and $y_{ij} = 0$ for $i \ne j$ unless $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$. Ordering each block by decreasing l, AN is the group of upper triangular matrices of G with positive diagonal, and $G = K'AN$ is the Iwasawa decomposition (Gram–Schmidt orthonormalisation of the columns, block by block). The Lie algebra $\mathfrak{a}$ of A consists of the real diagonal matrices H of trace zero in each block; the restricted

roots are $H \mapsto H_i - H_j$ ($i \neq j$ in one block), each with root space $\mathbb{C}E_{ij}$ of real dimension 2, and those occurring in the Lie algebra of N are the ones with $l_i > l_j$. Hence

$$\begin{aligned} 2\rho(H) &= 2 \sum_{\substack{\varepsilon_i = \varepsilon_j \\ l_i > l_j}} (H_i - H_j) \\ &= 2 \sum_i H_i (\#\{j : \varepsilon_j = \varepsilon_i,\ l_j < l_i\} - \#\{j : \varepsilon_j = \varepsilon_i,\ l_j > l_i\}) = 2 \sum_i 2\rho_l^{\mathrm{c}}(i) H_i, \end{aligned}$$

so $e^{-2\rho(H)} = \prod_i a_i^{-2 \cdot 2\rho_l^{\mathrm{c}}(i)}$ for $a = \exp H = \operatorname{diag}(a_i)$. The centraliser M of A in K' consists of diagonal unitary matrices.

Conclusion. For $g \in G$ write $g = \kappa(g) \exp(H(g))\, n(g)$ as in Theorem A.5.22. The matrix $\exp(H(g))\, n(g)$ lies in B_l and has diagonal $a = \exp H(g)$, so the transformation rule of F gives

$$F(g) = \left|a^{-2\rho_l^{\mathrm{c}}}\right|^2 F(\kappa(g)) = e^{-2\rho(H(g))} F(\kappa(g)).$$

Let f be the restriction of F to K'; it is continuous, and for $m \in M \subseteq \mathrm{B}_l$, $f(km) = |m^{-2\rho_l^{\mathrm{c}}}|^2 f(k) = f(k)$ since $|m_{ii}| = 1$. By Theorem A.5.22, for $x' \in G$,

$$\int_{K'} F(x'k')\, dk' = \int_{K'} f(\kappa(x'k'))\, e^{-2\rho(H(x'k'))}\, dk' = \int_{K'} f(k')\, dk' = \int_{K'} F(k')\, dk'.$$

□

Lemma 5.6.29. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $H \geq 0$ an integer and $l \in \mathbb{Z}^n$ a vector with gap H for ε. Then for every $g \in \mathrm{U}(\operatorname{diag}\varepsilon)$:*

1. $|c_{l/2}(g)|^2\, |\det \mathrm{bd}_\varepsilon(g)|^c \leq 1$ *for every integer* $0 \leq c \leq H$;
2. $c_{-l/2}(g) = \overline{c_{l/2}(g)}$.

Proof. Write $K = K_\varepsilon$ with Haar probability measure du and $\mu = \mu_l$. A vector with gap H has gap 0, so Lemma 5.6.26 and Lemma 5.6.27 (iii) apply to l and to $-l$. We use the facts of Lemma 5.6.30 on $\mathrm{U}(\operatorname{diag}\varepsilon)$: for x in it, $|\det x| = 1$, $|\Delta_{n \smallsetminus P}(x)| = |\Delta_P(x)|$ and $m_w(x^{-1}) = m_{-w}(x) = \overline{m_w(x)}$ (part (i)); every g in it is $g = kz$ with $k \in K$ and z a positive definite element (part (ii)); and $\mathrm{bd}_\varepsilon(xyx') = x\, \mathrm{bd}_\varepsilon(y)\, x'$ for block-diagonal x, x' (part (iii)), so $\mathrm{bd}_\varepsilon(kz) = k\, \mathrm{bd}_\varepsilon(z)$ and $\mathrm{bd}_\varepsilon(u^* z u) = u^* \mathrm{bd}_\varepsilon(z) u$ for $u \in K$.

The polar formula. Let $g = kz$ as above. The splitting $g = k\, z\, 1^*$ ($p = k$, $q = 1$ invertible block-diagonal, z accretive) and Lemma 5.6.26 (i), (ii) give

$$c_{l/2}(g) = \frac{1}{\|m_\mu\|^2} \int_K \frac{m_\mu(ku)\, \overline{m_\mu(u)}}{m_{-l^\rho}(u^* z u)}\, du. \tag{5.105}$$

(ii). By Lemma 5.6.27 (iii), $\mu_{-l} = -\mu$ and $(-l)^\rho = -l^\rho$, so (5.105) for $-l$ has integrand $m_{-\mu}(ku)\overline{m_{-\mu}(u)}/m_{l^\rho}(u^* z u)$ and normalisation $\|m_{-\mu}\|^2$. The matrices ku, u, $u^* z u$ lie in $\mathrm{U}(\operatorname{diag}\varepsilon)$, so by $m_{-w}(x) = \overline{m_w(x)}$ there, this integrand is the complex conjugate of that for l, and $\|m_{-\mu}\|^2 = \|m_\mu\|^2$. Hence $c_{-l/2}(g) = \overline{c_{l/2}(g)}$.

A determinant bound. Let $y \in \mathrm{U}(\operatorname{diag}\varepsilon)$ be positive definite, $a = \mathrm{bd}_\varepsilon(y)$ and $0 \leq c \leq H$ an integer. We show

$$|\det a|^c \leq |m_{-l^\rho}(y)|^2. \tag{5.106}$$

By Lemma 5.6.30 (ii), $a = \frac{1}{2}(y + y^{-1})$ is positive definite. Put $\nu = l^\rho$ and $v = \nu + c$ (add c to each entry); from (3.1), $m_v(x) = (\det x)^c m_\nu(x)$. Choose an integer B with all entries of ν and v in $[-B, B]$; then (3.1) reads $m_w(x) = (\det x)^{-B} \prod_{-B<t\le B} \Delta_{\{w\ge t\}}(x)$ for $w \in \{\nu, v\}$, where $\{w \ge t\} = \{i : w_i \ge t\}$. Fix t and put $Q = \{\nu \ge t\}$, $P = \{v \ge t\}$, $R = P \smallsetminus Q = \{i : t - c \le \nu_i \le t - 1\}$ and $S = \{v < t\} = n \smallsetminus P$. All indices in R have the same sign: if $\varepsilon_i \ne \varepsilon_j$ and, say, $l_i > l_j$, then $l_i - l_j \ge 2H$ by the gap and $2\rho_l(i) \ge 2\rho_l(j) + 2$, so $2\nu_i - 2\nu_j = l_i - l_j + 2\rho_l(i) - 2\rho_l(j) \ge 2H + 2$, both by Lemma 5.6.27 (iii), whereas $|\nu_i - \nu_j| \le c - 1 \le H - 1$ for $i, j \in R$. Hence a and y have the same $R \times R$ block. Fischer's inequality $\Delta_{X\sqcup Y}(A) \le \Delta_X(A)\Delta_Y(A)$ for positive definite A ([133], 7.8.5), applied to a with $P = Q \sqcup R$, then the complement identity for y ($n \smallsetminus R = Q \sqcup S$), then Fischer for y, gives

$$\Delta_P(a) \le \Delta_Q(a)\,\Delta_R(y) = \Delta_Q(a)\,\Delta_{Q\sqcup S}(y) \le \Delta_Q(a)\,\Delta_Q(y)\,\Delta_S(y),$$

all minors being positive. By Jacobi's formula and $|\det y| = 1$, $\Delta_S(y) = |\Delta_P(y^{-1})|$. Taking the product over $-B < t \le B$ and the factors $(\det\cdot)^{-B}$ (with $|\det y| = |\det y^{-1}| = 1$),

$$|m_v(a)| \le |m_\nu(a)|\,|m_\nu(y)|\,|m_v(y^{-1})| = |m_\nu(a)|\,|m_\nu(y)|\,|m_\nu(y^{-1})|,$$

and $|m_v(a)| = (\det a)^c |m_\nu(a)|$ with $m_\nu(a) \ne 0$. Dividing, and using $|m_\nu(y^{-1})| = |m_\nu(y)| = |m_{-\nu}(y)|$ by Lemma 5.6.30 (i), gives (5.106).

(i). Let $g = kz$ as above and $D = |\det \mathrm{bd}_\varepsilon(g)|^c = |\det \mathrm{bd}_\varepsilon(z)|^c > 0$ ($\mathrm{bd}_\varepsilon(g)$ is invertible by Lemma 5.6.25). For $u \in K$, $y = u^* z u$ is a positive definite element of $\mathrm{U}(\mathrm{diag}\,\varepsilon)$ with $\mathrm{bd}_\varepsilon(y) = u^* \mathrm{bd}_\varepsilon(z) u$, so (5.106) gives $|m_{-l^\rho}(u^* z u)| \ge D^{1/2}$. In (5.105), $2|m_\mu(ku)\,m_\mu(u)| \le |m_\mu(ku)|^2 + |m_\mu(u)|^2$, and $\int_K |m_\mu(ku)|^2 du = \int_K |m_\mu(u)|^2 du = \|m_\mu\|^2$ by the invariance of Haar measure. Therefore

$$|c_{l/2}(g)| \le \frac{1}{\|m_\mu\|^2} \cdot \frac{1}{D^{1/2}} \cdot \frac{\|m_\mu\|^2 + \|m_\mu\|^2}{2} = D^{-1/2},$$

that is $|c_{l/2}(g)|^2\,|\det \mathrm{bd}_\varepsilon(g)|^c \le 1$. □

Lemma 5.6.30. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$ and $J = \mathrm{diag}(\varepsilon)$.*

1. *Every $x \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ satisfies $x^{-1} = Jx^*J$, $\|x^{-1}\| = \|x\| \ge 1$ and $|\det x| = 1$, and for all $P \subseteq n$ and $w \in \mathbb{Z}^n$*

$$\Delta_P(x^{-1}) = \overline{\Delta_P(x)}, \qquad |\Delta_{n\smallsetminus P}(x)| = |\Delta_P(x)|, \qquad m_w(x^{-1}) = m_{-w}(x) = \overline{m_w(x)}.$$

2. *Every $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ is a product $g = kz$ with $k \in K_\varepsilon$ and $z \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ positive definite. For such z, $z^{-1} = JzJ$ and $\mathrm{bd}_\varepsilon(z) = \frac{1}{2}(z + z^{-1})$ is positive definite; and $\|g\| = \|z\|$.*

3. *If x, x' are matrices with $x_{ij} = x'_{ij} = 0$ whenever $\varepsilon_i \ne \varepsilon_j$, then $\mathrm{bd}_\varepsilon(xyx') = x\,\mathrm{bd}_\varepsilon(y)\,x'$ for every matrix y.*

Proof. (i). From $x^*Jx = J$ and $J^2 = 1$, $(Jx^*J)x = 1$, so $x^{-1} = Jx^*J$; as J is unitary, $\|x^{-1}\| = \|x^*\| = \|x\|$, and $1 \le \|x\|\,\|x^{-1}\| = \|x\|^2$. Taking determinants in $x^*Jx = J$ gives $|\det x|^2 = 1$. For $P \subseteq n$, $(x^{-1})_{PP} = J_{PP}(x_{PP})^* J_{PP}$ with J_{PP} diagonal of entries ± 1, so $\Delta_P(x^{-1}) = (\det J_{PP})^2 \overline{\Delta_P(x)} = \overline{\Delta_P(x)}$ (for $P = \emptyset$ both sides are 1). Jacobi's complementary minor formula $\Delta_P(x^{-1}) = \Delta_{n\smallsetminus P}(x)/\det x$ ([133], 0.8.4) and $|\det x| = 1$ give $|\Delta_{n\smallsetminus P}(x)| = |\Delta_P(x)|$. By (3.1), $m_w(x^{-1})$ is built from the $\Delta_P(x^{-1})$ and $\det x^{-1}$ exactly as $m_w(x)$ from the $\Delta_P(x)$ and $\det x$, so $m_w(x^{-1}) = \overline{m_w(x)}$; and $m_{-w}(x) = m_w(x^{-1})$ by Lemma 5.6.27 (i).

(ii). Let $z = (g^*g)^{1/2}$ be the positive definite square root. The hermitian matrix g^*g lies in $\mathrm{U}(\mathrm{diag}\,\varepsilon)$, so by (i) $J(g^*g)J = (g^*g)^{-1}$. Conjugation by the unitary involution J commutes with the continuous functional calculus of hermitian matrices, hence $JzJ = \left((g^*g)^{-1}\right)^{1/2} = z^{-1}$, and $z^*Jz = zJz = J\,(JzJ)\,z = J$: $z \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$. Then $k = gz^{-1} \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ and $k^*k = z^{-1}g^*gz^{-1} = 1$; from $k^*Jk = J$ and $k^* = k^{-1}$ we get $Jk = kJ$, so $k_{ij} = 0$ whenever $\varepsilon_i \neq \varepsilon_j$, and $k \in K_\varepsilon$. For any positive definite $z \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$, (i) gives $z^{-1} = Jz^*J = JzJ$, and $\mathrm{bd}_\varepsilon(z) = \frac{1}{2}(z + JzJ)$ (the entries with $\varepsilon_i = \varepsilon_j$ are kept, the others cancel), which is $\frac{1}{2}(z + z^{-1})$, positive definite as a sum of positive definite matrices. Finally $\|g\| = \|kz\| = \|z\|$ as k is unitary.

(iii). $(xyx')_{ij} = \sum_{a,b} x_{ia}y_{ab}x'_{bj}$, and a nonzero term has $\varepsilon_a = \varepsilon_i$ and $\varepsilon_b = \varepsilon_j$. If $\varepsilon_i = \varepsilon_j$, then $\varepsilon_a = \varepsilon_b$ in every nonzero term, so $(xyx')_{ij} = (x\,\mathrm{bd}_\varepsilon(y)\,x')_{ij}$. If $\varepsilon_i \neq \varepsilon_j$, then $(\mathrm{bd}_\varepsilon(xyx'))_{ij} = 0$, and every term of $(x\,\mathrm{bd}_\varepsilon(y)\,x')_{ij}$ would need $\varepsilon_i = \varepsilon_a = \varepsilon_b = \varepsilon_j$, so it vanishes as well. □

Lemma 5.6.31. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $l \in \mathbb{Z}^n$ a vector with gap 0 for ε, $\lambda = \frac{1}{2}l$ and $\mu = \mu_l$; for $o, \beta \in \mathbb{Z}^n$ put $o \cdot \beta = \sum_{i\in n} o_i\beta_i$.*

(i) For all $x, b \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$

$$\int_{K_\varepsilon} \overline{m_\mu(k)}\; c_\lambda(xkb)\,dk = \|m_\mu\|^2\, c_\lambda(x)\, c_\lambda(b).$$

(ii) Let $\nu \in \mathbb{Z}^n$ satisfy $\nu_i \geq \nu_j$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$, and suppose that some $o \in \mathbb{Z}^n$ with $o_i < o_j$ whenever $l_i > l_j$ has $o \cdot (\nu - \mu) > 0$. Then for all $x, b \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$

$$\int_{K_\varepsilon} \overline{m_\nu(k)}\; c_\lambda(xkb)\,dk = 0.$$

Proof. Write $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, $J = \mathrm{diag}(\varepsilon)$, $K = K_\varepsilon$, $c = c_\lambda$, $\|\cdot\|$ for the operator norm, $\Delta_{P,Q}(y)$ for the minor of y with rows P and columns Q ($\Delta_P = \Delta_{P,P}$), and $t^w = \prod_i t_{ii}^{w_i}$. Fix $\nu \in \mathbb{Z}^n$ with $\nu_i \geq \nu_j$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$, and $o \in \mathbb{Z}^n$ with $o_i < o_j$ whenever $l_i > l_j$, such that $N = o \cdot (\nu - \mu) \geq 0$ and $N = 0$ only if $\nu = \mu$. We show, for all $x, b \in G$,

$$\int_K \overline{m_\nu(k)}\, c(xkb)\,dk = \begin{cases} \|m_\mu\|^2\, c(x)\, c(b) & \text{if } \nu = \mu, \\ 0 & \text{if } \nu \neq \mu. \end{cases} \tag{5.107}$$

For (i) take $\nu = \mu$ and $o = -l$: μ satisfies the condition on ν by Lemma 5.6.27 (iii), and $N = 0$. For (ii), $N > 0$ forces $\nu \neq \mu$. As the entries of l are distinct, o is injective: for $i \neq j$ with $l_i > l_j$, $o_i < o_j$. For $Q \subseteq n$ put $o(Q) = \sum_{i\in Q} o_i$.

Let B_l be as in Lemma 5.6.27, and let B' be the group of invertible t with $t_{ij} = 0$ unless $l_i \leq l_j$; Lemma 5.6.27 (ii), applied to the signs $(1, \dots, 1)$ and the vector $-l$ (for which its group is B') and to the weight $-l^\rho$ (admissible, since $l_i^\rho \leq l_j^\rho$ when $l_i < l_j$ by Lemma 5.6.27 (iii)), gives

$$m_{-l^\rho}(c^*Zt) = \overline{c^{-l^\rho}}\; t^{-l^\rho}\; m_{-l^\rho}(Z) \qquad (Z \text{ invertible},\ c, t \in \mathrm{B}'). \tag{5.108}$$

For $s \in \mathbb{C}^\times$ put $\tau_s = \mathrm{diag}(s^{o_i})_{i\in n}$; for $|s| = 1$, $\tau_s \in K$ and $\tau_s^* = \tau_s^{-1}$. For $x, b \in G$ put $T_x(b) = \int_K \overline{m_\nu(k)}\, c(xkb)\,dk$.

Step 1: Gauss factorisation. Number $n = \{i_1, \dots, i_n\}$ so that $l_{i_1} < \cdots < l_{i_n}$, and let $\mathcal{N}$ be the open set of matrices y whose leading principal minors $\Delta_{\{i_1,\dots,i_m\}}(y)$ $(1 \leq m \leq n)$ do not vanish; by Lemma 5.6.25 (ii) it contains every accretive matrix. Gaussian elimination in the order $i_1, \dots, i_n$ writes every $y \in \mathcal{N}$ uniquely as $y = L(y)U(y)$ with $L(y)$ unipotent and $L(y)_{ij} = 0$ unless $i = j$ or $l_i > l_j$, and $U(y) \in \mathrm{B}'$; the entries of $L(y)$ and $U(y)$ are rational functions of

the entries of y whose denominators are leading principal minors, so they are continuous on $\mathcal{N}$, and $L(1) = U(1) = 1$. For $s \in \mathbb{C}$ let $A_y(s)$ be the matrix with entries $L(y)_{ij} s^{o_j - o_i}$; wherever $i \neq j$ and $L(y)_{ij} \neq 0$ we have $l_i > l_j$, so $o_j - o_i$ is a positive integer; thus A_y is a polynomial in s, $A_y(0) = 1$, and $A_y(s) = \tau_s^{-1} L(y) \tau_s$ for $s \neq 0$. Since $L(y)^* \in \mathrm{B}'$ has diagonal 1, (5.108) gives $m_{-l^\rho}(L(y)Z) = m_{-l^\rho}(Z)$ for invertible Z, and therefore

$$m_{-l^\rho}(y) = U(y)^{-l^\rho}, \qquad m_{-l^\rho}(w\,\tau_s^{-1} y \tau_s) = m_{-l^\rho}(y)\, m_{-l^\rho}(w\, A_y(s)) \tag{5.109}$$

for $y \in \mathcal{N}$, $|s| = 1$ and every w with $wA_y(s)$ invertible: indeed $\tau_s^{-1} y \tau_s = A_y(s)\, U_s$ with $U_s = \tau_s^{-1} U(y) \tau_s \in \mathrm{B}'$, whose diagonal is that of $U(y)$, and (5.108) applies.

Step 2: m_ν along a torus. For $j, k \in K$ there is a polynomial $P_{k,j}$ with $P_{k,j}(0) = m_\nu(k)\, m_\nu(j^{-1})$ and

$$m_\nu(k \tau_s j^{-1}) = s^{o \cdot \nu} P_{k,j}(s) \qquad (s \in \mathbb{C}^\times).$$

For $P \subseteq n$, the Cauchy–Binet formula and the diagonality of τ_s give

$$\Delta_P(k \tau_s j^{-1}) = \sum_Q \Delta_{P,Q}(k)\, s^{o(Q)}\, \Delta_{Q,P}(j^{-1}),$$

the sum over $Q \subseteq n$ with $\#Q = \#P$. As k is block-diagonal for the sign blocks $\beta = \{i : \varepsilon_i = \pm 1\}$, $\Delta_{P,Q}(k) = 0$ unless $\#(Q \cap \beta) = \#(P \cap \beta)$ for both blocks. Now let $P = P_t = \{i : \nu_i \geq t\}$. By the condition on ν, $P_t \cap \beta$ consists of the $\#(P_t \cap \beta)$ indices of β with the largest l_i, that is, with the smallest o_i; as o is injective, every other subset of β of the same size has a strictly larger sum of the o_i. Hence every $Q \neq P_t$ with nonzero term has $o(Q) > o(P_t)$, and $\Delta_{P_t}(k \tau_s j^{-1}) = s^{o(P_t)} (\Delta_{P_t}(k) \Delta_{P_t}(j^{-1}) + s\, R_t(s))$ with a polynomial R_t; also $\det(k \tau_s j^{-1}) = \det(k) \det(j^{-1})\, s^{o(n)}$. Inserting this in (3.1) gives the claim, with

$$P_{k,j}(s) = (\det k \det j^{-1})^{\min_i \nu_i} \prod_{\min \nu < t \leq \max \nu} (\Delta_{P_t}(k) \Delta_{P_t}(j^{-1}) + s R_t(s)),$$

the exponent being $o(n) \min_i \nu_i + \sum_{\min \nu < t \leq \max \nu} o(P_t) = \sum_i o_i \nu_i$.

Step 3: a double integral, for b near 1. Fix $x \in G$, put $a = \mathrm{bd}_\varepsilon(x)$ and $z = a^{-1} x$, accretive by Lemma 5.6.25 (i). The set $\{j^* z j : j \in K\}$ is a compact set of accretive matrices and accretivity is an open condition, so there is $\delta \in (0, 1)$ such that wA is accretive whenever $w = j^* z j$ $(j \in K)$ and $\|A - 1\| \leq \delta$. By continuity of L at 1 there is $\delta' \in (0, \delta]$ such that every y with $\|y - 1\| \leq \delta'$ lies in $\mathcal{N}$ and satisfies $\|A_y(s) - 1\| \leq \delta$ for $|s| \leq 2$ (the entries of $A_y(s) - 1$ are $L(y)_{ij} s^{o_j - o_i}$, $i \neq j$). Let $\mathcal{U} = \{b \in G : \|b - 1\| \leq \delta'\}$, a neighbourhood of 1; for $b \in \mathcal{U}$ and $k \in K$, $y = k^* b k$ has $\|y - 1\| = \|b - 1\| \leq \delta'$, and b is accretive since $b + b^* \geq 2 - 2\|b - 1\| > 0$.

Let $b \in \mathcal{U}$ and $r \in K$. Then ar is block-diagonal and invertible and $(ar)^{-1}(xrb) = (r^* z r)\, b$ is accretive, so by Lemma 5.6.26 (i) and (3.2)

$$\|m_\mu\|^2 c(xrb) = \int_K \frac{m_\mu(ark)\, \overline{m_\mu(k)}}{m_{-l^\rho}(k^* r^* z r b k)}\, dk.$$

With $j = rk$ we have $k^* r^* z r b k = (j^* z j)(k^* b k)$, and $\overline{m_\nu(r)} = m_\nu(r^{-1}) = m_\nu(k j^{-1})$ by Lemma 5.6.30 (i). Put

$$H(j, k) = \frac{m_\nu(k j^{-1})\, m_\mu(aj)\, \overline{m_\mu(k)}}{m_{-l^\rho}((j^* z j)(k^* b k))} \qquad (j, k \in K),$$

continuous on $K \times K$, the argument of the denominator being accretive. Then

$$\overline{m_\nu(r)}\, \|m_\mu\|^2 c(xrb) = \int_K H(rk, k)\, dk;$$

integrating over r, using Fubini's theorem and, for fixed k, the invariance of dr under $r \mapsto rk$,

$$\|m_\mu\|^2\, T_x(b) = \int_K \int_K H(j,k)\, dj\, dk.$$

Step 4: averaging over the circle. For $|s| = 1$ the map $(j,k) \mapsto (j, k\tau_s)$ preserves $dj\, dk$, so, averaging over $s = e^{i\theta}$ and using Fubini's theorem, $\iint H = \iint M$ with $M(j,k) = \frac{1}{2\pi}\int_0^{2\pi} H(j, k\tau_{e^{i\theta}})\, d\theta$. Fix j, k, put $w = j^* z j$, $y = k^* b k$, and let $|s| = 1$. Then $(k\tau_s)^* b (k\tau_s) = \tau_s^{-1} y \tau_s$, $wA_y(s)$ is accretive, and (5.109) gives $m_{-l^\rho}(w\,\tau_s^{-1} y \tau_s) = m_{-l^\rho}(y)\, m_{-l^\rho}(wA_y(s))$. As $\tau_s \in \mathrm{B}_l$ is diagonal, $m_\mu(k\tau_s) = \tau_s^\mu m_\mu(k) = s^{o\cdot\mu} m_\mu(k)$ by Lemma 5.6.27 (ii) (for the weight μ, admissible by Lemma 5.6.27 (iii)), so $\overline{m_\mu(k\tau_s)} = s^{-o\cdot\mu}\, \overline{m_\mu(k)}$. With Step 2,

$$H(j, k\tau_s) = s^N P_{k,j}(s)\, q(s), \qquad q(s) = \frac{m_\mu(aj)\, \overline{m_\mu(k)}}{m_{-l^\rho}(y)\, m_{-l^\rho}\big(wA_y(s)\big)}.$$

For $|s| < 2$ the matrix $wA_y(s)$ is accretive, so its determinant and principal minors do not vanish, and q is holomorphic on $\{|s| < 2\}$. By the mean value property of the holomorphic function $s^N P_{k,j} q$, $M(j,k)$ is its value at $s = 0$. If $\nu \neq \mu$, then $N > 0$ and $M(j,k) = 0$. If $\nu = \mu$, then $N = 0$, and since $A_y(0) = 1$ and $m_\mu(j^{-1}) = \overline{m_\mu(j)}$ (Lemma 5.6.30 (i)),

$$M(j,k) = P_{k,j}(0)\, q(0) = \frac{m_\mu(aj)\, \overline{m_\mu(j)}}{m_{-l^\rho}(j^* z j)} \cdot \frac{|m_\mu(k)|^2}{m_{-l^\rho}(k^* b k)}.$$

Step 5: (5.107) *for* $b \in \mathcal{U}$. If $\nu \neq \mu$, Steps 3 and 4 give $\|m_\mu\|^2 T_x(b) = 0$; note $\|m_\mu\|^2 > 0$. If $\nu = \mu$: by (3.2), $\int_K \frac{m_\mu(aj)\overline{m_\mu(j)}}{m_{-l^\rho}(j^* z j)} dj = \|m_\mu\|^2 \mathrm{FJ}_l(a, a^{-1}x) = \|m_\mu\|^2 c(x)$, and $\int_K \frac{|m_\mu(k)|^2}{m_{-l^\rho}(k^* b k)} dk = \|m_\mu\|^2 \mathrm{FJ}_l(1, b) = \|m_\mu\|^2 c(b)$ by Lemma 5.6.26 (i) (1 is block-diagonal and b accretive). Hence $\|m_\mu\|^2 T_x(b) = \|m_\mu\|^4 c(x) c(b)$, that is $T_x(b) = \|m_\mu\|^2 c(x) c(b)$.

Step 6: all b*, by analytic continuation.* Let $b \in G$. By Lemma 5.6.30 (ii), $b = k_0 z_0$ with $k_0 \in K$ and $z_0 \in G$ positive definite, $z_0^{-1} = J z_0 J$. Let Z_0 be the hermitian logarithm of z_0; as J is a unitary involution, $\log(J z_0 J) = J Z_0 J$, so $J Z_0 J = -Z_0$, whence $Z_0^* J + J Z_0 = 0$. The block-diagonal unitary k_0 is e^{X_0} with X_0 block-diagonal and skew-hermitian (a logarithm in each block), so X_0 commutes with J and $X_0^* J + J X_0 = 0$. Thus $\gamma(t) = e^{tX_0} e^{tZ_0}$ is a curve in G with real-analytic entries, $\gamma(0) = 1$, $\gamma(1) = b$.

Let $\phi(t)$ be the right side of (5.107) at $\gamma(t)$: 0 if $\nu \neq \mu$, and $\|m_\mu\|^2 c(x) c(\gamma(t))$ if $\nu = \mu$; it is real-analytic in t, since c is locally the restriction of a holomorphic function (Lemma 5.6.24 (ii)). So is $t \mapsto T_x(\gamma(t))$: let $y_0 \in G$. For $r_0 \in K$ put $a_{r_0} = \mathrm{bd}_\varepsilon(x r_0 y_0)$; since $a_{r_0}^{-1} x r_0 y_0$ is accretive (Lemma 5.6.25 (i)), there are open sets $N_{r_0} \ni r_0$ in K and $V_{r_0} \ni y_0$ in $\mathrm{GL}_n(\mathbb{C})$ with $a_{r_0}^{-1} x r y$ accretive for $(r, y) \in N_{r_0} \times V_{r_0}$. Choose $r_1, \dots, r_m$ with $K = \bigcup_i N_{r_i}$, put $V = \bigcap_i V_{r_i}$, and let (χ_i) be a continuous partition of unity on K with $\operatorname{supp}\chi_i \subseteq N_{r_i}$. For $y \in V \cap G$, Lemma 5.6.26 (i) gives

$$T_x(y) = \sum_{i=1}^m \int_K \chi_i(r)\, \overline{m_\nu(r)}\, \mathrm{FJ}_l(a_{r_i}, a_{r_i}^{-1} x r y)\, dr,$$

and each term extends to a holomorphic function of $y \in V$: its integrand is continuous on $\operatorname{supp}\chi_i \times V$ and holomorphic in y (by (3.2), $\mathrm{FJ}_l(a, z)$ is the K-integral of a function continuous in (k, z) and holomorphic in z on accretive z, the denominator being a product of powers of principal minors of the accretive matrix $k^* z k$), so by Morera's theorem and Fubini's theorem in each variable the integral is holomorphic. Hence T_x is locally the restriction of a holomorphic function and $T_x \circ \gamma$ is real-analytic. The two real-analytic functions $T_x \circ \gamma$ and ϕ agree for t near 0, where $\gamma(t) \in \mathcal{U}$ (Step 5), hence on $[0,1]$; at $t = 1$ this is (5.107) for b. □

Lemma 5.6.32. *Let ι be a nonempty finite set of N elements, $\zeta \in \{\pm 1\}^\iota$, S a group with a σ-algebra for which left and right translations are measurable, ν a right-invariant measure on S, and $j\colon S \to \mathrm{U}(\operatorname{diag}\zeta)$ a homomorphism.*

1. *Let $y \in \mathrm{U}(\operatorname{diag}\zeta)$ and $D, R \geq 1$, $K \geq 3DR^2$ be reals. Then*

$$\nu\{s : \|j(s)y\| \leq R\} \leq K^{2N^2}\, \nu\{s : \|j(s) - 1\| \leq D^{-1}\}.$$

2. *Suppose moreover that S carries a topology whose Borel σ-algebra is the given one, that ν is finite on compact sets and that j is proper. Then $\nu\{s : \|j(s) - 1\| \leq R\} < \infty$ for every real R, and for every $y \in \mathrm{U}(\operatorname{diag}\zeta)$ and every integer $c > 8N^2$ the function $s \mapsto (2/\|j(s)y\|)^c$ is ν-integrable with*

$$\int_S \Big(\frac{2}{\|j(s)y\|}\Big)^c d\nu(s) \leq 16^c\, \nu\{s : \|j(s) - 1\| \leq 1\}.$$

Proof. For $g \in \mathrm{U}(\operatorname{diag}\zeta)$ and $Z = \operatorname{diag}(\zeta)$ we have $g^{-1} = Zg^*Z$, so $\|g^{-1}\| = \|g\|$, and $1 = \|Z\| = \|g^*Zg\| \leq \|g\|^2$, so $\|g\| \geq 1$. Where a set below is not known to be measurable, ν is applied as an outer measure; right translations are measurable bijections with measurable inverses, so the outer measure is right invariant as well.

(i) Put $f(s) = j(s)y$, $\mathcal{A} = \{s : \|f(s)\| \leq R\}$, $\mathcal{B} = \{s : \|j(s) - 1\| \leq D^{-1}\}$ and $\delta = (DR)^{-1}$. Call a subset $F \subseteq \mathcal{A}$ separated if $\|f(s) - f(s')\| \geq \delta$ for distinct $s, s' \in F$. For a separated F the closed balls of radius $\delta/2$ (operator norm) about the points $f(s)$, $s \in F$, have disjoint interiors and lie in the ball of radius $R + \delta/2$ about 0 in the real vector space of complex $N \times N$ matrices, of dimension $2N^2$; comparing Lebesgue measures, which scale by r^{2N^2} under dilation by r,

$$\#F \leq \Big(\frac{R + \delta/2}{\delta/2}\Big)^{2N^2} = (1 + 2DR^2)^{2N^2} \leq (3DR^2)^{2N^2} \leq K^{2N^2},$$

as $DR^2 \geq 1$. Take a separated F of maximal cardinality. For $s \in \mathcal{A} \setminus F$, $F \cup \{s\}$ is not separated, so there is $s' \in F$ with $\|f(s) - f(s')\| < \delta$; for $s \in F$ take $s' = s$. Then

$$\|j(ss'^{-1}) - 1\| = \|(f(s) - f(s'))f(s')^{-1}\| \leq \delta\, \|f(s')\| \leq \delta R = D^{-1},$$

since $f(s')^{-1} \in \mathrm{U}(\operatorname{diag}\zeta)$ has the norm of $f(s')$. So $s \in \mathcal{B}s'$, and $\mathcal{A} \subseteq \bigcup_{s' \in F} \mathcal{B}s'$. By right invariance $\nu(\mathcal{A}) \leq \#F\, \nu(\mathcal{B}) \leq K^{2N^2}\nu(\mathcal{B})$.

(ii) The set $\{s : \|j(s) - 1\| \leq R\}$ is the preimage under the proper map j of the intersection of the closed group $\mathrm{U}(\operatorname{diag}\zeta)$ with a closed ball of matrices, a compact set; so it is compact and has finite measure. Let $y \in \mathrm{U}(\operatorname{diag}\zeta)$, $c > 8N^2$, $F(s) = \|j(s)y\| \geq 1$, a continuous function, and $U_1 = \{s : \|j(s) - 1\| \leq 1\}$. For $0 < u < 1$ apply (i) with $D = 1$, $R = u^{-1/c} \geq 1$, $K = 3R^2$:

$$\nu\{s : F(s)^{-c} > u\} \leq \nu\{s : F(s) \leq u^{-1/c}\} \leq 3^{2N^2} u^{-4N^2/c}\, \nu(U_1),$$

while $\{F^{-c} > u\} = \emptyset$ for $u \geq 1$. By the layer-cake formula and $4N^2/c < \frac{1}{2}$,

$$\int_S F^{-c}\, d\nu = \int_0^1 \nu\{F^{-c} > u\}\, du \leq 3^{2N^2}\nu(U_1) \int_0^1 u^{-4N^2/c}\, du \leq 2 \cdot 3^{2N^2}\nu(U_1) < \infty.$$

So $(2/F)^c = 2^c F^{-c}$ is ν-integrable and, as $2N^2 + 1 \leq c$, $\int_S (2/F)^c\, d\nu \leq 2^c \cdot 2 \cdot 3^{2N^2}\nu(U_1) \leq 6^c\nu(U_1) \leq 16^c\nu(U_1)$. □

This group identifies the Bessel-period map at a suitable point with a combination of class Poincaré series, and computes the moments of a map with amplitude blocks near the Bessel subgroup. The first task is Lemma 5.6.33: the Bessel period of a source form, an integral over the compact quotient of the Bessel group, is represented by a unique form, and at a suitable point and linear form this form is the combination of the class Poincaré series with the source coordinates as coefficients. Its proof unfolds the Bessel period class by class into integrals over the real Bessel group (Proposition 5.6.35). The compactness rests on that of the adelic quotients of a unipotent group and of a definite unitary group [37], and the Bessel average of Flensted-Jensen's function is reproduced by the discrete-series kernel (Lemma 5.6.37). For Bessel periods of unitary groups see [96], for the real groups $\mathrm{U}(p,q)$ [125], and for the uniqueness of Bessel models at the real places [153].

After the lemma the parameters of the normalised Poincaré map are fixed for the rest of the paper: the Poincaré map is the Bessel-period map at a Bessel pair, the seesaw constant is one that Proposition 4.2.25 supplies for this map, and the divisibility errors are a family that Proposition 4.2.54 supplies. These parameters are used in two places only: in the proof of the main inequality (Section 5.9) and in the comparison operator of Section 6 (Proposition 6.6.13).

The second task is Proposition 5.6.42. On the level elements that agree with the Bessel subgroup at the chosen places above one prime, the Gram blocks of a map with amplitude blocks are the Bessel translates, up to a second moment of at most $b^{-12}\mathcal{D}_{\mathrm{id}}$. The traces of the Bessel translates are read through the reduced character, whose conjugation mean has square sum at most 2 (Lemma 5.6.43). The proposition also gives the passage from the terms of nonzero discriminant to all terms and the bound for the scalar cosets that Theorem 5.1.13 uses. The near-isometry Proposition 5.6.41, printed before it, rests on its later clauses: for central idempotents of small defect at the chosen places above p_0 and p_1, the good part of the map is a near-isometry with error $5b^{-4}$. With the rarity of bad types this is part (i) of Proposition 5.6.48.

Lemma 5.6.33. *Let D be admissible data.*

(i) For $g \in G(F_\infty)$, a linear form t on W_λ, $\varphi \in \mathcal{S}$ and $y \in \mathcal{A}_M(Y_0)$, the function $r \mapsto \mathcal{W}_{t,\varphi}(r)\,\overline{y(r\,(g,1))}$ on $R(\mathbb{A})$ is continuous, left invariant under $R(E)$ and integrable over $[R]$. There is a unique $\mathcal{P}_{g,t}\varphi \in \mathcal{A}_M(Y_0)$ with

$$\langle y, \mathcal{P}_{g,t}\varphi\rangle = \mathrm{BP}_{g,t}(\varphi, y) \qquad \text{for every } y \in \mathcal{A}_M(Y_0),$$

and $\mathcal{P}_{g,t}\colon \mathcal{S} \to \mathcal{A}_M(Y_0)$ is linear.

*(ii) Let p be the matrix of Proposition 5.7.3 (it has the properties required in Lemma 5.6.18), and Π_a ($a \in \mathcal{C}\times I$) the class Poincaré series of Lemma 5.6.18 (ii) for this p. There are $g_\infty \in G(F_\infty)$ and a linear form t_0 on W_λ (a **Bessel pair**) such that for every $\varphi \in \mathcal{S}$*

$$\mathcal{P}_{g_\infty,t_0}\,\varphi = \sum_{a\in\mathcal{C}\times I} \theta(\varphi)_a\,\Pi_a.$$

Proof. (i). A form $y \in \mathcal{A}_M(Y_0)$ is continuous and bounded and left invariant under the image of $G(E)$ ((FT2) of Definition 3.2.4); read on $G(\mathbb{A})$ through the frames, $x \mapsto y(x)$ is continuous on $G(\mathbb{A})$ and left $G(E)$-invariant, so $r \mapsto \overline{y(r(g,1))}$ is continuous on $R(\mathbb{A})$ and left $R(E)$-invariant. By Lemma 5.6.34 (iv) so is $\mathcal{W}_{t,\varphi}$, hence the product, which is therefore integrable over $[R]$ by Lemma 5.6.34 (iii). Consequently $\mathrm{BP}_{g,t}(\varphi, y)$ is linear in φ ($\mathcal{W}_{t,\varphi}$ is linear in φ) and conjugate-linear in y. By Proposition 5.8.4 with $V = V' = Y_0$ (its hypothesis is (iii) there), $\mathcal{A}_M(Y_0)$ is finite-dimensional. The Petersson product is positive definite on it: if $\langle F, F\rangle = 0$, the continuous

$|F|^2$ vanishes almost everywhere on a Borel fundamental set of the image of $G(E)$, hence almost everywhere by invariance, hence everywhere, Haar measure charging every nonempty open set. So $w \mapsto \langle \cdot, w\rangle$ is an injective linear map of $\mathcal{A}_M(Y_0)$ into the space of conjugate-linear forms on $\mathcal{A}_M(Y_0)$, which has the same finite dimension; it is bijective, and $\mathcal{P}_{g,t}\varphi$ exists and is unique. Linearity in φ follows from uniqueness and the linearity of $\mathrm{BP}_{g,t}$ in φ.

(ii). Let g_∞ and t_0 be as in Proposition 5.6.35, and $\varphi \in \mathcal{S}$. The form $\Sigma = \sum_a \theta(\varphi)_a \Pi_a$ lies in $\mathcal{A}_M(Y_0)$ by Lemma 5.6.18 (ii), and for every $y \in \mathcal{A}_M(Y_0)$

$$\langle y, \Sigma\rangle = \mathrm{BP}_{g_\infty,t_0}(\varphi, y) = \langle y, \mathcal{P}_{g_\infty,t_0}\varphi\rangle$$

by Proposition 5.6.35 and (i). Taking $y = \Sigma - \mathcal{P}_{g_\infty,t_0}\varphi$ and using positive definiteness gives $\Sigma = \mathcal{P}_{g_\infty,t_0}\varphi$. □

Let D be admissible data. From here on the following three choices are fixed.

- A Bessel pair (g_∞, t_0) as in Lemma 5.6.33 (ii) is fixed, and the **Poincaré map** is $\mathcal{P} = \mathcal{P}_{g_\infty,t_0} \colon \mathcal{S} \to \mathcal{A}_M(Y_0)$ of Lemma 5.6.33 (i): the linear map with $\langle y, \mathcal{P}\varphi\rangle = \mathrm{BP}_{g_\infty,t_0}(\varphi, y)$ for every $\varphi \in \mathcal{S}$ and every $y \in \mathcal{A}_M(Y_0)$.
- The **seesaw constant** $c_{\mathrm{ss}} \in \mathbb{C}^\times$ is a scalar as in Proposition 4.2.25, for this Poincaré map, fixed once.
- The **divisibility errors** $\mathrm{err} = (\mathrm{err}_\ell)_\ell = (\epsilon_\ell)_\ell$ are a family of nonnegative real numbers as in Proposition 4.2.54, indexed by the rational primes, fixed once.

The gain exponents g_ℓ, the inverse gain factor c_B, the normalised Poincaré map $\mathfrak{p} \colon \mathcal{S}^{\mathrm{ram}} \to \mathcal{T}$ and its translates $s\mathfrak{p}$ ($s \in \bar{G}$) of D are those of Definition 3.2.37 for the parameters $(\mathcal{P}, c_{\mathrm{ss}}, \mathrm{err})$. These parameters have the properties assumed of them in the results stated for parameters: the family err satisfies the error conditions of Definition 3.2.37 and has the uniform local property of Proposition 4.2.54, by that proposition; for every ordinary twist ϑ the coefficient function Ψ_ϑ of Proposition 4.2.25 is admissible for ϑ and satisfies the seesaw identity $\Theta_\vartheta(\mathcal{P}\varphi) = c_{\mathrm{ss}} B_{\vartheta,\Psi_\vartheta}(\varphi)$ for every $\varphi \in \mathcal{S}^{\mathrm{ram}}$, by conditions 1–4 there; and $\mathcal{P}\varphi = \sum_{a \in \mathcal{C}\times I} \theta(\varphi)_a \, \Pi_a$ for every $\varphi \in \mathcal{S}$, with the coordinates θ and the class Poincaré series Π_a of Lemma 5.6.33 (ii), by that lemma.

Lemma 5.6.34. *Let D be admissible data, and put $\mathsf{U}(E) = \mathsf{U}(\mathbb{A}) \cap G(E)$.*

(i) $R(\mathbb{A})$ is a closed subgroup of $G(\mathbb{A})$ containing $\mathsf{U}(\mathbb{A})$ and $\iota(\mathrm{U}(X_0)(\mathbb{A}_{E^+}))$. For $r \in R(\mathbb{A})$, $a(r) \in \mathrm{U}(X_0)(\mathbb{A}_{E^+})$; $r \mapsto a(r)$ is a continuous homomorphism with kernel $\mathsf{U}(\mathbb{A})$ and $a(\iota(h)) = h$; hence $u(r) \in \mathsf{U}(\mathbb{A})$ and $r = u(r)\,\iota(a(r))$.

(ii) On $\mathsf{U}(\mathbb{A})$, ψ_{U} is a continuous homomorphism to the unit circle, trivial on $\mathsf{U}(E)$, and $\psi_{\mathsf{U}}(\iota(h) u\, \iota(h)^{-1}) = \psi_{\mathsf{U}}(u)$ for $h \in \mathrm{U}(X_0)(\mathbb{A}_{E^+})$, $u \in \mathsf{U}(\mathbb{A})$.

(iii) $R(E)$ is a discrete subgroup of the locally compact group $R(\mathbb{A})$, the quotient $R(E)\backslash R(\mathbb{A})$ is compact, and every continuous left $R(E)$-invariant function on $R(\mathbb{A})$ is bounded and integrable over $[R]$, for every left Haar measure dr.

(iv) For $\varphi \in \mathcal{S}$ and a linear form t on W_λ, $\mathcal{W}_{t,\varphi}$ is continuous and $\mathcal{W}_{t,\varphi}(\gamma r) = \mathcal{W}_{t,\varphi}(r)$ for $\gamma \in R(E)$, $r \in R(\mathbb{A})$.

Proof. Matrices are taken in the basis of Y_0, over the ring $\mathbb{A}_E$. For an even integer d let P_d be the $\mathbb{A}_E$-span of the basis vectors of grade $\geq d$. Grades are even, so a basis vector of grade $> g$ has grade $\geq g+2$. The form pairs v_i with $v_{2\varrho+2-i}$ (grades g and $-g$), is the identity on X_0 and has $\langle v_{\varrho+1}, v_{\varrho+1}\rangle = -N$; hence $P_2 = \langle v_1, \dots, v_\varrho\rangle$ is isotropic, $P_2^\perp = P_0 = P_2 \oplus X_0 \oplus \langle v_{\varrho+1}\rangle$, and P_0/P_2 with the induced form has the orthogonal basis X_0, $v_{\varrho+1}$, of norms 1 and $-N \in \mathbb{A}_E^\times$.

(i). By definition, $g \in G(\mathbb{A})$ lies in $R(\mathbb{A})$ if and only if $(g-1)v_k \in P_{\mathrm{gr}(v_k)+2}$ for every string vector v_k of grade ≥ 0 (that is $k \leq \varrho+1$). Such g maps P_d into itself for every even $d \geq 2$ (P_d is spanned by string vectors of grade $\geq d$), hence onto itself (g is injective and P_d is free of finite rank, so $g|_{P_d}$ is invertible by the determinant), and $P_0 = P_2^\perp$ onto itself as g is unitary. If $g, g' \in R(\mathbb{A})$ then $(gg'-1)v_k = g(g'-1)v_k + (g-1)v_k \in P_{\mathrm{gr}(v_k)+2}$ and $(g^{-1}-1)v_k = -g^{-1}(g-1)v_k \in P_{\mathrm{gr}(v_k)+2}$; the conditions are closed. So $R(\mathbb{A})$ is a closed subgroup; it contains $\mathsf{U}(\mathbb{A})$ (whose conditions include these) and $\iota(\mathrm{U}(X_0)(\mathbb{A}_{E^+}))$ (which fixes every v_i). Let $r \in R(\mathbb{A})$. It acts on P_0/P_2 by a unitary map $\bar r$ fixing $\bar v_{\varrho+1}$, so $\bar r$ preserves $\bar v_{\varrho+1}^\perp = \bar X_0$: for $x \in X_0$, $rx \equiv a(r)x \pmod{P_2}$, where $a(r)$ is the X_0-block of r, and $a(r)$ is unitary on X_0. As $r \mapsto \bar r$ is multiplicative, so is a; it is continuous (entries), and $a(\iota(h)) = h$. If $a(r) = 1$, then $r \in \mathsf{U}(\mathbb{A})$: the conditions $r_{ik} = \delta_{ik}$ for $\mathrm{gr}(i) \leq \mathrm{gr}(k)$ hold for string k of grade ≥ 0 by definition; for $k = x \in X_0$ because $rx \in x + P_2$; and for $k = v_j$ of grade $g_j < 0$ by unitarity: the coefficient of a basis vector i with $\mathrm{gr}(i) \leq g_j$ in rv_j is $\langle i^\vee, rv_j\rangle = \langle r^{-1}i^\vee, v_j\rangle$, where $i^\vee$ is the basis vector paired with i (up to the factor $-1/N$ only for $i = v_{\varrho+1}$, which has grade $0 > g_j$ and does not occur), of grade $-\mathrm{gr}(i) \geq -g_j \geq 2$; so $r^{-1}i^\vee \in i^\vee + P_{-\mathrm{gr}(i)+2}$ ($r^{-1} \in R(\mathbb{A})$), and $P_{-\mathrm{gr}(i)+2}$ is orthogonal to v_j because v_j pairs only with the vector of grade $-g_j < -\mathrm{gr}(i)+2$; hence the coefficient is $\langle i^\vee, v_j\rangle = \delta_{i,v_j}$. Conversely $\mathsf{U}(\mathbb{A}) \subseteq \ker a$, as its elements fix X_0 modulo P_2. So $\ker a = \mathsf{U}(\mathbb{A})$, and $u(r) = r\,\iota(a(r))^{-1} \in \ker a$.

(ii). Let $\mathfrak{e}$ be as in Definition 3.2.36: its entry (i,k) vanishes unless $\mathrm{gr}(i) = \mathrm{gr}(k) - 2$, so $\mathrm{tr}\,\mathfrak{e} = 0$. For $u \in \mathsf{U}(\mathbb{A})$ the entry (i,k) of $u-1$ vanishes unless $\mathrm{gr}(i) \geq \mathrm{gr}(k)+2$. For $u, u' \in \mathsf{U}(\mathbb{A})$ the entries (i,k) of $\mathfrak{e}(u-1)(u'-1)$ vanish unless $\mathrm{gr}(i) \geq \mathrm{gr}(k)+2$, so its trace is 0, and

$$\mathrm{tr}(\mathfrak{e}uu') = \mathrm{tr}(\mathfrak{e}u) + \mathrm{tr}(\mathfrak{e}u') - \mathrm{tr}(\mathfrak{e}) + \mathrm{tr}\big(\mathfrak{e}(u-1)(u'-1)\big) = \mathrm{tr}(\mathfrak{e}u) + \mathrm{tr}(\mathfrak{e}u').$$

As ψ_E is a continuous character of $\mathbb{A}_E$ trivial on E, ψ_{U} is a continuous homomorphism on $\mathsf{U}(\mathbb{A})$ with values of modulus one, and for $u \in \mathsf{U}(E)$, $\mathrm{tr}(\mathfrak{e}u)/(2M\varpi) \in E$, so $\psi_{\mathsf{U}}(u) = 1$. Finally $\iota(h)^{-1}\mathfrak{e}\,\iota(h) = \mathfrak{e}$: $\mathfrak{e}$ vanishes on X_0, which $\iota(h)$ preserves, and maps string vectors to multiples of string vectors, which $\iota(h)$ fixes; so $\mathrm{tr}(\mathfrak{e}\,\iota(h)u\iota(h)^{-1}) = \mathrm{tr}(\mathfrak{e}u)$.

(iii). $G(E)$ is discrete in $G(\mathbb{A})$, as E is discrete in $\mathbb{A}_E$, so $R(E)$ is discrete in the closed subgroup $R(\mathbb{A})$, which is locally compact. The group U is the unipotent radical of the stabiliser of the isotropic flag $P_{2\varrho} \subset \cdots \subset P_2$, a unipotent group over E^+; by Theorem A.4.3 there is a compact $C_{\mathsf{U}} \subseteq \mathsf{U}(\mathbb{A})$ with $\mathsf{U}(\mathbb{A}) = \mathsf{U}(E)C_{\mathsf{U}}$. The form of X_0 is definite at every embedding, so by Theorem A.4.5 there is a compact $C_H \subseteq \mathrm{U}(X_0)(\mathbb{A}_{E^+})$ with $\mathrm{U}(X_0)(\mathbb{A}_{E^+}) = \mathrm{U}(X_0)(E^+)C_H$. Let $r \in R(\mathbb{A})$; by (i), $r = u\,\iota(h)$ with $u \in \mathsf{U}(\mathbb{A})$, and $h = \delta c$ with δ rational, $c \in C_H$. Then $\iota(\delta)^{-1}u\,\iota(\delta) \in \mathsf{U}(\mathbb{A})$ ($\mathsf{U}(\mathbb{A}) = \ker a$ is normal) equals $u'c'$ with $u' \in \mathsf{U}(E)$, $c' \in C_{\mathsf{U}}$, and $r = \iota(\delta)u'{\cdot}c'\iota(c) \in R(E){\cdot}C$ with $C = C_{\mathsf{U}}\,\iota(C_H)$ compact. So $R(E)\backslash R(\mathbb{A})$ is compact. Let F be a Borel fundamental set for $R(E)$ in $R(\mathbb{A})$ (Lemma 5.6.20); as every orbit meets C, $1 \leq \sum_{\gamma\in R(E)} \mathbf{1}_C(\gamma x)$ for $x \in F$, and by left invariance of dr and disjointness of the γF,

$$dr(F) \leq \sum_{\gamma\in R(E)} dr(F \cap \gamma^{-1}C) = \sum_{\gamma\in R(E)} dr(\gamma F \cap C) \leq dr(C) < \infty.$$

A continuous left $R(E)$-invariant function takes on $R(\mathbb{A}) = R(E)C$ only the values it takes on C, so it is bounded, and it is integrable over $[R]$ (that is, on F).

(iv). Let $\gamma \in R(E)$. Its Levi part $a(\gamma)$ is the X_0-block of a rational matrix, so $a(\gamma) \in \mathrm{U}(X_0)(E^+)$, $\iota(a(\gamma)) \in G(E)$ and $u(\gamma) \in \mathsf{U}(E)$; the components of $a(\gamma)$ at $v \in \Phi$ are $F_v(a(\gamma))$.

By (i), $a(\gamma r) = a(\gamma)a(r)$ and $u(\gamma r) = \gamma r\,\iota(a(r))^{-1}\iota(a(\gamma))^{-1} = u(\gamma)\cdot\iota(a(\gamma))u(r)\iota(a(\gamma))^{-1}$, so $\psi_{\mathsf{U}}(u(\gamma r)) = \psi_{\mathsf{U}}(u(r))$ by (ii). The transformation law of source forms gives $\varphi(a(\gamma)_f a(r)_f) = \rho_\lambda((\overline{F_v(a(\gamma))})_v)\varphi(a(r)_f)$, and $\rho_\lambda((\overline{a(\gamma r)_v})_v)^{-1} = \rho_\lambda((\overline{a(r)_v})_v)^{-1}\rho_\lambda((\overline{F_v(a(\gamma))})_v)^{-1}$; inserting both in (3.5) gives $\mathcal{W}_{t,\varphi}(\gamma r) = \mathcal{W}_{t,\varphi}(r)$. Continuity: a, u, ψ_{U} and ρ_λ are continuous, and φ is locally constant, being right invariant under the open subgroup K_0. □

Proposition 5.6.35. *Let D be admissible data, let p be the matrix of Proposition 5.7.3 (it has the properties required in Lemma 5.6.18, by (iii) there), and let $\Pi_a \in \mathcal{A}_M(Y_0)$ ($a \in \mathcal{C}\times I$) be the class Poincaré series of Lemma 5.6.18 (ii) for this p. There are $g_\infty \in G(F_\infty)$ and a linear form t_0 on W_λ such that for every $\varphi \in \mathcal{S}$ and every $y \in \mathcal{A}_M(Y_0)$*

$$\Big\langle y,\ \sum_{a\in\mathcal{C}\times I} \theta(\varphi)_a\,\Pi_a \Big\rangle = \mathrm{BP}_{g_\infty,t_0}(\varphi, y).$$

Proof. Read everything on $G(\mathbb{A}) = G(F_\infty)\times G(\mathbb{A}_f)$ as a group of operators, $\Gamma = G(E)$. Let μ_∞ and μ_f be the Haar measures of $G(F_\infty)$ and $G(\mathbb{A}_f)$ that correspond through the frames of Y_0 to the measures of $G_\infty^{Y_0}$ and G_f fixed in (FT2), $\mu = \mu_\infty\otimes\mu_f$, $V_M = \mu_f(\mathrm{K}_M) > 0$, and F_Γ a Borel set meeting every orbit Γx in exactly one point (Lemma 5.6.20); the Petersson product is $\langle y, y'\rangle = \int_{F_\Gamma} \overline{y}\,y'\,d\mu$. Let $e(h) = e_\varsigma((P_v^{-1}h_vP_v)_v)$ be the type kernel read on $G(F_\infty)$. By (S6) of Lemma 5.2.12, $2\varsigma(v)$ has gap $500r^3 + r^7 \geq 500r^3$ for the signs of Y_0, so by Lemma 5.6.21 (with $B = 0$) e_ς is a cusp kernel, in particular continuous and integrable, and so is e for μ_∞. Read through the frames, (FT2) says that every $y \in \mathcal{A}_M(Y_0)$ is continuous, bounded, left Γ-invariant, right K_M-invariant and satisfies

$$\int_{G(F_\infty)} e(h)\,y(x\,(h,1))\,d\mu_\infty(h) = y(x) \qquad (x \in G(\mathbb{A})). \tag{5.110}$$

Fix a left Haar measure ds of $R(F_\infty)$; let g_∞ and t be as in Lemma 5.6.36 and κ as in Lemma 5.6.40 (iii) (for ds and the measure dr of Definition 3.2.36). Put $t_0 = (V_M/\kappa)\,t$. Fix $\varphi \in \mathcal{S}$ and $y \in \mathcal{A}_M(Y_0)$, and for $c \in \mathcal{C}$ put $W_c(s) = \mathcal{W}_{t,\varphi}(s, \hat{h}_c)$ ($s \in R(F_\infty)$) and $\Psi_c(x) = \sum_{i\in I}\theta(\varphi)_{(c,i)}W_i^{\mathrm{full}}(\mathbf{y}(x))$ ($x \in G(F_\infty)$).

Step 1: folding. The function $\overline{y}$ is bounded, Borel, left Γ-invariant and right K_M-invariant. By Lemma 5.6.17 for $z = \overline{y}$ and each $a = (c,i)$, and linearity of the Petersson product in the second argument,

$$\Big\langle y, \sum_a \theta(\varphi)_a\Pi_a\Big\rangle = \sum_a \theta(\varphi)_a \int_{F_\Gamma} \overline{y}\,\Pi_a\,d\mu = V_M\sum_{c\in\mathcal{C}}\int_{G(F_\infty)} \beta_c(\mathbf{y}(x))\,\Psi_c(x)\,\overline{y(x,\hat{h}_c)}\,d\mu_\infty(x),$$

each integral converging absolutely.

Step 2: the functions W_c. (a) W_c is continuous, by Lemma 5.6.34 (iv). (b) $W_c(us) = W_c(s)$ for $u \in \mathsf{U}_c(M)$, us the product of the archimedean component of u with s: in $R(\mathbb{A})$, $u\cdot(s,\hat{h}_c) = (us, \hat{h}_ck_u) = (us,\hat{h}_c)(1,k_u)$ with $k_u \in J_f'$ (Lemma 5.6.40 (i)), so $W_c(us) = \mathcal{W}_{t,\varphi}(u\cdot(s,\hat{h}_c)\cdot(1,k_u)^{-1}) = \mathcal{W}_{t,\varphi}(u\cdot(s,\hat{h}_c)) = W_c(s)$ by Lemma 5.6.38 (ii) and the left $R(E)$-invariance of Lemma 5.6.34 (iv). (c) $\mathcal{W}_{t,\varphi}$ is continuous, left $R(E)$-invariant (Lemma 5.6.34 (iv)), right J_f'-invariant (Lemma 5.6.38 (ii)) and integrable over $[R]$ (Lemma 5.6.34 (iii)); so by Lemma 5.6.40 (iii), $s\mapsto\beta_c(\mathbf{y}(s))W_c(s)$ is integrable on $R(F_\infty)$.

Step 3: the Bessel formula. By Lemma 5.6.36, for every $x \in G(F_\infty)$,

$$\Psi_c(x)\,\overline{y(x,\hat{h}_c)} = \int_{R(F_\infty)}\Phi_c(s,x)\,ds, \qquad \Phi_c(s,x) = W_c(s)\,\overline{e(g_\infty^{-1}s^{-1}x)}\,\overline{y(x,\hat{h}_c)}.$$

Step 4: moving the quotient. (a) $\Phi_c(us,ux)=\Phi_c(s,x)$ for $u\in \mathsf{U}_c(M)$ (archimedean components acting on the left): $W_c(us)=W_c(s)$ by Step 2 (b), $(us)^{-1}ux=s^{-1}x$, and $u\cdot(x,\hat h_c)=(ux,\hat h_c)(1,k_u)$ with $k_u\in J_f'\subseteq \mathrm{K}_M$, so $y(ux,\hat h_c)=y(u\cdot(x,\hat h_c)(1,k_u)^{-1})=y(x,\hat h_c)$ by right K_M- and left Γ-invariance. (b) A swap: for every Borel $\Theta\ge 0$ on $R(F_\infty)\times G(F_\infty)$ with $\Theta(us,ux)=\Theta(s,x)$ for $u\in \mathsf{U}_c(M)$,

$$\iint \beta_c(\mathbf{y}(x))\,\Theta(s,x)\,ds\,d\mu_\infty(x)=\iint \beta_c(\mathbf{y}(s))\,\Theta(s,x)\,ds\,d\mu_\infty(x).$$

Indeed, by Lemma 5.6.40 (ii) for s (an element of $G(F_\infty)$) and Tonelli's theorem, the left side is $\sum_u\iint \beta_c(\mathbf{y}(us))\beta_c(\mathbf{y}(x))\Theta(s,x)$; the substitution $(s,x)\mapsto(u^{-1}s,u^{-1}x)$, which preserves $ds\otimes\mu_\infty$ (left Haar measures), and the invariance of Θ turn the term of u into $\iint \beta_c(\mathbf{y}(s))\beta_c(\mathbf{y}(u^{-1}x))\Theta(s,x)$; summing over u ($u\mapsto u^{-1}$ permutes the group $\mathsf{U}_c(M)$) and using Lemma 5.6.40 (ii) for x gives the right side. (c) For $\Theta=|\Phi_c|$ the right side is finite: substituting $x=sg_\infty h$ (left invariance of μ_∞),

$$\iint \beta_c(\mathbf{y}(s))\,|\Phi_c(s,x)|\le \|y\|_\infty\,\|e\|_{L^1(\mu_\infty)}\int_{R(F_\infty)}\beta_c(\mathbf{y}(s))\,|W_c(s)|\,ds<\infty$$

by Step 2 (c). So both sides of (b) are finite for $|\Phi_c|$, hence for the positive and negative parts of $\operatorname{Re}\Phi_c$ and $\operatorname{Im}\Phi_c$, which are invariant by (a); subtracting, (b) holds for $\Theta=\Phi_c$, both sides being absolutely convergent. (d) The two sides. By Step 3 and Fubini's theorem the left side of (b) for Φ_c is $\int_{G(F_\infty)}\beta_c(\mathbf{y}(x))\Psi_c(x)\overline{y(x,\hat h_c)}\,d\mu_\infty(x)$. For fixed s, substituting $x=sg_\infty h$ and using (5.110) at the point $(sg_\infty,\hat h_c)$,

$$\int_{G(F_\infty)}\overline{e(g_\infty^{-1}s^{-1}x)}\,\overline{y(x,\hat h_c)}\,d\mu_\infty(x)=\overline{\int_{G(F_\infty)}e(h)\,y((sg_\infty,\hat h_c)(h,1))\,d\mu_\infty(h)}=\overline{y(sg_\infty,\hat h_c)},$$

so the right side of (b) for Φ_c is $\int_{R(F_\infty)}\beta_c(\mathbf{y}(s))\,W_c(s)\,\overline{y(sg_\infty,\hat h_c)}\,ds$. With Step 1,

$$\Big\langle y,\sum_a\theta(\varphi)_a\Pi_a\Big\rangle=V_M\sum_{c\in\mathcal{C}}\int_{R(F_\infty)}\beta_c(\mathbf{y}(s))\,W_c(s)\,\overline{y(sg_\infty,\hat h_c)}\,ds.$$

Step 5: the period, class by class. Let $F(r)=\mathcal{W}_{t,\varphi}(r)\,\overline{y(r\,(g_\infty,1))}$ on $R(\mathbb{A})$. It is continuous and left $R(E)$-invariant (Step 2 (c) and the left Γ-invariance of y), right J_f'-invariant ($r(1,k)(g_\infty,1)=r(g_\infty,1)(1,k)$, $k\in\mathrm{K}_M$, and Step 2 (c)), and integrable over $[R]$ (Lemma 5.6.34 (iii)). As $(s,\hat h_c)(g_\infty,1)=(sg_\infty,\hat h_c)$, $F(s,\hat h_c)=W_c(s)\overline{y(sg_\infty,\hat h_c)}$, and Lemma 5.6.40 (iii) gives

$$\mathrm{BP}_{g_\infty,t}(\varphi,y)=\int_{[R]}F\,dr=\kappa\sum_{c\in\mathcal{C}}\int_{R(F_\infty)}\beta_c(\mathbf{y}(s))\,W_c(s)\,\overline{y(sg_\infty,\hat h_c)}\,ds.$$

Comparing with Step 4 and using that $\mathcal{W}_{t,\varphi}$ is linear in t, $\langle y,\sum_a\theta(\varphi)_a\Pi_a\rangle=(V_M/\kappa)\,\mathrm{BP}_{g_\infty,t}(\varphi,y)=\mathrm{BP}_{g_\infty,t_0}(\varphi,y)$. □

Lemma 5.6.36. *Let D be admissible data, p the matrix of Proposition 5.7.3, $\mathbf{y}=\mathbf{y}_p$, and let $R(F_\infty)$, $\hat h_c=\eta^{-1}h_c$ be as in Lemma 5.6.40. Fix a left Haar measure ds of $R(F_\infty)$, and read the type kernel on $G(F_\infty)$ through the frames: $e(g)=e_\varsigma((P_v^{-1}g_vP_v)_v)$. There are $g_\infty\in G(F_\infty)$ and a linear form t on W_λ such that for every $\varphi\in\mathcal{S}$, $c\in\mathcal{C}$ and $x\in G(F_\infty)$ the function $s\mapsto\overline{e(g_\infty^{-1}s^{-1}x)}\,\mathcal{W}_{t,\varphi}(s,\hat h_c)$ is integrable on $R(F_\infty)$ and*

$$\sum_{i\in I}\theta(\varphi)_{(c,i)}\,W_i^{\mathrm{full}}(\mathbf{y}(x))=\int_{R(F_\infty)}\overline{e(g_\infty^{-1}s^{-1}x)}\;\mathcal{W}_{t,\varphi}(s,\hat h_c)\,ds.$$

Proof. Write $G_\infty = \prod_v G_1$, $B_v = \mathrm{diag}(\mathrm{bs}_v)$ and H_v for the Gram matrix of $Y_0 \otimes_{E,v} \mathbb{C}$; then $B_v^* H_v B_v = J_1$ (RD1), $P_v^* H_v P_v = \mathrm{diag}(s)$ (frames), $p^* J_1 p = \mathrm{diag}(s)$, and $\mathbf{y}(x)_v = B_v^{-1} x_v P_v p^{-1}$. For $v \in \Phi$ let $\mathfrak{B}_v$ be the Bessel system of Proposition 5.7.3 at v, with index set I_v, representation ρ_v and full function W_v, and $l_v = 2\varsigma(v)$; write $c^{(v)}(g) = c_{\varsigma(v)}(p^{-1}gp)$ for $g \in G_1$.

Step 1: the local integrals. By Proposition 5.7.3 (iv) there are $c_v \in \mathbb{R}$, $q_v \in G_1$ and a unit vector $e_v \in \mathbb{C}^{I_v}$ with $W_v = c_v\, W^{(v)}$, where $W^{(v)}(y) = \int_R c^{(v)}(q_v^{-1} s' y)\, \mathrm{wave}(-\sigma(s'))\, \rho_v(h_{s'})^{-1} e_v\, ds'$ and $ds' = du\, dh$. By (S6) of Lemma 5.2.12, l_v has large gap r^7 for s, so by Lemma 5.6.37 (i) the integral converges absolutely for every $y \in G_1$. The measure ds' is invariant under left translations and under $s' \mapsto s'^{-1}$: du is a two-sided Haar measure of U, invariant under $u \mapsto u^{-1}$ (Lemma 5.2.34), conjugation by $h \in H$ preserves du (Lemma 5.5.30 (vi)) and dh is the Haar probability measure of the compact group H; now $u_1 \cdot uh = (u_1 u)h$, $h_1 \cdot uh = (h_1 u h_1^{-1})(h_1 h)$ and $(uh)^{-1} = (h^{-1}u^{-1}h)h^{-1}$, and for fixed h the maps $u \mapsto u_1 u$, $u \mapsto h_1 u h_1^{-1}$, $u \mapsto h^{-1}u^{-1}h$ preserve du, so by Tonelli's theorem the three maps preserve $du \otimes dh$. By Lemma 5.5.30 (i), (ii), $h_{s'^{-1}} = h_{s'}^{-1}$ and $\sigma(s'^{-1}) = -\sigma(s')$; substituting $s' \mapsto s'^{-1}$,

$$W^{(v)}(y) = \int_R F_{v,y}(s')\, ds', \qquad F_{v,y}(s') = c^{(v)}(q_v^{-1} s'^{-1} y)\, \mathrm{wave}(\sigma(s'))\, \rho_v(h_{s'}) e_v, \tag{5.111}$$

with $F_{v,y}$ integrable. In particular ds' is a left Haar measure of R.

Step 2: the real Bessel group. For $s \in R(F_\infty)$ put $s'_v = B_v^{-1} s_v B_v$. As $B_v^* H_v B_v = J_1$, $s'_v \in G_1$. The conditions defining $R(\mathbb{A})$ at the frame vectors f_b (the string vectors of grade ≥ 0: $gf_b - f_b$ lies in the span of the vectors of larger grade, $f_0, \dots, f_{b-1}$) are, by Lemma 5.5.30 (i), those defining $R \subseteq G_1$, and conjugation by the diagonal B_v preserves them; so $s \mapsto (s'_v)_v$ is an isomorphism of topological groups $R(F_\infty) \to \prod_v R$, with inverse $(r_v) \mapsto (B_v r_v B_v^{-1})_v$. Since $\mathrm{bs}_v = 1$ on X_0, $h_{s'_v} = a(s)_v$ (the X_0-block). By Lemma 5.5.30 (ii) and (5.5), with $\mathrm{bs}_v(f_{a+1})/\mathrm{bs}_v(f_a) = \mathrm{rs}_v^{-1}$,

$$\sigma(s'_v) = \sum_{a<\varrho} (s_v)_{f_a f_{a+1}}\, \mathrm{rs}_v^{-1} = \mathrm{rs}_v^{-1}\, \alpha(u(s))_v,$$

with α as in Lemma 5.6.38 (i): the pairs (f_a, f_{a+1}) are the pairs (v_j, v_{j+1}), $j \leq \varrho$, and $u(s) = s\, \iota(a(s))^{-1}$ has the same entries in the columns f_{a+1}, as $\iota(a(s))$ fixes the string vectors. As both ds and $\prod_v ds'_v$ are left Haar measures, there is $c_1 > 0$ with $\int_{\prod_v R} \Phi \prod_v ds'_v = c_1 \int_{R(F_\infty)} \Phi((s'_v)_v)\, ds$ for every integrable or nonnegative Borel Φ. Finally $\mathbf{y}(s^{-1}x)_v = B_v^{-1} s_v^{-1} B_v\, \mathbf{y}(x)_v = s'^{-1}_v \mathbf{y}(x)_v$.

Step 3: the unipotent character at real points. Let $s \in R(F_\infty)$. The finite components of $u(s)$ are 1, so $\alpha(u(s))$ has finite component 0, and by Lemma 5.6.38 (i) and (WD4), $\psi_{\mathsf{U}}(u(s)) = \prod_v \exp(2\pi i \cdot 2\,\mathrm{Re}(\alpha_v/(Mv(\varpi))))$, $\alpha_v = \alpha(u(s))_v$. Since $\bar{\varpi} = -\varpi$ (Lemma 3.2.35 (i)), $Mv(\varpi)/2\pi i$ is real, so $Mv(\varpi) = 2\pi i\, \mathrm{rs}_v$; with $\sigma_v = \sigma(s'_v) = \alpha_v/\mathrm{rs}_v$ we get $2\pi i \cdot 2\,\mathrm{Re}(\sigma_v/(2\pi i)) = 2i\,\mathrm{Im}\,\sigma_v = \sigma_v - \bar{\sigma}_v$, hence

$$\psi_{\mathsf{U}}(u(s)) = \prod_{v \in \Phi} \mathrm{wave}(\sigma(s'_v)).$$

Step 4: the kernel. Put $g_v = B_v q_v p P_v^{-1}$. Then

$$g_v^* H_v g_v = P_v^{-*} p^* q_v^* J_1 q_v p P_v^{-1} = P_v^{-*} \mathrm{diag}(s) P_v^{-1} = H_v,$$

so $g_\infty = (g_v)_v \in G(F_\infty)$ and $\mathbf{y}(g_\infty) = (q_v)_v$. For $z \in G(F_\infty)$, $q_v^{-1}\mathbf{y}(z)_v = p\, P_v^{-1}(g_\infty^{-1} z)_v P_v\, p^{-1}$, so with $d = \prod_v d_{\varsigma(v)}$ (a positive real: $d_{\varsigma(v)} = \mathrm{d}(\varsigma(v)) > 0$ by Proposition 5.7.3 (i), the degree of a Bessel system being positive)

$$\prod_{v \in \Phi} c^{(v)}(q_v^{-1}\mathbf{y}(z)_v) = \prod_v c_{\varsigma(v)}(P_v^{-1}(g_\infty^{-1} z)_v P_v) = d^{-1}\, \overline{e(g_\infty^{-1} z)}. \tag{5.112}$$

Step 5: the source function at a class point. By Proposition 5.6.4 (ii), $\eta = \iota(u_0^{-1}1_{X_0})$, so $\hat{h}_c = \iota(u_0 h_c)$ (writing h_c also for its preimage in $\mathrm{U}(X_0)(\mathbb{A}_f)$). For $s \in R(F_\infty)$, by Lemma 5.6.34 (i), $a(s,\hat{h}_c)$ has the archimedean components $a(s)_v$ and the finite component $u_0 h_c$, and $u(s,\hat{h}_c) = (s,\hat{h}_c)\,\iota(a(s,\hat{h}_c))^{-1} = u(s)$. So, with $\xi_c = \varphi(h_c u_0)$ (u_0 is central in $\mathrm{U}(X_0)(\mathbb{A}_f)$),

$$\mathcal{W}_{t,\varphi}(s,\hat{h}_c) = \psi_{\mathsf{U}}(u(s))\; t\Big(\rho_\lambda\big((\overline{a(s)_v})_v\big)^{-1}\xi_c\Big).$$

Step 6: assembling. Let $A = \bigotimes_v A_v$ be as in Lemma 5.6.14, so $\theta(\varphi)_{(c,\cdot)} = A(\xi_c)$, a row vector in $\mathbb{C}^I$, and for $h = (h_v) \in \prod_v \mathrm{U}(k)$, tensoring (a) there over v, $A(\xi)(\bigotimes_v \rho_v(h_v)) = A(\rho_\lambda((h_v^{\mathsf{T}})_v)\xi) = A\big(\rho_\lambda((\bar{h}_v)_v)^{-1}\xi\big)$, as $h_v^{\mathsf{T}} = \bar{h}_v^{-1}$ for unitary h_v. Define the linear form

$$t(\zeta) = c_1\, d^{-1}\Big(\prod_v c_v\Big)\, A(\zeta)\cdot\Big(\bigotimes_v e_v\Big) \qquad (\zeta \in W_\lambda).$$

Fix φ, c, x and put $y = \mathbf{y}(x)$. As $W_i^{\mathrm{full}}(y) = \prod_v W_{v,i_v}(y_v)$, (5.111) and Fubini's theorem for the finitely many integrable functions F_{v,y_v} on the product $\prod_v R$ give

$$\sum_i \theta(\varphi)_{(c,i)} W_i^{\mathrm{full}}(y) = \Big(\prod_v c_v\Big)\int_{\prod_v R}\Big(\prod_v c^{(v)}(q_v^{-1}s_v'^{-1}y_v)\,\mathrm{wave}(\sigma(s_v'))\Big)\\ A(\xi_c)\Big(\bigotimes_v \rho_v(h_{s_v'})\Big)\Big(\bigotimes_v e_v\Big)\prod_v ds_v',$$

the integrand being integrable (it is a finite sum of products of coordinates of the F_{v,y_v}). Transport the integral to $R(F_\infty)$ by Step 2 ($s_v'^{-1}y_v = \mathbf{y}(s^{-1}x)_v$, $h_{s_v'} = a(s)_v$) and insert (5.112) with $z = s^{-1}x$, Step 3 and the identity for A above: the right side equals

$$c_1\, d^{-1}\Big(\prod_v c_v\Big)\int_{R(F_\infty)} \overline{e(g_\infty^{-1}s^{-1}x)}\;\psi_{\mathsf{U}}(u(s))\; A\Big(\rho_\lambda\big((\overline{a(s)_v})_v\big)^{-1}\xi_c\Big)\cdot\Big(\bigotimes_v e_v\Big)\,ds\\ = \int_{R(F_\infty)} \overline{e(g_\infty^{-1}s^{-1}x)}\;\mathcal{W}_{t,\varphi}(s,\hat{h}_c)\,ds,$$

by the definition of t and Step 5. The integrand on $R(F_\infty)$ is integrable, as its transport to $\prod_v R$ is. □

Lemma 5.6.37. *Fix the setting of Definition 5.1.6, signs s on the r basis indices of V_1 and a sign frame p for s. Let $l \in \mathbb{Z}^r$ have large gap A for s ($A \geq 0$ an integer); write $c_l^{G_1}(g) = c_{l/2}(p^{-1}gp)$ for $g \in G_1$, and d_l for the formal degree $(\int |c_{l/2}|^2)^{-1}$ for the Haar measure on $\mathrm{U}(\mathrm{diag}\, s)$ that $g \mapsto p^{-1}gp$ carries from dy. Every $s' \in R$ is uniquely $s' = uh$ with $u \in \mathsf{U}$, $h \in H$; put $h_{s'} = h$ and $\sigma(s') = \sigma(u)$, and let $ds' = du\,dh$ on R, dh the Haar probability measure. Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be a continuous unitary representation on $\mathbb{C}^I$, $v \in \mathbb{C}^I$ and $x \in G_1$. Then:*

(i) for every $y \in G_1$ the integral

$$W_x(y) = \int_R c_l^{G_1}(x^{-1}s'y)\,\mathrm{wave}(-\sigma(s'))\,\rho(h_{s'})^{-1}v\,ds'$$

converges absolutely; W_x is a continuous Bessel function of type ρ, integrable and square integrable on $\mathsf{U}\backslash G_1$; and $\int_{G_1} d_l\, c_l^{G_1}(a^{-1})\,W_x(ya)\,da = W_x(y)$ for every $y \in G_1$;

(ii) if moreover $u_0 \in \mathbb{Z}^k$ and $\langle v, \rho(m)v\rangle = c_{u_0/2}(m)$ for every $m \in \mathrm{U}(k)$ (Flensted-Jensen's function for the signs $(1,\dots,1)$), the period equals the squared norm:

$$\int_R c_l^{G_1}(x^{-1}s'x)\,\overline{c_{u_0/2}(h_{s'})}\,e^{\overline{\sigma(s')}-\sigma(s')}\,ds' = \langle v, W_x(x)\rangle = d_l\int_{\mathsf{U}\backslash G_1}\|W_x\|^2.$$

Proof. Write $c = c_l^{G_1}$, $W = W_x$, $\|\cdot\|_{\mathrm{op}}$ for the operator norm and $\langle\cdot,\cdot\rangle$ for the standard inner product of $\mathbb{C}^I$, conjugate-linear in the first argument. The map $\iota(g) = p^{-1}gp$ is an isomorphism of topological groups $G_1 \to \mathrm{U}(\mathrm{diag}\, s)$ (as $p^* J_1 p = \mathrm{diag}(s)$ and p is unitary, $\|\iota(g)\|_{\mathrm{op}} = \|g\|_{\mathrm{op}}$), and dy goes to a Haar measure dg of $\mathrm{U}(\mathrm{diag}\, s)$. The large gap $500r^3 + A$ exceeds $8r^2$, so Lemma 5.6.23 applies to l and dg; transporting by ι: c is continuous and integrable on G_1, $d_l > 0$, and by Lemma 5.6.23 (ii) with first argument g and second 1, together with $\overline{c(a)} = c(a^{-1})$ (Lemma 5.7.40),

$$\int_{G_1} d_l\, c(a^{-1})\, c(ga)\, da = c(g) \qquad (g \in G_1). \tag{5.113}$$

By Lemma 5.7.40 with exponent $9r^2 \le 500r^3 + A$, $|c(g)| \le (2/\|g\|_{\mathrm{op}})^{9r^2}$.

The group R. By (i), (ii) and (v) of Lemma 5.5.30, R is a closed subgroup of G_1, $s' \mapsto h_{s'}$ is a homomorphism, $\sigma(s's'') = \sigma(s') + \sigma(s'')$ on R, and ds' (the measure ds there) is a right-invariant Borel measure on R, finite on compact sets.

Unfolding. For Borel $f \ge 0$ on G_1, (vi) of Lemma 5.5.30 gives

$$\int_{\mathsf{U}\backslash G_1} \int_R f(s'y)\, ds'\, dy = \int_{G_1} f(g)\, dg, \tag{5.114}$$

and applied to the positive and negative parts of the real and imaginary parts, the identity holds for every integrable Borel f.

(i). The norm of the integrand is $|c(x^{-1}s'y)|\,\|v\|$, since ρ is unitary and $|\mathrm{wave}| = 1$. Apply Lemma 5.6.32 (ii) to the group R with ds', the homomorphism $j(s') = \iota(x^{-1}s'x)$ into $\mathrm{U}(\mathrm{diag}\, s)$, proper since R is closed and ι and conjugation are homeomorphisms, and the point $\iota(x^{-1}y)$: as $j(s')\iota(x^{-1}y) = \iota(x^{-1}s'y)$,

$$\int_R |c(x^{-1}s'y)|\, ds' \le \int_R \Big(\frac{2}{\|\iota(x^{-1}s'y)\|_{\mathrm{op}}}\Big)^{9r^2} ds' \le 16^{9r^2}\,\nu_x, \qquad \nu_x = \int_R \mathbf{1}\big[\|j(s')-1\|_{\mathrm{op}} \le 1\big]\, ds' < \infty,$$

uniformly in y. So W is defined and bounded by $\|v\|\, 16^{9r^2}\nu_x$. Continuity: for y in a compact neighbourhood C of y_0, $\|\iota(x^{-1}s'y)\|_{\mathrm{op}} \ge \|\iota(x^{-1}s'y_0)\|_{\mathrm{op}}/M$ with $M = \sup_{y\in C}\|y^{-1}y_0\|_{\mathrm{op}}$, so the norms of the integrands are dominated by the integrable $\|v\| M^{9r^2}(2/\|\iota(x^{-1}s'y_0)\|_{\mathrm{op}})^{9r^2}$, and dominated convergence applies. Equivariance: for $s'' \in R$, substituting $s' \mapsto s's''^{-1}$ (right invariance) and using the additivity of σ and $h_{s's''^{-1}} = h_{s'}h_{s''}^{-1}$,

$$W(s''y) = \int_R c(x^{-1}s'y)\,\mathrm{wave}\big(\sigma(s'') - \sigma(s')\big)\,\rho(h_{s''})\rho(h_{s'})^{-1}v\, ds' = \mathrm{wave}(\sigma(s''))\,\rho(h_{s''})\,W(y),$$

as $\mathrm{wave}(a+b) = \mathrm{wave}(a)\mathrm{wave}(b)$; for $s'' = u \in \mathsf{U}$ and $s'' = h \in H$ these are the two conditions of a Bessel function of type ρ. Integrability over $\mathsf{U}\backslash G_1$: $\|W(y)\| \le \|v\| \int_R |c(x^{-1}s'y)|\, ds'$, and by (5.114) the integral of the right side over $\mathsf{U}\backslash G_1$ is $\int_{G_1} |c(x^{-1}g)|\, dg = \int_{G_1} |c| < \infty$; as W is bounded it is also square integrable. Reproduction: the function $(a, s') \mapsto d_l\, c(a^{-1})\, c(x^{-1}s'ya)$ is integrable on $G_1 \times R$, the integral of its norm in s' being at most $d_l|c(a^{-1})|\,\|v\|\, 16^{9r^2}\nu_x$; by Fubini's theorem and (5.113) with $g = x^{-1}s'y$,

$$\int_{G_1} d_l\, c(a^{-1})W(ya)\, da = \int_R \Big(\int_{G_1} d_l\, c(a^{-1})\, c(x^{-1}s'ya)\, da\Big)\mathrm{wave}(-\sigma(s'))\rho(h_{s'})^{-1}v\, ds' = W(y).$$

(ii). First equality: $\overline{c_{u_0/2}(h)} = \overline{\langle v, \rho(h)v\rangle} = \langle \rho(h)v, v\rangle = \langle v, \rho(h)^{-1}v\rangle$ and $e^{\overline{\sigma}-\sigma} = \mathrm{wave}(-\sigma)$, so the period is $\int_R \langle v, c(x^{-1}s'x)\,\mathrm{wave}(-\sigma(s'))\rho(h_{s'})^{-1}v\rangle\, ds' = \langle v, W(x)\rangle$. Second equality: put

$\Phi(g) = d_l\,\overline{c(x^{-1}g)}\,\langle v, W(g)\rangle$, integrable on G_1 since c is integrable and W bounded. For $y \in G_1$ and $s' \in R$, by the equivariance, $\overline{\mathrm{wave}(\sigma)} = \mathrm{wave}(-\sigma)$ and unitarity,

$$\begin{aligned}\Phi(s'y) &= d_l\,\overline{c(x^{-1}s'y)}\,\mathrm{wave}(\sigma(s'))\,\langle \rho(h_{s'})^{-1}v, W(y)\rangle \\ &= d_l\,\overline{\langle W(y),\, c(x^{-1}s'y)\,\mathrm{wave}(-\sigma(s'))\,\rho(h_{s'})^{-1}v\rangle},\end{aligned}$$

so $\int_R \Phi(s'y)\,\overline{ds'} = d_l\overline{\langle W(y), W(y)\rangle} = d_l\|W(y)\|^2$. By (5.114), the substitution $g = xa$ (left invariance), $\overline{c(a)} = c(a^{-1})$ and the reproduction in (i) at $y = x$,

$$d_l \int_{\mathsf{U}\backslash G_1} \|W\|^2 = \int_{G_1} \Phi = \int_{G_1} d_l\, c(a^{-1})\,\langle v, W(xa)\rangle\, da = \Big\langle v, \int_{G_1} d_l\, c(a^{-1}) W(xa)\, da\Big\rangle = \langle v, W(x)\rangle.$$

□

Lemma 5.6.38. *Let D be admissible data and ϖ the generator of the different of E of Lemma 3.2.35.*

(i) For $u \in \mathsf{U}(\mathbb{A})$ put $\alpha(u) = \sum_{j=1}^{\varrho} u_{v_j v_{j+1}} \in \mathbb{A}_E$, the sum of the entries of u in the rows v_j and the columns v_{j+1} (matrices in the basis of Y_0). Then $\psi_{\mathsf{U}}(u) = \psi_E(-\alpha(u)/(M\varpi))$.

(ii) Let J' be the group of the $k \in R(\mathbb{A})$ whose components at the infinite places are 1 and whose finite component lies in K_M. Then $\mathcal{W}_{t,\varphi}(rk) = \mathcal{W}_{t,\varphi}(r)$ for every $\varphi \in \mathcal{S}$, every linear form t on W_λ, every $r \in R(\mathbb{A})$ and every $k \in J'$.

Proof. Matrices are taken in the basis of Y_0; g_{ik} is the coefficient of the basis vector i in g applied to the basis vector k. By (HP2), (HP3), $v_i = e_i$ and $v_{2\varrho+2-i} = e_i^*$ for $1 \le i \le \varrho$, and $v_{\varrho+1} = z$. Write the hermitian form $\langle\cdot,\cdot\rangle$ linear in the second argument (its Gram matrix is real, so the other convention gives the same formulas). Let P_2 be the span of $e_1, \dots, e_\varrho$ and $P_0 = P_2 \oplus X_0 \oplus \langle z\rangle$ (over $\mathbb{A}_E$); $P_0 = P_2^{\perp}$.

Step 1: two facts on additive characters. (a) $\psi_E(\bar{x}) = \psi_E(x)$ for $x \in \mathbb{A}_E$: the archimedean factor of ψ_E in (WD4) depends on $\mathrm{Re}\, x_v$ only, and if $x_f - a \in \hat{\mathcal{O}}$ with $a \in E$ then $\bar{x}_f - \bar{a} \in \hat{\mathcal{O}}$ and $\mathrm{Tr}_{E/\mathbb{Q}}(\bar{a}) = \mathrm{Tr}_{E/\mathbb{Q}}(a)$. If $\bar{z} = -z$, then $\psi_E(-z) = \psi_E(\bar{z}) = \psi_E(z)$, so $\psi_E(z)^2 = \psi_E(z)\psi_E(-z) = 1$; as $z/2$ has the same property, $\psi_E(z) = \psi_E(z/2)^2 = 1$. Applied to $z = (x - \bar{x})/2$:

$$\psi_E\Big(\frac{x+\bar{x}}{2}\Big) = \psi_E(x) \qquad (x \in \mathbb{A}_E). \tag{5.115}$$

(b) $\psi_f(y) = 1$ for $y \in \varpi^{-1}\hat{\mathcal{O}}$, with ϖ the generator of the different of Lemma 3.2.35: as $\mathcal{O}_E$ is dense in $\hat{\mathcal{O}}$ and $\varpi\hat{\mathcal{O}}$ is open, $\hat{\mathcal{O}} = \mathcal{O}_E + \varpi\hat{\mathcal{O}}$, so $y = a + o$ with $a \in \varpi^{-1}\mathcal{O}_E$ and $o \in \hat{\mathcal{O}}$; $\varpi^{-1}\mathcal{O}_E$ is the inverse different (Lemma 3.2.35 (i)), so $\mathrm{Tr}_{E/\mathbb{Q}}(a) \in \mathbb{Z}$ and $\psi_f(y) = \exp(2\pi i\,\mathrm{Tr}_{E/\mathbb{Q}}(a)) = 1$.

Step 2: the unipotent character in the entries above the diagonal. Let $u \in \mathsf{U}(\mathbb{A})$ and write $u_{j,j+1}$ for $u_{v_j v_{j+1}}$. Then $u = 1 + n$ with $n_{ik} \ne 0$ only if $\mathrm{gr}(i) \ge \mathrm{gr}(k) + 2$, so n is nilpotent, n^2 has nonzero entries only where $\mathrm{gr}(i) \ge \mathrm{gr}(k) + 4$, and $u^{-1} = 1 - n + n^2 - \dots$ has $(u^{-1})_{j,j+1} = -u_{j,j+1}$. The coefficient of v_i in a vector w is $\langle v_i^\vee, w\rangle$ with $v_i^\vee = v_{2\varrho+2-i}$ for $i \ne \varrho+1$ and $v_{\varrho+1}^\vee = -N^{-1}v_{\varrho+1}$. As u is unitary, $\langle v_i^\vee, u^{-1}w\rangle = \langle uv_i^\vee, w\rangle$, so

$$-u_{j,j+1} = (u^{-1})_{j,j+1} = \langle uv_j^\vee, v_{j+1}\rangle = \overline{\langle v_{j+1}, uv_j^\vee\rangle}.$$

For $1 \le j < \varrho$, $v_j^\vee = v_{2\varrho+2-j}$ and $\langle v_{j+1}, w\rangle$ is the coefficient of $v_{2\varrho+1-j}$ in w; for $j = \varrho$, $v_\varrho^\vee = v_{\varrho+2}$ and $\langle v_{\varrho+1}, w\rangle = -N$ times the coefficient of $v_{\varrho+1}$. Hence

$$u_{2\varrho+1-j,2\varrho+2-j} = -\overline{u_{j,j+1}} \quad (1 \le j < \varrho), \qquad N\,u_{\varrho+1,\varrho+2} = \overline{u_{\varrho,\varrho+1}}. \tag{5.116}$$

The shift $\mathfrak{e}$ of Definition 3.2.36 sends $v_l \mapsto c_l v_{l+1}$ ($1 \le l \le 2\varrho$) with $c_l = 1$ for $l \ne \varrho+1$, $c_{\varrho+1} = -N$, and kills X_0 and $v_{2\varrho+1}$; so $\mathrm{tr}(\mathfrak{e}u) = \sum_{l=1}^{2\varrho} c_l u_{l,l+1}$, and by (5.116), with $\alpha(u) = \sum_{j=1}^{\varrho} u_{j,j+1}$,

$$\mathrm{tr}(\mathfrak{e}u) = \sum_{j=1}^{\varrho} u_{j,j+1} - \overline{u_{\varrho,\varrho+1}} - \sum_{j=1}^{\varrho-1} \overline{u_{j,j+1}} = \alpha(u) - \overline{\alpha(u)}.$$

Put $x = \alpha(u)/(M\varpi)$. Since M is real and $\bar\varpi = -\varpi$, $\bar x = -\overline{\alpha(u)}/(M\varpi)$, so $\mathrm{tr}(\mathfrak{e}u)/(2M\varpi) = (x+\bar x)/2$, and by (5.115)

$$\psi_{\mathsf{U}}(u) = \psi_E\big(-\alpha(u)/(M\varpi)\big) \qquad (u \in \mathsf{U}(\mathbb{A})), \tag{5.117}$$

which is (i). Steps 3 to 5 prove (ii).

Step 3: the Levi part of an element of J'. By Proposition 5.6.4 (ii) the filling datum $\mathfrak{S}_D$ has the space Y_0 (same basis and form), $\mathrm{K}_M = \eta\,\mathrm{K}(M)\,\eta^{-1}$ with $\eta = \iota(u_0^{-1}1_{X_0})$, and η commutes with $\iota(\mathrm{U}(X_0)(\mathbb{A}_f))$. Let $k \in J'$ and $k' = \eta^{-1}k\eta$. As $\eta \in R(\mathbb{A})$ (Lemma 5.6.34 (i)), $k' \in R(\mathbb{A}) \cap \mathrm{K}(M)$, and $a(k') = a(\eta)^{-1}a(k)a(\eta) = a(k)$, $a(\eta)$ being the scalar u_0^{-1}. By Lemma 5.6.39 for $t = k'$, $a(k) = a(k')$ has components 1 at the infinite places and finite component in K_0, and $u' = u(k') = k'\iota(a(k'))^{-1} \in \mathsf{U}(\mathbb{A}) \cap \mathrm{K}(M)$, its components at the infinite places are 1, and $u(k) = k\,\iota(a(k))^{-1} = \eta k'\eta^{-1}\iota(a(k'))^{-1} = \eta u'\eta^{-1}$.

Step 4: $\psi_{\mathsf{U}}(u(k)) = 1$. The lattice L_0 of (FG3) has the basis e_a, e_a^* ($1 \le a \le \varrho$), z, $x_1, \dots, x_{k-1}$ and $x'_k = \bar\pi^{-1}x_k + N^{-1}z$ ($\pi = \pi_N$). Let u'_L be the matrix of u' in this basis: it is integral and reduces to 1 at every chosen place, so its off-diagonal entries lie in $\hat{\mathcal{O}}$ and are $\equiv 0$ modulo every chosen w. The basis vectors e_a, e_a^*, z of Y_0 are basis vectors of L_0, and z also occurs in x'_k with coefficient N^{-1}, while e_a, e_a^* occur in no other basis vector of L_0. Reading coefficients,

$$u'_{e_j,e_{j+1}} = (u'_L)_{e_j,e_{j+1}}, \quad u'_{e_\varrho,z} = (u'_L)_{e_\varrho,z}, \quad u'_{e^*_{j+1},e^*_j} = (u'_L)_{e^*_{j+1},e^*_j}, \quad u'_{z,e^*_\varrho} = (u'_L)_{z,e^*_\varrho} + N^{-1}(u'_L)_{x'_k,e^*_\varrho}.$$

So $u'_{j,j+1} \in \hat{\mathcal{O}}$ and $u'_{j,j+1} \equiv 0$ modulo every chosen w ($1 \le j \le \varrho$). By (5.116), $\overline{u'_{j,j+1}} = -u'_{e^*_{j+1},e^*_j}$ for $j < \varrho$ and $\overline{u'_{\varrho,\varrho+1}} = Nu'_{z,e^*_\varrho} = N(u'_L)_{z,e^*_\varrho} + (u'_L)_{x'_k,e^*_\varrho}$, which are $\equiv 0$ modulo every chosen w as well. By (FG2) (M divides $x \in \hat{\mathcal{O}}$ if and only if $x \equiv \bar x \equiv 0$ modulo every chosen place), $\alpha(u') \in M\hat{\mathcal{O}}$; and the archimedean components of $\alpha(u')$ vanish. So $y = -\alpha(u')/(M\varpi)$ has archimedean components 0 and finite component in $\varpi^{-1}\hat{\mathcal{O}}$, and by (5.117), (WD4) and Step 1 (b), $\psi_{\mathsf{U}}(u') = \psi_f(y_f) = 1$. By Lemma 5.6.34 (ii), $\psi_{\mathsf{U}}(u(k)) = \psi_{\mathsf{U}}(\eta u'\eta^{-1}) = \psi_{\mathsf{U}}(u') = 1$.

Step 5: conclusion. Let $r \in R(\mathbb{A})$. By Lemma 5.6.34 (i), $a(rk) = a(r)a(k)$, where $a(k)$ has components 1 at the infinite places (as k has) and finite component in K_0 (Step 3); and

$$u(rk) = rk\,\iota(a(k))^{-1}\iota(a(r))^{-1} = r\,u(k)\,\iota(a(r))^{-1} = u(r)\cdot\iota(a(r))\,u(k)\,\iota(a(r))^{-1},$$

so $\psi_{\mathsf{U}}(u(rk)) = \psi_{\mathsf{U}}(u(r))\,\psi_{\mathsf{U}}(u(k)) = \psi_{\mathsf{U}}(u(r))$ by Lemma 5.6.34 (ii) and Step 4. The archimedean components of $a(rk)$ are those of $a(r)$, and $\varphi(a(rk)_f) = \varphi(a(r)_f a(k)_f) = \varphi(a(r)_f)$ because φ is right K_0-invariant. Inserting this in (3.5) gives $\mathcal{W}_{t,\varphi}(rk) = \mathcal{W}_{t,\varphi}(r)$. □

Lemma 5.6.39. *Let D be admissible data, and let $t \in R(\mathbb{A})$ have components 1 at the infinite places and finite component in $\mathrm{K}(M)$. Then $a(t)$ has components 1 at the infinite places, its finite component lies in K_0, and $\iota(a(t))$ and $u(t)$ lie in $\mathrm{K}(M)$.*

Proof. By Proposition 5.6.4 (ii) the space of $\mathfrak{S}_D$ is Y_0 with the same basis and form, and by Proposition 5.6.4 (i) $\mathfrak{S}_D$ is admissible, with source level K_0. The components of $a(t)$ at the

infinite places are the X_0-blocks of those of t, which are 1. Let P_2 be the span of $e_1, \dots, e_\varrho$ and $P_0 = P_2 \oplus X_0 \oplus \langle z \rangle$, over $\mathbb{A}_E$, so that $P_0 = P_2^\perp$.

t on P_0/P_2. By the definition of $R(\mathbb{A})$ (the entries $t_{ik} = \delta_{ik}$ for every string vector k of grade ≥ 0 and every i with $\mathrm{gr}(i) \leq \mathrm{gr}(k)$), t maps e_a into $e_a + \langle e_1, \dots, e_{a-1} \rangle$ and z into $z + P_2$. So t maps P_2 onto itself (its matrix there is unitriangular), hence, being unitary, $P_0 = P_2^\perp$ onto itself, and it induces on P_0/P_2 an isometry of the induced form, which has the orthogonal basis given by X_0 and z, with $\langle z, z \rangle = -N$ a unit of $\mathbb{A}_E$; this isometry fixes the class of z, hence preserves the class of its orthogonal complement X_0, on which it acts by the block $a(t)$. Therefore

$$t\lambda \in \iota(a(t))\lambda + P_2 \qquad (\lambda \in (X_0 \oplus Ez) \otimes \mathbb{A}_f).$$

The lattice. The basis of L_0 (FG3) consists of e_a, e_a^* $(1 \leq a \leq \varrho)$, z, $x_1, \dots, x_{k-1}$ and $x_k' = \bar{\pi}^{-1} x_k + N^{-1} z$, $\pi = \pi_N$. Hence $L_0 = S_e \oplus \Lambda \oplus S_{e^*}$, where S_e, S_{e^*} are the $\hat{\mathcal{O}}$-spans of the e_a and of the e_a^* and Λ is the $\hat{\mathcal{O}}$-span of $x_1, \dots, x_{k-1}, x_k', z$, a lattice in $(X_0 \oplus Ez) \otimes \mathbb{A}_f$; and $L_0 \cap P_0 = S_e \oplus \Lambda$, $L_0 \cap P_2 = S_e$. Let $\lambda \in \Lambda$. As $t \in K$, $t\lambda \in L_0 \cap P_0 = S_e \oplus \Lambda$, and by the display $\iota(a(t))\lambda \in (X_0 \oplus Ez) \otimes \mathbb{A}_f$ is the Λ-component of $t\lambda$; so $\iota(a(t))\Lambda \subseteq \Lambda$. The same holds for t^{-1}, which satisfies the hypotheses, and $a(t^{-1}) = a(t)^{-1}$ (Lemma 5.6.34 (i)); so $\iota(a(t))\Lambda = \Lambda$. For a chosen place w, t reduces to 1 at w, that is $(t-1)L_0 \subseteq \mathfrak{p}_w L_0$ at w; taking Λ-components, $(\iota(a(t)) - 1)\Lambda \subseteq \mathfrak{p}_w \Lambda$ at w. Since $\iota(a(t))$ fixes S_e and S_{e^*} pointwise, it maps L_0 onto itself and reduces to 1 at every chosen place: $\iota(a(t)) \in \mathrm{K}(M)$. By (FA1), the finite component of $a(t)$ lies in the source level $\mathrm{K}_X = \mathrm{K}_0$. Finally $u(t) = t\,\iota(a(t))^{-1}$ is a product of two elements of $\mathrm{K}(M)$. □

Lemma 5.6.40. *Let D be admissible data and p a sign frame for the signs of Y_0. Put $R(F_\infty) = \{s \in G(F_\infty) : (s,1) \in R(\mathbb{A})\}$, $R(\mathbb{A}_f) = \{g \in G(\mathbb{A}_f) : (1,g) \in R(\mathbb{A})\}$, $J_f' = R(\mathbb{A}_f) \cap \mathrm{K}_M$ and $\hat{h}_c = \eta^{-1} h_c$ $(c \in \mathcal{C})$, and fix a left Haar measure ds of $R(F_\infty)$. Let $\mathsf{U}_c(M)$ be as in (RD2) of Definition 5.1.11.*

(i) *$\mathsf{U}_c(M) \subseteq R(E)$, and for $u \in \mathsf{U}_c(M)$ the element $k_u = \hat{h}_c^{-1} u \hat{h}_c$ (u read by its finite component) lies in J_f'.*

(ii) *$\sum_{u \in \mathsf{U}_c(M)} \beta_c(\mathbf{y}(ux)) = 1$ for every $c \in \mathcal{C}$ and $x \in G(F_\infty)$, where $ux \in G(F_\infty)$ is the product of the archimedean component of u and x.*

(iii) *There is a real $\kappa > 0$ such that for every Borel $F\colon R(\mathbb{A}) \to \mathbb{C}$ that is left invariant under $R(E)$, satisfies $F(r\,(1,k)) = F(r)$ for $r \in R(\mathbb{A})$, $k \in J_f'$, and is integrable over $[R]$: for every $c \in \mathcal{C}$ the function $s \mapsto \beta_c(\mathbf{y}(s))\, F(s, \hat{h}_c)$ is integrable on $R(F_\infty)$, and*

$$\int_{[R]} F\, dr = \kappa \sum_{c \in \mathcal{C}} \int_{R(F_\infty)} \beta_c(\mathbf{y}(s))\, F(s, \hat{h}_c)\, ds.$$

Proof. By Proposition 5.6.4 (i), (ii), $\mathfrak{S}_D$ is admissible, E carries Weil data, the space of $\mathfrak{S}_D$ is Y_0 with the same basis and form, $\mathrm{K}_M = \eta\, \mathrm{K}(M)\, \eta^{-1}$, $\eta = \iota(u_0^{-1} 1_{X_0})$ commutes with $\iota(\mathrm{U}(X_0)(\mathbb{A}_f))$, and the source level is $\mathrm{K}_X = \mathrm{K}_0$. We write h_c also for the element of $\mathrm{U}(X_0)(\mathbb{A}_f)$ with ι-image h_c. Since η commutes with h_c,

$$\hat{h}_c^{-1} x \in \mathrm{K}_M \iff h_c^{-1} x\, \eta \in \mathrm{K}(M) \qquad (x \in G(\mathbb{A}_f)), \tag{5.118}$$

because $\eta^{-1} \hat{h}_c^{-1} = \eta^{-1} h_c^{-1} \eta = h_c^{-1}$. The conditions defining $R(\mathbb{A})$ are conditions on matrix entries, imposed componentwise, so $R(\mathbb{A}) = R(F_\infty) \times R(\mathbb{A}_f)$, a product of closed subgroups;

$\hat h_c \in \iota(\mathrm{U}(X_0)(\mathbb{A}_f)) \subseteq R(\mathbb{A}_f)$ by Lemma 5.6.34 (i). The group $\mathsf{U}(\mathbb{A})$ of Definition 3.2.36 (the g with $g_{ik} = \delta_{ik}$ whenever $\mathrm{gr}(i) \le \mathrm{gr}(k)$) consists of the isometries acting trivially on the successive quotients of the flag $\langle e_1\rangle \subset \cdots \subset \langle e_1,\dots,e_\varrho\rangle \subset \langle e_1,\dots,e_\varrho\rangle^\perp \subset \dots$, so $\mathsf{U}(\mathbb{A}) \cap G(E)$ is the group $\mathsf{U}(E)$ of (RD2), and $\mathsf{U}_c(M) \subseteq \mathsf{U}(E) \subseteq R(E)$.

Step 1: the measures. Let dr_f be a left Haar measure of $R(\mathbb{A}_f)$. Then $ds \otimes dr_f$ is a left Haar measure of $R(\mathbb{A})$, so $dr = \kappa_0\, ds \otimes dr_f$ for some $\kappa_0 > 0$. J'_f is an open compact subgroup of $R(\mathbb{A}_f)$ (K_M is open and compact in $G(\mathbb{A}_f)$), so $0 < dr_f(J'_f) < \infty$; put $\kappa = \kappa_0\, dr_f(J'_f)$.

Step 2: the class cutoffs sum to one along $\mathsf{U}_c(M)$. For $\gamma \in G(E)$ and $x \in G(\mathbb{A})$, $\mathbf{y}(\gamma x) = \gamma_\infty \mathbf{y}(x)$, since $B_v^{-1} v(\gamma) x_v P_v p^{-1} = (B_v^{-1} v(\gamma) B_v)(B_v^{-1} x_v P_v p^{-1})$ and $B_v^{-1} v(\gamma) B_v = \gamma_v$ by (5.5). By (i) of Lemma 5.2.36 for the admissible datum $\mathfrak{S}_D$ with Weil data,

$$\sum_{u \in \mathsf{U}_c(M)} \beta_c(u \cdot y) = 1 \qquad (y \in G_\infty). \tag{5.119}$$

With $y = \mathbf{y}(x)$ and $\mathbf{y}(ux) = u \cdot \mathbf{y}(x)$ ($x \in G(F_\infty)$) this is (ii).

Step 3: the class weights. For $c \in \mathcal{C}$ and $r = (s, g) \in R(\mathbb{A})$ put $w_c(r) = \beta_c(\mathbf{y}(s))\, \mathbf{1}[\hat h_c^{-1} g \in \mathrm{K}_M] \ge 0$, a Borel function. We show $\sum_{\gamma \in R(E)} \sum_c w_c(\gamma r) = 1$ for every r.

(a) If $u \in \mathsf{U}_c(M)$ and $\hat h_c^{-1} g \in \mathrm{K}_M$, then $\hat h_c^{-1} u g \in \mathrm{K}_M$. Indeed $m = h_c^{-1} u h_c \in \mathrm{K}(M)$ by (RD2), so $u\hat h_c = u h_c \eta^{-1} = h_c m \eta^{-1} = \hat h_c (\eta m \eta^{-1})$ with $\eta m \eta^{-1} \in \mathrm{K}_M$, and $\hat h_c^{-1} u g = (\eta m \eta^{-1})(\hat h_c^{-1} g)$. As u, $\hat h_c \in R$, $k_u = \hat h_c^{-1} u \hat h_c = \eta m \eta^{-1}$ lies in $R(\mathbb{A}_f) \cap \mathrm{K}_M = J'_f$; with $\mathsf{U}_c(M) \subseteq R(E)$ (shown above) this is (i).

(b) For every $r = (s, g)$ there are $\gamma \in R(E)$ and c with $\hat h_c^{-1} \gamma g \in \mathrm{K}_M$. Let $g' = g\eta \in R(\mathbb{A}_f)$. By (FG4), $a(1, g') = \delta h_c \kappa'$ with $\delta \in \mathrm{U}(X_0)(E^+)$, a class c and $\kappa' \in \mathrm{K}_X$; by Lemma 5.6.34 (i), $\iota(\delta)^{-1} g' = n\, \iota(h_c \kappa')$ with $n = u(\iota(\delta)^{-1} g') \in \mathsf{U}(\mathbb{A}_f)$ (finite components). The group $O = h_c \mathrm{K}(M) h_c^{-1} \cap \mathsf{U}(\mathbb{A}_f)$ is an open subgroup of $\mathsf{U}(\mathbb{A}_f)$, so by strong approximation for the unipotent group U over E^+ [233] $n = u_1 o$ with $u_1 \in \mathsf{U}(E)$, $o \in O$. For $\gamma = u_1^{-1} \iota(\delta)^{-1} \in R(E)$, $h_c^{-1} \gamma g \eta = h_c^{-1} o\, \iota(h_c \kappa') = (h_c^{-1} o h_c)\, \iota(\kappa') \in \mathrm{K}(M)$, as $\iota(\kappa') \in \mathrm{K}(M)$ by (FA1); by (5.118), $\hat h_c^{-1} \gamma g \in \mathrm{K}_M$.

(c) If $\hat h_d^{-1} g \in \mathrm{K}_M$, $\gamma \in R(E)$ and $\hat h_c^{-1} \gamma g \in \mathrm{K}_M$, then $c = d$ and $\gamma \in \mathsf{U}_c(M)$. Indeed $\hat h_c^{-1} \gamma \hat h_d = (\hat h_c^{-1} \gamma g)(\hat h_d^{-1} g)^{-1} \in \mathrm{K}_M$, so $t = \eta^{-1} \hat h_c^{-1} \gamma \hat h_d \eta = h_c^{-1} \gamma h_d \in \mathrm{K}(M)$ (finite components), and $(1, t) \in R(\mathbb{A})$. By Lemma 5.6.39, $a(1, t) = h_c^{-1} a(\gamma)_f h_d \in \mathrm{K}_0 = \mathrm{K}_X$, where $a(\gamma) \in \mathrm{U}(X_0)(E^+)$ is the X_0-block of the rational matrix γ. So $h_d \in a(\gamma)^{-1} h_c \mathrm{K}_X$, whence $c = d$, and $a(\gamma) \in \mathrm{U}(X_0)(E^+) \cap h_c \mathrm{K}_X h_c^{-1} = \{1\}$ by (FG4). Hence $\gamma \in \mathsf{U}(\mathbb{A}) \cap G(E) = \mathsf{U}(E)$ (Lemma 5.6.34 (i)) and $h_c^{-1} \gamma h_c = t \in \mathrm{K}(M)$: $\gamma \in \mathsf{U}_c(M)$.

Let $r \in R(\mathbb{A})$; by (b) choose $\gamma_0 \in R(E)$ and d with $\hat h_d^{-1} (\gamma_0 r)_f \in \mathrm{K}_M$, and put $r' = \gamma_0 r = (s', g')$. Reindexing $\gamma \mapsto \gamma\gamma_0$, $\sum_\gamma \sum_c w_c(\gamma r) = \sum_\gamma \sum_c w_c(\gamma r')$. By (c) only $c = d$ and $\gamma \in \mathsf{U}_d(M)$ contribute; by (a) and Step 2, $w_d(ur') = \beta_d(\mathbf{y}(us')) = \beta_d(u \cdot \mathbf{y}(s'))$ for $u \in \mathsf{U}_d(M)$; by (5.119) the sum is 1.

Step 4: unfolding. $R(E)$ is discrete in $R(\mathbb{A})$ (Lemma 5.6.34 (iii)) and $R(\mathbb{A})$ has a countable base, so by Lemma 5.6.20 there is a Borel set F_R meeting every orbit $R(E)r$ in exactly one point; $R(\mathbb{A}) = \bigsqcup_{\gamma \in R(E)} \gamma F_R$, and the integral over $[R]$ is the integral over F_R. Put $w = \sum_c w_c$. For Borel $\phi \ge 0$, left invariance and monotone convergence give $\int_{R(\mathbb{A})} \phi\, dr = \int_{F_R} \sum_\gamma \phi(\gamma x)\, dr(x)$. With $\phi = w|F|$ and Step 3, $\int_{R(\mathbb{A})} w|F|\, dr = \int_{F_R} |F|\, dr < \infty$; applying the same identity to the positive and negative parts of the real and imaginary parts of the integrable wF, and using $F(\gamma x) = F(x)$,

$$\int_{R(\mathbb{A})} w\, F\, dr = \int_{F_R} \sum_\gamma w(\gamma x) F(x)\, dr(x) = \int_{[R]} F\, dr.$$

Step 5: one class. Let $g \in R(\mathbb{A}_f)$. As $\hat{h}_c \in R(\mathbb{A}_f)$, $\hat{h}_c^{-1} g \in \mathrm{K}_M$ if and only if $g \in \hat{h}_c J_f'$, and then $F(s,g) = F((s,\hat{h}_c)(1,\hat{h}_c^{-1}g)) = F(s,\hat{h}_c)$. So $w_c(s,g)F(s,g) = \beta_c(\mathbf{y}(s))F(s,\hat{h}_c)\,\mathbf{1}_{\hat{h}_c J_f'}(g)$, with $dr_f(\hat{h}_c J_f') = dr_f(J_f')$. Since $w_c|F| \le w|F|$ is integrable, Tonelli's theorem for $dr = \kappa_0\, ds \otimes dr_f$ shows that $s \mapsto \beta_c(\mathbf{y}(s))F(s,\hat{h}_c)$ (a Borel function) is integrable on $R(F_\infty)$, and Fubini's theorem gives $\int_{R(\mathbb{A})} w_c F\, dr = \kappa \int_{R(F_\infty)} \beta_c(\mathbf{y}(s))F(s,\hat{h}_c)\, ds$. Summing over the finitely many classes and using Step 4 proves the identity (iii). □

Proposition 5.6.41. *Let $\mathfrak{S}$ be an admissible filling datum over a field E with Weil data, let ρ be a unitary representation of $\bar{G}$ on a finite-dimensional Hilbert space $\mathcal{H}$, and let $P\colon \mathbb{C}^{\mathcal{C}\times I} \to \mathcal{H}$ have amplitude blocks (TA6). For $i = 0, 1$ let g_i be a central idempotent of $\mathbb{C}[\bar{G}_i]$ with*

$$\operatorname{Re}(1 - g_i)(1) \le \tfrac{1}{2}\, b^{-8}.$$

Then $\rho(g_0 \otimes g_1)\, P$ is a near-isometry with error $5b^{-4}$: for every subspace $U \subseteq \mathbb{C}^{\mathcal{C}\times I}$,

$$\|\rho(g_0 \otimes g_1) P \operatorname{pr}_U\|_{\mathrm{HS}}^2 \;\ge\; \dim U - 5b^{-4} D_X.$$

Proof. We use the following facts from Proposition 5.6.42, for $i \in \{0,1\}$; here Ω_i' is the set of $s \in \bar{G}$ that agree with an element of $\bar{R}_0$ at every chosen place above p_{1-i} (the set Ω_{1-i} there):

(M1) $\sum_{s\in\Omega_i'} \|P_s - r_\psi(s)\|^2 \le b^{-12}\mathcal{D}_{\mathrm{id}}$, and $\|P^*P - 1\|^2 \le b^{-12} D_X$ (clause (iii));

(M2) for $r \in \bar{R}_0$ and $s \in \bar{G}$: $r_\psi(r)$ is unitary, $r_\psi(rs) = r_\psi(r) r_\psi(s)$ and $P_{rs} = r_\psi(r) P_s$ (clause (v));

(M3) $\operatorname{tr} r_\psi(\iota_i t) = D_X\, \psi_U(\iota_i t)$ for $t \in \bar{G}_i$ (clause (vi)), and $\sum_{s\in\bar{G}} |\psi_U^\natural(s)|^2 \le 2$ (clause (iv)).

Central idempotents. A central idempotent x of $\mathbb{C}[H]$, H a finite group, is a sum of the primitive central idempotents $\chi(1)\#H^{-1}\sum_h \overline{\chi(h)} h$, so $x(h^{-1}) = \overline{x(h)}$ and x is a class function. Hence for a unitary representation σ of H, $\sigma(x) = \sum_h x(h)\sigma(h)$ is self-adjoint and idempotent, an orthogonal projection; and comparing coefficients at 1 in $x^2 = x$ gives $\sum_h |x(h)|^2 = x(1)$, which is real.

Step 1: P is nearly an isometry. For a subspace U, $\|P\operatorname{pr}_U\|^2 - \dim U = \operatorname{tr}(\operatorname{pr}_U(P^*P - 1))$, so by Cauchy–Schwarz for the Hilbert–Schmidt inner product, $\|\operatorname{pr}_U\|^2 = \dim U \le D_X$ and (M1),

$$\|P \operatorname{pr}_U\|^2 \ge \dim U - \sqrt{D_X}\,\sqrt{b^{-12} D_X} = \dim U - b^{-6} D_X.$$

Step 2: one prime. Let x be a central idempotent of $\mathbb{C}[\bar{G}_i]$ with $\operatorname{Re} x(1) \le \frac{1}{2} b^{-8}$ and $E_x = \rho(\iota_i x)$, an orthogonal projection. We show $\|E_x P\|^2 \le 2b^{-4} D_X$. Since $E_x^* E_x = E_x$,

$$\|E_x P\|^2 = \operatorname{tr}(P^* E_x P) = \sum_{t\in\bar{G}_i} x(t) \operatorname{tr} r_\psi(\iota_i t) + \operatorname{tr} Y, \qquad Y = \sum_{t\in\bar{G}_i} x(t)\big(P_{\iota_i t} - r_\psi(\iota_i t)\big),$$

and we bound the real parts of the two terms.

The Bessel term. By (M3) it is $D_X \sum_t x(t)\psi_U(\iota_i t)$. For $g \in \bar{G}$, $g\,\iota_i(t) g^{-1} = \iota_i(g_i t g_i^{-1})$, and $t \mapsto g_i t g_i^{-1}$ is a bijection of $\bar{G}_i$ preserving x; averaging over g replaces ψ_U by $\psi_U^\natural$. By Cauchy–Schwarz, $\sum_t |x(t)|^2 = x(1) \le \frac{1}{2} b^{-8}$ and (M3), $\big|\sum_t x(t)\psi_U^\natural(\iota_i t)\big|^2 \le \frac{1}{2} b^{-8} \cdot 2$, so the Bessel term has real part at most $b^{-4} D_X$.

The remainder. Let $F\colon \bar G \to \mathrm{End}(\mathbb{C}^{\mathcal{C}\times I})$ be $F(s) = P_s - r_\psi(s)$ for $s \in \Omega_i'$ and $F(s) = 0$ otherwise. The right convolution $(R_xF)(s) = \sum_t x(t)F(s\,\iota_i t)$ is $\sigma(x)$ for the right regular representation σ of $\bar G_i$ on the Hilbert space of functions $\bar G \to \mathrm{End}$ with $\|F\|^2 = \sum_s \|F(s)\|^2$, which is unitary; so R_x is an orthogonal projection and $\sum_s \|(R_xF)(s)\|^2 \le \sum_s \|F(s)\|^2$. For $r \in \bar R_0$ and $t \in \bar G_i$, $r\,\iota_i(t)$ agrees with r in the factor $\bar G_{1-i}$, so lies in Ω_i', and by (M2) $F(r\,\iota_i t) = r_\psi(r)F(\iota_i t)$; hence $(R_xF)(r) = r_\psi(r)Y$ has norm $\|Y\|$. With (M1),

$$\#\bar R_0\,\|Y\|^2 \le \sum_{s\in\bar G} \|(R_xF)(s)\|^2 \le \sum_{s\in\Omega_i'} \|P_s - r_\psi(s)\|^2 \le b^{-12}\#\bar R_0\,D_X,$$

so $|\operatorname{tr} Y| = |\langle 1, Y\rangle_{\mathrm{HS}}| \le \sqrt{D_X}\,\|Y\| \le b^{-6}D_X \le b^{-4}D_X$. Adding, $\|E_xP\|^2 \le 2b^{-4}D_X$.

Step 3: both primes. Let $E_i = \rho(\iota_i g_i)$, commuting orthogonal projections with $\rho(g_0 \otimes g_1) = E_0E_1$. Each $1 - g_i$ is a central idempotent of $\mathbb{C}[\bar G_i]$ with $\mathrm{Re}(1-g_i)(1) \le \frac12 b^{-8}$ and $\rho(\iota_i(1-g_i)) = 1 - E_i$, so Step 2 gives $\|(1-E_i)P\|^2 \le 2b^{-4}D_X$. For every vector y, $(1-E_0E_1)y = (1-E_0)y + E_0(1-E_1)y$ is an orthogonal sum and $\|E_0(1-E_1)y\| \le \|(1-E_1)y\|$; applied to $y = Pe$ for the vectors e of an orthonormal basis,

$$\|(1-E_0E_1)P\|^2 \le \|(1-E_0)P\|^2 + \|(1-E_1)P\|^2 \le 4b^{-4}D_X.$$

Step 4: conclusion. As E_0E_1 is an orthogonal projection, $\|P\mathrm{pr}_U\|^2 = \|E_0E_1P\mathrm{pr}_U\|^2 + \|(1-E_0E_1)P\mathrm{pr}_U\|^2$, and $\|(1-E_0E_1)P\mathrm{pr}_U\| \le \|(1-E_0E_1)P\|$. By Steps 1 and 3 and $b \ge 1$,

$$\|\rho(g_0\otimes g_1)P\,\mathrm{pr}_U\|^2 \ge \dim U - b^{-6}D_X - 4b^{-4}D_X \ge \dim U - 5b^{-4}D_X.$$

□

Proposition 5.6.42. *Let $\mathfrak{S}$ be admissible with Weil data. For $i \in \{0,1\}$ let Ω_i be the set of $s \in \bar G$ that agree with an element of $\bar R_0$ at every chosen place above p_i.*

(i) If $\Omega \subseteq \bar G$ avoids the scalar cosets (no $s \in \Omega$ is ζt with $t \in \bar R_0$ at every chosen place, for an integral $\zeta \ne 1$ with $\zeta\bar\zeta = 1$), $C \ge 0$ and $\mathrm{LM}(\{\mathsf{g} \ne 0\}, \Omega) \le C\nu^2$, then $\sqrt{\mathrm{SM}(A^{\mathrm{full}}_{G(E)\backslash R(E)}, \Omega)} \le \sqrt{C} + b^{-15}\sqrt{\mathcal{D}_{\mathrm{id}}}$.

(ii) $\mathrm{SM}(A^{\mathrm{full}}_{G(E)\backslash R(E)}, \Omega_i) \le b^{-12}\mathcal{D}_{\mathrm{id}}$.

(iii) If P has amplitude blocks for a representation ρ of $\bar G$, then $\sum_{s\in\Omega_i} \|P^*\rho(s)P - r_\psi(s)\|^2_{\mathrm{HS}} \le b^{-12}\mathcal{D}_{\mathrm{id}}$; in particular $\|P^*P - 1\|^2_{\mathrm{HS}} \le b^{-12}D_X$ and $\|P^*P\|^2_{\mathrm{HS}} \le 2D_X$.

(iv) $\sum_{s\in\bar G} |\psi^\natural_U(s)|^2 \le 2$.

(v) Equivariance. For $t \in \bar R_0$ and $s \in \bar G$, $r_\psi(t)$ is unitary and $r_\psi(ts) = r_\psi(t)r_\psi(s)$; if P has amplitude blocks for a unitary ρ, then moreover $P^*\rho(ts)P = r_\psi(t)\,P^*\rho(s)P$.

(vi) Trace. Write $\bar G = \bar G_0 \times \bar G_1$, $\bar G_i = \prod_{w\in S_i} \mathrm{GL}_r(k_w)$, and $\iota_i\colon \bar G_i \to \bar G$ for the inclusion of the factor i. If $s \in \bar G$ has trivial component in $\bar G_0$ or in $\bar G_1$, then $\operatorname{tr} r_\psi(s) = D_X\,\psi_U(s)$; in particular $\operatorname{tr} r_\psi(\iota_i t) = D_X\,\psi_U(\iota_i t)$ for $t \in \bar G_i$.

ar cosets and fixers. Call s in a scalar coset *if $s = \zeta t$ at every chosen place for some integral ζ with $\zeta\bar\zeta = 1$ and $t \in \bar R_0$. If $s \notin \bar R_0$ then $A^{\mathrm{full}}_{G(E)}(c,s,c') = A^{\mathrm{full}}_{G(E)\backslash R(E)}(c,s,c')$ for all c, c'. Open elements are in no scalar coset. If $\Theta\colon \bar G \to [0, 2D_X]$, then $\sum_{s \text{ in a scalar coset}} \Theta(s) \le 2M^f\mathcal{D}_{\mathrm{id}}$. Every $s \in \mathrm{Fix}(S_0, d)$ has meet norm at least p_0^f.*

Proof. Throughout, D_{id} stands for $\mathcal{D}_{\mathrm{id}} = \#\bar{R}_0\,\#\mathcal{C}\,\#I$; as $1 \in \bar{R}_0$ and $I \neq \emptyset$, $\#\mathcal{C} \leq \mathcal{D}_{\mathrm{id}}$. By (FG6), $k \geq 1000$ and $f \geq 1$, so $kf \geq 40$.

Step 0: blocks split along $R(E)$, and the entries of $P^*\rho(s)P$ and $r_\psi(s)$. For every $T \subseteq G(E)$ and every block (c,s,c') the amplitudes of the terms in T over (c,s,c') form an absolutely summable family, since their norms are bounded by the amplitude majorants, which are summable by Lemma 5.2.29 (ii). Hence

$$A_{G(E)}(c,s,c') = A_{R(E)}(c,s,c') + A_{G(E)\setminus R(E)}(c,s,c') \tag{5.120}$$

for the full and the cut amplitude sums. If P has amplitude blocks (TA6) for a representation ρ, then for $x = (c_x, i_x)$, $y = (c_y, i_y)$,

$$(P^*\rho(s)P)_{xy} = \langle Pe_x, \rho(s)Pe_y\rangle = \overline{\langle \rho(s)Pe_y, Pe_x\rangle} = \nu^{-1}\,\overline{A^{\mathrm{full}}_{G(E)}(c_x,s,c_y)_{i_x i_y}},$$

and $r_\psi(s)_{xy} = \nu^{-1}\overline{A^{\mathrm{full}}_{R(E)}(c_x,s,c_y)_{i_x i_y}}$ by (TA7). Terms compose and invert: if $h_c^{-1}\gamma h_{c'} = \kappa \in K$ with $\mathrm{red}(\kappa) = s$ and $h_{c'}^{-1}\delta h_{c''} = \kappa' \in K$ with $\mathrm{red}(\kappa') = t$, then $h_c^{-1}\gamma\delta h_{c''} = \kappa\kappa'$ and $h_{c'}^{-1}\gamma^{-1}h_c = \kappa^{-1}$, so $\gamma\delta$ is a term over (c, st, c'') and γ^{-1} one over (c', s^{-1}, c), red being a homomorphism. If $\mathcal{M}, \mathcal{N}$ are action matrices of $\gamma, \delta \in R(E)$, then $\mathcal{M}\mathcal{N}$ is one of $\gamma\delta$, and if $\mathcal{N}$ is unitary, $\mathcal{N}^* = \mathcal{N}^{-1}$ is one of δ^{-1} (apply $W(y) = W(\delta\cdot(\delta^{-1}\cdot y)) = \mathcal{N}W(\delta^{-1}\cdot y)$).

Step 1: elements of $\bar{R}_0$ fix the first frame vector. Let $t = \mathrm{red}(\kappa)$ with $\kappa \in R(\mathbb{A}_f) \cap K$. The vector $f_0 = e_1$ is a vector of the lattice basis (FG3) (only x_k is changed there), and $\kappa e_1 = e_1$: U acts trivially on the line $\langle e_1\rangle$, the first step of the flag it stabilises, and $H = \mathrm{U}(X_0)$ fixes e_1. As κ is an isometry, $h(e_1, \kappa x) = h(\kappa^{-1}e_1, x) = h(e_1, x)$, so the row of κ that gives the coordinate along e_1^* in the lattice basis is that of the identity. Reducing at a chosen place w, t_w fixes e_1, and so does the inverse adjoint of t_w (it fixes e_1 exactly when the e_1^*-row of t_w is that of the identity). Consequently, if $s \in \bar{G}$ and $s_w = t_w$, then s meets at $(w,0)$ and at $(w,1)$ (TA11), with $x = y$ the first coordinate vector.

Step 2: a root of unity that is 1 at the places of S_i is 1. Let $\zeta \in \mathcal{O}_E$, $\zeta\bar{\zeta} = 1$, with $\zeta \equiv 1$ modulo every $w \in S_i$. For every embedding $\sigma\colon E \to \mathbb{C}$, $\sigma(\bar{\zeta}) = \overline{\sigma(\zeta)}$ (E is CM), so $|\sigma(\zeta)|^2 = \sigma(\zeta\bar{\zeta}) = 1$. If $\zeta \neq 1$, then $\zeta - 1$ is a nonzero element of the product of the f distinct primes $w \in S_i$, each of norm p_i, so $p_i^f \leq |\mathrm{N}_{E/\mathbb{Q}}(\zeta - 1)| = \prod_\sigma |\sigma(\zeta) - 1| \leq 2^{2f}$, against $p_i \geq b^{10} > 4$ (FG6). Hence $\zeta = 1$.

Proof of (v). By Step 0 and Lemma 5.6.45 (ii), $A^{\mathrm{full}}_{R(E)}(c_y, s, c_x) = A^{\mathrm{full}}_{R(E)}(c_x, s^{-1}, c_y)^*$, whence $(r_\psi(s)^*)_{xy} = \overline{r_\psi(s)_{yx}} = r_\psi(s^{-1})_{xy}$: $r_\psi(s)^* = r_\psi(s^{-1})$ for all s. Let $t \in \bar{R}_0$ and $d \in \mathcal{C}$. By Lemma 5.6.45 (iii) (for d and $t^{-1} \in \bar{R}_0$) and (i) there are d' and a term $\delta \in R(E)$ over (d, t^{-1}, d') with a unitary action matrix $\mathcal{N}$. By Lemma 5.6.45 (ii), $A^{\mathrm{full}}_{R(E)}(d, t^{-1}, e) = \nu\,\delta_{ed'}\mathcal{N}$, so $A^{\mathrm{full}}_{R(E)}(e, t, d) = \nu\,\delta_{ed'}\mathcal{N}^*$ and

$$r_\psi(t)\,e_{(d,j)} = \sum_{l\in I} \mathcal{N}_{jl}\,e_{(d',l)} \qquad (j \in I). \tag{5.121}$$

For $t' \in \bar{R}_0$ choose likewise δ' over (d, t'^{-1}, d') with $\mathcal{N}'$, and δ over (d', t^{-1}, d'') with $\mathcal{N}$. Then $\delta'\delta \in R(E)$ is a term over $(d, (tt')^{-1}, d'')$ with action matrix $\mathcal{N}'\mathcal{N}$ (Step 0), so (5.121) gives $r_\psi(tt')e_{(d,j)} = \sum_l (\mathcal{N}'\mathcal{N})_{jl}e_{(d'',l)} = r_\psi(t)r_\psi(t')e_{(d,j)}$. With $\delta = 1$ over $(d, 1, d)$ and $\mathcal{N} = 1$, $r_\psi(1) = 1$; hence $r_\psi(t)^*r_\psi(t) = r_\psi(t^{-1})r_\psi(t) = 1$ and $r_\psi(t)$ is unitary. If $s \notin \bar{R}_0$, then $ts \notin \bar{R}_0$, no term of $R(E)$ lies over a block at s or at ts (Lemma 5.6.45 (ii)), and $r_\psi(ts) = 0 = r_\psi(t)r_\psi(s)$; if $s \in \bar{R}_0$ this was shown. So $r_\psi(ts) = r_\psi(t)r_\psi(s)$.

Now let P have amplitude blocks for a representation ρ (not necessarily unitary), and write $P_s = P^*\rho(s)P$. *Right equivariance: $P_{st} = P_s r_\psi(t)$ for $s \in \bar{G}$, $t \in \bar{R}_0$.* With $\delta, \mathcal{N}$ for d and t^{-1} as

above, Lemma 5.6.45 (iv) for the stable set $T = G(E)$ gives $A^{\mathrm{full}}_{G(E)}(c, st, d) = A^{\mathrm{full}}_{G(E)}(c, s, d')\mathcal{N}^*$, and by Step 0 and (5.121)

$$(P_s r_\psi(t))_{x,(d,j)} = \sum_l (P_s)_{x,(d',l)}\mathcal{N}_{jl} = \nu^{-1}\,\overline{(A^{\mathrm{full}}_{G(E)}(c_x, s, d')\mathcal{N}^*)_{i_x j}} = (P_{st})_{x,(d,j)}.$$

Left equivariance for unitary ρ. Let $t \in \bar{R}_0$, $\phi \in \mathbb{C}^{\mathcal{C}\times I}$ and $\Delta = \rho(t)P\phi - Pr_\psi(t)\phi$. For $s \in \bar{G}$ and ϕ', unitarity and right equivariance give $\langle \rho(s)P\phi', \Delta\rangle = \langle \phi', (P_{s^{-1}t} - P_{s^{-1}} r_\psi(t))\phi\rangle = 0$. Taking $(s, \phi') = (t, \phi)$ and $(1, r_\psi(t)\phi)$, $\langle \Delta, \Delta\rangle = 0$, so $\rho(t)P = Pr_\psi(t)$. Hence $P^*\rho(t) = (\rho(t^{-1})P)^* = (Pr_\psi(t^{-1}))^* = r_\psi(t)P^*$, and $P^*\rho(ts)P = r_\psi(t)\, P^*\rho(s)P$.

Proof of (vi). Let s have component 1 in $\bar{G}_j$, that is at every $w \in S_j$; so has s^{-1}. By Step 0, (v) and Lemma 5.6.45 (ii), (v),

$$\operatorname{tr} r_\psi(s) = \nu^{-1}\sum_{c\in\mathcal{C}}\sum_{i\in I}\overline{A^{\mathrm{full}}_{R(E)}(c, s, c)_{ii}} = \nu^{-1}\sum_{c,i} A^{\mathrm{full}}_{R(E)}(c, s^{-1}, c)_{ii} = \#\mathcal{C}\,\#I\,\psi_U(s) = D_X\,\psi_U(s).$$

For $t \in \bar{G}_i$, $\iota_i t$ has component 1 in $\bar{G}_{1-i}$.

Proof of (vii). If $s \notin \bar{R}_0$, no term of $R(E)$ lies over (c, s, c') (Lemma 5.6.45 (ii)), so $A^{\mathrm{full}}_{R(E)}(c, s, c') = 0$ and (5.120) gives the first claim. Let s be in a scalar coset, $s_w = \zeta t_w$ at every chosen place with $t \in \bar{R}_0$. By Step 1, $s_w f_0 = \zeta t_w e_1 = \zeta e_1$, so the leading minor of order 1 of $Z_w(s)$ is $h_w(e_1, \zeta e_1) = \zeta\, h(e_1, e_1) = 0$ at every $w \in S_0$ (e_1 is isotropic, and $\varrho \geq 1$); so s is not open (TA10). The element s is determined by t and by the residues of ζ at the $2f$ chosen places; by (FG2) there are at most $\prod_w \#k_w = p_0^f p_1^f = M^f$ families of residues, so at most $M^f \#\bar{R}_0$ elements lie in a scalar coset, and $\sum_{s \text{ in a scalar coset}} \Theta(s) \leq 2D_X\, M^f \#\bar{R}_0 = 2M^f \mathcal{D}_{\mathrm{id}}$. Finally let $s \in \mathrm{Fix}(S_0, d)$, $d = (d_w)_{w\in S_0}$, $d_w = (\epsilon_w, v_w)$. At each $w \in S_0$ the element g of (TA10) fixes $f \cdot v_w$, so $f \cdot v_w = g\, f \cdot v_w$ with $v_w \neq 0$: s meets at (w, ϵ_w). These are $\#S_0 = f$ distinct pairs, each contributing p_0, and the other factors of the meet norm are ≥ 1; so the meet norm of s is at least p_0^f.

Proof of (i). *Off $R(E)$ the blocks are those of Γ^*.* By Lemma 5.6.46, $A^{\mathrm{full}}_{G(E)\setminus R(E)}(c, s, c') = A^{\mathrm{full}}_{\Gamma^*}(c, s, c')$ for $s \in \Omega$. *Minkowski.* $\nu\sqrt{\mathrm{SM}(A, \Omega)}$ is the norm of the family $(A(c, s, c'))_{c,c'\in\mathcal{C},\, s\in\Omega}$ in the Hilbert space $\bigoplus \mathbb{C}^{I\times I}$ with Hilbert–Schmidt norms, so by the triangle inequality

$$\sqrt{\mathrm{SM}(A^{\mathrm{full}}_{\Gamma^*}, \Omega)} \leq \sqrt{\mathrm{SM}(A^{\mathrm{full}}_{\Gamma^*} - A^{\mathrm{cut}}_{\Gamma^*}, \Omega)} + \sqrt{\mathrm{SM}(A^{\mathrm{cut}}_{\Gamma^*}, \Omega)}.$$

The cost of the cut. Put $\eta = \nu/(2b^{k^3 f})$. For fixed (c, s), $\sum_{c'} \|A^{\mathrm{full}}_{\Gamma^*}(c, s, c') - A^{\mathrm{cut}}_{\Gamma^*}(c, s, c')\|^2 \leq \big(\sum_{c'} \|\cdots\|\big)^2 \leq \eta^2$ by Lemma 5.3.62 (ii). Summing over $c \in \mathcal{C}$ and $s \in \bar{G}$, and using $\#\bar{G} \leq \prod_w \#\mathrm{GL}_r(k_w) \leq M^{fr^2} \leq b^{23fr^2}$ (FG2), (FG6),

$$\mathrm{SM}(A^{\mathrm{full}}_{\Gamma^*} - A^{\mathrm{cut}}_{\Gamma^*}, \Omega) \leq \nu^{-2}\#\mathcal{C}\,\#\bar{G}\,\eta^2 \leq \tfrac{1}{4}\, b^{23fr^2 - 2k^3 f}\,\mathcal{D}_{\mathrm{id}} \leq b^{-40}\mathcal{D}_{\mathrm{id}},$$

The cut part. By Theorem 5.3.2 (iii) with $w = C$, $\mathrm{SM}(A^{\mathrm{cut}}_{\Gamma^*}, \Omega) \leq C + \mathcal{D}_{\mathrm{id}}/b^{kf} \leq C + b^{-40}\mathcal{D}_{\mathrm{id}}$. *Together,* with $\sqrt{x+y} \leq \sqrt{x} + \sqrt{y}$ and $2 \leq b^5$,

$$\sqrt{\mathrm{SM}(A^{\mathrm{full}}_{G(E)\setminus R(E)}, \Omega)} \leq b^{-20}\sqrt{\mathcal{D}_{\mathrm{id}}} + \sqrt{C} + b^{-20}\sqrt{\mathcal{D}_{\mathrm{id}}} \leq \sqrt{C} + b^{-15}\sqrt{\mathcal{D}_{\mathrm{id}}}.$$

Proof of (ii). *Ω_i avoids the scalar cosets.* Let $s \in \Omega_i$, $s_w = t_w$ for $w \in S_i$ with $t \in \bar{R}_0$, and suppose $s_w = \zeta t'_w$ at every chosen place with $\zeta \in \mathcal{O}_E$, $\zeta\bar{\zeta} = 1$, $t' \in \bar{R}_0$. For $w \in S_i$, Step 1 gives $e_1 = t_w e_1 = s_w e_1 = \zeta t'_w e_1 = \zeta e_1$ modulo w, so $\zeta \equiv 1$ modulo w, and $\zeta = 1$ by Step 2. *Meet*

norm. By Step 1 every $s \in \Omega_i$ meets at the $2f$ pairs (w, ϵ), $w \in S_i$, $\epsilon \in \{0,1\}$, so its meet norm is at least $q = p_i^{2f}$. *Links.* By Theorem 5.3.2 (iv), (FA6), and $M = p_i p_{1-i} \le p_i\, b^{11} \le b\, p_i^2$ (FG6),

$$\mathrm{LM}(\{\mathfrak{g} \neq 0\}, \Omega_i) \le \Big(\frac{b^{2f}}{p_i^{2f}}\Big)^k \Big(\frac{M}{b^6}\Big)^{kf} \mathcal{D}_{\mathrm{id}}\, \nu^2 \le \Big(\frac{b^2}{p_i^2} \cdot \frac{b\, p_i^2}{b^6}\Big)^{kf} \mathcal{D}_{\mathrm{id}}\, \nu^2 = b^{-3kf} \mathcal{D}_{\mathrm{id}}\, \nu^2 \le b^{-30} \mathcal{D}_{\mathrm{id}}\, \nu^2.$$

Conclusion. By (i) with $C = b^{-30}\mathcal{D}_{\mathrm{id}}$, $\sqrt{\mathrm{SM}(A^{\mathrm{full}}_{G(E)\backslash R(E)}, \Omega_i)} \le 2b^{-15}\sqrt{\mathcal{D}_{\mathrm{id}}}$, so $\mathrm{SM} \le 4b^{-30}\mathcal{D}_{\mathrm{id}} \le b^{-12}\mathcal{D}_{\mathrm{id}}$.

Proof of (iii). By Step 0 and (5.120), $(P_s - r_\psi(s))_{xy} = \nu^{-1}\overline{A^{\mathrm{full}}_{G(E)\backslash R(E)}(c_x, s, c_y)_{i_x i_y}}$, so $\|P_s - r_\psi(s)\|^2 = \nu^{-2}\sum_{c,c'} \|A^{\mathrm{full}}_{G(E)\backslash R(E)}(c, s, c')\|^2$, and summing over $s \in \Omega_i$ gives $\mathrm{SM}(A^{\mathrm{full}}_{G(E)\backslash R(E)}, \Omega_i) \le b^{-12}\mathcal{D}_{\mathrm{id}}$ by (ii). For $t \in \bar{R}_0$, right equivariance (proof of (v)) and $r_\psi(1) = 1$ give $P_t - r_\psi(t) = (P^*P - 1)r_\psi(t)$, whose norm is $\|P^*P - 1\|$ as $r_\psi(t)$ is unitary. Since $\bar{R}_0 \subseteq \Omega_i$, $\#\bar{R}_0\, \|P^*P - 1\|^2 \le b^{-12}\mathcal{D}_{\mathrm{id}} = b^{-12}\#\bar{R}_0 D_X$, so $\|P^*P - 1\|^2 \le b^{-12} D_X$. Then $\|P^*P\| \le \|P^*P - 1\| + \|1\| \le (b^{-6} + 1)\sqrt{D_X}$, and $\|P^*P\|^2 \le (1 + b^{-6})^2 D_X \le 2D_X$.

Proof of (iv). This is Lemma 5.6.43. □

Lemma 5.6.43. *Let $\mathfrak{S}$ be an admissible filling datum over a field E that carries Weil data. Then*

$$\sum_{s \in \bar{G}} \big|\psi^{\natural}_U(s)\big|^2 \le 2.$$

Proof. **Step 1: the set T.** Let T be the set of the chosen places $w \in S_0 \cup S_1$ and their conjugates $\bar{w}$; it is finite and stable under conjugation. By (FG2) the $2f$ chosen places are distinct, $\bar{w} \notin S_0 \cup S_1$ for chosen w, and conjugation is injective, so $\#T = 4f$ and, for $i = 0, 1$, T contains $2f$ distinct places above p_i, each of residue cardinality $q_w = p_i$. As $\sum_{w|p_i} e_w f_w = [E : \mathbb{Q}] = 2f$, these are all the places above p_0 and p_1; so $M = p_0 p_1$ is a unit at every finite place outside T, i.e. M^{-1} is a T-integer. By Lemma 5.2.82 there is a filling datum (P, F) at T; F is a large lattice datum with level unit M (the image of M in E_T). Write θ for its group measure, G_T for its unitary group, $K_1 = \mathrm{K}_T(1)$ and $K_M = \mathrm{K}_T(M)$, and χ_M for its extended Bessel character. Put

$$a(x) = \int_{K_1} \chi_M(yxy^{-1})\, d\theta(y) \qquad (x \in G_T),$$

well defined as χ_M is continuous with $|\chi_M| \le 1$ and $0 < \theta(K_1) < \infty$ (Lemma 5.5.44 (b), (d), with the intermediate group K_1).

Step 2: lifting and reduction at T. (a) The map $m \mapsto m_T$ sends K onto K_1: m and m^{-1} are integral at every place, so $m_T \in K_1$; conversely, for $y \in K_1$ the element $m \in \mathrm{GL}_r(\mathbb{A}_f)$ with components y_w at $w \in T$ and 1 elsewhere (in the lattice basis) is unitary (T is stable under conjugation), integral with integral inverse, so $m \in K$ and $m_T = y$. (b) For $y \in K_1$ let $\bar{y} \in \bar{G}$ have the components $y_w \bmod w$ at the chosen places w ($w \in T$); then $\bar{y} = \mathrm{red}(m)$ for every $m \in K$ with $m_T = y$, and $y \mapsto \bar{y}$ is a homomorphism $K_1 \to \bar{G}$, surjective by (a) and (FA2). Its kernel K_1' is open (it contains K_M, as $M \in \mathfrak{p}_w$ at each chosen w), and its fibres are the cosets gK_1'.

Step 3: $a(l_T) = \theta(K_1)\,\psi^{\natural}_U(\mathrm{red}(l))$ for $l \in K$. Let $s = \mathrm{red}(l)$ and $y \in K_1$; choose $m \in K$ with $m_T = y$ (Step 2). Then $y l_T y^{-1} = (mlm^{-1})_T$ with $mlm^{-1} \in K$ and $\mathrm{red}(mlm^{-1}) = \bar{y}s\bar{y}^{-1}$, so by Lemma 5.6.44

$$\chi_M(y l_T y^{-1}) = \psi_U(\bar{y}\, s\, \bar{y}^{-1}).$$

The integrand is constant on the fibres of $y \mapsto \bar{y}$. By Lemma 5.5.41 (1), θ is a Haar measure, so the $\#\bar{G}$ fibres $gK_1' \subseteq K_1$, translates of K_1', have equal measure $\theta(K_1)/\#\bar{G}$. Hence

$$a(l_T) = \frac{\theta(K_1)}{\#\bar{G}} \sum_{g \in \bar{G}} \psi_U(gsg^{-1}) = \theta(K_1)\, \psi_U^\natural(s).$$

Step 4: a on cosets of K_M. For $x \in G_T$, $k \in K_M$ and $y \in K_1$, $yxky^{-1} = (yxy^{-1})(yky^{-1})$ with $yky^{-1} \in K_M$ (Lemma 5.5.44 (a)), and χ_M is right K_M-invariant (Lemma 5.5.44 (b)); so $a(xk) = a(x)$. For each $s \in \bar{G}$ choose $l_s \in K$ with $\mathrm{red}(l_s) = s$ (FA2), and put $C_s = (l_s)_T K_M$. If $C_s \cap C_{s'} \neq \emptyset$ then $(l_s)_T^{-1}(l_{s'})_T \in K_M$, so $s = s'$ by Lemma 5.2.46 (ii): the C_s are pairwise disjoint, and $a = a((l_s)_T)$ on C_s.

Step 5: the mass integral. By Step 4, and since $\theta(C_s) = \theta(K_M)$ (translation invariance),

$$\theta(K_M) \sum_{s \in \bar{G}} |a((l_s)_T)|^2 = \sum_s \int_{C_s} |a|^2 d\theta \leq \int_{G_T} |a|^2 d\theta = \mathrm{mi}(K_1).$$

Apply Lemma 5.5.42 to F, $Z = K_1$, $Q = 2$, $t = n$. Its hypotheses hold: if c is a unit of E_T in $\mathcal{O}_T$ with $c^{-1} \notin \mathcal{O}_T$, some component c_w lies in $\mathfrak{p}_w$, so $|c| = \prod_{w \in T} |c_w|_w \leq q_w^{-1} \leq \min(p_0, p_1)^{-1} \leq b^{-10} \leq \frac{1}{2}$ by (FG6); and $n + 2 \cdot 10^9 n^4 \leq 10^{10} n^4 \leq n^6 \leq n^7 \leq k$ by (FG6). So $\mathrm{mi}(K_1) \leq \theta(K_1)\, \theta(K_M)\, (\theta(K_1) + 2^{-n})$. The Haar measure of E_T with $\mathcal{O}_T$ of mass 1 is the product of the local ones with $\mathcal{O}_w$ of mass 1, so $\mathcal{O}_T \setminus \mathcal{O}_T^\times = \bigcup_{w \in T} \{x \in \mathcal{O}_T : x_w \in \mathfrak{p}_w\}$ has measure at most $\sum_{w \in T} q_w^{-1} \leq 4f\, b^{-10} \leq \frac{1}{2}$ ($f \leq b/1000$ by (FG6)); by Lemma 5.2.87, $\theta(K_1) \geq 2^{-n}$. Hence $\mathrm{mi}(K_1) \leq 2\, \theta(K_1)^2 \theta(K_M)$.

Step 6: conclusion. By Step 3, $|a((l_s)_T)| = \theta(K_1) |\psi_U^\natural(s)|$. With Step 5,

$$\theta(K_M)\, \theta(K_1)^2 \sum_{s \in \bar{G}} |\psi_U^\natural(s)|^2 \leq 2\, \theta(K_1)^2\, \theta(K_M),$$

and $0 < \theta(K_M), \theta(K_1) < \infty$ (Lemma 5.5.44 (d)); dividing gives the claim. □

Lemma 5.6.44. *Let $\mathfrak{S}$ be a filling datum, T a finite set of finite places of E stable under complex conjugation such that M^{-1} is a T-integer, (P, F) a filling datum at T, and χ_M the extended Bessel character of F. Then*

$$\chi_M(m_T) = \psi_U(\mathrm{red}(m)) \qquad \textit{for every } m \in K.$$

Proof. Write U_T for the Bessel unipotent group of F over E_T; for $u \in \mathsf{U}(\mathbb{A}_f)$, $u_T \in \mathsf{U}_T$. The entries of u just above the diagonal of the frame block lie in the rows $e_1, \ldots, e_\varrho$; the coefficient of e_a of a vector is the same in the standard basis and in the lattice basis (they differ only in x_k, $x' = x_k/\bar{\pi} + z/N$, z), so $\sigma(u_T) = \sigma(u)_T$, and $\sigma(u) \in \hat{\mathcal{O}}$ if $u \in K$.

Step 1: ψ_f is trivial on $\varpi^{-1}\hat{\mathcal{O}}$. Let $x \in \varpi^{-1}\hat{\mathcal{O}}$ and $a \in E$ with $x - a \in \hat{\mathcal{O}}$. As $\varpi \in \mathcal{O}_E$, $a \in \varpi^{-1}\hat{\mathcal{O}} \cap E = \varpi^{-1}\mathcal{O}_E$, the inverse different of $E/\mathbb{Q}$ (ϖ generates the different), so $\mathrm{Tr}_{E/\mathbb{Q}}(a) \in \mathbb{Z}$ and $\psi_f(x) = 1$.

Step 2: the phase. Let $u \in \mathsf{U}(\mathbb{A}_f) \cap K$ and $x = M^{-1}\sigma(u) \in \mathbb{A}_f$. Let $\tilde{x} \in \mathbb{A}_f$ have the components of x at T and 0 elsewhere. Then $x - \tilde{x}$ vanishes at T, and at $w \notin T$ its component $M^{-1}\sigma(u)_w$ lies in $\mathcal{O}_w$, since M^{-1} is a T-integer and $\sigma(u)$ is integral. By additivity of ψ_f and Step 1,

$$\psi(u) = \psi_f(-x/\varpi) = \psi_f(-\tilde{x}/\varpi)\, \psi_f\big(-(x - \tilde{x})/\varpi\big) = \psi_T(x_T) = \psi_T\big(M^{-1}\sigma(u_T)\big).$$

Step 3: $\mathrm{red}(m) \in \bar{\mathsf{U}}$. Then $\mathrm{red}(m) = \mathrm{red}(u)$ for some $u \in \mathsf{U}(\mathbb{A}_f) \cap K$, and by Lemma 5.2.46 (ii) $u_T^{-1} m_T \in \mathrm{K}_T(M)$ with $u_T \in \mathsf{U}_T$. By the definition of χ_M and Step 2, $\chi_M(m_T) = \psi_T(M^{-1}\sigma(u_T)) = \psi(u) = \psi_U(\mathrm{red}(m))$, the last equality by (TA8).

Step 4: $\mathrm{red}(m) \notin \bar{\mathsf{U}}$. Then $\psi_U(\mathrm{red}(m)) = 0$. Suppose $\chi_M(m_T) \neq 0$: there is $u \in \mathsf{U}_T$ with $u^{-1} m_T \in \mathrm{K}_T(M)$. As m and m^{-1} have integral entries, $m_T \in \mathrm{K}_T(1)$, and so $u = m_T (u^{-1} m_T)^{-1} \in \mathrm{K}_T(1)$. Let $\tilde{u} \in G(\mathbb{A}_f)$ have, in the lattice basis, the components of u at the places of T and 1 at the other places. It is unitary, because the unitarity of u over E_T is the unitarity of its components at the places of T (T is stable under conjugation) and 1 is unitary; it lies in U at every place; and $\tilde{u}$, $\tilde{u}^{-1}$ have integral entries at every place. So $\tilde{u} \in \mathsf{U}(\mathbb{A}_f) \cap K$ and $\tilde{u}_T = u$, whence $\tilde{u}_T^{-1} m_T \in \mathrm{K}_T(M)$ and $\mathrm{red}(m) = \mathrm{red}(\tilde{u}) \in \bar{\mathsf{U}}$ by Lemma 5.2.46 (ii), a contradiction. Hence $\chi_M(m_T) = 0 = \psi_U(\mathrm{red}(m))$. □

Lemma 5.6.45. *Let $\mathfrak{S}$ be admissible with Weil data. For $\gamma \in R(E)$ call a matrix $\mathcal{M} \in \mathbb{C}^{I \times I}$ an* action matrix *of γ if $W(\gamma \cdot y) = \mathcal{M}\, W(y)$ for every $y \in G_\infty$.*

(i) Every $\gamma \in R(E)$ has a unitary action matrix.

(ii) Let $c, c' \in \mathcal{C}$ and $s \in \bar{G}$. If some $\gamma \in R(E)$ is a term over (c, s, c'), then $s \in \bar{R}_0$, and for every action matrix $\mathcal{M}$ of γ and every $d \in \mathcal{C}$

$$A^{\mathrm{full}}_{R(E)}(c, s, d) = \begin{cases} \nu\, \mathcal{M}, & d = c', \\ 0, & d \neq c'. \end{cases}$$

Moreover $A^{\mathrm{full}}_{R(E)}(c', s^{-1}, c) = A^{\mathrm{full}}_{R(E)}(c, s, c')^*$ for all $c, c' \in \mathcal{C}$ and $s \in \bar{G}$.

(iii) For every $c \in \mathcal{C}$ and $t \in \bar{R}_0$ there are $c' \in \mathcal{C}$ and a term $\gamma \in R(E)$ over (c, t, c').

(iv) Let $T \subseteq G(E)$ be stable, let $\delta \in R(E)$ be a term over (d, t, d') with an action matrix $\mathcal{N}$, and suppose that $\gamma \in T$ if and only if $\gamma\delta^{-1} \in T$, for every $\gamma \in G(E)$. Then for all $c \in \mathcal{C}$ and $s \in \bar{G}$

$$A^{\mathrm{full}}_T(c, st^{-1}, d) = A^{\mathrm{full}}_T(c, s, d')\, \mathcal{N}^*.$$

(v) Let $j \in \{0, 1\}$ and let $s \in \bar{G}$ have component 1 at every chosen place in S_j. Then $A^{\mathrm{full}}_{R(E)}(c, s^{-1}, c) = \nu\, \psi_U(s)\, 1_I$ for every $c \in \mathcal{C}$.

Proof. Write $X = \langle e_1, \dots, e_\varrho \rangle$, $X^* = \langle e_1^*, \dots, e_\varrho^* \rangle$ and $V_{\mathrm{m}} = X_0 \oplus Ez$, so that $V = X \oplus V_{\mathrm{m}} \oplus X^*$ and $X^\perp = X \oplus V_{\mathrm{m}}$; the lattice basis consists of the e_a, the e_a^* and a basis of $L_{\mathrm{m}} = L_0 \cap V_{\mathrm{m}}(\mathbb{A}_f)$ (the x_i, $i < k$, $x_k/\bar{\pi} + z/N$ and z), and matrices of elements of $G(\mathbb{A}_f)$ are taken in it, with blocks indexed by X, V_{m}, X^*. For $y \in G_\infty$ write $W(y) \otimes \overline{W(y)}$ for the matrix with entries $W(y)_i \overline{W(y)_j}$; for a matrix $\mathcal{M}$ and vectors p, q, $p \otimes \overline{\mathcal{M}q} = (p \otimes \bar{q})\, \mathcal{M}^*$ and $\mathcal{M}p \otimes \bar{q} = \mathcal{M}(p \otimes \bar{q})$.

Step 1: the Bessel subgroup. Let $A \in \{E, \mathbb{A}_f\}$, $u \in \mathsf{U}(A)$, $h \in H(A)$. (a) h fixes every e_a, e_a^* and z, so it stabilises the flag and acts trivially on its graded pieces; hence $h^{-1}uh$ stabilises the flag, acts trivially on the graded pieces, and acts on $X^\perp/X$ as the conjugate of the identity by the action of h, that is trivially; so $h^{-1}uh \in \mathsf{U}(A)$. (b) If $h \in \mathsf{U}(A)$, then for $x \in X_0 \subseteq X^\perp$, $hx \in (x + X) \cap X_0 = \{x\}$, so $h = 1$. By (a) and (b), $R(A)$ is a group and every element of it is uh for a unique pair (u, h). (c) For $x \in V_{\mathrm{m}} \subseteq X^\perp$, $hx \in V_{\mathrm{m}}$ and $uhx \in hx + X$, as u acts trivially on $X^\perp/X$. Hence, for $A = \mathbb{A}_f$, the $(V_{\mathrm{m}}, V_{\mathrm{m}})$-block of the matrix of uh is the matrix of $h|_{V_{\mathrm{m}}}$, while the matrix of h is the identity on the blocks X, X^* and has no other off-diagonal blocks. As $(uh)^{-1} = (h^{-1}u^{-1}h)h^{-1}$ is of the same form, we obtain: (d) if $uh \in K$, then h and h^{-1} have integral matrices, so $h \in K$; (e) if $uh \in K$ and uh reduces to 1 at a chosen place w,

then so does h, the entries of $h-1$ being 0 or entries of $uh-1$. In particular $uh \in \mathrm{K}(M)$ implies $h \in \mathrm{K}(M)$ and $u = (uh)h^{-1} \in \mathrm{K}(M)$.

Step 2: terms, conjugation, cutoffs. As K is a group and red a homomorphism: if γ is a term over (c, s, c') and δ one over (c', t, d), then $\gamma\delta$ is a term over (c, st, d) and γ^{-1} one over (c', s^{-1}, c). Let $\gamma \in R(E)$ be a term over (c, s, c'). Since $h_c, h_{c'} \in H(\mathbb{A}_f)$, $h_c^{-1}\gamma h_{c'} \in R(\mathbb{A}_f) \cap K$, so $s \in \bar{R}_0$. Moreover $\gamma\, \mathsf{U}_{c'}(M)\, \gamma^{-1} = \mathsf{U}_c(M)$: for $v \in \mathsf{U}_{c'}(M)$, $\gamma v \gamma^{-1} \in \mathsf{U}(E)$ by Step 1 (a), and $h_c^{-1}\gamma v\gamma^{-1}h_c = k(h_{c'}^{-1}vh_{c'})k^{-1} \in \mathrm{K}(M)$ with $k = h_c^{-1}\gamma h_{c'} \in K$, as $\mathrm{K}(M)$ is normal in K; the same with γ^{-1}, a term over (c', s^{-1}, c), gives the reverse inclusion. Finally, for every c and $y \in G_\infty$,

$$\sum_{v \in \mathsf{U}_c(M)} \beta_c(v \cdot y) = \sum_{v \in \mathsf{U}_c(M)} \beta_c(v^{-1} \cdot y) = 1 : \tag{5.122}$$

the first sum is (i) of Lemma 5.2.36, and the second is the first reindexed by $v \mapsto v^{-1}$, a bijection of the group $\mathsf{U}_c(M)$.

Step 3: the terms of $R(E)$ over $(c, 1, c')$ are $\mathsf{U}_c(M)$ if $c = c'$, and there are none if $c \neq c'$. Every $v \in \mathsf{U}_c(M)$ is such a term with $c' = c$. Conversely let $\gamma = u\alpha \in R(E)$ ($u \in \mathsf{U}(E)$, $\alpha \in H(E)$) with $h_c^{-1}\gamma h_{c'} \in \mathrm{K}(M)$. Then $h_c^{-1}\gamma h_{c'} = (h_c^{-1}uh_c)(h_c^{-1}\alpha h_{c'})$ with $h_c^{-1}uh_c \in \mathsf{U}(\mathbb{A}_f)$ (Step 1 (a)) and $h_c^{-1}\alpha h_{c'} \in H(\mathbb{A}_f)$, so by Step 1 (e) $h_c^{-1}\alpha h_{c'} \in \mathrm{K}(M) \cap \mathrm{U}(X_0)(\mathbb{A}_f) = \mathrm{K}_X$ (FA1). Thus $h_{c'} \in \alpha^{-1}h_c\mathrm{K}_X$ with $\alpha \in \mathrm{U}(X_0)(E^+)$, so $h_{c'}$ and h_c lie in the same double coset and $c = c'$. Then $h_c^{-1}\alpha h_c \in \mathrm{K}_X \cap h_c^{-1}\mathrm{U}(X_0)(E^+)h_c = \{1\}$ by (FG4), so $\alpha = 1$, $\gamma = u$, and $h_c^{-1}uh_c \in \mathrm{K}(M)$: $\gamma \in \mathsf{U}_c(M)$.

Step 4: proof of (i). Let $\gamma = u\alpha$ as in Step 3, with $u \in \mathsf{U}(E)$, $\alpha \in H(E)$. At $v \in \Phi$ the basis scales are 1 on X_0 and α fixes the other basis vectors, so by (5.5) α_v is the element of $H \subseteq G_1$ acting on $X_0 = \mathbb{C}^k$ by the matrix $v(\alpha)$; it is unitary, because α preserves the unit form of X_0 and $v(\bar{a}) = \overline{v(a)}$ for $a \in E$ (E is a CM field). As W_v is a Bessel function of type ρ_v, $W_v(\alpha_v y_v) = \rho_v(v(\alpha))W_v(y_v)$, so $W(\alpha \cdot y) = \mathcal{N}_\alpha W(y)$ with the Kronecker product $\mathcal{N}_\alpha = \bigotimes_{v \in \Phi} \rho_v(v(\alpha))$, a unitary matrix on $\mathbb{C}^I$. By Lemma 5.2.43, $W(\gamma \cdot y) = W(u \cdot (\alpha \cdot y)) = \psi(u)^{-1}\mathcal{N}_\alpha W(y)$. Since $|\psi(u)| = 1$ (Lemma 5.2.44 (i)), $\mathcal{M}_\gamma = \psi(u)^{-1}\mathcal{N}_\alpha$ is a unitary action matrix of γ.

Step 5: the identity integral. We show: for every $c \in \mathcal{C}$, $\int_{G_\infty} \beta_c(y)\|W(y)\|^2 dy = \nu\, \#I$, and

$$\int_{G_\infty} \beta_c(y)\, W(y) \otimes \overline{W(y)}\, dy = \nu\, 1_I. \tag{5.123}$$

For each v fix a Borel $\chi_v \colon G_1 \to [0, \infty]$ with $\int_{\mathsf{U}} \chi_v(ux)\, du = 1$ for all x (Definition 5.1.6), and put $\chi(y) = \prod_v \chi_v(y_v)$; by Tonelli $\int_{\mathsf{U}_\infty} \chi(uy)\, du = 1$. Since $|\mathrm{wave}(\cdot)| = 1$, each $\|W_v\|^2$ and each $W_{v,i}\overline{W_{v,j}}$ is left U-invariant, so $\phi_{ij}(y) = W(y)_i\overline{W(y)_j}$ and $\|W\|^2$ are left U_∞-invariant. Let $\phi \in \{\|W\|^2, \phi_{ij}\}$ and $F(u, y) = \beta_c(u^{-1}y)\chi(y)\phi(y)$ on $\mathsf{U}_\infty \times G_\infty$, a Borel function. By Tonelli, the invariance of du under inversion (Lemma 5.2.34 (iv)) and Lemma 5.2.33,

$$\begin{aligned}\iint |F|\, du\, dy &= \int_{G_\infty} \chi|\phi| \int_{\mathsf{U}_\infty} \beta_c(uy)\, du\, dy = \nu \int_{G_\infty} \chi|\phi| \\ &\leq \nu \int_{G_\infty} \chi\|W\|^2 = \nu \prod_v \int_{\mathsf{U}\backslash G_1} \|W_v\|^2 = \nu\, \#I\end{aligned}$$

by (BS1). So Fubini's theorem applies to F; with the substitution $y \mapsto uy$ in the inner integral (left invariance of the Cayley measures, Lemma 5.2.41) and $\phi(uy) = \phi(y)$,

$$\int_{G_\infty} \chi\phi\, \nu\, dy = \int_{\mathsf{U}_\infty} \int_{G_\infty} \beta_c(u^{-1}y)\chi(y)\phi(y)\, dy\, du = \int_{\mathsf{U}_\infty} \int_{G_\infty} \beta_c(y)\chi(uy)\phi(y)\, dy\, du = \int_{G_\infty} \beta_c\phi\, dy,$$

the same computation with $|\phi|$ showing that $\beta_c\phi$ is integrable. For $\phi = \|W\|^2$ this gives the first claim. For $\phi = \phi_{ij}$, $\int \chi\phi_{ij} = \prod_v \int_{G_1} \chi_v W_{v,i_v}\overline{W_{v,j_v}} = \prod_v \int_{\mathsf{U}\backslash G_1} W_{v,i_v}\overline{W_{v,j_v}}$ by Fubini and Lemma 5.5.29 (i) (complex form; the integrands are dominated by $\|W_v\|^2$). As

ρ_v is irreducible and $\int_{\mathsf{U}\backslash G_1}\|W_v\| < \infty$ by (BS1), Lemma 5.5.28 gives $\int_{\mathsf{U}\backslash G_1} W_{v,i_v}\overline{W_{v,j_v}} = \delta_{i_v j_v}\#I_v^{-1}\int_{\mathsf{U}\backslash G_1}\|W_v\|^2 = \delta_{i_v j_v}$. Hence $\int \beta_c\phi_{ij} = \nu\delta_{ij}$, which is (5.123).

Step 6: every action matrix is unitary, and $W(\gamma^{-1}\cdot y) = \mathcal{M}^*W(y)$. Let $\gamma \in R(E)$ and let $\mathcal{M}$ be an action matrix of γ. With $\mathcal{M}_\gamma$ of Step 4, $(\mathcal{M}-\mathcal{M}_\gamma)W(y) = 0$ for all y; multiplying by $\beta_c(y)\overline{W(y)}$, integrating (Step 5) and using (5.123), $0 = (\mathcal{M}-\mathcal{M}_\gamma)\int \beta_c\, W\otimes\overline{W}\,dy = \nu(\mathcal{M}-\mathcal{M}_\gamma)$. So $\mathcal{M} = \mathcal{M}_\gamma$ is unitary, and $W(y) = W(\gamma\cdot(\gamma^{-1}\cdot y)) = \mathcal{M}W(\gamma^{-1}\cdot y)$ gives $W(\gamma^{-1}\cdot y) = \mathcal{M}^*W(y)$; in particular $\mathcal{M}^*$ is the action matrix of γ^{-1}.

Step 7: proof of (ii). Let $\gamma \in R(E)$ be a term over (c,s,c') with action matrix $\mathcal{M}$; $s \in \bar{R}_0$ by Step 2. For $d \in \mathcal{C}$, by Step 2 the map $\delta \mapsto \gamma\delta$ is a bijection from the terms of $R(E)$ over $(c',1,d)$ onto those over (c,s,d) (with inverse $\gamma' \mapsto \gamma^{-1}\gamma'$). By Step 3 there are none if $d \neq c'$, so $A^{\mathrm{full}}_{R(E)}(c,s,d) = 0$; and for $d = c'$ the terms are the γv, $v \in \mathsf{U}_{c'}(M)$. For such v, $W(v^{-1}\cdot z) = W(z)$ (Lemma 5.2.42), so by Step 6

$$A_{\gamma v}(c,c') = \int_{G_\infty} \beta_c(y)\,\beta_{c'}(v^{-1}\cdot\gamma^{-1}y)\,W(y)\otimes\overline{\mathcal{M}^*W(y)}\,dy.$$

The integrands have norms $\beta_c(y)\beta_{c'}(v^{-1}\cdot\gamma^{-1}y)\|W(y)\|^2$ ($\mathcal{M}$ unitary), whose integrals add up over v, by (5.122) at $\gamma^{-1}y$ and Tonelli, to $\int\beta_c\|W\|^2 = \nu\#I < \infty$ (Step 5). So the sum over v may be taken inside the integral, and by (5.122) and (5.123)

$$A^{\mathrm{full}}_{R(E)}(c,s,c') = \int_{G_\infty}\beta_c(y)\,(W(y)\otimes\overline{W(y)})\mathcal{M}\,dy = \nu\,\mathcal{M}.$$

For the adjoint relation let $c,c' \in \mathcal{C}$, $s \in \bar{G}$. If some $\gamma \in R(E)$ is a term over (c,s,c'), with action matrix $\mathcal{M}$, then $\gamma^{-1} \in R(E)$ is a term over (c',s^{-1},c) with action matrix $\mathcal{M}^*$ (Steps 2 and 6), and by what was just shown $A^{\mathrm{full}}_{R(E)}(c',s^{-1},c) = \nu\mathcal{M}^* = A^{\mathrm{full}}_{R(E)}(c,s,c')^*$. Otherwise there is no term of $R(E)$ over (c',s^{-1},c) either (its inverse would be one over (c,s,c')), and both sums are empty, hence 0.

Step 8: proof of (iii). Let $c \in \mathcal{C}$ and $t \in \bar{R}_0$, $t = \mathrm{red}(m)$ with $m \in R(\mathbb{A}_f)\cap K$. By Step 1, $h_c m = uh$ with $u \in \mathsf{U}(\mathbb{A}_f)$ and $h \in H(\mathbb{A}_f)$, and by the class decomposition (FG4), $h = \alpha h_{c'}a$ with $c' \in \mathcal{C}$, $\alpha \in \mathrm{U}(X_0)(E^+) = H(E)$ and $a \in \mathrm{K}_X \subseteq \mathrm{K}(M)$ (FA1). The group $\mathsf{U}(\mathbb{A}_f)\cap h\mathrm{K}(M)h^{-1}$ is open in $\mathsf{U}(\mathbb{A}_f)$, as $\mathrm{K}(M)$ is open in $G(\mathbb{A}_f)$. By strong approximation for the unipotent group U over E^+ (Theorem A.4.7, S the archimedean places), $u = u_1k^{-1}$ with $u_1 \in \mathsf{U}(E)$ and $k \in \mathsf{U}(\mathbb{A}_f)\cap h\mathrm{K}(M)h^{-1}$. Put $\gamma = u_1\alpha \in R(E)$. Then

$$\gamma h_{c'} = uk\alpha h_{c'} = uk\,h\,a^{-1} = uh\,(h^{-1}kh)\,a^{-1} = h_c m\,k'', \qquad k'' = (h^{-1}kh)a^{-1} \in \mathrm{K}(M),$$

so $h_c^{-1}\gamma h_{c'} = mk'' \in K$ has reduction $\mathrm{red}(m) = t$: γ is a term over (c,t,c').

Step 9: proof of (iv). Let T, δ, $\mathcal{N}$ be as in (iv), $c \in \mathcal{C}$, $s \in \bar{G}$. By Step 2 and the hypothesis on T, $\gamma' \mapsto \gamma'\delta^{-1}$ is a bijection from the terms of T over (c,s,d') onto those of T over (c,st^{-1},d), with inverse $\gamma \mapsto \gamma\delta$. Since $W(\delta\cdot z) = \mathcal{N}W(z)$, for a term γ' of T over (c,s,d')

$$W(y)\otimes\overline{W(\delta\gamma'^{-1}y)} = (W(y)\otimes\overline{W(\gamma'^{-1}y)})\mathcal{N}^*.$$

Put $\varphi(\gamma',y) = \beta_c(y)\beta_d(\delta\cdot\gamma'^{-1}y)$. For a term $\gamma' \in T$ over (c,s,d') and $(v,v') \in \mathsf{U}_c(M)\times\mathsf{U}_{d'}(M)$, $\varphi(v\gamma'v'^{-1}, v\cdot y) = \beta_c(v\cdot y)\,\beta_d((\delta v'\delta^{-1})\cdot(\delta\cdot\gamma'^{-1}y))$; as $v' \mapsto \delta v'\delta^{-1}$ is a bijection of $\mathsf{U}_{d'}(M)$ onto $\mathsf{U}_d(M)$ (Step 2), (5.122) gives $\sum_{(v,v')}\varphi(v\gamma'v'^{-1}, v\cdot y) = 1$. By Lemma 5.2.40 ($T$ is stable), each $y \mapsto \varphi(\gamma',y)W(y)\otimes\overline{W(\gamma'^{-1}y)}$ is integrable and $A^{\mathrm{full}}_T(c,s,d') = \sum_{\gamma'}\int\varphi(\gamma',y)W(y)\otimes\overline{W(\gamma'^{-1}y)}\,dy$. By the display, the integrand of the amplitude $A_{\gamma'\delta^{-1}}(c,d)$ is this integrand times

$\mathcal{N}^*$, so $A_{\gamma'\delta^{-1}}(c,d) = (\int \varphi(\gamma',y)W(y)\otimes\overline{W(\gamma'^{-1}y)}\,dy)\mathcal{N}^*$. The series $A_T^{\mathrm{full}}(c,st^{-1},d)$ converges absolutely (Lemma 5.2.29 (ii)), so it may be reindexed by the bijection, and

$$A_T^{\mathrm{full}}(c,st^{-1},d) = \sum_{\gamma'} A_{\gamma'\delta^{-1}}(c,d) = A_T^{\mathrm{full}}(c,s,d')\,\mathcal{N}^*.$$

Step 10: proof of (v). Let j, s be as in (v) and $c\in\mathcal{C}$. First let $\gamma = u\alpha \in R(E)$ ($u\in\mathsf{U}(E)$, $\alpha\in H(E)$) be a term over (c,s^{-1},c). Then $m = h_c^{-1}\gamma h_c = (h_c^{-1}uh_c)h$ with $h = h_c^{-1}\alpha h_c \in H(\mathbb{A}_f)$ and $m\in K$ reducing to s^{-1}, which is 1 at every $w\in S_j$. By Step 1 (d), (e), $h\in K$ and h reduces to 1 at every $w\in S_j$. Let $t = \mathrm{tr}_{X_0}(\alpha) - k \in E$. Since α acts trivially on $X_0^\perp$ (of dimension $r-k$) and the trace is invariant under conjugation and change of basis, $t = \mathrm{tr}(h) - r = \mathrm{tr}(h-1)$, computed on the matrix of h in the lattice basis. Its entries are integral, so $t\in E\cap\hat{\mathcal{O}} = \mathcal{O}_E$, and its diagonal entries lie in the maximal ideal at every $w\in S_j$, so $t\in\mathfrak{p}_w$ for the f distinct places $w\in S_j$, each of norm p_j. For every embedding $\sigma\colon E\to\mathbb{C}$ the matrix $\sigma(\alpha)$ is unitary (Step 4), so $|\sigma(\mathrm{tr}_{X_0}\alpha)|\le k$ and $|\sigma(t)|\le 2k$. If $t\neq 0$, then $p_j^f \le |N_{E/\mathbb{Q}}(t)| = \prod_\sigma|\sigma(t)| \le (2k)^{2f}$, so $p_j\le 4k^2$; but $k\le f\le b/1000$ and $p_j\ge b^{10}$ (FG6), so $4k^2 < b^{10}\le p_j$. Hence $t=0$: the unitary matrix $\sigma(\alpha)$ has trace k, so its k eigenvalues, of absolute value 1 with sum k, all equal 1, and $\sigma(\alpha)$, being diagonalisable, is 1. As σ is injective, $\alpha = 1$ and $\gamma = u\in\mathsf{U}(E)$. By Step 4 its action matrix is $\psi(u)^{-1}1_I$, and by Lemma 5.2.44 (v), (iv), $s^{-1}\in\bar{\mathsf{U}}$ and $\psi(u) = \psi_U(s^{-1}) = \psi_U(s)^{-1}$, so the action matrix is $\psi_U(s)1_I$ and by (ii) $A^{\mathrm{full}}_{R(E)}(c,s^{-1},c) = \nu\,\psi_U(s)1_I$. It remains to see that such a term exists when $s\in\bar{\mathsf{U}}$, and that $\psi_U(s)=0$ otherwise. If $s\notin\bar{\mathsf{U}}$, then $\psi_U(s)=0$ (TA8), and by the first part there is no term of $R(E)$ over (c,s^{-1},c) (it would give $s^{-1}\in\bar{\mathsf{U}}$, a subgroup by Lemma 5.2.44 (iv)); the sum is empty and both sides vanish. If $s\in\bar{\mathsf{U}}$, let $g\in\mathsf{U}(\mathbb{A}_f)\cap K$ reduce to s^{-1}. By Step 1 (a), $h_cgh_c^{-1}\in\mathsf{U}(\mathbb{A}_f)$, and $\mathsf{U}(\mathbb{A}_f)\cap h_c\mathrm{K}(M)h_c^{-1}$ is an open subgroup, so by Theorem A.4.7 there is $u_1\in\mathsf{U}(E)$ with $u_1\in h_cgh_c^{-1}\,h_c\mathrm{K}(M)h_c^{-1}$, that is $h_c^{-1}u_1h_c\in g\,\mathrm{K}(M)\subseteq K$, of reduction s^{-1}. So u_1 is a term of $R(E)$ over (c,s^{-1},c), and the first part applies. □

Lemma 5.6.46. *Let $\mathfrak{S}$ be admissible with Weil data, and let $\Omega\subseteq\bar{G}$ contain no s of the following form: there are $\zeta\in\mathcal{O}_E$ with $\zeta\bar{\zeta}=1$ and $\zeta\neq 1$, and $t\in\bar{R}_0$, such that $s_w = \zeta\,t_w$ at every chosen place w (with ζ read in the residue field k_w). Then for all $s\in\Omega$, $c,c'\in\mathcal{C}$, and for the full as well as the cut amplitude sums,*

$$A_{G(E)\backslash R(E)}(c,s,c') = A_{\Gamma^*}(c,s,c').$$

Proof. Fix $s\in\Omega$, $c,c'\in\mathcal{C}$, and the side (full or cut). Put $T_0 = (G(E)\setminus R(E))\setminus\Gamma^*$, let T_1 be the set of $\gamma\in T_0$ without agreeing characters and $T_2 = T_0\setminus T_1$.

Step 1: splitting. By Lemma 5.3.18 (iii), $\Gamma^*\subseteq G(E)\setminus R(E)$, so $G(E)\setminus R(E)$ is the disjoint union of Γ^*, T_1 and T_2. The norm of each amplitude is at most its amplitude majorant, and the majorants of all terms over (c,s,c') have a finite sum (Lemma 5.2.29 (ii)); so the series of amplitudes over the terms of $G(E)\setminus R(E)$ converges absolutely and splits along the partition:

$$A_{G(E)\backslash R(E)}(c,s,c') = A_{\Gamma^*}(c,s,c') + A_{T_1}(c,s,c') + A_{T_2}(c,s,c').$$

Step 2: $A_{T_1}(c,s,c')=0$. T_1 is obtained from $R(E)$, Γ^* and the set of elements with agreeing characters by complements and intersections, so it is stable by Lemma 5.3.18 (ii); no element of it has agreeing characters. By Lemma 5.6.47, $A_{T_1}(c,s,c')=0$.

Step 3: no element of T_2 is a term over (c,s,c'). Suppose $\gamma\in T_2$ is one, and let $k = h_c^{-1}\gamma h_{c'}\in K$, with $\mathrm{red}(k) = s$. Since γ has agreeing characters and $\gamma\notin\Gamma^*$, $\mathsf{g}(\gamma)=0$ and

$\gamma X = X$. For $1 \le j \le \varrho$, $D_j(\gamma)$ is the determinant of $(h(e_{a+1}, \gamma e_{b+1}))_{a,b<j}$, which vanishes because $\gamma e_{b+1} \in X$ and X is isotropic; so $D_j(\gamma) = 0$ for $1 \le j \le \varrho$. Let j be the least integer in $\{0, \dots, \varrho+1\}$ such that some $\zeta \in E$ with $\zeta\bar{\zeta} = 1$ has $(\zeta, 1)$ occurring at every $a \ge j$. By Lemma 5.3.31 (ii), $j \le \varrho$ and γ satisfies the conditions of cell rank j, among them $D_j(\gamma) \ne 0$. Hence $j = 0$: there is ζ with $\zeta\bar{\zeta} = 1$ such that for every $a \in \{0, \dots, \varrho\}$ some $x, y \in E^{\varrho+1}$ satisfy $\sum_b x_b f_b = \gamma \sum_b y_b f_b$, $x_a = \zeta$, $y_a = 1$ and $x_b = y_b = 0$ for $b > a$. By induction on a, $\gamma f_a \in \zeta f_a + P_a$ with $P_a = \langle f_b : b < a \rangle$: the relation at a gives $\gamma f_a = \sum_{b \le a} x_b f_b - \sum_{b<a} y_b \gamma f_b$, and $\gamma f_b \in P_a$ for $b < a$ by induction. So $\gamma' = \bar{\zeta}\gamma \in G(E)$ satisfies $\gamma' f_a \in f_a + P_a$ for all a. Hence γ' stabilises each $F_b = \langle e_1, \dots, e_b \rangle$, acts trivially on F_b/F_{b-1} $(1 \le b \le \varrho)$, stabilises $X^\perp$, and induces on $X^\perp/X$ an isometry ι of the induced form fixing the class of z. Identify $X^\perp/X$ isometrically with $X_0 \oplus Ez \subseteq X^\perp$; ι fixes z, so it preserves $X_0 = z^\perp \cap (X_0 \oplus Ez)$, and its restriction defines $h_0 \in H(E)$. Then $g = \gamma' h_0^{-1}$ stabilises the flag and acts trivially on every F_b/F_{b-1} and on $X^\perp/X$; such elements form the unipotent radical of the stabiliser of the flag (its kernel to the Levi quotient $\prod_b \mathrm{GL}(F_b/F_{b-1}) \times \mathrm{U}(X^\perp/X)$), so $g \in \mathsf{U}(E)$ and $\gamma' = g h_0 \in R(E)$. At $a = 0$ the relation reads $\gamma e_1 = \zeta e_1$. As h_c and $h_{c'}$ fix e_1, $k e_1 = \zeta e_1$; e_1 is a vector of the lattice basis and k is integral, so $\zeta \in E \cap \hat{\mathcal{O}} = \mathcal{O}_E$. Then $k' = h_c^{-1}\gamma' h_{c'} = \bar{\zeta} k$ and its inverse ζk^{-1} are integral, so $k' \in K$; and $k' \in R(\mathbb{A}_f)$, as $h_c, h_{c'} \in H(\mathbb{A}_f)$ and $\gamma' \in R(E)$. So $t = \mathrm{red}(k') \in \bar{R}_0$, and $k = \zeta k'$ gives $s_w = \zeta\, t_w$ at every chosen place w, with ζ read in k_w. As $s \in \Omega$, the hypothesis forces $\zeta = 1$, so $\gamma = \gamma' \in R(E)$, contradicting $\gamma \in T_2 \subseteq G(E) \setminus R(E)$.

Step 4: conclusion. By Step 3 the sum $A_{T_2}(c, s, c')$ is empty, hence 0; with Steps 1 and 2, $A_{G(E)\setminus R(E)}(c, s, c') = A_{\Gamma^*}(c, s, c')$. □

Lemma 5.6.47. *Let $\mathfrak{S}$ be admissible with Weil data, and let $T \subseteq G(E)$ be stable and such that no element of T has agreeing characters. Then $A_T(c, s, c') = 0$ for all $c, c' \in \mathcal{C}$ and $s \in \bar{G}$, for the full and for the cut amplitude sums.*

Proof. Fix $W \in \{W^{\mathrm{full}}, W^{\mathrm{cut}}\}$, c, c' and s, and write $K(\gamma, y) = W(y) \otimes \overline{W(\gamma^{-1} y)}$, a continuous function of y (the functions of a Bessel system are continuous). Let X be the set of terms of T over (c, s, c').

Step 1: the action on G_∞. As $\gamma \mapsto \gamma_\infty$ is a homomorphism (RD1), $G(E)$ acts on G_∞ by $g \cdot y = g_\infty y$. Each map $y \mapsto g \cdot y$ is continuous, and $\int_{G_\infty} H(g \cdot y)\, dy = \int_{G_\infty} H\, dy$ for every Borel $H \colon G_\infty \to [0, \infty]$: the map is the product over $v \in \Phi$ of the left translations by $g_v \in G_1$, each of which preserves the Cayley measure (Lemma 5.2.41), and Tonelli's theorem applies to the product measure. For a subgroup $\Lambda \subseteq G(E)$ (countable, as $G(E)$ is), a Λ-*cutoff* is a Borel $\chi \colon G_\infty \to [0, \infty]$ with $\sum_{g \in \Lambda} \chi(g \cdot y) = 1$ for all y.

Step 2: equal indices. Let $\gamma \in G(E)$, $\Lambda = \mathsf{U}_c(M) \cap \gamma \mathsf{U}_{c'}(M)\gamma^{-1}$, and $u \in \mathsf{U}(E) \cap \gamma \mathsf{U}(E)\gamma^{-1}$. We show that $\Lambda \cap u^{-1}\Lambda u$ has the same finite index in Λ and in $u^{-1}\Lambda u$. The intersection $N = \mathsf{U} \cap \gamma \mathsf{U} \gamma^{-1}$ is a closed subgroup of the unipotent group U over E^+ (γ is rational), hence a unipotent linear algebraic group over E^+, with $N(E^+) = \mathsf{U}(E) \cap \gamma \mathsf{U}(E)\gamma^{-1} \ni u$ and $N_f = N(\mathbb{A}_{E^+,f}) = \mathsf{U}(\mathbb{A}_f) \cap \gamma \mathsf{U}(\mathbb{A}_f)\gamma^{-1}$, a closed subgroup of $G(\mathbb{A}_f)$. Put $O = h_c \mathrm{K}(M) h_c^{-1} \cap \gamma h_{c'} \mathrm{K}(M) h_{c'}^{-1} \gamma^{-1}$, a compact open subgroup of $G(\mathbb{A}_f)$; then $\Lambda = N(E^+) \cap O$ and $u^{-1}\Lambda u = N(E^+) \cap u^{-1} O u$. Let $B = N_f \cap O$ and $B' = B \cap u^{-1} B u$, compact open subgroups of N_f; then $\Lambda \cap u^{-1}\Lambda u = N(E^+) \cap B'$. For compact open subgroups $C' \subseteq C$ of N_f, the map $(N(E^+) \cap C)/(N(E^+) \cap C') \to C/C'$ induced by inclusion is injective, and surjective since every coset gC' is open in N_f and $N(E^+)$ is dense in N_f by strong approximation (Theorem A.4.7, S the archimedean places of E^+); and $[C : C'] = \mu(C)/\mu(C') < \infty$ for a Haar measure μ of N_f. Hence the two indices are $\mu(B)/\mu(B')$ and $\mu(u^{-1}Bu)/\mu(B')$. By left invariance, $\mu(u^{-1}Bu) = \mu(Bu) = \Delta(u)\mu(B)$, with the modular function Δ of N_f, a continuous homomorphism to $\mathbb{R}_{>0}$. As $u - 1$ is nilpotent, $u^l = \sum_{i<r} \binom{l}{i} (u-1)^i$ for $l \in \mathbb{Z}$, so all powers of u have entries in $d_0^{-1}\hat{\mathcal{O}}$ for a fixed

integer $d_0 \geq 1$ (in the lattice basis); the closure of $\langle u \rangle$ is compact, its image under Δ is a compact subgroup of $\mathbb{R}_{>0}$, so $\Delta(u) = 1$ and the indices agree.

Step 3: invariance and twist of the kernel. Let $\gamma \in X$ and $\Lambda_\gamma = \mathsf{U}_c(M) \cap \gamma \mathsf{U}_{c'}(M)\gamma^{-1}$. For $g = \gamma v \gamma^{-1} \in \Lambda_\gamma$ ($v \in \mathsf{U}_{c'}(M)$), $W(g \cdot y) = W(y)$ and $W(\gamma^{-1}(g \cdot y)) = W(v \cdot \gamma^{-1} y) = W(\gamma^{-1} y)$ by Lemma 5.2.42, so $K(\gamma, g \cdot y) = K(\gamma, y)$. As γ has no agreeing characters, there are $u, u' \in \mathsf{U}(E)$ with $u\gamma = \gamma u'$ and $\psi(u) \neq \psi(u')$; then $u = \gamma u' \gamma^{-1} \in \mathsf{U}(E) \cap \gamma \mathsf{U}(E) \gamma^{-1}$, and by Lemma 5.2.43 and $\gamma^{-1} u = u' \gamma^{-1}$,

$$K(\gamma, u \cdot y) = \psi(u)^{-1} W(y) \otimes \overline{\psi(u')^{-1} W(\gamma^{-1} y)} = c_0 \, K(\gamma, y), \qquad c_0 = \psi(u)^{-1} \psi(u') \neq 1,$$

since $|\psi(u')| = 1$ (Lemma 5.2.44 (i)).

Step 4: a weight adapted to the stabilisers. By (i) of Lemma 5.2.36, $\sum_{v \in \mathsf{U}_d(M)} \beta_d(v \cdot z) = 1$ for every class d and $z \in G_\infty$. As T is stable and $\mathrm{K}(M)$ is the kernel of red, X is invariant under left multiplication by $\mathsf{U}_c(M)$ and right multiplication by $\mathsf{U}_{c'}(M)$. Let $Q = \{\gamma \mathsf{U}_{c'}(M) : \gamma \in X\}$, on which $\mathsf{U}_c(M)$ acts by left multiplication, and choose $Q_0 \subseteq Q$ meeting every orbit in exactly one element. For $x = \gamma \mathsf{U}_{c'}(M) \in Q$ the stabiliser of x in $\mathsf{U}_c(M)$ is Λ_γ; choose representatives P_x of the cosets $\Lambda_\gamma \backslash \mathsf{U}_c(M)$ and put $\chi_x(y) = \sum_{p \in P_x} \beta_c(p \cdot y)$, a Λ_γ-cutoff, since $\sum_{g \in \Lambda_\gamma} \sum_p \beta_c(gp \cdot y) = \sum_{v \in \mathsf{U}_c(M)} \beta_c(v \cdot y) = 1$. Define $\varphi(\gamma, y) = \beta_{c'}(\gamma_\infty^{-1}) \, \chi_{\gamma \mathsf{U}_{c'}(M)}(y)$ if $\gamma \in X$ and $\gamma \mathsf{U}_{c'}(M) \in Q_0$, and $\varphi(\gamma, y) = 0$ otherwise; it is Borel in y. Let $\gamma \in X$, $x = \gamma \mathsf{U}_{c'}(M)$, $y \in G_\infty$. For $(v, v') \in \mathsf{U}_c(M) \times \mathsf{U}_{c'}(M)$, $(v \gamma v'^{-1})_\infty^{-1} = v'_\infty (v\gamma)_\infty^{-1}$ and $v \gamma v'^{-1} \mathsf{U}_{c'}(M) = vx$; summing first over v' (the identity above at $z = (v\gamma)_\infty^{-1}$),

$$\sum_{(v, v')} \varphi(v \gamma v'^{-1}, v \cdot y) = \sum_{v \in \mathsf{U}_c(M),\ vx \in Q_0} \chi_{vx}(v \cdot y) = \sum_{g \in \Lambda_{\gamma_0}} \chi_{x_0}(g a \cdot y) = 1,$$

where $x_0 = \gamma_0 \mathsf{U}_{c'}(M)$ is the element of Q_0 in the orbit of x, $a \in \mathsf{U}_c(M)$ satisfies $ax = x_0$, and $\{v : vx = x_0\} = \Lambda_{\gamma_0} a$.

Step 5: conclusion. By Lemma 5.2.40 (T is stable), each $y \mapsto \varphi(\gamma, y) K(\gamma, y)$ ($\gamma \in X$) is integrable and $A_T(c, s, c') = \sum_{\gamma \in X} \int \varphi(\gamma, y) K(\gamma, y) \, dy$. Let $\gamma \in X$ with $\varphi(\gamma, \cdot) \neq 0$; then $x = \gamma \mathsf{U}_{c'}(M) \in Q_0$ and $\beta_{c'}(\gamma_\infty^{-1}) > 0$, so $\int \chi_x \|K(\gamma, \cdot)\| < \infty$. Apply (iii) of Lemma 5.2.45 to the action of $G(E)$ on G_∞ of Step 1, $\Lambda = \Lambda_\gamma$, the Λ_γ-cutoff χ_x (in the roles of χ and χ'), $F = K(\gamma, \cdot)$ (Borel and Λ_γ-invariant by Step 3), and u, c_0 of Step 3; the indices agree by Step 2. Hence $\int \chi_x K(\gamma, y) \, dy = 0$, so $\int \varphi(\gamma, y) K(\gamma, y) \, dy = 0$ for every $\gamma \in X$, and $A_T(c, s, c') = 0$. □

The section closes with the two moments of a Poincaré map of class-series form (Proposition 5.6.48). For a map with $\mathcal{P}\varphi = \sum_a \theta(\varphi)_a \, \Pi_a$ there are an inner product on $\mathcal{S}$ and a scaling $L = c\mathcal{P}$ which, after e_0, is a near-isometry with error $5b^{-4} D_X$, and whose translated Gram operators satisfy the averaged second moment bound. These are exactly the hypotheses of Theorem B and of Proposition 5.1.4, and by Lemma 5.6.33 (ii) the Bessel-period map at a Bessel pair has this form. The proof assembles the results of Section 5: part (i) comes from the rarity of bad types and the near-isometry of the good part, and part (ii) from the averaged second moment, in which the main moment becomes the stated constant. Two facts produce that constant: the degree of the Bessel system at each infinite place is the Weyl product of the target parameter, which is the formal degree in Harish-Chandra's theorem [119] (Theorem 5.7.41), and the mass of the filling datum is that of the standard hermitian lattice.

Proposition 5.6.48. *Let D be admissible data, put $D_X = \dim \mathcal{S}$, and suppose that $\mathcal{P}\varphi = \sum_{a \in \mathcal{C} \times I} \theta(\varphi)_a \, \Pi_a$ for every $\varphi \in \mathcal{S}$. Then $D_X \geq 1$, and there are an inner product on $\mathcal{S}$ and a real $c > 0$ such that $L = c\mathcal{P} \colon \mathcal{S} \to \mathcal{A}_M(Y_0)$ satisfies:*

(i) $\|e_0 L \operatorname{pr}_U\|_{\mathrm{HS}}^2 \geq \dim U - 5b^{-4} D_X$ *for every subspace $U \subseteq \mathcal{S}$;*

(ii) $\displaystyle\sum_{s\in\bar G}\|L^{*}sL\|_{\mathrm{HS}}^{2}\le\Big(1+\frac{9}{b^{4}}\Big)\frac{D_X^{2}}{\operatorname{mass}(I_r)\prod_{v\in\Phi}\mathrm{d}(\varsigma(v))}.$

Proof. Let $\mathfrak{S}_D$ be the admissible filling datum of Proposition 5.6.4; E carries Weil data and the level group of $\mathfrak{S}_D$ is $\bar G$ (Proposition 5.6.4 (i), (ii)). By Proposition 5.6.4 (iii) there is a linear isomorphism $\theta\colon\mathcal{S}\to\mathbb{C}^{\mathcal{C}\times I}$, so $D_X=\#\mathcal{C}\cdot\#I\ge 1$ since both sets are nonempty. Give $\mathcal{S}$ the inner product transported by θ from the standard one, so that θ is unitary and Hilbert–Schmidt norms of maps out of $\mathcal{S}$ are computed in the coordinates. Let $c=c_{\mathcal{P}}=(V_M\nu)^{-1/2}>0$ be the constant of Proposition 5.6.16 and $L=c\,\mathcal{P}$. By Proposition 5.6.16 (ii), whose hypothesis on $\mathcal{P}$ is the one assumed here, the map $L\theta^{-1}=c_{\mathcal{P}}\,\mathcal{P}\circ\theta^{-1}\colon\mathbb{C}^{\mathcal{C}\times I}\to\mathcal{A}_M(Y_0)$ (the map written L in Proposition 5.6.16 (ii); here L is defined on $\mathcal{S}$) has amplitude blocks (TA6) for the action ρ of $\bar G$, which is unitary.

(i) Let g_0,g_1 be the central idempotents of Proposition 5.2.10 (iii). They satisfy $\operatorname{Re}\operatorname{coeff}_1(1-g_i)\le b^{-8}/2$, and $\rho(g_0\otimes g_1)=e_0$ on $\mathcal{A}_M(Y_0)$. By Proposition 5.6.41, applied to $P=L\theta^{-1}$, the map $e_0L\theta^{-1}$ is a near-isometry with error $5b^{-4}$. For a subspace $U\subseteq\mathcal{S}$, $\theta(U)$ has the same dimension and $\mathrm{pr}_{\theta(U)}=\theta\,\mathrm{pr}_U\theta^{-1}$ because θ is unitary; hence $\|e_0L\,\mathrm{pr}_U\|_{\mathrm{HS}}=\|e_0L\theta^{-1}\mathrm{pr}_{\theta(U)}\|_{\mathrm{HS}}$ and (i) follows.

(ii) By Theorem 5.1.13, applied to $P=L\theta^{-1}$, $\sum_s\|(L\theta^{-1})^{*}\rho(s)L\theta^{-1}\|_{\mathrm{HS}}^{2}\le(1+9b^{-4})\mathcal{D}_{\mathrm{main}}$, and the left side equals $\sum_s\|L^{*}sL\|_{\mathrm{HS}}^{2}$ by unitarity of θ. For $\mathfrak{S}_D$, $\mathcal{D}_{\mathrm{main}}=D_X^{2}/(\deg\cdot\operatorname{mass}(E,r))$ with $\deg=\prod_v\deg_v=\prod_v\mathrm{d}(\varsigma(v))$ by Proposition 5.7.3 (i), and $\operatorname{mass}(E,r)=\operatorname{mass}(I_r)$, the mass of the standard rank-r genus. Here $\operatorname{mass}(E,r)$ of Definition 5.1.9 is, by definition, the mass of the genus of the standard lattice $\mathcal{O}_E^{r}$ with the unit form, that is $\operatorname{mass}(I_r)$ of Definition 3.2.5: the classes $\mathrm{U}_r(E^{+})gK_0$ in $\mathrm{U}_r(\mathbb{A}_{E^{+},f})$, K_0 the stabiliser of $\widehat{\mathcal{O}}_E^{r}$, are the isometry classes in the genus, with $\mathrm{U}_r(E^{+})\cap gK_0g^{-1}$ the automorphism group of the lattice $g\widehat{\mathcal{O}}_E^{r}\cap E^{r}$; this is the same quantity that enters Proposition 5.8.54. □

5.7 Discrete series, Laplace's method and Bessel systems

This section supplies the archimedean ingredients of Section 5. Its main statement, Proposition 5.7.3, gives a Bessel system of discrete-series type at every infinite place: its degree is the Weyl product of the target parameter, it is reproduced by the discrete-series kernel built from Flensted-Jensen's function c_λ [81], and it is a multiple of a Bessel average at a point of controlled Bessel length. The degree turns the main moment into the constant of Proposition 5.6.48; the reproducing property is what the class Poincaré series and the Bessel point require; and the local bounds that Theorem 5.5.3 provides for these systems enter the archimedean factors of the sieve.

The heart of the section is the formal degree. For the Cayley measure, $\big(\int|c_\lambda|^{2}\big)^{-1}$ is the Weyl product when the parameter has a large gap (Lemma 5.7.4). This rests on Harish-Chandra's identities for the orbital integrals of c_λ on the compact torus (Proposition 5.7.5), proved by writing these integrals as antisymmetric Laurent polynomials and comparing top coefficients, with the multiplicities of the K-types; in our reading these multiplicities are the parts of Blattner's formula that the argument needs (compare Theorem A.5.13). The discrete series of the real unitary groups are Harish-Chandra's [119]; for their lowest K-types see [250], for accounts [251, 163, 315], and for characters of the maximal compact subgroup, Weyl modules and Schur functors [92, 3, 91]. The section continues with Laplace's method (Theorem 5.7.21), which gives the lower bound for a period that the construction needs, and closes with the properties of the Bessel averages (Proposition 5.7.30) and Harish-Chandra's formula for the formal degree (Theorem 5.7.41). The arrangement follows [259].

Definition 5.7.1. Let E be a CM field with maximal totally real subfield E^+, $N \geq 1$, and $\mathbb{A}_{E,f}$ the finite adeles of E; $G_f = \{g \in \mathrm{GL}_N(\mathbb{A}_{E,f}) : \bar{g}^{\mathsf{T}} g = 1\}$ as in (FT1).

Rational isometries as matrices. Let U be a framed space of rank N. Fix a basis of U over E and write the finite frame x_U and the elements of $\mathrm{U}(U)(E^+)$ as matrices in it, so $x_U \in \mathrm{GL}_N(\mathbb{A}_{E,f})$ and $\gamma \in \mathrm{GL}_N(E)$. The **characteristic polynomial** $\mathrm{charpoly}(\gamma) \in E[X]$ of γ is that of this matrix. Elements of $\mathrm{U}(U)(E^+)$ are identified with their images in $\Gamma_U \subseteq G_\infty \times G_f$.

Orbital integrals. For functions $k\colon G_\infty \to \mathbb{C}$ and $\phi\colon G_f \to \mathbb{C}$ write $(k \otimes \phi)(g) = k(g_\infty)\,\phi(g_f)$ for $g = (g_\infty, g_f) \in G_\infty \times G_f$. For $\gamma \in \mathrm{U}(U)(E^+)$ let $Z_\gamma \subseteq \Gamma_U$ be the image of its centraliser in $\mathrm{U}(U)(E^+)$. The **orbital integral** of $k \otimes \phi$ at γ is

$$I_\gamma(k \otimes \phi) = \int_{Z_\gamma \backslash (G_\infty \times G_f)} (k \otimes \phi)(x^{-1}\gamma x)\,dx, \tag{5.124}$$

for the quotient of the measure of $G_\infty \times G_f$ of (FT2) by counting measure on Z_γ.

Definition 5.7.2. A **Laplace datum** consists of nonempty finite sets $\mathfrak{n}$, $\mathfrak{m}$, signs $\varepsilon \in \{\pm 1\}^{\mathfrak{n}}$ and $\eta \in \{\pm 1\}^{\mathfrak{m}}$, integer vectors $l \in \mathbb{Z}^{\mathfrak{n}}$ and $k \in \mathbb{Z}^{\mathfrak{m}}$ (with lowest K-types μ_l for the signs ε and μ_k for the signs η), a group S, a homomorphism $j = (j_1, j_2)\colon S \to \mathrm{U}(\mathrm{diag}\,\varepsilon) \times \mathrm{U}(\mathrm{diag}\,\eta)$, a function $\varphi\colon S \to \mathbb{C}$, a finite set X, an integer $M \geq 0$, a bijection $e\colon X \sqcup \{0, \dots, M-1\} \to \mathfrak{n}$, a map $\tau\colon X \to \mathfrak{m}$, reals $B \geq 1$ and $\beta \geq 10^{12}$ and integers $L, h \geq 0$, such that (LA1)–(LA4) below hold. Here ι_e and ι_τ are the $\mathfrak{n} \times X$ and $\mathfrak{m} \times X$ matrices whose column x is the standard basis vector at $e(x)$, respectively at $\tau(x)$.

(LA1) Steep. $\varepsilon_{e(x)} = 1$ and $\mu_l(e(x)) = 0$ for $x \in X$; $\varepsilon_{e(i)} = (-1)^i$ for $0 \leq i < M$; and $i \mapsto \mu_l(e(i))$ is strictly decreasing on $\{0, \dots, M-1\}$ with values in $[-3B, -B]$.

(LA2) Phase. For all $s, t \in S$:

$$\varphi(s) = \mathrm{tr}\big(\mathrm{diag}(\mu_l)(j_1(s) - 1)\big) - \mathrm{tr}\big(\mathrm{diag}(\mu_k)(j_2(s) - 1)\big), \qquad \varphi(st) = \varphi(s) + \varphi(t),$$

$\mathrm{Re}\,\varphi(s) = 0$, and $\mathrm{tr}(j_1(s) - 1) = \mathrm{tr}(j_2(s) - 1)$.

(LA3) Second factor and diagonal copy. $\eta_{\tau(x)} = 1$ and $\mu_k(\tau(x)) = 0$ for $x \in X$; $\mu_k(i) \geq 0$ for every $i \in \mathfrak{m}$, and $\mu_k(i) \leq 3B$ for every $i \in \mathfrak{m}$ such that $\eta_{i'} \neq \eta_i$ for some $i' \in \mathfrak{m}$; and for every unitary $X \times X$ matrix u there is $s \in S$ with $j_1(s) - 1 = \iota_e(u - 1)\iota_e^*$ and $j_2(s) - 1 = \iota_\tau(u - 1)\iota_\tau^*$.

(LA4) Gap and size. l has large gap h for ε and k has large gap h for η; $|l_a| \leq L$ and $|k_b| \leq L$ for all $a \in \mathfrak{n}$, $b \in \mathfrak{m}$; $\#\mathfrak{n} + \#\mathfrak{m} + L \leq \beta$ and $10^{30}\big((\#\mathfrak{n} + \#\mathfrak{m})^2 \log \beta\big)^3 \leq h$.

For $\mathfrak{n}$, ε, l, X, M, e and B as above (without the other data), l is **steep** for (ε, e, B) if (LA1) holds.

Proposition 5.7.3. *Let D be admissible data, $\varrho = (r - k - 1)/2$, and $s \in \{\pm 1\}^r$ the signs of Y_0. There is a unitary $r \times r$ matrix p with $p^* J_1 p = \mathrm{diag}(s)$ such that for every $v \in \Phi$ there is a Bessel system $\mathfrak{B}_v$ for (ϱ, k, b, f), with representation ρ and full function W, such that:*

(i) its degree is $d(\varsigma(v))$;

(ii) there is an invertible matrix B_v with $B_v\,\rho(h) = S_{w_v}(h^{\mathsf{T}})^{\mathsf{T}} B_v$ for every unitary $k \times k$ matrix h, where S_{w_v} is the Schur matrix (polynomial representation of $\mathrm{GL}_k(\mathbb{C})$ in the standard basis of its Weyl module) of the Young diagram with $\mathrm{cols}_v(t)$ columns of height t for $1 \leq t < k$ and no columns of height $t \geq k$;

(iii) for every Haar measure dg on $\mathrm{U}(\operatorname{diag} s)$, with $d_{\varsigma(v)}$ the formal degree for it, and every $y \in G_1$,

$$\int_{\mathrm{U}(\operatorname{diag} s)} d_{\varsigma(v)}\, \overline{c_{\varsigma(v)}(g)}\, W(y\, pgp^{-1})\, dg = W(y);$$

(iv) there are $c \in \mathbb{R}$, a point $x \in G_1$ with $\ell(x) \le b^{5n}$ and a unit vector $e \in \mathbb{C}^I$ such that $W = c\, W_x$, where W_x is the Bessel average of Proposition 5.7.30 formed with the signs s, the matrix p, $l = 2\varsigma(v)$, the representation ρ and the vector e; and $W^\flat$ is the cut of W.

Proof. Throughout, $n = \varrho + 1$, a is the long order of D, and the r basis vectors of Y_0 (numbered as in Definition 3.2.16) and of V_1 (in the order $e_1, \dots, e_\varrho$, the basis of X_0, z, $e_1^*, \dots, e_\varrho^*$) are both identified with $\{0, \dots, r-1\}$; signs and parameters are read through this identification. Since $k = r + 1 - m$ with $m \ge 2$ lifts, $k \le r$, and $\varrho = (r - k - 1)/2 = m/2 - 1$.

Step 1: the sign frame. By Lemma 5.7.20 (for $z = \mathrm{I}$) there is a bijection e_0 from $X \sqcup \{0, \dots, 2\varrho + 1\}$, $X = \{0, \dots, k-2\}$, to the indices of Y_0 with $s(e_0(x)) = 1$ and $s(e_0(i)) = (-1)^i$; so s has exactly $\varrho + 1$ entries -1. The hermitian involution J_1 has the eigenvalue -1 with multiplicity $\varrho + 1$: on each hyperbolic plane $\langle e_b, e_b^* \rangle$ its matrix $\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right)$ has eigenvalues ± 1, it is 1 on X_0 and -1 on z. By the spectral theorem $J_1 = q \operatorname{diag}(s')\, q^*$ with q unitary and s' a sign vector with $\varrho + 1$ entries -1; for a permutation matrix w with $w^{\mathsf{T}} \operatorname{diag}(s') w = \operatorname{diag}(s)$, the matrix $p = qw$ is unitary with $p^* J_1 p = \operatorname{diag}(s)$. Fix it. Then $\iota(g) = p^{-1} g p$ is an isomorphism of topological groups $G_1 \to \mathrm{U}(\operatorname{diag} s)$ that preserves operator norms.

Step 2: the measures. The map ι carries the Cayley measure dy of G_1 to the Cayley measure dg of $\mathrm{U}(\operatorname{diag} s)$. Indeed, with S as in Definition 3.2.1, let $y \mapsto y'$ be the real-linear bijection of $\mathrm{M}_r(\mathbb{R})$ with $S(y') = p^* S(y) p$. As $p^{-1} J_1 = \operatorname{diag}(s) p^*$, ι carries $(1 + \frac{1}{2} J_1 S(y))(1 - \frac{1}{2} J_1 S(y))^{-1}$ to $(1 + \frac{1}{2}\operatorname{diag}(s) S(y'))(1 - \frac{1}{2}\operatorname{diag}(s) S(y'))^{-1}$, and $\det(1 - \frac{1}{2} J_1 S(y)) = \det(1 - \frac{1}{2}\operatorname{diag}(s) S(y'))$. The coordinates $\operatorname{Im} x_{aa}$, $\operatorname{Re} x_{ab}$, $\operatorname{Im} x_{ab}$ $(a < b)$ of skew-hermitian matrices are orthogonal for the euclidean structure $\operatorname{Re}\operatorname{tr}(X^* Y)$, with fixed lengths, so Lebesgue measure in them is a constant multiple of the euclidean volume, which $X \mapsto p^* X p$ preserves; as S carries Lebesgue measure of $\mathrm{M}_r(\mathbb{R})$ to Lebesgue measure in these coordinates, $y \mapsto y'$ preserves Lebesgue measure. So the two Cayley measures, images of the same density under corresponding charts, correspond under ι. Consequently, for a parameter l, the formal degree d_l of Proposition 5.7.30 (for the measure carried from dy) is the formal degree for the Cayley measure of $\mathrm{U}(\operatorname{diag} s)$.

Fix $v \in \Phi$ for the rest of the proof.

Step 3: the parameter. Put $l = 2\varsigma(v) \in \mathbb{Z}^r$, so $c_l^{G_1}(g) = c_{\varsigma(v)}(\iota(g))$. By (S6), l has large gap r^7 for s and $|l_i| \le 3a$. Since $r \ge 100$ (S4), $r^7 \ge 10 r^5$, so l also has large gap $10 r^5$, and by Lemma 5.7.4 and Step 2, $d_l = \mathrm{d}(\varsigma(v))$; in particular $d_l > 0$.

Step 4: the representation on the values. Let $x_1, \dots, x_k$ be the standard basis of X_0 and w the weight with $w(h) = \operatorname{cols}_v(h)$ for $1 \le h < k$; its highest weight is $\lambda_w(0) = \operatorname{cols}_v(1)$ and $\lambda_w(p) = 0$ for $p \ge 1$, as $\operatorname{cols}_v(h) = 0$ for $1 < h < k$ (Definition 2.3.4). Let $u(i) = 2\lambda_w(i-1) + k + 1 - 2i$ $(1 \le i \le k)$; it is a doubled Harish-Chandra parameter of $(w, 0)$. By Lemma 5.7.17, u has every gap for the signs $(1, \dots, 1)$, its lowest K-type is $\mu_u(i_0) = \operatorname{cols}_v(1)$ at the index $i_0 = 1$ and $\mu_u = 0$ elsewhere, and there are a continuous unitary representation $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$, $I = I_w$, an invertible matrix B_v and a unit vector e with $B_v \rho(h) = S_w(h^{\mathsf{T}})^{\mathsf{T}} B_v$, $\langle e, \rho(h) e \rangle = c_{u/2}(h)$, and only scalars commuting with ρ; as ρ is unitary and finite dimensional, it is irreducible. Since $\operatorname{cols}_v(1) \le a$ and $k \le a$ (S4), $|u(i)| \le 2a + k - 1 \le 3a$.

Step 5: a stationary point. Apply Proposition 5.7.30 (a) with the signs s, l, the set X and the bijection e_0 of Step 1, a bijection $\tau\colon X \sqcup \{*\} \to \{1, \dots, k\}$ with $\tau(*) = i_0$, $B = \kappa_0(v)$, the integer called a there equal to $\operatorname{cols}_v(1)$, $h = r^7$, $L = 3a$ and $\beta = b^3$. Its hypotheses hold:

steepness of $l = 2\varsigma(v)$ for $(s, e_0, \kappa_0(v))$ with $M = 2\varrho + 2 = 2n$ is Lemma 5.7.20; the lowest K-type of u is as required by Step 4; $3\kappa_0(v) + \mathrm{cols}_v(1) \le 3\kappa_0(v) + a \le b^2$ (S6); $8nr \le b$ (S4); l and u have large gap r^7 (Steps 3, 4); $|l_i|, |u_i| \le 3a$; $10^{12} \le b^3$ (S6), $r + k + 3a \le b^3$ and $10^{30}((r+k)^2 \log b^3)^3 \le r^7$ (S4). So there is $x \in G_1$ with $\ell(x) \le b^{5n}$ and $V(x) \le b^{60(r+k)^2}\,|\Pi|$, Π the period of Proposition 5.7.30 (a) for u. As $\langle e, \rho(h)e\rangle = c_{u/2}(h)$, Proposition 5.7.30 (b) with $P = b^{60(r+k)^2}$ gives $V(x) \le b^{60(r+k)^2}\, d_l \int_{\mathsf{U}\backslash G_1} \|W_x\|^2$, where W_x is the Bessel average for ρ, e and x.

Step 6: the cut pair and Schur's bound. Apply Proposition 5.7.30 (c) with $A = r^7$, $L = 3a$, $m = 60(r+k)^2$, f and b: $\|e\| = 1$; the volume bound and $\ell(x) \le b^{5n}$ are Step 5; $b \ge 2000$, $r \ge 100$ and $r + 3a + 1 \le b^4$ are (S4); $m + 99r^2 \le 240r^2 + 99r^2 \le 400r^2$ as $k \le r$; and $3r^3 f \le r^7$ is (S6). So there are $c \in \mathbb{R}$ and a continuous $W = c\,W_x$ with $\int_{G_1} d_l\, c_l^{G_1}(a'^{-1}) W(ya')\, da' = W(y)$ for all y, such that $(W, W^\flat)$, $W^\flat = \chi(\ell(\cdot))W$, is a cut pair for b, f. Then $W^\flat$ is continuous: χ is continuous, and so is ℓ, because $\ell(y') \le \ell(y)\,\|y^{-1}y'\|_{\mathrm{op}}$ for all y, y' (as $\|sy'\|_{\mathrm{op}} + 1 \le (\|sy\|_{\mathrm{op}} + 1)\|y^{-1}y'\|_{\mathrm{op}}$, elements of G_1 having operator norm at least 1). By (BS1), W is integrable over $\mathsf{U}\backslash G_1$ and $\int_{\mathsf{U}\backslash G_1} \|W\|^2 = \#I$. For $P \ge b^5$, Proposition 5.7.30 (d) with $A = r^7$, $L = 3a$ and $B = P$ applies, since $(r+1)^4(3a + r + 1 + 2n^2) \le b^5 \le P$ (S4): W has Schur's bound $(P, d_l^{-1}\#I)$.

Step 7: local bounds. Apply Theorem 5.5.3 to the cut pair $(W, W^\flat)$ of the irreducible type ρ, with $\deg = d_l$. Its hypotheses: $b \ge 2$; $8r \le 8nr \le b \le b^{6n+2}$; $k = s_0 + 3n + 6$ with $s_0 = k - 3n - 6 > 10^9 n^3$ (S4); $n^7 \le k$ (S1); $10^8 \le \varrho$ (S6); $4000n \le f$ (S4). The coefficient bound: by Lemma 5.7.19 (ii) for $F = W$ (a Bessel function of type ρ, integrable over $\mathsf{U}\backslash G_1$ and reproduced by $d_l c_l^{G_1}$, l of large gap r^7),

$$\int_{G_1} \Big| \int_{\mathsf{U}\backslash G_1} \langle W(y), W(yx)\rangle\, dy \Big|^2 dx = d_l^{-1} \Big(\int_{\mathsf{U}\backslash G_1} \|W\|^2 \Big)^2 = \frac{(\#I)^2}{d_l}.$$

The constant: $d_l = \mathrm{d}(\varsigma(v)) = \prod_{i<j} \frac{|l_i - l_j|/2}{j-i} \le (3a)^{r^2} \le b^{2r^2}$, as $|l_i - l_j|/2 \le 3a \le b^2$ (S4); and with Θ of Definition 5.1.6, $\mathrm{vol}\,\mathrm{U}(k)/\mathrm{vol}\,\mathrm{U}(r) = \prod_{i=k}^{r-1} \frac{i!}{2\pi^{i+1}} \le r^{r^2} \le b^{r^2}$ ($i! \le r^r$, $2\pi^{i+1} \ge 1$, $r \le b$) and $\pi^{(2\varrho+1)k} \le b^{r^2}$ ($\pi \le b$, $(2\varrho+1)k \le r^2$, (S4)); so $d_l\Theta \le b^{4r^2}$. The ball volume: by Lemma 5.7.38 (3) for $\mathrm{U}(\mathrm{diag}\, s)$ with the measure carried from dy, the large gap r^7, $L = 3a$ and $c = 9r^2 > 8r^2$, and as ι preserves operator norms,

$$\int_{G_1} d_l \Big(\frac{2}{\|g\|_{\mathrm{op}}} \Big)^{9r^2} dg \le 8\big(2000(r + 3a + 1)^6\big)^{2r^2} 2^{9r^2} \le 8\big(2000\, b^{24}\big)^{2r^2} 2^{9r^2} \le b^{50r^2+1} 2^{9r^2},$$

using $r+3a+1 \le b^4$ and $8 \le 2000 \le b$. For $T \ge 1$ and $\|g\|_{\mathrm{op}} \le T$ we have $1 \le (T/2)^{9r^2}(2/\|g\|_{\mathrm{op}})^{9r^2}$, hence $d_l\,\mathrm{vol}\{g \in G_1 : \|g\|_{\mathrm{op}} \le T\} \le T^{9r^2} b^{50r^2+1} \le T^{9r^2} b^{99r^2}$. So Theorem 5.5.3 gives forms J that are local bounds for $W^\flat$ with degree d_l.

Step 8: the Bessel system. I is finite and nonempty, ρ is irreducible and unitary, $(W, W^\flat)$ are continuous Bessel functions of type ρ forming a cut pair, $\deg = d_l > 0$, $8r \le b$, W has Schur's bound $(P, \deg^{-1}\#I)$ for every $P \ge b^5$, and J are local bounds for $W^\flat$ with degree deg: this is a Bessel system $\mathfrak{B}_v$ for (ϱ, k, b, f). (i) is Step 3. (ii) is Step 4, the Young diagram of w having $\mathrm{cols}_v(t)$ columns of height t for $1 \le t < k$ and none of height $t \ge k$. (iii): let dg' be a Haar measure of $\mathrm{U}(\mathrm{diag}\, s)$ and d' the formal degree for it; then $d'dg' = d_l\, dg$, the formal degree scaling inversely to the measure. Substituting $a' = \iota^{-1}(g) = pgp^{-1}$ in the reproduction of Step 6 and using $c_{\varsigma(v)}(g^{-1}) = \overline{c_{\varsigma(v)}(g)}$ (Lemma 5.7.40),

$$W(y) = \int_{\mathrm{U}(\mathrm{diag}\, s)} d_l\, \overline{c_{\varsigma(v)}(g)}\, W(ypgp^{-1})\, dg = \int_{\mathrm{U}(\mathrm{diag}\, s)} d'\, \overline{c_{\varsigma(v)}(g)}\, W(ypgp^{-1})\, dg'.$$

(iv): $W = c\,W_x$ with c real, $\ell(x) \le b^{5n}$ and W_x the Bessel average for the signs s, p, $l = 2\varsigma(v)$, ρ and the unit vector e (Steps 1 and 3 to 6), and $W^\flat$ is its cut (Step 6). □

Lemma 5.7.4. *Let $n = \{1, \dots, N\}$ ($N \geq 1$), $\varepsilon \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have large gap $10N^5$ for ε; put $\lambda = \frac{1}{2}l$. Let dg be the Cayley measure of $\mathrm{U}(\operatorname{diag}\varepsilon)$. Then*

$$\Big(\int_{\mathrm{U}(\operatorname{diag}\varepsilon)} |c_\lambda|^2\, dg\Big)^{-1} = \mathrm{d}(\lambda) = \prod_{1\leq a<b\leq N} \frac{|\lambda_a - \lambda_b|}{b-a}.$$

Proof. Write d_λ for the left side and dk for the Haar probability measure of $\mathrm{U}(n)$. For $a \in n$ let $p(a) = \#\{a' : l_{a'} > l_a\}$; as l is injective, p is a bijection $n \to \{0, \dots, N-1\}$, and we write a_p for the index with $p(a_p) = p$.

The lowest K-type for the compact form. Let Λ be the lowest K-type of l for the signs $(1, \dots, 1)$ (Definition 3.2.3). All signs agree, so $2\rho_l^{\mathrm{c}} = 2\rho_l$ with $2\rho_l(a) = (N-1-p(a)) - p(a)$. As l has a gap, $l_a \equiv N-1 \pmod 2$, so $l_a + 2\rho_l(a)$ is even and $l^\rho(a) = \lambda_a + \frac{N-1}{2} - p(a)$; hence

$$\Lambda(a) = l^\rho(a) - 2\rho_l(a) = \lambda_a - \tfrac{N-1}{2} + p(a).$$

Put $L_p = \Lambda(a_p)$. The entries of l are distinct and of the same parity, so $\lambda_{a_p} - \lambda_{a_{p+1}} \geq 1$ and $L_p \geq L_{p+1}$.

A Weyl module with coefficient m_Λ. Let $w(h) = L_{h-1} - L_h \geq 0$ for $1 \leq h < N$, a weight for the rank N, with highest weight $\lambda_w(p) = \sum_{p<h<N} w(h) = L_p - L_{N-1}$, and put $u(a) = 2\lambda_w(p(a)) + N - 1 - 2p(a)$. The numbers $2\lambda_w(q) + N - 1 - 2q$ are strictly decreasing in q, so u is injective and is a doubled Harish-Chandra parameter of $(w, 0)$ ((WM6) of Definition 3.2.19), and $\#\{a' : u(a') > u(a)\} = p(a)$. By Lemma 5.7.17 (for $k = N$, the rows indexed by $n = \{1, \dots, N\}$), $\mu_u(a) = \lambda_w(p(a)) = \Lambda(a) - c_0$ with $c_0 = L_{N-1}$, and there are an irreducible unitary representation ρ of $\mathrm{U}(n)$ on $\mathbb{C}^{I_w}$ and a unit vector e with $m_{\mu_u}(h) = \langle e, \rho(h)e\rangle$ for $h \in \mathrm{U}(n)$, where $\#I_w = d_N(\lambda_w)$. By Schur's orthogonality relations for the compact group $\mathrm{U}(n)$, $\int |\langle e, \rho(k)e\rangle|^2 dk = 1/\#I_w$. By (3.1), $\min_a \mu_u(a) = \lambda_w(N-1) = 0$, and $\{a : \Lambda(a) \geq t\} = \{a : \mu_u(a) \geq t - c_0\}$, so $m_\Lambda(h) = (\det h)^{c_0} m_{\mu_u}(h)$; as $|\det k| = 1$ on $\mathrm{U}(n)$,

$$\int_{\mathrm{U}(n)} |m_\Lambda(k)|^2\, dk = \frac{1}{d_N(\lambda_w)}.$$

Conclusion. By Proposition 5.7.5 (i), $d_\lambda \int_{\mathrm{U}(n)} |m_\Lambda|^2 dk = 1$, so $d_\lambda = d_N(\lambda_w)$. Finally, as $\lambda_w(p) - \lambda_w(q) + q - p = L_p - L_q + q - p = \lambda_{a_p} - \lambda_{a_q} > 0$ for $p < q$,

$$d_N(\lambda_w) = \prod_{0\leq p<q<N} \frac{\lambda_{a_p} - \lambda_{a_q}}{q-p} = \frac{\prod_{1\leq a<b\leq N} |\lambda_a - \lambda_b|}{\prod_{1\leq a<b\leq N} (b-a)} = \mathrm{d}(\lambda),$$

because both products of differences run over all unordered pairs of indices, and $\prod_{0\leq p<q<N}(q-p) = \prod_{j=1}^{N-1} j! = \prod_{1\leq a<b\leq N}(b-a)$. □

Proposition 5.7.5. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have large gap $10N^5$ for ε; put $\lambda = \frac{1}{2}l$. Let dg be the Cayley measure of $\mathrm{U}(\operatorname{diag}\varepsilon)$ and $d_\lambda = \big(\int_{\mathrm{U}(\operatorname{diag}\varepsilon)} |c_\lambda|^2 dg\big)^{-1}$.*

(i) Let Λ be the lowest K-type of l for the signs $(1, \dots, 1)$, and dk the Haar probability measure of the group $\mathrm{U}(n)$ of unitary $n \times n$ matrices. Then

$$d_\lambda \int_{\mathrm{U}(n)} |m_\Lambda(k)|^2\, dk = 1.$$

(ii) Let $\kappa_a = \frac{1}{2}(l_a + N - 1)$ $(a \in n)$, *and for* $x \in \mathbb{C}^n$ *put*

$$V_{\mathrm{c}}(x) = \prod_{\substack{\varepsilon_a = \varepsilon_b \\ l_b < l_a}} (x_a - x_b), \qquad D(x) = \prod_{\substack{\varepsilon_a \neq \varepsilon_b \\ l_a < l_b}} (x_a - x_b), \qquad A(x) = \sum_{\substack{w \in S_n \\ \varepsilon \circ w = \varepsilon}} \operatorname{sgn}(w) \prod_{a \in n} x_a^{\kappa_{w(a)}},$$

the products over ordered pairs (a, b). *If* $x_a \in \mathbb{C}$, $|x_a| = 1$, *are pairwise distinct, then* $g \mapsto c_\lambda(g^{-1} \operatorname{diag}(x)\, g)$ *is integrable on* $\mathrm{U}(\operatorname{diag} \varepsilon)$ *and*

$$V_{\mathrm{c}}(x)\, D(x)\, d_\lambda \int_{\mathrm{U}(\operatorname{diag}\varepsilon)} c_\lambda(g^{-1}\operatorname{diag}(x) g)\, dg = A(x).$$

Proof. For $x \in \mathbb{C}^n$ with $|x_a| = 1$ write $t_x = \operatorname{diag}(x)$ and, when the entries are pairwise distinct, $\Theta(x) = d_\lambda \int c_\lambda(g^{-1} t_x g)\, dg$. By Lemma 5.6.23 (i) (the gap h exceeds $8N^2$) d_λ is a positive real number. Let $\delta_{\mathrm{c}}(a) = \#\{b : \varepsilon_b = \varepsilon_a,\ l_b < l_a\}$, let p, q be the numbers of indices with $\varepsilon = 1$, $\varepsilon = -1$, and number n as $a_0, \dots, a_{N-1}$ by decreasing l, so $o(a_j) = j$.

Step 1: three identities. As $l_a \equiv N - 1 \pmod 2$ and $\#\{b : l_b < l_a\} = N - 1 - o(a)$, $2\rho_l(a) = N - 1 - 2o(a)$ and $l^\rho = \kappa - o$. (α) For the signs $(1, \dots, 1)$, $2\rho_l^{\mathrm{c}} = 2\rho_l$, so $\Lambda_{\mathrm{c}} = l^\rho - 2\rho_l$, that is $\Lambda_{\mathrm{c}}(a_j) = \kappa(a_j) - (N-1) + j$; it is nonincreasing in j (κ is strictly increasing along l, Lemma 5.7.18 (a)), and $\Lambda_{\mathrm{c}}(a_j) + N - 1 - j = \kappa(a_j)$. (β) For the signs ε, $2\rho_l^{\mathrm{c}}(a) = \delta_{\mathrm{c}}(a) - \#\{b : \varepsilon_b = \varepsilon_a,\ l_b > l_a\}$, so $\mu_l + \delta_{\mathrm{c}} = \kappa - o + \#\{b : \varepsilon_b = \varepsilon_a,\ l_b > l_a\} = \kappa - \delta$, and $\mu_l + \delta_{\mathrm{c}} + (N'+1)\delta = \mathrm{top}$. (γ) $V = V_{\mathrm{c}} \prod_{\varepsilon_a \neq \varepsilon_b,\, l_b < l_a} (X_a - X_b) = (-1)^{pq} V_{\mathrm{c}} D$, each of the pq unordered pairs of opposite signs giving one factor of D with the opposite orientation.

Step 2: the two Laurent polynomials. By Proposition 5.7.6, $g \mapsto c_\lambda(g^{-1} t_x g)$ is integrable at every x with distinct entries, and there is a W_K-antisymmetric $P \in \mathcal{R}$, a cone-series multiple of $D^{N'+1}$ at $\mu_l + \delta_{\mathrm{c}}$, with $P(x) = V_{\mathrm{c}}(x) D(x)^{N'+1} \Theta(x)$ at these x. By (β) and Lemma 5.7.18 (b), $P_{\mathrm{top}} = 1$ and every exponent of P has a W_K-conjugate of level at most $o \cdot \mathrm{top}$. Put $\mathrm{num}^\eta = D^{N'} A_\kappa^\eta$ $(\eta \in \{\varepsilon, \mathbf{1}\})$. By Lemma 5.7.18 (c), then (b) with $a = \kappa$, $k = N'$, num^ε is W_K-antisymmetric, $\mathrm{num}^\varepsilon_{\mathrm{top}} = 1$, and every exponent of num^ε has a W_K-conjugate of level at most $o \cdot \mathrm{top}$.

Step 3: comparison on the accretive torus. Let σ and Off be as in Proposition 5.7.10, and let x have $|x_a| = 1$, distinct entries and Jt_x accretive. By (a) there, $\Theta(x) = \frac{d_\lambda}{\sigma}\big(\|m_{\Lambda_{\mathrm{c}}}\|^2 \chi(t_x) - \mathrm{Off}(Jt_x)\big)$. Weyl's character formula [92], in the numbering $a_0, \dots, a_{N-1}$ with the highest weight Λ_{c} (nonincreasing by (α)), gives

$$\chi(t_x) = \frac{\det\big(x_{a_k}^{\Lambda_{\mathrm{c}}(a_j) + N - 1 - j}\big)_{j,k}}{\det\big(x_{a_k}^{N-1-j}\big)_{j,k}} = \frac{\det\big(x_b^{\kappa_a}\big)_{a,b}}{\prod_{j<k}(x_{a_j} - x_{a_k})} = \frac{A_\kappa^{\mathbf{1}}(x)}{V(x)},$$

by (α), by reindexing rows and columns by the same bijection, and by the Leibniz formula $\det(x_b^{\kappa_a}) = \sum_{v \in S_n} \operatorname{sgn}(v) \prod_a x_a^{\kappa_{v(a)}}$; here $V(x) = \prod_{j<k}(x_{a_j} - x_{a_k}) \neq 0$. With (γ), $V_{\mathrm{c}}(x) D(x) \chi(t_x) = (-1)^{pq} A_\kappa^{\mathbf{1}}(x)$. Hence, with

$$s = (-1)^{pq}\, \frac{d_\lambda \|m_{\Lambda_{\mathrm{c}}}\|^2}{\sigma}, \qquad Q = -(-1)^{pq} \frac{d_\lambda}{\sigma}\, V\, D^{N'} \in \mathcal{R},$$

and $V_{\mathrm{c}} D^{N'+1} = (-1)^{pq} V D^{N'}$,

$$(P - s\, \mathrm{num}^{\mathbf{1}})(x) = V_{\mathrm{c}}(x) D(x)^{N'+1} \Theta(x) - s\, D(x)^{N'} A_\kappa^{\mathbf{1}}(x) = Q(x)\, \mathrm{Off}(Jt_x).$$

Step 4: low levels. Let $o \cdot \gamma \leq o \cdot \mathrm{top}$. The exponents β of Q are exponents of $V D^{N'}$, so by Lemma 5.7.18 (d), $o \cdot \gamma \leq o \cdot \mathrm{top} < o \cdot (\kappa - o) + o \cdot \beta + h$. By Step 3 and Proposition 5.7.10

(b), $(P - s\,\mathrm{num}^{\mathbf{1}})_\gamma = 0$, and by Lemma 5.7.18 (d), $\mathrm{num}^{\mathbf{1}}_\gamma = \mathrm{num}^\varepsilon_\gamma$. So $P_\gamma = s\,\mathrm{num}^\varepsilon_\gamma$ whenever $o\cdot\gamma \le o\cdot\mathrm{top}$.

Step 5: identification. By Steps 2 and 4 and Lemma 5.7.18 (e) (with $m = o\cdot\mathrm{top}$, $c = s$), $P = s\,\mathrm{num}^\varepsilon$. Comparing the coefficients at top (Step 2), $1 = s\cdot 1$, so $s = 1$.

Step 6: conclusion. (i): $1 = |s| = d_\lambda \|m_{\Lambda_\mathrm{c}}\|^2/|\sigma| = d_\lambda \int_{\mathrm{U}(n)} |m_\Lambda(k)|^2 dk$, as $d_\lambda > 0$, $|\sigma| = 1$ and $\Lambda = \Lambda_\mathrm{c}$. (ii): integrability is Step 2; and for x with $|x_a| = 1$ and distinct entries, $P = \mathrm{num}^\varepsilon$ gives $V_\mathrm{c}(x)D(x)^{N'+1}\Theta(x) = D(x)^{N'}A^\varepsilon_\kappa(x)$, where $D(x)\neq 0$ (distinct entries) and

$$A^\varepsilon_\kappa(x) = \sum_{w\in S_n,\,\varepsilon\circ w=\varepsilon} \mathrm{sgn}(w)\prod_a x_a^{\kappa_{w(a)}} = A(x);$$

dividing by $D(x)^{N'}$ gives

$$V_\mathrm{c}(x)D(x)\,d_\lambda \int c_\lambda(g^{-1}\mathrm{diag}(x)g)\,dg = A(x).$$

□

Proposition 5.7.6. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon\in\{\pm1\}^n$, and let $l\in\mathbb{Z}^n$ have large gap $10N^5$ for ε; put $\lambda = \frac12 l$, let dg be the Cayley measure of $\mathrm{U}(\mathrm{diag}\,\varepsilon)$ and $d_\lambda = \left(\int |c_\lambda|^2 dg\right)^{-1}$. For $x\in\mathbb{C}^n$ with $|x_a| = 1$ let $t_x = \mathrm{diag}(x)\in\mathrm{U}(\mathrm{diag}\,\varepsilon)$. Let the Laurent polynomial ring $\mathcal{R}$, coefficients P_γ, W_K, D, $N' = 4N^2$, W_K-antisymmetry and cone-series multiples be as in Lemma 5.7.18 for these n,ε,l, and put $V_\mathrm{c} = \prod_{\varepsilon_a=\varepsilon_b,\ l_b<l_a}(X_a - X_b)$ and $\delta_\mathrm{c}(a) = \#\{b : \varepsilon_b = \varepsilon_a,\ l_b < l_a\}$. Then for every x with $|x_a| = 1$ and pairwise distinct entries the function $g\mapsto c_\lambda(g^{-1}t_x g)$ is integrable on $\mathrm{U}(\mathrm{diag}\,\varepsilon)$, and there is $P\in\mathcal{R}$ which is W_K-antisymmetric, is a cone-series multiple of $D^{N'+1}$ at $\mu_l + \delta_\mathrm{c}$, and satisfies*

$$P(x) = V_\mathrm{c}(x)\,D(x)^{N'+1}\,d_\lambda \int_{\mathrm{U}(\mathrm{diag}\,\varepsilon)} c_\lambda(g^{-1}t_x g)\,dg$$

for every such x.

Proof. Write $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, $K = K_\varepsilon$, $Y = D^{N'+1}\in\mathcal{R}$, and for x with $|x_a| = 1$ and distinct entries $\Theta(x) = d_\lambda\int_G c_\lambda(g^{-1}t_x g)\,dg$. The vector l is injective, and μ_l is K-dominant (Lemma 5.6.27 (iii)). Every factor of D is $\pm(X_a - X_b)$ with $\varepsilon_a = 1$, $\varepsilon_b = -1$, each such pair once, and W_K permutes the indices of each sign; so $D(X\circ w) = D(X)$ and $Y_{\beta\circ w} = Y_\beta$ for $w\in W_K$, and Y has integer coefficients.

Step 1: integrability and the class function. If x has distinct entries, $D(x)\neq 0$, and by Lemma 5.7.8 (iii) $g\mapsto c_\lambda(g^{-1}t_x g)$ is integrable. Let d, Φ and h be as in Lemma 5.7.8: h is a continuous class function on K with $h(t_x) = Y(x)\Theta(x)$ at these x.

Step 2: the coefficients of h are integers. Let ν be K-dominant and $a_\nu = \int_K \overline{\chi^K_\nu}\,h\,dk$. For $g\in G$ let $\psi_g(k) = c_\lambda(g^{-1}kg)$, continuous on K. Since $|d(k)\psi_g(k)|\le\Phi(g)$ with Φ integrable and χ^K_ν is bounded, Fubini and Lemma 5.7.9 (c) (for $D = Y$, $f = \psi_g$) give

$$a_\nu = d_\lambda\int_G\int_K \overline{\chi^K_\nu}\,d\,\psi_g\,dk\,dg = d_\lambda\int_G\sum_\beta Y_\beta\,s_{e(\beta)}\,R_{\nu_{e(\beta)}}(g)\,dg = \sum_\beta Y_\beta\,s_{e(\beta)}\,m(\nu_{e(\beta)}),$$

$e(\beta) = \nu + \delta_\mathrm{c} - \beta$, using that each $R_{\nu'}$ is integrable with $d_\lambda\int_G R_{\nu'} = m(\nu')$ (Proposition 5.7.7). Hence $a_\nu\in\mathbb{Z}$.

Step 3: finitely many coefficients. By the theorem of the highest weight for $\mathrm{U}(n_+)\times\mathrm{U}(n_-)$, the χ^K_ν (ν K-dominant) are the characters of a set of representatives of the irreducible continuous

representations of K; by Theorem A.5.21 (i) they are orthonormal in $L^2(K)$, so by Bessel's inequality $\sum_\nu |a_\nu|^2 \le \int_K |h|^2 dk < \infty$. As the a_ν are integers, the set F of ν with $a_\nu \ne 0$ is finite.

Step 4: completeness. The continuous class function $f = h - \sum_{\nu\in F} a_\nu \chi^K_\nu$ satisfies $\int_K f\,\overline{\chi^K_\nu}\,dk = 0$ for every K-dominant ν, hence for every irreducible character; by Theorem A.5.21 (ii) it vanishes almost everywhere, hence everywhere (it is continuous and dk charges every nonempty open set). So $h = \sum_{\nu\in F} a_\nu \chi^K_\nu$.

Step 5: the Laurent polynomial. Put $P = \sum_{\nu\in F} a_\nu A^\varepsilon_{\nu+\delta_c} \in \mathcal{R}$. Each alternant is W_K-antisymmetric ($(A^\varepsilon_\mu)_{\gamma\circ w} = \mathrm{sgn}(w)(A^\varepsilon_\mu)_\gamma$), hence so is P. By Lemma 5.7.9 (a), $P(x) = V_c(x)h(t_x)$ for every x on the torus, and by Step 1, $P(x) = V_c(x)D(x)^{N'+1}\Theta(x)$ when x has distinct entries.

Step 6: P is a cone-series multiple of $D^{N'+1}$ at $\mu_l+\delta_c$. Let $t(\gamma) = s_\gamma\, m(\nu_\gamma)$. By Lemma 5.7.9 (b), $A^\varepsilon_{e\circ w} = \mathrm{sgn}(w)A^\varepsilon_e$ for $w \in W_K$ forces $s_{e\circ w} = \mathrm{sgn}(w)s_e$ and, when $s_e \ne 0$, $\nu_{e\circ w} = \nu_e$ (alternants $A^\varepsilon_{\mu+\delta_c}$ of distinct K-dominant μ have disjoint sets of exponents); so $t(e\circ w) = \mathrm{sgn}(w)t(e)$. Hence $Q_\gamma = \sum_\beta Y_\beta\, t(\gamma-\beta)$ (a finite sum) is W_K-antisymmetric in γ, by the substitution $\beta \mapsto \beta\circ w$ and the invariance of Y. Two W_K-antisymmetric functions on $\mathbb{Z}^n$ that agree at every $\nu+\delta_c$ with ν K-dominant agree everywhere: by (b), every γ with $s_\gamma \ne 0$ is $(\nu_\gamma+\delta_c)\circ w$ for some $w \in W_K$, and at a γ fixed by an odd element of W_K both vanish. At $\gamma = \nu+\delta_c$, $s_\gamma = 1$ and $\nu_\gamma = \nu$, so $P_\gamma = a_\nu$ by (b), and $Q_\gamma = \sum_\beta Y_\beta s_{e(\beta)} m(\nu_{e(\beta)}) = a_\nu$ by Step 2. So $P_\gamma = \sum_\beta Y_\beta\, t(\gamma-\beta)$ for all γ. Further $t(\mu_l+\delta_c) = 1\cdot m(\mu_l) = 1$. If $t(\gamma) \ne 0$, then $s_\gamma \ne 0$ and $m(\nu_\gamma) \ne 0$, so $\nu_\gamma - \mu_l \in C_l$ (Proposition 5.7.7), and $\mu = \nu_\gamma + \delta_c$ satisfies $(A^\varepsilon_\mu)_\gamma = s_\gamma \ne 0$ by (b) and $\mu - (\mu_l+\delta_c) \in C_l$. This is the cone condition of Lemma 5.7.18. □

Proposition 5.7.7. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon \in \{\pm1\}^n$, and let $l \in \mathbb{Z}^n$ have large gap $10N^5$ for ε; put $\lambda = \frac12 l$, let dg be the Cayley measure of $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, $d_\lambda = \left(\int_G |c_\lambda|^2 dg\right)^{-1}$, and dk the Haar probability measure of $K = K_\varepsilon$. Call $\nu \in \mathbb{Z}^n$ K-*dominant *if $\nu(i) \ge \nu(j)$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$, and for such ν let χ^K_ν be the character of the irreducible continuous representation of K of highest weight ν for the diagonal torus and the Borel subgroup of the invertible matrices b with $b_{ij} = 0$ unless $\varepsilon_i = \varepsilon_j$ and $l_i \ge l_j$. Let $C_l = \{\beta \in \mathbb{Z}^n : o'\cdot\beta \le 0$ for every $o' \in \mathbb{Z}^n$ with $o'(a) < o'(b)$ whenever $l_b < l_a\}$. Then for every K-dominant ν the function*

$$R_\nu(g) = \int_K c_\lambda(g^{-1}kg)\,\overline{\chi^K_\nu(k)}\,dk$$

is integrable on G, and $m(\nu) = d_\lambda \int_G R_\nu(g)\,dg$ is a nonnegative integer, with $m(\mu_l) = 1$, and $m(\nu) = 0$ unless $\nu - \mu_l \in C_l$.

Proof. Write $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, $K = K_\varepsilon$, $c = c_\lambda$, $d = d_\lambda$, $\mu = \mu_l$, and $\|m_w\|^2 = \int_K |m_w|^2 dk$ for $w \in \mathbb{Z}^n$, a positive number since m_w is continuous on K with $m_w(1) = 1$. The large gap $10N^5$ is the gap $500N^3 + 10N^5 > 8N^2$, hence also gap 0. The Cayley measure dg is a Haar measure on G, invariant under left and right translations (Lemma 5.2.41). By Lemma 5.6.23 (i), c is continuous and square integrable and $d > 0$; by Lemma 5.7.40, $|c| \le 1$ and $c(g^{-1}) = \overline{c(g)}$; and $c(1) = 1$ by (3.2), as $\mathrm{bd}_\varepsilon(1) = 1$ and $m_w(1) = 1$. The lowest K-type μ is K-dominant by Lemma 5.6.27 (iii). Fix a K-dominant ν.

Step 1: the character as a conjugation mean. We show

$$\int_K m_\nu(y^{-1}ky)\,dy = \|m_\nu\|^2\,\chi^K_\nu(k) \qquad (k \in K). \tag{5.125}$$

Let $n_\pm = \{a : \varepsilon_a = \pm1\}$, so that $K = \mathrm{U}(n_+)\times\mathrm{U}(n_-)$, $k = (k_+, k_-)$, and dk is the product of the Haar probability measures; for $w \in \mathbb{Z}^n$ let $w_\pm$ be its restriction to $n_\pm$. For block-diagonal invertible g and $P \subseteq n$, $\Delta_P(g) = \Delta_{P\cap n_+}(g_+)\Delta_{P\cap n_-}(g_-)$; in (3.1) the factors of block $n_\pm$ with $t \le \min w_\pm$ are $\det g_\pm$ and those with $t > \max w_\pm$ are 1, so $m_w(g) = m_{w_+}(g_+)\,m_{w_-}(g_-)$ (a factor

for an empty block being 1). By the theorem of the highest weight for the connected compact group K, the irreducible representation of highest weight ν (for the diagonal torus and the Borel subgroup of the statement) is the outer tensor product of the irreducible representations of $\mathrm{U}(n_\pm)$ of highest weights $\nu_\pm$ for the Borel subgroups of invertible $b_\pm$ with $(b_\pm)_{ij}=0$ when $l_i<l_j$; so $\chi^K_\nu(k)=\chi_{\nu_+}(k_+)\chi_{\nu_-}(k_-)$, where $\chi_{\nu_\pm}$ is the character of Lemma 5.7.16 for $n_\pm$ and the numbering of $n_\pm$ by decreasing l (along which $\nu_\pm$ decreases, by K-dominance; for an empty block put $\chi=1$). By Fubini's theorem $\|m_\nu\|^2=\|m_{\nu_+}\|^2\|m_{\nu_-}\|^2$, and Lemma 5.7.16 (iv) in each nonempty block gives (5.125).

Consequently, for $g\in G$: the integrand of $R_\nu(g)$ is continuous on K, and inserting the complex conjugate of (5.125), using Fubini's theorem on $K\times K$ (continuous integrand) and the invariance of dk under $k\mapsto yky^{-1}$,

$$R_\nu(g)=\frac{1}{\|m_\nu\|^2}\int_K\int_K \overline{m_\nu(k)}\; c(g^{-1}y\,k\,y^{-1}g)\,dk\,dy. \tag{5.126}$$

Step 2: the lowest K-type. For $\nu=\mu$, Lemma 5.6.31 (i) with $x=g^{-1}y$, $b=y^{-1}g$ turns (5.126) into $R_\mu(g)=\int_K c(g^{-1}y)\,c(y^{-1}g)\,dy=\int_K|c(y^{-1}g)|^2dy\ge 0$. By Tonelli's theorem and left invariance, $\int_G R_\mu\,dg=\int_K\int_G|c(y^{-1}g)|^2dg\,dy=\int_G|c|^2dg=d^{-1}$. So R_μ is integrable and $d\int_G R_\mu\,dg=1$.

Step 3: off the cone. If $\nu-\mu\notin C_l$, there is $o\in\mathbb{Z}^n$ with $o(a)<o(b)$ whenever $l_b<l_a$ and $o\cdot(\nu-\mu)>0$. By Lemma 5.6.31 (ii) the inner integral in (5.126) vanishes for every y, so $R_\nu=0$: R_ν is integrable with integral 0.

Step 4: the representation generated by c. On $L^2(G)=L^2(G,dg)$ let $\langle u,w\rangle=\int_G\overline{u}\,w\,dg$ and $(R_xf)(g)=f(gx)$. By right invariance each R_x is unitary, $R_xR_{x'}=R_{xx'}$, and $x\mapsto R_xf$ is continuous (continuity of translation in L^2 of a locally compact group). Let V be the closed span of the R_xc, $x\in G$; it is $R(G)$-stable. For $x,y\in G$, the substitution $g\mapsto gx^{-1}$ and Lemma 5.6.23 (ii) with $(x,a)=(1,x^{-1}y)$ give

$$\langle R_xc,R_yc\rangle=\int_G\overline{c(g)}\,c(gx^{-1}y)\,dg=d^{-1}c(1)c(x^{-1}y)=d^{-1}c(x^{-1}y). \tag{5.127}$$

We show

$$\int_G|\langle R_gc,u\rangle|^2\,dg=d^{-2}\|u\|^2\qquad(u\in V). \tag{5.128}$$

Let first $u=\sum_i\alpha_iR_{x_i}c$, a finite sum. By (5.127),

$$\langle R_gc,u\rangle=d^{-1}\sum_i\alpha_ic(g^{-1}x_i)\quad\text{and}\quad\overline{c(g^{-1}x_i)}\,c(g^{-1}x_j)=c(x_i^{-1}g)\,\overline{c(x_j^{-1}g)};$$

the substitution $g=x_jy$ and Lemma 5.6.23 (ii) with $(x,a)=(x_i^{-1}x_j,1)$ give

$$\int_G c(x_i^{-1}g)\overline{c(x_j^{-1}g)}\,dg=d^{-1}c(x_i^{-1}x_j)=\langle R_{x_i}c,R_{x_j}c\rangle.$$

Summing with the weights $\overline{\alpha_i}\alpha_j$ gives (5.128) for u. For general $u\in V$ choose u_m in the span with $u_m\to u$. By the case just shown, applied to $u_m-u_{m'}$, the functions $F_m(g)=\langle R_gc,u_m\rangle$ form a Cauchy sequence in $L^2(G)$; they converge pointwise to $F(g)=\langle R_gc,u\rangle$, since $|F_m(g)-F(g)|\le\|c\|\,\|u_m-u\|$. A subsequence of an L^2-convergent sequence converges almost everywhere, so the L^2 limit is F and $\|F\|_2=\lim\|F_m\|_2=d^{-1}\|u\|$.

Step 5: V is irreducible. Define the bounded operator Q on $L^2(G)$ by

$$\langle w,Qf\rangle=\|m_\mu\|^{-2}\int_K\overline{m_\mu(k)}\,\langle w,R_kf\rangle\,dk$$

(the integrand is continuous in k and bounded by $\sup_K |m_\mu| \, \|w\| \, \|f\|$; Riesz's theorem). Let $b \in G$ and $w \in L^2(G)$. The function $(k,g) \mapsto \overline{m_\mu(k)}\,\overline{w(g)}\,c(gkb)$ is integrable on $K \times G$, because $\int_K \int_G |w(g)|\,|c(gkb)|\,dg\,dk \le \|w\|\,\|c\|$ (Cauchy–Schwarz and right invariance) and m_μ is bounded on K. So Fubini's theorem and Lemma 5.6.31 (i) with $x = g$ give

$$\langle w, QR_b c\rangle = \|m_\mu\|^{-2} \int_G \overline{w(g)} \int_K \overline{m_\mu(k)}\, c(gkb)\, dk\, dg = c(b)\,\langle w, c\rangle,$$

that is, $QR_b c = c(b)\,c$. By linearity and continuity $Q(V) \subseteq \mathbb{C}c$, and $Qc = c(1)c = c$. Now let A be a bounded operator on V with $AR_x u = R_x A u$ for $x \in G$, $u \in V$, and let A^* be its adjoint on V. For $u, w \in V$,

$$\begin{aligned}\langle w, QAu\rangle &= \frac{1}{\|m_\mu\|^2} \int_K \overline{m_\mu(k)}\,\langle w, AR_k u\rangle\, dk \\ &= \frac{1}{\|m_\mu\|^2} \int_K \overline{m_\mu(k)}\,\langle A^* w, R_k u\rangle\, dk = \langle A^* w, Qu\rangle = \langle w, AQu\rangle,\end{aligned}$$

and QAu, AQu lie in V, so $QA = AQ$ on V. Hence $Ac = AQc = QAc \in \mathbb{C}c$, say $Ac = \alpha c$; then $AR_x c = R_x A c = \alpha R_x c$ for every x, and $A = \alpha$ on V by linearity and continuity. If $V' \subseteq V$ is a closed $R(G)$-stable subspace, then so is its orthogonal complement in V (the R_x are unitary and preserve V), so the orthogonal projection of V onto V' commutes with every R_x and is 0 or 1. As $c \ne 0$, $V \ne 0$; so R restricted to V is an irreducible unitary representation of G.

Step 6: $m(\nu)$ is a nonnegative integer. Let τ_ν be the irreducible representation of K with character χ_ν^K, $d_\nu = \chi_\nu^K(1)$ its dimension, and V_ν the closed span of the K-subrepresentations of V isomorphic to τ_ν. By Theorem A.5.17 (1) (with $j = \varepsilon$) and Step 5, V_ν is finite-dimensional. A finite-dimensional space spanned by irreducible K-stable subspaces, all isomorphic to τ_ν, is the direct sum of some of them, so $\dim V_\nu = r_\nu d_\nu$ with $r_\nu \in \mathbb{N}$. By the Peter–Weyl theory for the unitary representation $k \mapsto R_k|_V$ of the compact group K ([163], Chapter I), the operator E on V defined by $\langle w, Eu\rangle = d_\nu \int_K \overline{\chi_\nu^K(k)}\,\langle w, R_k u\rangle\, dk$ is the orthogonal projection of V onto V_ν. Let $e_1, \dots, e_D$ be an orthonormal basis of V_ν, $D = r_\nu d_\nu$. For $g \in G$ and $k \in K$, (5.127) with $(x,y) = (g, kg)$ gives $c(g^{-1}kg) = d\,\langle R_g c, R_k R_g c\rangle$, and $R_g c \in V$; hence

$$R_\nu(g) = d \int_K \overline{\chi_\nu^K(k)}\,\langle R_g c, R_k R_g c\rangle\, dk = \frac{d}{d_\nu}\,\langle R_g c, E R_g c\rangle = \frac{d}{d_\nu}\,\|E R_g c\|^2 = \frac{d}{d_\nu} \sum_{i=1}^{D} |\langle R_g c, e_i\rangle|^2.$$

This is a nonnegative continuous function of g, and by (5.128), $\int_G R_\nu\, dg = \frac{d}{d_\nu}\, D\, d^{-2} = r_\nu / d$. So R_ν is integrable and $m(\nu) = d \int_G R_\nu\, dg = r_\nu$ is a nonnegative integer. With Step 2, $m(\mu) = 1$; with Step 3, $m(\nu) = 0$ unless $\nu - \mu \in C_l$. □

Lemma 5.7.8. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon \in \{\pm 1\}^n$, let $l \in \mathbb{Z}^n$ have large gap $10N^5$ for ε, $\lambda = \frac{1}{2} l$, $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$ with its Cayley measure dg, $d_\lambda = (\int_G |c_\lambda|^2 dg)^{-1}$, $K = K_\varepsilon$, $N' = 4N^2$, $\|\cdot\|$ the operator norm, and*

$$D(x) = \prod_{\substack{\varepsilon_a \ne \varepsilon_b \\ l_a < l_b}} (x_a - x_b) \qquad (x \in \mathbb{C}^n),$$

the product over ordered pairs; for $x \in \mathbb{C}^n$ with $|x_a| = 1$ let $t_x = \mathrm{diag}(x)$. Then:

(i) there is a continuous function d on K with $d(yky^{-1}) = d(k)$ and $d(yt_x y^{-1}) = D(x)^{N'+1}$ for all $y, k \in K$ and all x with $|x_a| = 1$;

(ii) there is a dg-integrable function Φ on G with $|d(k)\, c_\lambda(g^{-1}kg)| \le \Phi(g)$ for all $k \in K$, $g \in G$;

(iii) the function $h(k) = d_\lambda \int_G d(k)\, c_\lambda(g^{-1}kg)\, dg$ *is continuous on* K *with* $h(yky^{-1}) = h(k)$, *and for every* x *with* $|x_a| = 1$ *and* $D(x) \neq 0$ *the function* $g \mapsto c_\lambda(g^{-1}t_x g)$ *is* dg*-integrable and*

$$h(yt_xy^{-1}) = D(x)^{N'+1}\, d_\lambda \int_G c_\lambda(g^{-1}t_x g)\, dg \qquad (y \in K).$$

Proof. Let $n_\pm = \{a : \varepsilon_a = \pm 1\}$, $p = \#n_+$, $q = \#n_-$; write matrices in blocks for $n = n_+ \sqcup n_-$, so that $K = \mathrm{U}(n_+) \times \mathrm{U}(n_-)$ consists of the block-diagonal unitary $k = (k_+, k_-)$. Every factor of D is $\pm(x_a - x_b)$ with $a \in n_+$, $b \in n_-$, and every such pair occurs once, so $D = \sigma_D\, D_+$ with $D_+(x) = \prod_{a\in n_+,\, b\in n_-}(x_a - x_b)$ and a fixed sign σ_D. The large gap gives gap $h_0 = 500N^3 + 10N^5$, and $pq(N'+1) \leq N^2(4N^2+1) \leq h_0$.

(i). Put $R(k) = \det(k_+ \otimes 1 - 1 \otimes k_-)$ on $\mathbb{C}^{n_+} \otimes \mathbb{C}^{n_-}$ (for $p = 0$ or $q = 0$, $R = 1$), a polynomial in the entries of k, and $d = (\sigma_D R)^{N'+1}$. For $y \in K$, $(yky^{-1})_+ \otimes 1 - 1 \otimes (yky^{-1})_-$ is the conjugate of $k_+ \otimes 1 - 1 \otimes k_-$ by $y_+ \otimes y_-$, so d is a class function; at $k = t_x$ the operator is diagonal with entries $x_a - x_b$, so $d(t_x) = (\sigma_D D_+(x))^{N'+1} = D(x)^{N'+1}$.

A bound for the noncompact root product. Let $u \in G$, $|x_a| = 1$ and $g' = u^{-1}t_x u$. Then

$$\Big(\frac{\|u\|}{2}\Big)^2 |D(x)| \leq (2\|g'\|)^{pq}. \tag{5.129}$$

If $p = 0$ or $q = 0$, then G is a unitary group, $\|u\| = \|g'\| = 1$ and $D = 1$, and (5.129) is clear; let $p, q \geq 1$ and write $u = \begin{pmatrix} A & B \\ C & E \end{pmatrix}$. From $u^*Ju = J$, $A^*A = 1 + C^*C$ and $E^*E = 1 + B^*B$; from $uJu^* = J$ (as $u^{-1} = Ju^*J$), $EE^* = 1 + CC^*$. So all singular values of A are ≥ 1, $\|A\|^2 = 1 + \|C\|^2 = \|E\|^2$ and $\|B\|^2 = \|E\|^2 - 1$; hence $\|u\|^2 \leq \|AA^* + BB^*\| + \|CC^* + EE^*\| \leq \|A\|^2 + \|B\|^2 + \|C\|^2 + \|E\|^2 \leq 4\|A\|^2$, and $(\|u\|/2)^2 \leq \|A\|^2 \leq |\det A|^2$. Let $T = \prod_{b\in n_-}(t_x - x_b)$, diagonal with $T_{aa} = 0$ for $a \in n_-$ and $T_{aa} = \prod_{b\in n_-}(x_a - x_b)$ for $a \in n_+$, and $M = u^{-1}Tu = \prod_{b\in n_-}(g' - x_b)$. As T vanishes on n_-, the $n_+ \times n_+$ block of M is $(u^{-1})_{++}T_{++}A$, and $(u^{-1})_{++} = (Ju^*J)_{++} = A^*$; so $\Delta_{n_+}(M) = |\det A|^2 D_+(x)$. On the other hand $\|g'\| \geq 1$ (it lies in G; apply the above to g'), so $\|M\| \leq (\|g'\| + 1)^q \leq (2\|g'\|)^q$, and a principal minor of size p is at most $\|M\|^p$ in modulus. This gives (5.129).

(ii). Let $k \in K$, $g \in G$. By the spectral theorem in each block, $k = yt_xy^{-1}$ with $y \in K$ and $|x_a| = 1$; put $u = y^{-1}g \in G$, so $\|u\| = \|g\|$ and $g^{-1}kg = u^{-1}t_x u = g'$. By Lemma 5.7.40 with $c = pq(N'+1) \leq h_0$ and (5.129),

$$\begin{aligned} |d(k)\, c_\lambda(g^{-1}kg)| = |D(x)|^{N'+1}|c_\lambda(g')| &\leq \Big(\frac{(2\|g'\|)^{pq}\, 4}{\|g\|^2}\Big)^{N'+1}\Big(\frac{2}{\|g'\|}\Big)^{pq(N'+1)} \\ &= 4^{pq(N'+1)}\Big(\frac{2}{\|g\|}\Big)^{2N'+2} = \Phi(g). \end{aligned}$$

Φ is integrable by Lemma 5.7.38 (3) with $c = 2N'+2 = 8N^2+2 > 8N^2$ (dg is a Haar measure by Lemma 5.2.41, and $d_\lambda > 0$).

(iii). c_λ is continuous (Lemma 5.6.23 (i)), so $(k, g) \mapsto d(k)c_\lambda(g^{-1}kg)$ is continuous and, by (ii) and dominated convergence, h is continuous. For $y \in K$, the substitution $g \mapsto yg$ (left invariance, Lemma 5.2.41) and $d(yky^{-1}) = d(k)$ give $h(yky^{-1}) = h(k)$. If $D(x) \neq 0$, then $|c_\lambda(g^{-1}t_x g)| \leq \Phi(g)/|D(x)|^{N'+1}$, so the orbital integral converges absolutely, and $h(yt_xy^{-1}) = h(t_x) = D(x)^{N'+1} d_\lambda \int_G c_\lambda(g^{-1}t_x g)\, dg$. □

Lemma 5.7.9. *Let* n *be a nonempty finite set,* $\varepsilon \in \{\pm 1\}^n$, $l \in \mathbb{Z}^n$ *injective,* $K = K_\varepsilon$, *and for* $x \in \mathbb{C}^n$ *with* $|x_a| = 1$ *let* $t_x = \mathrm{diag}(x)$. *Put* $\delta_{\mathrm{c}}(a) = \#\{b : \varepsilon_b = \varepsilon_a,\ l_b < l_a\}$ *and* $V_{\mathrm{c}} = \prod_{\varepsilon_a = \varepsilon_b,\ l_b < l_a}(X_a - X_b)$ *(ordered pairs).*

(a) *(Weyl) For K-dominant ν and every x with $|x_a| = 1$, $V_{\mathrm{c}}(x)\,\chi^K_\nu(t_x) = A^\varepsilon_{\nu+\delta_{\mathrm{c}}}(x)$.*

(b) *(Straightening) For every $e \in \mathbb{Z}^n$ there are $s_e \in \{0, 1, -1\}$ and a K-dominant ν_e with $A^\varepsilon_e = s_e\, A^\varepsilon_{\nu_e+\delta_{\mathrm{c}}}$; and for K-dominant μ and $\gamma \in \mathbb{Z}^n$, the coefficient of X^γ in $A^\varepsilon_{\mu+\delta_{\mathrm{c}}}$ is s_γ if $s_\gamma \neq 0$ and $\nu_\gamma = \mu$, and 0 otherwise.*

(c) *(Brauer's rule) Let $D \in \mathcal{R}$ satisfy $D_{\beta\circ w} = D_\beta$ for $w \in W_K$, and let d be a continuous function on K with $d(yt_xy^{-1}) = D(x)$ for $y \in K$ and $|x_a| = 1$. Then for every continuous f on K and every K-dominant ν,*

$$\int_K \overline{\chi^K_\nu(k)}\, d(k) f(k)\, dk = \sum_\beta D_\beta\, s_{\nu+\delta_{\mathrm{c}}-\beta} \int_K \overline{\chi^K_{\nu_{\nu+\delta_{\mathrm{c}}-\beta}}(k)}\, f(k)\, dk.$$

Proof. Let $n_\pm = \{a : \varepsilon_a = \pm 1\}$, so $K = \mathrm{U}(n_+) \times \mathrm{U}(n_-)$ and $W_K = S(n_+) \times S(n_-)$; every element of K is yt_xy^{-1} with $y \in K$ and $|x_a| = 1$ (spectral theorem in each block). Call x regular if $x_a \neq x_b$ whenever $a \neq b$ and $\varepsilon_a = \varepsilon_b$; the regular points are dense in the torus. For $\mu \in \mathbb{Z}^n$, $A^\varepsilon_\mu = A^+_\mu A^-_\mu$ with $A^\pm_\mu = \sum_{v\in S(n_\pm)} \mathrm{sgn}(v) \prod_{a\in n_\pm} X_a^{\mu(v(a))}$, as sgn is multiplicative on W_K.

(a). The irreducible representation of K of highest weight ν is the outer tensor product of the irreducible representations of $\mathrm{U}(n_\pm)$ of highest weights $\nu|_{n_\pm}$ (for the diagonal tori and the upper triangular Borel subgroups in the numberings by decreasing l), so $\chi^K_\nu(t_x) = \chi^+(t_{x,+})\chi^-(t_{x,-})$. Number n_+ as $a_0, \dots, a_{p-1}$ by decreasing l; then $\delta_{\mathrm{c}}(a_i) = p - 1 - i$ and $\nu(a_0) \geq \cdots \geq \nu(a_{p-1})$. For regular x, Theorem A.5.20 gives $\chi^+(t_{x,+}) = \det(x_{a_k}^{\nu(a_j)+p-1-j})_{j,k} / \det(x_{a_k}^{p-1-j})_{j,k}$; by the Leibniz formula (with $v(a_j) = a_{\pi(j)}$) the numerator is $A^+_{\nu+\delta_{\mathrm{c}}}(x)$, and the denominator is $\prod_{j<k}(x_{a_j} - x_{a_k}) = \prod_{a,b\in n_+,\, l_b<l_a}(x_a - x_b)$. The same holds for n_-, and V_{c} is the product of the two Vandermonde products. So (a) holds at regular x, and at all x by continuity of both sides.

(b). If $e(a) = e(b)$ for some $a \neq b$ with $\varepsilon_a = \varepsilon_b$, the transposition τ of a, b lies in W_K, is odd and fixes e, so $A^\varepsilon_e = \sum_w \mathrm{sgn}(\tau w) X^{e\circ\tau w} = -A^\varepsilon_e$; take $s_e = 0$ and any ν_e. Otherwise there is a unique $w_0 \in W_K$ such that $e' = e \circ w_0$ satisfies $e'(i) > e'(j)$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$. Put $\nu_e = e' - \delta_{\mathrm{c}}$ and $s_e = \mathrm{sgn}(w_0)$. If $\varepsilon_i = \varepsilon_j$, $l_i > l_j$ and no c of the same sign has $l_j < l_c < l_i$, then $\delta_{\mathrm{c}}(i) = \delta_{\mathrm{c}}(j) + 1$ and $e'(i) \geq e'(j) + 1$, so $\nu_e(i) \geq \nu_e(j)$; by transitivity ν_e is K-dominant. Substituting $w = w_0w'$, $A^\varepsilon_e = \sum_{w'} \mathrm{sgn}(w_0w') X^{e'\circ w'} = s_e A^\varepsilon_{\nu_e+\delta_{\mathrm{c}}}$. For the second claim: $\mu + \delta_{\mathrm{c}}$ is strictly decreasing along decreasing l in each block, so the monomials $X^{(\mu+\delta_{\mathrm{c}})\circ w}$, $w \in W_K$, are distinct, and X^γ occurs iff $\gamma = (\mu + \delta_{\mathrm{c}}) \circ w$ for some w, with coefficient $\mathrm{sgn}(w)$; this holds iff γ has distinct entries in each block, $w_0 = w^{-1}$ for γ, i.e. $\nu_\gamma = \mu$, and then $\mathrm{sgn}(w) = s_\gamma$.

(c). For $|x_a| = 1$, $\overline{D(x)} = \sum_\beta \overline{D_\beta} x^{-\beta}$. By the invariance of the coefficients of D, reindexing $\beta \mapsto \beta \circ w$ in each term,

$$\overline{D(x)}\, A^\varepsilon_{\nu+\delta_{\mathrm{c}}}(x) = \sum_w \mathrm{sgn}(w) \sum_\beta \overline{D_\beta}\, x^{(\nu+\delta_{\mathrm{c}}-\beta)\circ w} = \sum_\beta \overline{D_\beta}\, A^\varepsilon_{\nu+\delta_{\mathrm{c}}-\beta}(x) = \sum_\beta \overline{D_\beta}\, s_e\, A^\varepsilon_{\nu_e+\delta_{\mathrm{c}}}(x),$$

with $e = \nu + \delta_{\mathrm{c}} - \beta$, by (b). By (a), at regular x (where $V_{\mathrm{c}}(x) \neq 0$) this says $\overline{d}\,\chi^K_\nu = \sum_\beta \overline{D_\beta} s_e \chi^K_{\nu_e}$ at t_x; by continuity at every t_x, and since both sides are class functions on K, on all of K. Multiplying the complex conjugate of this identity by f and integrating gives (c) (s_e is real). □

Proposition 5.7.10. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have large gap $10N^5$ for ε; put $\lambda = \frac{1}{2}l$, $J = \mathrm{diag}(\varepsilon)$, let dg be the Cayley measure of $\mathrm{U}(\mathrm{diag}\,\varepsilon)$, and for $x \in \mathbb{C}^n$ with $|x_a| = 1$ let $t_x = \mathrm{diag}(x)$. Let Λ_{c} be the lowest K-type of l for the signs $(1, \dots, 1)$, $\|m_{\Lambda_{\mathrm{c}}}\|^2 = \int_{\mathrm{U}(n)} |m_{\Lambda_{\mathrm{c}}}(k)|^2 dk$ (dk the Haar probability measure), and χ the character of the irreducible representation of $\mathrm{U}(n)$ whose highest weight, in the numbering of n by decreasing*

l, is Λ_{c}. Let $\mathcal{R}$, the coefficients P_γ, exponents, the level $o\cdot\gamma$, κ and $h = 500N^3 + 10N^5$ be as in Lemma 5.7.18. There are $\sigma \in \mathbb{C}$ with $|\sigma| = 1$ and a function Off *on the accretive $n\times n$ matrices such that:*

(a) for every x with $|x_a| = 1$, pairwise distinct entries and Jt_x accretive,

$$\sigma \int_{\mathrm{U}(\operatorname{diag}\varepsilon)} c_\lambda(g^{-1}t_x g)\,dg = \|m_{\Lambda_{\mathrm{c}}}\|^2\,\chi(t_x) - \mathrm{Off}(Jt_x);$$

(b) if $P, Q \in \mathcal{R}$ satisfy $P(x) = Q(x)\,\mathrm{Off}(Jt_x)$ for every such x, and $\gamma \in \mathbb{Z}^n$ satisfies $o\cdot\gamma < o\cdot(\kappa - o) + o\cdot\beta + h$ for every exponent β of Q, then $P_\gamma = 0$.

Proof. Write $G = \mathrm{U}(\operatorname{diag}\varepsilon)$, $K = K_\varepsilon$, $\mu = \mu_l$ (for the signs ε), $\Lambda = \Lambda_{\mathrm{c}}$, $m = m_\Lambda$, $\|m\|^2 = \|m_\Lambda\|^2$, and let dk, du, dv, dy denote the Haar probability measure of $\mathrm{U}(n)$. The vector l has gap $h = 500N^3 + 10N^5$, in particular gap 0, so its entries are distinct and $\equiv N-1 \pmod 2$. For a diagonal matrix $\operatorname{diag}(d)$, $m_w(\operatorname{diag}(d)) = \prod_a d_a^{w_a}$ ((5.134) of Lemma 5.7.13). By Lemma 5.6.27 (iii), l^ρ is strictly increasing along l, $\mu(i) \ge \mu(j)$ whenever $\varepsilon_i = \varepsilon_j$ and $l_i > l_j$, and $\Lambda(i) \ge \Lambda(j)$ whenever $l_i > l_j$; and $\Lambda = l^\rho - 2\rho_l$ ($2\rho_l^{\mathrm{c}} = 2\rho_l$ for constant signs). Put

$$\sigma = m_{-\Lambda-\mu}(J) = \prod_a \varepsilon_a^{-\Lambda(a)-\mu(a)}, \qquad \text{Off the off-orbit integral of Lemma 5.7.13 for } (\varepsilon, l);$$

$|\sigma| = 1$, and neither depends on x.

Step 1: the density. Fix x with $|x_a| = 1$, distinct entries and $A = Jt_x$ accretive. For $y \in \mathrm{GL}_n(\mathbb{C})$, y^*Ay is accretive ($y^*(A + A^*)y$ is positive definite), so its principal minors are nonzero (Lemma 5.6.25 (ii)), and y^*Jy is invertible; so

$$F(y) = \frac{m_{-\Lambda}(y^*Jy)}{m_{-l^\rho}(y^*Ay)}$$

is continuous on $\mathrm{GL}_n(\mathbb{C})$. The weights $-\Lambda$ and $-l^\rho$ are nonincreasing along l, so Lemma 5.6.27 (ii), for the signs $(1,\dots,1)$ and the vector $-l$ (whose triangular group is B_l'), gives $m_w(b^*Zb) = |b^w|^2 m_w(Z)$ for $b \in \mathrm{B}_l'$ and $w \in \{-\Lambda, -l^\rho\}$. With $(yb)^*M(yb) = b^*(y^*My)b$,

$$F(yb) = \left|b^{l^\rho-\Lambda}\right|^2 F(y) = \left|b^{2\rho_l}\right|^2 F(y) \qquad (b \in \mathrm{B}_l').$$

By Lemma 5.7.11, F is integrable on G and, by the definition of Off,

$$\int_G F(g)\,dg = \int_{\mathrm{U}(n)\cap\Omega_{\varepsilon,l}} F(k)\,dk = \int_{\mathrm{U}(n)} F(k)\,dk - \mathrm{Off}(Jt_x). \tag{5.130}$$

Step 2: the orbital integral. Let $g \in G$. Then $g^{-1}t_x g \in G$, and since $g^{-1} = Jg^*J$, $J^{-1}(g^{-1}t_x g) = g^*Ag$ is accretive; J is block-diagonal. By Lemma 5.6.26 (i) and (3.2),

$$c_\lambda(g^{-1}t_x g) = \mathrm{FJ}_l(J, g^*Ag) = \frac{1}{\|m_\mu\|^2}\int_K \frac{m_\mu(Jk)\,\overline{m_\mu(k)}}{m_{-l^\rho}(k^*g^*Agk)}\,dk.$$

By Lemma 5.6.27 (ii) (with $c = J$, $b = 1$), $m_\mu(Jk) = J^\mu m_\mu(k)$, $J^\mu = \prod_a \varepsilon_a^{\mu(a)}$. For $k \in K$, $k^*g^*Jgk = k^*Jk = J$, so $F(gk) = m_{-\Lambda}(J)/m_{-l^\rho}((gk)^*A(gk))$ with $m_{-\Lambda}(J) = \prod_a \varepsilon_a^{\Lambda(a)}$. Hence, with $w(k) = |m_\mu(k)|^2/\|m_\mu\|^2$, a continuous function of integral 1 on K,

$$\sigma\, c_\lambda(g^{-1}t_x g) = \int_K w(k)\,F(gk)\,dk.$$

By Tonelli and the right invariance of dg under $K \subseteq G$ (Lemma 5.2.41), $\int_G \int_K w(k)|F(gk)|\,dk\,dg = \int_G |F|\,dg < \infty$; so $g \mapsto c_\lambda(g^{-1}t_x g)$ (continuous, as a parameter integral over K) is integrable on G, and by Fubini

$$\sigma \int_G c_\lambda(g^{-1}t_x g)\,dg = \int_K w(k) \int_G F(gk)\,dg\,dk = \int_G F(g)\,dg. \tag{5.131}$$

Step 3: the integral over the unitary group. Number n by decreasing l; this numbering has Λ nonincreasing, so Lemma 5.7.16 applies to $\nu = \Lambda$, with $\chi_\Lambda = \chi$. Let ρ, e be as in its (i) and $d = d_\Lambda$. For the signs $(1, \dots, 1)$, $K_{(1,\dots,1)} = \mathrm{U}(n)$, every matrix is block-diagonal, the lowest K-type of l is Λ, and Flensted-Jensen's function c^{c} of λ for these signs satisfies, for $h' \in \mathrm{U}(n)$ (where $\mathrm{bd}(h') = h'$ and $m_{-l^\rho}(k^*k) = 1$),

$$c^{\mathrm{c}}(h') = \frac{1}{\|m\|^2} \int_{\mathrm{U}(n)} m(h'k)\overline{m(k)}\,dk = d \int \langle \rho(h')^* e, \rho(k)e\rangle \overline{\langle e, \rho(k)e\rangle}\,dk = \langle \rho(h')^* e, e\rangle = m(h'),$$

by Lemma 5.7.16 (i), (ii) and Schur's orthogonality relations. Let $y \in \mathrm{U}(n)$, $a_y = y^{-1}Jy$ (unitary) and $z_y = y^{-1}Ay$ (accretive); then $a_y z_y = y^{-1}t_x y \in \mathrm{U}(n)$ and $a_y^{-1}(a_y z_y) = z_y$, so by Lemma 5.6.26 (i) for the signs $(1, \dots, 1)$,

$$m(y^{-1}t_x y) = c^{\mathrm{c}}(a_y z_y) = \mathrm{FJ}_l^{\mathrm{c}}(a_y, z_y) = \frac{1}{\|m\|^2} \int_{\mathrm{U}(n)} \frac{m(a_y k)\,\overline{m(k)}}{m_{-l^\rho}(k^* z_y k)}\,dk,$$

$\mathrm{FJ}_l^{\mathrm{c}}$ being Flensted-Jensen's integral for these signs. The integrand is continuous on $\mathrm{U}(n) \times \mathrm{U}(n)$ in (y, k). By Lemma 5.7.16 (iv) and the substitution $(y, k) = (vu, u^{-1})$, which preserves $dy\,dk$ (right translation in the first factor, then inversion in the second), under which $a_y k = u^{-1}a_v$, $\overline{m(u^{-1})} = m(u)$ (Lemma 5.6.27 (i)) and $k^* z_y k = v^* A v$,

$$\|m\|^2 \chi(t_x) = \int m(y^{-1}t_x y)\,dy = \frac{1}{\|m\|^2} \int_{\mathrm{U}(n)} \frac{\int_{\mathrm{U}(n)} m(u^{-1}a_v)\,m(u)\,du}{m_{-l^\rho}(v^*Av)}\,dv = \int_{\mathrm{U}(n)} \frac{m(a_v)}{m_{-l^\rho}(v^*Av)}\,dv,$$

by Lemma 5.7.16 (iii). Finally $m(a_v) = m_{-\Lambda}(a_v^{-1}) = m_{-\Lambda}(v^*Jv)$ by Lemma 5.6.27 (i) and $J^{-1} = J$; so $\|m\|^2 \chi(t_x) = \int_{\mathrm{U}(n)} F\,dv$.

Step 4: (a). By (5.131), (5.130) and Step 3, $\sigma \int_G c_\lambda(g^{-1}t_x g)\,dg = \|m_{\Lambda_{\mathrm{c}}}\|^2 \chi(t_x) - \mathrm{Off}(Jt_x)$.

Step 5: (b). The vector $o(a) = \#\{b : l_b > l_a\}$ satisfies $o(a) < o(b)$ whenever $l_b < l_a$, and $2\rho_l(a) = N - 1 - 2o(a)$, so $l^\rho = \frac{1}{2}(l + 2\rho_l) = \kappa - o$. Hence the hypothesis of (b) reads $o \cdot \gamma < o \cdot l^\rho + o \cdot \beta + h$ for every exponent β of Q, and l has gap h; Lemma 5.7.15 gives $P_\gamma = 0$. □

Lemma 5.7.11. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$ with its Cayley measure dg, $\mathrm{U}(n)$ the group of unitary $n \times n$ matrices with its Haar probability measure dk, and $l \in \mathbb{Z}^n$ injective. For $b \in \mathrm{B}_l'$ and $w \in \mathbb{Z}^n$ put $b^w = \prod_i b_{ii}^{w_i}$. Let $F\colon \mathrm{GL}_n(\mathbb{C}) \to \mathbb{C}$ be continuous with*

$$F(yb) = \left|b^{2\rho_l}\right|^2 F(y) \qquad (y \in \mathrm{GL}_n(\mathbb{C}),\ b \in \mathrm{B}_l').$$

Then F restricted to G is dg-integrable, and

$$\int_G F(g)\,dg = \int_{\mathrm{U}(n) \cap \Omega_{\varepsilon,l}} F(k)\,dk.$$

Proof. Write $\Omega = \Omega_{\varepsilon,l}$, $N = \#n$, $J = \operatorname{diag}(\varepsilon)$, and let dt be the Haar probability measure of the compact group T. Call a function Φ on $\mathrm{GL}_n(\mathbb{C})$ a density if $\Phi(yb) = |b^{2\rho_l}|^2\Phi(y)$ for all y and $b \in \mathrm{B}'_l$. By Lemma 5.6.28, applied to the signs $(1,\dots,1)$ and the vector $-l$ (then the group $K_{\mathbb{C}}$ there is $\mathrm{GL}_n(\mathbb{C})$, K_ε is $\mathrm{U}(n)$, its triangular group is B'_l, and $-2\rho^{\mathrm{c}}_{-l} = 2\rho_l$),

$$\int_{\mathrm{U}(n)} \Phi(xk)\,dk = \int_{\mathrm{U}(n)} \Phi(k)\,dk \qquad (x \in \mathrm{GL}_n(\mathbb{C})) \tag{5.132}$$

for every continuous density Φ.

Step 1: an invariant functional. For $f \in C_c(G)$ let $F_f(y) = |\beta(y)^{2\rho_l}|^2 \int_{\mathrm{T}} f(\gamma(y)t)\,dt$ for $y \in \Omega$ and $F_f(y) = 0$ for $y \in \mathrm{GL}_n(\mathbb{C}) \smallsetminus \Omega$. It is a density: for $y \in \Omega$ and $b \in \mathrm{B}'_l$, Lemma 5.7.12 (i) gives $\gamma(yb) = \gamma(y)t_b$ and $|\beta(yb)^{2\rho_l}| = |\beta(y)^{2\rho_l}|\,|b^{2\rho_l}|$, and dt is invariant under t_b; if $y \notin \Omega$ then $yb \notin \Omega$. It is continuous: $C = \operatorname{supp}(f)\,\mathrm{T}$ is compact, $C\mathrm{B}'_l$ is closed in $\mathrm{GL}_n(\mathbb{C})$ (a product of a compact set and a closed subgroup) and contained in Ω, F_f vanishes outside it, and F_f is continuous on the open set Ω by Lemma 5.7.12 (ii); the open sets Ω and $\mathrm{GL}_n(\mathbb{C}) \smallsetminus C\mathrm{B}'_l$ cover $\mathrm{GL}_n(\mathbb{C})$. Moreover, for $g_0 \in G$, $\gamma(g_0^{-1}y) = g_0^{-1}\gamma(y)$ and $\beta(g_0^{-1}y) = \beta(y)$, so the function $f(g_0^{-1}\cdot)$ gives the density $F_f(g_0^{-1}\cdot)$. Put

$$\Lambda(f) = \int_{\mathrm{U}(n)} F_f(k)\,dk.$$

Λ is a positive linear functional on $C_c(G)$, and left invariant by (5.132) with $x = g_0^{-1}$. By Lemma 5.2.41 the Cayley measure is a Haar measure of the locally compact group G, so by the Riesz representation theorem and the uniqueness of Haar measure there is $c \geq 0$ with $\Lambda(f) = c\int_G f\,dg$ for all $f \in C_c(G)$. For $t \in \mathrm{T}$, right translation by t preserves $\mathrm{U}(n) \cap \Omega$ and dk, and $\gamma(kt) = \gamma(k)t$, $|\beta(kt)^{2\rho_l}| = |\beta(k)^{2\rho_l}|$; so by Fubini on $\mathrm{U}(n) \times \mathrm{T}$,

$$\Lambda(f) = \int_{\mathrm{U}(n)\cap\Omega} \bigl|\beta(k)^{2\rho_l}\bigr|^2 f(\gamma(k))\,dk. \tag{5.133}$$

Step 2: the unitary factor. For $g \in G$ let $g = \phi(g)b$ with $\phi(g)$ unitary and $b \in \mathrm{B}^+_l$ (Lemma 5.7.12 (iii)). Then $\phi(g) = gb^{-1} \in \mathrm{U}(n) \cap \Omega$ and $\gamma(\phi(g)) = g$; for $k \in \mathrm{U}(n) \cap \Omega$, $\gamma(k) = k\beta(k)^{-1}$, so $\phi(\gamma(k)) = k$. By Lemma 5.7.12 (ii) (also for the signs $(1,\dots,1)$), ϕ is a diffeomorphism of G onto the open subset $\mathrm{U}(n) \cap \Omega$ of $\mathrm{U}(n)$, with inverse γ. Let $\mathfrak{t}_l$ be the real space of the Y with $Y_{ij} = 0$ for $l_i > l_j$ and real diagonal. Differentiating $g = \phi(g)\,b(g)$ at $g = 1$ in the direction $X \in \mathfrak{u}(J) = \{X : X^*J + JX = 0\}$ gives $X = d\phi_1(X) + Z$ with $d\phi_1(X)$ skew-hermitian and $Z \in \mathfrak{t}_l$; a skew-hermitian matrix in $\mathfrak{t}_l$ is 0 (its entries below the pattern vanish, hence all off-diagonal entries, and its diagonal is imaginary and real), so this decomposition is unique: $d\phi_1(X) = K$ with $K_{ij} = X_{ij}$ for $l_i > l_j$ and $K_{ii} = X_{ii}$ (the diagonal of $X \in \mathfrak{u}(J)$ is imaginary).

Step 3: the differential in Cayley coordinates. Let $T_J(y) = JS(y)$ and $T_1(y) = S(y)$ for $y \in \mathrm{M}_n(\mathbb{R})$, the coordinates of Definition 3.2.1, and $L = T_1^{-1} \circ d\phi_1 \circ T_J$. For $X = JS(y)$ and $K = d\phi_1(X) = S(y')$: $\mathrm{i}y'_{ii} = K_{ii} = \varepsilon_i \mathrm{i} y_{ii}$, and for $l_i > l_j$, $S(y')_{ij} = K_{ij} = \varepsilon_i S(y)_{ij}$. Since $(y_{ij}, y_{ji}) \mapsto S(y)_{ij}$ is a real-linear bijection $\mathbb{R}^2 \to \mathbb{C}$, the map $(y_{ij}, y_{ji}) \mapsto (y'_{ij}, y'_{ji})$ is conjugate to multiplication by $\varepsilon_i \in \{\pm 1\}$ on $\mathbb{C} \cong \mathbb{R}^2$; so L is block diagonal with blocks of determinant ± 1, and $|\det L| = 1$.

Step 4: $c = 1$. Write $\operatorname{cay}(Y) = (1 + \frac{1}{2}Y)(1 - \frac{1}{2}Y)^{-1}$; its differential at 0 is the identity, and by (5.20) of Lemma 5.2.41, in the coordinates y,

$$\int_G \psi\,dg = \frac{1}{\operatorname{vol}\mathrm{U}(N)} \int \psi(\operatorname{cay}(T_J y))\,m_J(y)\,dy, \qquad m_J(y) = |\det(1 - \tfrac{1}{2}T_J(y))|^{-2N},$$

for Borel $\psi \ge 0$, the integral over the y with $\det(1 - \frac{1}{2}T_J(y)) \neq 0$; the same holds for the Cayley measure of $\mathrm{U}(n)$ with T_1, m_1, and that measure is dk, being a Haar measure (Lemma 5.2.41) of total mass 1 (Lemma 5.5.21). By the inverse function theorem there is an open neighbourhood W of 0 in $\mathrm{M}_n(\mathbb{R})$ on which $\Psi(y) = T_1^{-1}(\mathrm{cay}^{-1}(\phi(\mathrm{cay}(T_J y))))$ is defined, is a diffeomorphism onto an open set, and $y \mapsto \mathrm{cay}(T_J y)$ is a diffeomorphism onto an open neighbourhood U_0 of 1 in G; here $\Psi(0) = 0$ and $d\Psi_0 = L$ by the chain rule. Let $f \in C_c(G)$ be supported in U_0. In (5.133) the integrand vanishes unless $\gamma(k) \in U_0$, i.e. $k = \phi(\gamma(k)) \in \phi(U_0)$; substituting $k = \mathrm{cay}(T_1\Psi(y)) = \phi(\mathrm{cay}(T_J y))$, $\gamma(k) = \mathrm{cay}(T_J y)$,

$$\Lambda(f) = \frac{1}{\mathrm{vol}\,\mathrm{U}(N)} \int_W f(\mathrm{cay}(T_J y))\, h(y)\, dy, \qquad h(y) = \left|\beta(\phi(\mathrm{cay}(T_J y)))^{2\rho_l}\right|^2 m_1(\Psi(y))\, |\det d\Psi_y|,$$

while $c\int_G f\, dg = \frac{c}{\mathrm{vol}\,\mathrm{U}(N)} \int_W f(\mathrm{cay}(T_J y))\, m_J(y)\, dy$. As $f(\mathrm{cay}(T_J \cdot))$ runs over $C_c(W)$ and h, m_J are continuous on W, $h = c\, m_J$ on W. At $y = 0$: $\beta(\phi(1)) = \beta(1) = 1$, $m_1(0) = m_J(0) = 1$ and $|\det d\Psi_0| = |\det L| = 1$; so $c = 1$.

Step 5: conclusion. First let $F \ge 0$, and $f = F|_G$, continuous. For $y \in \Omega$, $F(y) = F(\gamma(y)\beta(y)) = |\beta(y)^{2\rho_l}|^2 f(\gamma(y))$. For $j \ge 1$ let $\chi_j(g) = \min\bigl(1, \max(0, j + 1 - \|g\|)\bigr)$ ($\|\cdot\|$ the operator norm); then $f_j = \chi_j f \in C_c(G)$ and $0 \le f_j \uparrow f$ pointwise. By Steps 1 and 4, (5.133) and monotone convergence on both sides,

$$\int_G f\, dg = \lim_j \int_G f_j\, dg = \lim_j \int_{\mathrm{U}(n)\cap\Omega} \left|\beta(k)^{2\rho_l}\right|^2 f_j(\gamma(k))\, dk = \int_{\mathrm{U}(n)\cap\Omega} F(k)\, dk \le \int_{\mathrm{U}(n)} F\, dk < \infty.$$

For general F, the four functions $\max(\pm\mathrm{Re}\, F, 0)$, $\max(\pm\mathrm{Im}\, F, 0)$ are continuous nonnegative densities (the factor $|b^{2\rho_l}|^2$ is positive); each is integrable on G with the asserted identity, and F is their combination with coefficients $1, -1, \mathrm{i}, -\mathrm{i}$. □

Lemma 5.7.12. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon \in \{\pm 1\}^n$, $J = \mathrm{diag}(\varepsilon)$, $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, and let $l \in \mathbb{Z}^n$ be injective. Let B_l' be the group of invertible complex $n \times n$ matrices b with $b_{ij} = 0$ whenever $l_i > l_j$, B_l^+ its subgroup of the b with positive real diagonal entries, T the group of diagonal matrices with entries of modulus 1, and*

$$\Omega_{\varepsilon,l} = \{gb :\ g \in G,\ b \in \mathrm{B}_l'\}.$$

(i) $G \cap \mathrm{B}_l' = \mathrm{T}$. *Every $y \in \Omega_{\varepsilon,l}$ is $y = \gamma(y)\beta(y)$ for exactly one pair $\gamma(y) \in G$, $\beta(y) \in \mathrm{B}_l^+$. For $y \in \Omega_{\varepsilon,l}$, $g \in G$ and $b \in \mathrm{B}_l'$: $gyb \in \Omega_{\varepsilon,l}$, $\gamma(gyb) = g\,\gamma(y)\,t_b$ with $t_b = \mathrm{diag}(b_{ii}/|b_{ii}|)$, and $\beta(gyb)_{ii} = \beta(y)_{ii}\,|b_{ii}|$ for every i.*

(ii) *$\Omega_{\varepsilon,l}$ is open in $\mathrm{M}_n(\mathbb{C})$, and $\gamma\colon \Omega_{\varepsilon,l} \to G$ and $\beta\colon \Omega_{\varepsilon,l} \to \mathrm{B}_l^+$ are smooth.*

(iii) *For $\varepsilon = (1, \dots, 1)$, $\Omega_{\varepsilon,l} = \mathrm{GL}_n(\mathbb{C})$: every invertible y is $y = kb$ with k unitary and $b \in \mathrm{B}_l^+$, both unique.*

(iv) *$K_\varepsilon \subseteq G \subseteq \Omega_{\varepsilon,l}$.*

Proof. Write $\Omega = \Omega_{\varepsilon,l}$. For $X \in \mathrm{M}_n(\mathbb{C})$, $X^*J + JX = 0$ means $X_{ij} = -\varepsilon_i\varepsilon_j\overline{X_{ji}}$ for all i, j; these X form the Lie algebra $\mathfrak{u}(J)$ of the closed subgroup G of $\mathrm{GL}_n(\mathbb{C})$, of real dimension N^2 ($X \mapsto JX$ is a real-linear bijection onto the skew-hermitian matrices). Let $\mathfrak{t}_l$ be the real vector space of the Y with $Y_{ij} = 0$ whenever $l_i > l_j$ and $Y_{ii} \in \mathbb{R}$; it has real dimension $N(N-1) + N = N^2$, and B_l^+ is an open subset of it. The diagonal of a product of elements of B_l' is the product of their diagonals, so B_l^+ is a group.

(i). Let $t \in G \cap \mathrm{B}_l'$. Then $t^{-1} \in \mathrm{B}_l'$, so $(t^{-1})_{ij} \neq 0$ implies $l_i \le l_j$; and $t^{-1} = Jt^*J$, so $(t^{-1})_{ij} = \varepsilon_i\varepsilon_j\overline{t_{ji}} \neq 0$ implies $l_j \le l_i$. As l is injective, t^{-1} and hence t is diagonal, and $t^*Jt = J$ gives $|t_{ii}| = 1$. Conversely $\mathrm{T} \subseteq G \cap \mathrm{B}_l'$. Let $y = gb \in \Omega$; with t_b as in the statement, $t_b \in \mathrm{T} \subseteq G$ and $b_+ = t_b^{-1}b \in \mathrm{B}_l^+$, so $y = (gt_b)b_+$ is a factorisation. If $g_1b_1 = g_2b_2$ with $g_i \in G$, $b_i \in \mathrm{B}_l^+$, then $g_2^{-1}g_1 = b_2b_1^{-1} \in G \cap \mathrm{B}_l^+$, a diagonal matrix with entries of modulus 1 and positive, so $g_1 = g_2$ and $b_1 = b_2$. Finally, for $y \in \Omega$, $g \in G$, $b \in \mathrm{B}_l'$ write $b = t_bb_+$ as above; then

$$gyb = \big(g\gamma(y)t_b\big)\big(t_b^{-1}\beta(y)t_b\, b_+\big),$$

where $g\gamma(y)t_b \in G$ and $t_b^{-1}\beta(y)t_bb_+ \in \mathrm{B}_l^+$ (conjugation by a diagonal matrix keeps the pattern of zeros and the diagonal); by uniqueness $\gamma(gyb) = g\gamma(y)t_b$, and the diagonal entries of $\beta(gyb)$ are $\beta(y)_{ii}|b_{ii}|$.

(ii). Let $\mu\colon G \times \mathrm{B}_l^+ \to \mathrm{M}_n(\mathbb{C})$, $\mu(g,b) = gb$, a smooth map between manifolds of real dimension $2N^2$, whose image is Ω by (i). The tangent spaces at (g,b) are $g\,\mathfrak{u}(J)$ and $\mathfrak{t}_l$, and

$$d\mu_{(g,b)}(gX,Y) = gXb + gY = g\big(X + Yb^{-1}\big)b \qquad (X \in \mathfrak{u}(J),\ Y \in \mathfrak{t}_l).$$

The map $Y \mapsto Yb^{-1}$ is a linear bijection of $\mathfrak{t}_l$ (the product has the zero pattern of B_l' and real diagonal entries Y_{ii}/b_{ii}; its inverse is $Y' \mapsto Y'b$). So $d\mu_{(g,b)}$ is bijective as soon as $\mathfrak{u}(J) \cap \mathfrak{t}_l = 0$, by dimensions. Let $X \in \mathfrak{u}(J) \cap \mathfrak{t}_l$: for $l_i > l_j$, $X_{ij} = 0$ and hence $X_{ji} = -\varepsilon_i\varepsilon_j\overline{X_{ij}} = 0$, so X is diagonal; $X_{ii} = -\overline{X_{ii}}$ is imaginary and real, so $X = 0$. By the inverse function theorem μ is a local diffeomorphism; it is injective by (i). Hence $\Omega = \mu(G \times \mathrm{B}_l^+)$ is open, μ is a diffeomorphism onto Ω, and $(\gamma,\beta) = \mu^{-1}$ is smooth.

(iii). Let $\varepsilon = (1,\dots,1)$, so G is the unitary group. List n as $c_1,\dots,c_N$ with $l(c_1) < \cdots < l(c_N)$; then $b \in \mathrm{B}_l'$ if and only if $b_{c_ic_j} = 0$ for $i > j$. For invertible y, the Gram–Schmidt process applied to the columns $y_{\bullet c_1},\dots,y_{\bullet c_N}$ gives orthonormal vectors $k_{\bullet c_1},\dots,k_{\bullet c_N}$ and numbers $b_{c_ic_j}$ $(i \le j)$, $b_{c_jc_j} > 0$, with $y_{\bullet c_j} = \sum_{i\le j} k_{\bullet c_i}b_{c_ic_j}$; that is $y = kb$ with k unitary and $b \in \mathrm{B}_l^+$. Uniqueness is (i).

(iv). $K_\varepsilon \subseteq G$ by definition, and $g = g \cdot 1$ with $1 \in \mathrm{B}_l'$. □

Lemma 5.7.13. *Let n be a nonempty finite set, $\varepsilon \in \{\pm1\}^n$, $J = \mathrm{diag}(\varepsilon)$, $h \in \mathbb{N}$, and let $l \in \mathbb{Z}^n$ have gap h for ε. Let Λ_{c} be the lowest K-type of l for the signs $(1,\dots,1)$, $\mathrm{U}(n)$ the group of unitary $n \times n$ matrices with its Haar probability measure dk, and for an accretive $n \times n$ matrix A put*

$$\mathrm{Off}(A) = \int_{\mathrm{U}(n)\smallsetminus\Omega_{\varepsilon,l}} \frac{m_{-\Lambda_{\mathrm{c}}}(k^*Jk)}{m_{-l^\rho}(k^*Ak)}\,dk.$$

(i) The integrand is continuous on $\mathrm{U}(n)$, and Off is a holomorphic function of the entries of A on the open set of accretive matrices; in particular it is continuous there.

(ii) Let $o \in \mathbb{Z}^n$ satisfy $o(a) < o(b)$ whenever $l_b < l_a$, and let $e \in \mathbb{Z}^n$. There are $C \ge 0$ and $s_0 \in \mathbb{N}$ such that for every integer $s \ge s_0$,

$$\Big|\mathrm{Off}\big(\mathrm{diag}(2^{-s\,o(a)-e(a)})_{a\in n}\big)\Big| \le C\,2^{-s\,(o\cdot l^\rho+h)}, \qquad o\cdot l^\rho = \sum_a o(a)\,l_a^\rho.$$

Proof. Write $\Omega = \Omega_{\varepsilon,l}$ and $\mu = l^\rho$. For a diagonal matrix $\mathrm{diag}(d)$ with nonzero entries, $\Delta_P(\mathrm{diag}(d)) = \prod_{a\in P} d_a$, so by (3.1)

$$m_w(\mathrm{diag}(d)) = \prod_a d_a^{w_- + \#\{t\colon w_- < t \le w_a\}} = \prod_a d_a^{w_a} \qquad (w \in \mathbb{Z}^n,\ w_- = \min w). \tag{5.134}$$

By Lemma 5.6.27 (iii) (the entries of l are distinct and $\equiv \#n - 1 \pmod 2$), $2\mu = l + 2\rho_l$ and $2\rho_l$ is strictly increasing along l; so μ is strictly increasing along l, and $|\mu_a - \mu_b| \geq \frac{1}{2}|l_a - l_b|$.

(i). For k unitary, k^*Jk is invertible and k^*Ak is accretive when A is, so all principal minors of k^*Ak are nonzero (Lemma 5.6.25 (ii)). By (3.1), $m_{-\mu}(Z)$ is a power of $\det Z$ times a product of principal minors of Z; hence $(A,k) \mapsto m_{-\Lambda_c}(k^*Jk)/m_{-\mu}(k^*Ak)$ is continuous on (accretive matrices)$\times$U(n) and, for fixed k, a rational function of the entries of A without poles on the accretive matrices. Ω is open (Lemma 5.7.12 (ii)), so $\mathrm{U}(n) \setminus \Omega$ is compact. A parameter integral over a compact set of a jointly continuous function that is holomorphic in each parameter is continuous and, by Morera's theorem in each variable with Fubini, holomorphic in each variable separately, hence holomorphic (Osgood's lemma).

A large entry outside the orbit. There is $r > 0$ such that every $k \in \mathrm{U}(n) \setminus \Omega$ has indices i, j with $\varepsilon_i \neq \varepsilon_j$ and

$$r\,|m_{-\Lambda_c}(k^*Jk)| < |k_{ij}|^{2h}. \tag{5.135}$$

Indeed, let $k \in \mathrm{U}(n) \setminus \Omega$. If $k_{ij} = 0$ whenever $\varepsilon_i \neq \varepsilon_j$, then k commutes with J, so $k^*Jk = J$ and $k \in K_\varepsilon \subseteq \Omega$ (Lemma 5.7.12 (iv)); so some $k_{ij} \neq 0$ with $\varepsilon_i \neq \varepsilon_j$. The function $(r', k') \mapsto |k'_{ij}|^{2h} - r'|m_{-\Lambda_c}(k'^*Jk')|$ is continuous and positive at $(0, k)$, hence positive on $[0, r_k) \times V_k$ for some $r_k > 0$ and some open neighbourhood V_k of k. Finitely many V_k cover the compact set $\mathrm{U}(n) \setminus \Omega$; take r half the least of the corresponding r_k.

(ii). Let $C' \in \mathbb{N}$ with $C' \geq 2\max_a |e(a)|$, let $s \geq s_0 = C'$, $f = -(s\,o + e)$, $D = \mathrm{diag}(2^{f_a})$, and $m = s - C' \geq 0$. We apply Lemma 5.7.14 with $w = -\mu$. If $w_c < w_a$, then $\mu_a < \mu_c$, so $l_a < l_c$ and $o(c) + 1 \leq o(a)$; hence $f_a \leq -s(o(c)+1) - e(a) = f_c - s + e(c) - e(a) \leq f_c - |m|$. For $k \in \mathrm{U}(n) \setminus \Omega$ take i, j as in (5.135); then $k_{ij} \neq 0$ and, as $\varepsilon_i \neq \varepsilon_j$, $|w_i - w_j| \geq \frac{1}{2}|l_i - l_j| \geq h$. By Lemma 5.7.14 and (5.134),

$$|m_{-\mu}(k^*Dk)| \geq |m_{-\mu}(D)|\big(|k_{ij}|^2 2^{s-C'}\big)^h = 2^{s\,o\cdot\mu + e\cdot\mu}\,|k_{ij}|^{2h}\,2^{(s-C')h},$$

and with (5.135) the integrand of $\mathrm{Off}(D)$ at k has modulus at most $r^{-1}2^{C'h - e\cdot\mu}\,2^{-s(o\cdot\mu+h)}$. As dk has mass 1, (ii) holds with $C = r^{-1}2^{C'h - e\cdot\mu}$. □

Lemma 5.7.14. *Let n be a nonempty finite set, $w, f \in \mathbb{Z}^n$, $m \in \mathbb{Z}$, $h \in \mathbb{N}$ and $i, j \in n$, such that*

$$f_a + |m| \leq f_c \quad \textit{whenever } w_c < w_a, \qquad h \leq |w_i - w_j|.$$

Let $D = \mathrm{diag}(2^{f_a})_{a\in n}$ and let u be a unitary $n \times n$ matrix. Then

$$|m_w(D)|\,\big(|u_{ij}|^2\,2^m\big)^h \leq |m_w(u^*Du)|.$$

Proof. For $f' \in \mathbb{Z}^n$ write $M_{f'} = u^*\mathrm{diag}(2^{f'_a})u$, a positive definite matrix with $\det M_{f'} = 2^{\sum_a f'_a}$, so its principal minors are positive. If $f' \leq f''$ entrywise then $M_{f''} - M_{f'}$ is positive semidefinite, hence so is every principal submatrix of it, and the determinant is monotone on positive definite matrices for this order:

$$\Delta_P(M_{f'}) \leq \Delta_P(M_{f''}) \qquad (P \subseteq n,\ f' \leq f''). \tag{5.136}$$

Reduction to $w_j \leq w_i$. The hypotheses hold for $(-w, -f)$ in place of (w, f): if $-w_c < -w_a$ then $w_a < w_c$, so $f_c + |m| \leq f_a$, that is $-f_a + |m| \leq -f_c$. By Lemma 5.6.27 (i), $m_{-w}(z^{-1}) = m_w(z)$, and $(u^*Du)^{-1} = u^*D^{-1}u$, $D^{-1} = \mathrm{diag}(2^{-f_a})$; so both sides of the assertion are unchanged. Exchanging w with $-w$ if necessary we may assume $w_j \leq w_i$, hence $w_j \leq w_i - h$.

Expansion. Let $w_- = \min w$, $w_+ = \max w$ and $P_t = \{a : w_a \geq t\}$. By (3.1) and $\det(u^*Du) = \det D$,

$$\frac{|m_w(u^*Du)|}{|m_w(D)|} = \prod_{w_- < t \leq w_+} \frac{\Delta_{P_t}(M_f)}{\Delta_{P_t}(M_f|_{u=1})}, \qquad \Delta_{P_t}(M_f|_{u=1}) = \Delta_{P_t}(D) = 2^{\sum_{a\in P_t} f_a}.$$

As $w_- \leq w_j \leq w_i - h$ and $w_i \leq w_+$, the interval $(w_i - h, w_i]$ contains exactly h integers, all in $(w_-, w_+]$. It therefore suffices to show, for each integer t with $w_- < t \leq w_+$,

$$\Delta_{P_t}(D)\, g_t \leq \Delta_{P_t}(M_f), \qquad g_t = \begin{cases} |u_{ij}|^2 2^m & \text{if } w_i - h < t \leq w_i, \\ 1 & \text{otherwise.} \end{cases} \tag{5.137}$$

Proof of (5.137). Fix t, let $P = P_t$ and $Q = n \smallsetminus P = \{a : w_a < t\}$, nonempty as $t > w_-$. Choose $c \in Q$ with $f_c = \min_Q f$ and put $g' = \min(f, f_c)$ entrywise. For $a \in P$, $w_c < t \leq w_a$, so $f_a + |m| \leq f_c$; hence $g' = f$ on P and $g' = f_c$ on Q. Let $q = \{j\}$ if $w_i - h < t \leq w_i$ and $q = \emptyset$ otherwise; in the first case $w_j \leq w_i - h < t$, so $q \subseteq Q$; put $p = Q \smallsetminus q$, so $n \smallsetminus q = p \sqcup P$. First, $g_t \leq 2^{f_c \# q}\, \Delta_q(M_{g'}^{-1})$: for $q = \emptyset$ both sides are 1; for $q = \{j\}$, $M_{g'}^{-1} = u^* \mathrm{diag}(2^{-g'_a}) u$ has (j,j) entry $\sum_a |u_{aj}|^2 2^{-g'_a} \geq |u_{ij}|^2 2^{-f_i}$ ($i \in P$ as $w_i \geq t$), and $f_c - f_i \geq |m| \geq m$. Second, by Jacobi's complementary minor formula ([133], 0.8.4), Fischer's inequality for the positive definite matrix $(M_{g'})_{n\smallsetminus q, n\smallsetminus q}$ and the partition $p \sqcup P$ ([133], 7.8.5), and (5.136) with $g' \leq f_c$ and $g' \leq f$,

$$\Delta_q(M_{g'}^{-1}) = \frac{\Delta_{n\smallsetminus q}(M_{g'})}{\det M_{g'}} \leq \frac{\Delta_p(M_{g'})\, \Delta_P(M_{g'})}{\det M_{g'}} \leq \frac{\Delta_p(2^{f_c}\cdot 1)\, \Delta_P(M_f)}{2^{\sum_a g'_a}} = \frac{2^{f_c \# p}\, \Delta_P(M_f)}{2^{\sum_P f_a + f_c \# Q}},$$

using $M_{f_c} = 2^{f_c}\cdot 1$ (u unitary). Since $\#p + \#q = \#Q$, the two estimates give $g_t \leq \Delta_P(M_f)/2^{\sum_P f_a}$, which is (5.137). □

Lemma 5.7.15. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $J = \mathrm{diag}(\varepsilon)$, $h \in \mathbb{N}$, let $l \in \mathbb{Z}^n$ have gap h for ε, and let* Off *be the off-orbit integral of Lemma 5.7.13 for (ε, l). In $\mathcal{R} = \mathbb{C}[X_a^{\pm 1} : a \in n]$ write P_γ for the coefficient of $X^\gamma = \prod_a X_a^{\gamma_a}$ and call the γ with $P_\gamma \neq 0$ the exponents of P. For $x \in \mathbb{C}^n$ with $|x_a| = 1$ let $t_x = \mathrm{diag}(x)$. Let $P, Q \in \mathcal{R}$ satisfy*

$$P(x) = Q(x)\, \mathrm{Off}(J t_x)$$

for every x with $|x_a| = 1$, pairwise distinct entries and Jt_x accretive. Let $o \in \mathbb{Z}^n$ satisfy $o(a) < o(b)$ whenever $l_b < l_a$, and let $\gamma \in \mathbb{Z}^n$ satisfy $o\cdot\gamma < o\cdot l^\rho + o\cdot\beta + h$ for every exponent β of Q ($o\cdot\gamma = \sum_a o(a)\gamma_a$). Then $P_\gamma = 0$.

Proof. Step 1: all accretive points of the torus. Let A be the set of $x \in (S^1)^n$ with Jt_x accretive, an open subset of the torus. The points of A with two equal entries lie in finitely many subtori $\{x_a = x_b\}$ ($a \neq b$), closed with empty interior; so the points with distinct entries are dense in A. Both sides of the identity are continuous on A (Off is continuous on the accretive matrices by Lemma 5.7.13 (i)), so $P(x) = Q(x)\mathrm{Off}(Jt_x)$ for all $x \in A$.

Step 2: continuation to the positive axis. Let $f \in \mathbb{Z}^n$. For $z \in \mathbb{C} \smallsetminus \{0\}$ put $D(z) = \mathrm{diag}(z^{f_a})$ and, for a Laurent polynomial R, $T_R(z) = \sum_\gamma R_\gamma\, \varepsilon^\gamma z^{f\cdot\gamma}$ with $\varepsilon^\gamma = \prod_a \varepsilon_a^{\gamma_a}$. For $|z| = 1$ the point $x(z) = (\varepsilon_a z^{f_a})_a$ lies on the torus, $Jt_{x(z)} = D(z)$ and $R(x(z)) = T_R(z)$. The set U of $z \neq 0$ with $D(z)$ accretive is open and contains $(0,\infty)$ ($D(z)$ is then positive definite); let U_1 be its connected component containing $(0,\infty)$. On U the function $z \mapsto T_P(z) - T_Q(z)\,\mathrm{Off}(D(z))$ is holomorphic (Lemma 5.7.13 (i)); by Step 1 it vanishes at the points $e^{\mathrm{i}\theta} \in U$ with θ small, which accumulate at $1 \in U_1$. By the identity theorem it vanishes on U_1:

$$T_P(z) = T_Q(z)\, \mathrm{Off}\big(\mathrm{diag}(z^{f_a})\big) \qquad (z > 0). \tag{5.138}$$

Step 3: the lowest level of P vanishes. Suppose $P_\gamma \neq 0$. Let β_0 be an exponent of P of least level $o\cdot\beta_0$; then $o\cdot\beta_0 \le o\cdot\gamma$. Put $L = o\cdot l^\rho + h$, fix $e\in\mathbb{Z}^n$, and define the polynomials (in t)

$$p(t) = \sum_{\gamma'} P_{\gamma'}\varepsilon^{\gamma'} 2^{-e\cdot\gamma'}\, t^{\,o\cdot\gamma' - o\cdot\beta_0}, \qquad q(t) = \sum_{\beta} Q_\beta \varepsilon^\beta 2^{-e\cdot\beta}\, t^{\,o\cdot\beta + L - o\cdot\beta_0},$$

over the exponents of P, resp. of Q. The exponents of t in p are ≥ 0 by the choice of β_0, and those in q are ≥ 1, since $o\cdot\beta_0 \le o\cdot\gamma < L + o\cdot\beta$; so $q(0)=0$. Take $f = s\,o + e$ and $z = \frac12$ in (5.138): then $T_P(\frac12) = 2^{-s\,o\cdot\beta_0} p(2^{-s})$ and $T_Q(\frac12) = 2^{-s\,o\cdot\beta_0} 2^{sL} q(2^{-s})$, so

$$p(2^{-s}) = 2^{sL} q(2^{-s})\,\mathrm{Off}\big(\mathrm{diag}(2^{-s\,o(a)-e(a)})\big) \qquad (s\in\mathbb{N}).$$

By Lemma 5.7.13 (ii), $|p(2^{-s})| \le C|q(2^{-s})|$ for $s\ge s_0$; letting $s\to\infty$, $p(0)=0$, that is

$$\sum_{\gamma'\in E_0} P_{\gamma'}\varepsilon^{\gamma'}\, 2^{-e\cdot\gamma'} = 0 \qquad (e\in\mathbb{Z}^n),$$

where E_0 is the set of exponents γ' of P with $o\cdot\gamma' = o\cdot\beta_0$. For distinct γ' the homomorphisms $e\mapsto 2^{-e\cdot\gamma'}$ from $\mathbb{Z}^n$ to $\mathbb{C}^\times$ are distinct (they differ at a unit vector), hence linearly independent (Dedekind–Artin). So $P_{\beta_0}\varepsilon^{\beta_0} = 0$, contradicting the choice of β_0. Hence $P_\gamma = 0$. □

Lemma 5.7.16. *Let n be a nonempty finite set, $N = \#n$, $\mathrm{U}(n)$ the group of unitary $n\times n$ matrices with its Haar probability measure dk, and $\nu\in\mathbb{Z}^n$. Let $a_0,\dots,a_{N-1}$ be a numbering of n with $\nu(a_0)\ge\nu(a_1)\ge\cdots\ge\nu(a_{N-1})$. Let χ_ν be the character of the irreducible continuous representation of $\mathrm{U}(n)$ of highest weight $(\nu(a_0),\dots,\nu(a_{N-1}))$ for the diagonal torus and the Borel subgroup of the invertible matrices b with $b_{a_i a_j}=0$ for $i>j$, let $d_\nu = \chi_\nu(1)$, and $\|m_\nu\|^2 = \int_{\mathrm{U}(n)} |m_\nu(k)|^2\,dk$. Then:*

(i) there are a continuous homomorphism ρ from $\mathrm{U}(n)$ to the unitary group of a finite-dimensional complex Hilbert space H, such that $\operatorname{tr}\rho(k) = \chi_\nu(k)$ for $k\in\mathrm{U}(n)$ and only the scalars commute with every $\rho(k)$, and a unit vector $e\in H$ with $m_\nu(k) = \langle e, \rho(k)e\rangle$ for every $k\in\mathrm{U}(n)$;

(ii) $\|m_\nu\|^2 = 1/d_\nu$;

(iii) $\int_{\mathrm{U}(n)} m_\nu(u^{-1}a)\,m_\nu(u)\,du = \|m_\nu\|^2\, m_\nu(a)$ for every $a\in\mathrm{U}(n)$;

(iv) $\int_{\mathrm{U}(n)} m_\nu(y^{-1}ty)\,dy = \|m_\nu\|^2\,\chi_\nu(t)$ for every $t\in\mathrm{U}(n)$.

Proof. Step 1: transport to the rows $1,\dots,N$. Let $c = \nu(a_{N-1}) = \min\nu$ and $\nu' = \nu - c$. In (3.1), $\min\nu' = 0$, $\max\nu' = \max\nu - c$ and $\{i:\nu'_i\ge t\} = \{i:\nu_i\ge t+c\}$, so

$$m_\nu(g) = (\det g)^c\, m_{\nu'}(g) \qquad (g \text{ invertible}). \tag{5.139}$$

For a matrix z indexed by n let z' be the $N\times N$ matrix with $z'_{i+1,j+1} = z_{a_i a_j}$ $(0\le i,j<N)$; then $z' = PzP^{-1}$ for the permutation matrix P with $Pe_{a_j} = e_{j+1}$, and $\Delta_S(z) = \Delta_{S'}(z')$ for $S\subseteq n$ and $S' = \{j+1 : a_j\in S\}$, the two submatrices differing by the same reordering of rows and columns. Put $k = N$, $w(h) = \nu'(a_{h-1}) - \nu'(a_h) \ge 0$ for $1\le h<N$; its highest weight is $\lambda(p) = \sum_{p<h<N} w(h) = \nu'(a_p)$, as $\nu'(a_{N-1}) = 0$. Let $u(j) = 2\lambda(j-1) + N + 1 - 2j$ $(1\le j\le N)$. As λ is nonincreasing, u is strictly decreasing, so it is injective and $\#\{j' : u(j') > u(j)\} = j-1$; each value $u(j) = 2(0+\lambda(p)) + N - 1 - 2p$ with $p = j-1$, so u is a doubled Harish-Chandra

parameter of $(w,0)$. By Lemma 5.7.17 (i), $\mu_u(j) = \lambda(j-1) = \nu'(a_{j-1})$; hence $\{j : \mu_u(j) \geq t\} = \{i : \nu'_i \geq t\}'$ for every t, and by (3.1)

$$m_{\mu_u}(z') = m_{\nu'}(z) \qquad (z \text{ invertible}). \tag{5.140}$$

Step 2: proof of (i). Let ρ_0, e be as in Lemma 5.7.17 (ii), on $H = \mathbb{C}^{I_w}$, and put $\rho(k) = (\det k)^c \rho_0(k')$ for $k \in \mathrm{U}(n)$. Since $k \mapsto k' = PkP^{-1}$ is an isomorphism of $\mathrm{U}(n)$ onto $\mathrm{U}(N)$ and $|\det k| = 1$, ρ is a continuous homomorphism into the unitary group of H, and a matrix commuting with every $\rho(k)$ commutes with every $\rho_0(h)$, so it is a scalar. By (5.139), (5.140) and Lemma 5.7.17 (ii), $\langle e, \rho(k)e\rangle = (\det k)^c m_{\mu_u}(k') = (\det k)^c m_{\nu'}(k) = m_\nu(k)$. By Lemma 5.7.17 (iii), $\operatorname{tr}\rho(k) = (\det k)^c \chi_\lambda(PkP^{-1})$. Conjugation by P carries the diagonal torus of $\mathrm{U}(N)$ to that of $\mathrm{U}(n)$ and the upper triangular Borel subgroup to the group of the b with $b_{a_i a_j} = 0$ for $i > j$ (as $(PbP^{-1})_{i+1,j+1} = b_{a_i a_j}$), and twisting by the character $\det^c$ adds c to every weight; so $k \mapsto (\det k)^c \chi_\lambda(PkP^{-1})$ is the character of the irreducible representation of $\mathrm{U}(n)$ of highest weight $(\lambda(0)+c, \dots, \lambda(N-1)+c) = (\nu(a_0), \dots, \nu(a_{N-1}))$, that is χ_ν. In particular $d_\nu = \dim H$.

Step 3: proof of (ii)–(iv). By (i), ρ is irreducible and unitary, so Schur's orthogonality relations for the compact group $\mathrm{U}(n)$ give

$$\int_{\mathrm{U}(n)} \langle x, \rho(k)y\rangle \, \overline{\langle x', \rho(k)y'\rangle}\, dk = d_\nu^{-1} \langle x, x'\rangle \langle y', y\rangle \qquad (x, y, x', y' \in H).$$

With $x = y = x' = y' = e$ this is (ii). For (iii), $m_\nu(u^{-1}a) = \langle e, \rho(u)^{-1}\rho(a)e\rangle = \langle \rho(u)e, \rho(a)e\rangle = \overline{\langle \rho(a)e, \rho(u)e\rangle}$, so with $x = y = y' = e$, $x' = \rho(a)e$,

$$\int m_\nu(u^{-1}a)\, m_\nu(u)\, du = \int \langle e, \rho(u)e\rangle \, \overline{\langle \rho(a)e, \rho(u)e\rangle}\, du = d_\nu^{-1} \langle e, \rho(a)e\rangle = \|m_\nu\|^2 m_\nu(a).$$

For (iv), let $T = \int_{\mathrm{U}(n)} \rho(y)^{-1}\rho(t)\rho(y)\, dy$, the integral of a continuous function with values in the operators on H. The substitution $y \mapsto yz$ shows $\rho(z)^{-1} T \rho(z) = T$ for $z \in \mathrm{U}(n)$, so $T = \tau \cdot 1$ by (i), and taking traces $\tau d_\nu = \operatorname{tr}\rho(t) = \chi_\nu(t)$. Hence $\int m_\nu(y^{-1}ty)\, dy = \langle e, Te\rangle = \chi_\nu(t)/d_\nu = \|m_\nu\|^2 \chi_\nu(t)$. □

Lemma 5.7.17. *Let $k \geq 1$, let w be a weight for the rank k (integers $w(h) \geq 0$ for $1 \leq h < k$), with highest weight $\lambda(p) = \sum_{p<h<k} w(h)$ $(0 \leq p < k)$, and let $\mathbb{V}_w$ be its Weyl module, the rows of the arrays of (WM1) being indexed by $\{1, \dots, k\}$. Let $u \in \mathbb{Z}^k$ be a doubled Harish-Chandra parameter of $(w,0)$, and for $1 \leq a \leq k$ put $p(a) = \#\{a' : u(a') > u(a)\}$. Write $\mathrm{U}(k)$ for the group of unitary $k \times k$ matrices and $\langle \cdot, \cdot \rangle$ for the standard inner product of $\mathbb{C}^{I_w}$ (conjugate-linear in the first argument).*

(i) $u(a) = 2\lambda(p(a)) + k - 1 - 2p(a)$ *for every $1 \leq a \leq k$; for the signs $(1, \dots, 1)$, u has gap h for every $h \in \mathbb{N}$, and its lowest K-type is $\mu_u(a) = \lambda(p(a))$ $(1 \leq a \leq k)$.*

(ii) There are a continuous homomorphism ρ from $\mathrm{U}(k)$ to the group of unitary $I_w \times I_w$ matrices, an invertible complex $I_w \times I_w$ matrix C and a unit vector $e \in \mathbb{C}^{I_w}$ such that

$$C\,\rho(h) = S_w(h^{\mathsf{T}})^{\mathsf{T}}\, C \quad \text{and} \quad \langle e, \rho(h)e\rangle = c_{u/2}(h) = m_{\mu_u}(h) \qquad (h \in \mathrm{U}(k)),$$

where $c_{u/2}$ is Flensted-Jensen's function for the signs $(1, \dots, 1)$, and every complex matrix that commutes with $\rho(h)$ for all $h \in \mathrm{U}(k)$ is a scalar multiple of the identity. Moreover $\#I_w = d_k(\lambda) = \prod_{0 \leq p < q < k} \frac{\lambda(p) - \lambda(q) + q - p}{q - p}$.

(iii) For $h \in \mathrm{U}(k)$, $\operatorname{tr}\rho(h) = \chi_\lambda(h)$, where χ_λ is the character of the irreducible continuous representation of $\mathrm{U}(k)$ of highest weight $(\lambda(0), \dots, \lambda(k-1))$ for the diagonal torus and the Borel subgroup of upper triangular matrices.

Proof. Minors are taken with rows in increasing order.

(i). By (WM6), u is injective and each value $u(a)$ is one of the k numbers $\ell_p = 2\lambda(p) + k - 1 - 2p$ $(0 \le p < k)$. As λ is nonincreasing, $\ell_0 > \ell_1 > \cdots > \ell_{k-1}$; so u is a bijection of $\{1,\dots,k\}$ onto $\{\ell_0,\dots,\ell_{k-1}\}$, and the index a with $u(a) = \ell_p$ has exactly p larger values, that is $p(a) = p$. Every $\ell_p \equiv k-1 \pmod 2$, and no two indices carry different signs, so u has gap h for every h ((WM8) of Definition 3.2.19). For the lowest K-type of Definition 3.2.3: all signs agree, so $2\rho_u^{\mathrm c} = 2\rho_u$, and $2\rho_u(a) = \#\{u(a') < u(a)\} - \#\{u(a') > u(a)\} = k - 1 - 2p(a)$. Hence $u^\rho(a) = \lfloor \frac12 (u(a) + 2\rho_u(a)) \rfloor = \lambda(p(a)) + k - 1 - 2p(a)$ and $\mu_u(a) = u^\rho(a) - 2\rho_u(a) = \lambda(p(a))$.

Properties of the Schur matrices. By Lemma 4.6.10 (a), (b): $S_w(zz') = S_w(z)S_w(z')$, $S_w(1) = 1$, $S_w(z)^{\mathsf T} G_w = G_w S_w(z^{\mathsf T})$ for all complex $k \times k$ matrices z, z', and $G_w = F_w^{\mathsf T} F_w$ is a real positive definite matrix. By Lemma 4.6.10 (c) with $e = 0$, where $\rho_{w,0}(h) = S_w(\bar h)$, we have $\langle S_w(\bar h)\xi, S_w(\bar h)\xi'\rangle_w = \langle \xi, \xi'\rangle_w$ for unitary h; as $\bar h$ runs over all unitary matrices when h does, $S_w(g)^* G_w S_w(g) = G_w$ for every unitary g. The entries of $S_w(z)$ are polynomials in the entries of z: by (WM2) the coefficients of $b_i(zy)$ in the basis $(b_j(y))$ are, for the matrix of indeterminates z over $\mathbb Z[z_{ab}]$, polynomials in the z_{ab}, and they specialise to $S_w(z)$.

The representation and the intertwiner. Let B be the positive definite square root of G_w (real symmetric, $B^2 = G_w$) and put $\rho(h) = B\, S_w(h)\, B^{-1}$ and $C = B$. Then ρ is a homomorphism, continuous because S_w has polynomial entries, and $\rho(h)$ is unitary for $h \in \mathrm U(k)$: $\rho(h)^*\rho(h) = B^{-1} S_w(h)^* G_w S_w(h) B^{-1} = B^{-1} G_w B^{-1} = 1$. The identity $S_w(z)^{\mathsf T} G_w = G_w S_w(z^{\mathsf T})$ with $z = h^{\mathsf T}$ reads $S_w(h^{\mathsf T})^{\mathsf T} G_w = G_w S_w(h)$, so

$$C\rho(h) = G_w S_w(h) B^{-1} = S_w(h^{\mathsf T})^{\mathsf T} G_w B^{-1} = S_w(h^{\mathsf T})^{\mathsf T} C.$$

Only scalars commute with ρ. Let M commute with every $\rho(h)$, and $M' = B^{-1} M B$; then $M' S_w(h) = S_w(h) M'$ for $h \in \mathrm U(k)$. Each entry of $M' S_w(g) - S_w(g) M'$ is a polynomial in the entries of $g \in \mathrm M_k(\mathbb C)$ that vanishes on $\mathrm U(k)$, so it vanishes identically by Lemma 4.6.13 (one factor, $n = k$). Hence M' commutes with $S_w(z)$ for every $z \in \mathrm{GL}_k(\mathbb C)$, and $M'^{\mathsf T}$ commutes with $\pi(g) = S_w(g^{\mathsf T})^{\mathsf T}$ for every $g \in \mathrm{GL}_k(\mathbb C)$. Let $\mathcal N$ be the complex span of the products of minors Δ_T; the b_i, a $\mathbb Z$-basis of the $\mathbb Z$-module ∇_w of integer polynomials, are linearly independent over $\mathbb Q$ and hence over $\mathbb C$, so $\xi \mapsto \sum_i \xi_i b_i$ is an isomorphism $\mathbb C^{I_w} \to \mathcal N$, and it carries $\pi(g)$ to $P \mapsto P(g^{\mathsf T}\cdot)$: $\sum_i \xi_i b_i(g^{\mathsf T} y) = \sum_{i,j} \xi_i S_w(g^{\mathsf T})_{ij} b_j(y)$. Only the columns $0 \le c < k-1$ of the arrays occur in the minors, so $\mathcal N$ is a space of polynomials in the entries of a $k \times k$ matrix $X = (y_{a,c})_{1\le a\le k, 0\le c<k}$. A minor Δ_A on h rows and the columns $0,\dots,h-1$ is homogeneous of degree 1 in each column $c < h$ and does not involve the others, so Δ_T is homogeneous of degree $\sum_{h>c} w(h) = \lambda(c)$ in column c; and adding a multiple of a column c' to a later column c changes no minor (if $c < h$ then $c' < h$ and the determinant is unchanged; if $c \ge h$ column c does not occur). So $\mathcal N$ is a nonzero subspace, stable under $P \mapsto P(g^{\mathsf T}\cdot)$, of the module $\nabla_{\mathbb C}(\lambda)$ of Theorem A.5.19 (λ is nonincreasing and $\lambda(k-1) = 0$). That module is irreducible, so $\mathcal N = \nabla_{\mathbb C}(\lambda)$, π is irreducible, and $\#I_w = \dim \nabla_{\mathbb C}(\lambda) = d_k(\lambda)$ by the dimension formula of Theorem A.5.19. By Schur's lemma $M'^{\mathsf T}$, hence M' and $M = BM'B^{-1}$, is a scalar.

The diagonal coefficient of the highest vector. Let y^u be the array of (WM6), $y^u_{a,c} = 1$ if $c = p(a)$ and 0 otherwise, $v^+ = \mathrm{ev}_w(y^u)$ and $e = Bv^+$. As B is real symmetric, $\langle e, \rho(h)e\rangle = \overline{v^+}^{\mathsf T} G_w S_w(h) v^+ = \langle v^+, S_w(h)v^+\rangle_w$. By the definition of S_w, $S_w(h)\,\mathrm{ev}_w(y) = \mathrm{ev}_w(hy)$, and by the definition of F_w, $F_w\,\mathrm{ev}_w(y) = (\Delta_T(y))_{T\in\mathcal C_w}$; since F_w is real,

$$\langle \mathrm{ev}_w(y), \mathrm{ev}_w(y')\rangle_w = \sum_{T\in\mathcal C_w} \overline{\Delta_T(y)}\,\Delta_T(y').$$

For $1 \le h < k$ put $P_h = \{a : p(a) < h\}$ and let a_c be the index with $p(a_c) = c$. The columns $0,\dots,h-1$ of y^u are the unit vectors at $a_0,\dots,a_{h-1}$; so for a set A of h rows, $\Delta_A(y^u) = 0$ unless

$A = P_h$, and $\Delta_{P_h}(y^u) = \sigma_h$, the sign of the permutation that lists $a_0, \dots, a_{h-1}$ in increasing order. Hence $\Delta_T(y^u) = 0$ for every increasing filling except the filling T^+ with $T^+(h,j) = P_h$ for all h, j, for which $\Delta_{T^+}(y^u) = \prod_h \sigma_h^{w(h)}$. Further $(hy^u)_{a,c} = h_{a\,a_c}$, so $\Delta_{P_{h'}}(hy^u)$ is the determinant of the submatrix of h with rows $P_{h'}$ and columns $a_0, \dots, a_{h'-1}$, which is $\sigma_{h'}\,\Delta_{P_{h'}}(h)$. Therefore

$$\langle e, \rho(h)e\rangle = \prod_{1\le h'<k} \sigma_{h'}^{2w(h')}\,\Delta_{P_{h'}}(h)^{w(h')} = \prod_{1\le h'<k} \Delta_{P_{h'}}(h)^{w(h')} = m_{\mu_u}(h).$$

For the last equality use (3.1) with $\mu_u(a) = \lambda(p(a))$ from (i): $\min \mu_u = \lambda(k-1) = 0$, and for $\lambda(h') < t \le \lambda(h'-1)$ $(1 \le h' < k)$ the set $\{a : \mu_u(a) \ge t\}$ is $P_{h'}$, a range of $\lambda(h'-1) - \lambda(h') = w(h')$ values of t. At $h = 1$ this gives $\|e\|^2 = m_{\mu_u}(1) = 1$.

Flensted-Jensen's function on $\mathrm{U}(k)$. For the signs $(1, \dots, 1)$, $K_\varepsilon = \mathrm{U}(k)$, $\mathrm{bd}(h) = h$ and $h^{-1}h = 1$ is accretive, so by (3.2), with $m_{-u^\rho}(k'^* k') = m_{-u^\rho}(1) = 1$,

$$c_{u/2}(h) = \frac{1}{\|m_{\mu_u}\|^2} \int_{\mathrm{U}(k)} m_{\mu_u}(hk')\,\overline{m_{\mu_u}(k')}\,dk'.$$

Here $m_{\mu_u}(g) = \langle e, \rho(g)e\rangle$ and $m_{\mu_u}(hk') = \langle \rho(h)^* e, \rho(k')e\rangle$. The representation ρ is unitary and irreducible of dimension $\delta = \#I_w$, so Schur's orthogonality relations for the compact group $\mathrm{U}(k)$ with its Haar probability measure give $\int \langle x, \rho(k')y\rangle\overline{\langle x', \rho(k')y'\rangle}\,dk' = \delta^{-1}\langle x, x'\rangle\langle y', y\rangle$. Hence $\|m_{\mu_u}\|^2 = \delta^{-1}$ and the integral is $\delta^{-1}\langle \rho(h)^* e, e\rangle = \delta^{-1}\langle e, \rho(h)e\rangle$; so $c_{u/2}(h) = \langle e, \rho(h)e\rangle = m_{\mu_u}(h)$.

(iii). By the paragraph on the commutant, $\xi \mapsto \sum_i \xi_i b_i$ is an isomorphism of $\mathbb{C}^{I_w}$ onto $\nabla_{\mathbb{C}}(\lambda)$ that carries $\pi(g) = S_w(g^{\mathsf{T}})^{\mathsf{T}}$ to $P \mapsto P(g^{\mathsf{T}}\cdot)$; by Theorem A.5.19 this is the irreducible rational $\mathrm{GL}_k(\mathbb{C})$-module of highest weight λ for the diagonal torus and the upper triangular Borel subgroup. Its restriction to $\mathrm{U}(k)$ is irreducible, because $\pi(h) = C\rho(h)C^{-1}$ and only scalars commute with ρ; so it is the irreducible continuous representation of $\mathrm{U}(k)$ of highest weight $(\lambda(0), \dots, \lambda(k-1))$, the torus weights of a rational module being those of its restriction. Hence $\chi_\lambda(h) = \operatorname{tr}\pi(h) = \operatorname{tr}(C\rho(h)C^{-1}) = \operatorname{tr}\rho(h)$. □

Lemma 5.7.18. *Let n be a nonempty finite set, $N = \#n$, $\varepsilon \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have gap $h = 500N^3 + 10N^5$ for ε. In the Laurent polynomial ring $\mathcal{R} = \mathbb{C}[X_a^{\pm 1} : a \in n]$ write P_γ for the coefficient of $X^\gamma = \prod_a X_a^{\gamma_a}$ $(\gamma \in \mathbb{Z}^n)$; the* exponents *of P are the γ with $P_\gamma \ne 0$. Let $W_K = \{w \in S_n : \varepsilon \circ w = \varepsilon\}$, $o(a) = \#\{b : l_b > l_a\}$, the* level *$o\cdot\gamma = \sum_a o(a)\gamma_a$, $\kappa = \frac{1}{2}(l + N - 1)$, $\delta(a) = \#\{b : \varepsilon_b \ne \varepsilon_a,\ l_a < l_b\}$, $N' = 4N^2$ and* top *$= \kappa + N'\delta$. Put*

$$D = \prod_{\substack{\varepsilon_a \ne \varepsilon_b \\ l_a < l_b}} (X_a - X_b), \qquad V = \prod_{l_b < l_a} (X_a - X_b), \qquad A_\mu^\eta = \sum_{w \in S_n,\ \eta\circ w = \eta} \operatorname{sgn}(w)\, X^{\mu\circ w} \quad (\eta \in \{\varepsilon, \mathbf{1}\}),$$

the products over ordered pairs, $\mathbf{1}$ the constant sign $+1$. The cone *of l is $C_l = \{\beta \in \mathbb{Z}^n : o'\cdot\beta \le 0$ for every $o' \in \mathbb{Z}^n$ with $o'(a) < o'(b)$ whenever $l_b < l_a\}$. For $a \in \mathbb{Z}^n$ and $k \in \mathbb{N}$, $P \in \mathcal{R}$ is a* cone-series multiple of D^k at a *if there is $t\colon \mathbb{Z}^n \to \mathbb{C}$ with $t(a) = 1$, $P_\gamma = \sum_\beta (D^k)_\beta\, t(\gamma - \beta)$ for all γ, and, whenever $t(\gamma) \ne 0$, some μ with $(A_\mu^\varepsilon)_\gamma \ne 0$ and $\mu - a \in C_l$. P is W_K-*antisymmetric *if $P_{\gamma\circ w} = \operatorname{sgn}(w) P_\gamma$ for $w \in W_K$ and all γ. Then:*

(a) $\kappa \in \mathbb{Z}^n$; κ and top *are strictly increasing along l ($l_j < l_i$ implies $\kappa_j < \kappa_i$ and $\mathrm{top}_j < \mathrm{top}_i$).*

(b) If P is a cone-series multiple of D^k at a and $a + k\delta =$ top, then $P_{\mathrm{top}} = 1$, and every exponent γ of P has some $w \in W_K$ with $o\cdot(\gamma\circ w) \le o\cdot$ top.

(c) $D^{N'} A_\kappa^\varepsilon$ is W_K-antisymmetric and a cone-series multiple of $D^{N'}$ at κ.

(d) If $o\cdot\gamma \le o\cdot\mathrm{top}$, then $(D^{N'}A^{\mathbf{1}}_{\kappa})_\gamma = (D^{N'}A^{\varepsilon}_{\kappa})_\gamma$; and every exponent β of $VD^{N'}$ satisfies $o\cdot\mathrm{top} < o\cdot(\kappa-o)+o\cdot\beta+h$.

(e) Let $P,Q\in\mathcal{R}$ be W_K-antisymmetric, $m\in\mathbb{Z}$ and $c\in\mathbb{C}$, such that every exponent γ of P or of Q has some $w\in W_K$ with $o\cdot(\gamma\circ w)\le m$, and $P_\gamma = cQ_\gamma$ whenever $o\cdot\gamma\le m$. Then $P=cQ$.

Proof. As l has a gap, it is injective and $l_a \equiv N-1 \pmod 2$, so $\kappa\in\mathbb{Z}^n$; o is a bijection $n\to\{0,\dots,N-1\}$ that strictly reverses the order of l ($l_b<l_a \Rightarrow o(a)<o(b)$), and $0\le\delta\le N$. If $\varepsilon_a\ne\varepsilon_b$, then $|\kappa_a-\kappa_b| = \frac12|l_a-l_b|\ge h$.

Step 1: rearrangement with a gain. Let $b\in\mathbb{Z}^n$ be injective and strictly increasing along l, so that o strictly reverses its order. Then for $w\in S_n$ and $i\in n$,

$$o\cdot b + |b_i - b_{w(i)}| \le o\cdot(b\circ w), \tag{5.141}$$

and in particular $o\cdot(b\circ w)\ge o\cdot b$ with equality only for $w=1$. Indeed, for $c\in\{1,-1\}$ the integer vector $o+c\,e_i$ still weakly reverses the order of b (if $b_j<b_{j'}$ then $o(j')\le o(j)-1$), so by the rearrangement inequality $(o+ce_i)\cdot b\le(o+ce_i)\cdot(b\circ w)$, that is $o\cdot b+cb_i\le o\cdot(b\circ w)+cb_{w(i)}$; take the better of $c=\pm1$. If $w\ne1$, some i has $b_{w(i)}\ne b_i$, and (5.141) is strict.

Step 2: proof of (a). κ is strictly increasing along l. Let $l_j<l_i$. If $\kappa_i-\kappa_j>N'N$, then $\mathrm{top}_i-\mathrm{top}_j\ge\kappa_i-\kappa_j-N'N>0$ as $0\le\delta\le N$. Otherwise $0<\kappa_i-\kappa_j\le 4N^3<h$, so every a with $l_j\le l_a\le l_i$ has $\varepsilon_a=\varepsilon_i=\varepsilon_j$ (else $|\kappa_a-\kappa_i|\ge h$ or $|\kappa_a-\kappa_j|\ge h$, while $\kappa_j\le\kappa_a\le\kappa_i$). Then every b counted in $\delta(j)$ ($\varepsilon_b\ne\varepsilon_j$, $l_b>l_j$) has $l_b>l_i$ and $\varepsilon_b\ne\varepsilon_i$, so $\delta(j)\le\delta(i)$ and $\mathrm{top}_j<\mathrm{top}_i$.

Step 3: the monomials of D^k. Each factor X_a-X_b of D has $l_a<l_b$, so $o(a)>o(b)$: the monomial X_a has the larger level. Expanding the product, X^δ (the product of the first terms) has coefficient 1 in D and every other monomial has strictly smaller level; the same holds for D^k and $X^{k\delta}$, and all exponents of D^k are ≥0. Moreover $D(X\circ w)=D(X)$ for $w\in W_K$: writing each factor as $\pm(X_a-X_b)$ with $\varepsilon_a=+1$, $\varepsilon_b=-1$, $D=\pm\prod_{\varepsilon_a=1,\varepsilon_b=-1}(X_a-X_b)$ with a fixed sign, and w permutes the indices of each sign; so $(D^k)_{\beta\circ w}=(D^k)_\beta$.

Step 4: proof of (b). Let t be as in the definition. Suppose $(D^k)_\beta\, t(\gamma-\beta)\ne0$. There is μ with $(A^\varepsilon_\mu)_{\gamma-\beta}\ne0$ and $\mu-a\in C_l$; so $\gamma-\beta=\mu\circ v$ for some $v\in W_K$, that is $\mu=(\gamma-\beta)\circ w$ with $w=v^{-1}\in W_K$, and $o\cdot(\mu-a)\le0$ gives $o\cdot(\gamma\circ w)\le o\cdot(\beta\circ w)+o\cdot a$. By Step 3, $\beta\circ w$ is an exponent of D^k, so $o\cdot(\beta\circ w)\le k\,o\cdot\delta$, with equality only if $\beta\circ w=k\delta$. Hence

$$o\cdot(\gamma\circ w)+[\beta\circ w\ne k\delta]\le o\cdot\mathrm{top}. \tag{5.142}$$

If γ is an exponent of P, some β has $(D^k)_\beta t(\gamma-\beta)\ne0$, and (5.142) gives the second claim. For $\gamma=\mathrm{top}$: if a term β is nonzero, (5.142) and Step 1 (for $b=\mathrm{top}$, strictly increasing along l by (a)) force $w=1$ and then $\beta=k\delta$. So $P_{\mathrm{top}}=(D^k)_{k\delta}\,t(\mathrm{top}-k\delta)=t(a)=1$.

Step 5: proof of (c). By Step 3 and $\mathrm{sgn}(wv)=\mathrm{sgn}(w)\mathrm{sgn}(v)$, $D^{N'}$ is W_K-invariant and A^ε_κ is W_K-antisymmetric, hence so is the product (the coefficient of $X^{\gamma\circ w}$ in a product FG with F invariant is $\sum_\beta F_{\beta\circ w}G_{(\gamma-\beta)\circ w}$). Take $t(\gamma)=(A^\varepsilon_\kappa)_\gamma$: then $(D^{N'}A^\varepsilon_\kappa)_\gamma=\sum_\beta(D^{N'})_\beta t(\gamma-\beta)$; $t(\kappa)=1$, because $\kappa\circ w=\kappa$ only for $w=1$ (κ is injective); and if $t(\gamma)\ne0$, $\mu=\kappa$ works, $0\in C_l$.

Step 6: proof of (d). Let $o\cdot\gamma\le o\cdot\mathrm{top}$. The coefficient $(D^{N'}A^{\mathbf{1}}_\kappa)_\gamma$ is $\sum_\beta(D^{N'})_\beta\sum_v\mathrm{sgn}(v)[\kappa\circ v=\gamma-\beta]$ over all $v\in S_n$, and the same with $v\in W_K$ for A^ε. Suppose $\kappa\circ v=\gamma-\beta$ with $(D^{N'})_\beta\ne0$ and $v\notin W_K$: some i has $\varepsilon_{v(i)}\ne\varepsilon_i$, and (5.141) for $b=\kappa$ gives $o\cdot\kappa+h\le o\cdot(\kappa\circ v)=o\cdot\gamma-o\cdot\beta\le o\cdot\gamma$ ($\beta\ge0$, $o\ge0$); but $o\cdot\gamma\le o\cdot\kappa+N'o\cdot\delta\le o\cdot\kappa+4N^2\cdot N^3<o\cdot\kappa+h$ (as $0\le o(a)<N$ and $0\le\delta(a)\le N$). So only $v\in W_K$ contribute, and the two coefficients agree. For the bound, $VD^{N'}$ is a polynomial, so $o\cdot\beta\ge0$ for its exponents, and $o\cdot\mathrm{top}-o\cdot(\kappa-o)=o\cdot o+N'\,o\cdot\delta\le N\cdot N^2+4N^2\cdot N^3<h$.

Step 7: proof of (e). Let γ be an exponent of P or of Q and $w \in W_K$ with $o \cdot (\gamma \circ w) \le m$. Then $\operatorname{sgn}(w) P_\gamma = P_{\gamma\circ w} = cQ_{\gamma\circ w} = c\operatorname{sgn}(w) Q_\gamma$, so $P_\gamma = cQ_\gamma$; if γ is an exponent of neither, both sides vanish. □

Lemma 5.7.19. *Fix the setting of Definition 5.1.6, signs ε on the r basis indices of V_1 and a sign frame p for ε. Let $l \in \mathbb{Z}^r$ have large gap A for ε ($A \ge 0$ an integer); write $\psi(g) = c_{l/2}(p^{-1}gp)$ ($g \in G_1$), d_l for the formal degree $(\int |c_{l/2}|^2)^{-1}$ for the Haar measure on $\mathrm{U}(\operatorname{diag}\varepsilon)$ carried from dy by $g \mapsto p^{-1}gp$, and $e = d_l\psi$. Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be a unitary representation on $\mathbb{C}^I$, with the standard inner product $\langle\cdot,\cdot\rangle$ of $\mathbb{C}^I$ (conjugate-linear in the first argument), and F a Bessel function of type ρ, integrable over $\mathsf{U}\backslash G_1$, with $\int_{G_1} e(a^{-1})F(ya)\,da = F(y)$ for all $y \in G_1$; put $\|F\|_2^2 = \int_{\mathsf{U}\backslash G_1} \|F\|^2$. Then:*

(i) for all $a, b \in G_1$ the following integral converges absolutely, and

$$\int_{\mathsf{U}\backslash G_1} \langle F(ya), F(yb)\rangle\, dy = \psi(a^{-1}b)\, \|F\|_2^2;$$

(ii) $\displaystyle\int_{G_1} \Big| \int_{\mathsf{U}\backslash G_1} \langle F(y), F(yg)\rangle\, dy \Big|^2 dg = d_l^{-1}\, \|F\|_2^4;$

(iii) let $X\colon G_1 \to \mathbb{C}$ be integrable with $\int_{G_1} X(a^{-1})\, e(ya)\, da = X(y)$ for all y, and put $V(y) = \int_{G_1} X(a^{-1})F(ya)\, da$. Then for every integrable ϕ on G_1

$$\int_{\mathsf{U}\backslash G_1} \Big\| \int_{G_1} \phi(y)\, V(\gamma y)\, dy \Big\|^2 d\gamma \le \Big(d_l^{-1} \int_{G_1} |X|^2 \Big) \Big(d_l^{-1}\, \|F\|_2^2 \Big) \int_{G_1} |\phi|^2.$$

Proof. Write $G = G_1$, $c = c_{l/2}$, $d = d_l$, $\iota(g) = p^{-1}gp$, $M_F = \sup_G \|F\| < \infty$ (F is bounded) and $\|F\|_1 = \int_{\mathsf{U}\backslash G} \|F\| < \infty$. Integrals over G without a named measure are for dy, and integrable means integrable for dy.

The group and the kernel. As p is unitary and $p^* J_1 p = \operatorname{diag}(\varepsilon)$, ι is an isomorphism of topological groups $G \to \mathrm{U}(\operatorname{diag}\varepsilon)$; let dg be the image of dy, the Haar measure of the statement. By Lemma 5.2.41, dy is invariant under $y \mapsto ayb$ for all $a, b \in G$. It is also invariant under $y \mapsto y^{-1}$: the image of dy under inversion is again invariant under left and right translations, hence equal to $\gamma_0\, dy$ for some $\gamma_0 > 0$ by the uniqueness of Haar measure, and applying inversion twice gives $\gamma_0^2 = 1$. The vector l has gap $500r^3 + A > 8r^2$ for ε ((WM8) of Definition 3.2.19), so Lemma 5.6.23 (i), (ii) and Lemma 5.7.40 apply to l and dg. Transported by ι they give: ψ is continuous and integrable, $|\psi| \le 1$, $\psi(g^{-1}) = \overline{\psi(g)}$, $d > 0$, $\int_G |\psi|^2 = d^{-1}$, and

$$d \int_G \psi(xya)\, \overline{\psi(y)}\, dy = \psi(x)\, \psi(a) \qquad (x, a \in G). \tag{5.143}$$

Hence e is continuous and integrable, $|e| \le d$, $e(g^{-1}) = \overline{e(g)}$, and

$$\int_G e(z)\, e(x^{-1}z^{-1}y)\, dz = \frac{e(x^{-1})\, e(y)}{d} \qquad (x, y \in G): \tag{5.144}$$

after the substitution $z \mapsto z^{-1}$ the left side is $d^2 \int_G \overline{\psi(z)}\, \psi(x^{-1}zy)\, dz = d\, \psi(x^{-1})\psi(y)$ by (5.143). Finally X is bounded, $|X(y)| \le \int_G |X(a^{-1})|\, |e(ya)|\, da \le d \int_G |X|$, hence square integrable.

A coefficient identity. Let E be $\mathbb{C}^I$ or $\mathbb{C}$ with its standard inner product, μ a σ-finite Borel measure on G and $f\colon G\to E$ a bounded Borel function with $\int\|f\|\,d\mu<\infty$ such that, for all $y,s,t\in G$,

$$\begin{aligned} f(y)&=\int_G e(t^{-1})f(yt)\,dt,\\ \int\|f(ys)\|\,d\mu(y)&=\int\|f\|\,d\mu,\\ \int\langle f(ys),f(yt)\rangle\,d\mu(y)&=\int\langle f(y),f(ys^{-1}t)\rangle\,d\mu(y). \end{aligned}\tag{5.145}$$

Claim: for all $a,b\in G$, $\int\langle f(ya),f(yb)\rangle\,d\mu(y)=\psi(a^{-1}b)\int\|f\|^2d\mu$. Put $M=\sup\|f\|$, $m=\int\|f\|\,d\mu$ and $k(g)=\int\langle f(y),f(yg)\rangle\,d\mu(y)$; the integrand is bounded by $M\|f(y)\|$, so $|k|\le Mm$, and k is Borel by Tonelli's theorem applied to the positive and negative parts of the real and imaginary parts of $(y,g)\mapsto\langle f(y),f(yg)\rangle$. By the third identity of (5.145), $\int\langle f(ys),f(yt)\rangle\,d\mu=k(s^{-1}t)$; with $(s,t)=(g,1)$ this gives $k(g^{-1})=\int\langle f(yg),f(y)\rangle\,d\mu=\overline{k(g)}$. With $(s,t)=(g^{-1},1)$, $k(g)=\int\langle f(yg^{-1}),f(y)\rangle\,d\mu(y)$; insert $f(y)=\int e(t^{-1})f(yt)\,dt$. The function $(y,t)\mapsto e(t^{-1})\langle f(yg^{-1}),f(yt)\rangle$ is integrable for $\mu\otimes dt$, as it is bounded by $M|e(t^{-1})|\,\|f(yg^{-1})\|$, whose double integral is $Mm\int|e|$ by the second identity of (5.145). By Fubini's theorem,

$$k(g)=\int_G e(t^{-1})\int\langle f(yg^{-1}),f(yt)\rangle\,d\mu(y)\,dt=\int_G e(t^{-1})\,k(gt)\,dt\qquad(g\in G).\tag{5.146}$$

Conjugating (5.146) at g^{-1} and using $\overline{e(t^{-1})}=e(t)$, $\overline{k(g^{-1}t)}=k(t^{-1}g)$ gives

$$k(g)=\int_G e(s)\,k(s^{-1}g)\,ds.$$

Insert (5.146) at $s^{-1}g$ and substitute $t\mapsto g^{-1}st$:

$$k(g)=\int_G e(s)\int_G e(t^{-1})\,k(s^{-1}gt)\,dt\,ds=\int_G e(s)\int_G e(t^{-1}s^{-1}g)\,k(t)\,dt\,ds.$$

The integrand is bounded by $Mm\,|e(s)|\,|e(t^{-1}s^{-1}g)|$, whose double integral is $Mm(\int|e|)^2$ by the invariance of dt; so Fubini's theorem, (5.144) with $(x,y)=(t,g)$ and (5.146) at $g=1$ give

$$k(g)=\int_G k(t)\int_G e(s)\,e(t^{-1}s^{-1}g)\,ds\,dt=\frac{e(g)}{d}\int_G e(t^{-1})\,k(t)\,dt=\psi(g)\,k(1).$$

As $k(1)=\int\|f\|^2d\mu$, the claim follows from $\int\langle f(ya),f(yb)\rangle\,d\mu=k(a^{-1}b)$.

Integrals over $\mathsf{U}\backslash G$. By Definition 5.1.6, $\int_{\mathsf{U}\backslash G}\Theta=\int_G\Theta\,\chi\,dy$ for left U-invariant Θ, where $\chi\ge0$ is a Borel cutoff with $\int_{\mathsf{U}}\chi(uy)\,du=1$ for every y. For left U-invariant Borel $\Theta\ge0$, every $g\in G$ and any two such cutoffs χ,χ',

$$\int_G\Theta(yg)\,\chi(y)\,dy=\int_G\Theta(y)\,\chi'(y)\,dy.\tag{5.147}$$

Indeed $\chi_g(y)=\chi(yg^{-1})$ is again a cutoff and $\int\Theta(yg)\chi(y)\,dy=\int\Theta(y)\chi_g(y)\,dy$ by right invariance; and for cutoffs χ_1,χ_2, by Tonelli's theorem on $\mathsf{U}\times G$, the substitution $y\mapsto u^{-1}y$ (left invariance of dy) and $\Theta(u^{-1}y)=\Theta(y)$,

$$\int_G\Theta\chi_2\,dy=\int_{\mathsf{U}}\int_G\chi_1(uy)\chi_2(y)\Theta(y)\,dy\,du=\int_{\mathsf{U}}\int_G\chi_1(y)\chi_2(u^{-1}y)\Theta(y)\,dy\,du=\int_G\chi_1\Theta\,dy,$$

since $\int_{\mathsf{U}}\chi_2(u^{-1}y)\,du=\int_{\mathsf{U}}\chi_2(uy)\,du=1$ by the inversion invariance of du (Lemma 5.2.34 (iv)). By linearity (5.147) holds for complex left U-invariant Θ with $\int|\Theta|\chi\,dy<\infty$. Fix χ and put $\nu=\chi\,dy$, a σ-finite measure (dy is σ-finite and ν is finite on $C\cap\{\chi\le m\}$ for compact C).

For Bessel functions F_1, F_2 of type ρ and $a, b \in G$ the functions $y \mapsto \langle F_1(ya), F_2(yb)\rangle$ and $y \mapsto \|F_1(ya)\|$ are left U-invariant, as $F_i(uya) = \mathrm{wave}(\sigma(u))F_i(ya)$ with $|\mathrm{wave}| = 1$. So by (5.147), $\int \|F(ys)\|\,d\nu = \|F\|_1$, $\int \|F(ys)\|^2 d\nu = \|F\|_2^2 \le M_F\|F\|_1$, and $\int\langle F(ys), F(yt)\rangle\,d\nu = \int\langle F(y), F(ys^{-1}t)\rangle\,d\nu$ (apply (5.147) with $g = s$ to $\Theta(y) = \langle F(y), F(ys^{-1}t)\rangle$, bounded by $M_F\|F(y)\|$). Together with the reproduction of F, these are the hypotheses (5.145) for $f = F$ and $\mu = \nu$.

(i) and (ii). The integrand of (i) is bounded by $M_F\|F(ya)\|$, which is ν-integrable; the claim for (F, ν) gives (i). For (ii), (i) with $(a, b) = (1, g)$ makes the inner integral $\psi(g)\|F\|_2^2$, and $\int_G |\psi|^2 = d^{-1}$.

Schur orthogonality for X. The function $Y(y) = \overline{X(y^{-1})}$ is bounded, Borel and integrable, and $\int e(t^{-1})Y(yt)\,dt = \overline{\int e(t)X(t^{-1}y^{-1})\,dt} = \overline{\int X(a^{-1})e(y^{-1}a)\,da} = Y(y)$ (conjugate, use $\overline{e(t^{-1})} = e(t)$, substitute $t = y^{-1}a$). With $\mu = dy$ the other two identities of (5.145) hold by right invariance. The claim for (Y, dy), followed by the substitution $y \mapsto y^{-1}$, gives

$$\int_G X(a^{-1}g)\,\overline{X(b^{-1}g)}\,dg = \psi(a^{-1}b)\int_G |X|^2 \qquad (a, b \in G). \tag{5.148}$$

The translates in $L^2(\nu)$. Let $\mathcal{H} = L^2(G, \nu; \mathbb{C}^I)$ with $\langle f, f'\rangle_{\mathcal{H}} = \int\langle f, f'\rangle\,d\nu$, and $w_a \in \mathcal{H}$ the class of $y \mapsto F(ya)$. By (i), $\langle w_a, w_b\rangle_{\mathcal{H}} = \psi(a^{-1}b)\|F\|_2^2$, so $\|w_a\|_{\mathcal{H}} = \|F\|_2$ and $\|w_a - w_b\|_{\mathcal{H}}^2 = 2\|F\|_2^2\,\mathrm{Re}(\psi(1) - \psi(a^{-1}b))$, which tends to 0 as $b \to a$. Thus $a \mapsto w_a$ is continuous and bounded, hence strongly measurable (G is second countable), and for integrable f the Bochner integral $\int f(a)w_a\,da \in \mathcal{H}$ exists, with $\langle u, \int f(a)w_a\,da\rangle_{\mathcal{H}} = \int f(a)\langle u, w_a\rangle_{\mathcal{H}}\,da$ for $u \in \mathcal{H}$. Put $v_g = \int X(a^{-1})w_{ga}\,da = \int X(a^{-1}g)\,w_a\,da$ $(g \in G)$. Then $\|v_g - v_{g'}\|_{\mathcal{H}} \le \|F\|_2\int |X(ag) - X(ag')|\,da$, which tends to 0 as $g' \to g$ by the continuity of right translation in $L^1(G)$; so $g \mapsto v_g$ is continuous, with $\|v_g\|_{\mathcal{H}} \le \|F\|_2\int |X|$. By (i) and the reproduction of X,

$$\langle w_b, v_g\rangle_{\mathcal{H}} = \|F\|_2^2\int_G X(a^{-1})\,\psi(b^{-1}ga)\,da = \frac{\|F\|_2^2}{d}\,X(b^{-1}g) \qquad (b, g \in G), \tag{5.149}$$

and $\langle u, v_g\rangle_{\mathcal{H}} = 0$ for every g if u is orthogonal to all w_a. In particular, as $\langle v_1, w_a\rangle_{\mathcal{H}} = \overline{\langle w_a, v_1\rangle_{\mathcal{H}}}$,

$$\|v_1\|_{\mathcal{H}}^2 = \int_G X(a^{-1})\,\langle v_1, w_a\rangle_{\mathcal{H}}\,da = \frac{\|F\|_2^2}{d}\int_G |X(a^{-1})|^2\,da = \frac{\|F\|_2^2}{d}\int_G |X|^2. \tag{5.150}$$

Orthogonality on the span. Let H_0 be the linear span of the w_a. For $u \in H_0$, by (5.149) the function $g \mapsto \langle u, v_g\rangle_{\mathcal{H}}$ is a finite linear combination of left translates of X, hence bounded and integrable, and for $u, u' \in H_0$

$$\int_G \langle u, v_g\rangle_{\mathcal{H}}\,\langle v_g, u'\rangle_{\mathcal{H}}\,dg = \frac{\|v_1\|_{\mathcal{H}}^2}{d}\,\langle u, u'\rangle_{\mathcal{H}}. \tag{5.151}$$

Both sides are conjugate-linear in u and linear in u', so it suffices to take $u = w_a$, $u' = w_b$: by (5.149) and (5.148) the left side is $(\|F\|_2^2/d)^2\int X(a^{-1}g)\overline{X(b^{-1}g)}\,dg = (\|F\|_2^2/d)^2\psi(a^{-1}b)\int |X|^2$, and by (5.150) and (i) so is the right side.

(iii). Let ϕ be integrable; if $\int |\phi|^2 = \infty$ there is nothing to prove. Put $\Omega = \int_G \phi(g)\,v_g\,dg \in \mathcal{H}$ and $B = d^{-1}\|v_1\|_{\mathcal{H}}^2\int |\phi|^2$. For $u \in H_0$, by the Cauchy–Schwarz inequality and (5.151) with $u' = u$,

$$|\langle u, \Omega\rangle_{\mathcal{H}}|^2 = \Big|\int_G \phi(g)\,\langle u, v_g\rangle_{\mathcal{H}}\,dg\Big|^2 \le \int_G |\phi|^2\int_G |\langle u, v_g\rangle_{\mathcal{H}}|^2\,dg = B\,\|u\|_{\mathcal{H}}^2.$$

Both sides are continuous in u, so the inequality holds on the closure $\overline{H_0}$. If u is orthogonal to H_0, then $\langle u, \Omega\rangle_{\mathcal{H}} = \int \phi(g)\langle u, v_g\rangle_{\mathcal{H}}\,dg = 0$; so $\Omega \in (H_0^{\perp})^{\perp} = \overline{H_0}$, and $u = \Omega$ gives $\|\Omega\|_{\mathcal{H}}^4 \le B\|\Omega\|_{\mathcal{H}}^2$, that is $\|\Omega\|_{\mathcal{H}}^2 \le B$.

It remains to compare Ω with the function on the left of (iii). Put $Z(s) = \int_G \phi(y)X(sy)\,dy$; by Tonelli's theorem and right invariance $\int|Z| \le \int|\phi|\int|X|$. For $\gamma \in G$, the substitution $a = y^{-1}t$ and Fubini's theorem (the integrand $\phi(y)X(t^{-1}y)F(\gamma t)$ has norm with double integral at most $M_F\int|\phi|\int|X|$) give

$$\Phi(\gamma) := \int_G \phi(y)\,V(\gamma y)\,dy = \int_G \phi(y)\int_G X(t^{-1}y)\,F(\gamma t)\,dt\,dy = \int_G Z(t^{-1})\,F(\gamma t)\,dt.$$

So Φ is bounded by $M_F\int|Z|$, Borel by Tonelli's theorem, a Bessel function of type ρ (the left transformations pass through the integral), and $\int\|\Phi\|\,d\nu \le \int|Z(t^{-1})|\int\|F(\gamma t)\|\,d\nu(\gamma)\,dt = \|F\|_1\int|Z|$; hence its class $\tilde\Phi$ lies in $\mathcal{H}$. In $\mathcal{H}$, $\int Z(t^{-1})w_t\,dt = \Omega$: for $u \in \mathcal{H}$, by the substitution $a = y^{-1}t$ and Fubini's theorem ($|\langle u, w_t\rangle_{\mathcal{H}}| \le \|u\|_{\mathcal{H}}\|F\|_2$),

$$\begin{aligned}\langle u,\Omega\rangle_{\mathcal{H}} &= \int_G \phi(y)\int_G X(a^{-1})\langle u, w_{ya}\rangle_{\mathcal{H}}\,da\,dy = \int_G\Big(\int_G \phi(y)X(t^{-1}y)\,dy\Big)\langle u, w_t\rangle_{\mathcal{H}}\,dt\\ &= \Big\langle u, \int_G Z(t^{-1})\,w_t\,dt\Big\rangle_{\mathcal{H}}.\end{aligned}$$

By Fubini's theorem for $\nu\otimes dt$ (the integrand $\langle\Phi(\gamma), Z(t^{-1})F(\gamma t)\rangle$ is bounded by

$$\sup\|\Phi\|\,|Z(t^{-1})|\,\|F(\gamma t)\|,$$

of double integral $\sup\|\Phi\|\,\|F\|_1\int|Z|$),

$$\|\tilde\Phi\|_{\mathcal{H}}^2 = \int\Big\langle\Phi(\gamma), \int_G Z(t^{-1})F(\gamma t)\,dt\Big\rangle\,d\nu(\gamma) = \int_G Z(t^{-1})\,\langle\tilde\Phi, w_t\rangle_{\mathcal{H}}\,dt = \langle\tilde\Phi,\Omega\rangle_{\mathcal{H}} \le \|\tilde\Phi\|_{\mathcal{H}}\|\Omega\|_{\mathcal{H}}.$$

Hence $\|\tilde\Phi\|_{\mathcal{H}} \le \|\Omega\|_{\mathcal{H}}$. As $\|\Phi\|^2$ is left U-invariant, the left side of (iii) is $\|\tilde\Phi\|_{\mathcal{H}}^2 \le \|\Omega\|_{\mathcal{H}}^2 \le B$, and by (5.150) $B = (d^{-1}\int|X|^2)(d^{-1}\|F\|_2^2)\int|\phi|^2$. □

Lemma 5.7.20. *Let D be admissible data, $\varrho = m/2-1$ and $z \in \{\mathrm{I},\mathrm{II}\}$. Let $\mathfrak{n}_z = \{0,\dots,r-1+[z]\}$ be the index set of the node $(z,0,0)$ (the basis of Y_0, and for $z=\mathrm{II}$ the basis of $\tilde Y_0^0 = Y_0\oplus\langle 1\rangle$), let ε_z be its signs, and for $v\in\Phi$ let $\lambda_z(v) = \frac12 p_{z,0,0}(v)$, that is $\lambda_z(v)(i) = \varsigma_i(v) + \frac12[z]$; thus $\lambda_{\mathrm{I}}(v) = \varsigma(v)$ is the Harish-Chandra parameter of Y_0 and $\lambda_{\mathrm{II}}(v)$ is minus that of $\tilde Y_0^0$. Let $X = \{0,\dots,k-2\}$ and let $e\colon X\sqcup\{0,\dots,2\varrho+1+[z]\}\to\mathfrak{n}_z$ be given by $e(x) = x$ for $x\in X$ and $e(i) = k-1+i$ on the second summand. Then e is a bijection, and for every $v\in\Phi$ the doubled parameter $l = p_{z,0,0}(v) = 2\lambda_z(v)$ is steep for $(\varepsilon_z, e, \kappa_0(v))$: with $\mu_z(v) = \mu_l$ the lowest K-type of l for the signs ε_z,*

$$\varepsilon_z(e(x)) = 1,\quad \mu_z(v)(e(x)) = 0 \qquad (x\in X), \qquad\qquad \varepsilon_z(e(i)) = (-1)^i \qquad (0\le i\le 2\varrho+1+[z]),$$

and $i\mapsto\mu_z(v)(e(i))$ is strictly decreasing with values in $[-3\kappa_0(v), -\kappa_0(v)]$.

Proof. Fix z and $v\in\Phi$ and write $N = r+[z]$, $\lambda_i = \lambda_z(v)(i)$, $\varepsilon_i = \varepsilon_z(i)$, $\mu = \mu_z(v)$, $\kappa = \kappa(v)$ and $\kappa_j = \kappa_j(v)$; note $\kappa_{j+1}-\kappa_j = \Delta$ and $\kappa_0 = \kappa + \frac{\Delta}{2}$.

Sizes. We use three inequalities:

$$\text{(a) } m+1 < r, \qquad \text{(b) } N \le r+1 < \Delta, \qquad \text{(c) } \Delta^2 \le \kappa. \tag{5.152}$$

By Lemma 2.3.6, $\log x \ge 10^{14}C_P \ge 10^{14}\cdot 18480$, $x^{10^6} \le x_1$ and $x_1^{10^6} \le b$. By (AD2), $m \le 2\sqrt{x} < x^5 - 1 \le r-1$, which is (a), and (b) holds since $\Delta = 2r^8$. For (c): by (AD2), $\Delta^2 = 4r^{16} \le 4\cdot 3^{16}x^{80} \le x^{81} \le x_1$, and by (AD4), $\kappa\in\{b,\ xb/x_1\}$, so $\kappa \ge b/x_1 \ge x_1 \ge \Delta^2$, because $x\ge 1$ and $x_1^2 \le b$.

The bijection and the signs. Since $r = k-1+m$ and $m = 2\varrho+2$, $\#\mathfrak{n}_z = N = (k-1)+(2\varrho+2+[z])$, and e maps X onto $\{0,\dots,k-2\}$ and the second summand onto $\{k-1,\dots,N-1\}$; so e is a bijection. At the node $(z,0,0)$ there are no blocks, and by (GP5) with $b=0$ the sign of the base index i is $(-1)^{e_i}$ with $e_i = \max(i+1-k,0)$. Hence $\varepsilon_i = 1$ for $i \le k-1$ and $\varepsilon_{k-1+a} = (-1)^a$ for $a \ge 0$; in particular $\varepsilon(e(x)) = 1$ for $x \in X$ and $\varepsilon(e(i)) = (-1)^i$.

The entries. By (GP5),

$$\lambda_i = \tfrac{k}{2} - 1 - i + \tfrac{1}{2}[z] \quad (0 \le i \le k-2), \qquad \lambda_{k-1+a} = \tfrac{\Delta}{2} - \kappa_{a+1} + \tfrac{1}{2}[z] \quad (0 \le a \le m-1+[z]).$$

The sequence (λ_i) is strictly decreasing: it falls by 1 along the first range, by Δ along the second, and $\lambda_{k-1} - \lambda_{k-2} = -\kappa - \Delta - 1 + \frac{k}{2} < 0$ since $k < \Delta$. So λ is regular; its entries lie in $\mathbb{Z} + \frac{N-1}{2}$ because r is odd (AD2); it is a Harish-Chandra parameter for $\mathrm{U}(\operatorname{diag}\varepsilon)$.

The lowest K-type. Let $l = 2\lambda = p_{z,0,0}(v)$. As (λ_i) is strictly decreasing, the definitions of Definition 3.2.3 give $2\rho_l(i) = \#\{i' : i' > i\} - \#\{i' : i' < i\} = N-1-2i$ and $2\rho_l^{\mathrm{c}}(i) = \sum \operatorname{sgn}(i'-i)$ over the $i' \ne i$ with $\varepsilon_{i'} = \varepsilon_i$. The entries of λ lie in $\mathbb{Z} + \frac{N-1}{2}$, so $l_i + 2\rho_l(i) = 2\lambda_i + N - 1 - 2i$ is even and $l_i^\rho = \lambda_i + \rho_l(i)$; hence $2\mu(i) = 2\lambda_i + 2\rho_l(i) - 4\rho_l^{\mathrm{c}}(i)$. In $2\rho_l(i) - 4\rho_l^{\mathrm{c}}(i)$ an index $i' \ne i$ contributes $-\operatorname{sgn}(i'-i)$ if $\varepsilon_{i'} = \varepsilon_i$ and $\operatorname{sgn}(i'-i)$ otherwise, that is $-\varepsilon_i\varepsilon_{i'}\operatorname{sgn}(i'-i)$. Therefore

$$2\mu(i) = 2\lambda_i - L_i, \qquad L_i = \sum_{i' \ne i} \varepsilon_i\varepsilon_{i'} \operatorname{sgn}(i'-i), \qquad |L_i| \le N-1. \tag{5.153}$$

The near entries. Let $0 \le i \le k-2$, so $\varepsilon_i = 1$. The indices $i' < i$ have sign $+1$ and contribute $-i$ to L_i; the indices $i < i' \le k-1$ have sign $+1$ and contribute $k-1-i$; the indices $i' = k-1+a$, $1 \le a \le m-1+[z]$, contribute $\sum_{a=1}^{m-1+[z]}(-1)^a$, which is -1 for $[z]=0$ and 0 for $[z]=1$ (m is even), that is $[z]-1$. So $L_i = k-2-2i+[z] = 2\lambda_i$, and (5.153) gives $\mu(e(x)) = \mu(x) = 0$ for $x \in X$.

The far entries. Let $0 \le a \le m-1+[z]$ and $i = e(a) = k-1+a$. By (5.153),

$$2\mu(e(a)) = \Delta - 2\kappa_{a+1} + [z] - L_{k-1+a}.$$

Strict decrease: $2\mu(e(a+1)) - 2\mu(e(a)) = -2\Delta + L_{k-1+a} - L_{k+a} \le -2\Delta + 2(N-1) < 0$ by (5.152)(b). Upper bound: $[z] - L_i \le N$, so $2\mu(e(a)) \le \Delta - 2\kappa_1 + N = -2\kappa - 2\Delta + N \le -2\kappa - \Delta = -2\kappa_0$, by (b). Lower bound: $[z] - L_i \ge -N$ and $a+1 \le m+1$, so

$$2\mu(e(a)) \ge \Delta - 2\kappa_{m+1} - N = -2\kappa - 2(m+1)\Delta - N \ge -2\kappa - 3\Delta^2 \ge -6\kappa - 3\Delta = -6\kappa_0,$$

where $2(m+1)\Delta + N \le 2\Delta^2 + \Delta \le 3\Delta^2$ by (a), (b), and $3\Delta^2 \le 3\kappa \le 4\kappa + 3\Delta$ by (c). Hence $\mu(e(a)) \in [-3\kappa_0, -\kappa_0]$ for every a, which completes the proof. □

The construction of a Bessel system needs a lower bound for a period: an integral, over a group S mapped into two real unitary groups, of a coefficient of one discrete series against the conjugate of a coefficient of another, twisted by a unitary phase. Theorem 5.7.21 gives it under four conditions on the parameters, the phase and the embedding. It is used in the stationary point of the Bessel averages (Proposition 5.7.30 (a)) and again in Section 6, for the auxiliary forms (Lemma 6.4.109, Lemma 6.4.98). The method is Laplace's [66] (see [132] for the related method of stationary phase). After the phase is removed, Flensted-Jensen's function near the identity has a Gaussian shape (Lemma 5.7.24); in our reading the integrand is then nonnegative up to a small error near the identity and decays away from it. The Gaussian shape rests on an expansion to second order of the principal minors in Flensted-Jensen's formula (Proposition 5.7.25, Proposition 5.7.26).

Theorem 5.7.21. *Let $(\mathfrak{n},\mathfrak{m},\varepsilon,\eta,l,k,S,j,\varphi,X,M,e,\tau,B,\beta,L,h)$ be a Laplace datum, $j=(j_1,j_2)$. Suppose that S carries a topology and its Borel σ-algebra, for which left and right translations are measurable, that ν is a right-invariant measure on S that is finite on compact sets, and that j_1 is proper and j_2 continuous. Then $\theta(s)=c_{l/2}(j_1(s))\,\overline{c_{k/2}(j_2(s))}\,e^{-\varphi(s)}$ is ν-integrable, the set $\{s\in S:\|j_1(s)\|_{\mathrm{op}}\le\beta+1,\ \|j_2(s)\|_{\mathrm{op}}\le\beta+1\}$ has finite measure, and*

$$\nu\{s\in S:\|j_1(s)\|_{\mathrm{op}}\le\beta+1,\ \|j_2(s)\|_{\mathrm{op}}\le\beta+1\}\le\beta^{20(\#\mathfrak{n}+\#\mathfrak{m})^2}\Big|\int_S\theta\,d\nu\Big|.$$

Proof. Put $N=(\#\mathfrak{n}+\#\mathfrak{m})^2\ge1$ and let $J\colon S\to\mathrm{U}(\mathrm{diag}(\varepsilon\oplus\eta))$, $J(s)=\mathrm{diag}(j_1(s),j_2(s))$, the block sum, a homomorphism into the unitary group of the $(\mathfrak{n}\sqcup\mathfrak{m})$-indexed signs $\varepsilon\oplus\eta$. For block-diagonal matrices $\|J(s)\|=\max(\|j_1(s)\|,\|j_2(s)\|)$ and $\|J(s)-1\|=\max(\|j_1(s)-1\|,\|j_2(s)-1\|)$. Let G be as in Lemma 5.7.22, so $G(s)=(2/\|J(s)\|)^{9N}$.

Step 1: J is proper. j_1 is proper, hence continuous, and j_2 is continuous, so J is continuous. If $C\subseteq\mathrm{U}(\mathrm{diag}(\varepsilon\oplus\eta))$ is compact, its image C_1 under the continuous map $g\mapsto$ (upper left $\mathfrak{n}\times\mathfrak{n}$ block) is compact, and $J^{-1}(C)$ is a closed subset (closed as J is continuous and C is closed in the Hausdorff group) of the compact set $j_1^{-1}(C_1\cap\mathrm{U}(\mathrm{diag}\,\varepsilon))$; so $J^{-1}(C)$ is compact.

Step 2: integrability. The function $c_{l/2}$ is continuous on $\mathrm{U}(\mathrm{diag}\,\varepsilon)$: by Lemma 5.6.25, in (3.2) of Definition 3.2.3 with $a=\mathrm{bd}_\varepsilon(g)$, $z=a^{-1}g$, the integrand is a continuous function of $(g,k)\in\mathrm{U}(\mathrm{diag}\,\varepsilon)\times K_\varepsilon$ (its denominators do not vanish), and an integral over the compact K_ε of a jointly continuous function is continuous in the parameter. Likewise for $c_{k/2}$, and φ is continuous by the formula of (LA2). So θ is continuous, hence measurable. By Lemma 5.6.32 (ii) for the proper J, $y=1$ and $c=9N>8N$, G is ν-integrable and

$$\int_S G\,d\nu\le16^{9N}\,\nu(U_1),\qquad U_1=\{s:\|J(s)-1\|\le1\},\tag{5.154}$$

and by Lemma 5.7.22 (i), $|\theta|\le G$, so θ is ν-integrable.

Step 3: covering. Let $\mathcal{L}=\{s:\|j_1(s)\|\le\beta+1,\ \|j_2(s)\|\le\beta+1\}=\{s:\|J(s)\|\le\beta+1\}$ and $\mathcal{S}=\{s:\|J(s)-1\|\le(200\beta^5)^{-1}\}$. Apply Lemma 5.6.32 (i) to J (index set of $\#\mathfrak{n}+\#\mathfrak{m}$ elements) with $y=1$, $D=200\beta^5$, $R=\beta+1$, $K=\beta^8$: indeed $3DR^2=600\beta^5(\beta+1)^2\le1200\beta^7\le\beta^8$ as $\beta\ge1200$. So

$$\nu(\mathcal{L})\le\beta^{16N}\nu(\mathcal{S}),$$

and $\nu(\mathcal{S})<\infty$ by Lemma 5.6.32 (ii); hence $\nu(\mathcal{L})<\infty$. Also $U_1\subseteq\mathcal{L}$, since $\|J(s)\|\le1+\|J(s)-1\|\le2\le\beta+1$.

Step 4: integration of the pointwise bounds. By Lemma 5.7.22 (ii), $|\theta|\ge\frac14$ on $\mathcal{S}$, and by (i), $|\theta|\le2\,\mathrm{Re}\,\theta+6\beta^{-50N}G$ everywhere. Hence, with (5.154),

$$\tfrac14\nu(\mathcal{S})\le\int_S|\theta|\,d\nu\le2\,\mathrm{Re}\int_S\theta\,d\nu+6\beta^{-50N}\int_S G\,d\nu\le2I+6\beta^{-50N}16^{9N}\nu(\mathcal{L}),\qquad I=\Big|\int_S\theta\,d\nu\Big|.$$

Step 5: conclusion. Write $V=\nu(\mathcal{L})<\infty$. Steps 3 and 4 give $V\le\beta^{16N}(8I+24\beta^{-50N}16^{9N}V)$. Since $16\le\beta$ and $48\le\beta$, $48\cdot16^{9N}\beta^{16N}\le\beta\cdot\beta^{9N}\beta^{16N}\le\beta^{50N}$, so $24\beta^{16N}\beta^{-50N}16^{9N}\le\frac12$ and $V\le8\beta^{16N}I+\frac12V$, i.e. $V\le16\beta^{16N}I\le\beta^{20N}I$, as $16\le\beta^{4N}$. □

Lemma 5.7.22. *Let $(\mathfrak{n},\mathfrak{m},\varepsilon,\eta,l,k,S,j,\varphi,X,M,e,\tau,B,\beta,L,h)$ be a Laplace datum, $j=(j_1,j_2)$. Put $N=(\#\mathfrak{n}+\#\mathfrak{m})^2$,*

$$\theta(s)=c_{l/2}(j_1(s))\,\overline{c_{k/2}(j_2(s))}\,e^{-\varphi(s)}\quad\text{and}\quad G(s)=\big(2/\max(\|j_1(s)\|,\|j_2(s)\|)\big)^{9N}.$$

Then for every $s\in S$:

1. $|\theta(s)| \le G(s)$ *and* $|\theta(s)| \le 2\operatorname{Re}\theta(s) + 6\beta^{-50N}G(s)$;

2. *if* $\max(\|j_1(s)-1\|, \|j_2(s)-1\|) \le (200\beta^5)^{-1}$, *then* $|\theta(s)| \ge \frac{1}{4}$.

Proof. Throughout, $s \in S$, $g_1 = j_1(s)$, $g_2 = j_2(s)$, $x_i = g_i - 1$, and $y(g) = g - \mathrm{bd}(g)$ is the noncompact part (for the signs of the group of g). By (LA2), $\operatorname{Re}\varphi = 0$, so

$$|\theta(s)| = |c_{l/2}(g_1)|\,|c_{k/2}(g_2)|. \tag{5.155}$$

Since $\beta \ge 10^{12} > e$, $\log\beta \ge 1$; put $T = N\log\beta \ge 1$. By (LA4), $h \ge 10^{30}T^3 \ge 18N$. The vectors l, k have gap $500(\#\mathfrak{n})^3 + h \ge h$, respectively $500(\#\mathfrak{m})^3 + h \ge h$, and so does $-k$ (gaps are invariant under $l \mapsto -l$).

Step 1: decay. By Lemma 5.7.38 (1), $|c_{l/2}| \le 1$, $|c_{k/2}| \le 1$ and $|c_{l/2}(g)| \le (2/\|g\|)^c$, $|c_{k/2}(g)| \le (2/\|g\|)^c$ for every integer $0 \le c \le h$. Bounding by (5.155) the factor at the component of larger norm by the decay and the other by 1, with $c = 9N$ and $c = 18N$:

$$|\theta(s)| \le G(s), \qquad |\theta(s)| \le G(s)^2. \tag{5.156}$$

This is the first claim of (i).

Step 2: far from the compact subgroups. Put $\rho = 10^{-13}/T$ and suppose $\|y(g_1)\|_{\mathrm{HS}}^2 + \|y(g_2)\|_{\mathrm{HS}}^2 \ge \rho^2$. For $g \in \mathrm{U}(\operatorname{diag}\sigma)$, $J = \operatorname{diag}(\sigma)$ and $g' = JgJ$ we have $\mathrm{bd}(g) = \frac{1}{2}(g+g')$, $y(g) = \frac{1}{2}(g-g')$ and $g^*g' = g^*JgJ = 1 = g'^*g$, hence $\mathrm{bd}(g)^*\mathrm{bd}(g) - y(g)^*y(g) = \frac{1}{2}(g^*g' + g'^*g) = 1$. With $\sigma_i \ge 0$ the eigenvalues of y^*y,

$$|\det \mathrm{bd}(g)|^2 = \det(1+y^*y) = \prod_i (1+\sigma_i) \ge 1 + \sum_i \sigma_i = 1 + \|y(g)\|_{\mathrm{HS}}^2.$$

By Lemma 5.6.29 (i) with $c = h$, $|c_{l/2}(g_1)|^4 \le |\det \mathrm{bd}(g_1)|^{-2h} \le (1+\|y(g_1)\|_{\mathrm{HS}}^2)^{-h}$, and likewise for $c_{k/2}(g_2)$. By (5.155),

$$|\theta(s)|^4 \le \big((1+\|y(g_1)\|_{\mathrm{HS}}^2)(1+\|y(g_2)\|_{\mathrm{HS}}^2)\big)^{-h} \le (1+\rho^2)^{-h}.$$

As $\log(1+u) \ge 2u/(u+2)$ for $u \ge 0$, $\rho \le 10^{-13}$ and $\rho^2T^2 = 10^{-26}$,

$$h\log(1+\rho^2) \ge 10^{30}T^3\frac{2\rho^2}{\rho^2+2} = \frac{2\cdot 10^4\,T}{\rho^2+2} \ge 400\,T,$$

so $|\theta(s)| \le e^{-100T}$, and therefore $|\theta(s)| \le 2\operatorname{Re}\theta(s) + 3e^{-100T}$, as $\operatorname{Re}\theta \ge -|\theta|$.

Step 3: the phase at the logarithms. For pairs $Z = (Z_1, Z_2)$ of $\mathfrak{n}\times\mathfrak{n}$ and $\mathfrak{m}\times\mathfrak{m}$ matrices (added and multiplied componentwise) put $\Psi(Z) = \operatorname{tr}(\operatorname{diag}(\mu_l)Z_1) - \operatorname{tr}(\operatorname{diag}(\mu_k)Z_2)$, a linear form, and $x(t) = (j_1(t)-1, j_2(t)-1)$, so that $\Psi(x(t)) = \varphi(t)$ by (LA2). Since $x(s)(1+x(t)) = x(st) - x(t)$, (LA2) gives $\Psi(x(s)(1+x(t))) = \varphi(st) - \varphi(t) = \varphi(s)$, and by induction on i, writing $x = x(s)$,

$$\Psi\big(x^i x(1+x(t))\big) = 0^i\varphi(s) \quad (t \in S,\ i \ge 0),$$

because $x^{i+1}x(1+x(t)) = x^i x(1+x(st)) - x^i x(1+x(t))$. With $t = 1$: $\Psi(x^{i+1}) = 0^i\varphi(s)$. If $\|x_1\|_{\mathrm{HS}}, \|x_2\|_{\mathrm{HS}} \le \frac{1}{2}$, then $(1+rx)^{-1}x = \sum_{i\ge0}(-r)^i x^{i+1}$ converges absolutely for $0 \le r \le 1$, and integrating over r (lg as in Lemma 5.7.24, applied componentwise),

$$\Psi\big(\lg(x_1), \lg(x_2)\big) = \int_0^1 \sum_{i\ge0}(-r)^i 0^i\varphi(s)\,dr = \varphi(s). \tag{5.157}$$

Step 4: near the compact subgroups. Suppose $\|y(g_1)\|_{\mathrm{HS}}^2+\|y(g_2)\|_{\mathrm{HS}}^2\le\rho^2$. As $\rho\le\frac16$, Lemma 5.7.23 gives $t\in S$ with $\theta(t)=\theta(s)$ and $\|j_i(t)-1\|_{\mathrm{HS}}\le\delta:=4\rho$, $\delta T=4\cdot10^{-13}\le10^{-12}$; replace s by t, so that $\|x_i\|_{\mathrm{HS}}\le\delta\le\frac12$. By Lemma 5.6.29 (ii), $\overline{c_{k/2}(g_2)}=c_{-k/2}(g_2)$. From the definition of the lowest K-type (Definition 3.2.3), $2\rho_{-k}=-2\rho_k$ and $2\rho^{\mathrm c}_{-k}=-2\rho^{\mathrm c}_k$, and $k_i+2\rho_k(i)$ is even (the entries of k are distinct and $\equiv\#\mathfrak m-1 \bmod 2$, and $2\rho_k(i)\equiv\#\mathfrak m-1 \bmod 2$), so $\mu_{-k}=-\mu_k$. By (5.157),

$$\theta(s)=R_1R_2,\qquad R_1=\frac{c_{l/2}(g_1)}{\exp\mathrm{tr}(\mathrm{diag}(\mu_l)\lg(x_1))},\quad R_2=\frac{c_{-k/2}(g_2)}{\exp\mathrm{tr}(\mathrm{diag}(\mu_{-k})\lg(x_2))}.$$

Apply Lemma 5.7.24 to (ε,l,g_1) and to $(\eta,-k,g_2)$, with $A=h$, L, δ, T: $1\le T$; $(\#\mathfrak n)^2\le N\le T$; $(\#\mathfrak n)^2\log(\#\mathfrak n+L+1)\le N\log\beta=T$ since $\#\mathfrak n+L+1\le\beta$ by (LA4); the same for $\mathfrak m$; $\delta T\le10^{-12}$. So $|R_i-\varkappa_i|\le\varkappa_i/10+E$ with $\varkappa_i\in[0,1]$ and $E=e^{-100T}\in[0,1]$. Writing $R_1R_2-\varkappa_1\varkappa_2=\varkappa_1(R_2-\varkappa_2)+(R_1-\varkappa_1)\varkappa_2+(R_1-\varkappa_1)(R_2-\varkappa_2)$,

$$|\theta(s)-p|\le\varkappa_1(\tfrac{\varkappa_2}{10}+E)+(\tfrac{\varkappa_1}{10}+E)\varkappa_2+(\tfrac{\varkappa_1}{10}+E)(\tfrac{\varkappa_2}{10}+E)\le0.21\,p+4E,\qquad p=\varkappa_1\varkappa_2\in[0,1].$$

Hence $|\theta(s)|\le p+|\theta(s)-p|$ and $\mathrm{Re}\,\theta(s)\ge p-|\theta(s)-p|$ give $|\theta(s)|-2\,\mathrm{Re}\,\theta(s)\le3|\theta(s)-p|-p\le12E$.

Step 5: the cone with a decaying error. By Steps 2 and 4, $d(s):=|\theta(s)|-2\,\mathrm{Re}\,\theta(s)\le12E$ for every s, and $E=\beta^{-100N}=(\beta^{-50N})^2$. Also $d(s)\le3|\theta(s)|\le3G(s)^2$ by (5.156). If $d(s)>6\beta^{-50N}G(s)$ (≥0), then $d(s)^2>36\beta^{-100N}G(s)^2\ge12\beta^{-100N}\cdot3G(s)^2\ge d(s)\cdot d(s)$, a contradiction. So $|\theta(s)|\le2\,\mathrm{Re}\,\theta(s)+6\beta^{-50N}G(s)$, which completes (i).

Step 6: near the identity. By (3.2) of Definition 3.2.3,

$$c_{l/2}(1)=\mathrm{FJ}_l(1,1)=\|m_{\mu_l}\|^{-2}\int_{K_\varepsilon}|m_{\mu_l}(k)|^2/m_{-l^\rho}(1)\,dk=1,$$

as every principal minor of 1 is 1; likewise $c_{k/2}(1)=1$. By Lemma 5.7.38 (2) with $x=1$ (large gap h, entries bounded by L), $|c_{l/2}(g_1)-1|\le100(\#\mathfrak n+L+1)^5\|g_1-1\|\le100\beta^5(200\beta^5)^{-1}=\frac12$ under the hypothesis of (ii), as $\#\mathfrak n+L+1\le\beta$. So $|c_{l/2}(g_1)|\ge\frac12$, likewise $|c_{k/2}(g_2)|\ge\frac12$, and (5.155) gives (ii). □

Lemma 5.7.23. *Let $\mathfrak n,\mathfrak m,\varepsilon,\eta,l,k,S,j=(j_1,j_2),\varphi,X,M,e,\tau,B$ be data as in Definition 5.7.2 (without β, L, h), with $B\ge1$, and suppose that (LA1), (LA2) and (LA3) of Definition 5.7.2 hold. Put $\theta(s)=c_{l/2}(j_1(s))\,\overline{c_{k/2}(j_2(s))}\,e^{-\varphi(s)}$, and for g in $\mathrm U(\mathrm{diag}\,\varepsilon)$ or $\mathrm U(\mathrm{diag}\,\eta)$ let $y(g)=g-\mathrm{bd}(g)$ be its noncompact part (for the signs ε, respectively η). Let $0<r\le\frac16$ and $s\in S$ with*

$$\|y(j_1(s))\|_{\mathrm{HS}}^2+\|y(j_2(s))\|_{\mathrm{HS}}^2\le r^2.$$

Then there is $t\in S$ with $\theta(t)=\theta(s)$, $\|j_1(t)-1\|_{\mathrm{HS}}\le4r$ and $\|j_2(t)-1\|_{\mathrm{HS}}\le4r$.

Proof. All norms are Hilbert–Schmidt norms. For g in a unitary group $\mathrm U(\mathrm{diag}\,\sigma)$ ($\sigma=\varepsilon$ or η) write $x(g)=g-1$ and $J=\mathrm{diag}(\sigma)$.

Step 1: the row identity. For $g\in\mathrm U(\mathrm{diag}\,\sigma)$ and every index i,

$$2\,\mathrm{Re}\,x(g)_{ii}=2\sum_j|y(g)_{ij}|^2-\sum_j|x(g)_{ij}|^2.\tag{5.158}$$

Indeed $g^*Jg=J$ gives $g^{-1}=Jg^*J$, so $(gJg^*J)_{ii}=1$, i.e. $\sum_j\sigma_i\sigma_j|g_{ij}|^2=1$, i.e. $\sum_j|g_{ij}|^2-2\sum_j|y(g)_{ij}|^2=1$; and $\sum_j|x(g)_{ij}|^2=\sum_j|g_{ij}|^2-2\,\mathrm{Re}\,g_{ii}+1$, $\mathrm{Re}\,x(g)_{ii}=\mathrm{Re}\,g_{ii}-1$. Summing (5.158) over i:

$$\|x(g)\|^2=2\|y(g)\|^2-2\,\mathrm{Re}\,\mathrm{tr}\,x(g).\tag{5.159}$$

Step 2: a weighted form. Let v, w be real vectors and a, C reals with $av_i^2 \le w_i$ for all i and $w_i \le C$ for every i such that $\sigma_{i'} \ne \sigma_i$ for some i'. Then

$$a\|\mathrm{diag}(v)x(g)\|^2 + 2\,\mathrm{Re}\,\mathrm{tr}\big(\mathrm{diag}(w)x(g)\big) \le 2C\|y(g)\|^2. \tag{5.160}$$

Multiply (5.158) by w_i and sum: the left side of (5.160) is

$$\sum_i (av_i^2 - w_i) \sum_j |x(g)_{ij}|^2 + \sum_i 2w_i \sum_j |y(g)_{ij}|^2.$$

The first sum is ≤ 0; in the second, $y(g)_{ij} \ne 0$ only if $\sigma_i \ne \sigma_j$, and then $w_i \le C$.

Step 3: rows and columns off X. Let P be the diagonal $\mathfrak{n} \times \mathfrak{n}$ matrix with entry 1 at the indices $e(i)$, $0 \le i < M$, and 0 at the indices $e(x)$, $x \in X$. For $s \in S$ write $g_1 = j_1(s)$, $g_2 = j_2(s)$, $Y(s) = \|y(g_1)\|^2 + \|y(g_2)\|^2$. Apply (5.160) to g_1 with $v =$ diag entries of P, $w = -\mu_l$, $a = B$, $C = 3B$: by (LA1), $-\mu_l = 0 \ge B \cdot 0$ on $e(X)$ and $B \le -\mu_l \le 3B$ off $e(X)$. Apply it to g_2 with $v = 0$, $w = \mu_k$, $a = 0$, $C = 3B$, legitimate by (LA3). This gives

$$B\|Px(g_1)\|^2 - 2\,\mathrm{Re}\,\mathrm{tr}\big(\mathrm{diag}(\mu_l)x(g_1)\big) \le 6B\|y(g_1)\|^2, \qquad 2\,\mathrm{Re}\,\mathrm{tr}\big(\mathrm{diag}(\mu_k)x(g_2)\big) \le 6B\|y(g_2)\|^2.$$

By (LA2) the difference of the two traces is $\varphi(s)$, which has real part 0. Adding and dividing by $B > 0$:

$$\|P\,x(j_1(s))\|^2 \le 6\,Y(s) \qquad (s \in S). \tag{5.161}$$

For the columns apply (5.161) to s^{-1}: $j_1(s^{-1}) = g_1^{-1} = Jg_1^*J$ ($J = \mathrm{diag}(\varepsilon)$), so $x(j_1(s^{-1})) = Jx(g_1)^*J$ and $\|PJx(g_1)^*J\| = \|x(g_1)P\|$ (J is diagonal unitary and commutes with P); likewise $y(g^{-1}) = Jy(g)^*J$ has the norm of $y(g)$, so $Y(s^{-1}) = Y(s)$. Hence $\|x(j_1(s))P\|^2 \le 6Y(s)$.

Step 4: the block on X. Let a be the $X \times X$ matrix $a_{xx'} = (g_1)_{e(x)e(x')}$, $g_1 = j_1(s)$, and $W = Px(g_1)$. Since $\varepsilon = 1$ on $e(X)$, the $(e(x), e(x'))$ entry of $g_1^*Jg_1 = J$ reads $(a^*a)_{xx'} + \sum_{i \notin e(X)} \varepsilon_i \overline{(g_1)_{i,e(x)}} (g_1)_{i,e(x')} = \delta_{xx'}$, and $(g_1)_{i,e(x)} = W_{i,e(x)}$ for $i \notin e(X)$. So $a^*a - 1$ is a submatrix of $-W^*JW$, and by (5.161) and the hypothesis

$$\|a^*a - 1\| \le \|W\|^2 \le 6r^2 \le r < 1.$$

Hence a^*a is invertible, a is invertible, and $a = k_1 z_1$ with k_1 unitary and $z_1 = (a^*a)^{1/2}$ positive definite. If $\sigma_i \ge 0$ are the eigenvalues of z_1, then $|\sigma_i - 1| \le |\sigma_i - 1|(\sigma_i + 1) = |\sigma_i^2 - 1|$, so $\|z_1 - 1\| \le \|z_1^2 - 1\| \le r$.

Step 5: translation by the diagonal copy. By (LA3) there is $s_0 \in S$ with $j_1(s_0) - 1 = \iota_e(k_1^* - 1)\iota_e^*$ and $j_2(s_0) - 1 = \iota_\tau(k_1^* - 1)\iota_\tau^*$; put $t = s_0 s$, $h_1 = j_1(s_0)$, $h_2 = j_2(s_0)$. The matrix $h_1 - 1$ is supported on $e(X) \times e(X)$, where $\varepsilon = 1$ and $\mu_l = 0$ (LA1); the matrix $h_2 - 1$ is supported on $\tau(X) \times \tau(X)$, where $\eta = 1$ and $\mu_k = 0$ (LA3). (a) $\varphi(t) = \varphi(s)$: by (LA2), $\varphi(s_0) = \mathrm{tr}(\mathrm{diag}(\mu_l)(h_1 - 1)) - \mathrm{tr}(\mathrm{diag}(\mu_k)(h_2 - 1)) = 0$, as the diagonals of $h_1 - 1$, $h_2 - 1$ live where the weights vanish, and $\varphi(t) = \varphi(s_0) + \varphi(s)$. (b) $c_{l/2}(h_1 g) = c_{l/2}(g)$ for every $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$, and likewise $c_{k/2}(h_2 g') = c_{k/2}(g')$. Let $h = h_1$, $\mu = \mu_l$. The off-diagonal entries of h lie in $e(X) \times e(X)$, where the signs agree, so h is block diagonal, $\mathrm{bd}_\varepsilon(hg) = h\,\mathrm{bd}_\varepsilon(g)$ and $\mathrm{bd}_\varepsilon(hg)^{-1}hg = \mathrm{bd}_\varepsilon(g)^{-1}g$. By (3.2) of Definition 3.2.3 it remains to show $m_\mu(hy) = m_\mu(y)$ for invertible y. If $X = \emptyset$ then $h = 1$. Otherwise $\min \mu \le 0 \le \max \mu$. For $t \in \mathbb{Z}$ and $Q = \{i : \mu_i \ge t\}$, $h_{ij} = 0$ for $i \in Q$, $j \notin Q$ (such $i \ne j$ have $\mu_i \ne \mu_j$, while h has off-diagonal entries only between indices of weight 0), so $\Delta_Q(hy) = \Delta_Q(h)\Delta_Q(y)$; and $\Delta_Q(h) = \det h$ if $t \le 0$ (then $Q \supseteq e(X)$) and $\Delta_Q(h) = 1$ if $t > 0$ (then $Q \cap e(X) = \emptyset$). By (3.1), $m_\mu(hy) = m_\mu(y) \cdot (\det h)^{\min \mu} (\det h)^{\#\{t : \min \mu < t \le 0\}} = m_\mu(y)$. The same argument applies to h_2, μ_k, η. (c) Hence $\theta(t) = \theta(s)$. (d) The noncompact parts keep their norms: h_1 is block diagonal and in $\mathrm{U}(\mathrm{diag}\,\varepsilon)$, hence commutes with J and is unitary;

$y(h_1 g) = h_1 g - h_1 \mathrm{bd}_\varepsilon(g) = h_1 y(g)$ has the norm of $y(g)$. Likewise for h_2. So $Y(t) = Y(s) \le r^2$. (e) The block of $j_1(t) = h_1 g_1$ on X: the rows $e(x)$ of h_1 are those of $\iota_e k_1^* \iota_e^*$, so this block is $k_1^* a = z_1$.

Step 6: the bounds at t. Every entry of $x(j_1(t))$ lies in a row off $e(X)$, or a column off $e(X)$, or in $e(X) \times e(X)$, so by Step 3 at t, Step 5 (d), (e) and Step 4,

$$\|x(j_1(t))\|^2 \le \|Px(j_1(t))\|^2 + \|x(j_1(t))P\|^2 + \|z_1 - 1\|^2 \le 6r^2 + 6r^2 + r^2 = 13r^2.$$

By (5.159) for $j_1(t)$ and $j_2(t)$ and $\operatorname{tr} x(j_1(t)) = \operatorname{tr} x(j_2(t))$ (LA2), $\|x(j_2(t))\|^2 = \|x(j_1(t))\|^2 - 2\|y(j_1(t))\|^2 + 2\|y(j_2(t))\|^2 \le 13r^2 + 2r^2 = 15r^2$. Since $15 < 16$, both norms are $\le 4r$. □

Lemma 5.7.24. *For a complex square matrix Y with $\|Y\|_{\mathrm{HS}} \le \frac{1}{2}$ put $\lg(Y) = \int_0^1 (1+tY)^{-1} Y\, dt$, the logarithm of $1+Y$. Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $l \in \mathbb{Z}^n$, $A, L \ge 0$ integers and δ, T reals. Suppose that l has large gap A for ε, $|l_i| \le L$ for every i, and*

$$1 \le T, \qquad (\#n)^2 \le T, \qquad (\#n)^2 \log(\#n + L + 1) \le T, \qquad \delta T \le 10^{-12}.$$

Then for every $g \in \mathrm{U}(\operatorname{diag}\varepsilon)$ with $\|g - 1\|_{\mathrm{HS}} \le \delta$ there is a real number $\varkappa \in [0,1]$ with

$$\Big| \frac{c_{l/2}(g)}{\exp \operatorname{tr}\big(\operatorname{diag}(\mu_l) \lg(g-1)\big)} - \varkappa \Big| \le \frac{\varkappa}{10} + e^{-100T}.$$

Proof. Write $N = \#n$, $X = g - 1$, $\mu = \mu_l$, $\Upsilon = l^\rho$, $c_\mu = \|m_\mu\|^2 = \int_{K_\varepsilon} |m_\mu|^2 dh$, $\|\cdot\|$ for the Hilbert–Schmidt norm, and gw_w as in Lemma 5.7.28. Since $T \ge 1$, $\|X\| \le \delta \le \delta T \le 10^{-12}$. Put

$$E = \operatorname{tr}\big(\operatorname{diag}(\mu) \lg(X)\big), \qquad q_0 = \tfrac{1}{4}\mathrm{gw}_\Upsilon(X) \ge 0, \qquad \varkappa = e^{-q_0} \in (0,1].$$

A vector with large gap A has gap 0.

The formula. Proposition 5.7.25 gives an accretive matrix y with $c_{l/2}(g) = \mathrm{FJ}_l(1, y)$, that is, by (3.2),

$$c_{l/2}(g) = \frac{1}{c_\mu} \int_{K_\varepsilon} \frac{|m_\mu(h)|^2}{m_{-\Upsilon}(h^* y h)}\, dh. \tag{5.162}$$

The denominator. Fix $h \in K_\varepsilon$. Let $w = -\Upsilon$, $w_\pm$ its largest and smallest entry, $P_\tau = \{i : w_i \ge \tau\}$ and p_τ the diagonal projection onto P_τ. If $i \in P_\tau$ and $i' \notin P_\tau$, then $\Upsilon_i < \Upsilon_{i'}$, hence $l_i < l_{i'}$ (if $l_i > l_{i'}$, then $\Upsilon_i \ge \Upsilon_{i'}$ by Lemma 5.6.27 (iii)). So Proposition 5.7.25 applies to every P_τ and gives numbers η_τ with

$$\Delta_{P_\tau}(h^* y h) = \exp\Big(\operatorname{tr}(p_\tau \lg(X)) + \tfrac{1}{4}\|[p_\tau, X]\|^2 + \eta_\tau\Big), \qquad |\eta_\tau| \le 2 \cdot 10^5\, \delta(\|[p_\tau, X]\|^2 + \|[p_\tau, h]\|^2);$$

applied to the set n itself, where both commutators vanish, it gives $\det(h^* y h) = \exp \operatorname{tr} \lg(X)$. Inserting this into (3.1) for the weight w and summing over $w_- < \tau \le w_+$ with Lemma 5.7.28 (i) (the traces add up to $\operatorname{tr}(\operatorname{diag}(w) \lg(X))$, the squares to $\mathrm{gw}_w(X) = \mathrm{gw}_\Upsilon(X)$),

$$m_{-\Upsilon}(h^* y h) = \exp\big(q_0 - E - r(h)\big), \qquad r(h) = \operatorname{tr}\big(\operatorname{diag}(\Upsilon - \mu) \lg(X)\big) - \sum_\tau \eta_\tau. \tag{5.163}$$

Bound for $r(h)$. By definition $\Upsilon - \mu = 2\rho_l^{\mathrm{c}}$, whose entries have absolute value at most N, and $|\lg(X)_{ii}| \le \|\lg(X)\| \le 2\delta$ by Lemma 5.7.27; so the trace term is at most $2N^2\delta$. By Lemma 5.7.28 (i), $\sum_\tau \|[p_\tau, X]\|^2 = 4q_0$ and $\sum_\tau \|[p_\tau, h]\|^2 = \mathrm{gw}_\Upsilon(h) \le \mathrm{gw}_\mu(h) + 2N\|h\|^2 = \mathrm{gw}_\mu(h) + 2N^2$, since $|\Upsilon_i - \Upsilon_{i'}| \le |\mu_i - \mu_{i'}| + 2N$ and $\|h\|^2 = N$ for unitary h. Hence, with $G_0(h) = q_0 + \frac{1}{2}\mathrm{gw}_\mu(h)$,

$$|r(h)| \le 2N^2\delta + 2 \cdot 10^5 \delta\big(4q_0 + \mathrm{gw}_\mu(h) + 2N^2\big) \le 10^6 \delta\big(G_0(h) + N^2\big). \tag{5.164}$$

The comparison. By (5.162), (5.163) and $\int |m_\mu(h)|^2 dh = c_\mu$ (the measure has mass one),

$$\frac{c_{l/2}(g)}{e^E} - \varkappa = \frac{1}{c_\mu}\int_{K_\varepsilon} |m_\mu(h)|^2 e^{-q_0}\big(e^{r(h)}-1\big)dh,$$
$$\frac{\varkappa}{10} + e^{-100T} = \frac{1}{c_\mu}\int_{K_\varepsilon} \Big(\frac{\varkappa}{10}|m_\mu(h)|^2 + e^{-100T}c_\mu\Big)dh.$$

So it suffices to show, for every $h \in K_\varepsilon$,

$$|m_\mu(h)|^2 e^{-q_0}\big|e^{r(h)}-1\big| \le \frac{\varkappa}{10}|m_\mu(h)|^2 + e^{-100T}c_\mu. \tag{5.165}$$

If $|r(h)| < \frac{1}{20}$, then $|e^{r(h)}-1| \le |r(h)|e^{|r(h)|} < \frac{1}{10}$ and (5.165) holds without the last term. Suppose $|r(h)| \ge \frac{1}{20}$. Since $10^6\delta \le 10^{-6}/T$ and $N^2 \le T$, (5.164) gives $\frac{1}{20} \le 10^{-6}(G_0(h)+T)/T$, that is $G_0(h) \ge (5\cdot 10^4 - 1)T$, and also $|r(h)| \le 10^{-6}(G_0(h)+T)$. By Lemma 5.7.28 (ii), $|m_\mu(h)|^2 e^{-q_0} \le e^{-G_0(h)}$, and $|e^r - 1| \le e^{|r|}$, so the left side of (5.165) is at most

$$\exp\big(-G_0(h)+|r(h)|\big) \le \exp\big(-(1-10^{-6})G_0(h) + 10^{-6}T\big) \le e^{-49998\,T}.$$

By Lemma 5.7.29, $c_\mu \ge \frac{1}{4}(30N(N+L))^{-2N^2}$, so, with $\log 4 < 2$, $\log 30 < 4$ and $\log(N(N+L)) \le 2\log(N+L+1)$,

$$\log c_\mu \ge -2 - 8N^2 - 4N^2\log(N+L+1) \ge -14T$$

by the three lower bounds for T. Hence $e^{-49998T} \le e^{-100T}c_\mu$, which proves (5.165); integrating it and dividing by c_μ gives the claim with $\varkappa = e^{-q_0}$. □

Proposition 5.7.25. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $l \in \mathbb{Z}^n$ a vector with gap 0 for ε, and $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ with $X = g - 1$ satisfying $\|X\| < \frac{1}{1000}$. For $\Pi \subseteq n$ let p_Π be the diagonal matrix with entry 1 at the indices in Π and 0 elsewhere. Then there is an accretive matrix y with $c_{l/2}(g) = \mathrm{FJ}_l(1,y)$ such that for every $\Pi \subseteq n$ with $l_i < l_{i'}$ for all $i \in \Pi$, $i' \notin \Pi$, and every $h \in K_\varepsilon$, there is a complex number η with*

$$\Delta_\Pi(h^* y h) = \exp\Big(\mathrm{tr}\big(p_\Pi \lg(X)\big) + \tfrac{1}{4}\big\|[p_\Pi, X]\big\|^2 + \eta\Big), \qquad |\eta| \le 200000\,\|X\|\big(\|[p_\Pi,X]\|^2 + \|[p_\Pi,h]\|^2\big).$$

Proof. Write $J = \mathrm{diag}(\varepsilon)$ and $\delta_0 = \|X\|$. For a matrix Z let $Z^\uparrow$ keep the entries $Z_{ii'}$ with $\varepsilon_i = \varepsilon_{i'}$ and $l_i < l_{i'}$ and replace the others by 0, and $Z^\downarrow$ the same with $l_i > l_{i'}$. Replacing entries by 0 does not increase $\|\cdot\|$, and $\|M\|_{\mathrm{op}} \le \|M\|$; we use $\|MN\| \le \|M\|\|N\|$ freely. Put

$$y = (1 - X^\uparrow)\, g\, (1 - X^\downarrow).$$

With $X_1 = (1-X^\uparrow)g - 1 = X - X^\uparrow - X^\uparrow X$ we have $y - 1 = X_1 - X^\downarrow - X_1 X^\downarrow$, and

$$\|X_1\| \le 2\delta_0 + \delta_0^2, \qquad \|y-1\| \le 3\delta_0 + 3\delta_0^2 + \delta_0^3 \le 4\delta_0 < \tfrac{1}{2}. \tag{5.166}$$

The formula. A matrix Z with $\|Z-1\|_{\mathrm{op}} < 1$ is accretive, since $Z + Z^* = 2 + (Z-1) + (Z-1)^*$. So g and y are accretive. By Lemma 5.6.26 (i) with the block-diagonal factor 1, $c_{l/2}(g) = \mathrm{FJ}_l(1,g)$. Let $b_1 = (1-X^\uparrow)^*$ and $b_2 = 1 - X^\downarrow$. Both are invertible, with diagonal entries 1 and with $(b_1)_{ij} = (b_2)_{ij} = 0$ whenever $\varepsilon_i \ne \varepsilon_j$ or $l_i < l_j$ (a nonzero off-diagonal entry $(b_1)_{ij} = -\overline{X^\uparrow_{ji}}$ needs $l_j < l_i$, and $(b_2)_{ij} = -X^\downarrow_{ij}$ needs $l_i > l_j$). Since $y = b_1^* g b_2$, Lemma 5.6.26 (iii) gives $\mathrm{FJ}_l(1,y) = \mathrm{FJ}_l(1,g) = c_{l/2}(g)$, the two characters being 1 at matrices with diagonal entries 1.

Minors of products. If $M_{ii'}=0$ for all $i\in\Pi$, $i'\notin\Pi$, or $N_{i'i}=0$ for all $i'\notin\Pi$, $i\in\Pi$, then $\Delta_\Pi(MN)=\Delta_\Pi(M)\Delta_\Pi(N)$, because $(MN)_{\Pi\Pi}=M_{\Pi\Pi}N_{\Pi\Pi}+M_{\Pi,n\smallsetminus\Pi}N_{n\smallsetminus\Pi,\Pi}$. Let $\Pi'\subseteq n$ satisfy $l_{i'}<l_i$ for all $i\in\Pi'$, $i'\notin\Pi'$. Then $(X^\uparrow)_{ii'}=0$ and $(X^\downarrow)_{i'i}=0$ for $i\in\Pi'$, $i'\notin\Pi'$, so the minor on Π' is multiplicative on the three factors of y; and $\Delta_{\Pi'}(1-X^\uparrow)=\Delta_{\Pi'}(1-X^\downarrow)=1$, the submatrices being triangular with diagonal 1 in the order of l. Hence

$$\Delta_{\Pi'}(y)=\Delta_{\Pi'}(g);\qquad\text{in particular}\quad\det y=\det g. \tag{5.167}$$

Setting up. Fix Π and h as in the statement; write $p=p_\Pi$, $A=[p,X]$, $\alpha_0=\|A\|$, $\kappa_0=\|[p,h]\|$. The map $Z\mapsto[p,Z]$ multiplies the entry $Z_{ii'}$ by 1, -1 or 0; so it commutes with $Z\mapsto Z^\uparrow, Z^\downarrow, \mathrm{bd}_\varepsilon(Z)$ and kills diagonal entries. Let $A_\mathrm{c}=\mathrm{bd}_\varepsilon(A)=A^\uparrow+A^\downarrow$ and $A_\mathrm{n}=A-A_\mathrm{c}$; they have norm at most α_0, $\|A_\mathrm{n}-A_\mathrm{c}\|=\alpha_0$ (disjoint supports), and $\mathrm{tr}(A_\mathrm{c}A_\mathrm{n})=0$, since a product of an entry of A_c at (i,j) and of A_n at (j,i) would need $\varepsilon_i=\varepsilon_j$ and $\varepsilon_i\neq\varepsilon_j$.

The commutator of y. With $G=A^\uparrow X+X^\uparrow A$ we have $[p,X_1]=A-A^\uparrow-G$, and then

$$[p,y-1]=A_\mathrm{n}-R,\qquad R=G+X_1A^\downarrow+(A-A^\uparrow-G)X^\downarrow, \tag{5.168}$$

with $\|R\|\le 2\delta_0\alpha_0+(2\delta_0+\delta_0^2)\alpha_0+(\alpha_0+2\delta_0\alpha_0)\delta_0\le 7\,\delta_0\alpha_0$.

Three expansions. Let $p'=1-p=p_{n\smallsetminus\Pi}$ and $q=hph^*$, an orthogonal projection with $\|p-q\|=\|[p,h]h^*\|=\kappa_0$. We apply Proposition 5.7.26 three times, with the data (p,q,X,Y,δ,c) there as follows; $4\delta_0<\frac12$ throughout.

1. $(p',p',X,-A,\delta_0,\alpha_0)$: $[p',X]=-A$. So $\det(1+p'X)=\exp(\mathrm{tr}(p'\lg(X))-\frac14\mathrm{tr}(A^2)+\eta_1)$ with $|\eta_1|\le 100\,\delta_0\alpha_0^2$.

2. $(p',p',y-1,-A_\mathrm{n},4\delta_0,4\alpha_0)$: by (5.166) and (5.168), $\|y-1\|\le 4\delta_0$ and $[p',y-1]+A_\mathrm{n}=R$ has norm at most $16\delta_0\alpha_0$. So $\det(1+p'(y-1))=\exp(\mathrm{tr}(p'\lg(y-1))-\frac14\mathrm{tr}(A_\mathrm{n}^2)+\eta_2)$ with $|\eta_2|\le 6400\,\delta_0\alpha_0^2$.

3. $(q,p,y-1,A_\mathrm{n},4\delta_0,4(\alpha_0+\kappa_0))$: h and p commute with J, so $[q,p]$ is block-diagonal and its trace against A_n, supported on the pairs of different signs, vanishes; and $[q,y-1]-A_\mathrm{n}=[q-p,y-1]-R$ has norm at most $2\kappa_0\cdot4\delta_0+7\delta_0\alpha_0\le16\delta_0(\alpha_0+\kappa_0)$. So $\det(1+q(y-1))=\exp(\mathrm{tr}(p\lg(y-1))-\frac14\mathrm{tr}(A_\mathrm{n}^2)+\eta_3)$ with $|\eta_3|\le 6400\,\delta_0(\alpha_0+\kappa_0)^2$.

The left sides are minors: $1+p'Z$ is block triangular with the identity block on Π, so $\det(1+p'X)=\Delta_{n\smallsetminus\Pi}(g)$ and $\det(1+p'(y-1))=\Delta_{n\smallsetminus\Pi}(y)$; and $\det(1+q(y-1))=\det\big(h(1+p(h^*yh-1))h^*\big)=\Delta_\Pi(h^*yh)$. The complement of Π satisfies the condition on Π' above, so the first two are equal by (5.167), and nonzero. By Lemma 5.7.27 and (5.167), $\exp\mathrm{tr}\lg(y-1)=\det y=\det g=\exp\mathrm{tr}\lg(X)$. Multiplying (iii) by (ii), dividing by (i) and using $p+p'=1$,

$$\Delta_\Pi(h^*yh)=\exp\Big(\mathrm{tr}(p\lg(X))+\tfrac14\mathrm{tr}(A^2)-\tfrac12\mathrm{tr}(A_\mathrm{n}^2)+\eta_2+\eta_3-\eta_1\Big). \tag{5.169}$$

The sign. Put $V=g^{-1}-1$ and $E=VA+AV+VAV$. From $g^*=Jg^{-1}J$, $X^*=JVJ$; and $[p,V]=[p,g^{-1}]=-g^{-1}Ag^{-1}=-(A+E)$, so $A^*=-[p,X^*]=-J[p,V]J=J(A+E)J$ (p commutes with J). Conjugation by J fixes A_c and changes the sign of A_n, so

$$\|A\|^2=\mathrm{tr}(A^*A)=\mathrm{tr}\big((A+E)(A_\mathrm{c}-A_\mathrm{n})\big)=\mathrm{tr}(A_\mathrm{c}^2)-\mathrm{tr}(A_\mathrm{n}^2)+\mathrm{tr}\big(E(A_\mathrm{c}-A_\mathrm{n})\big).$$

With $\mathrm{tr}(A^2)=\mathrm{tr}(A_\mathrm{c}^2)+\mathrm{tr}(A_\mathrm{n}^2)$ the exponent of (5.169) becomes $\mathrm{tr}(p\lg(X))+\frac14\|A\|^2+\eta$ with

$$\eta=\eta_2+\eta_3-\eta_1+\tfrac14\mathrm{tr}\big(E(A_\mathrm{n}-A_\mathrm{c})\big).$$

By Lemma 5.7.27, $\|V\| \le 2\delta_0$, so $\|E\| \le (4\delta_0 + 4\delta_0^2)\alpha_0 \le 5\delta_0\alpha_0$. Therefore

$$\begin{aligned}|\eta| &\le \delta_0(6400\alpha_0^2 + 6400(\alpha_0+\kappa_0)^2 + 100\alpha_0^2 + 2\alpha_0^2)\\ &\le 19302\,\delta_0(\alpha_0^2+\kappa_0^2) \le 200000\,\|X\|(\|[p,X]\|^2 + \|[p,h]\|^2).\end{aligned}$$

□

Proposition 5.7.26. *Let Ω be a finite set, p, q, X, Y complex $\Omega\times\Omega$ matrices and δ, c real numbers. Suppose that p and q are orthogonal projections ($p = p^2 = p^*$, $q = q^2 = q^*$), that $\delta \le \frac12$, and that*

$$\|X\| \le \delta, \qquad \operatorname{tr}([p,q]\,Y) = 0, \qquad \|[p,X] - Y\| \le \delta c, \qquad \|Y\| \le c, \qquad \|q-p\| \le c.$$

Then there is a complex number η with $|\eta| \le 100\,\delta c^2$ and

$$\det(1+pX) = \exp\Big(\operatorname{tr}\big(q\lg(X)\big) - \tfrac14\operatorname{tr}(Y^2) + \eta\Big).$$

Proof. The numbers δ and c are nonnegative, being bounds of norms. We use $|\operatorname{tr}(MN)| \le \|M\|\|N\|$, $\|MN\| \le \|M\|_{\mathrm{op}}\|N\|$, $\|N\|_{\mathrm{op}} \le \|N\|$ and $\|p\|_{\mathrm{op}}, \|q\|_{\mathrm{op}} \le 1$ throughout. Put $A = [p,X]$ and $D = q - p$; then $\|A\| \le \|Y\| + \|A - Y\| \le c + \delta c \le \frac32 c$, and $\|pX\| \le \|X\| \le \delta \le \frac12$.

Reduction to an integral. By Lemma 5.7.27, $\det(1+pX) = \exp\operatorname{tr}\lg(pX)$, and $\operatorname{tr}\lg(pX)$ and $\operatorname{tr}(q\lg(X))$ are integrals over $s\in[0,1]$. For $s\in[0,1]$ put $W = (1+sX)^{-1}$, $V = (1+spX)^{-1}$; by Lemma 5.7.27, $\|W\|_{\mathrm{op}}, \|V\|_{\mathrm{op}} \le 2$ and $\|W-1\|, \|V-1\| \le 2\delta$. Since $\frac14 = \int_0^1 \frac{s}{2}\,ds$, the assertion holds with

$$\eta = \int_0^1 \mathcal{J}(s)\,ds, \qquad \mathcal{J}(s) = \operatorname{tr}(VpX) - \operatorname{tr}(qWX) + \tfrac{s}{2}\operatorname{tr}(Y^2),$$

and it suffices to show $|\mathcal{J}(s)| \le 100\,\delta c^2$ for each s. As $\operatorname{tr}(A^2 - Y^2) = \operatorname{tr}((A-Y)(A+Y))$, we split $\mathcal{J} = \mathcal{J}_1 + \mathcal{J}_2 + \mathcal{J}_3$ with

$$\mathcal{J}_1 = \operatorname{tr}(VpX) - \operatorname{tr}(pWX) + \tfrac{s}{2}\operatorname{tr}(A^2), \qquad \mathcal{J}_2 = -\operatorname{tr}(DWX), \qquad \mathcal{J}_3 = -\tfrac{s}{2}\operatorname{tr}\big((A-Y)(A+Y)\big).$$

At once $|\mathcal{J}_3| \le \frac12\delta c(\frac32 c + c) = \frac54\delta c^2$.

The term $\mathcal{J}_1$. Direct computation gives $pAp = 0 = (1-p)A(1-p)$, $pA = pX(1-p)$, $Ap = -(1-p)Xp$, and $\operatorname{tr}(pA^2) = \operatorname{tr}(pA(1-p)A) = \operatorname{tr}((1-p)ApA) = \operatorname{tr}((1-p)A^2)$, so $\operatorname{tr}(pA^2) = \frac12\operatorname{tr}(A^2)$. From $p(1+sX) - (1+spX)p = s\,pA$, multiplying by V on the left and W on the right, $Vp - pW = s\,VpAW$; hence

$$\operatorname{tr}(VpX) - \operatorname{tr}(pWX) = s\operatorname{tr}(pA\,WXV) = s\operatorname{tr}\big(pA(1-p)\,WXV\,p\big),$$

using $pA = pA(1-p)$ and $\operatorname{tr}(pM) = \operatorname{tr}(pMp)$. Now $[p,W] = -W[p,W^{-1}]W = -sWAW$, so $(1-p)W = W(1-p) + sWAW$; and $(1-p)V^{-1} = 1-p$ gives $(1-p)V = 1-p$, so $(1-p)Vp = 0$ and $Vp = pVp$. Therefore

$$(1-p)WXVp = W(1-p)XpVp + sWAWXVp = -WAVp + sWAWXVp.$$

With $\frac{s}{2}\operatorname{tr}(A^2) = s\operatorname{tr}(pA\,Ap)$ and $WAV - A = (W-1)AV + A(V-1)$,

$$\mathcal{J}_1 = -s\operatorname{tr}\big(pA((W-1)AV + A(V-1))p\big) + s^2\operatorname{tr}\big(pA\cdot WAW\cdot XVp\big),$$

so $|\mathcal{J}_1| \le \|A\|^2(2\delta\cdot 2 + 2\delta) + \|A\|\cdot 2\cdot 2\|A\|\cdot\delta\cdot 2 = 14\,\delta\|A\|^2 \le \frac{63}{2}\delta c^2$.

The term $\mathcal{J}_2$. From $p^2=p$, $q^2=q$: $D^2 = p+q-pq-qp$ commutes with p ($pD^2 = D^2p = p-pqp$), $pDp = -pD^2$ and $(1-p)D(1-p) = (1-p)q(1-p) = (1-p)D^2$. Hence $D = D_0 + D_1$ with

$$D_0 = (1-2p)D^2, \qquad D_1 = pq(1-p) + (1-p)qp, \qquad \text{while} \qquad [p,q] = pq(1-p) - (1-p)qp.$$

For every matrix Z, $[p,Z] = pZ(1-p) - (1-p)Zp$, and multiplying out, $\operatorname{tr}([p,q][p,Z]) = -\operatorname{tr}(pq(1-p)Z) - \operatorname{tr}((1-p)qpZ) = -\operatorname{tr}(D_1 Z)$. For $Z = WX$, $[p,WX] = [p,W]X + W[p,X] = WA - sWAWX$, and with the hypothesis $\operatorname{tr}([p,q]Y) = 0$,

$$\mathcal{J}_2 = -\operatorname{tr}(D_0 WX) + \operatorname{tr}\Big([p,q]\big((A-Y) + (W-1)A - sWAWX\big)\Big).$$

Here $\|D_0\| = \|D^2\| \le \|D\|_{\mathrm{op}}\|D\| \le c^2$ because $1-2p$ is unitary; $\|WX\| \le 2\delta$; $\|[p,q]\| = \|D_1\| \le \|D\| \le c$, since $[p,q]$ and D_1 have the same entries up to sign in the blocks $p\cdot(1-p)$ and $(1-p)\cdot p$, which are the off-diagonal blocks of D; and the second factor has norm at most $\delta c + 2\delta\cdot\frac{3}{2}c + 2\cdot\frac{3}{2}c\cdot 2\cdot\delta = 10\,\delta c$. Hence $|\mathcal{J}_2| \le 2\delta c^2 + 10\delta c^2$.

Together $|\mathcal{J}(s)| \le (\frac{63}{2} + 12 + \frac{5}{4})\delta c^2 \le 100\,\delta c^2$. □

Lemma 5.7.27. *Let Y be a complex square matrix with $\|Y\|_{\mathrm{HS}} \le \frac{1}{2}$. Then for every $s \in [0,1]$ the matrix $1+sY$ is invertible, with*

$$\|(1+sY)^{-1}\|_{\mathrm{op}} \le 2, \qquad \|(1+sY)^{-1} - 1\|_{\mathrm{HS}} \le 2s\|Y\|_{\mathrm{HS}},$$

and the matrix $\lg(Y) = \int_0^1 (1+sY)^{-1}Y\,ds$ satisfies

$$\det(1+Y) = \exp\operatorname{tr}\lg(Y), \qquad \|\lg(Y)\|_{\mathrm{HS}} \le 2\|Y\|_{\mathrm{HS}}.$$

Proof. Since $\|sY\|_{\mathrm{op}} \le \|Y\|_{\mathrm{HS}} \le \frac{1}{2}$, the Neumann series $\sum_{k\ge 0}(-sY)^k$ converges to $(1+sY)^{-1}$ and $\|(1+sY)^{-1}\|_{\mathrm{op}} \le \sum_k 2^{-k} = 2$. From $(1+sY)^{-1} - 1 = -sY(1+sY)^{-1}$ and $\|MN\|_{\mathrm{HS}} \le \|M\|_{\mathrm{HS}}\|N\|_{\mathrm{op}}$ we get $\|(1+sY)^{-1}-1\|_{\mathrm{HS}} \le 2s\|Y\|_{\mathrm{HS}}$, and likewise $\|(1+sY)^{-1}Y\|_{\mathrm{HS}} \le 2\|Y\|_{\mathrm{HS}}$, which integrates to $\|\lg(Y)\|_{\mathrm{HS}} \le 2\|Y\|_{\mathrm{HS}}$. The function $f(s) = \det(1+sY)$ is a polynomial without zeros on $[0,1]$, and by Jacobi's formula for the derivative of a determinant, $f'(s) = f(s)\operatorname{tr}\big((1+sY)^{-1}Y\big)$. Hence $\frac{d}{ds}\big(f(s)\exp(-\int_0^s \operatorname{tr}((1+\sigma Y)^{-1}Y)\,d\sigma)\big) = 0$, and with $f(0) = 1$,

$$\det(1+Y) = f(1) = \exp\int_0^1 \operatorname{tr}\big((1+sY)^{-1}Y\big)ds = \exp\operatorname{tr}\lg(Y).$$

□

Lemma 5.7.28. *Let n be a nonempty finite set and $w \in \mathbb{Z}^n$; put $w_- = \min_i w_i$, $w_+ = \max_i w_i$, let p_t ($t \in \mathbb{Z}$) be the diagonal matrix with entry 1 at the indices i with $w_i \ge t$ and 0 elsewhere, and for a complex $n\times n$ matrix Z put*

$$\mathrm{gw}_w(Z) = \sum_{i,i'\in n} |w_i - w_{i'}|\,|Z_{ii'}|^2.$$

1. *For every complex $n\times n$ matrix Z,*

$$\sum_{w_- < t \le w_+} \big\|[p_t, Z]\big\|^2 = \mathrm{gw}_w(Z), \qquad w_-\operatorname{tr}(Z) + \sum_{w_- < t \le w_+} \operatorname{tr}(p_t Z) = \operatorname{tr}\big(\operatorname{diag}(w)Z\big).$$

2. *For every unitary $n\times n$ matrix h, $|m_w(h)|^2 \le \exp\big(-\frac{1}{2}\mathrm{gw}_w(h)\big)$.*

Proof. (i). The entry of $[p_t, Z]$ at (i,i') is $Z_{ii'}$ times the difference of the indicators of $w_i \ge t$ and $w_{i'} \ge t$. This difference is ± 1 for the integers t with $\min(w_i, w_{i'}) < t \le \max(w_i, w_{i'})$, which are $|w_i - w_{i'}|$ in number and lie in $(w_-, w_+]$, and 0 otherwise; summing $|[p_t, Z]_{ii'}|^2$ over t and (i,i') gives the first identity. The diagonal entry of $p_t Z$ at i is Z_{ii} for the $w_i - w_-$ integers $t \in (w_-, w_+]$ with $t \le w_i$, and 0 otherwise; so the left side of the second identity is $\sum_i (w_- + w_i - w_-) Z_{ii}$.

(ii). As $|\det h| = 1$, (3.1) gives $|m_w(h)|^2 = \prod_{w_- < t \le w_+} |\Delta_{P_t}(h)|^2$ with $P_t = \{i : w_i \ge t\}$, and by (i) it suffices to show $|\Delta_P(h)|^2 \le \exp(-\frac{1}{2}\|[p,h]\|^2)$ for every $P \subseteq n$ and $p = p_P$ the diagonal projection onto P. The matrix $(1-p) + ph$ has the rows of h at the indices in P and those of 1 elsewhere, so its determinant is $\Delta_P(h)$; by Sylvester's identity $\det(1 + MN) = \det(1 + NM)$ with $M = -p$, $N = p(1-h)$,

$$\Delta_P(h) = \det\bigl(1 - p(1-h)\bigr) = \det\bigl(1 - p(1-h)p\bigr) = \det Z, \qquad Z = (1-p) + php.$$

Now $Z^*Z = (1-p) + ph^*php$ is positive semidefinite, and for its eigenvalues $a \ge 0$ the inequality $a \le e^{a-1}$ gives $|\det Z|^2 = \det(Z^*Z) \le \exp(\operatorname{tr}(Z^*Z) - \#n) = \exp(\|php\|^2 - \operatorname{tr} p)$. As h is unitary, $\|ph\|^2 = \|hp\|^2 = \operatorname{tr} p$, and $[p,h] = ph(1-p) - (1-p)hp$ with the two terms supported on disjoint sets of entries, so

$$\|[p,h]\|^2 = \|ph(1-p)\|^2 + \|(1-p)hp\|^2 = (\operatorname{tr} p - \|php\|^2) + (\operatorname{tr} p - \|php\|^2),$$

and the exponent is $-\frac{1}{2}\|[p,h]\|^2$. □

Lemma 5.7.29. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $L \ge 0$ an integer and $l \in \mathbb{Z}^n$ a vector with gap 0 for ε and $|l_i| \le L$ for all i. Then $|\mu_l(i)| \le \frac{1}{2}(L + \#n)$ for all i, and*

$$\|m_{\mu_l}\|^2 \ge \tfrac{1}{4}\bigl(30\,\#n\,(\#n + L)\bigr)^{-2(\#n)^2}.$$

Proof. Write $N = \#n$, $\mu = \mu_l$, $K = K_\varepsilon$ with Haar probability measure ν, and $\|\cdot\|$ for the operator norm.

Size of μ. By Lemma 5.6.27 (iii), $2l^\rho = l + 2\rho_l$, so with σ the sign function,

$$2\mu(i) = l_i + 2\rho_l(i) - 2 \cdot 2\rho_l^{\mathrm{c}}(i) = l_i + \sum_{k:\,\varepsilon_k \ne \varepsilon_i} \sigma(l_i - l_k) - \sum_{k:\,\varepsilon_k = \varepsilon_i} \sigma(l_i - l_k),$$

and $|2\mu(i)| \le L + N - 1$. Put $M = \frac{1}{2}(L+N)$, so $|\mu(i)| \le M$.

m_μ near 1. Let $h \in K$ with $\|h - 1\| \le r$, where $r = 1/D$ and $D = 10N(N+L)$. By (3.1), $m_\mu(h)$ is a product of $|\mu_-|$ factors $(\det h)^{\pm 1}$ and $\mu_+ - \mu_-$ principal minors $\Delta_P(h)$ ($\mu_\pm$ the largest and smallest entry), at most $3M \le 2(L+N)$ factors z in all. For a minor, $\Delta_P(h) = \det(1+E)$ with $E = (h-1)_{PP}$, $\|E\| \le r$, so its eigenvalues e_j satisfy $|e_j| \le r$ and $|\Delta_P(h) - 1| = |\prod_j (1 + e_j) - 1| \le \prod_j (1 + |e_j|) - 1 \le e^{Nr} - 1$; the same holds for $\det h$, and $|(\det h)^{-1} - 1| = |\det h - 1|$ as $|\det h| = 1$. As $Nr \le \frac{1}{10}$, $e^{Nr} - 1 \le 2Nr$. With $|\prod_j z_j - 1| \le \prod_j (1 + |z_j - 1|) - 1$ (induction on the number of factors),

$$|m_\mu(h) - 1| \le \exp\bigl(2(L+N) \cdot 2Nr\bigr) - 1 = e^{0.4} - 1 < \tfrac{1}{2},$$

so $|m_\mu(h)| \ge \frac{1}{2}$ whenever $\|h - 1\| \le 1/D$.

Measure of a small ball. Apply Lemma 5.6.32 (i) to the group $S = K$ with the right-invariant measure ν, the inclusion $j\colon K \to \mathrm{U}(\operatorname{diag}\varepsilon)$, $y = 1$, $R = 1$, the given $D \ge 1$ and the constant $3D$: since every $h \in K$ is unitary, $\|h\| = 1$, and

$$1 = \nu\{h : \|h\| \le 1\} \le (3D)^{2N^2}\, \nu\{h : \|h - 1\| \le 1/D\}.$$

Hence $\|m_\mu\|^2 \ge \frac{1}{4}\,\nu\{h : \|h-1\| \le 1/D\} \ge \frac{1}{4}(3D)^{-2N^2} = \frac{1}{4}\bigl(30N(N+L)\bigr)^{-2N^2}$. □

The Bessel systems of the data are Bessel averages of Flensted-Jensen's function, and Proposition 5.7.30 proves the four properties of these averages that the construction uses: a stationary point of controlled Bessel length, a bound for the ball volume, a cut pair reproduced by the discrete-series kernel, and Schur's bound. The stationary point comes from Laplace's method applied to the Bessel subgroup and is found with Witt's extension theorem for hermitian spaces (Theorem A.6.7; for the quadratic case see [330]); the ball volume follows from the identity for the Bessel average (Lemma 5.6.37). Schur's bound needs control of derivatives: a bounded function reproduced by the kernel has derivatives given by convolution with derivative kernels, which are bounded through the filtration of the module generated by Flensted-Jensen's function (Lemma 5.7.35, Lemma 5.7.36); see [315, 165].

The section closes with Harish-Chandra's formula for the formal degree (Theorem 5.7.41): for every sign vector and every strictly decreasing parameter with the right integrality, the square-integrable representation exists, is unique up to equivalence, and has the Weyl product as formal degree for the Haar measure normalised by the compact dual. The proof combines Harish-Chandra's formula [119, 251] with Godement's Schur orthogonality and Weyl's dimension formula [92]. In the definite case the formula is Weyl's dimension formula, and this is how the trace comparison reads it (Proposition 5.8.54, Lemma 5.8.56).

Proposition 5.7.30. *Fix the setting of Definition 5.1.6, signs ε on the r basis indices of V_1 and a unitary matrix p with $p^{*}J_1p=\operatorname{diag}(\varepsilon)$. For $l\in\mathbb{Z}^r$ (a doubled parameter, $\lambda=\frac12 l$) write $c_l^{G_1}(g)=c_\lambda(p^{-1}gp)$ for $g\in G_1$, and d_l for the formal degree of c_λ for the Haar measure on $\mathrm{U}(\operatorname{diag}\varepsilon)$ that $g\mapsto p^{-1}gp$ carries from dy. Let ds be the measure $du\,dh$ on R and, for $s=uh\in R$, $h_s=h$. Let $\rho\colon\mathrm{U}(k)\to\mathrm{U}(I)$ be a continuous unitary representation on $\mathbb{C}^I$, $v\in\mathbb{C}^I$ and $x\in G_1$; the **Bessel average** is*

$$W_x(y)=\int_R c_l^{G_1}(x^{-1}sy)\,\mathrm{wave}\big(-\sigma(s)\big)\,\rho(h_s)^{-1}v\,ds\qquad(y\in G_1),$$

*and the **ball volume** is $V(x)=\mathrm{vol}_R\{s\in R:\|p^{-1}x^{-1}sxp-1\|_{\mathrm{op}}\le 1\}$.*

(a) Stationary point. Let X be a finite set, $e\colon X\sqcup\{0,\dots,2n-1\}\to\{1,\dots,r\}$ and $\tau\colon X\sqcup\{*\}\to\{1,\dots,k\}$ bijections, $B\ge1$, b,β reals and $a,L,h\ge0$ integers. Suppose that l is steep for (ε,e,B) (with $M=2n$); that $u\in\mathbb{Z}^k$ has, for the signs all $+1$, lowest K-type $\mu_u(\tau(*))=a$ and $\mu_u=0$ elsewhere; that $3B+a\le b^2$ and $8nr\le b$; that l (for ε) and u have large gap h; that $|l_i|\le L$ and $|u_i|\le L$ for all entries; and that $10^{12}\le\beta$, $r+k+L\le\beta$ and $10^{30}\big((r+k)^2\log\beta\big)^3\le h$. Then there is $x\in G_1$ with $\ell(x)\le b^{5n}$ and

$$V(x)\le\beta^{20(r+k)^2}\Big|\int_R c_l^{G_1}(x^{-1}sx)\,\overline{c_{u/2}(h_s)}\,e^{\overline{\sigma(s)}-\sigma(s)}\,ds\Big|.$$

(b) Ball volume. Suppose that l has large gap A for ε for some integer $A\ge0$, that $\langle v,\rho(m)v\rangle=c_{u/2}(m)$ for every $m\in\mathrm{U}(k)$, where $u\in\mathbb{Z}^k$ (signs all $+1$), and that

$$V(x)\le P\,\Big|\int_R c_l^{G_1}(x^{-1}sx)\,\overline{c_{u/2}(h_s)}\,e^{\overline{\sigma(s)}-\sigma(s)}\,ds\Big|$$

for a real $P\ge0$. Then $V(x)\le P\,d_l\int_{\mathrm{U}\backslash G_1}\|W_x\|^2$.

(c) Cut pair. Let $A,L,m\ge0$ and $f\ge1$ be integers and b real. Suppose that l has large gap A for ε and $|l_i|\le L$ for all i, that $\|v\|=1$, $V(x)\le b^m d_l\int_{\mathrm{U}\backslash G_1}\|W_x\|^2$, $\ell(x)\le b^{5n}$, $b\ge2000$, $r\ge100$, $m+99r^2\le400r^2$, $r+L+1\le b^4$ and $3r^3f\le A$. Then there are $c\in\mathbb{R}$ and a continuous F with $F=cW_x$, $\int_{G_1}d_l\,c_l^{G_1}(a^{-1})F(ya)\,da=F(y)$ for all y, and such that $(F,\chi(\ell(\cdot))F)$ is a cut pair (for b,f), where $\chi=1$ on $[0,\frac12 b^{6n+2}]$, $\chi=0$ on $[b^{6n+2},\infty)$, and χ is linear in between.

(d) Schur's bound. Let $A, L \geq 0$ be integers and B real. Suppose that l has large gap A for ε, $|l_i| \leq L$ for all i, and $(r+1)^4(L+r+1+2n^2) \leq B$. If F is a Bessel function of type ρ, integrable over $\mathsf{U}\backslash G_1$, with $\int_{G_1} d_l\, c_l^{G_1}(a^{-1})F(ya)\,da = F(y)$ for all y, then F has Schur's bound $(B,\ d_l^{-1}\int_{\mathsf{U}\backslash G_1}\|F\|^2)$.

Proof. The objects $c_l^{G_1}$, d_l, ds, h_s, $\sigma(s)$, W_x and $V(x)$ of the statement are those of Lemma 5.7.31, Lemma 5.6.37, Lemma 5.7.33 and Lemma 5.7.34 (with $u_0 = u$), and $V(x) = \int_R \mathbf{1}[\|p^{-1}x^{-1}sxp - 1\|_{\mathrm{op}} \leq 1]\,ds$.

(a) is Lemma 5.7.31, whose hypotheses are those of (a).

(b). The representation ρ is continuous and unitary, l has large gap A, and $\langle v, \rho(m)v\rangle = c_{u/2}(m)$ for $m \in \mathrm{U}(k)$; so Lemma 5.6.37 (ii) applies and shows that the period

$$\int_R c_l^{G_1}(x^{-1}sx)\overline{c_{u/2}(h_s)}e^{\overline{\sigma(s)}-\sigma(s)}ds$$

equals $d_l\int_{\mathsf{U}\backslash G_1}\|W_x\|^2$, a nonnegative real number. Hence its modulus is $d_l\int_{\mathsf{U}\backslash G_1}\|W_x\|^2$, and the hypothesis $V(x) \leq P\,|\text{period}|$ gives $V(x) \leq P\,d_l\int_{\mathsf{U}\backslash G_1}\|W_x\|^2$.

(c) is Lemma 5.7.33, whose hypotheses are those of (c) (ρ continuous, $\|v\| = 1$).

(d) is Lemma 5.7.34, whose hypotheses are those of (d). □

Lemma 5.7.31. *Fix the setting of Definition 5.1.6, signs ε on the r basis indices of V_1 and a sign frame p for ε. Every $s \in R$ is uniquely $s = uh$ with $u \in \mathsf{U}$, $h \in H$; put $h_s = h$, $\sigma(s) = \sigma(u)$, and let $ds = du\,dh$ on R, dh the Haar probability measure. Let X be a finite set, $e\colon X \sqcup \{0,\dots,2n-1\} \to \{1,\dots,r\}$ and $\tau\colon X \sqcup \{*\} \to \{1,\dots,k\}$ bijections, $B \geq 1$, b, β reals, $a, L, h \geq 0$ integers, $l \in \mathbb{Z}^r$ and $u_0 \in \mathbb{Z}^k$. Suppose that l is steep for (ε, e, B) (with $M = 2n$); that u_0 has, for the signs all $+1$, lowest K-type $\mu_{u_0}(\tau(*)) = a$ and $\mu_{u_0} = 0$ elsewhere; that $3B + a \leq b^2$ and $8nr \leq b$; that l (for ε) and u_0 (for the signs all $+1$) have large gap h; that $|l_i| \leq L$ and $|u_{0,i}| \leq L$ for all entries; and that $10^{12} \leq \beta$, $r + k + L \leq \beta$ and $10^{30}\big((r+k)^2\log\beta\big)^3 \leq h$. Then there is $x \in G_1$ with $\ell(x) \leq b^{5n}$ and*

$$\int_R \mathbf{1}[\|p^{-1}x^{-1}sxp - 1\|_{\mathrm{op}} \leq 1]\,ds \leq \beta^{20(r+k)^2}\Big|\int_R c_{l/2}(p^{-1}x^{-1}sxp)\,\overline{c_{u_0/2}(h_s)}\,e^{\overline{\sigma(s)}-\sigma(s)}\,ds\Big|.$$

Proof. Write b_i for the basis vector of V_1 at the index i, $p_i = pb_i$ for the column of p at i, $\Lambda = \mu_l$ (for ε) and $\Lambda' = \mu_{u_0}$ (for the signs all $+1$). The columns p_i are orthonormal, and $p_i^* J_1 p_{i'} = \varepsilon_i\delta_{ii'}$. The steepness hypothesis is (LA1) of Definition 5.7.2 for l, the signs ε, e, B and $M = 2n = 2\varrho+2$: $\varepsilon_{e(\xi)} = 1$ and $\Lambda(e(\xi)) = 0$ for $\xi \in X$; $\varepsilon_{e(m)} = (-1)^m$ for $0 \leq m \leq 2\varrho+1$; and $m \mapsto \Lambda(e(m))$ is strictly decreasing on $\{0,\dots,2\varrho+1\}$ with values in $[-3B, -B]$. All values of Λ are integers.

Nodes and Lagrange weights. Put $t_0 = 0$ and $t_{m+1} = \Lambda(e(m)) - a$ for $0 \leq m \leq 2\varrho+1$. These $2\varrho+3$ integers satisfy $t_0 > t_1 > \cdots > t_{2\varrho+2}$, since $\Lambda(e(m)) - a \leq -B < 0$, and $|t_{m+1}| \leq 3B + a \leq b^2$. For $0 \leq m \leq 2\varrho+2$ the product $\prod_{m'\neq m}(t_m - t_{m'})$ has exactly m negative factors and absolute value at least 1; so $\omega_m = \big|\prod_{m'\neq m}(t_m - t_{m'})\big|^{1/2} \geq 1$ and $\omega_m^2 = (-1)^m\prod_{m'\neq m}(t_m - t_{m'})$. By Lagrange interpolation at the $2\varrho+3$ nodes, for every polynomial π of degree at most $2\varrho+2$,

$$[\text{coefficient of } t^{2\varrho+2} \text{ in } \pi] = \sum_{m=0}^{2\varrho+2}\frac{\pi(t_m)}{\prod_{m'\neq m}(t_m - t_{m'})} = \sum_{m=0}^{2\varrho+2}(-1)^m\frac{\pi(t_m)}{\omega_m^2}. \tag{5.170}$$

Lagrange vectors. Define

$$w^{(0)} = \omega_0 \sum_{m=0}^{2\varrho+1} \frac{1}{\omega_{m+1}}\, p_{e(m)}, \qquad w^{(k)} = \sum_{m=0}^{2\varrho+1} \frac{t_{m+1}^k}{\omega_{m+1}}\, p_{e(m)} \quad (k \geq 1).$$

As $\varepsilon_{e(m)} = (-1)^m$, for $k, k' \geq 1$ with $K = k + k' \leq 2\varrho + 2$, (5.170) for $\pi = t^K$ (which vanishes at $t_0 = 0$) gives

$$w^{(k)*} J_1 w^{(k')} = \sum_{m=0}^{2\varrho+1} (-1)^m \frac{t_{m+1}^K}{\omega_{m+1}^2} = -\sum_{m=0}^{2\varrho+2} (-1)^m \frac{t_m^K}{\omega_m^2} = -\delta_{K,2\varrho+2}.$$

Likewise, (5.170) for $\pi = 1$ and for $\pi = t^{k''}$ gives $w^{(0)*} J_1 w^{(0)} = \omega_0^2(\omega_0^{-2} - 0) = 1$ and $w^{(0)*} J_1 w^{(k'')} = -\omega_0 \delta_{k'',2\varrho+2} = 0$ for $1 \leq k'' \leq 2\varrho + 1$. Summarising, for $k, k' \geq 1$, $k + k' \leq 2\varrho + 2$ and $1 \leq k'' \leq 2\varrho + 1$:

$$w^{(0)*} J_1 w^{(0)} = 1, \qquad w^{(0)*} J_1 w^{(k'')} = 0, \qquad w^{(k)*} J_1 w^{(k')} = \begin{cases} -1 & k + k' = 2\varrho + 2, \\ 0 & k + k' < 2\varrho + 2. \end{cases} \tag{5.171}$$

The vectors $p_{e(\xi)}$, $\xi \in X$, are J_1-orthonormal with squares $\varepsilon_{e(\xi)} = 1$ and J_1-orthogonal to every $w^{(k)}$, which is a combination of the $p_{e(m)}$. Since the p_i are orthonormal, $\|w^{(k)}\|^2 = \sum_m t_{m+1}^{2k} \omega_{m+1}^{-2} \leq (2\varrho + 2) b^{4k}$ for $k \geq 1$.

The point x. Compare the families

$$\Phi = \big((p_{e(\xi)})_{\xi \in X},\ w^{(0)}, w^{(1)}, \ldots, w^{(\varrho+1)}\big), \qquad \Psi = \big((e^0_{\tau(\xi)})_{\xi \in X},\ e^0_{\tau(*)},\ f_0, \ldots, f_\varrho\big).$$

By (5.171) with $k = a' + 1$, $k' = a'' + 1$ ($0 \leq a', a'' \leq \varrho$, so $k + k' \leq 2\varrho + 2$ with equality only for $a' = a'' = \varrho$) and $k'' \leq \varrho + 1 \leq 2\varrho + 1$, the Gram matrix of Φ for h is the identity on the first $\#X + 1$ vectors, -1 at $(w^{(\varrho+1)}, w^{(\varrho+1)})$ and 0 elsewhere; this is the Gram matrix of Ψ, since the e_i^0 are orthonormal for h and orthogonal to the f_c, and $h(f_c, f_{c'}) = -\delta_{c\varrho}\delta_{c'\varrho}$. The family Ψ consists of distinct basis vectors. The family Φ is independent: its matrix of J_1-products with the vectors $p_{e(\xi)}$ ($\xi \in X$), $w^{(0)}$, $w^{(2\varrho+1)}, w^{(2\varrho)}, \ldots, w^{(\varrho+1)}$ is triangular with diagonal entries ± 1, because by (5.171) $w^{(2\varrho+2-c)*} J_1 w^{(c')}$ is 0 for $1 \leq c' < c$ and -1 for $c' = c$, $w^{(2\varrho+2-c)*} J_1 w^{(0)} = 0$ ($1 \leq c \leq \varrho + 1$), and the $p_{e(\xi)}$ are orthogonal to all $w^{(k)}$. So the linear map from $\langle \Phi \rangle$ to V_1 sending Φ to Ψ termwise is injective and preserves h, and by Witt's theorem for the nondegenerate hermitian form h on $\mathbb{C}^r$ ([249], Chapter 7) there is $x \in G_1$ with

$$x p_{e(\xi)} = e^0_{\tau(\xi)}\ (\xi \in X), \qquad x w^{(0)} = e^0_{\tau(*)}, \qquad x w^{(c+1)} = f_c\ (0 \leq c \leq \varrho). \tag{5.172}$$

Its Bessel length. Put $w_c = w^{(c+1)}$ for $0 \leq c \leq 2\varrho$. Then $w_c = x^{-1} f_c$ for $c \leq \varrho$ by (5.172); $h(w_c, w_{c'})$ is -1 if $c + c' = 2\varrho$ and 0 if $c + c' < 2\varrho$ by (5.171); and $\|w_c\|^2 \leq (2\varrho + 2) b^{4(2\varrho+1)} \leq b^{8\varrho+6}$, as $2\varrho + 2 \leq 8nr \leq b$ and $b \geq 1$. By Lemma 5.7.32 with $M = b^{4\varrho+3} \geq 1$,

$$\ell(x) \leq 4(\varrho + 1)\, b^{4\varrho+3} \leq b^{4\varrho+4} \leq b^{5n},$$

since $4n \leq b$ and $4\varrho + 4 \leq 5\varrho + 5$.

The conjugated weight matrix. Put $q = xp$. Then $q^* J_1 q = p^* J_1 p = \operatorname{diag}(\varepsilon)$, so $q^{-1} = \operatorname{diag}(\varepsilon) q^* J_1$ and $g \mapsto q^{-1} g q$ maps G_1 onto $\mathrm{U}(\operatorname{diag} \varepsilon)$. Let $D = q \operatorname{diag}(\Lambda)\, q^{-1}$, so that

$$\operatorname{tr}(\operatorname{diag}(\Lambda)\, q^{-1} Y q) = \operatorname{tr}(DY) \quad \text{for every } r \times r \text{ matrix } Y.$$

The matrix $p\,\mathrm{diag}(\Lambda)p^{-1}$ multiplies p_i by $\Lambda(i)$, so it kills $p_{e(\xi)}$, and since $\Lambda(e(m)) = t_{m+1} + a$ it sends $w^{(k)}$ to $aw^{(k)} + w^{(k+1)}$ for $k \geq 1$ and $w^{(0)}$ to $aw^{(0)} + \omega_0 w^{(1)}$. Applying x and (5.172):

$$De^0_{\tau(\xi)} = 0, \qquad De^0_{\tau(*)} = a\, e^0_{\tau(*)} + \omega_0 f_0, \qquad Df_c = a\, f_c + f_{c+1} \quad (0 \leq c < \varrho). \tag{5.173}$$

Moreover $J_1 D = J_1 q\,\mathrm{diag}(\Lambda)\mathrm{diag}(\varepsilon)\, q^* J_1$ is hermitian, so $h(v, Dv') = h(Dv, v')$ for all v, v'.

$D - C$ is block upper triangular for the levels, that is, $(D-C)b_j$ lies in the span of the basis vectors of level at most that of b_j, for every basis vector b_j. Recall that the e^*_c-coordinate of a vector v is $h(e_c, v)$, and that $e_c = f_{c-1}$ for $1 \leq c \leq \varrho$, so $De_c = ae_c + f_c$ by (5.173). For $b_j = e_c$: $(D-C)e_c = ae_c + f_c - f_c = ae_c$. For $b_j = e^0_i$: $Ce^0_i = 0$ and, τ being a bijection, De^0_i lies in $\langle e^0_{\tau(*)}, f_0\rangle$, of levels $\varrho+1$ and 1. For $b_j = z$ (level $\varrho+1$): $h(e_c, Dz) = h(De_c, z) = h(ae_c + f_c, z) = -\delta_{c\varrho}$, so the e^*-part of Dz is $-e^*_\varrho = Cz$, and $(D-C)z$ has levels at most $\varrho+1$. For $b_j = e^*_d$ (level $2\varrho + 2 - d$): $h(e_c, De^*_d) = h(ae_c + f_c, e^*_d) = a\delta_{cd} + \delta_{c+1,d}$ (a is real), so the e^*-part of De^*_d is $ae^*_d + e^*_{d-1}$ (the second term absent for $d = 1$), while $Ce^*_d = e^*_{d-1}$ (and $Ce^*_1 = 0$); hence $(D-C)e^*_d$ is ae^*_d plus vectors of level at most $\varrho+1$. Finally, the block of D on X_0 is, by (5.173), the diagonal matrix with entry a at $\tau(*)$ and 0 elsewhere, which is $\mathrm{diag}(\Lambda')$ by the hypothesis on u_0; and C vanishes on X_0.

The data for Laplace's method. Take $S = R$ with the topology of G_1 and its Borel sets, $\nu = ds$, $\mathfrak{n}$ the r basis indices with the signs ε, $\mathfrak{m} = \{1, \dots, \dim X_0\}$ with the signs $\eta = (1, \dots, 1)$, the vectors l and $k = u_0$, $j = (j_1, j_2)$ with $j_1(s) = q^{-1}sq \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ and $j_2(s) = h_s \in H$, $\varphi(s) = \sigma(s) - \overline{\sigma(s)}$, the set X, $M = 2n$, the bijection e, the map $\tau|_X$, and B, β, L, h. By Lemma 5.5.30 (v), translations of R are continuous and ds is right invariant and finite on compact sets. By (i) of the same lemma, j_2 is a continuous homomorphism, and j_1 is a homomorphism which is the restriction to the closed subset R of the homeomorphism $g \mapsto q^{-1}gq$ of G_1 onto $\mathrm{U}(\mathrm{diag}\,\varepsilon)$, hence proper. We check that these data form a Laplace datum, that is (LA1)–(LA4) of Definition 5.7.2.

(LA1) is the steepness hypothesis.

(LA2) Let $s \in R$. By Lemma 5.5.30 (iii) for $Z = D - C$, (iv), and the description of $D - C$ on X_0 (where $h_s - 1$ is supported),

$$\begin{aligned}\mathrm{tr}\big(\mathrm{diag}(\Lambda)(j_1(s)-1)\big) &= \mathrm{tr}\big(D(s-1)\big)\\ &= \mathrm{tr}\big((D-C)(s-h_s)\big) + \mathrm{tr}\big((D-C)(h_s-1)\big) + \mathrm{tr}\big(C(s-1)\big)\\ &= 0 + \mathrm{tr}\big(\mathrm{diag}(\Lambda')(h_s-1)\big) + \sigma(s) - \overline{\sigma(s)},\end{aligned}$$

which is the first condition. By Lemma 5.5.30 (ii), φ is additive, and $\mathrm{Re}\,\varphi = 0$. By (iii) for $Z = 1$, $\mathrm{tr}(j_1(s) - 1) = \mathrm{tr}(s - 1) = \mathrm{tr}(h_s - 1) = \mathrm{tr}(j_2(s) - 1)$.

(LA3) $\eta_{\tau(\xi)} = 1$ and $\Lambda'(\tau(\xi)) = 0$ for $\xi \in X$; $\Lambda' \geq 0$ since $a \geq 0$; all signs η_i are equal, so the bound by $3B$ is not required. Let u be a unitary $X \times X$ matrix and $h_u = 1 + \iota_\tau(u - 1)\iota^*_\tau \in H$, regarded as an element of $H \subseteq R$; then $j_2(h_u) - 1 = \iota_\tau(u-1)\iota^*_\tau$. By (5.172), $q^{-1}e^0_{\tau(\xi)} = b_{e(\xi)}$; and since $J_1 e^0_i = e^0_i$ and $J_1 q = (q^{-1})^*\mathrm{diag}(\varepsilon)$, $(e^0_{\tau(\xi)})^* q = (e^0_{\tau(\xi)})^* J_1 q = (q^{-1}e^0_{\tau(\xi)})^*\mathrm{diag}(\varepsilon) = \varepsilon_{e(\xi)} b^*_{e(\xi)} = b^*_{e(\xi)}$. As $h_u - 1 = \sum_{\xi,\xi' \in X} (u-1)_{\xi\xi'}\, e^0_{\tau(\xi)}(e^0_{\tau(\xi')})^*$, we get $j_1(h_u) - 1 = q^{-1}(h_u - 1)q = \iota_e(u-1)\iota^*_e$.

(LA4) are the hypotheses on gaps, entries, β and h, with $\#\mathfrak{n} + \#\mathfrak{m} = r + k$.

Conclusion. By Theorem 5.7.21, $\theta(s) = c_{l/2}(p^{-1}x^{-1}sxp)\,\overline{c_{u_0/2}(h_s)}\, e^{\overline{\sigma(s)} - \sigma(s)}$ is ds-integrable and

$$ds\{s \in R : \|j_1(s)\| \leq \beta + 1,\ \|h_s\| \leq \beta + 1\} \leq \beta^{20(r+k)^2} \Big| \int_R \theta\, ds \Big|.$$

If $\|p^{-1}x^{-1}sxp-1\| \le 1$, then $\|j_1(s)\| \le 2 \le \beta+1$, and $\|h_s\| = 1 \le \beta+1$ as h_s is unitary. So the closed set $\{s \in R : \|p^{-1}x^{-1}sxp-1\| \le 1\}$ lies in the set on the left, which proves the inequality of the lemma; and $\ell(x) \le b^{5n}$ was shown above. □

Lemma 5.7.32. *Fix the setting of Definition 5.1.6. Let $y \in G_1$, $M \ge 1$ a real number and $w_0, \dots, w_{2\varrho} \in V_1$ with*

- *$w_a = y^{-1}f_a$ for $0 \le a \le \varrho$;*
- *$\|w_a\| \le M$ (Euclidean norm of $\mathbb{C}^r$) for $0 \le a \le 2\varrho$;*
- *$h(w_a, w_{a'}) = -1$ if $a + a' = 2\varrho$ and $h(w_a, w_{a'}) = 0$ if $a + a' < 2\varrho$.*

Then $\ell(y) \le 4(\varrho+1)M$.

Proof. The matrix J_1 is real symmetric with $J_1^2 = 1$, so it is unitary; it exchanges e_b and e_b^*, fixes the x_i and sends z to $-z$. Hence $|h(v,v')| = |\langle v, J_1 v'\rangle| \le \|v\|\,\|v'\|$.

Gram–Schmidt. The vectors $w_0, \dots, w_\varrho$ are the images under y^{-1} of the independent vectors $f_0, \dots, f_\varrho$, so they are independent. Let $o_0, \dots, o_\varrho$ be their Gram–Schmidt orthogonalisation for the Euclidean product, not normalised: o_a is the orthogonal projection of w_a to the orthogonal complement of $\langle w_b : b < a\rangle$. Then the o_a are pairwise orthogonal and nonzero, $\|o_a\| \le \|w_a\| \le M$, and $o_a = \sum_{b \le a} c_{ba} w_b$ with complex c_{ba} and $c_{aa} = 1$. For $0 \le a \le \varrho$ we have $2\varrho - a \le 2\varrho$, and $h(w_{2\varrho-a}, w_b)$ is 0 for $b < a$ and -1 for $b = a$; hence

$$-1 = h(w_{2\varrho-a}, o_a), \qquad 1 \le \|w_{2\varrho-a}\|\,\|o_a\| \le M\|o_a\|,$$

so $M^{-1} \le \|o_a\| \le M$.

An isometry with prescribed columns. For $a < \varrho$ put $v_a = \|o_a\|^{-2} o_a$, so that $\langle o_b, v_a\rangle = \delta_{ab}$ for $b \le \varrho$. Compare the families

$$\Phi = (o_0, \dots, o_\varrho,\ J_1 v_0, \dots, J_1 v_{\varrho-1}), \qquad \Psi = (f_0, \dots, f_\varrho,\ e_1^*, \dots, e_\varrho^*).$$

Their Gram matrices for h agree: $h(o_a, o_b) = \sum_{a' \le a,\, b' \le b} \overline{c_{a'a}} c_{b'b} h(f_{a'}, f_{b'})$, where $h(f_{a'}, f_{b'}) = -1$ if $a' = b' = \varrho$ and 0 otherwise, and $c_{\varrho a} = \delta_{\varrho a}$ for $a \le \varrho$; so $h(o_a, o_b) = -\delta_{a\varrho}\delta_{b\varrho} = h(f_a, f_b)$. Next $h(o_b, J_1 v_a) = \langle o_b, J_1^2 v_a\rangle = \delta_{ab} = h(f_b, e_{a+1}^*)$, since $f_b = e_{b+1}$ for $b < \varrho$ and $f_\varrho = z \perp e_{a+1}^*$. Last $h(J_1 v_a, J_1 v_b) = h(v_a, v_b) = \|o_a\|^{-2}\|o_b\|^{-2} h(o_a, o_b) = 0 = h(e_{a+1}^*, e_{b+1}^*)$ for $a, b < \varrho$. The family Ψ is part of the basis and its Gram matrix is invertible (it consists of the hyperbolic pairs (e_b, e_b^*) and $h(z,z) = -1$); so a relation $\sum_i \alpha_i \Phi_i = 0$ gives, after pairing with each Φ_j, the product of this invertible matrix with α, hence $\alpha = 0$. Thus Φ is independent, and the linear map from $\langle\Psi\rangle$ to V_1 sending Ψ_i to Φ_i is injective and preserves h. By Witt's theorem for the nondegenerate hermitian form h on $\mathbb{C}^r$ ([249], Chapter 7) it extends to an isometry A of (V_1, h); so $A \in G_1$, $Af_a = o_a$ $(a \le \varrho)$ and $Ae_{a+1}^* = J_1 v_a$ $(a < \varrho)$.

The norm of A^{-1}. Here $\|Af_a\| = \|o_a\| \le M$ for $0 \le a \le \varrho$, and $\|Ae_b^*\| = \|J_1 v_{b-1}\| = \|o_{b-1}\|^{-1} \le M$ for $1 \le b \le \varrho$, as J_1 is unitary. So Lemma 5.3.58, applied to $A^{-1} \in G_1$, gives $\|A^{-1}\| + 1 \le 4(\varrho+1)M$.

An element of R. Put $s = A^{-1}y^{-1} \in G_1$. For $b \le \varrho$, $s^{-1}f_b = yAf_b = yo_b = \sum_{b' \le b} c_{b'b}\, y w_{b'} = f_b + \sum_{b' < b} c_{b'b} f_{b'}$. By Lemma 5.5.30 (i), $s^{-1} \in R$, hence $s \in R$, and $sy = A^{-1}$. Therefore $\ell(y) \le \|sy\| + 1 = \|A^{-1}\| + 1 \le 4(\varrho+1)M$. □

Lemma 5.7.33. *Fix the setting of Definition 5.1.6, signs ε on the r basis indices of V_1 and a sign frame p for ε. Let $A, L, m \ge 0$ and $f \ge 1$ be integers and b real, and let $l \in \mathbb{Z}^r$ have large*

gap A for ε with $|l_i| \le L$ for all i; write $c_l^{G_1}(g) = c_{l/2}(p^{-1}gp)$ $(g \in G_1)$ and d_l for the formal degree $(\int |c_{l/2}|^2)^{-1}$ for the Haar measure on $\mathrm{U}(\operatorname{diag}\varepsilon)$ carried from dy by $g \mapsto p^{-1}gp$. Every $s \in R$ is uniquely $s = uh$ with $u \in \mathsf{U}$, $h \in H$; put $h_s = h$, $\sigma(s) = \sigma(u)$, $ds = du\,dh$ with dh the Haar probability measure. Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be a continuous unitary representation on $\mathbb{C}^I$, $v \in \mathbb{C}^I$ with $\|v\| = 1$, $x \in G_1$, and

$$W_x(y) = \int_R c_l^{G_1}(x^{-1}sy)\,\mathrm{wave}\big(-\sigma(s)\big)\,\rho(h_s)^{-1}v\,ds, \qquad V(x) = \int_R \mathbf{1}\big[\|p^{-1}x^{-1}sxp - 1\|_{\mathrm{op}} \le 1\big]\,ds.$$

Suppose that $V(x) \le b^m d_l \int_{\mathsf{U}\backslash G_1} \|W_x\|^2$, $\ell(x) \le b^{5n}$, $b \ge 2000$, $r \ge 100$, $m + 99r^2 \le 400r^2$, $r + L + 1 \le b^4$ and $3r^3 f \le A$. Then there are $c \in \mathbb{R}$ and a continuous $F\colon G_1 \to \mathbb{C}^I$ with $F = c\,W_x$, $\int_{G_1} d_l\, c_l^{G_1}(a^{-1})F(ya)\,da = F(y)$ for all $y \in G_1$, and such that $(F, \chi(\ell(\cdot))F)$ is a cut pair (for b, f), where $\chi = 1$ on $[0, \frac{1}{2}b^{6n+2}]$, $\chi = 0$ on $[b^{6n+2}, \infty)$, and χ is linear in between.

Proof. Write $\psi = c_l^{G_1}$ and $\iota(g) = p^{-1}gp$. As p is unitary with $p^*J_1p = \operatorname{diag}(\varepsilon)$, ι is an isomorphism of topological groups $G_1 \to \mathrm{U}(\operatorname{diag}\varepsilon)$ with $\|\iota(g)\| = \|g\|$ and $\|\iota(g) - 1\| = \|g - 1\|$; it carries the Cayley measure dy, which is left and right invariant (Lemma 5.2.41) and finite on compact sets, to a Haar measure dg of $\mathrm{U}(\operatorname{diag}\varepsilon)$, and d_l is the formal degree for dg. Every $g \in G_1$ has $\|g\| \ge 1$, since $g^{-1} = J_1g^*J_1$ has the same norm and $1 \le \|g\|\,\|g^{-1}\|$. The vector l has gap $500r^3 + A$. Put $N = 9r^2$.

Inputs on the coefficient. By Lemma 5.7.40, transported by ι,

$$|\psi(g)| \le \Big(\frac{2}{\|g\|}\Big)^j \qquad (g \in G_1,\ 0 \le j \le 500r^3 + A). \tag{5.174}$$

By Lemma 5.7.38 (3) with the integer $N > 8r^2$, transported by ι, $d_l > 0$ and, using $2000 \le b$, $r + L + 1 \le b^4$ and $8 \le b$,

$$d_l \int_{G_1} \Big(\frac{2}{\|g\|}\Big)^N dg \le 8\big(2000(r + L + 1)^6\big)^{2r^2} 2^N \le b \cdot b^{50r^2} \cdot 2^N. \tag{5.175}$$

The Bessel average. By Lemma 5.6.37 (i) (ρ continuous unitary, l of large gap A), $W = W_x$ is a continuous Bessel function of type ρ, integrable and square integrable over $\mathsf{U}\backslash G_1$, and $\int_{G_1} d_l\psi(a^{-1})W(ya)\,da = W(y)$. As ρ is unitary, $|\mathrm{wave}| = 1$ and $\|v\| = 1$,

$$\|W(y)\| \le \int_R |\psi(x^{-1}sy)|\,ds \qquad (y \in G_1). \tag{5.176}$$

The ball has positive finite volume. The map $j(s) = \iota(x^{-1}sx)$ is a homomorphism $R \to \mathrm{U}(\operatorname{diag}\varepsilon)$; it is the restriction to the closed subgroup R (Lemma 5.5.30 (i)) of a homeomorphism, hence proper, and $V(x) = ds\{s : \|j(s) - 1\| \le 1\}$. By Lemma 5.6.32 (ii), applicable by Lemma 5.5.30 (v), $V(x) < \infty$. The set $\{s \in R : \|x^{-1}sx - 1\| < 1\}$ is an open neighbourhood of 1 in R contained in the ball. Its preimage under the homeomorphism $(u, h) \mapsto uh$ of Lemma 5.5.30 (i) contains a product $O_1 \times O_2$ of nonempty open sets of U and H, and $du(O_1) > 0$, $dh(O_2) > 0$: countably many left translates of O_1 cover the second countable group U, whose measure is $du(\mathsf{U}) = \infty$ by Lemma 5.2.34 (iii) (applied to the whole coordinate space), and du is left invariant (Lemma 5.2.34 (iv)); likewise finitely many translates of O_2 cover H, of mass 1. Hence $V(x) > 0$.

Normalisation. Let $Q = \int_{\mathsf{U}\backslash G_1} \|W\|^2 < \infty$. By hypothesis $0 < V(x) \le b^m d_l Q$, so $Q > 0$. Put $c = (\#I/Q)^{1/2}$ and $F = cW$. Then F is a continuous Bessel function of type ρ, integrable over $\mathsf{U}\backslash G_1$, with $\int_{\mathsf{U}\backslash G_1} \|F\|^2 = \#I$, and $\int_{G_1} d_l\psi(a^{-1})F(ya)\,da = F(y)$ by linearity.

The Bessel length along R. For $y, y' \in G_1$ and $s' \in R$, $\|s'y'\| + 1 \le \|s'y\|\,\|y^{-1}y'\| + \|y^{-1}y'\|$ (as $\|y^{-1}y'\| \ge 1$); taking the infimum over s', $\ell(y') \le \|y^{-1}y'\|\,\ell(y)$. Hence ℓ is continuous (as $\|y^{-1}y'\| \to 1$ when $y' \to y$), and since $s' \mapsto s's$ is a bijection of R for $s \in R$, $\ell(sy) = \ell(y)$. For $s \in R$ and $y \in G_1$ this gives $\ell(y) = \ell(sy) \le \|x^{-1}sy\|\,\ell(x) \le \|x^{-1}sy\|\,b^{5n}$, so with $\lambda(y) = \max(1, \ell(y)/b^{6n})$:

$$\ell(y)/b^{6n} \le \|x^{-1}sy\|/b^n \le \|x^{-1}sy\|/2.$$

The decay majorant. Let $\Phi(y) = \int_R (2/\|x^{-1}sy\|)^N ds$, a Borel function of y by Tonelli's theorem, left R-invariant by the right invariance of ds. Let $j_0 = 3r^3 f \le A$ and $g = x^{-1}sy$. If $\lambda(y) = 1$, (5.174) with exponent N gives $\lambda(y)^{j_0}|\psi(g)| \le (2/\|g\|)^N$. Otherwise $\lambda(y) = \ell(y)/b^{6n} \le \|g\|/2$, and (5.174) with exponent $j_0 + N \le A + 500r^3$ gives $\lambda(y)^{j_0}|\psi(g)| \le (\|g\|/2)^{j_0}(2/\|g\|)^{j_0+N} = (2/\|g\|)^N$. Integrating over s and using (5.176),

$$\lambda(y)^{3r^3 f}\,\|F(y)\| \le c\,\Phi(y) \qquad (y \in G_1). \tag{5.177}$$

By Lemma 5.6.32 (ii) for j, the point $\iota(x^{-1}y)$ (so that $j(s)\iota(x^{-1}y) = \iota(x^{-1}sy)$) and the integer $N > 8r^2$: $\Phi(y) \le 16^N V(x)$. By the unfolding Lemma 5.5.30 (vi) and left invariance of dy, $\int_{\mathsf{U}\backslash G_1} \Phi = \int_{G_1} (2/\|x^{-1}g\|)^N dg = \int_{G_1} (2/\|g\|)^N dg$. Put $A_{\mathrm{m}} = c\,\Phi$ and $a = c\,16^N V(x) < \infty$. Then $A_{\mathrm{m}} \le a$, and by the hypothesis on $V(x)$, $c^2 Q = \#I$ and (5.175),

$$\begin{aligned} a \int_{\mathsf{U}\backslash G_1} A_{\mathrm{m}} &= c^2\,16^N V(x) \int_{G_1} \Big(\frac{2}{\|g\|}\Big)^N dg \le \#I\, b^m\, 16^N\, d_l \int_{G_1} \Big(\frac{2}{\|g\|}\Big)^N dg \\ &\le \#I\, b^{m+1+50r^2}\, 32^N \le b^{m+99r^2} \#I \le b^{400r^2} \#I, \end{aligned}$$

using $32^N \le b^N = b^{9r^2}$ and $1 + 59r^2 \le 99r^2$.

The cut. Let $F^\flat(y) = \chi(\ell(y))F(y)$. As $\chi \in [0,1]$ and ℓ is continuous and left R-invariant, $F^\flat$ is a bounded Borel Bessel function of type ρ with $\|F^\flat\| \le \|F\|$ and $\|F^\flat - F\| = (1-\chi(\ell))\|F\| \le \|F\|$. We check (BS1)–(BS3) of a cut pair for $(F, F^\flat)$.

(BS1) F is integrable over $\mathsf{U}\backslash G_1$, $\int \|F\|^2 = \#I$ and $\int \|F^\flat\|^2 \le \int \|F\|^2 = \#I$.

(BS3) A_{m} is Borel, left R-invariant, $A_{\mathrm{m}} \le a < \infty$, $\lambda^{3r^3 f}\|F\| \le A_{\mathrm{m}}$ by (5.177), $\lambda^{3r^3 f}\|F^\flat\| \le \lambda^{3r^3 f}\|F\| \le A_{\mathrm{m}}$, and $a \int A_{\mathrm{m}} \le b^{400r^2}\#I$.

(BS2) If $\ell(y) > b^{6n+2}$ then $\chi(\ell(y)) = 0$, so $F^\flat$ vanishes outside the cut; if $F^\flat(y) \ne F(y)$ then $\chi(\ell(y)) \ne 1$, so $\ell(y) > \frac{1}{2}b^{6n+2}$. At such y, $\lambda(y) \ge \ell(y)/b^{6n} > b^2/2 \ge b$, so $b^{3r^3 f}\|F^\flat(y) - F(y)\| \le \lambda(y)^{3r^3 f}\|F(y)\| \le A_{\mathrm{m}}(y) \le a$; this holds trivially where $F^\flat = F$. Multiplying the two bounds, $b^{6r^3 f}\|F^\flat - F\|^2 \le a\,A_{\mathrm{m}}$ on G_1, both sides left U-invariant, and integrating, $\int_{\mathsf{U}\backslash G_1} \|F^\flat - F\|^2 \le b^{400r^2 - 6r^3 f}\#I \le b^{-2r^3 f}\#I$, because $400r^2 \le 4r^3 \le 4r^3 f$ for $r \ge 100$, $f \ge 1$, and $b \ge 1$.

So $(F, \chi(\ell(\cdot))F)$ is a cut pair for b, f, with $F = cW_x$ continuous and reproduced, as claimed. □

Lemma 5.7.34. *Fix the setting of Definition 5.1.6, signs ε on the r basis indices of V_1 and a sign frame p for ε. Let $A, L \ge 0$ be integers, B real, and $l \in \mathbb{Z}^r$ with large gap A for ε and $|l_i| \le L$ for all i; write $c_l^{G_1}(g) = c_{l/2}(p^{-1}gp)$ $(g \in G_1)$ and d_l for the formal degree $(\int |c_{l/2}|^2)^{-1}$ for the Haar measure on $\mathrm{U}(\mathrm{diag}\,\varepsilon)$ carried from dy by $g \mapsto p^{-1}gp$. Suppose $(r+1)^4(L+r+1+2n^2) \le B$. Let $\rho\colon \mathrm{U}(k) \to \mathrm{U}(I)$ be a unitary representation on $\mathbb{C}^I$ and F a Bessel function of type ρ, integrable over $\mathsf{U}\backslash G_1$, with $\int_{G_1} d_l\, c_l^{G_1}(a^{-1})F(ya)\,da = F(y)$ for all $y \in G_1$. Then F has Schur's bound $(B,\ d_l^{-1}\int_{\mathsf{U}\backslash G_1}\|F\|^2)$.*

Proof. Write $\psi = c_l^{G_1}$, $e = d_l\psi$, $D = d_l^{-1}\int_{\mathsf{U}\backslash G_1}\|F\|^2$, and let X_w be the kernels of Lemma 5.7.35. The Bessel function F is bounded and Borel and $\int e(a^{-1})F(ya)\,da = F(y)$; so by Lemma 5.7.35 (iii) the functions $V_w(y) = \int_{G_1} X_w(a^{-1})F(ya)\,da$ are Bessel functions of type ρ, $V_\emptyset = F$, and $\frac{d}{dt}V_w(\gamma(t)) = \sum_{a,b} Z_{ab}V_{(a,b)w}(\gamma(t))$ whenever $\gamma'(t) = \gamma(t)Z$. Let $|w| \le 2n^2$ and ϕ be integrable on G_1. By Lemma 5.7.35 (i), X_w is integrable with $\int X_w(a^{-1})e(ya)\,da = X_w(y)$, so Lemma 5.7.19 (iii) applies to F and $X = X_w$:

$$\int_{\mathsf{U}\backslash G_1}\Big\|\int_{G_1}\phi(y)V_w(\gamma y)\,dy\Big\|^2 d\gamma \le \Big(d_l^{-1}\int_{G_1}|X_w|^2\Big)D\int_{G_1}|\phi|^2 \le B^{2|w|}D\int_{G_1}|\phi|^2,$$

by Lemma 5.7.35 (ii) and $(r+1)^4(L+r+1+|w|) \le (r+1)^4(L+r+1+2n^2) \le B$. So V_w satisfies Schur$(B^{2|w|}D)$ for $|w| \le 2n^2$, and F has Schur's bound (B, D). □

Lemma 5.7.35. *Fix the setting of Definition 5.1.6, signs ε on the r basis indices of V_1 and a sign frame p for ε. Let $A, L \ge 0$ be integers and $l \in \mathbb{Z}^r$ with large gap A for ε and $|l_i| \le L$ for all i; write $\psi(g) = c_{l/2}(p^{-1}gp)$, d_l for the formal degree for the Haar measure on $\mathrm{U}(\operatorname{diag}\varepsilon)$ carried from dy by $g \mapsto p^{-1}gp$, and $e = d_l\psi$. Words are finite sequences w of pairs of basis indices, $|w|$ is the length and $(a,b)w$ the word with the letter (a,b) prefixed. There are functions $X_w\colon G_1 \to \mathbb{C}$ such that:*

(i) $X_\emptyset = e$; every X_w is integrable and square integrable, and $\int_{G_1} X_w(a^{-1})\,e(ya)\,da = X_w(y)$ for all $y \in G_1$;

(ii) $d_l^{-1}\int_{G_1}|X_w|^2 \le \big((r+1)^4(L+r+1+|w|)\big)^{2|w|}$ for every word w;

(iii) if $F\colon G_1 \to \mathbb{C}^I$ is bounded and Borel with $\int_{G_1} e(a^{-1})F(ya)\,da = F(y)$ for all y, then the functions $V_w(y) = \int_{G_1} X_w(a^{-1})F(ya)\,da$ are bounded and continuous, $V_\emptyset = F$, and for every differentiable curve γ in G_1 with $\gamma'(t) = \gamma(t)Z$ at t,

$$\frac{d}{dt}V_w(\gamma(t)) = \sum_{a,b} Z_{ab}\,V_{(a,b)w}(\gamma(t));$$

if moreover F is a Bessel function of type ρ for a unitary representation ρ of $\mathrm{U}(k)$, so is every V_w.

Proof. Let $\iota(g) = p^{-1}gp$, an isomorphism of topological groups $G_1 \to G$ carrying dy to dg (a Haar measure: dy is left and right invariant by Lemma 5.2.41); write $c = c_{l/2}$, so $\psi = c \circ \iota$, and $d = d_l$. The gap $500r^3 + A$ exceeds $8r^2$. For a basis pair (a,b) let $\hat{E}_{ab} = p^{-1}E_{ab}p$, of operator norm 1 as p is unitary. By Lemma 5.7.36 (ii) there is a smooth compactly supported β on G with $c = f_\beta$. Define bumps $\beta_\emptyset = \beta$, $\beta_{(a,b)w} = (\beta_w)_{\hat{E}_{ab}}$, and put $X_w = d\,f_{\beta_w} \circ \iota$ and $b_w = \beta_w \circ \iota$, a smooth compactly supported function on G_1.

(ii). By Lemma 5.7.36 (ii), $f_{\beta_w} = \hat{E}_{a_1b_1}(\cdots(\hat{E}_{a_sb_s}c))$ for $w = ((a_1,b_1),\dots,(a_s,b_s))$. As $c \in M_0$, Lemma 5.7.37 applied s times (to steps $s-1,\dots,0$, with $\|\hat{E}_{ab}\| = 1$) gives $\|f_{\beta_w}\|_2 \le \prod_{j<s}(r+1)^4(L+r+1+j)\,\|c\|_2 \le \big((r+1)^4(L+r+1+s)\big)^s d^{-1/2}$, using $\|c\|_2^2 = d^{-1}$; so $d^{-1}\int_{G_1}|X_w|^2 = d\,\|f_{\beta_w}\|_2^2$ is at most the claimed bound.

(i). $X_\emptyset = d\,c \circ \iota = e$. Each f_φ is bounded and square integrable (Lemma 5.7.36 (i)) and integrable, since $\int_G |f_\varphi| \le \|\varphi\|_1\|c\|_1$ (c is integrable, Lemma 5.6.23 (i)). For the reproduction it suffices, transporting by ι, to show $d\int_G f_\varphi(a^{-1})c(ya)\,da = f_\varphi(y)$. By Fubini's theorem (the integrand is bounded by $|\varphi(z)||c(a^{-1}z)|$, integrable) this is $\int \varphi(z)\,d\int c(ya)c(a^{-1}z)\,da\,dz$, and

with $c(a^{-1}z) = \overline{c(z^{-1}a)}$ (Lemma 5.7.40), the substitution $a = zu$ and Lemma 5.6.23 (ii) with $x = yz$ and $a = 1$, $d\int c(yzu)\overline{c(u)}\,du = c(yz)c(1) = c(yz)$; so the integral is $f_\varphi(y)$.

(iii). Let F be as stated and $\|F\| \le C$. By the definition of f_{β_w} and the transport, $X_w(a^{-1}) = d\int_{G_1} b_w(z)\psi(a^{-1}z)\,dz$, so by Fubini's theorem (integrand bounded by $C|b_w(z)||\psi(a^{-1}z)|$) and the substitution $a = zt$,

$$V_w(y) = \int_{G_1} b_w(z)\Big(\int_{G_1} e(t^{-1})F(yzt)\,dt\Big)dz = \int_{G_1} b_w(z)F(yz)\,dz.$$

Hence (also directly from $X_\emptyset = e$) $V_\emptyset(y) = \int e(a^{-1})F(ya)\,da = F(y)$; $\|V_w\| \le C\|b_w\|_1$; and $V_w(y) = \int b_w(y^{-1}x)F(x)\,dx$ is continuous in y by dominated convergence (for y in a compact set the integrands are supported in a fixed compact set and bounded). For the derivative let $\gamma'(t) = \gamma(t)Z$, so $Z = \gamma(t)^{-1}\gamma'(t)$ lies in the Lie algebra of G_1 and $\gamma(t+s)^{-1} = (1 - sZ + o(s))\gamma(t)^{-1}$. By the chain rule, $\frac{d}{dt}b_w(\gamma(t)^{-1}x) = (b_w)_Z(\gamma(t)^{-1}x)$, where $(b_w)_Z(x) = \frac{d}{ds}|_0 b_w(e^{-sZ}x)$; for t in a compact interval these derivatives are bounded and supported in a fixed compact set, so differentiation under the integral gives $\frac{d}{dt}V_w(\gamma(t)) = \int (b_w)_Z(\gamma(t)^{-1}x)F(x)\,dx$. Since $\iota(e^{-sZ}x) = e^{-s\iota(Z)}\iota(x)$, $(b_w)_Z = (\beta_w)_{p^{-1}Zp}\circ\iota$, and by complex linearity of $X \mapsto (\beta_w)_X$ (Lemma 5.7.36 (i)) and $p^{-1}Zp = \sum_{a,b} Z_{ab}\hat{E}_{ab}$, $(b_w)_Z = \sum Z_{ab}\, b_{(a,b)w}$. Hence $\frac{d}{dt}V_w(\gamma(t)) = \sum_{a,b} Z_{ab}V_{(a,b)w}(\gamma(t))$. Finally, if F is a Bessel function of type ρ, then $V_w(uy) = \int X_w(a^{-1})\mathrm{wave}(\sigma(u))F(ya)\,da = \mathrm{wave}(\sigma(u))V_w(y)$ for $u \in \mathsf{U}$ and likewise $V_w(hy) = \rho(h)V_w(y)$ for $h \in H$ (the linear map $\rho(h)$ commutes with the integral); with boundedness and continuity, V_w is a Bessel function of type ρ. □

Lemma 5.7.36. *Let n be a nonempty finite set, $\varepsilon \in \{\pm1\}^n$, $J = \mathrm{diag}(\varepsilon)$, $G = \mathrm{U}(J)$ with a Haar measure dg, $\mathfrak{u}(J) = \{Y : Y^*J + JY = 0\}$, and E_{ab} the matrix units. Let $h > 8(\#n)^2$ be an integer, $l \in \mathbb{Z}^n$ with gap h for ε, $c = c_{l/2}$, $\mu = \mu_l$, $d = (\int_G |c|^2)^{-1}$, and $\langle u, v\rangle = \int_G \overline{u}\,v$ on $L^2(G)$. For a smooth compactly supported φ on G put $f_\varphi(g) = \int_G \varphi(y)\,c(gy)\,dy$; for $Y \in \mathfrak{u}(J)$ put $\varphi_Y(y) = \frac{d}{dt}|_{t=0}\varphi(e^{-tY}y)$, and for $X = Y_1 + iY_2$ with $Y_1, Y_2 \in \mathfrak{u}(J)$ (a unique decomposition) put $\varphi_X = \varphi_{Y_1} + i\varphi_{Y_2}$. Let $\mathcal{H}_c$ be the span of the functions $X_1(X_2(\cdots(X_s c)))$, $s \ge 0$, $X_j \in \mathrm{M}_n(\mathbb{C})$.*

- *(i) φ_Y and φ_X are smooth with support in that of φ, $X \mapsto \varphi_X$ is complex linear, $|f_\varphi| \le \|\varphi\|_1$, $\|f_\varphi\|_2 \le \|\varphi\|_1\|c\|_2$, and for $Y \in \mathfrak{u}(J)$: $\frac{d}{dt}|_{t=0} f_\varphi(ge^{tY}) = f_{\varphi_Y}(g)$ for every g, and $t^{-1}(f_\varphi(\cdot\, e^{tY}) - f_\varphi) \to f_{\varphi_Y}$ in $L^2(G)$ as $t \to 0$.*
- *(ii) There is a smooth compactly supported β with $c = f_\beta$; for every word, $X_1(X_2(\cdots(X_s c))) = f_\varphi$ with $\varphi = (\cdots((\beta_{X_s})_{X_{s-1}})\cdots)_{X_1}$. So $\mathcal{H}_c$ consists of bounded square integrable functions f_φ, is stable under every $X \in \mathrm{M}_n(\mathbb{C})$, and $X(X'u) - X'(Xu) = (XX' - X'X)u$ for $u \in \mathcal{H}_c$.*
- *(iii) $\langle E_{ab}u, v\rangle = \varepsilon_a\varepsilon_b\langle u, E_{ba}v\rangle$ for $u, v \in \mathcal{H}_c$ and $a, b \in n$.*
- *(iv) $\|c\|_2^2 = d^{-1}$ and $|u(g)| \le d^{1/2}\|u\|_2$ for every $u \in \mathcal{H}_c$ and $g \in G$.*
- *(v) $E_{aa}c = \mu_a c$; $E_{ab}c = 0$ if $a \ne b$, $\varepsilon_a = \varepsilon_b$ and $l_a > l_b$; and $\Omega u = \kappa_l u$ for every $u \in \mathcal{H}_c$, where $\Omega u = \sum_{a,b} E_{ab}(E_{ba}u)$ and $\kappa_l = \frac{1}{4}\sum_a (l_a^2 - (2\rho_l(a))^2) \ge -\frac{1}{4}(\#n)^3$.*

Proof. G is unimodular, so dg is invariant under left and right translations; write R_x for right translation, a unitary operator on $L^2(G)$. By Lemma 5.6.23 ($h > 8(\#n)^2$), c is continuous, integrable and square integrable, $d > 0$, Schur orthogonality (ii) holds, and there is a smooth compactly supported β with $f_\beta = c$ (part (iii) there). By Lemma 5.7.40, $|c| \le 1$.

(i). Smoothness and support are clear, and $Y \mapsto \varphi_Y$ is real linear on $\mathfrak{u}(J)$; as $\mathrm{M}_n(\mathbb{C}) = \mathfrak{u}(J) \oplus i\,\mathfrak{u}(J)$ ($X = Y_1 + iY_2$ with $Y_1 = \frac{1}{2}(X - JX^*J)$, $Y_2 = \frac{1}{2i}(X + JX^*J)$), $X \mapsto \varphi_X$ is complex linear.

$|f_\varphi| \le \|\varphi\|_1$ as $|c| \le 1$, and by Minkowski's integral inequality $\|f_\varphi\|_2 \le \int |\varphi(y)|\,\|R_y c\|_2\,dy = \|\varphi\|_1\|c\|_2$. For $Y \in \mathfrak{u}(J)$, left invariance gives $f_\varphi(ge^{tY}) = \int \varphi(e^{-tY}y)c(gy)\,dy = f_{\varphi(e^{-tY}\cdot)}(g)$. The functions $\psi_t = t^{-1}(\varphi(e^{-tY}\cdot) - \varphi) - \varphi_Y$, $0 < |t| \le 1$, are supported in the compact set $\{e^{-sY} : |s| \le 1\}\operatorname{supp}\varphi$ and tend to 0 uniformly (Taylor's formula; the second t-derivative of $\varphi(e^{-tY}y)$ is bounded there); so $\|\psi_t\|_1 \to 0$, and $|f_{\psi_t}| \le \|\psi_t\|_1$, $\|f_{\psi_t}\|_2 \le \|\psi_t\|_1\|c\|_2$ give both limits.

(ii). By induction on s: the function $u = X_2(\cdots(X_s c))$ equals $f_{\varphi'}$ with φ' the bump of the claim for the shorter word, and u is locally holomorphic (Lemma 5.6.24 (i), (ii)). For $X_1 = Y_1 + iY_2$, Lemma 5.6.24 (i) gives $X_1 u = Y_1 u + iY_2 u$ with $(Y_j u)(g) = \frac{d}{dt}|_0 u(ge^{tY_j}) = f_{\varphi'_{Y_j}}(g)$ by (i); so $X_1 u = f_{\varphi'_{X_1}}$. The rest follows from (i) and the commutator identity of Lemma 5.6.24 (i).

(iii). Let $u = f_\varphi$, $v = f_{\varphi'}$ in $\mathcal{H}_c$ and $Y \in \mathfrak{u}(J)$. The function $t \mapsto \langle R_{e^{tY}}u, R_{e^{tY}}v\rangle = \langle u, v\rangle$ is constant, and by the L^2 limit of (i) its derivative at 0 is $\langle Yu, v\rangle + \langle u, Yv\rangle$ (with $Yu = f_{\varphi_Y}$ by (ii)). So $\langle Yu, v\rangle = -\langle u, Yv\rangle$. For $X = Y_1 + iY_2$, as the product is conjugate-linear in the first argument, $\langle Xu, v\rangle = \langle u, (-Y_1 + iY_2)v\rangle = \langle u, (JX^*J)v\rangle$; for $X = E_{ab}$, $JE_{ba}J = \varepsilon_a\varepsilon_b E_{ba}$.

(iv). $\|c\|_2^2 = d^{-1}$ by definition. Let $u = f_\varphi \in \mathcal{H}_c$ and $g \in G$. By Fubini's theorem (the integrand is bounded by $|\varphi(y)||c(z)|$) and Lemma 5.6.23 (ii) with $x = 1$, $a = gy$, $c(1) = 1$: $\langle c, R_g u\rangle = \int \varphi(y) \int c(zgy)\overline{c(z)}\,dz\,dy = d^{-1}u(g)$. By Cauchy–Schwarz, $|u(g)| \le d\,\|c\|_2\|R_g u\|_2 = d^{1/2}\|u\|_2$.

(v). The first two statements are Lemma 5.6.24 (iii) (gap $h \ge 0$). By Lemma 5.6.24 (iv), $\Omega c = \kappa_l c$. The element $\sum_{a,b} E_{ab}E_{ba}$ is central in the universal enveloping algebra of $\mathfrak{gl}_n$: from $[E_{cd}, E_{ab}] = \delta_{da}E_{cb} - \delta_{bc}E_{ad}$,

$$\sum_{a,b}[E_{cd}, E_{ab}]E_{ba} = \sum_b E_{cb}E_{bd} - \sum_a E_{ad}E_{ca}, \qquad \sum_{a,b} E_{ab}[E_{cd}, E_{ba}] = \sum_a E_{ad}E_{ca} - \sum_b E_{cb}E_{bd},$$

so $\sum_{a,b}[E_{cd}, E_{ab}E_{ba}] = 0$. By the commutator identity of (ii), the operator Ω on $\mathcal{H}_c$ therefore commutes with every E_{cd}, hence with every word, and $\Omega(X_1\cdots X_s c) = X_1\cdots X_s\Omega c = \kappa_l X_1\cdots X_s c$. Finally $|2\rho_l(a)| \le \#n - 1$, so $\kappa_l \ge -\frac{1}{4}\#n(\#n-1)^2 \ge -\frac{1}{4}(\#n)^3$. □

Lemma 5.7.37. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $B, L \ge 0$ integers, and $l \in \mathbb{Z}^n$ with large gap B for ε and $|l_a| \le L$ for all a; let $\mathcal{H}_c$ be as in Lemma 5.7.36. Let $M_0 \subseteq \mathcal{H}_c$ be the span of the functions $E_{a_1b_1}(\cdots(E_{a_mb_m}c))$ with $m \ge 0$ and $\varepsilon_{a_j} = \varepsilon_{b_j}$ for all j, and $M_{s+1} = M_s + \sum_{a,b} E_{ab}M_s$. Then for every $s \ge 0$, $y \in M_s$ and $X \in \mathrm{M}_n(\mathbb{C})$, $Xy \in M_{s+1}$ and*

$$\|Xy\|_2 \le (\#n + 1)^4\,(L + \#n + 1 + s)\,\|X\|\,\|y\|_2,$$

with $\|X\|$ the operator norm.

Proof. Write $N_0 = \#n$, $\mu = \mu_l$, call (a, b) *compact* if $\varepsilon_a = \varepsilon_b$, *lowering* if moreover $l_a < l_b$, and put $\Omega_K = \sum_{(a,b)\text{ compact}} E_{ab}E_{ba}$, an operator on $\mathcal{H}_c$ by (ii). The gap $500N_0^3 + B > 8N_0^2$, so Lemma 5.7.36 applies. $Xy \in M_{s+1}$ since $Xy = \sum X_{ab}E_{ab}y$ by complex linearity.

Step 1: weights. From $[E_{aa}, E_{cd}] = (\delta_{ac} - \delta_{ad})E_{cd}$ and (v), for a word $w = ((a_1, b_1), \ldots, (a_m, b_m))$ and $wc = E_{a_1b_1}(\cdots(E_{a_mb_m}c))$ we get $E_{aa}(wc) = \nu_w(a)\,wc$ with $\nu_w = \mu + \sum_j(\delta_{a_j} - \delta_{b_j})$ (here δ_a is the indicator vector of a), an integer vector with $|\nu_w(a) - \mu_a| \le m$. By (iii) E_{aa} is symmetric on $\mathcal{H}_c$, so weight vectors of distinct weights are orthogonal. The entries of l are distinct integers in $[-L, L]$ of one parity, so $N_0 \le L + 1$; $2\rho_l(a) = (N_0 - 1) - 2\#\{j : l_j > l_a\}$ and l_a are both congruent to $N_0 - 1$ modulo 2, so $\mu_a = \frac{1}{2}(l_a + 2\rho_l(a)) - 2\rho_l^{\mathrm{c}}(a)$; with $|2\rho_l(a)|, |2\rho_l^{\mathrm{c}}(a)| \le N_0 - 1$, $|\mu_a| \le \frac{1}{2}(L + N_0 - 1) + N_0 - 1 \le L + N_0$.

Step 2: highest vectors. Call $z \in \mathcal{H}_c$ *K-highest of weight ν* if $E_{aa}z = \nu_a z$ for all a and $E_{ab}z = 0$ for compact (a,b) with $l_a > l_b$. For such z, as in the computation for c: for compact (a,b) with $l_a > l_b$, $E_{ab}E_{ba}z = E_{ba}E_{ab}z + (E_{aa} - E_{bb})z = (\nu_a - \nu_b)z$, and $E_{ba}z = 0$ when $l_a < l_b$; hence

$$\Omega_K z = c_K(\nu)z, \qquad c_K(\nu) = \sum_a \nu_a^2 + \sum_{\varepsilon_a=\varepsilon_b,\ l_a>l_b} (\nu_a - \nu_b) = \sum_a \nu_a(\nu_a + 2\rho_l^{\mathrm{c}}(a)).$$

If $W \neq 0$ is a finite-dimensional subspace of $\mathcal{H}_c$ stable under the E_{ab} with (a,b) compact, then W contains a nonzero K-highest vector: the E_{aa} commute and are symmetric on W (by (iii)), so W is the orthogonal sum of joint eigenspaces, with real weights; take a weight ν of W maximising $\sum_a l_a\nu_a$ and $z \neq 0$ of weight ν; for compact (a,b) with $l_a > l_b$, $E_{ab}z \in W$ has weight $\nu + \delta_a - \delta_b$ of larger pairing with l, so $E_{ab}z = 0$.

Step 3: a closure property. Let $T \subseteq \mathcal{H}_c$ be a subspace stable under the lowering E_{ab} and containing wc for all words w of length at most s (arbitrary letters). Then $M_s \subseteq T$. Indeed, for a set Σ of pairs of signs and a lowering-stable subspace U, the space $U^\Sigma = \{y : E_{cd}y \in U \text{ whenever } (\varepsilon_c,\varepsilon_d) \in \Sigma\}$ is lowering-stable: for lowering (a,b) and $y \in U^\Sigma$, $E_{cd}E_{ab}y = E_{ab}E_{cd}y + \delta_{da}E_{cb}y - \delta_{bc}E_{ad}y$, and $(\varepsilon_c,\varepsilon_b)$, $(\varepsilon_a,\varepsilon_d)$ equal $(\varepsilon_c,\varepsilon_d)$ when the deltas are nonzero (as $\varepsilon_a = \varepsilon_b$). For $s = 0$: let T_0 be the smallest lowering-stable subspace containing c. Then $c \in T_0^{\Sigma_0}$ for Σ_0 the diagonal pairs of signs (lowering letters map c into T_0, $E_{aa}c = \mu_a c$, raising compact letters kill c), and $T_0^{\Sigma_0}$ is lowering-stable, so $T_0 \subseteq T_0^{\Sigma_0}$: T_0 is stable under all compact E_{ab}, hence $M_0 \subseteq T_0 \subseteq T$. For $s+1$: T^{all} (Σ all pairs) is lowering-stable and contains wc for $|w| \leq s$, so by induction $M_s \subseteq T^{\mathrm{all}}$, i.e. $E_{ab}M_s \subseteq T$; with $M_s \subseteq T$ this gives $M_{s+1} \subseteq T$.

Step 4: M_s is finite-dimensional and stable under compact letters. Ω_K commutes with the compact E_{cd} (it is the sum of the Casimir elements of the two blocks $\{\varepsilon = \pm 1\}$, each central in its enveloping algebra by the identity of Lemma 5.7.36 (v) for that block), so $\Omega_K = c_K(\mu)$ on M_0, as c is K-highest of weight μ by (v). By Step 3 ($s = 0$, $T = T_0$), M_0 is spanned by the vectors wc with all letters lowering. For such w of length m with $wc \neq 0$, by (iii) and Step 1, $c_K(\mu)\|wc\|^2 = \langle wc, \Omega_K wc\rangle = \sum_{\text{compact}} \|E_{ba}wc\|^2 \geq \sum_a \nu_w(a)^2\|wc\|^2$, while $\sum_a l_a\nu_w(a) \leq \sum_a l_a\mu_a - m$ (each lowering letter changes the pairing by $l_a - l_b \leq -1$). Hence $0 \leq \sum_a (l_a + \nu_w(a))^2 \leq \sum_a l_a^2 + 2\sum_a l_a\mu_a - 2m + c_K(\mu)$, which bounds m; so M_0 is spanned by finitely many vectors, and M_{s+1} is a finite sum of images of M_s. Stability under compact E_{cd} by induction: $E_{cd}E_{ab}y = E_{ab}E_{cd}y + [E_{cd}, E_{ab}]y$, with $[E_{cd}, E_{ab}]$ a combination of matrix units.

Step 5: Ω_K on M_s. Put $N = L + N_0 + s$. By (iii), Ω_K is symmetric on $\mathcal{H}_c$ and maps M_s into itself (Step 4); let e be an eigenvalue of $\Omega_K|_{M_s}$ and $W \subseteq M_s$ its eigenspace, stable under compact letters (they commute with Ω_K). By Step 2, W contains a nonzero K-highest z of some weight ν, and $e = c_K(\nu)$. Some word w of length at most s has $\langle wc, z\rangle \neq 0$: otherwise the orthogonal complement of z, which is lowering-stable (by (iii) the adjoint of a lowering E_{ab} is E_{ba}, and $E_{ba}z = 0$), would contain $M_s \ni z$ by Step 3. Pairing $E_{aa}wc = \nu_w(a)wc$ with z and using the symmetry of E_{aa} gives $\nu = \nu_w$, so $|\nu_a| \leq |\mu_a| + s \leq N$ by Step 1 and $e = c_K(\nu) \leq \sum_a |\nu_a|(|\nu_a| + N_0) \leq N_0N(N + N_0) \leq 2N_0N^2$. As M_s has an orthonormal eigenbasis of Ω_K, $\langle y, \Omega_K y\rangle \leq 2N_0N^2\|y\|_2^2$ for $y \in M_s$.

Step 6: conclusion. For $y \in \mathcal{H}_c$, by (iii), $\|E_{ab}y\|^2 = \varepsilon_a\varepsilon_b\langle y, E_{ba}E_{ab}y\rangle$; summing over compact pairs gives $\langle y, \Omega_K y\rangle$ and over the others $-\langle y, (\Omega - \Omega_K)y\rangle$. So by (v), for $y \in M_s$,

$$\sum_{a,b} \|E_{ab}y\|^2 = 2\langle y, \Omega_K y\rangle - \kappa_l\|y\|^2 \leq (4N_0N^2 + \tfrac{1}{4}N_0^3)\|y\|^2 \leq 5N_0N^2\|y\|^2.$$

Since $|X_{ab}| \leq \|X\|$ and by Cauchy–Schwarz over the N_0^2 pairs, $\|Xy\| \leq \|X\| \sum_{a,b} \|E_{ab}y\| \leq \|X\|N_0(5N_0N^2)^{1/2}\|y\| \leq (N_0+1)^4(N+1)\|X\|\,\|y\|$. □

Lemma 5.7.38. *Let $n \geq 1$, $s \in \{\pm 1\}^n$, $l \in \mathbb{Z}^n$, $\lambda = \frac{1}{2}l$, let dg be a Haar measure on $\mathrm{U}(\operatorname{diag} s)$, d_λ the formal degree with respect to it, and $\|\cdot\|$ the operator norm. Let $h, B, L \in \mathbb{N}$.*

1. *If l has gap h for s, then $c_\lambda(g^{-1}) = \overline{c_\lambda(g)}$, $|c_\lambda(g)| \leq 1$, and $|c_\lambda(g)| \leq (2/\|g\|)^c$ for every integer $0 \leq c \leq h$ and every g.*
2. *If l has large gap B for s and $|l_i| \leq L$ for all i, then for all $x, g \in \mathrm{U}(\operatorname{diag} s)$*
$$|c_\lambda(xg) - c_\lambda(x)| \leq 100(n + L + 1)^5 \, \|g - 1\|.$$
3. *If l has large gap B for s, $|l_i| \leq L$ for all i, and $c > 8n^2$ is an integer, then $d_\lambda > 0$, $g \mapsto d_\lambda (2/\|g\|)^c$ is integrable, and*
$$\int_{\mathrm{U}(\operatorname{diag} s)} d_\lambda \Big(\frac{2}{\|g\|}\Big)^c dg \leq 8\big(2000(n + L + 1)^6\big)^{2n^2} 2^c.$$

Proof. Write $J = \operatorname{diag}(s)$, $G = \mathrm{U}(\operatorname{diag} s)$, $K = K_s$ (the unitary elements of G), and call a matrix block-diagonal if its (i, j) entry vanishes whenever $s_i \neq s_j$. A vector with large gap B has gap 0. By Lemma 5.6.30: every $x \in G$ satisfies $\|x^{-1}\| = \|x\| \geq 1$ and $m_w(x^{-1}) = \overline{m_w(x)}$ (part (i)); every $g \in G$ is $g = kz$ with $k \in K$ and $z \in G$ positive definite, $\|g\| = \|z\|$, $z^{-1} = JzJ$ and $\mathrm{bd}_s(z) = \frac{1}{2}(z + z^{-1})$ (part (ii)); and $\mathrm{bd}_s(g) = k \, \mathrm{bd}_s(z)$ (part (iii)), so $|\det \mathrm{bd}_s(g)| = |\det \mathrm{bd}_s(z)|$.

(1) is Lemma 5.7.40.

Differentiability. By Lemma 5.6.24 (ii), for $g_0 \in G$ and $a = \mathrm{bd}_s(g_0)$ there are an open neighbourhood W of g_0 in $\mathrm{GL}_n(\mathbb{C})$ and the holomorphic function $F(x) = \mathrm{FJ}_l(a, a^{-1}x)$ on W with $c_\lambda = F$ on $W \cap G$. Consequently, for a differentiable curve γ in G and $x \in G$, $t \mapsto c_\lambda(x\gamma(t))$ is differentiable with derivative $DF(y)[y\,X]$ at t, where $y = x\gamma(t)$ and $X = \gamma(t)^{-1}\gamma'(t)$; differentiating $\gamma^* J \gamma = J$ gives $X^*J + JX = 0$, and $DF(y)[yX] = \frac{d}{d\sigma}\big|_{\sigma=0} c_\lambda(ye^{\sigma X})$ because $\sigma \mapsto ye^{\sigma X}$ is a curve in G with derivative yX at 0.

(2). Let $x, g \in G$ and $A = g - 1$. If $\|A\| \geq 1$, then $|c_\lambda(xg) - c_\lambda(x)| \leq 2 \leq 100(n + L + 1)^5 \|A\|$ by (1). Let $\|A\| < 1$. For $t \in [0, 1]$ put $u_t = 1 - \frac{t-1}{2}A$; as $\|\frac{t-1}{2}A\| \leq \frac{1}{2}$, u_t is invertible with $\|u_t^{-1}\| \leq 2$ (Neumann series). Put $\gamma(t) = 1 + tAu_t^{-1}$. Then $\gamma(0) = 1$, $\gamma(1) = 1 + A = g$, and $\gamma(t) \in G$: indeed $\gamma(t)u_t = 1 + \frac{1+t}{2}A$, and with $\alpha = \frac{1+t}{2}$, $\beta = \frac{1-t}{2}$ (so $u_t = 1 + \beta A$, $\alpha + \beta = 1$, $\alpha - \beta = t$),

$$(1 + \alpha A)^* J (1 + \alpha A) - (1 + \beta A)^* J (1 + \beta A) = t(A^*J + JA + A^*JA) = t\,(g^*Jg - J) = 0,$$

so $u_t^* \gamma(t)^* J \gamma(t) u_t = u_t^* J u_t$ and $\gamma(t)^* J \gamma(t) = J$. Moreover $\frac{d}{dt} u_t^{-1} = \frac{1}{2} u_t^{-1} A u_t^{-1}$, so

$$\gamma'(t) = Au_t^{-1} + \tfrac{t}{2}\, Au_t^{-1}Au_t^{-1}, \qquad \|\gamma'(t)\| \leq 2\|A\| + 2\|A\|^2 \leq 4\|A\|, \qquad \|\gamma(t)\| \leq 1 + 2\|A\| \leq 3.$$

With $X_t = \gamma(t)^{-1}\gamma'(t)$, $\|X_t\| \leq \|\gamma(t)^{-1}\| \, \|\gamma'(t)\| = \|\gamma(t)\| \, \|\gamma'(t)\| \leq 12\|A\|$. By the differentiability paragraph and Lemma 5.7.39 (large gap B, entries bounded by L), $\phi(t) = c_\lambda(x\gamma(t))$ is differentiable on $[0, 1]$ with $|\phi'(t)| \leq (n+1)^4(n + L + 1) \cdot 12\|A\| \leq 12(n + L + 1)^5 \|A\|$. The mean value inequality gives $|c_\lambda(xg) - c_\lambda(x)| = |\phi(1) - \phi(0)| \leq 100(n + L + 1)^5 \|g - 1\|$.

(3). Let $c' > 8n^2$ be the integer of the statement (written c there) and put $\delta = (200(n + L + 1)^5)^{-1}$, $\kappa = 2000(n + L + 1)^6$. We apply Lemma 5.6.32 to the group $S = G$ with the Haar measure $\nu = dg$ (right invariant, as G is unimodular; finite on compact sets), j the identity (a proper homomorphism) and $y = 1$.

Square integrability and $d_\lambda > 0$. By (1) with $c = 500n^3 \leq 500n^3 + B$, $|c_\lambda(g)|^2 \leq (2/\|g\|)^{1000n^3}$ and $1000n^3 > 8n^2$, so $|c_\lambda|^2$ is integrable by Lemma 5.6.32 (ii). By (2) with $x = 1$ and $c_\lambda(1) = 1$,

$|c_\lambda(g)| \geq \frac{1}{2}$ whenever $\|g-1\| \leq \delta$; this set contains a neighbourhood of 1, of positive Haar measure. Hence $0 < \int_G |c_\lambda|^2 dg < \infty$ and $d_\lambda = (\int_G |c_\lambda|^2)^{-1} > 0$, and

$$\nu\{g : \|g-1\| \leq \delta\} \leq \int_G 4|c_\lambda|^2 \, dg = \frac{4}{d_\lambda}.$$

Balls. For $R \geq 1$, Lemma 5.6.32 (i) with $D = \delta^{-1}$ and the constant $\kappa R^2 \geq 3 \cdot 200(n+L+1)^5 R^2 = 3DR^2$ in the place of its K gives

$$\nu\{g : \|g\| \leq R\} \leq (\kappa R^2)^{2n^2} \cdot \frac{4}{d_\lambda}.$$

Integrability and the bound. The function $g \mapsto d_\lambda (2/\|g\|)^{c'}$ is integrable by Lemma 5.6.32 (ii). Since $\|g\| \geq 1$, the layer-cake formula gives

$$\int_G \|g\|^{-c'} dg = \int_0^1 \nu\{g : \|g\| < \tau^{-1/c'}\} \, d\tau \leq \frac{4\kappa^{2n^2}}{d_\lambda} \int_0^1 \tau^{-4n^2/c'} d\tau = \frac{4\kappa^{2n^2}}{d_\lambda} \cdot \frac{c'}{c'-4n^2} \leq \frac{8\kappa^{2n^2}}{d_\lambda},$$

as $c' > 8n^2$. Multiplying by $d_\lambda 2^{c'}$ gives $\int_G d_\lambda (2/\|g\|)^{c'} dg \leq 8\big(2000(n+L+1)^6\big)^{2n^2} 2^{c'}$. Replacing dg by a positive multiple divides d_λ by the same factor, so the left side does not depend on the choice of dg. □

Lemma 5.7.39. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $B, L \geq 0$ integers, and $l \in \mathbb{Z}^n$ a vector with large gap B for ε and $|l_i| \leq L$ for all i. Let $y \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ and let X be a complex $n \times n$ matrix with $X^* \mathrm{diag}(\varepsilon) + \mathrm{diag}(\varepsilon) X = 0$. Then $t \mapsto c_{l/2}(ye^{tX})$ is differentiable at $t = 0$ and*

$$\Big| \frac{d}{dt}\Big|_{t=0} c_{l/2}(ye^{tX}) \Big| \leq (\#n+1)^4 \, (\#n+L+1) \, \|X\|.$$

Proof. Write $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$ with a Haar measure, $c = c_{l/2}$, $d = (\int_G |c|^2)^{-1}$, and use the module $\mathcal{H}_c$, the smoothings f_φ and the bumps φ_X of Lemma 5.7.36; the gap $500(\#n)^3 + B$ exceeds $8(\#n)^2$. By Lemma 5.7.36 (ii), $c = f_\beta$ for a smooth compactly supported β, and $Xc = f_{\beta_X} \in \mathcal{H}_c$. By (i) of the same lemma, $t \mapsto f_\beta(ye^{tX})$ is differentiable at 0 with derivative $f_{\beta_X}(y) = (Xc)(y)$. As $c \in M_0$ (the filtration of Lemma 5.7.37), that lemma with $s = 0$ gives $\|Xc\|_2 \leq (\#n+1)^4 (L + \#n + 1) \|X\| \, \|c\|_2$, and by Lemma 5.7.36 (iv),

$$\begin{aligned} \Big| \frac{d}{dt}\Big|_{t=0} c(ye^{tX}) \Big| &= |(Xc)(y)| \leq d^{1/2} \|Xc\|_2 \\ &\leq (\#n+1)^4 (\#n+L+1) \, \|X\| \, d^{1/2} \|c\|_2 = (\#n+1)^4 (\#n+L+1) \, \|X\|. \end{aligned}$$

□

Lemma 5.7.40. *Let n be a nonempty finite set, $\varepsilon \in \{\pm 1\}^n$, $h \geq 0$ an integer and $l \in \mathbb{Z}^n$ a vector with gap h for ε. Then for every $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$*

$$c_{l/2}(g^{-1}) = \overline{c_{l/2}(g)}, \qquad |c_{l/2}(g)| \leq 1, \qquad |c_{l/2}(g)| \leq \Big(\frac{2}{\|g\|}\Big)^c \quad \textit{for every integer } 0 \leq c \leq h.$$

Proof. Write $G = \mathrm{U}(\mathrm{diag}\,\varepsilon)$, $J = \mathrm{diag}(\varepsilon)$, $K = K_\varepsilon$, $\mu = \mu_l$ and $c = c_{l/2}$ where no exponent is meant; call a matrix block-diagonal if its (i,j) entry vanishes whenever $\varepsilon_i \neq \varepsilon_j$. A vector with gap h has gap 0, so Lemma 5.6.26 and Lemma 5.6.29 apply. By Lemma 5.6.30: every $x \in G$ satisfies $\|x^{-1}\| = \|x\|$ and $m_w(x^{-1}) = \overline{m_w(x)}$ for $w \in \mathbb{Z}^n$ (part (i)); every $g \in G$ is $g = kz$ with $k \in K$ and $z \in G$ positive definite, $\|g\| = \|z\|$, $z^{-1} = JzJ$ and $\mathrm{bd}_\varepsilon(z) = \frac{1}{2}(z + z^{-1})$ (part (ii)); and $\mathrm{bd}_\varepsilon(g) = k\,\mathrm{bd}_\varepsilon(z)$ (part (iii)), so $|\det \mathrm{bd}_\varepsilon(g)| = |\det \mathrm{bd}_\varepsilon(z)|$ as $|\det k| = 1$.

Inversion. Let $g = kz$ as above. Then $g = k\,z\,1^*$ and $g^{-1} = 1 \cdot z^{-1} \cdot k^*$ are splittings as in Lemma 5.6.26 (ii), with block-diagonal invertible outer factors ($p = k$, $q = 1$, respectively $p = 1$, $q = k$) and positive definite, hence accretive, middle factors z and z^{-1}. By Lemma 5.6.26 (i), (ii),

$$c(g) = \frac{1}{\|m_\mu\|^2} \int_K \frac{m_\mu(ku)\,\overline{m_\mu(u)}}{m_{-l^\rho}(u^* z u)}\,du, \qquad c(g^{-1}) = \frac{1}{\|m_\mu\|^2} \int_K \frac{m_\mu(u)\,\overline{m_\mu(ku)}}{m_{-l^\rho}(u^* z^{-1} u)}\,du.$$

For $u \in K$ the matrix $u^* z u$ lies in G and $u^* z^{-1} u = (u^* z u)^{-1}$, so $m_{-l^\rho}(u^* z^{-1} u) = \overline{m_{-l^\rho}(u^* z u)}$ by Lemma 5.6.30 (i). Hence the second integrand is the complex conjugate of the first, and $c(g^{-1}) = \overline{c(g)}$.

Bound by one. Lemma 5.6.29 (i) with exponent 0 gives $|c(g)|^2 \leq 1$.

Decay. We show $(\|g\|/2)^2 \leq |\det \mathrm{bd}_\varepsilon(g)|$. Diagonalise the positive definite matrix z by a unitary matrix, with eigenvalues $x_1, \ldots, x_n > 0$; then z^{-1} has the eigenvalues x_i^{-1} in the same eigenbasis, so $\mathrm{bd}_\varepsilon(z) = \frac{1}{2}(z + z^{-1})$ has the eigenvalues $\frac{1}{2}(x_i + x_i^{-1}) \geq 1$, and $\det \mathrm{bd}_\varepsilon(z) = \prod_i \frac{1}{2}(x_i + x_i^{-1})$, each factor being at least 1. Moreover $\|z\| = \max_i x_i$. Since $z^{-1} = JzJ$ is unitarily conjugate to z, the eigenvalues of z^{-1}, which are the x_i^{-1}, are those of z with multiplicities; hence $\max_i x_i^{-1} = \max_i x_i = \|z\|$, that is $\min_i x_i = \|z\|^{-1}$. If the maximum and the minimum are attained at different indices, then

$$\det \mathrm{bd}_\varepsilon(z) \geq \tfrac{1}{2}(\|z\| + \|z\|^{-1}) \cdot \tfrac{1}{2}(\|z\|^{-1} + \|z\|) \geq (\|z\|/2)^2;$$

otherwise $\max_i x_i = \min_i x_i = \|z\|^{-1}$ forces $\|z\| = 1$ and $\det \mathrm{bd}_\varepsilon(z) \geq 1 \geq (\|z\|/2)^2$. With $\|g\| = \|z\|$ this proves the claim. Now Lemma 5.6.29 (i) gives, for every integer $0 \leq c \leq h$,

$$|c(g)|^2 \Big(\frac{\|g\|}{2}\Big)^{2c} \leq |c(g)|^2\,|\det \mathrm{bd}_\varepsilon(g)|^c \leq 1,$$

that is $|c(g)| \leq (2/\|g\|)^c$. □

Theorem 5.7.41. *Let $N \geq 1$ and let $\varepsilon \in \{+,-\}^N$ be a sign vector, with the groups J_ε, G_ε, K_ε of (Dp1) and, for $\lambda \in \mathbb{R}^N$, the Weyl product $\mathrm{d}(\lambda)$ of (Dp2) in Definition 5.1.1.*

Let ω be a left-invariant holomorphic differential form of top degree on $\mathrm{GL}_N(\mathbb{C})$ such that the measure $|\omega|$ induced on $\mathrm{U}(N)$ has total mass 1, and let $\mu_\varepsilon^{\mathrm{cd}}$ be the measure $|\omega|$ induced on G_ε (the compact-dual Haar measure*; it is a Haar measure on G_ε and does not depend on the choice of ω). Let $\lambda \in \mathbb{R}^N$ be strictly decreasing with $\lambda_a - \frac{N-1}{2} \in \mathbb{Z}$ for all a. Then:*

(i) there is a square-integrable representation of G_ε with Harish-Chandra parameter λ relative to ε, and any two are unitarily equivalent;

(ii) for every such representation σ on $\mathcal{H}$ and all $v, w, v', w' \in \mathcal{H}$ the function

$$g \mapsto \langle w, \sigma(g)v\rangle \overline{\langle w', \sigma(g)v'\rangle}$$

is $\mu_\varepsilon^{\mathrm{cd}}$-integrable and

$$\int_{G_\varepsilon} \langle w, \sigma(g)v\rangle\,\overline{\langle w', \sigma(g)v'\rangle}\,d\mu_\varepsilon^{\mathrm{cd}}(g) = \frac{\langle v', v\rangle\,\langle w, w'\rangle}{\mathrm{d}(\lambda)};$$

(iii) for every Haar measure dg on G_ε, with $c>0$ defined by $\mu_\varepsilon^{\mathrm{cd}} = c\,dg$ (so c depends only on ε and dg), the same function is dg-integrable and

$$\int_{G_\varepsilon} \langle w, \sigma(g)v\rangle\, \overline{\langle w', \sigma(g)v'\rangle}\, dg = \frac{\langle v', v\rangle\, \langle w, w'\rangle}{c\,\mathrm{d}(\lambda)}.$$

Proof. **Step 0: $\mu_\varepsilon^{\mathrm{cd}}$ is a well-defined Haar measure, and G_ε is unimodular.** The Lie algebra of G_ε is $\mathfrak{u}_\varepsilon = \{X : X^*J_\varepsilon + J_\varepsilon X = 0\}$; $X \mapsto J_\varepsilon X$ maps it bijectively onto the skew-hermitian matrices, so $\dim_{\mathbb{R}} \mathfrak{u}_\varepsilon = N^2$, and $\mathfrak{u}_\varepsilon \cap i\mathfrak{u}_\varepsilon = 0$ (if $X, iX \in \mathfrak{u}_\varepsilon$ then $J_\varepsilon X = 0$). Hence a real basis of $\mathfrak{u}_\varepsilon$ is a complex basis of $\mathfrak{gl}_N(\mathbb{C})$. A left-invariant holomorphic top-degree form is $\omega_g = \omega_e \circ \Lambda^{N^2}(dL_{g^{-1}})$ with $0 \neq \omega_e \in \Lambda^{N^2}_{\mathbb{C}}(\mathfrak{gl}_N(\mathbb{C}))^*$, unique up to a factor in $\mathbb{C}^\times$; its restriction to G_ε is therefore nowhere zero and invariant under left translation by G_ε, so $|\omega|$ induces a left Haar measure on G_ε (and on $\mathrm{U}(N)$, of finite positive mass since $\mathrm{U}(N)$ is compact). The normalisation fixes the factor up to absolute value 1, so $\mu_\varepsilon^{\mathrm{cd}}$ does not depend on ω. The real form $(X,Y) \mapsto \mathrm{tr}(XY)$ on $\mathfrak{u}_\varepsilon$ is real-valued ($\overline{\mathrm{tr}(XY)} = \mathrm{tr}(Y^*X^*) = \mathrm{tr}(J_\varepsilon Y J_\varepsilon J_\varepsilon X J_\varepsilon) = \mathrm{tr}(XY)$), nondegenerate (its complexification is the trace form of $\mathfrak{gl}_N(\mathbb{C})$) and Ad-invariant, so $|\det \mathrm{Ad}(g)| = 1$ for $g \in G_\varepsilon$ and G_ε is unimodular.

Step 1: decomposition of $\mu_\varepsilon^{\mathrm{cd}}$. Let $m\colon \mathrm{SL}_N(\mathbb{C}) \times \mathbb{C}^\times \to \mathrm{GL}_N(\mathbb{C})$, $m(x,z) = zx$. It is a surjective holomorphic homomorphism ($z^N = \det g$, $x = z^{-1}g$), with kernel $\{(\zeta^{-1}I, \zeta) : \zeta^N = 1\}$ of order N and $dm_e(X,t) = X + tI$ bijective. Let ω_1 be a left-invariant holomorphic top-degree form on $\mathrm{SL}_N(\mathbb{C})$ with $|\omega_1|$ of total mass 1 on $\mathrm{SU}(N)$, and $\omega_2 = (2\pi i)^{-1} z^{-1} dz$ on $\mathbb{C}^\times$, so that $|\omega_2|$ induces the probability Haar measure dz on $Z = \{\zeta I : |\zeta| = 1\} \cong \{|\zeta| = 1\}$. Let ω' be the left-invariant form on $\mathrm{GL}_N(\mathbb{C})$ with $\omega'_e \circ \Lambda^{N^2}(dm_e) = (\mathrm{pr}_1^*\omega_1 \wedge \mathrm{pr}_2^*\omega_2)_e$; since m is a homomorphism, $m^*\omega'$ is left-invariant and agrees with $\mathrm{pr}_1^*\omega_1 \wedge \mathrm{pr}_2^*\omega_2$ at e, so the two are equal. Let $H \in \{\mathrm{U}(N), G_\varepsilon\}$ and $H_1 = H \cap \mathrm{SL}_N(\mathbb{C})$. For $g \in H$, $|\det g| = 1$ (from $g^*J_\varepsilon g = J_\varepsilon$, resp. $g^*g = I$), so m maps $H_1 \times Z$ onto H; the fibre over $m(x,z)$ is $\{(\zeta^{-1}x, \zeta z) : \zeta^N = 1\} \subseteq H_1 \times Z$, of N elements; and dm_e maps $\mathrm{Lie}(H_1) \oplus i\mathbb{R}$ bijectively onto $\mathrm{Lie}(H)$. So $m\colon H_1 \times Z \to H$ is an N-sheeted covering, and the change of variables formula gives, for Borel $f \geq 0$ on H,

$$\int_{H_1}\int_Z f(zx)\, dz\, d|\omega_1|(x) = N \int_H f\, d|\omega'|,$$

the density induced by $m^*\omega' = \mathrm{pr}_1^*\omega_1 \wedge \mathrm{pr}_2^*\omega_2$ on $H_1 \times Z$ being the product of those induced by ω_1 and ω_2. For $H = \mathrm{U}(N)$ and $f = 1$ this gives $N|\omega'|(\mathrm{U}(N)) = 1$; so $N\omega'$ is normalised as ω in the statement and, by Step 0, $\mu_\varepsilon^{\mathrm{cd}} = N|\omega'|$ on G_ε. With $G_1 = G_\varepsilon \cap \mathrm{SL}_N(\mathbb{C})$ and μ_1 the measure induced by $|\omega_1|$ on G_1,

$$\int_{G_\varepsilon} f\, d\mu_\varepsilon^{\mathrm{cd}} = \int_{G_1}\int_Z f(zx)\, dz\, d\mu_1(x) \tag{1}$$

for Borel $f \geq 0$, and by Fubini for every $\mu_\varepsilon^{\mathrm{cd}}$-integrable f.

Step 2: ε not constant. Then $N \geq 2$ and both signs occur. Statement (i) is Lemma 5.7.42 (c). Let σ on $\mathcal{H}$ be square-integrable with Harish-Chandra parameter λ relative to ε, i.e. a discrete series with parameter λ. By Lemma 5.7.42 (b), $\sigma(\zeta I) = \zeta^{c(\lambda)}\mathrm{id}$ and $\sigma|_{G_1}$ is unitarily equivalent to Harish-Chandra's discrete series π_{λ° of $G_1 \cong \mathrm{SU}(p,q)$, where $\lambda^\circ = \lambda - \frac{c(\lambda)}{N}(1,\dots,1)$. Apply Theorem A.5.12 with $\mathfrak{g} = \mathfrak{sl}_N(\mathbb{C})$, $G = \mathrm{SL}_N(\mathbb{C})$, $\mathfrak{g}_{\mathbb{R}} = \mathrm{Lie}(G_1)$ with Cartan involution $\theta(X) = J_\varepsilon X J_\varepsilon$ (that is, $X \mapsto -X^*$), $G_{\mathbb{R}} = G_1$ (connected and linear, Lemma 5.7.42), $T_{\mathbb{R}} = T_1$ the diagonal torus of G_1, $K_{\mathbb{R}} = K_\varepsilon \cap G_1$, $U_{\mathbb{R}} = \mathrm{SU}(N)$ (its Lie algebra $\mathfrak{su}(N)$ is a compact real form of $\mathfrak{sl}_N(\mathbb{C})$ and $J_\varepsilon\mathfrak{su}(N)J_\varepsilon = \mathfrak{su}(N)$), $\omega = \omega_1$, so $\mu_{\mathbb{R}} = \mu_1$; $\Phi = \{e_a - e_b : a \neq b\}$ on $\mathbb{R}^N_0$ as in Lemma 5.7.42, $\Phi^+ = \{e_a - e_b : a < b\}$, $\rho_a = \frac{N+1}{2} - a$, $\Lambda = P_1$ and $\nu = \lambda^\circ$, which lies in $\rho + P_1$ and is regular by Lemma 5.7.42 (a), and is dominant for Φ^+ because λ is strictly decreasing.

By Theorem A.5.12 (b) the character of π_{λ° is Θ_{λ°, so by (c) its formal degree with respect to μ_1 is $\prod_{a<b}(\lambda^\circ, e_a - e_b)/(\rho, e_a - e_b)$. The Killing form of $\mathfrak{sl}_N(\mathbb{C})$ is $2N\,\mathrm{tr}(XY)$, so the induced form on $\mathbb{R}_0^N$ is a positive multiple of the euclidean inner product, and the factor cancels in each quotient: the formal degree is $\prod_{a<b}(\lambda_a - \lambda_b)/(b-a) = \mathrm{d}(\lambda)$. A unitary equivalence U preserves inner products and matrix coefficients ($\langle w, \sigma(x)v\rangle = \langle Uw, \pi_{\lambda^\circ}(x)Uv\rangle$), so by Theorem A.5.18 for π_{λ° (irreducible, square-integrable by Theorem A.5.12 (a)), for all $v, w, v', w' \in \mathcal{H}$

$$\int_{G_1} \langle w, \sigma(x)v\rangle \overline{\langle w', \sigma(x)v'\rangle}\, d\mu_1(x) = \frac{\langle v', v\rangle\langle w, w'\rangle}{\mathrm{d}(\lambda)},$$

the integrand being μ_1-integrable. Let $F(g) = \langle w, \sigma(g)v\rangle\overline{\langle w', \sigma(g)v'\rangle}$. For $x \in G_1$, $|\zeta| = 1$, $\sigma(\zeta x) = \zeta^{c(\lambda)}\sigma(x)$ and $|\zeta^{c(\lambda)}| = 1$, so $F(\zeta x) = F(x)$. By (1) and Tonelli, $\int_{G_\varepsilon} |F|\, d\mu_\varepsilon^{\mathrm{cd}} = \int_{G_1} |F|\, d\mu_1 < \infty$, and by (1) and Fubini $\int_{G_\varepsilon} F\, d\mu_\varepsilon^{\mathrm{cd}} = \int_{G_1} F\, d\mu_1$. This is (ii).

Step 3: ε constant. Then $J_\varepsilon = \pm I$, $G_\varepsilon = K_\varepsilon = \mathrm{U}(N)$, $\mu_\varepsilon^{\mathrm{cd}}$ is the Haar probability measure, $\rho_n(\varepsilon) = 0$ and $\rho_c(\varepsilon)_a = \frac{N+1}{2} - a$. Put $\Lambda = \Lambda_\varepsilon(\lambda) = \lambda - \rho_c(\varepsilon)$. Then $\Lambda_a = (\lambda_a - \frac{N-1}{2}) + a - 1 \in \mathbb{Z}$ and $\Lambda_a - \Lambda_{a+1} = \lambda_a - \lambda_{a+1} - 1 \geq 0$, so Λ is a dominant weight; let V_Λ be the irreducible representation of $\mathrm{U}(N)$ with highest weight Λ, with an invariant inner product. Put $\Lambda' = \Lambda - \Lambda_N(1, \dots, 1)$, nonincreasing with $\Lambda'_N = 0$. By Theorem A.5.19 (with $K = \mathbb{C}$, $k = N$), $\nabla_{\mathbb{C}}(\Lambda') \otimes \det^{\Lambda_N}$ is an irreducible rational $\mathrm{GL}_N(\mathbb{C})$-module of highest weight Λ and dimension $d_N(\Lambda') = d_N(\Lambda)$ (d_N depends only on the differences $\Lambda_a - \Lambda_b$); as $\mathrm{U}(N)$ is Zariski dense in $\mathrm{GL}_N(\mathbb{C})$, its restriction to $\mathrm{U}(N)$ is irreducible of highest weight Λ, hence isomorphic to V_Λ (theorem of the highest weight). Hence

$$\dim V_\Lambda = \prod_{a<b} \frac{\Lambda_a - \Lambda_b + b - a}{b - a} = \prod_{a<b} \frac{\lambda_a - \lambda_b}{b - a} = \mathrm{d}(\lambda).$$

(i): V_Λ is finite-dimensional, so strongly continuous with bounded, hence square-integrable, matrix coefficients; its only K_ε-type is Λ, so the occurrence and minimality conditions hold. If σ on $\mathcal{H}$ is square-integrable with parameter λ, $\mathcal{H}$ contains a finite-dimensional, hence closed, invariant subspace on which $\mathrm{U}(N)$ acts by V_Λ; by irreducibility it is $\mathcal{H}$, and by Schur's lemma the two invariant inner products are proportional, so σ is unitarily equivalent to V_Λ. (ii): $\dim \mathcal{H} = D = \mathrm{d}(\lambda)$, F is continuous on the compact group, hence integrable, and Theorem A.5.18 gives a formal degree d_σ for $\mu_\varepsilon^{\mathrm{cd}}$. For a unit vector v and an orthonormal basis $e_1, \dots, e_D$ of $\mathcal{H}$,

$$\frac{D}{d_\sigma} = \sum_{i=1}^{D} \int_{G_\varepsilon} |\langle e_i, \sigma(g)v\rangle|^2\, d\mu_\varepsilon^{\mathrm{cd}}(g) = \int_{G_\varepsilon} \|\sigma(g)v\|^2\, d\mu_\varepsilon^{\mathrm{cd}}(g) = 1,$$

so $d_\sigma = \mathrm{d}(\lambda)$, which is (ii).

Step 4: (iii). If $\mu_\varepsilon^{\mathrm{cd}} = c\, dg$, then F is dg-integrable and $\int F\, dg = c^{-1} \int F\, d\mu_\varepsilon^{\mathrm{cd}}$; (ii) gives (iii). The constant c is determined by the two Haar measures $\mu_\varepsilon^{\mathrm{cd}}$ and dg alone. □

Lemma 5.7.42. *Let $n \geq 2$, $j \in \{\pm 1\}^n$ with $p(j), q(j) \geq 1$, and let λ be a Harish-Chandra parameter. Put $G = \mathrm{U}(J_j)$, $G_1 = \{g \in G : \det g = 1\}$, $T_1 = T \cap G_1$, $Z = \{\zeta I : |\zeta| = 1\}$,*

$$c(\lambda) = \sum_{a=1}^{n} \lambda_a, \qquad \lambda^\circ = \lambda - \frac{c(\lambda)}{n}(1, \dots, 1),$$

and identify the differentials of characters of T_1 with elements of $\mathbb{R}_0^n = \{x \in \mathbb{R}^n : \sum_a x_a = 0\}$, x corresponding to $\mathrm{diag}(e^{i\theta_1}, \dots, e^{i\theta_n}) \mapsto e^{i\sum_a x_a\theta_a}$. Then:

(a) $c(\lambda) \in \mathbb{Z}$, *and* λ° *is regular for the roots* $e_a - e_b$ *of* $(\mathfrak{sl}_n(\mathbb{C}), \mathfrak{t}_1)$ *and lies in* $\rho + P_1$, *where* P_1 *is the lattice of differentials of characters of* T_1 *and* $\rho_a = \frac{n+1}{2} - a$;

(b) every discrete series $(\pi, \mathcal{H})$ *of* G *with parameter* λ *satisfies* $\pi(\zeta I) = \zeta^{c(\lambda)} \operatorname{id}_{\mathcal{H}}$ *for* $|\zeta| = 1$, *and* $\pi|_{G_1}$ *is unitarily equivalent to Harish-Chandra's discrete series* π_{λ° *of* G_1;

(c) there is a discrete series of G *with parameter* λ, *and any two are unitarily equivalent.*

Proof. **Setting.** $G_1 \cong \mathrm{SU}(p(j), q(j))$ is a connected linear semisimple Lie group with finite centre, $K_1 = K_j \cap G_1$ is a maximal compact subgroup and T_1 a compact Cartan subgroup. The roots of $(\mathfrak{sl}_n(\mathbb{C}), \mathfrak{t}_1)$ are the $e_a - e_b$ $(a \neq b)$, with root space $\mathbb{C}E_{ab}$, compact if and only if $j_a = j_b$. Let $\Phi_c^+ = \{e_a - e_b : a < b,\ j_a = j_b\}$; its half-sum is $\rho_c(j)$, and the Weyl group W_c of K_1 is the group of permutations preserving j. We use the euclidean inner product on $\mathbb{R}^n$ and the orthogonal projection $\mathrm{pr}\colon \mathbb{R}^n \to \mathbb{R}^n_0$. The restriction to T_1 of the character of T of weight $\mu \in \mathbb{Z}^n$ has differential $\mathrm{pr}(\mu)$, and every character of the subtorus T_1 extends to T; so $P_1 = \mathrm{pr}(\mathbb{Z}^n)$, and a character of T_1 is determined by its differential. Note $\rho, \rho_c(j), \rho_n(j) \in \mathbb{R}^n_0$ and $\rho = \rho_c(j) + \rho_n(j)$. Put

$$\Lambda = \beta_j(\lambda) = \lambda + \rho_n(j) - \rho_c(j) = \lambda + \rho - 2\rho_c(j).$$

Proof of (a), and integrality of Λ. As $\lambda_a - \frac{n-1}{2} \in \mathbb{Z}$, $c(\lambda) \in \frac{n(n-1)}{2} + \mathbb{Z} = \mathbb{Z}$. $\lambda^\circ_a - \lambda^\circ_b = \lambda_a - \lambda_b \neq 0$ for $a \neq b$, so λ° is regular. Since $\lambda_a - \rho_a = (\lambda_a - \frac{n-1}{2}) + a - 1 \in \mathbb{Z}$, we have $\lambda - \rho \in \mathbb{Z}^n$ and $\lambda^\circ - \rho = \mathrm{pr}(\lambda - \rho) \in P_1$. Moreover $\lambda + \rho \in \mathbb{Z}^n$ (as $\lambda_a + \rho_a = (\lambda_a - \frac{n-1}{2}) + n - a$) and $2\rho_c(j) \in \mathbb{Z}^n$, so $\Lambda \in \mathbb{Z}^n$, $\mathrm{pr}(\Lambda) = \lambda^\circ + \rho_n(j) - \rho_c(j)$ and $\sum_a \Lambda_a = c(\lambda)$.

Step 1: the minimal K_1-type of $\pi_{\lambda'}$. Let $\lambda' \in \rho + P_1$ be regular and dominant for Φ_c^+, let $\Phi'^+ = \{e_a - e_b : \lambda'_a > \lambda'_b\}$ (so $\Phi'^+ \supseteq \Phi_c^+$ and $\Phi'^+ \cap \Phi_c = \Phi_c^+$), Φ'^+_n its noncompact part with half-sum ρ'_n, i.e.

$$(\rho'_n)_a = \tfrac{1}{2}\big(\#\{b : j_b \neq j_a,\ \lambda'_b < \lambda'_a\} - \#\{b : j_b \neq j_a,\ \lambda'_b > \lambda'_a\}\big),$$

and $\rho' = \rho_c(j) + \rho'_n$ the half-sum of Φ'^+. For a K_1-type of $\pi_{\lambda'}$ with highest weight ν (for Φ_c^+) put $\nu^\sharp = \nu + \rho_c(j)$, which lies in $\rho_c(j) + P_1$ and is regular and dominant for Φ_c^+. We claim: $\|\nu + 2\rho_c(j)\| \geq \|\lambda' + \rho'\|$, with equality if and only if $\nu^\sharp = \mu_0 := \lambda' + \rho'_n$, and the K_1-type with $\nu^\sharp = \mu_0$ occurs in $\pi_{\lambda'}$ with multiplicity one. By Blattner's formula (Theorem A.5.13, with the positive system Φ'^+ for which λ' is dominant) the multiplicity of ν is $\sum_{w \in W_c} \varepsilon(w) \mathcal{P}_n(w\nu^\sharp - \lambda' - \rho'_n) \geq 1$, so some $w \in W_c$ has $w\nu^\sharp = \lambda' + \rho'_n + S$ with S a sum of elements of Φ'^+_n. As $\nu^\sharp$ is dominant, $\nu^\sharp - w\nu^\sharp$ is a nonnegative combination of Φ_c^+, each element of which pairs positively with $\rho_c(j)$; with $\|w\nu^\sharp\| = \|\nu^\sharp\|$ this gives

$$\begin{aligned}\|\nu^\sharp + \rho_c(j)\|^2 &= \|w\nu^\sharp + \rho_c(j)\|^2 + 2\langle \nu^\sharp - w\nu^\sharp, \rho_c(j)\rangle \\ &\geq \|\lambda' + \rho' + S\|^2 = \|\lambda' + \rho'\|^2 + 2\langle \lambda' + \rho', S\rangle + \|S\|^2 \geq \|\lambda' + \rho'\|^2,\end{aligned}$$

since $\lambda' + \rho'$ pairs positively with every element of Φ'^+. Equality forces $S = 0$ and $\langle \nu^\sharp - w\nu^\sharp, \rho_c(j)\rangle = 0$, hence $w\nu^\sharp = \nu^\sharp$, $w = 1$ ($\nu^\sharp$ is regular) and $\nu^\sharp = \mu_0$. Conversely, $\mu_0 - \rho_c(j) - (\lambda' - \rho) = 2\rho + (\rho' - \rho) - 2\rho_c(j)$ lies in the root lattice, which is contained in P_1, so $\mu_0 \in \rho_c(j) + P_1$; and μ_0 is regular and dominant for Φ_c^+: for $a < b$ with $j_a = j_b$, $\lambda'_a - \lambda'_b$ is a positive integer (it is $\langle \lambda', e_a - e_b\rangle$, an integer as $\lambda' \in \rho + P_1$), and $(\rho'_n)_a \geq (\rho'_n)_b$ because $\lambda'_a > \lambda'_b$. Its multiplicity is $\sum_w \varepsilon(w) \mathcal{P}_n(w\mu_0 - \mu_0) = 1$: for $w \neq 1$, $w\mu_0 - \mu_0 = -C$ with $C \neq 0$ a nonnegative combination of Φ_c^+, so $\langle \lambda', -C\rangle < 0$, whereas every sum of elements of Φ'^+_n pairs nonnegatively with λ'; thus $\mathcal{P}_n(-C) = 0$.

Step 2: restriction of a discrete series with parameter λ. Let $(\pi,\mathcal{H})$ be a discrete series of G with parameter λ. By Schur's lemma $\pi(\zeta I)=\chi(\zeta)\mathrm{id}$ for a character χ of the central subgroup Z. A vector of T-weight μ is multiplied by $\zeta^{\sum_a \mu_a}$ under $\zeta I\in T$; hence every T-weight μ occurring in a K_j-type of π has $\sum_a \mu_a = c$ for one integer c with $\chi(\zeta)=\zeta^c$, and since Λ is the highest weight of a K_j-type of π, $c=\sum_a \Lambda_a = c(\lambda)$. This is the first claim of (b). As $G=G_1Z$ and Z acts by scalars, $\pi_1=\pi|_{G_1}$ is irreducible. The multiplication map $G_1\times Z\to G$ is a surjective homomorphism with finite kernel, so it carries a Haar measure of $G_1\times Z$ to a Haar measure of G; since $|\langle v,\pi(xz)u\rangle| = |\langle v,\pi(x)u\rangle|$ $(x\in G_1,\ z\in Z)$, the matrix coefficients of π_1 are square-integrable on G_1. By Harish-Chandra's classification (Theorem A.5.14) $\pi_1\cong\pi_{\lambda'}$ for some regular $\lambda'\in\rho+P_1$, which after conjugation by W_c is dominant for Φ_c^+. Since $K_j=K_1Z$ with Z scalar, each K_j-isotypic subspace of $\mathcal{H}$ of highest weight μ is K_1-isotypic of highest weight $\mathrm{pr}(\mu)$, so the K_1-types of π_1 are the $\mathrm{pr}(\mu)$, μ running over the K_j-types of π, all with $\sum_a\mu_a=c(\lambda)$, and

$$\|\mu+2\rho_c(j)\|^2 = \|\mathrm{pr}(\mu)+2\rho_c(j)\|^2 + \frac{c(\lambda)^2}{n}.$$

By the definition of a discrete series with parameter λ, Λ minimises $\|\mu+2\rho_c(j)\|$ over the K_j-types of π; hence $\mathrm{pr}(\Lambda)$ minimises $\|\nu+2\rho_c(j)\|$ over the K_1-types ν of $\pi_1\cong\pi_{\lambda'}$, and by the uniqueness in Step 1

$$\lambda^\circ+\rho_n(j)=\mathrm{pr}(\Lambda)+\rho_c(j)=\lambda'+\rho'_n. \tag{$*$}$$

Step 3: $(*)$ forces $\lambda'=\lambda^\circ$. Adding $\rho_c(j)$ to both sides of $(*)$ gives

$$v:=\lambda^\circ+\rho=\lambda'+\rho'.$$

For $a<b$, $v_a-v_b=(\lambda_a-\lambda_b)+(b-a)>0$; so v is regular and $\{\alpha:\langle v,\alpha\rangle>0\}=\Phi^+_{\mathrm{st}}:=\{e_a-e_b:a<b\}$. On the other hand ρ' is the half-sum of $\Phi'^+=\{e_a-e_b:\lambda'_a>\lambda'_b\}$, so $\rho'_a=\frac12(\#\{b:\lambda'_b<\lambda'_a\}-\#\{b:\lambda'_b>\lambda'_a\})$, and $\lambda'_a>\lambda'_b$ implies $\rho'_a-\rho'_b\geq 1$. Hence every $e_a-e_b\in\Phi'^+$ has $\langle v,e_a-e_b\rangle=(\lambda'_a-\lambda'_b)+(\rho'_a-\rho'_b)>0$, i.e. $\Phi'^+\subseteq\Phi^+_{\mathrm{st}}$. Both sets contain exactly one of $\pm\alpha$ for every root α, so $\Phi'^+=\Phi^+_{\mathrm{st}}$, $\rho'=\rho$ and $\rho'_n=\rho'-\rho_c(j)=\rho_n(j)$. Now $(*)$ gives $\lambda'=\lambda^\circ$, so $\pi|_{G_1}\cong\pi_{\lambda^\circ}$. This proves (b).

Step 4: existence. By (a), π_{λ° is defined; let it act on $\mathcal{H}_0$. The centre $G_1\cap Z=\{\zeta I:\zeta^n=1\}$ of G_1 acts by scalars $\chi_0(\zeta)$ (Schur's lemma). By Step 1 with $\lambda'=\lambda^\circ$ (strictly decreasing, so $\rho'_n=\rho_n(j)$ and $\mu_0-\rho_c(j)=\mathrm{pr}(\Lambda)$), π_{λ° contains the K_1-type of highest weight $\mathrm{pr}(\Lambda)$; its highest weight vector transforms under T_1 by the restriction of the character of T of weight Λ, and for $\zeta^n=1$ the element $\zeta I\in T_1$ multiplies it by $\zeta^{\sum_a\Lambda_a}=\zeta^{c(\lambda)}$. Hence $\chi_0(\zeta)=\zeta^{c(\lambda)}$, and

$$\pi(x\,\zeta I)=\zeta^{c(\lambda)}\pi_{\lambda^\circ}(x)\qquad(x\in G_1,\ |\zeta|=1)$$

is well defined: if $x\zeta I=x'\zeta' I$ then $x'^{-1}x=(\zeta'/\zeta)I\in G_1\cap Z$ and $\pi_{\lambda^\circ}(x)=(\zeta'/\zeta)^{c(\lambda)}\pi_{\lambda^\circ}(x')$. It is a unitary representation of G, strongly continuous because the multiplication map $G_1\times Z\to G$ is a surjective homomorphism of Lie groups with finite kernel, hence open, and irreducible because its restriction to G_1 is. Its matrix coefficients are square-integrable on G by the Haar measure argument of Step 2. Its K_j-types are the representations of $K_j=K_1Z$ obtained from the K_1-types ν of π_{λ° by letting ζI act by $\zeta^{c(\lambda)}$, with highest weight the unique μ with $\mathrm{pr}(\mu)=\nu$ and $\sum_a\mu_a=c(\lambda)$. For $\nu=\mathrm{pr}(\Lambda)$ this is $\mu=\Lambda$, so Λ occurs; and by the displayed identity of Step 2 and the minimality in Step 1 (where $\|\nu+2\rho_c(j)\|=\|\nu^\sharp+\rho_c(j)\|$ is minimal exactly at $\nu=\mathrm{pr}(\Lambda)$), every K_j-type μ satisfies $\|\mu+2\rho_c(j)\|\geq\|\Lambda+2\rho_c(j)\|$. So π is a discrete series of G with parameter λ.

Step 5: uniqueness. If π,π' are discrete series of G with parameter λ, by (b) there is a unitary U with $U\pi(x)=\pi'(x)U$ for $x\in G_1$, and $\pi(\zeta I)=\zeta^{c(\lambda)}=\pi'(\zeta I)$; as $G=G_1Z$, U intertwines π and π'. This proves (c). □

5.8 The trace formula, equal multiplicities and the target dimension

This section compares forms of the target rank on spaces of different signatures. It opens with framed spaces of rank r, whose unitary groups are identified with one group G_f at the finite places, with the spherical Hecke operators away from the level and their eigenparts (Definition 5.6.1; see [248, 49, 109]), and with the objects of the geometric side of the trace formula.

The main statement is Proposition 5.8.4: on two framed spaces on which the target parameter has the gap, every Hecke operator away from M has the same trace, characteristic polynomial and determinant on the good forms, every eigensystem has the same multiplicity, and the good forms on each W_j have dimension $d_{\mathcal{T}}$. Its input is the trace comparison Theorem 5.8.5, for Hecke functions cuspidal at one split place. The section also shows that a series of translations with coefficients independent of the space acts as one Hecke operator on all framed spaces (Proposition 5.8.55), and it bounds the target dimension by a mass, since on the definite space the forms are vector-valued functions on the finite adelic group [110] (Lemma 5.8.56, Proposition 5.8.54).

The comparison uses simple trace formulas, in the tradition from Selberg [258] through Arthur and Clozel [8, 7] to Labesse's comparison for unitary groups and discrete series [177, 58]. It has three steps. The simple trace formula (Theorem 5.8.6) uses a kernel at the infinite places made of coefficients of the lowest K-types scaled by formal degrees, which under the gap is a cusp kernel; in our reading such kernels play the part of pseudo-coefficients of discrete series [59]. The key step is the term-by-term matching (Theorem 5.8.30). Characteristic polynomials with a root off the unit circle contribute nothing; elliptic ones contribute a constant times the compact characters at the eigenvalues, by Harish-Chandra's formula for elliptic orbital integrals [119] (Lemma 5.8.49); and reducible ones contribute nothing for Hecke functions cuspidal at one place with a simple zero modulo another. The last step removes the simple-zero hypothesis by cutting the level at an auxiliary split place (Theorem 5.8.50). The comparison of unitary groups of different signatures is also part of the endoscopic classification [209, 156]; here only parameters with a large gap and test functions cuspidal at one place are needed, so that the non-elliptic terms vanish and the elliptic ones match directly.

Definition 5.8.1. Let F be a totally real number field of degree f, E/F a CM extension unramified at every finite place, $D_E = |d_E|$, V an E-vector space of dimension n with a nondegenerate hermitian form h (E-linear in the first variable), L an $\mathcal{O}_E$-lattice in V that is self-dual for h, and $G = \mathrm{U}(V,h)$. For every real place v of F fix a complex place w of E above v, put $V_v = V \otimes_{E,w} \mathbb{C}$ with the hermitian form h_v induced by h, and fix a **majorant** h_v^+: for an h_v-orthogonal decomposition $V_v = V_v^+ \oplus V_v^-$ with h_v positive definite on V_v^+ and negative definite on V_v^-, $h_v^+ = h_v$ on V_v^+, $h_v^+ = -h_v$ on V_v^-, and $V_v^+ \perp V_v^-$ for h_v^+.

Lattices and metrics at a point. For $x \in G(\mathbb{A}_F)$ let Λ_x be the $\mathcal{O}_E$-lattice of V with completions $x_v L_v$ at every finite place v, and for every real place v let

$$\langle y, z\rangle_{x,v} = h_v^+(x_v^{-1}y,\, x_v^{-1}z) \qquad (y, z \in V_v).$$

For a finitely generated $\mathcal{O}_E$-submodule $S \subseteq V$ of rank $r = \dim_E ES \geq 1$, the **lattice height** of S at x is

$$\mathrm{ht}_x(S) = 2^{fr} D_E^{-r/2}\, \mathrm{covol}_x(S),$$

where $\mathrm{covol}_x(S)$ is the covolume of S in $\prod_{v\ \mathrm{real}} (ES)_v$ (with $(ES)_v = ES \otimes_{E,w} \mathbb{C} \subseteq V_v$) for the Lebesgue measure of the euclidean inner product $\sum_v \mathrm{Re}\langle\cdot,\cdot\rangle_{x,v}$; and $\mathrm{ht}_x(0) = 1$. If $S' \subsetneq S$ is saturated in S ($S' = S \cap ES'$) of rank r', the **step size** of S over S' at x is

$$\mathrm{st}_x(S/S') = \big(\mathrm{ht}_x(S)/\mathrm{ht}_x(S')\big)^{1/(2f(r-r'))}.$$

Isotropic flags. For a composition $j = (j_1, \dots, j_a)$ of an integer $J \geq 1$ (positive integers with sum J), an **isotropic flag of type** j is a chain $W_\bullet = (0 = W_0 \subsetneq W_1 \subsetneq \cdots \subsetneq W_a)$ of E-subspaces of V with $\dim W_i - \dim W_{i-1} = j_i$ and $h(W_a, W_a) = 0$. Its **step-size vector** at x is

$$\mathrm{sv}_x(W_\bullet) = (t_1, \dots, t_a) \in (0,\infty)^a, \qquad t_i = \mathrm{st}_x\big((\Lambda_x \cap W_i)/(\Lambda_x \cap W_{i-1})\big).$$

Exponents and flag density. For such j put $c_i(j) = n - 2J + j_i + 2\sum_{k>i} j_k$ $(1 \leq i \leq a)$, $d(j) = 2nJ - 2J^2 - \sum_i j_i^2$, and define the **flag density** $\mathrm{fd}_j \colon (0,\infty)^a \to (0,\infty)$ by

$$\mathrm{fd}_j(t) = \prod_{i=1}^{a} 2f j_i \, t_i^{2f j_i c_i(j) - 1}. \tag{5.178}$$

Definition 5.8.2. Let E/F be a quadratic extension of number fields with nontrivial automorphism $e \mapsto \bar{e}$, and $r \geq 1$. For a commutative F-algebra k (in practice F or a completion F_v) write $E_k = E \otimes_F k$, with $e \otimes c \mapsto \bar{e} \otimes c$, and $V_k = V \otimes_F k$ for a hermitian space V over E, with the extended form.

For $P \in E[X]$ monic of degree r with $P(0) \neq 0$, its **conjugate reciprocal** is $P^{\#}(X) = \overline{P(0)}^{\,-1} X^r \bar{P}(X^{-1})$, $\bar{P}$ the polynomial with conjugated coefficients; P is **conjugate-reciprocal** if $P = P^{\#}$. $\mathcal{P}_r(E/F)$ is the set of monic irreducible conjugate-reciprocal $P \in E[X]$ of degree r.

For $P \in \mathcal{P}_r(E/F)$ let $L_P = E[X]/(P)$ (a field of degree r over E), α_P the class of X, and $z \mapsto z^*$ the F-algebra involution of L_P with $e^* = \bar{e}$ $(e \in E)$ and $\alpha_P^* = \alpha_P^{-1}$ (it exists because $\bar{P}(\alpha_P^{-1}) = 0$, as $P = P^{\#}$); $K_P = \{z \in L_P : z^* = z\}$. For k as above put $L_{P,k} = L_P \otimes_F k$, $K_{P,k} = K_P \otimes_F k$, extend $*$, and define:

- the **norm** $N(z) = zz^* \in K_{P,k}$ $(z \in L_{P,k})$, and the **norm-one torus** $T_P(k) = \{z \in L_{P,k}^\times : zz^* = 1\}$ (the k-points of an F-torus T_P);
- for $x \in K_{P,k}^\times$ the **trace form** h_x on the free E_k-module $L_{P,k}$ of rank r:

$$h_x(y, y') = \mathrm{Tr}_{L_{P,k}/E_k}(x\, y\, y'^*);$$

- the **class group** $C_P(k) = K_{P,k}^\times / N(L_{P,k}^\times)$, and, for a hermitian space V over E of rank r, the **local class set**

$$X_P(V,k) = \{[x] \in C_P(k) : (L_{P,k}, h_x) \text{ is isometric to } V_k\}.$$

For F-algebra maps $k \to k'$ (such as $F \to F_v$) the induced map $C_P(k) \to C_P(k')$ is written $c \mapsto c_{k'}$.

Definition 5.8.3. Let E/F be a CM extension, $r \geq 1$, V a hermitian space over E of rank r with an $\mathcal{O}_E$-lattice Λ, $G = \mathrm{U}(V)$, and $P \in \mathcal{P}_r(E/F)$. For a finite place v let $\mathcal{O}_{L,v}$ be the integral closure of $\mathcal{O}_{F,v}$ in L_{P,F_v} and $T_P(\mathcal{O}_v) = T_P(F_v) \cap \mathcal{O}_{L,v}^\times$, a compact open subgroup of $T_P(F_v)$.

(Oz1) Canonical embedding. Let k be F, a completion F_v, or $\mathbb{A}_F$, and let $\gamma \in G(k)$ have characteristic polynomial P (over E_k). Every $z \in L_{P,k} = E_k[X]/(P)$ is $z = q(\alpha_P)$ for some $q \in E_k[X]$, and $\iota_\gamma(z) = q(\gamma)$ is well defined because $P(\gamma) = 0$. The **canonical embedding** of γ is the restriction $\iota_\gamma \colon T_P(k) \to \mathrm{GL}_{E_k}(V_k)$; for $g \in G(k)$, $\iota_{g\gamma g^{-1}}(z) = g\, \iota_\gamma(z)\, g^{-1}$.

(Oz2) Torus measures. A **family of torus measures** for P is a family $(dt_v)_v$, indexed by all places v of F, of Haar measures dt_v on $T_P(F_v)$ with $dt_v(T_P(\mathcal{O}_v)) = 1$ for all but finitely many finite v. Its **product** dt is the restricted product measure on $T_P(\mathbb{A}_F)$ (restricted with respect to the $T_P(\mathcal{O}_v)$), and the **torus volume** is

$$\tau(P) = \mathrm{vol}\big(T_P(F)\backslash T_P(\mathbb{A}_F)\big) \in (0, \infty],$$

for the quotient of dt by the counting measure on the discrete subgroup $T_P(F)$.

(Oz3) Orbital integrals. Let v be a place of F, μ_v a Haar measure on $G(F_v)$, dt_v a Haar measure on $T_P(F_v)$, and $\gamma \in G(F_v)$ with characteristic polynomial P and centraliser G_γ such that $\iota_\gamma(T_P(F_v)) = G_\gamma$. For a function h on $G(F_v)$ the **orbital integral** is

$$O_\gamma(h) = \int_{G_\gamma\backslash G(F_v)} h(x^{-1}\gamma x)\, d\dot{x}, \qquad d\dot{x} = \mu_v/(\iota_\gamma)_* dt_v,$$

whenever the integral converges absolutely. It depends only on the $G(F_v)$-conjugacy class of γ (by (Oz1) and the invariance of μ_v under left translation).

(Oz4) Stable orbital integrals. With μ_v, dt_v as in (Oz3), let $\mathcal{C}_P(V, F_v)$ be the set of $G(F_v)$-conjugacy classes of elements of $G(F_v)$ with characteristic polynomial P. If $\mathcal{C}_P(V, F_v)$ is finite and every $O_{\gamma_C}(h)$ converges absolutely ($\gamma_C \in C$), the **stable orbital integral** of h along P is

$$SO_v(P, h) = \sum_{C \in \mathcal{C}_P(V, F_v)} O_{\gamma_C}(h)$$

(an empty sum is 0).

Proposition 5.8.4. *Let D be admissible data and let V, V' be framed spaces such that ς has gap Δ for V and for V'. Then $\mathcal{A}_M(V)$, $\mathcal{A}_M(V')$ are finite-dimensional, every T_a ($a \in \mathcal{H}^M$) preserves the good forms, and:*

(i) for every $a \in \mathcal{H}^M$, T_a has the same trace, the same characteristic polynomial and the same determinant on $\mathcal{A}^{\mathrm{good}}(V)$ as on $\mathcal{A}^{\mathrm{good}}(V')$;

(ii) for every eigensystem q,

$$\dim\big(\mathcal{A}^{\mathrm{good}}(V) \cap \mathcal{A}_M(V)[q]\big) = \dim\big(\mathcal{A}^{\mathrm{good}}(V') \cap \mathcal{A}_M(V')[q]\big);$$

(iii) ς has gap Δ for Y_0 and for W_j, $1 \le j \le m$, and $\dim \mathcal{A}^{\mathrm{good}}(W_j) = d_{\mathcal{T}}$ for $1 \le j \le m$.

Proof. Step 0: the field and the parameter. $E = K(\zeta_{q_1})$ with $q_1 = q_0 T(s)$, $18480 \mid q_0$ and $9 \mid T(s)$ ($l_0(s)$ is a power of 3 at least 81), so $5040 = 16 \cdot 9 \cdot 5 \cdot 7$ divides q_1 and E contains a primitive 5040-th root of unity; $[E^+ : \mathbb{Q}] = f = \varphi(q_1)$ is even (Lemma 2.3.7). The rank $r = 3^{e'+1} \ge x^5$ is odd and ≥ 2, so the entries of $\varsigma(v)$, which are integers, lie in $\frac{r-1}{2} + \mathbb{Z}$, and $\Delta = 2r^8 \ge 500r^3 + 10r^5$. Hence the gap hypothesis of Theorem 5.8.5 holds for $\lambda = \varsigma$ and V, V'. By Lemma 4.6.2(a) every chosen place w has $w \ne \bar{w}$ and $\bar{w}$ not chosen. Hence also the hypotheses of Theorem 5.8.6 hold for $U = V$ (and for $U = V'$), $N = r$, $\lambda = \varsigma$ and $K = \mathrm{K}_M$, and its clause (i) gives that $\mathcal{A}_M(V)$ and $\mathcal{A}_M(V')$ are finite-dimensional.

Step 1: Hecke operators preserve good forms. Let $\sigma\colon \bar{G} \to \mathrm{K}_f$ be a section of the reduction whose values have component 1 at every place of E^+ not below a chosen place. Then $\bar{g} \in \bar{G}$ acts on $\mathcal{A}_M(V)$ by $\rho_V(\sigma(\bar{g}))$. An element of G^M has component 1 at the places below the chosen

places, so it commutes with every $\sigma(\bar g)$ in G_f; hence $T_a(V)$ commutes with the action of $\bar G$, in particular with the projector e_0, and preserves $\mathcal{A}^{\mathrm{good}}(V)$.

Step 2: traces. As e_0 is a central idempotent of $\mathbb{C}[\bar G]$ with $e_0 = \sum_c e_c$, $e_c = \bigotimes_w e_{c_w}$, over the good families c,

$$\operatorname{tr}(T_a \mid \mathcal{A}^{\mathrm{good}}(V)) = \operatorname{tr}(T_a(V)\, e_0 \mid \mathcal{A}_M(V)) = \sum_c \operatorname{tr}(T_a(V)\, e_c \mid \mathcal{A}_M(V)),$$

and likewise for V'. Fix a good family c; it has a chosen place w with c_w primitive, hence irreducible. Put $\tilde e_c = \sum_{\bar g} e_c(\bar g)\,\sigma(\bar g) \in \mathbb{C}[\mathrm{K}_f]$ and $b = a\,\tilde e_c \in \mathbb{C}[G_f]$. As K_M is normal in K_f, b maps K_M-fixed vectors to K_M-fixed vectors in every representation, and $\rho_V(b) = T_a(V)e_c$ on $\mathcal{A}_M(V)$, the same for V'. Let $\phi(g) = \sum_h b_h \mathbf{1}_{\mathrm{K}_M}(h^{-1}g)$. Then $\phi(g) = \sum_h a_h \psi(h^{-1}g)$ with $\psi(y) = e_c(\bar y)$ for $y \in \mathrm{K}_f$ ($\bar y$ its reduction) and $\psi(y) = 0$ otherwise. Let T, t, $\tilde u$ be as in the definition of a function cuspidal at w, (FT4) of Definition 3.2.4, and $y \in G_f$. If $y \notin \mathrm{K}_f$, all $y\iota_w(\tilde u) \notin \mathrm{K}_f$. If $y \in \mathrm{K}_f$, the reduction of $y\iota_w(\tilde u)$ is $\bar y$ times the element with component ut at w and 1 at the other chosen places ($\bar w$ is not chosen), so

$$\sum_{u \in U_T} \psi(y\,\iota_w(\tilde u)) = \prod_{w' \neq w} e_{c_{w'}}(\bar y_{w'}) \cdot \sum_{u \in U_T} e_{c_w}(\bar y_w\, u\, t) = 0$$

by Theorem A.5.28. Applying this to $y = h^{-1}g$ gives the cuspidality of $\phi = \phi_b^{\mathrm{K}_M}$ at w. By Theorem 5.8.5 with $K = \mathrm{K}_M$, $\lambda = \varsigma$ and the element b in place of a, $\operatorname{tr}(T_a(V)e_c) = \operatorname{tr}(T_a(V')e_c)$. Summing over c gives equal traces.

Step 3: characteristic polynomials and determinants. $\mathcal{H}^M$ is a subalgebra containing 1 and $T_a^n = T_{a^n}$, so Step 2 gives $\operatorname{tr}(T_a^n)$ equal on both good spaces for all $n \geq 0$ ($n = 0$: equal dimensions). Over $\mathbb{C}$ the power sums of the eigenvalues determine the characteristic polynomial (Newton's identities), hence also the determinant.

Step 4: eigenparts. We show that $\mathcal{A}_M(V)$ is the direct sum of the eigenparts $\mathcal{A}_M(V)[q]$, finitely many of them nonzero. Give $\mathcal{A}_M(V)$ the Petersson inner product, for which every $\rho_V(g)$, $g \in G_f$, is unitary. Let w be split off the level and v the place of E^+ below it; then K_M has the full component $K_w = \mathrm{GL}_r(\mathcal{O}_w)$ at v, and for $d \in \mathrm{GL}_r(E_w)$ write $T_{[d]}$ for the operator $\rho_V(\sum_j g_j)$, g_j over $K_w d K_w / K_w$ placed at v. With the Haar measure of $\mathrm{GL}_r(E_w)$ giving K_w volume 1, $T_{[d]}x = \int_{K_w d K_w} \rho_V(h)x\, dh$ for $x \in \mathcal{A}_M(V)$; so the $T_{[d]}$ represent the convolution algebra $\mathcal{H}(\mathrm{GL}_r(E_w), K_w)$ of K_w-biinvariant compactly supported functions, which is commutative [109]. (a) Commutation: $T_{w,i}$ and $T_{w',i'}$ commute if w, w' lie over the same place of E^+ (both lie in the image of that commutative algebra; for $w' = \bar w$ through the identification of (HO4)), and otherwise because they translate at different components of G_f. (b) Adjoints: for $x, y \in \mathcal{A}_M(V)$, by unitarity and unimodularity, $\langle T_{[d]}x, y\rangle = \int_{K_w d K_w} \langle x, \rho_V(h^{-1})y\rangle dh = \langle x, T_{[d^{-1}]}y\rangle$. For $d = \operatorname{diag}(\varpi_w 1_i, 1_{r-i})$, $K_w d^{-1} K_w = \varpi_w^{-1} K_w \operatorname{diag}(\varpi_w 1_{r-i}, 1_i) K_w$ (a permutation matrix in K_w reorders the diagonal), so $T_{w,i}^* = T_{w,r}^{-1} T_{w,r-i}$ with $T_{w,0} = 1$; here $T_{w,r} = \rho_V(\varpi_w 1_r)$ is invertible, so $T_{w,r}^{-1}$ is a polynomial in $T_{w,r}$ by the Cayley–Hamilton theorem. Hence the algebra $\mathcal{B} \subseteq \operatorname{End} \mathcal{A}_M(V)$ generated by all $T_{w,i}$ is commutative and closed under adjoints; it is finite-dimensional, so it is generated by finitely many $T_{w,i}$, which are commuting normal operators. By the spectral theorem for commuting normal operators [133] (Theorem 2.5.5) they are simultaneously unitarily diagonalisable, so $\mathcal{A}_M(V)$ is the orthogonal direct sum of the joint eigenspaces of $\mathcal{B}$. Each joint eigenspace is $\mathcal{A}_M(V)[q]$ for the eigensystem q of its eigenvalues, eigenparts of distinct eigensystems meet in 0, and only finitely many are nonzero as $\dim \mathcal{A}_M(V) < \infty$. Since $\bar G$ commutes with the $T_{w,i}$ (Step 1), e_0 preserves each eigenpart and $\mathcal{A}^{\mathrm{good}}(V) = \bigoplus_q \mathcal{A}^{\mathrm{good}}(V) \cap \mathcal{A}_M(V)[q]$; the same for V'. Let F be the finite set of eigensystems occurring for V or V', and q an eigensystem. For

each $q' \in F \setminus \{q\}$ choose (w,i) with $q'(w,i) \neq q(w,i)$ and put

$$a = \prod_{q' \in F \setminus \{q\}} \frac{a_{w,i} - q'(w,i)}{q(w,i) - q'(w,i)} \in \mathcal{H}^M.$$

Then T_a is the identity on the q-part and 0 on the q'-parts, $q' \neq q$, on both spaces; its trace on good forms is the dimension in (ii), and Step 2 gives (ii).

Step 5: the spaces Y_0, W_j. Index the entries of $\varsigma(v)$ by $p = 0, \dots, r-1$ in the displayed order of Definition 3.2.16, matched with the basis of Y_0 by the numbering num of (HP2) of Definition 3.2.13: $\varsigma(v)_p$ with $p < k-1$ lies in $[1-\frac{k}{2}, \frac{k}{2}-1]$, and $\varsigma(v)_{k-2+i} = \frac{\Delta}{2} - \kappa_i(v) = -\kappa(v) - i\Delta$ for $1 \leq i \leq m$ (by (AD4), $\kappa_i = \kappa + (2i+1)\frac{\Delta}{2}$). The entries are pairwise distinct. Two entries $-\kappa - i\Delta$, $-\kappa - i'\Delta$ with $i \neq i'$ differ by at least Δ, and a small entry differs from $-\kappa - i\Delta$ by at least $\kappa + \Delta - \frac{k}{2} \geq \Delta$ ($\kappa \geq 1$, $k < r < \Delta$). So ς has gap Δ for any signs that are constant on the $k-1$ small indices. The signs of W_j are $+1$ on the first $k+j-1$ indices ((HP4) of Definition 3.2.13); the signs of Y_0 ((HP2) of Definition 3.2.13) are -1 exactly at the indices $k-2+i$ with $i \geq 2$ even (equivalently, at the indices p with $p-k$ non-negative and even), $m/2 = \varrho + 1$ of them. Both are constant on the small indices, which gives the gaps. Finally T_1 is the identity, so (i) for $a = 1$, $V = Y_0$, $V' = W_j$ gives $\dim \mathcal{A}^{\mathrm{good}}(W_j) = \dim \mathcal{A}^{\mathrm{good}}(Y_0) = d_{\mathcal{T}}$. □

Theorem 5.8.5. *Let E be a CM field with totally real subfield E^+ such that E contains a primitive 5040-th root of unity and $[E^+ : \mathbb{Q}]$ is even. Let $N \geq 2$, let $G_f = G_f(\{1,\dots,N\})$, $\mathrm{K}_f = \mathbf{K}_0(\{1,\dots,N\})$ be as in (VP1), and let V, V' be framed spaces of rank N over E whose signs do not depend on the infinite place: $s_v = s$ and $s'_v = s'$ for all v, with fixed $s, s' \colon \{1,\dots,N\} \to \{\pm 1\}$. Let $\lambda = (\lambda_v)_v$, indexed by the infinite places v of E^+, with $\lambda_v \in (\frac{N-1}{2} + \mathbb{Z})^N$ having pairwise distinct entries and*

$$|\lambda_{v,i} - \lambda_{v,j}| \;\geq\; 500N^3 + 10N^5 \quad \text{whenever } s_v(i) \neq s_v(j) \text{ or } s'_v(i) \neq s'_v(j).$$

For a framed space $U \in \{V, V'\}$ and an open subgroup $K \subseteq \mathrm{K}_f$ let $\mathcal{A}_K(U,\lambda)$ be the space of forms on $\mathrm{U}(U)$ of level K whose archimedean type at every v is the discrete series with Harish-Chandra parameter λ_v relative to the signs of U at v. Let $K \subseteq \mathrm{K}_f$ be open and let $a = \sum_g a_g\, g \in \mathbb{C}[G_f]$ be finitely supported such that $\pi(a)$ maps K-fixed vectors to K-fixed vectors in every representation π of G_f. Let w be a finite place of E with $w \neq \bar{w}$, and suppose that the function $\phi_a^K(g) = \sum_h a_h \mathbf{1}_K(h^{-1}g)$ on G_f is cuspidal at w. Then $\mathcal{A}_K(V,\lambda)$ and $\mathcal{A}_K(V',\lambda)$ are finite-dimensional, $\rho_V(a)$ and $\rho_{V'}(a)$ preserve them, and

$$\mathrm{tr}\big(\rho_V(a) \mid \mathcal{A}_K(V,\lambda)\big) = \mathrm{tr}\big(\rho_{V'}(a) \mid \mathcal{A}_K(V',\lambda)\big).$$

Proof. For $U \in \{V, V'\}$ let X_U be the space of forms on $\mathrm{U}(U)$ of type e_λ^U (of all levels), so that $X_U^K = \mathcal{A}_K(U,\lambda)$ for every open $K \subseteq \mathrm{K}_f$. Right translation by G_f commutes with right convolution by e_λ^U at the infinite places, so ρ_U is a representation of G_f on X_U; it is unitary for the Petersson inner product, because right translation preserves the invariant measure on $\Gamma_U \backslash G^U$, which has finite volume, and forms of type e_λ^U are bounded, hence square integrable. The hypothesis on λ says that λ satisfies the gap condition of Theorem 5.8.6 for the signs s and for the signs s'.

Step 1, finiteness and stability. By Theorem 5.8.6 (i), $\mathcal{A}_K(V,\lambda)$ and $\mathcal{A}_K(V',\lambda)$ are finite-dimensional. Since a maps K-fixed vectors to K-fixed vectors in every representation of G_f, $\rho_U(a)$ maps $X_U^K = \mathcal{A}_K(U,\lambda)$ into itself for $U = V, V'$.

Step 2, the auxiliary place. By Theorem 5.8.50 (CU1) there is a finite place $v \neq \bar{v}$ of E with $v \notin \{w, \bar{w}\}$, $\iota_v(\mathrm{GL}_N(\mathcal{O}_v)) \subseteq K$, and a a combination of elements integral at v. The group $K' = \{k \in K : \ k_v \in J_v\}$ is open in K_f, so by Theorem 5.8.6 (i) the spaces $X_V^{K'} = \mathcal{A}_{K'}(V, \lambda)$ and $X_{V'}^{K'} = \mathcal{A}_{K'}(V', \lambda)$ are finite-dimensional.

Step 3, equality of traces at the cut level. Let $l, m \geq 0$. By Theorem 5.8.50 (CU2), $\rho_U(b_{l,m})$ maps $\mathcal{A}_{K'}(U, \lambda)$ into itself, so Theorem 5.8.6 (iii), applied to U, the level K' and the element $b_{l,m}$, whose function at level K' is $\phi_{l,m}$, gives

$$\mu_f(K') \operatorname{tr}\big(\rho_U(b_{l,m}) \mid \mathcal{A}_{K'}(U, \lambda)\big) = \sum_{R \in E[X]} I_R^U(\phi_{l,m}) \qquad (U = V, V').$$

By Theorem 5.8.50 (CU3), $\phi_{l,m}$ is cuspidal at w, and every g with $\phi_{l,m}(g) \neq 0$ has g_v integral with 0 a simple root of the characteristic polynomial of its reduction modulo v. These are the hypotheses of (TM3) of Theorem 5.8.30 with $w' = v$; together with $\mu_{5040} \subseteq E$ and $[E^+ : \mathbb{Q}]$ even, the consequence stated there gives $I_R^V(\phi_{l,m}) = I_R^{V'}(\phi_{l,m})$ for every R. The two sums above are therefore equal, and since $\mu_f(K') > 0$ for the open subgroup K',

$$\operatorname{tr}\big(\rho_V(b_{l,m}) \mid X_V^{K'}\big) = \operatorname{tr}\big(\rho_{V'}(b_{l,m}) \mid X_{V'}^{K'}\big) \qquad \text{for all } l, m \geq 0.$$

Step 4, return to level K. The unitary representations ρ_V on X_V and $\rho_{V'}$ on $X_{V'}$, with finite-dimensional K'-fixed spaces (Step 2), the place v and the element a satisfy the hypotheses of Theorem 5.8.50 (CU2), and the traces of all $b_{l,m}$ agree by Step 3. Hence $\operatorname{tr}(\rho_V(a) \mid \mathcal{A}_K(V, \lambda)) = \operatorname{tr}(\rho_{V'}(a) \mid \mathcal{A}_K(V', \lambda))$. □

The simple trace formula is stated for one framed space. Its proof is reduction theory and decay: Mahler's criterion for framed spaces, uniform rapid decay of the forms reproduced by a cusp kernel, the kernel bound by the inverse first minimum, the uniform bound of the polynomial parts of the kernel, and the spectral expansion of the kernel. The finiteness of the volume of the adelic quotient (Theorem 4.2.18) rests on the theorem of Borel and Harish-Chandra (Theorem A.4.6; see [37] and [33]). For rapid decay of cusp forms see [120], [208] and [200].

Theorem 5.8.6. *Let E be a CM field with totally real subfield E^+ and a CM type fixing an embedding $\Phi_v \colon E \to \mathbb{C}$ for each infinite place v. Let $N \geq 2$, let U be a framed space of rank N over E whose signs do not depend on the infinite place, $s_v = s$ for all v with a fixed $s \colon \{1, \dots, N\} \to \{\pm 1\}$, and let $\lambda = (\lambda_v)_v$ with $\lambda_v \in (\frac{N-1}{2} + \mathbb{Z})^N$ having pairwise distinct entries and $|\lambda_{v,i} - \lambda_{v,j}| \geq 500N^3 + 10N^5$ whenever $s_v(i) \neq s_v(j)$. Put $G_\infty^U = G_\infty = \prod_v \mathrm{U}(\mathrm{diag}(s_v))$ and $G^U = G_\infty^U \times G_f$, with $\Gamma_U \subseteq G^U$ the image of $\mathrm{U}(U)(E^+)$ under the frames, as in (FT1). Let*

$$e_\lambda^U(g_\infty) = \prod_v d(\lambda_v, s_v)\, \overline{c_{\lambda_v, s_v}(g_v)},$$

where c_{λ_v, s_v} is Flensted-Jensen's function of the parameter λ_v for the signs s_v as in (FT3) (the matrix coefficient, at a vector of the lowest K-type, of the discrete series of $\mathrm{U}(\mathrm{diag}(s_v))$ with Harish-Chandra parameter λ_v, with $c_{\lambda_v, s_v}(1) = 1$), and $d(\lambda_v, s_v) = (\int |c_{\lambda_v, s_v}|^2)^{-1}$ its formal degree for the Haar measure fixed below. Let $K \subseteq \mathrm{K}_f$ be open, let $a \in \mathbb{C}[G_f]$ be finitely supported, and let $\phi(g) = \sum_h a_h \mathbf{1}_K(h^{-1}g)$. For a polynomial $R \in E[X]$ put

$$I_R^U(\phi) = \int_{\Gamma_U \backslash G^U} \sum_{\gamma \in \mathrm{U}(U)(E^+),\ \mathrm{charpoly}(\gamma) = R} (e_\lambda^U \otimes \phi)(x^{-1}\gamma x)\, dx,$$

with Haar measures fixed as follows: on each $\mathrm{U}(\mathrm{diag}(s_v))$ a fixed Haar measure, the same one as in $d(\lambda_v, s_v)$, on G_f a fixed Haar measure μ_f independent of U, and on $\Gamma_U \backslash G^U$ the quotient by the counting measure on Γ_U. Then:

1. *$\mathcal{A}_K(U,\lambda)$ is finite-dimensional;*

2. *for every R the inner sum converges absolutely for every x and is integrable on $\Gamma_U\backslash G^U$, and the family $(I_R^U(\phi))_{R\in E[X]}$ is absolutely summable;*

3. *if $\rho_U(a)$ maps $\mathcal{A}_K(U,\lambda)$ into itself, then*

$$\mu_f(K)\ \mathrm{tr}(\rho_U(a)\mid \mathcal{A}_K(U,\lambda)) = \sum_{R\in E[X]} I_R^U(\phi).$$

Proof. Write $G_\infty = G_\infty^U$, $\Gamma = \Gamma_U$, $\mathcal{A} = \mathcal{A}_K(U,\lambda)$, $e = e_\lambda^U$, and for $x \in G^U$ and $S \subseteq E[X]$

$$s_S(x) = \sum_{\gamma\in \mathrm{U}(U)(E^+),\ \mathrm{charpoly}(\gamma)\in S} (e\otimes\phi)(x^{-1}\gamma x),$$

so that $I_R^U(\phi) = \int_{\Gamma\backslash G^U} s_{\{R\}}$. The function ϕ is locally constant with compact support (a finite combination of indicators of compact open cosets hK).

Step 0: the kernel is a cusp kernel of order $B = 10N^5$. As $\lambda_v \in (\frac{N-1}{2}+\mathbb{Z})^N$ has pairwise distinct entries, $2\lambda_v \in \mathbb{Z}^N$ has distinct entries congruent to $N-1$ modulo 2, and $|2\lambda_{v,i} - 2\lambda_{v,j}| \geq 2(500N^3+B)$ when $s(i)\neq s(j)$: so $2\lambda_v$ has gap $500N^3+B$ for s in the sense of (DZ1) of Definition 5.6.3. By Lemma 5.6.21, e is a cusp kernel of order B on G_∞ (the formal degrees are taken for the fixed Haar measures). As $N\geq 2$, $B = 10N^5 \geq 13N^3 > 8N^2$. The space $\mathcal{A}$ consists of the continuous bounded functions on G^U that are left Γ-invariant, right K-invariant and satisfy $R(e)F = F$ (right K-invariance gives the open subgroup required in the type condition).

Step 1: (i). Let R_1 be the constant of Lemma 5.8.7 for e, K and $A = 1$, and $R_0 = \max(R_1, 1)$; let C be the compact set of Lemma 5.8.20 for $T = 2R_0$. By the continuity of left translation in $L^1(G_\infty)$ there is a neighbourhood W_∞ of 1 in G_∞ with $\int |e(u^{-1}h) - e(h)|\,dh \leq \frac{1}{2}$ for $u \in W_\infty$; put $W = W_\infty \times K$. For $F\in\mathcal{A}$ with $M = \sup|F|$, $g\in G^U$ and $w = (u,k)\in W$,

$$|F(gw) - F(g)| = |F(g(u,1)) - F(g)| = \left|\int (e(u^{-1}h) - e(h))F(g(h,1))\,dh\right| \leq \tfrac{1}{2}M, \qquad (1)$$

using right K-invariance, $F = R(e)F$ and the substitution $h\mapsto u^{-1}h$. The compact set C is covered by finitely many sets $a_1W,\dots,a_mW$ with $a_j\in C$. We claim that $F\mapsto (F(a_1),\dots,F(a_m))$ is injective on $\mathcal{A}$, so $\dim\mathcal{A}\leq m$. Let $F\in\mathcal{A}$ vanish at all a_j and suppose $M = \sup|F| > 0$. Choose g with $|F(g)| > M/2$. By Lemma 5.8.7, $|F(g)|\lambda_U(g)^{-1} \leq MR_0$ ($\lambda_U(g)$ the first minimum of (VP4) of Definition 3.2.2), so $\lambda_U(g)^{-1} < 2R_0$; by Lemma 5.8.20 some $\gamma\in\Gamma$ has $\gamma g\in C$, so $\gamma g \in a_jW$ for some j, and by (1) and Γ-invariance $|F(g)| = |F(\gamma g) - F(a_j)| \leq M/2$, a contradiction. So $F = 0$.

Step 2: (ii), the terms. By Proposition 5.8.22(ii) (with $k = e$, $j = 0$, $r = 1$, $g = x$, Z the γ with polynomial in S; (EK4)(b) and $B\geq 8N^2+1$), the series $s_S(x)$ converges absolutely for every x and every S. Each s_S is measurable (a countable sum of measurable functions) and left Γ-invariant: for $\delta\in\mathrm{U}(U)(E^+)$ the bijection $\gamma\mapsto\delta^{-1}\gamma\delta$ preserves characteristic polynomials and $(\delta x)^{-1}\gamma(\delta x) = x^{-1}(\delta^{-1}\gamma\delta)x$. By Proposition 5.8.23 there is D with $|s_S(x)|\leq D$ for all x and S. The quotient $\Gamma\backslash G^U$ has finite volume vol by Theorem 4.2.18 (through the frames G^U is the adelic unitary group of U and Γ its rational points). So every s_S is integrable on $\Gamma\backslash G^U$; in particular $I_R^U(\phi)$ is defined.

Step 3: (ii), summability. For a finite $F\subseteq E[X]$, absolute convergence gives $s_F = \sum_{R\in F} s_{\{R\}}$, hence $\int s_F = \sum_{R\in F} I_R^U(\phi)$. Given a finite F, let $F_1\subseteq F$ be the set of R with $\mathrm{Re}\, I_R^U(\phi)\geq 0$; then

$\sum_{R\in F_1} \operatorname{Re} I_R^U(\phi) = \operatorname{Re}\int s_{F_1} \le D\,\mathrm{vol}$, and likewise for the negative real parts and for the imaginary parts. So $\sum_{R\in F} |I_R^U(\phi)| \le 4D\,\mathrm{vol}$ for every finite F: the family is absolutely summable. To identify its sum, enumerate the countable set $E[X]$ as $R_1, R_2, \dots$ and put $F_n = \{R_1, \dots, R_n\}$. For each x, $s_{F_n}(x) \to s_{E[X]}(x)$ by absolute convergence of the series over γ, and $|s_{F_n}| \le D$; by dominated convergence on the finite measure space,

$$\sum_{R\in E[X]} I_R^U(\phi) = \lim_n \int s_{F_n} = \int_{\Gamma\backslash G^U} s_{E[X]}. \tag{2}$$

Step 4: (iii). Assume that $\rho_U(a)$ maps $\mathcal{A}$ into itself, and let (b_i) be an orthonormal basis of $\mathcal{A}$ for the Petersson product (finite by Step 1). By Proposition 5.8.28 (cusp kernel of order $B > 8N^2$, $K \subseteq \mathrm{K}_f$, $\mathcal{A}$ finite-dimensional) with $g = g' = x$,

$$s_{E[X]}(x) = \mu_f(K) \sum_i (\rho_U(a) b_i)(x)\, \overline{b_i(x)}.$$

Each product is integrable (bounded functions, finite volume), so integrating and using (2),

$$\sum_{R\in E[X]} I_R^U(\phi) = \mu_f(K) \sum_i \int_{\Gamma\backslash G^U} \overline{b_i}\, \rho_U(a) b_i = \mu_f(K) \sum_i \langle b_i, \rho_U(a) b_i\rangle = \mu_f(K)\, \mathrm{tr}\big(\rho_U(a) \mid \mathcal{A}\big).$$

□

Lemma 5.8.7. *Let E be a CM field, $N \ge 1$, $s \in \{\pm 1\}^N$, and U a framed space of rank N over E with signs $s_v = s$ at every infinite place v; let $G^U = G_\infty \times G_f$ with G_∞ the real group of s, and Γ_U the image of $\mathrm{U}(U)(E^+)$ under the frames. Let $B \ge 0$ and let e be a cusp kernel of order B on G_∞; let $K \subseteq G_f$ be an open subgroup and $A \ge 0$ an integer. There is $R \ge 0$ such that for every continuous bounded function F on G^U that is left Γ_U-invariant, right K-invariant and satisfies $R(e)F = F$, and every real c with $|F| \le c$ on G^U,*

$$|F(g)|\, \lambda_U(g)^{-A} \le c\, R \qquad (g \in G^U).$$

Proof. Put $J = K \cap \mathrm{K}_f$, an open subgroup of G_f. Let $\delta_0 > 0$ be the constant of Proposition 5.8.8 for the cusp kernel e and the exponent $j = NA$, and $\kappa_J > 0$ that of Proposition 5.8.13(ii) for J; put $\delta_1 = \min(\delta_0, 1)$ and

$$R = \big(\kappa_J/\delta_1^N\big)^A.$$

Let F and c be as in the statement; then $c \ge |F(1)| \ge 0$. Let $g \in G^U$. The first minimum $\lambda_U(g)$ is positive (the nonzero vectors of the lattice $L_{g,\infty}$ of Lemma 5.8.15(iii) have norm bounded below), so there is $\delta > 0$ with $\delta^N = \kappa_J \lambda_U(g)$. We show

$$|F(g)| \le (\delta/\delta_1)^{NA}\, c. \tag{1}$$

If $\delta \le 1$, Proposition 5.8.13(ii) gives a nonzero isotropic subspace $A_0 \subseteq U$ with $N_{A_0}(\mathbb{A}_{E^+})\, g \subseteq N_{A_0}(E^+)\, g\, Z_\delta\, J$. The function F is continuous, bounded by c, satisfies $R(e)F = F$, is right J-invariant ($J \subseteq K$) and left invariant under $N_{A_0}(E^+) \subseteq \Gamma_U$; so Proposition 5.8.8, with $T = c$, the subgroup J and $j = NA$, gives $|F(g)| \le (\delta/\delta_0)^{NA} c \le (\delta/\delta_1)^{NA} c$. If $\delta > 1$, then $\delta/\delta_1 > 1$ and (1) follows from $|F(g)| \le c$.

By (1),

$$|F(g)|\lambda_U(g)^{-A} \le c\Big(\frac{\delta^N}{\delta_1^N}\Big)^A \lambda_U(g)^{-A} = c\Big(\frac{\kappa_J}{\delta_1^N}\Big)^A = c\, R.$$

The constant R depends only on e, A, N, E and K. □

Proposition 5.8.8. *Let E be a CM field, $N \geq 1$, $s \in \{\pm 1\}^N$, $B \geq 0$, e a cusp kernel of order B on G_∞, and $j \geq 0$ an integer. There is $\delta_0 > 0$, depending only on e and j, with the following property. Let U be a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$, $A \subseteq U$ a nonzero isotropic subspace, $J \subseteq G_f$ a subgroup, $\delta \geq 0$ and $g \in G^U$ with $N_A(\mathbb{A}_{E^+})\, g \subseteq N_A(E^+)\, g\, Z_\delta\, J$. Let F be a continuous function on G^U with $|F| \leq T$, $R(e)F = F$, F right J-invariant and $F(\nu x) = F(x)$ for $\nu \in N_A(E^+)$. Then*

$$|F(g)| \leq \Big(\frac{\delta}{\delta_0}\Big)^j T.$$

Proof. Write $\|z\| = \|z\|_\infty$ for $z \in G_\infty$. For $z_v \in \mathrm{U}(\mathrm{diag}\, s)$, $z_v^{-1} = \mathrm{diag}(s)\bar{z}_v^{\mathsf{T}}\mathrm{diag}(s)$, so $\|z_v^{-1}\| = \|z_v\| \geq 1$; hence $\|z\| \geq \|z_v\| \geq 1$ for every v, and $\|zw\| \leq \|z\|\,\|w\|$.

Step 1: a reproducing bump. Let β be as in (EK4)(c). For a bounded measurable f on G^U with $R(e)f = f$, Fubini's theorem ($|\beta(x)e(x^{-1}y)|\sup|f|$ is integrable) and the substitution $y = xy'$ give

$$f(g') = \int e(y) f(g'(y,1))\, dy = \int \beta(x) \int e(y') f(g'(xy',1))\, dy'\, dx = \int \beta(x) f(g'(x,1))\, dx.$$

Step 2: small oscillation. Let $\Omega = \{ux : \max_v \|u_v - 1\| \leq 1,\ x \in \mathrm{supp}\,\beta\}$, a compact set; let $c \geq 1$ bound $\|\cdot\|$ on Ω, and choose $0 < \delta_0 \leq 1$ with $\int |\beta(u^{-1}x) - \beta(x)|\, dx \leq \frac{1}{2}c^{-2j}$ whenever $\max_v \|u_v - 1\| \leq \delta_0$ (continuity of left translation in L^1). Then: if f is bounded, continuous, $R(e)f = f$, $g' \in G^U$, $C' \geq 0$ and $|f(g'(w,1))| \leq C'\|w\|^{2j}$ for all $w \in G_\infty$, then $|f(g'(u,1)) - f(g')| \leq C'/2$ for $\max_v \|u_v - 1\| \leq \delta_0$. Indeed, by Step 1 and left invariance, $f(g'(u,1)) - f(g') = \int (\beta(u^{-1}x) - \beta(x)) f(g'(x,1))\, dx$; where the integrand is nonzero, $x \in \mathrm{supp}\,\beta$ or $u^{-1}x \in \mathrm{supp}\,\beta$, so $x \in \Omega$ and $|f(g'(x,1))| \leq C'c^{2j}$; so the difference is at most $C'c^{2j} \cdot \frac{1}{2}c^{-2j}$.

Step 3: halving. Put $b = (\delta/\delta_0)^j T$ and let $\mathcal{C}$ be the set of $C \geq 0$ with $|F(g(z,1))| \leq C\|z\|^{2j}$ for all $z \in G_\infty$; $T \in \mathcal{C}$. We show: if $C \in \mathcal{C}$ then $\max(C/2, b) \in \mathcal{C}$. Let $z \in G_\infty$.

If $\|z\|^2\delta \leq \delta_0$: for $x \in Z_\delta$ write $g(xz,1) = g(z,1)(u,1)$ with $u = z^{-1}xz$; then $\|u_v - 1\| = \|z_v^{-1}(x_v - 1)z_v\| \leq \|z\|^2\delta \leq \delta_0$. Step 2 at $g' = g(z,1)$ with $C' = C\|z\|^{2j}$ applies, since $|F(g(z,1)(w,1))| = |F(g(zw,1))| \leq C\|zw\|^{2j} \leq C'\|w\|^{2j}$; so $|F(g(xz,1)) - F(g(z,1))| \leq \frac{C}{2}\|z\|^{2j}$ for all $x \in Z_\delta$. By Lemma 5.8.9(ii) (with $y = z$, $D = \frac{C}{2}\|z\|^{2j}$), $|F(g(z,1))| \leq \frac{C}{2}\|z\|^{2j}$.

If $\|z\|^2\delta > \delta_0$: then $(\delta/\delta_0)^j\|z\|^{2j} \geq 1$ and $|F(g(z,1))| \leq T \leq b\|z\|^{2j}$.

Iterating from $C_0 = T$, $C_{k+1} = \max(C_k/2, b)$ gives $C_k \leq \max(2^{-k}T, b)$ in $\mathcal{C}$ for all k; at $z = 1$, $|F(g)| \leq \max(2^{-k}T, b)$ for every k, hence $|F(g)| \leq b$. The constant δ_0 was chosen from e and j only. □

Lemma 5.8.9. *Let E be a CM field, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$ and Γ_U the image of $\mathrm{U}(U)(E^+)$ under the frames. Let $A \subseteq U$ be a nonzero isotropic subspace, N_A the unipotent radical of its stabiliser in $\mathrm{U}(U)$ (a unipotent group over E^+), with $N_A(\mathbb{A}_{E^+}) \subseteq G^U$ through the frames and $N_A(E^+) \subseteq \Gamma_U$. Let $B \geq 0$, e a cusp kernel of order B on G_∞, and F a continuous bounded function on G^U with $R(e)F = F$ and $F(\nu x) = F(x)$ for $\nu \in N_A(E^+)$, $x \in G^U$. Let dn be the invariant probability measure on the compact quotient $N_A(E^+)\backslash N_A(\mathbb{A}_{E^+})$.*

(i) For every $g \in G^U$, $\int F(ng)\, dn = 0$.

(ii) Let $J \subseteq G_f$ be a subgroup such that F is right J-invariant, $\delta \geq 0$, and $g \in G^U$ with

$$N_A(\mathbb{A}_{E^+})\, g \subseteq N_A(E^+)\, g\, Z_\delta\, J, \qquad Z_\delta = \{z \in G_\infty : \max_v \|z_v - 1\| \leq \delta\}$$

(G_∞ and G_f embedded in G^U as $z \mapsto (z,1)$, $k \mapsto (1,k)$). If $y \in G_\infty$ and $D \geq 0$ satisfy $|F(g(zy,1)) - F(g(y,1))| \leq D$ for all $z \in Z_\delta$, then $|F(g(y,1))| \leq D$.

Proof. By Theorem A.4.3, applied to the unipotent group N_A over E^+, the subgroup $N_A(E^+)$ is discrete and cocompact in the unimodular group $N_A(\mathbb{A}_{E^+})$; so the quotient carries an invariant probability measure dn, invariant also under right translation by $N_A(\mathbb{A}_{E^+})$. Let $\Sigma = \sup|F|$. Fix an E-basis of U with Gram matrix J_U and frames X, so $c(u) = X^{-1}u$, G^U preserves the form D_s ($\mathrm{diag}(s)$ at each infinite place, 1 at the finite places), and let $Y \in M_N(E)$ be a nonzero matrix whose columns span A. An element $h \in G^U$ lies in $N_A(\mathbb{A}_{E^+})$ if and only if $hX^{-1}Y = X^{-1}Y$ and $\bar{w}^{\mathsf{T}} D_s h u = \bar{w}^{\mathsf{T}} D_s u$ for all adelic vectors u, w orthogonal (for D_s) to the columns of $X^{-1}Y$.

(i). Fix g and put $A' = g^{-1}X^{-1}Y$ and $A_v = A'_v \in M_N(\mathbb{C})$ at the infinite place v; $A_v \neq 0$ ($Y \neq 0$ and $g^{-1}X^{-1}$ is invertible) and $\bar{A}_v^{\mathsf{T}} \mathrm{diag}(s) A_v = \Phi_v(\bar{Y}^{\mathsf{T}} J_U Y) = 0$, as A is isotropic and g preserves D_s. Let $R_v \subseteq \mathrm{U}(\mathrm{diag}\, s)$ be as in Lemma 5.8.10 for A_v. For $r \in \prod_v R_v$ the element $n_r = g(r,1)g^{-1}$ lies in $N_A(\mathbb{A}_{E^+})$: $n_r X^{-1}Y = g(r,1)A' = gA' = X^{-1}Y$, since $r_v A_v = A_v$ and the finite component of $(r,1)$ is 1; and the orthogonality condition for n_r is that of $(r,1)$ for A', transported by g, which preserves D_s. Define, for $x \in G_\infty$,

$$\Psi(x) = \int F\big(ng(x,1)\big)\, dn,$$

well defined since $n \mapsto F(ng(x,1))$ is continuous, bounded and left $N_A(E^+)$-invariant. Ψ is bounded by Σ and continuous by dominated convergence (finite measure, F continuous and bounded). For $r \in \prod_v R_v$, $\Psi(rx) = \int F(nn_r g(x,1))\, dn = \Psi(x)$ by right invariance of dn. Since $F = R(e)F$ and $|e(x)|\Sigma$ is integrable on $G_\infty \times (N_A(E^+)\backslash N_A(\mathbb{A}_{E^+}))$, Fubini's theorem gives

$$\Psi(1) = \iint e(x) F\big(ng(x,1)\big)\, dx\, dn = \int_{G_\infty} e(x)\Psi(x)\, dx = 0$$

by Lemma 5.8.10 with $y = 1$. As $\Psi(1) = \int F(ng)\, dn$, this is (i).

(ii). Let $n \in N_A(\mathbb{A}_{E^+})$. By hypothesis $ng = \nu g(z,1)(1,k)$ with $\nu \in N_A(E^+)$, $z \in Z_\delta$, $k \in J$. As $(z,1)(1,k)(y,1) = (zy,1)(1,k)$, the invariances of F give $F(ng(y,1)) = F(g(zy,1))$, so $|F(ng(y,1)) - F(g(y,1))| \leq D$ for every n. Integrating against the probability measure dn and using (i) at the point $g(y,1)$,

$$|F(g(y,1))| = \Big|\int \big(F(g(y,1)) - F(ng(y,1))\big)\, dn\Big| \leq D.$$

□

Lemma 5.8.10. *Let E be a CM field with set of infinite places Φ, $N \geq 1$, $s \in \{\pm 1\}^N$, $B \geq 0$ and e a cusp kernel of order B on $G_\infty = \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}\, s)$. For each $v \in \Phi$ let $A_v \in M_N(\mathbb{C})$ be nonzero with $\bar{A}_v^{\mathsf{T}} \mathrm{diag}(s) A_v = 0$, and let R_v be the group of $r \in \mathrm{U}(\mathrm{diag}\, s)$ with $rA_v = A_v$ and $\bar{w}^{\mathsf{T}} \mathrm{diag}(s)\, ru = \bar{w}^{\mathsf{T}} \mathrm{diag}(s)\, u$ for all $u, w \in \mathbb{C}^N$ with $\bar{A}_v^{\mathsf{T}} \mathrm{diag}(s) u = \bar{A}_v^{\mathsf{T}} \mathrm{diag}(s) w = 0$ (the unipotent radical of the stabiliser of the column span of A_v). Let Ψ be a bounded continuous function on G_∞ with $\Psi(rx) = \Psi(x)$ for all $x \in G_\infty$ and $r \in \prod_v R_v$. Then*

$$\int_{G_\infty} e(x)\, \Psi(yx)\, dx = 0 \qquad (y \in G_\infty).$$

Proof. Write $J = \mathrm{diag}(s)$, $\|\cdot\|$ for operator norms, and $A_v^\perp = \{u \in \mathbb{C}^N : A_v^* J u = 0\}$ ($P^* = \bar{P}^{\mathsf{T}}$). For $z \in \mathrm{U}(J)$, $z^{-1} = Jz^*J$, so $\|z^{-1}\| = \|z\|$ and $1 \le \|z\|^2$; hence $\|x\|_\infty \ge \|x_v\| \ge 1$ for $x \in G_\infty$ and every v. We apply Lemma 5.8.11 to $G = G_\infty$ (a second countable locally compact group; the product dx of Haar measures is a left Haar measure) with the following data.

The kernel. e is integrable and, by (EK3) with $x = 1$, $\int e(z)e(z^{-1}y)\,dz = e(1)e(y)/e(1) = e(y)$.

The group D. Let D be the set of $(r, c) \in G_\infty \times \mathbb{C}^\times$ such that for every v: $r_v A_v = cA_v$, and $w^* J r_v u = w^* J u$ for all $u, w \in A_v^\perp$. If $(r, c) \in D$, then r_v maps $A_v^\perp$ onto itself: from $r_v^* J r_v = J$ and $r_v^{-1} A_v = c^{-1} A_v$, $A_v^* J r_v u = (r_v^{-1} A_v)^* J u = \bar{c}^{-1} A_v^* J u = 0$ for $u \in A_v^\perp$, and r_v is injective on the finite-dimensional space $A_v^\perp$. Hence D is a subgroup: for $(r, c), (r', c') \in D$, $r_v r'_v A_v = cc' A_v$ and $w^* J r_v r'_v u = w^* J r'_v u = w^* J u$ for $u, w \in A_v^\perp$ (as $r'_v u \in A_v^\perp$); and $r_v^{-1} A_v = c^{-1} A_v$, while for $u, w \in A_v^\perp$ the vector $u' = r_v^{-1} u$ lies in $A_v^\perp$, so $w^* J u = w^* J r_v u' = w^* J u' = w^* J r_v^{-1} u$; so $(r^{-1}, c^{-1}) \in D$. Moreover $(r, 1) \in D$ if and only if $r \in \prod_v R_v$, so Ψ satisfies the invariance hypothesis of Lemma 5.8.11.

The height. Fix $v_0 \in \Phi$ and put $H(x) = \log \|x_{v_0}^{-1} A_{v_0}\|$, defined and continuous as $A_{v_0} \neq 0$. For $(r, c) \in D$, $(rx)_{v_0}^{-1} A_{v_0} = x_{v_0}^{-1} r_{v_0}^{-1} A_{v_0} = c^{-1} x_{v_0}^{-1} A_{v_0}$, so $H(rx) = H(x) - \log|c|$. For $y, g \in G_\infty$: $\|(yg)_{v_0}^{-1} A_{v_0}\| \le \|g_{v_0}^{-1}\|\, \|y_{v_0}^{-1} A_{v_0}\|$ and $\|y_{v_0}^{-1} A_{v_0}\| \le \|g_{v_0}\|\, \|(yg)_{v_0}^{-1} A_{v_0}\|$, so with $\|g_{v_0}^{-1}\| = \|g_{v_0}\| \ge 1$,

$$|H(yg) - H(y)| \le \log \|g_{v_0}\| \le \|g_{v_0}\| \le \ell(g) := \|g\|_\infty.$$

ℓ is continuous, and $|e|\ell \le |e|\, \|\cdot\|_\infty^{B+1}$ is integrable by (EK4)(a).

Dilations near 1. Let W be a neighbourhood of 1 in G_∞; it contains $\{b : \|b_v - 1\| \le \delta \text{ for all } v\}$ for some $\delta > 0$. Put $c = 1 + \delta$, so $\log|c| > 0$. Let $x \in G_\infty$. For each v, Lemma 5.8.12 (with A_v, x_v, δ) gives $b_v \in \mathrm{U}(J)$ with $\|b_v - 1\| \le \delta$ such that $x_v b_v x_v^{-1}$ maps A_v to cA_v and satisfies $w^* J x_v b_v x_v^{-1} u = w^* J u$ for $u, w \in A_v^\perp$. Then $b = (b_v)_v \in W$ and $(xbx^{-1}, c) \in D$.

By Lemma 5.8.11 with $f = \Psi$, $\int e(x)\Psi(yx)\,dx = 0$ for every $y \in G_\infty$. □

Lemma 5.8.11. *Let G be a second countable locally compact group with a left Haar measure dg, and let $e \in L^1(G)$ satisfy $\int_G e(x)\, e(x^{-1}g)\,dx = e(g)$ for all $g \in G$. Let $H\colon G \to \mathbb{R}$ be continuous and $\ell\colon G \to [0, \infty)$ measurable with $|e|\,\ell$ integrable and*

$$|H(yg) - H(y)| \le \ell(g) \qquad (y, g \in G).$$

Let $D \subseteq G \times \mathbb{C}^\times$ be a subgroup with $H(rg) = H(g) - \log|c|$ for all $(r, c) \in D$, $g \in G$, and assume that for every neighbourhood W of 1 in G there is $c \in \mathbb{C}^\times$ with $\log|c| \neq 0$ such that for every $x \in G$ some $b \in W$ has $(xbx^{-1}, c) \in D$. Then for every bounded continuous $f\colon G \to \mathbb{C}$ with $f(rg) = f(g)$ whenever $(r, 1) \in D$ and $g \in G$,

$$\int_G e(g)\, f(xg)\,dg = 0 \qquad (x \in G).$$

Proof. Write C_b for the bounded continuous functions on G with the sup norm $\|\cdot\|$, and $\|e\|_1 = \int |e|$.

The operator T. For $\varphi \in C_b$ put $T\varphi(y) = \int e(g)\varphi(yg)\,dg$. Then $|T\varphi| \le \|e\|_1 \|\varphi\|$, and $T\varphi$ is continuous by dominated convergence (G is metrizable, φ continuous and bounded, e integrable). T is idempotent: by Fubini's theorem ($\iint |e(x)||e(x^{-1}g)|\,dg\,dx = \|e\|_1^2$ by left invariance) and the substitution $g \mapsto x^{-1}g$,

$$T(T\varphi)(y) = \int e(x) \int e(x^{-1}g)\varphi(yg)\,dg\,dx = \int \Big(\int e(x) e(x^{-1}g)\,dx \Big) \varphi(yg)\,dg = T\varphi(y).$$

Call φ *invariant* if $\varphi(rg) = \varphi(g)$ whenever $(r,1) \in D$. If φ is invariant, so is $T\varphi$ ($T\varphi(rg) = \int e(h)\varphi(rgh)\,dh$). Let $V = \{\varphi \in C_b : \ T\varphi = \varphi,\ \varphi \text{ invariant}\}$, a normed space; for invariant $\varphi \in C_b$ we have $T\varphi \in V$. As $Tf \in V$ and $Tf(x)$ is the integral of the statement, it suffices to show $V = 0$.

A translation close to 1. Left translation is continuous on $L^1(G)$, so $W = \{b \in G : \ \int |e(g) - e(b^{-1}g)|\,dg < \frac{1}{2}\}$ is a neighbourhood of 1. Let z be as in the hypothesis for W, $\tau = \log|z| \neq 0$, and for every $y \in G$ choose $b(y) \in W$ with $(yb(y)y^{-1}, z) \in D$; put $a = b(1)$, so $(a,z) \in D$. For $\varphi \in V$ let $U\varphi(y) = \varphi(ay)$. Then $U\varphi \in V$: $T(U\varphi)(y) = T\varphi(ay)$, and for $(r,1) \in D$ also $(ara^{-1},1) = (a,z)(r,1)(a,z)^{-1} \in D$, so $\varphi(arg) = \varphi(ara^{-1}\,ag) = \varphi(ag)$. We claim $\|\varphi - U\varphi\| \leq \frac{1}{2}\|\varphi\|$. Let $y \in G$ and $\beta = b(y)$. Since $(y\beta y^{-1}a^{-1},1) = (y\beta y^{-1},z)(a,z)^{-1} \in D$, invariance gives $\varphi(ay) = \varphi(y\beta y^{-1}a^{-1}\cdot ay) = \varphi(y\beta)$; with $T\varphi = \varphi$ and the substitution $g \mapsto \beta^{-1}g$,

$$\varphi(y) - \varphi(ay) = T\varphi(y) - T\varphi(y\beta) = \int (e(g) - e(\beta^{-1}g))\varphi(yg)\,dg,$$

of modulus at most $\frac{1}{2}\|\varphi\|$, as $\beta \in W$. So $\|1 - U\| \leq \frac{1}{2}$ in the algebra of bounded operators on V.

A twisted operator. Choose an integer $n \geq 1$ with $n > \frac{\pi}{|\tau|}\int |e|\ell$, put $\theta = -\pi/(\tau n)$ and $\chi(g) = \exp(i\theta H(g))$, a continuous function of modulus 1; χ is invariant, since $H(rg) = H(g)$ for $(r,1) \in D$. For $\varphi \in V$ the product $\chi\varphi$ is invariant, so $S\varphi = T(\chi\varphi) \in V$; S is a bounded operator on V. As $H(ag) = H(g) - \tau$, $\chi(ag) = \omega\chi(g)$ with $\omega = e^{i\pi/n}$, hence

$$U(S\varphi)(y) = \int e(g)\chi(ayg)\varphi(ayg)\,dg = \omega\int e(g)\chi(yg)\,(U\varphi)(yg)\,dg = \omega\,S(U\varphi)(y),$$

so $US = \omega SU$ and $US^n = \omega^n S^n U = -S^n U$.

$S^n = 0$. Let $X = S^n$, so $UX = -XU$. Then $(1-U)X + X(1-U) = 2X - UX - XU = 2X$, and $2\|X\| \leq \|1-U\|\,\|X\| + \|X\|\,\|1-U\| \leq \|X\|$, so $X = 0$.

S is injective. Let $\varphi \in V$ with $S\varphi = 0$, and $y \in G$. Then $T(\chi\varphi - \chi(y)\varphi)(y) = 0 - \chi(y)T\varphi(y) = -\chi(y)\varphi(y)$, so

$$|\varphi(y)| = \Big|\int e(g)\big(\chi(yg) - \chi(y)\big)\varphi(yg)\,dg\Big| \leq |\theta|\Big(\int |e|\ell\Big)\|\varphi\|,$$

using $|e^{it} - e^{is}| \leq |t-s|$ and $|H(yg) - H(y)| \leq \ell(g)$. Here $q = |\theta|\int |e|\ell = \frac{\pi}{|\tau|n}\int |e|\ell < 1$, so $\|\varphi\| \leq q\|\varphi\|$ and $\varphi = 0$.

Conclusion. For $\psi \in V$, $S^n\psi = 0$ and S is injective, so $\psi = 0$. Hence $V = 0$, $Tf = 0$, and $\int e(g)f(xg)\,dg = Tf(x) = 0$. □

Lemma 5.8.12. *Let $N \geq 1$, $s \in \{\pm 1\}^N$, $J = \mathrm{diag}(s)$ and $\mathrm{U}(J) = \{y \in \mathrm{GL}_N(\mathbb{C}) : y^*Jy = J\}$ ($y^* = \bar{y}^{\mathsf{T}}$), and write $\|\cdot\|$ for the operator norm. Let $A \in \mathrm{M}_N(\mathbb{C})$ with $A^*JA = 0$, $x \in \mathrm{U}(J)$ and $c > 0$. Then there is $y \in \mathrm{U}(J)$ with $\|y - 1\| \leq c$ such that $g = xyx^{-1}$ satisfies $gA = (1+c)A$ and $w^*Jgv = w^*Jv$ for all $v, w \in \mathbb{C}^N$ with $A^*Jv = A^*Jw = 0$.*

Proof. Note $J^* = J$, $J^2 = 1$, and $x^{-1} = Jx^*J$. Let $A' = x^{-1}A$ and $L \subseteq \mathbb{C}^N$ its column space; L is isotropic for J, since $A'^*JA' = A^*(x^{-1})^*Jx^{-1}A = A^*JA = 0$. Let p be the orthogonal projection (for the standard hermitian product) onto L, $p = PP^*$ for a matrix P whose columns are an orthonormal basis of L, and $q = JpJ$, the orthogonal projection onto JL. Isotropy gives $P^*JP = 0$, hence

$$pJp = 0, \qquad pq = pJpJ = 0, \qquad qp = (pq)^* = 0, \qquad pJu = 0 \text{ whenever } P^*Ju = 0. \tag{1}$$

Put $t = (1+c)^{-1} \in (0,1)$ and $y = 1 + c(p - tq)$.

$y \in \mathrm{U}(J)$. As p, q are self-adjoint, $y^* = y$. Using $qJ = Jp$, $Jq = pJ$, $p^2 = p$ and (1): $pJq = pJ$, $qJp = Jp$, $qJq = JpJpJ = 0$, so $(p - tq)J(p - tq) = -t(pJ + Jp)$, and

$$y^*Jy = J + c(pJ + Jp) - ct(qJ + Jq) + c^2(p - tq)J(p - tq) = J + (c - ct - c^2t)(pJ + Jp) = J,$$

since $ct + c^2t = c$. So y is invertible and lies in $\mathrm{U}(J)$.

$\|y - 1\| \le c$. By (1) the ranges of p and q are orthogonal, and $p - tq$ is 1 on the range of p, $-t$ on that of q and 0 on the orthogonal of both; so $\|p - tq\| \le \max(1, t) = 1$ and $\|y - 1\| = c\|p - tq\| \le c$.

The dilation. $pA' = A'$, and $qA' = Jp(JA') = 0$ by (1), since $P^*JA' = 0$ (L is isotropic and contains the columns of A'). So $yA' = (1 + c)A'$ and $gA = xyA' = (1 + c)A$.

Trivial on $A^\perp$ modulo A. Let v, w with $A^*Jv = A^*Jw = 0$ and $v' = x^{-1}v$, $w' = x^{-1}w$. Then $A'^*Jv' = A^*Jv = 0$, so $P^*Jv' = 0$ (the columns of P are combinations of those of A'), and likewise for w'. As $w^*Jx = w'^*x^*Jx = w'^*J$,

$$w^*Jgv - w^*Jv = c\, w'^*J(p - tq)v' = c((pJw')^*v' - t\, w'^*(pJv')) = 0$$

by (1), using $Jq = pJ$ and $(Jp)^* = pJ$. □

Proposition 5.8.13. *Let E be a CM field with maximal totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$, root discriminant $\mathrm{rd}_E = |d_E|^{1/(2f)}$ and different $\mathfrak{D}_E$; let $N \ge 1$. Say that a framed space U of rank N over E with hermitian form h has a* cusp frame of size δ at $g \in G^U = G_\infty \times G_f$ covered by $J \subseteq G_f$ *if there are a nonzero isotropic subspace $A \subseteq U$ and reals $0 \le a \le b$ with $ab \le \delta$ such that A is spanned by vectors $u \in L_g$ with $|u|_g \le a$, $A^\perp$ is spanned by vectors $w \in L_g$ with $|w|_g \le b$, and $N_A(\mathbb{A}_{E^+})\, g \subseteq N_A(E^+)\, g\, Z_\delta\, J$.*

(i) Let $N_D \ge 1$ be a rational integer in $\mathfrak{D}_E$, $\kappa = 8fN\,\mathrm{rd}_E + 48N^6f^2N_D + 1$, $M \ge 1$ an integer and $0 < \delta \le 1$. If U is a framed space of rank N over E and $g \in G^U$ satisfies $\lambda_U(g) < (\delta/(M\kappa^2))^N$, then U has a cusp frame of size δ at g covered by $\mathrm{K}(M)$.

(ii) For every open subgroup $J \subseteq G_f$ there is $\kappa_J > 0$, depending only on E, N and J, with the following property. Let U be a framed space of rank N over E, $g \in G^U$ and $\delta > 0$ with $\delta^N = \kappa_J\lambda_U(g)$. If $\delta \le 1$, then U has a cusp frame of size δ at g covered by J.

Proof. (i). We have $\kappa \ge 1$ and $\kappa^2 \ge \kappa \ge fN\,\mathrm{rd}_E$. Put $\theta = \delta/(M\kappa^2)$; then $0 \le \theta\kappa = \delta/(M\kappa) \le 1$ and $\lambda_U(g) < \theta^N$. By Lemma 5.8.14 there are a nonzero isotropic A and $0 \le a \le b$ with A, $A^\perp$ spanned by vectors of L_g of lengths at most a, b, and $ab \le \theta\kappa = \delta/(M\kappa)$. As $\kappa \ge 48N^6f^2N_D \ge 6N^2fN_D$, $ab \le \delta/(6MN^2fN_D)$, so Lemma 5.8.17 gives $N_A(\mathbb{A}_{E^+})g \subseteq N_A(E^+)gZ_\delta\mathrm{K}(M)$; and $ab \le \delta/(M\kappa) \le \delta$.

(ii). The principal levels $\mathrm{K}(M)$, $M \ge 1$, form a basis of neighbourhoods of 1 in G_f (the sets $1 + M\,\mathrm{M}_N(\widehat{\mathcal{O}}_E)$ form one in $\mathrm{GL}_N(\mathbb{A}_{E,f})$, and G_f carries the subspace topology), so there is $M \ge 1$ with $\mathrm{K}(M) \subseteq J$. Let $N_D = |d_E|$, which lies in $\mathfrak{D}_E$ (the norm of an ideal lies in the ideal, and $\mathrm{N}(\mathfrak{D}_E) = |d_E|$), let κ be as in (i) and put $c = M\kappa^2$ and $\kappa_J = 2c^N$; these depend only on E, N, J. Let U, g, δ be as in (ii) with $\delta \le 1$. The first minimum is positive (the nonzero points of the lattice $L_{g,\infty}$ of Lemma 5.8.15(iii) have norm bounded below), so $\lambda_U(g) = \delta^N/(2c^N) < (\delta/c)^N$, and (i) gives a cusp frame of size δ at g covered by $\mathrm{K}(M) \subseteq J$, hence by J. □

Lemma 5.8.14. *Let E be a CM field with maximal totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$ and root discriminant $\mathrm{rd}_E = |d_E|^{1/(2f)}$; let $N \ge 1$ and U a framed space of rank N over E with hermitian form h, and $G^U = G_\infty \times G_f$. Let κ, θ be real numbers with $\kappa^2 \ge fN\,\mathrm{rd}_E$ and*

$0 \le \theta\kappa \le 1$, *and let* $g \in G^U$ *with* $\lambda_U(g) < \theta^N$. *Then there are a nonzero isotropic subspace* $A \subseteq U$ *and real numbers* $0 \le a \le b$ *with* $ab \le \theta\kappa$ *such that* A *is spanned over* E *by vectors* $u \in L_g$ *with* $|u|_g \le a$, *and* $A^\perp = \{w \in U : h(u,w) = 0 \text{ for all } u \in A\}$ *is spanned over* E *by vectors* $w \in L_g$ *with* $|w|_g \le b$.

Proof. As $\kappa^2 \ge fN \operatorname{rd}_E \ge 1$, $\kappa \ge 1$, so $0 \le \theta \le 1$ and $\theta^N \le 1$; since $\lambda_U(g) = \min(1, \inf\{|u|_g : 0 \ne u \in L_g\}) < \theta^N \le 1$ (the set L_g being that of Lemma 5.8.15), there is $\xi \in L_g$, $\xi \ne 0$, with $|\xi|_g < \theta^N$. Let $y_1, \dots, y_N$ be the basis of Lemma 5.8.16 and $\alpha_j = |y_j|_g$, so $\alpha_1 \le \cdots \le \alpha_N$ and $\prod_j \alpha_j \le (fN \operatorname{rd}_E)^{N/2} \le \kappa^N$.

The longest vector is long: $|\xi|_g \, \alpha_N \ge 1$. Otherwise $|\xi|_g |y_j|_g \le |\xi|_g \alpha_N < 1$ for every j, so $h(\xi, y_j) = 0$ by Lemma 5.8.15(ii); as the y_j span U and h is nondegenerate, $\xi = 0$, a contradiction. In particular all $\alpha_j > 0$ (each $y_j \ne 0$, and $|u|_g > 0$ for $u \ne 0$ because $u \mapsto (g^{-1}c(u))_\infty$ is injective).

The other lengths have a small product. Hence

$$\prod_{j=1}^{N-1} \alpha_j = \frac{\prod_{j=1}^{N} \alpha_j}{\alpha_N} \le \kappa^N |\xi|_g < (\theta\kappa)^N.$$

Put $c = \theta\kappa \in [0,1]$. The left side is positive, so $c > 0$; and $N \ge 2$, since for $N = 1$ the empty product 1 would be $< c \le 1$. Let $k = N - 1 \ge 1$ and $P = \prod_{j=1}^{k} \alpha_j$; then $P^2 < c^{2k+2} \le c^k$ as $0 < c \le 1$.

Pairing from both ends. For $1 \le j \le k$ put $j' = N - j$, so $j \mapsto j'$ is an involution of $\{1, \dots, k\}$ and $\prod_{j=1}^{k} \alpha_j \alpha_{j'} = P^2 < c^k$. Hence $\alpha_j \alpha_{j'} < c$ for some j (otherwise the product of the k factors, each $\ge c > 0$, would be $\ge c^k$). Replacing j by j' if necessary, there is $i \in \{1, \dots, k\}$ with $\alpha_i \le \alpha_{i'}$ and $\alpha_i \alpha_{i'} < c$, where $i' = N - i$.

The frame. Let A be the E-span of $y_1, \dots, y_i$ and B that of $y_1, \dots, y_{i'}$; $\dim A = i \ge 1$ and $\dim B = N - i$. For $p \le i$ and $q \le i'$ we have $\alpha_p \alpha_q \le \alpha_i \alpha_{i'} < c \le 1$, and for $p, q \le i$ we have $\alpha_p \alpha_q \le \alpha_i^2 \le \alpha_i \alpha_{i'} < 1$; by Lemma 5.8.15(ii), $h(y_p, y_q) = 0$ in both cases. So A is isotropic and $B \subseteq A^\perp$; as h is nondegenerate, $\dim A^\perp = N - i = \dim B$, so $B = A^\perp$. With $a = \alpha_i$ and $b = \alpha_{i'}$: A is spanned by $y_1, \dots, y_i \in L_g$ of lengths $\le a$, $A^\perp$ by $y_1, \dots, y_{i'} \in L_g$ of lengths $\le b$, $0 \le a \le b$ and $ab < \theta\kappa$. □

Lemma 5.8.15. *Let* E *be a CM field with maximal totally real subfield* E^+, $f = [E^+ : \mathbb{Q}]$, *ring of integers* $\mathcal{O}_E$ *and discriminant* d_E, *and let* Φ *be the set of infinite places of* E^+. *Let* $N \ge 1$ *and let* U *be a framed space of rank* N *over* E *with hermitian form* h *(conjugate-linear in the first argument) and* $G^U = G_\infty \times G_f$. *Give* $\prod_{v \in \Phi} \mathbb{C}^N$ *the real inner product* $\langle a, b \rangle = \operatorname{Re} \sum_{v \in \Phi} \sum_{i=1}^{N} \bar{a}_{v,i} b_{v,i}$, *its norm* $\|\cdot\|$ *and the Lebesgue measure of* $\langle\,,\rangle$. *For* $g \in G^U$ *let* $L_g = L_g(U)$ *and* $|u|_g$ *be the lattice and the length at* g *of (VP4), that is,*

$$L_g = \{u \in U : \ (g^{-1}c(u))_f \in \widehat{\mathcal{O}}_E^N\}, \qquad |u|_g = \|(g^{-1}c(u))_\infty\|,$$

and put $L_{g,\infty} = \{(g^{-1}c(u))_\infty : \ u \in L_g\}$. *Then for every* $g \in G^U$:

(i) L_g *is a finitely generated* $\mathcal{O}_E$*-submodule of* U *that spans* U *over* E, *and* $L_g = \{w \in U : h(u,w) \in \mathcal{O}_E \text{ for all } u \in L_g\}$;

(ii) if $u, w \in L_g$ *and* $|u|_g \, |w|_g < 1$, *then* $h(u,w) = 0$;

(iii) $L_{g,\infty}$ *is a lattice in the real vector space* $\prod_{v \in \Phi} \mathbb{C}^N$ *of dimension* $2fN$, *and its covolume is* $2^{-fN} |d_E|^{N/2}$;

(iv) the dual lattice $L^*_{g,\infty} = \{y : \langle y, z\rangle \in \mathbb{Z} \text{ for all } z \in L_{g,\infty}\}$ *is* $\{\sigma((g^{-1}c(w))_\infty) : \ w \in 2\mathfrak{D}_E^{-1}L_g\}$*, where* $\mathfrak{D}_E$ *is the different of* E *and* σ *multiplies the coordinate* (v,i) *by the sign* s_i*.*

Proof. Fix an E-basis of U, so that $U = E^N$ and $h(u,w) = \bar{u}^{\mathsf{T}} J w$ with an invertible hermitian $J \in \mathrm{M}_N(E)$, and let $x \in \mathrm{GL}_N(\mathbb{A}_E)$ be the matrix of the frames, so that $c(u) = x^{-1}u$ and $\bar{x}^{\mathsf{T}} J x = D_s$, the adelic matrix equal to $\mathrm{diag}(s)$ at every $v \in \Phi$ and to 1 at the finite places. For $u \in E^N$ put $\alpha(u) = g^{-1}x^{-1}u \in \mathbb{A}_E^N$. As g and g^{-1} preserve D_s,

$$h(u,w) = \overline{\alpha(u)}^{\mathsf{T}} D_s\, \alpha(w) \qquad (u, w \in E^N), \tag{1}$$

an identity in $\mathbb{A}_E$, in which E is embedded diagonally. At $v \in \Phi$, with $\Phi_v \colon E \to \mathbb{C}$ the chosen embedding, (1) reads $\Phi_v(h(u,w)) = \sum_i s_i \overline{\alpha(u)_{v,i}}\, \alpha(w)_{v,i}$; at the finite places it reads $h(u,w) = \overline{\alpha(u)_f}^{\mathsf{T}} \alpha(w)_f$.

(i). We have $L_g = E^N \cap (xg)_f \widehat{\mathcal{O}}_E^N$. The set $(xg)_f\widehat{\mathcal{O}}_E^N$ is a compact open $\widehat{\mathcal{O}}_E$-submodule of $\mathbb{A}_{E,f}^N$, so there are nonzero integers m, m' with $m'\widehat{\mathcal{O}}_E^N \subseteq (xg)_f\widehat{\mathcal{O}}_E^N \subseteq m^{-1}\widehat{\mathcal{O}}_E^N$; as $E \cap \widehat{\mathcal{O}}_E = \mathcal{O}_E$, this gives $m'\mathcal{O}_E^N \subseteq L_g \subseteq m^{-1}\mathcal{O}_E^N$. So L_g is an $\mathcal{O}_E$-module ($\widehat{\mathcal{O}}_E$ is stable under $\mathcal{O}_E$), finitely generated ($\mathcal{O}_E$ is noetherian) and spans E^N. For $u, w \in L_g$ the finite form of (1) gives $h(u,w) \in \widehat{\mathcal{O}}_E \cap E = \mathcal{O}_E$. Conversely let $w \in E^N$ with $h(u,w) \in \mathcal{O}_E$ for all $u \in L_g$. The set $\{\alpha(u)_f : u \in L_g\} = \widehat{\mathcal{O}}_E^N \cap (g^{-1}x^{-1})_f E^N$ is dense in $\widehat{\mathcal{O}}_E^N$, since E^N is dense in $\mathbb{A}_{E,f}^N$ and $\widehat{\mathcal{O}}_E^N$ is open. So $\bar{a}^{\mathsf{T}}\alpha(w)_f \in \widehat{\mathcal{O}}_E$ for all a in a dense subset of $\widehat{\mathcal{O}}_E^N$, hence, $\widehat{\mathcal{O}}_E$ being closed, for all $a \in \widehat{\mathcal{O}}_E^N$; taking for a the unit vectors, $\alpha(w)_f \in \widehat{\mathcal{O}}_E^N$, that is, $w \in L_g$.

(ii). Let $t = h(u,w)$; by (i), $t \in \mathcal{O}_E$. For $v \in \Phi$, by (1) and the Cauchy–Schwarz inequality, $|\Phi_v(t)| \le \|\alpha(u)_v\|\,\|\alpha(w)_v\| \le |u|_g |w|_g < 1$, and the conjugate embedding gives the same modulus. Every embedding of E into $\mathbb{C}$ is Φ_v or its conjugate for some $v \in \Phi$, so $|\mathrm{N}_{E/\mathbb{Q}}(t)| = \prod_{v\in\Phi} |\Phi_v(t)|^2 < 1$; as $\mathrm{N}_{E/\mathbb{Q}}(t) \in \mathbb{Z}$, it is 0, and $t = 0$.

(iii). Let $\beta \colon E^N \otimes_{\mathbb{Q}} \mathbb{R} \to \prod_{v\in\Phi} \mathbb{C}^N$ be the $\mathbb{R}$-linear extension of $u \mapsto \alpha(u)_\infty$. It is the composite of the Minkowski isomorphism $E^N \otimes_{\mathbb{Q}} \mathbb{R} \to \prod_{v\in\Phi} \mathbb{C}^N$, $u \mapsto (\Phi_v(u))_v$ (all infinite places of E are complex, one above each $v \in \Phi$), with the $\mathbb{R}$-linear automorphism $(g^{-1}x^{-1})_\infty$; so β is an isomorphism, and $L_{g,\infty} = \beta(L_g)$ is a lattice, since L_g lies between the lattices $m'\mathcal{O}_E^N$ and $m^{-1}\mathcal{O}_E^N$ of $E^N \otimes \mathbb{R}$. The map σ of (iv) is an isometry of $\prod_v \mathbb{C}^N$. Since $\mathrm{Tr}_{E/\mathbb{Q}}(t) = 2\sum_{v\in\Phi} \mathrm{Re}\,\Phi_v(t)$, (1) gives

$$\mathrm{Tr}_{E/\mathbb{Q}}\, h(u,w) = 2\,\langle \beta(u), \sigma\beta(w)\rangle \qquad (u, w \in E^N). \tag{2}$$

The dual lattice. The form $B(u,w) = \frac{1}{2}\mathrm{Tr}_{E/\mathbb{Q}} h(u,w)$ is $\mathbb{Q}$-bilinear and nondegenerate on E^N (J is invertible and the trace form of $E/\mathbb{Q}$ is nondegenerate). Let $u_1, \dots, u_{2fN} \in L_g$ be a $\mathbb{Z}$-basis of L_g (a $\mathbb{Q}$-basis of E^N) and $w_1, \dots, w_{2fN} \in E^N$ the dual basis for B. By (2), $\langle \beta(u_k), \sigma\beta(w)\rangle = B(u_k, w)$ for $w \in E^N \otimes \mathbb{R}$ ($\mathbb{R}$-linear extension). Every $y \in \prod_v \mathbb{C}^N$ is $\sigma\beta(w)$ for one $w = \sum_k B(u_k,w) w_k \in E^N \otimes \mathbb{R}$, and y lies in the dual lattice $L^*_{g,\infty} = \{y : \langle y, z\rangle \in \mathbb{Z} \text{ for } z \in L_{g,\infty}\}$ if and only if all $B(u_k, w) \in \mathbb{Z}$. Hence $L^*_{g,\infty} = \sigma\beta(M)$ with

$$M = \{w \in E^N : \ \mathrm{Tr}_{E/\mathbb{Q}} h(u,w) \in 2\mathbb{Z} \text{ for all } u \in L_g\}.$$

$M = 2\mathfrak{D}_E^{-1}L_g$, with $\mathfrak{D}_E$ the different of E. As L_g is an $\mathcal{O}_E$-module and $h(tu, w) = \bar{t}\, h(u,w)$, $w \in M$ if and only if $\mathrm{Tr}_{E/\mathbb{Q}}(t\, h(u, \frac{w}{2})) \in \mathbb{Z}$ for all $t \in \mathcal{O}_E$ and $u \in L_g$, that is, $h(u, \frac{w}{2}) \in \mathfrak{D}_E^{-1}$ for all $u \in L_g$. We show $\{w' \in E^N : h(L_g, w') \subseteq \mathfrak{D}_E^{-1}\} = \mathfrak{D}_E^{-1}L_g$. The inclusion $\supseteq$ holds since $h(u, tw'') = t\, h(u, w'') \in \mathfrak{D}_E^{-1}$ for $t \in \mathfrak{D}_E^{-1}$, $u, w'' \in L_g$. Conversely, if $h(L_g, w') \subseteq \mathfrak{D}_E^{-1}$, then $h(L_g, tw') \subseteq \mathcal{O}_E$ for $t \in \mathfrak{D}_E$, so $tw' \in L_g$ by (i); writing $1 = \sum_k a_k t_k$ with $a_k \in \mathfrak{D}_E^{-1}$, $t_k \in \mathfrak{D}_E$, we get $w' = \sum_k a_k (t_k w') \in \mathfrak{D}_E^{-1}L_g$.

Covolumes. Write $\mathrm{cv}(X)$ for the covolume of a lattice X. The $\mathcal{O}_E$-module L_g is torsion free of rank N, so at every prime $\mathfrak{p}$ of $\mathcal{O}_E$ its localisation is free of rank N over the discrete valuation ring $\mathcal{O}_{E,\mathfrak{p}}$; the finite module $\mathfrak{D}_E^{-1}L_g/L_g$ is the direct sum of its localisations $\mathfrak{p}^{-e_\mathfrak{p}}L_{g,\mathfrak{p}}/L_{g,\mathfrak{p}} \cong (\mathcal{O}_{E,\mathfrak{p}}/\mathfrak{p}^{e_\mathfrak{p}})^N$, $e_\mathfrak{p} = v_\mathfrak{p}(\mathfrak{D}_E)$, so $[\mathfrak{D}_E^{-1}L_g : L_g] = \mathrm{N}(\mathfrak{D}_E)^N = |d_E|^N$ (Dedekind: the norm of the different is $|d_E|$). Hence, σ preserving volume and the real dimension being $2fN$,

$$\mathrm{cv}(L_{g,\infty}^*) = \mathrm{cv}(\beta(2\mathfrak{D}_E^{-1}L_g)) = 2^{2fN}\,|d_E|^{-N}\,\mathrm{cv}(L_{g,\infty}).$$

As $\mathrm{cv}(L_{g,\infty}^*)\,\mathrm{cv}(L_{g,\infty}) = 1$, we get $\mathrm{cv}(L_{g,\infty})^2 = 2^{-2fN}|d_E|^N$, which is (iii). The two displays $L_{g,\infty}^* = \sigma\beta(M)$ and $M = 2\mathfrak{D}_E^{-1}L_g$ are (iv). □

Lemma 5.8.16. *Let E be a CM field with maximal totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$, discriminant d_E and root discriminant $\mathrm{rd}_E = |d_E|^{1/(2f)}$; let $N \geq 1$, U a framed space of rank N over E and $G^U = G_\infty \times G_f$. For every $g \in G^U$ there is a basis $y_1, \dots, y_N$ of U over E with $y_j \in L_g$, $|y_1|_g \leq |y_2|_g \leq \cdots \leq |y_N|_g$ and*

$$\prod_{j=1}^{N} |y_j|_g \leq (fN\,\mathrm{rd}_E)^{N/2}.$$

Proof. Identify $U = E^N$ by an E-basis and let $x \in \mathrm{GL}_N(\mathbb{A}_E)$ be the matrix of the frames in this basis, so that $c(u) = x^{-1}u$. Put $a = x_f g_f \in \mathrm{GL}_N(\mathbb{A}_f)$ and $r_v = x_v g_v \in \mathrm{GL}_N(\mathbb{C})$ for $v \in \Phi$. In the notation of Lemma 5.3.83 (with $s = N$),

$$\Lambda = \{u \in E^N :\ g_f^{-1}x_f^{-1}u \in \widehat{\mathcal{O}}_E^N\} = L_g,$$
$$\|u\|_r = \Big(\sum_{v\in\Phi} \|g_v^{-1}x_v^{-1}v(u)\|^2\Big)^{1/2} = \|(g^{-1}c(u))_\infty\| = |u|_g,$$

and $j(\Lambda) = L_{g,\infty}$, for the same euclidean structure on $\prod_v \mathbb{C}^N$.

The determinant factor is 1. By Lemma 5.8.15 (iii), $L_{g,\infty}$ has covolume $2^{-fN}|d_E|^{N/2}$; by (i) of Lemma 5.3.83, it has covolume $2^{-fN}|d_E|^{N/2}[\det a]\prod_v |\det r_v|^{-2}$. Hence $\prod_v |\det r_v|^2\,[\det a]^{-1} = 1$.

The basis. By (ii) of Lemma 5.3.83 there is a basis $y_1, \dots, y_N$ of U over E with $y_j \in \Lambda = L_g$ and $\prod_j |y_j|_g^{2f} = \prod_j \|y_j\|_r^{2f} \leq (fN\,\mathrm{rd}_E)^{fN}$, that is $\prod_j |y_j|_g \leq (fN\,\mathrm{rd}_E)^{N/2}$. Renumbering the y_j by increasing length changes neither the product nor the other properties. □

Lemma 5.8.17. *Let E be a CM field with maximal totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$ and different $\mathfrak{D}_E$, and let $N_D \geq 1$ be a rational integer with $N_D \in \mathfrak{D}_E$. Let $N \geq 1$, U a framed space of rank N over E with hermitian form h, $G^U = G_\infty \times G_f$, and for an integer $M \geq 1$ let $\mathrm{K}(M) = \{k \in \mathrm{K}_f :\ k - 1 \in M\,\mathrm{M}_N(\widehat{\mathcal{O}}_E)\}$ be the principal level M. Let $0 < \delta \leq 1$, $g \in G^U$, $A \subseteq U$ a nonzero isotropic subspace and $0 \leq a \leq b$ real numbers such that A is spanned by vectors $u \in L_g$ with $|u|_g \leq a$, $A^\perp$ is spanned by vectors $w \in L_g$ with $|w|_g \leq b$, and*

$$ab \leq \frac{\delta}{6MN^2fN_D}.$$

Then

$$N_A(\mathbb{A}_{E^+})\,g \subseteq N_A(E^+)\,g\,Z_\delta\,\mathrm{K}(M).$$

Proof. Coordinates. Fix an E-basis $U = E^N$, with $h(u,w) = u^*Jw$ for an invertible hermitian $J \in \mathrm{M}_N(E)$ ($P^* = \bar{P}^{\mathsf{T}}$), and let $x \in \mathrm{GL}_N(\mathbb{A}_E)$ be the matrix of the frames: $c(u) = x^{-1}u$, $x^*Jx = D_s$, the adelic matrix equal to $\mathrm{diag}(s)$ at the infinite places and to 1 at the finite places, and $G^U = \{k \in \mathrm{GL}_N(\mathbb{A}_E) : k^*D_sk = D_s\}$. Put $p = xg$; then $p^*Jp = g^*D_sg = D_s$, that is, $J = (p^{-1})^*D_sp^{-1}$. Choose a basis of A among the given spanning vectors and let $X \in \mathrm{M}_N(E)$ have these vectors as its first columns and 0 as its other columns; likewise $Y \in \mathrm{M}_N(E)$ with a basis of $A^\perp$ chosen among the given spanning vectors. Then $X^*JX = 0$, $X^*JY = 0$, the columns of X and Y lie in L_g, and the columns of $\tilde{X} = p^{-1}X$ and $\tilde{Y} = p^{-1}Y$ are the vectors $g^{-1}c(u)$ of these columns. Let $\mathcal{N}$ and ρ be as in Lemma 5.8.18 for J, X. The unipotent radical of the stabiliser of the isotropic subspace A consists of the isometries that fix A pointwise and act trivially on $A^\perp/A$; for $R = E$ or $R = \mathbb{A}_E$ the second condition on u reads $w^*J(u-1)v = 0$ for $v, w \in R^N$ orthogonal to A, because $A \otimes_E R = \{z : \ w^*Jz = 0 \text{ for all } w \in A^\perp \otimes_E R\}$ ($A = (A^\perp)^\perp$ and R is free over E), and orthogonality to A is orthogonality to the columns of X. Since $G^U = x^{-1}\,\mathrm{U}(J)(\mathbb{A}_E)\,x$ through the frames, $k \mapsto xkx^{-1}$ maps $N_A(\mathbb{A}_{E^+})$ onto $\mathcal{N}(\mathbb{A}_E)$ and $N_A(E^+)$ onto $\mathcal{N}(E)$.

A splitting. There are $e, b' \in \mathrm{M}_N(E)$ with $Ye + b'X^*J = 1$: the kernel of $v \mapsto X^*Jv$ is $A^\perp$, the column space of Y; for a complement C of $A^\perp$ in E^N this map is injective on C, so there is b' with $b'X^*Jv = v$ for $v \in C$, and there is e with Ye the projection onto $A^\perp$ along C; then $v = Yev + b'X^*J(v - Yev) = Yev + b'X^*Jv$. Put $\beta_0 = b'/(2M)$, so $Ye + 2(M\beta_0)X^*J = 1$, and apply Lemma 5.8.18 with $b = M\beta_0$.

Reduction. Let $k \in N_A(\mathbb{A}_{E^+})$ and $n = xkx^{-1} \in \mathcal{N}(\mathbb{A}_E)$. By Lemma 5.8.18(iii), $n = \rho(Yc')$ with $c' = e(n - 1 - MX\beta_0^*Jn)M\beta_0 = Mc$, $c = e(n - 1 - MX\beta_0^*Jn)\beta_0 \in \mathrm{M}_N(\mathbb{A}_E)$. Applying Lemma 5.8.19 to each entry, choose $r(c) \in \mathrm{M}_N(E)$ such that $\Delta c = c - r(c)$ has finite part in $\mathrm{M}_N(\widehat{\mathcal{O}}_E)$ and all entries of modulus $\le \frac{1}{2}fN_D$ at every $v \in \Phi$. Put $c_2 = -M\,r(c)^*Y^*JYc \in \mathrm{M}_N(\mathbb{A}_E)$, choose $r(c_2)$ in the same way, $\Delta c_2 = c_2 - r(c_2)$, and let

$$Z_0 = M\big(Xr(c_2) - Yr(c)\big) \in \mathrm{M}_N(E), \qquad X^*JZ_0 = 0.$$

By Lemma 5.8.18(i) for $R = E$, $\nu_0 = \rho(Z_0) \in \mathcal{N}(E)$. As $Z_0^*J(MYc) = M^2\big(r(c_2)^*X^*JYc - r(c)^*Y^*JYc\big) = Mc_2$, Lemma 5.8.18(ii) gives

$$\nu_0 n = \rho\big(Z_0 + MYc - X(Mc_2)\big) = \rho(V), \qquad V = M\big(Y\Delta c - X\Delta c_2\big).$$

Conjugation by p. Let $T = VX^*$ and $\tilde{t} = (\tilde{Y}\Delta c - \tilde{X}\Delta c_2)\tilde{X}^*$, so $p^{-1}V = M(\tilde{Y}\Delta c - \tilde{X}\Delta c_2)$. From $J = (p^{-1})^*D_sp^{-1}$: $p^{-1}TJp = M\tilde{t}D_s$, $p^{-1}T^*Jp = \tilde{X}(p^{-1}V)^*D_s = M\tilde{t}^*D_s$ and $p^{-1}T^*JTJp = \tilde{X}(p^{-1}V)^*D_s(p^{-1}V)\tilde{X}^*D_s = M^2\tilde{t}^*D_s\tilde{t}D_s$. Hence

$$\kappa_0 := p^{-1}\nu_0 np = 1 + 2(M\tilde{t} - M\tilde{t}^* - M^2\tilde{t}^*D_s\tilde{t})D_s,$$

and $\kappa_0 = g^{-1}(x^{-1}\nu_0 x)\,k\,g \in G^U$.

Finite part. The columns of $\tilde{X}_f$, $\tilde{Y}_f$ lie in $\widehat{\mathcal{O}}_E^N$ (columns of X, Y lie in L_g), $\Delta c_f, (\Delta c_2)_f \in \mathrm{M}_N(\widehat{\mathcal{O}}_E)$ and $(D_s)_f = 1$, so $\tilde{t}_f \in \mathrm{M}_N(\widehat{\mathcal{O}}_E)$ and $(\kappa_0)_f - 1 \in M\,\mathrm{M}_N(\widehat{\mathcal{O}}_E)$. As $(\kappa_0)_f \in G_f$ is integral, $(\kappa_0)_f \in \mathrm{K}_f$, hence $(\kappa_0)_f \in \mathrm{K}(M)$.

Infinite part. Let $v \in \Phi$ and write $\|\cdot\|$ for the operator norm. A column of $\tilde{X}_v$ is $(g^{-1}c(u))_v$ with $\|(g^{-1}c(u))_v\| \le |u|_g \le a$, so $\|\tilde{X}_v\| \le \sqrt{N}\,a$ (Frobenius norm); likewise $\|\tilde{Y}_v\| \le \sqrt{N}\,b$, and $\|\Delta c_v\|, \|(\Delta c_2)_v\| \le N \cdot \frac{1}{2}fN_D$. With $a \le b$,

$$\|\tilde{t}_v\| \le (\sqrt{N}b + \sqrt{N}a)\tfrac{1}{2}NfN_D \cdot \sqrt{N}a \le N^2fN_D\,ab \le \frac{\delta}{6M}.$$

As $\|\mathrm{diag}(s)\| = 1$ and $\delta \le 1$, $\|(\kappa_0)_v - 1\| \le 2\big(\frac{\delta}{6} + \frac{\delta}{6} + \frac{\delta^2}{36}\big) = \frac{2\delta}{3} + \frac{\delta^2}{18} \le \delta$. So $(\kappa_0)_\infty \in Z_\delta$.

Conclusion. With $\nu = x^{-1}\nu_0 x \in N_A(E^+)$ we have $g^{-1}\nu kg = \kappa_0 \in Z_\delta\mathrm{K}(M)$ (G_∞ and G_f embedded as $z \mapsto (z,1)$, $k \mapsto (1,k)$), so $kg = \nu^{-1}g\kappa_0 \in N_A(E^+)\,g\,Z_\delta\,\mathrm{K}(M)$. □

Lemma 5.8.18. *Let E be a CM field and R a commutative E-algebra with an involution $r \mapsto \bar{r}$ extending complex conjugation of E (we use $R = E$ and $R = \mathbb{A}_E$); for a matrix P over R put $P^* = \bar{P}^{\mathsf{T}}$. Let $N \geq 1$, $J \in \mathrm{GL}_N(E)$ with $J^* = J$, and $X, Y, e, b \in \mathrm{M}_N(E)$ with*

$$X^*JX = 0, \qquad X^*JY = 0, \qquad Ye + 2bX^*J = 1.$$

Let $\mathcal{N}(R)$ be the set of $u \in \mathrm{M}_N(R)$ with $u^*Ju = J$, $uX = X$ and $w^*Juv = w^*Jv$ for all $v, w \in R^N$ with $X^*Jv = X^*Jw = 0$. For $W \in \mathrm{M}_N(R)$ with $X^*JW = 0$ put $T = WX^*$ and

$$\rho(W) = 1 + 2\,(T - T^* - T^*JT)\,J.$$

Then:

(i) $\rho(W) \in \mathcal{N}(R)$;

(ii) if also $X^*JZ = 0$, *then* $\rho(W)\rho(Z) = \rho(W + Z - X(W^*JZ))$;

(iii) every $u \in \mathcal{N}(R)$ *equals* $\rho(Yc)$ *with* $c = e\,(u - 1 - Xb^*Ju)\,b \in \mathrm{M}_N(R)$.

Proof. Throughout, P^* is additive, $(PQ)^* = Q^*P^*$ (R is commutative) and $J^* = J$. From $X^*JX = 0$ and $X^*JW = 0$ we get, by applying $*$, $X^*JX = 0$ and $W^*JX = 0$.

Notation for (i) and (ii). For W with $X^*JW = 0$ put $T_W = WX^*$ and $S_W = (T_W - T_W^*)J$. For two such W, Z:

$$\begin{aligned} T_W J T_Z &= W(X^*JZ)X^* = 0, \qquad & T_W^* J T_Z^* &= X(W^*JX)Z^* = 0, \\ T_W J T_Z^* &= W(X^*JX)Z^* = 0, \qquad & T_W^* J T_Z &= X(W^*JZ)X^*, \end{aligned}$$

so

$$\begin{aligned} &S_W S_Z = -X(W^*JZ)X^*J, \qquad S_W X = W(X^*JX) - X(W^*JX) = 0, \\ &X^*JS_W = \big(X^*JW\,X^* - X^*JX\,W^*\big)J = 0. \end{aligned} \tag{1}$$

By (1) every product of three of the matrices $S_W, S_Z, \ldots$ vanishes (the middle factor is killed on the left by X^*J or on the right by X), and $S_W^2 = -T_W^*JT_WJ$; hence

$$\rho(W) = 1 + 2S_W + 2S_W^2. \tag{2}$$

(i). We have $S_W^* = J(T_W^* - T_W)$, so $S_W^*J = -JS_W$ and $(S_W^*)^2J = -S_W^*JS_W = JS_W^2$. By (2), $\rho(W)^*J = J(1 - 2S_W + 2S_W^2)$, and as $S_W^3 = S_W^4 = 0$,

$$\rho(W)^*J\rho(W) = J(1 - 2S_W + 2S_W^2)(1 + 2S_W + 2S_W^2) = J(1 - 4S_W^2 + 4S_W^2) = J.$$

By (1) and (2), $\rho(W)X = X$. Let $v, w \in R^N$ with $X^*Jv = X^*Jw = 0$, hence $w^*JX = 0$. Then $S_Wv = W(X^*Jv) - X(W^*Jv) = -X(W^*Jv)$, so $w^*JS_Wv = -(w^*JX)(W^*Jv) = 0$ and $S_W^2v = -S_WX(W^*Jv) = 0$; hence $w^*J\rho(W)v = w^*Jv$. So $\rho(W) \in \mathcal{N}(R)$.

(ii). Put $V = W + Z - X(W^*JZ)$; then $X^*JV = 0$, and as $(W^*JZ)^* = Z^*JW$,

$$S_V = S_W + S_Z + C, \qquad C = -X\big(W^*JZ - Z^*JW\big)X^*J.$$

By (1), $CS = SC = 0$ for $S \in \{S_W, S_Z\}$ and $C^2 = 0$, so $S_V^2 = (S_W + S_Z)^2$. Expanding with (2) and dropping the products of three or four S's,

$$\rho(W)\rho(Z) - \rho(V) = 4S_WS_Z - 2S_WS_Z - 2S_ZS_W - 2C = 2(S_WS_Z - S_ZS_W) - 2C = 0$$

by the first identity of (1).

(iii). Let $u \in \mathcal{N}(R)$ and $n = u - 1$. Unitarity reads

$$n^*J + Jn + n^*Jn = 0. \tag{3}$$

From $u^*Ju = J$ and $uX = X$: $X^*Ju = (uX)^*Ju = X^*J$, so $X^*Jn = 0$ and, applying $*$, $n^*JX = 0$. The columns of Y satisfy $X^*JY = 0$, so the last condition on u gives $Y^*JnY = 0$. Applying $*$ to $Ye + 2bX^*J = 1$ gives $1 = e^*Y^* + 2JXb^*$; multiplying on the right by JnY,

$$JnY = e^*(Y^*JnY) + 2JX(b^*JnY) = 2JX\gamma, \qquad \text{so} \qquad nY = 2X\gamma, \quad \gamma = b^*JnY. \tag{4}$$

The parameter. With $c = e(n - Xb^*Ju)b$ and $Ye = 1 - 2bX^*J$,

$$W := Yc = (1 - 2bX^*J)(n - Xb^*Ju)b = nb - X\beta, \qquad \beta = b^*Jub,$$

since $X^*Jn = 0$ and $X^*JX = 0$. Also $X^*JW = X^*JYc = 0$. Put $T = WX^*$. *The three terms of* $\rho(W) - 1$. Using $2bX^*J = 1 - Ye$ and (4),

$$2TJ = 2nbX^*J - 2X\beta X^*J = n - nYe - 2X\beta X^*J = n - 2X\gamma e - 2X\beta X^*J.$$

Next $T^* = XW^* = X(b^*n^* - \beta^*X^*)$, so $2T^*J = 2Xb^*n^*J - 2X\beta^*X^*J$. Finally $W^*JW = (b^*n^* - \beta^*X^*)J(nb - X\beta) = b^*n^*Jnb$, the other three terms containing $n^*JX = 0$, $X^*Jn = 0$ or $X^*JX = 0$; so $2T^*JTJ = 2X(b^*n^*Jnb)X^*J$. Hence $\rho(W) - 1 = n + \mathcal{E}$ with

$$\mathcal{E} = -2X\gamma e - 2X(\beta - \beta^*)X^*J - 2Xb^*n^*J - 2X(b^*n^*Jnb)X^*J.$$

$\mathcal{E} = 0$. By (3), $-2Xb^*n^*J = 2Xb^*Jn + 2Xb^*n^*Jn$. Multiplying $n = n(Ye + 2bX^*J)$ on the left by b^*J and by b^*n^*J, and using (4) and $n^*JX = 0$,

$$b^*Jn = \gamma e + 2(b^*Jnb)X^*J, \qquad b^*n^*Jn = 2b^*(n^*JX)\gamma e + 2(b^*n^*Jnb)X^*J = 2(b^*n^*Jnb)X^*J.$$

Substituting,

$$\mathcal{E} = 2X\big(-(\beta - \beta^*) + 2b^*Jnb + b^*n^*Jnb\big)X^*J.$$

As $\beta = b^*Jb + b^*Jnb$ and $\beta^* = b^*u^*Jb = b^*Jb + b^*n^*Jb$, the bracket is $b^*(Jn + n^*J + n^*Jn)b = 0$ by (3). So $\rho(Yc) = 1 + n = u$. □

Lemma 5.8.19. *Let E be a CM field with maximal totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$, Φ the set of infinite places of E^+ with a chosen embedding $\Phi_v \colon E \to \mathbb{C}$ above each $v \in \Phi$, so that $E_\infty = \prod_{v\in\Phi} \mathbb{C}$, and $\mathfrak{D}_E$ the different of E. Let $N_D \geq 1$ be a rational integer with $N_D \in \mathfrak{D}_E$. Then for every $c = (c_\infty, c_f) \in \mathbb{A}_E$ there is $a \in E$ with*

$$c_f - a \in \widehat{\mathcal{O}}_E \qquad \text{and} \qquad |c_v - \Phi_v(a)| \leq \tfrac{1}{2} f N_D \quad \text{for every } v \in \Phi,$$

where $c_v \in \mathbb{C}$ is the component of c_∞ at v.

Proof. The finite part. E is dense in $\mathbb{A}_{E,f}$ (approximation theorem) and $\widehat{\mathcal{O}}_E$ is open, so there is $r \in E$ with $c_f - r \in \widehat{\mathcal{O}}_E$.

The lattice of integers and its dual. Give $\prod_{v\in\Phi} \mathbb{C}$ the real inner product $\langle y, z\rangle = \operatorname{Re} \sum_v \bar{y}_v z_v$, of dimension $2f$, and let $\phi \colon E \to \prod_v \mathbb{C}$, $\phi(t) = (\Phi_v(t))_v$. Every embedding of E is some Φ_v or its conjugate, so $\langle \phi(t), \phi(t')\rangle = \frac{1}{2}\operatorname{Tr}_{E/\mathbb{Q}}(\bar{t}t')$. The image $\Gamma = \phi(\mathcal{O}_E)$ is a lattice (Minkowski). Let $t_1, \ldots, t_{2f}$ be a $\mathbb{Z}$-basis of $\mathcal{O}_E$ and $t'_1, \ldots, t'_{2f} \in E$ the dual basis for the nondegenerate $\mathbb{Q}$-bilinear

form $\frac{1}{2}\mathrm{Tr}_{E/\mathbb{Q}}(\bar{t}t')$; then $\phi(t'_1),\dots,\phi(t'_{2f})$ is the dual basis of $\phi(t_1),\dots,\phi(t_{2f})$, so the dual lattice is

$$\Gamma^* = \phi(M), \qquad M = \{t' \in E :\ \mathrm{Tr}_{E/\mathbb{Q}}(\bar{t}t') \in 2\mathbb{Z} \text{ for all } t \in \mathcal{O}_E\} = 2\mathfrak{D}_E^{-1},$$

as $\bar{t}$ runs through $\mathcal{O}_E$ with t and $\mathfrak{D}_E^{-1} = \{y \in E : \mathrm{Tr}_{E/\mathbb{Q}}(y\mathcal{O}_E) \subseteq \mathbb{Z}\}$.

The dual minimum. Let $0 \neq t' \in M$ and $y = \frac{1}{2}N_D t'$. As $N_D \in \mathfrak{D}_E$, $y \in N_D\mathfrak{D}_E^{-1} \subseteq \mathfrak{D}_E\mathfrak{D}_E^{-1} = \mathcal{O}_E$, and $y \neq 0$, so $|\mathrm{N}_{E/\mathbb{Q}}(y)| = \prod_v |\Phi_v(y)|^2 \geq 1$ and $|\Phi_v(y)| \geq 1$ for some v. Hence $\|\phi(t')\| = \frac{2}{N_D}\|\phi(y)\| \geq \frac{2}{N_D}$.

Rounding. By Theorem A.6.1, with $d = 2f$ and $\lambda = 2/N_D$, the point $z = (c_v - \Phi_v(r))_v$ has some $t \in \mathcal{O}_E$ with $\|z - \phi(t)\| \leq \frac{2f}{2\cdot 2/N_D} = \frac{1}{2}fN_D$. Put $a = r + t$. Then $c_f - a = (c_f - r) - t \in \widehat{\mathcal{O}}_E$ and $|c_v - \Phi_v(a)| = |z_v - \Phi_v(t)| \leq \|z - \phi(t)\| \leq \frac{1}{2}fN_D$ for every v. □

Lemma 5.8.20. *Let E be a CM field, $N \geq 1$, U a framed space of rank N over E, $G^U = G^U_\infty \times G_f$ and $\Gamma_U \subseteq G^U$ the image of $\mathrm{U}(U)(E^+)$ under the frames. For every real T there is a compact set $C \subseteq G^U$ such that for every $g \in G^U$ with $\lambda_U(g)^{-1} \leq T$ some $\gamma \in \Gamma_U$ has $\gamma g \in C$.*

Proof. Fix an E-basis of U, so $U = E^N$ with Gram matrix J; the frames form $x \in \mathrm{GL}_N(\mathbb{A}_E)$ with $\bar{x}^{\mathsf{T}}Jx = D_s$ ($\mathrm{diag}(s_v)$ at the infinite place v, 1 at the finite places), $c(u) = x^{-1}u$, $G^U = \{h \in \mathrm{GL}_N(\mathbb{A}_E) : \bar{h}^{\mathsf{T}}D_s h = D_s\}$ and $\Gamma_U = \{x^{-1}\gamma x :\ \gamma \in \mathrm{GL}_N(E),\ \bar{\gamma}^{\mathsf{T}}J\gamma = J\}$. The set G^U is closed in $M_N(\mathbb{A}_E)$, and its topology is the subspace topology, since inversion $h \mapsto D_s\bar{h}^{\mathsf{T}}D_s$ is continuous for it. Let $c = fN|d_E|$, as in Lemma 5.8.21, and assume $T \geq 0$ (otherwise there is no g).

Step 1: a bounded rational basis. Let g satisfy $\lambda_U(g)^{-1} \leq T$. By Lemma 5.8.21 there is $Y \in \mathrm{GL}_N(E)$ whose columns u_j lie in L_g with $|u_j|_g \leq cT$. The adelic matrix $M = g^{-1}x^{-1}Y$ has columns $g^{-1}c(u_j)$, so M_f has entries in $\widehat{\mathcal{O}}_E$ and every entry of M at every infinite place has modulus at most cT. Thus M lies in the compact set

$$\mathrm{Bx} = \{M \in M_N(\mathbb{A}_E) :\ M_f \in M_N(\widehat{\mathcal{O}}_E),\ |M_{v,ij}| \leq cT \text{ for all } v,i,j\}.$$

As g preserves D_s, $\bar{Y}^{\mathsf{T}}JY = \bar{M}^{\mathsf{T}}\bar{g}^{\mathsf{T}}D_s g M = \bar{M}^{\mathsf{T}}D_s M$.

Step 2: finitely many Gram matrices. The set $Q = \{\bar{M}^{\mathsf{T}}D_s M :\ M \in \mathrm{Bx}\}$ is compact, and $M_N(E)$ is discrete and closed in $M_N(\mathbb{A}_E)$ (E is a discrete subgroup of $\mathbb{A}_E$); so $Q \cap M_N(E)$ is a finite set. For each of its elements T' that is the Gram matrix $\bar{Y}^{\mathsf{T}}JY$ of a basis Y arising in Step 1 choose one such basis $Y_{T'}$; let $F \subseteq \mathrm{GL}_N(\mathbb{A}_E)$ be the finite set of the matrices $Y_{T'}^{-1}x$.

Step 3: the compact set. Let $C = \{h \in G^U :\ h^{-1} \in \mathrm{Bx} \cdot F\}$. As $\mathrm{Bx} \cdot F$ is a finite union of continuous images of Bx, it is compact, $G^U \cap \mathrm{Bx} \cdot F$ is compact, and C, its image under inversion, is compact. For g, Y, M as in Step 1, let $T' = \bar{Y}^{\mathsf{T}}JY$ and $\gamma_0 = Y_{T'}Y^{-1} \in \mathrm{GL}_N(E)$. Then $\bar{\gamma}_0^{\mathsf{T}}J\gamma_0 = \bar{Y}^{-\mathsf{T}}T'Y^{-1} = J$, so $\gamma = x^{-1}\gamma_0 x \in \Gamma_U$, and

$$(\gamma g)^{-1} = g^{-1}x^{-1}\gamma_0^{-1}x = g^{-1}x^{-1}Y\,Y_{T'}^{-1}x = M\,(Y_{T'}^{-1}x) \in \mathrm{Bx} \cdot F.$$

Hence $\gamma g \in C$. □

Lemma 5.8.21. *Let E be a CM field with totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$ and discriminant d_E, let $N \geq 1$ and let U be a framed space of rank N over E, with real group G^U_∞ and $G^U = G^U_\infty \times G_f$. For $g \in G^U$ let*

$$L_g = \{u \in U :\ (g^{-1}c(u))_f \in \widehat{\mathcal{O}}_E^N\}, \qquad |u|_g = \|(g^{-1}c(u))_\infty\|,$$

$c(u) \in \mathbb{A}_E^N$ the coordinate vector of u and $\|\cdot\|$ the Euclidean norm on $\prod_v \mathbb{C}^N$. Then for every $g \in G^U$ there is a basis $u_1,\dots,u_N$ of U over E with $u_j \in L_g$ and

$$|u_j|_g \leq f\,N\,|d_E|\ \lambda_U(g)^{-1} \qquad (1 \leq j \leq N).$$

Proof. Let $L_{g,\infty} = \{(g^{-1}c(u))_\infty : u \in L_g\}$, $\langle\,,\rangle$ and σ be as in Lemma 5.8.15, and let β be the $\mathbb{R}$-linear extension of $u \mapsto (g^{-1}c(u))_\infty$ to $U \otimes_{\mathbb{Q}} \mathbb{R}$, so $|u|_g = \|\beta(u)\|$. Put $n = 2fN$ and $d = |d_E|$. By Lemma 5.8.15(iii), $L_{g,\infty}$ is a lattice of rank n in $\prod_v \mathbb{C}^N$, so $\lambda_1(L_{g,\infty}) = \min\{|u|_g : 0 \neq u \in L_g\} > 0$ and $\lambda_U(g) = \min(1, \lambda_1(L_{g,\infty}))$.

Step 1: $\lambda_1(L^*_{g,\infty}) \geq 2\lambda_1(L_{g,\infty})/d$. By Lemma 5.8.15(iv) a nonzero vector of $L^*_{g,\infty}$ is $\sigma\beta(w)$ with $0 \neq w \in 2\mathfrak{D}_E^{-1}L_g$, $\mathfrak{D}_E$ the different of E. The rational integer $d = \mathrm{N}(\mathfrak{D}_E)$ lies in $\mathfrak{D}_E$, so $\frac{d}{2}w \in d\mathfrak{D}_E^{-1}L_g \subseteq L_g$, and $\frac{d}{2}w \neq 0$. Hence $\lambda_1(L_{g,\infty}) \leq |\frac{d}{2}w|_g = \frac{d}{2}\|\beta(w)\| = \frac{d}{2}\|\sigma\beta(w)\|$.

Step 2: transference. By Banaszczyk's transference theorem [12], $\lambda_n(L_{g,\infty})\lambda_1(L^*_{g,\infty}) \leq n$; with Step 1,

$$\lambda_n(L_{g,\infty}) \leq \frac{n\,d}{2\lambda_1(L_{g,\infty})} = \frac{fN|d_E|}{\lambda_1(L_{g,\infty})} \leq \frac{fN|d_E|}{\lambda_U(g)}.$$

So there are $u'_1, \ldots, u'_n \in L_g$ with $|u'_k|_g \leq fN|d_E|\lambda_U(g)^{-1}$ and $\beta(u'_1), \ldots, \beta(u'_n)$ linearly independent over $\mathbb{R}$. Their E-span W is U: otherwise $\beta(W \otimes_{\mathbb{Q}} \mathbb{R})$ would contain them and have real dimension $2f \dim_E W < n$. Choose $u_1, \ldots, u_N$ among the u'_k forming an E-basis. □

Proposition 5.8.22. *Let E be a CM field, $f = [E^+ : \mathbb{Q}]$, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$ and Γ_U the image of $\mathrm{U}(U)(E^+)$ under the frames. Let $\varphi\colon G_f \to \mathbb{C}$ be locally constant with compact support.*

(i) There is $C \geq 0$ such that for all $g, x \in G^U$

$$\sum_{\gamma \in \Gamma_U} |\varphi((g^{-1}\gamma x)_f)|\, \|(g^{-1}\gamma x)_\infty\|_\infty^{-(8N^2+1)} \leq C\, \lambda_U(x)^{-4fN^2}.$$

(ii) Let $j \geq 0$ and $B \geq 8N^2 + 1 + j$ be integers and $k\colon G_\infty \to \mathbb{C}$ with $\sup_y |k(y)|\, \|y\|_\infty^B < \infty$. There is $C' \geq 0$ such that for all $g, x \in G^U$, every $Z \subseteq \Gamma_U$ and every real $r \geq 0$ with $r\,\|(g^{-1}\gamma x)_\infty\|_\infty \geq 1$ for all $\gamma \in Z$ with $\varphi((g^{-1}\gamma x)_f) \neq 0$,

$$\sum_{\gamma \in Z} |k((g^{-1}\gamma x)_\infty)\, \varphi((g^{-1}\gamma x)_f)| \leq C'\, r^j \lambda_U(x)^{-4fN^2}.$$

In particular ($j = 0$, $r = 1$) for $B > 8N^2$ these sums converge absolutely, with a bound uniform in g and Z.

Proof. Write $A = 8N^2+1$, $\mathrm{ht}(x) = \lambda_U(x)^{-1} \geq 1$ (the height $\mathrm{ht}_U(x)$ of (VP4) of Definition 3.2.2), $G_v = \mathrm{U}(\mathrm{diag}\, s)$, μ_v its Haar measure, and $m(y) = |\varphi(y_f)|\, \|y_\infty\|_\infty^{-A}$ for $y \in G^U$. For $z \in G_v$, $z^{-1} = \mathrm{diag}(s)\bar{z}^{\mathsf{T}}\mathrm{diag}(s)$, so $\|z^{-1}\| = \|z\|$, and $1 = \|zz^{-1}\| \leq \|z\|^2$; hence $\|y\|_\infty \geq 1$. Fix an E-basis of U with Gram matrix J and frames $X \in \mathrm{GL}_N(\mathbb{A}_E)$, so $c(u) = X^{-1}u$ and $\gamma \in \mathrm{U}(U)(E^+)$ goes to $X^{-1}\gamma X \in \Gamma_U$; then $c(\gamma u) = (X^{-1}\gamma X)\, c(u)$. Use L_x, $|u|_x$ as in Lemma 5.8.21 and $c_0 = fN|d_E|$.

Step 1: a level for φ. The support S of φ is compact and open. For $y \in S$ choose an open compact subgroup $J_y \subseteq \mathrm{K}_f$ with φ constant on yJ_y, and an open subgroup J'_y with $J'_yJ'_y \subseteq J_y$; finitely many $y_iJ'_{y_i}$ cover S, and $J = \bigcap_i J'_{y_i}$ is an open compact subgroup of K_f. If $y \in S$ and $u \in J$, then $y \in y_iJ'_{y_i}$ for some i and $y, yu \in y_iJ_{y_i}$, so $\varphi(yu) = \varphi(y)$; if $y \notin S$ and $yu \in S$, the same applied to yu and u^{-1} gives $y \in S$. So $\varphi(yu) = \varphi(y)$ for all $y \in G_f$, $u \in J$.

Step 2: nearly central rational points are trivial. Let $x \in G^U$ and $\gamma \in \Gamma_U$ (from $\gamma_0 \in \mathrm{U}(U)(E^+)$) with $t = x^{-1}\gamma x$, $t_f \in \mathrm{K}_f$ and $\|t_v - 1\| \leq ((c_0+1)\mathrm{ht}(x)^2)^{-1}$ for all v. By Lemma 5.8.21

there is a basis $u_1,\dots,u_N$ of U in L_x with $|u_j|_x \le c_0\mathrm{ht}(x)$. The vector $w=\gamma_0 u_j-u_j$ has $x^{-1}c(w)=(t-1)\,x^{-1}c(u_j)$; its finite part lies in $\widehat{\mathcal{O}}_E^N$ (as t_f is integral), so $w\in L_x$, and

$$|w|_x \le \max_v \|t_v-1\|\,|u_j|_x \le \frac{c_0\,\mathrm{ht}(x)}{(c_0+1)\mathrm{ht}(x)^2} < \lambda_U(x).$$

As every nonzero vector of L_x has length at least $\lambda_U(x)$ ((VP4) of Definition 3.2.2), $w=0$. So γ_0 fixes a basis, $\gamma_0=1$ and $\gamma=1$.

Step 3: disjoint boxes. For $0<\delta\le 1$ let $\mathrm{Bx}_\delta=\{z\in G^U:\ \|z_v-1\|\le\delta \text{ for all } v,\ z_f\in J\}$ and put $\delta(x)=(4(c_0+1)\mathrm{ht}(x)^2)^{-1}\le\frac14$. If $g^{-1}\gamma xz=g^{-1}\gamma' xz'$ with $\gamma,\gamma'\in\Gamma_U$ and $z,z'\in\mathrm{Bx}_{\delta(x)}$, then $x^{-1}\gamma'^{-1}\gamma x=z'z^{-1}$; here $(z'z^{-1})_f\in J\subseteq \mathrm{K}_f$ and, as $\|z_v^{-1}\|=\|z_v\|\le 1+\delta(x)\le 2$,

$$\|z'_v z_v^{-1}-1\|\le\|z'_v-z_v\|\,\|z_v^{-1}\|\le 2\delta(x)\cdot 2=((c_0+1)\mathrm{ht}(x)^2)^{-1}.$$

By Step 2, $\gamma=\gamma'$. So the sets $g^{-1}\gamma x\,\mathrm{Bx}_{\delta(x)}$, $\gamma\in\Gamma_U$, are pairwise disjoint.

Step 4: the majorant on a box and its integral. For $y\in G^U$ and $z\in\mathrm{Bx}_\delta$: $\|(yz)_v\|\le\|y_v\|\,\|z_v\|\le 2\|y_v\|$ and $\varphi((yz)_f)=\varphi(y_f)$ (Step 1), so $m(y)\le 2^{fA}m(yz)$. Next, $\int_{G^U} m=\prod_v\int_{G_v}\|z\|^{-A}d\mu_v\cdot\int_{G_f}|\varphi|$; the last factor is finite (φ is bounded with compact support), and so is each $\int_{G_v}\|z\|^{-A}$: with $h=500N^3$, the vector l with $l_i=N-1+2hi$ has gap h for s, so by Lemma 5.7.38(3) (large gap 0, $c=A>8N^2$) $z\mapsto d_{l/2}(2/\|z\|)^A$ is integrable with $d_{l/2}>0$.

Step 5: volume of a box. Let $\Omega=\{z\in G_v:\|z\|\le 2\}$, a neighbourhood of 1, so $\mu_v(\Omega)>0$. For $D\ge 1$ choose a maximal subset $\{z_i\}\subseteq\Omega$ with $\|z_i-z_{i'}\|>1/(2D)$ for $i\ne i'$. The balls of radius $1/(4D)$ about the z_i in $M_N(\mathbb{C})\cong\mathbb{R}^{2N^2}$ (operator norm) are disjoint and lie in the ball of radius 3 about 0, so comparing Lebesgue volumes there are at most $(12D)^{2N^2}$ of them. For $z\in\Omega$ some z_i has $\|z-z_i\|\le 1/(2D)$, and $w=z_i^{-1}z$ has $\|w-1\|\le\|z_i^{-1}\|\,\|z-z_i\|\le 1/D$. So Ω is covered by $(12D)^{2N^2}$ left translates of $\{w:\|w-1\|\le 1/D\}$, and by left invariance $\mu(\mathrm{Bx}_{1/D})\ge v_0(12D)^{-2N^2 f}$ with $v_0=\prod_v\mu_v(\Omega)\cdot\mu_f(J)>0$.

Step 6: (i). With $\delta=\delta(x)$, Steps 3 and 4 and left invariance of the Haar measure give

$$\mu(\mathrm{Bx}_\delta)\sum_{\gamma\in\Gamma_U} m(g^{-1}\gamma x)\le 2^{fA}\sum_\gamma\int_{\mathrm{Bx}_\delta} m(g^{-1}\gamma xz)\,dz=2^{fA}\sum_\gamma\int_{g^{-1}\gamma x\mathrm{Bx}_\delta} m\le 2^{fA}\int_{G^U} m.$$

By Step 5 with $D=\delta^{-1}=4(c_0+1)\mathrm{ht}(x)^2$, the sum is at most $2^{fA}v_0^{-1}\big(48(c_0+1)\big)^{2N^2 f}\int m\cdot\mathrm{ht}(x)^{4fN^2}$; this is (i).

Step 7: (ii). Let $C_k=\sup|k|\,\|\cdot\|_\infty^B$. For $\gamma\in Z$ with $\varphi((g^{-1}\gamma x)_f)\ne 0$ and $y=(g^{-1}\gamma x)_\infty$, $\|y\|_\infty\ge 1$ and $r\|y\|_\infty\ge 1$ give $\|y\|_\infty^{-B}\le\|y\|_\infty^{-A}\|y\|_\infty^{-j}\le r^j\|y\|_\infty^{-A}$. So each term is at most $C_k r^j m(g^{-1}\gamma x)$, and (i) gives (ii) with $C'=C_kC$. □

Proposition 5.8.23. *Let E be a CM field, $N\ge 1$, $s\in\{\pm1\}^N$, U a framed space of rank N over E with signs $s_v=s$ for all v, $G^U=G_\infty\times G_f$, and Γ_U the image of $\mathrm{U}(U)(E^+)$ under the frames; for $\gamma\in\Gamma_U$ let $\mathrm{charpoly}(\gamma)\in E[X]$ be the characteristic polynomial of the corresponding rational isometry of U. Let $B\ge 13N^3$, let e be a cusp kernel of order B on G_∞, and let $\varphi\colon G_f\to\mathbb{C}$ be locally constant with compact support. There is $D\ge 0$ such that for every $x\in G^U$ and every set $S\subseteq E[X]$*

$$\Big|\sum_{\gamma\in\Gamma_U,\ \mathrm{charpoly}(\gamma)\in S} e\big((x^{-1}\gamma x)_\infty\big)\,\varphi\big((x^{-1}\gamma x)_f\big)\Big|\le D,$$

the sum being absolutely convergent.

Proof. For $\gamma \in \Gamma_U$ write γ_0 for the rational isometry with image γ, so $\mathrm{charpoly}(\gamma) = \mathrm{charpoly}(\gamma_0)$, and $t_\gamma(x) = e((x^{-1}\gamma x)_\infty)\varphi((x^{-1}\gamma x)_f)$.

A left level of φ. Let S_φ be the support of φ, compact and open. For $y \in S_\varphi$ choose an open compact subgroup $J_y \subseteq G_f$ with φ constant on $J_y y$ and an open subgroup J'_y with $J'_y J'_y \subseteq J_y$; finitely many $J'_{y_i} y_i$ cover S_φ; put $J = \bigcap_i J'_{y_i}$, an open subgroup. If $y \in S_\varphi$ and $u \in J$, then $y \in J'_{y_i} y_i$ for some i, so $y, u^{-1}y \in J_{y_i} y_i$ and $\varphi(u^{-1}y) = \varphi(y)$. If $y \notin S_\varphi$ and $u^{-1}y \in S_\varphi$, the same applied to $u^{-1}y$ and u^{-1} gives $y \in S_\varphi$, which is absurd. So $\varphi(u^{-1}y) = \varphi(y)$ for all $u \in J$, $y \in G_f$.

Constants. As $\|y\|_\infty \geq 1$ on G_∞, Proposition 5.8.22(ii) with $j = 0$, $r = 1$, $k = e$ (bounded against $\|\cdot\|_\infty^B$ by (EK4)(b), $B \geq 8N^2 + 1$) gives C_0 with $\sum_{\gamma \in Z} |t_\gamma(x)| \leq C_0 \lambda_U(x)^{-4fN^2}$ for all $x \in G^U$ and $Z \subseteq \Gamma_U$ ($\lambda_U(x)$ the first minimum of (VP4) of Definition 3.2.2); in particular the sum in the statement converges absolutely. Let C_1 be the constant of Lemma 5.8.24 for $k = e$ and φ, C_2 that of Lemma 5.8.26 for e, φ and J, κ_J that of Proposition 5.8.13(ii) for J, and

$$D = \max(C_0,\ C_1 + C_2)\, \kappa_J^{4fN^2}.$$

The bound. Let $x \in G^U$ and $S \subseteq E[X]$, and $Z_S = \{\gamma : \mathrm{charpoly}(\gamma_0) \in S\}$. The first minimum is positive (the nonzero vectors of the lattice $L_{x,\infty}$ of Lemma 5.8.15(iii) have norm bounded below), so there is $\delta > 0$ with $\delta^N = \kappa_J \lambda_U(x)$.

If $\delta > 1$, then $\lambda_U(x)^{-1} = \kappa_J \delta^{-N} < \kappa_J$, and $|\sum_{Z_S} t_\gamma(x)| \leq C_0 \lambda_U(x)^{-4fN^2} \leq C_0 \kappa_J^{4fN^2} \leq D$.

If $\delta \leq 1$, Proposition 5.8.13(ii) gives a nonzero isotropic $A \subseteq U$ and $0 \leq a \leq b$ with $ab \leq \delta$, A and $A^\perp$ spanned by vectors of L_x of lengths at most a and b, and $N_A(\mathbb{A}_{E^+})x \subseteq N_A(E^+)x Z_\delta J$. Split Z_S into $Z_1 = \{\gamma \in Z_S : \gamma_0 A = A\}$ and $Z_2 = Z_S \setminus Z_1$; by absolute convergence $\sum_{Z_S} t_\gamma(x) = \sum_{Z_1} t_\gamma(x) + \sum_{Z_2} t_\gamma(x)$. By Lemma 5.8.26, $|\sum_{Z_1} t_\gamma(x)| \leq C_2(\delta^N \lambda_U(x)^{-1})^{4fN^2} = C_2 \kappa_J^{4fN^2}$, and by Lemma 5.8.24, applied to Z_2 and the frame (A, a, b), $|\sum_{Z_2} t_\gamma(x)| \leq C_1 \kappa_J^{4fN^2}$. Hence $|\sum_{Z_S} t_\gamma(x)| \leq (C_1 + C_2)\kappa_J^{4fN^2} \leq D$. □

Lemma 5.8.24. *Let E be a CM field, $f = [E^+ : \mathbb{Q}]$, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v and hermitian form h, $G^U = G_\infty \times G_f$, and for $\gamma \in \Gamma_U$ let $\gamma_0 \in \mathrm{U}(U)(E^+)$ be the rational isometry whose image is γ. Let $B \geq 13N^3$ be an integer, $k\colon G_\infty \to \mathbb{C}$ with $\sup_y |k(y)|\,\|y\|_\infty^B < \infty$, and $\varphi\colon G_f \to \mathbb{C}$ locally constant with compact support. There is $C \geq 0$ with the following property. Let $x \in G^U$, $\delta \geq 0$, $A \subseteq U$ a nonzero isotropic subspace and $0 \leq a \leq b$ with $ab \leq \delta$ such that A is spanned by vectors $u \in L_x$ with $|u|_x \leq a$ and $A^\perp$ by vectors $w \in L_x$ with $|w|_x \leq b$, and let $Z \subseteq \Gamma_U$ be a set with $\gamma_0 A \neq A$ for all $\gamma \in Z$. Then*

$$\sum_{\gamma \in Z} \left|k((x^{-1}\gamma x)_\infty)\, \varphi((x^{-1}\gamma x)_f)\right| \leq C\, (\delta^N \lambda_U(x)^{-1})^{4fN^2}.$$

Proof. Let Ω be the support of φ, a compact subset of G_f, and c_Ω the constant of Lemma 5.8.25 for Ω. Put $j = 4N^3$; then $8N^2 + 1 + j \leq 13N^3 \leq B$ (as $9N^3 \geq 9N^2 \geq 8N^2 + 1$), and let C' be the constant of Proposition 5.8.22(ii) for j, B, k, φ. Put $C = C' c_\Omega^{4fN^3}$.

Let x, δ, A, a, b, Z be as in the statement and $r = (c_\Omega \delta)^f$. Let $\gamma \in Z$ with $\varphi((x^{-1}\gamma x)_f) \neq 0$, so $(x^{-1}\gamma x)_f \in \Omega$. As γ_0 is injective and $\gamma_0 A \neq A$, $\gamma_0 A \not\subseteq A$, so some vector y of the given spanning set of A has $\gamma_0 y \notin A$. Since h is nondegenerate, $A = (A^\perp)^\perp$, so $h(w, \gamma_0 y) \neq 0$ for some $w \in A^\perp$; writing w as a combination of the given spanning vectors of $A^\perp$ (h is conjugate-linear in its first argument), some spanning vector y' of $A^\perp$ has $h(y', \gamma_0 y) \neq 0$. Here $y, y' \in L_x$ and $|y|_x |y'|_x \leq ab \leq \delta$, so Lemma 5.8.25 gives $r\,\|(x^{-1}\gamma x)_\infty\|_\infty \geq 1$.

So the hypothesis of Proposition 5.8.22(ii) holds for $g = x$, Z and r, and

$$\sum_{\gamma\in Z} \bigl|k((x^{-1}\gamma x)_\infty)\varphi((x^{-1}\gamma x)_f)\bigr| \le C' r^j \lambda_U(x)^{-4fN^2} = C' c_\Omega^{4fN^3} \delta^{4fN^3} \lambda_U(x)^{-4fN^2}$$
$$= C\bigl(\delta^N \lambda_U(x)^{-1}\bigr)^{4fN^2}.$$

□

Lemma 5.8.25. *Let E be a CM field, $f = [E^+ : \mathbb{Q}]$, $N \ge 1$, U a framed space of rank N over E with hermitian form h, $G^U = G_\infty \times G_f$, and for $\gamma \in \Gamma_U$ let $\gamma_0 \in \mathrm{U}(U)(E^+)$ be the rational isometry whose image is γ. Let $\Omega \subseteq G_f$ be compact. There is $c_\Omega \ge 0$ such that for all $x \in G^U$, $\gamma \in \Gamma_U$, $y, y' \in L_x$ and $\delta \ge 0$ with*

$$|y|_x\,|y'|_x \le \delta, \qquad (x^{-1}\gamma x)_f \in \Omega, \qquad h(y', \gamma_0 y) \ne 0,$$

one has $(c_\Omega\delta)^f\,\|(x^{-1}\gamma x)_\infty\|_\infty \ge 1$.

Proof. Fix an E-basis $U = E^N$ with Gram matrix J and let $P \in \mathrm{GL}_N(\mathbb{A}_E)$ be the matrix of the frames, so $c(u) = P^{-1}u$ and $\gamma = P^{-1}\gamma_0 P$. For $t = x^{-1}\gamma x$ and $u \in U$,

$$x^{-1}c(\gamma_0 u) = x^{-1}P^{-1}\gamma_0 P\,P^{-1}u = t\,x^{-1}c(u). \tag{1}$$

At $v \in \Phi$ the frame is a basis in which the form is $\mathrm{diag}(s)$, and x_v preserves $\mathrm{diag}(s)$; so $\Phi_v(h(u,w)) = \overline{(x^{-1}c(u))_v}^{\mathsf{T}}\mathrm{diag}(s)\,(x^{-1}c(w))_v$ and, by the Cauchy–Schwarz inequality,

$$|\Phi_v(h(u,w))| \le \|(x^{-1}c(u))_v\|\,\|(x^{-1}c(w))_v\| \qquad (u, w \in U). \tag{2}$$

The constant. The finite adeles are the increasing union of the open sets $(m!)^{-1}\widehat{\mathcal{O}}_E$, $m \ge 1$, so the compact set of entries of the matrices in Ω lies in one of them: there is an integer $c_\Omega \ge 1$ with $c_\Omega t_f \in \mathrm{M}_N(\widehat{\mathcal{O}}_E)$ for all $t_f \in \Omega$.

The estimate. Let x, γ, y, y', δ be as in the statement and $t = x^{-1}\gamma x$. By (1), $(x^{-1}c(c_\Omega\gamma_0 y))_f = c_\Omega t_f\,(x^{-1}c(y))_f \in \widehat{\mathcal{O}}_E^N$, so $c_\Omega\gamma_0 y \in L_x$, and by Lemma 5.8.15(i) the element $z = h(y', c_\Omega\gamma_0 y) = c_\Omega h(y', \gamma_0 y)$ lies in $\mathcal{O}_E$; it is nonzero. By (2) and (1), for every $v \in \Phi$,

$$|\Phi_v(z)| \le c_\Omega\|(x^{-1}c(y'))_v\|\,\|t_v\|\,\|(x^{-1}c(y))_v\| \le c_\Omega|y'|_x\,|y|_x\,\|t_v\| \le c_\Omega\delta\,\|t_v\|.$$

Every embedding of E is some Φ_v or its conjugate, so $1 \le |\mathrm{N}_{E/\mathbb{Q}}(z)| = \prod_v |\Phi_v(z)|^2$, hence $1 \le \prod_v |\Phi_v(z)| \le (c_\Omega\delta)^f \prod_v \|t_v\| = (c_\Omega\delta)^f \|t_\infty\|_\infty$. □

Lemma 5.8.26. *Let E be a CM field, $f = [E^+ : \mathbb{Q}]$, $N \ge 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$, and for $\gamma \in \Gamma_U$ let $\gamma_0 \in \mathrm{U}(U)(E^+)$ be the rational isometry whose image is γ. Let $B \ge 13N^3$ be an integer, e a cusp kernel of order B on G_∞, $\varphi\colon G_f \to \mathbb{C}$ locally constant with compact support, and $J \subseteq G_f$ an open subgroup with $\varphi(u^{-1}y) = \varphi(y)$ for all $u \in J$, $y \in G_f$. There is $C \ge 0$ with the following property. Let $x \in G^U$, $\delta \ge 0$ and $A \subseteq U$ a nonzero isotropic subspace with $N_A(\mathbb{A}_{E^+})\,x \subseteq N_A(E^+)\,x\,Z_\delta\,J$, and let $S \subseteq E[X]$. Then the sum below converges absolutely and*

$$\Bigl|\sum_{\substack{\gamma\in\Gamma_U:\ \gamma_0 A = A,\\ \mathrm{charpoly}(\gamma_0)\in S}} e\bigl((x^{-1}\gamma x)_\infty\bigr)\,\varphi\bigl((x^{-1}\gamma x)_f\bigr)\Bigr| \le C\,\bigl(\delta^N\lambda_U(x)^{-1}\bigr)^{4fN^2}.$$

Proof. Constants. Since $\|y\|_\infty \geq 1$ on G_∞ ($\|z_v^{-1}\| = \|z_v\|$ for $z_v \in \mathrm{U}(\operatorname{diag} s)$, so $1 \leq \|z_v\|^2$), the hypothesis of Proposition 5.8.22(ii) with $j = 0$ and $r = 1$ holds for every set of rational points; as $B \geq 8N^2 + 1$ and $\sup |e| \, \|\cdot\|_\infty^B < \infty$ by (EK4)(b), there is $C_0 \geq 0$ with

$$\sum_{\gamma \in Z} |e((g^{-1}\gamma x)_\infty)\varphi((g^{-1}\gamma x)_f)| \leq C_0 \lambda_U(x)^{-4fN^2} \qquad (g, x \in G^U,\ Z \subseteq \Gamma_U). \tag{1}$$

Let $\delta_0 > 0$ be the constant of Proposition 5.8.8 for e and $j' = 4fN^3$, and $C = C_0 \delta_0^{-4fN^3}$.

The partial kernel. Fix x, δ, A, S, let $Z = \{\gamma \in \Gamma_U : \gamma_0 A = A,\ \mathrm{charpoly}(\gamma_0) \in S\}$ and, for $g \in G^U$,

$$F(g) = \sum_{\gamma \in Z} t_\gamma(g), \qquad t_\gamma(g) = e\big((g^{-1}\gamma x)_\infty\big)\varphi\big((g^{-1}\gamma x)_f\big).$$

By (1) the sum converges absolutely and $|F| \leq T := C_0 \lambda_U(x)^{-4fN^2}$ on G^U; the sum in the statement is $F(x)$.

F is right J-invariant. For $u \in J$, $(g(1,u))^{-1}\gamma x = (1, u^{-1})\, g^{-1}\gamma x$, and $\varphi(u^{-1}y) = \varphi(y)$; so $t_\gamma(g(1,u)) = t_\gamma(g)$.

$R(e)F = F$. By (EK3) with $x = 1$, $\int e(z)e(z^{-1}y)\, dz = e(y)$ for $y \in G_\infty$. As $(g(h,1))^{-1}\gamma x = (h^{-1}, 1)\, g^{-1}\gamma x$, this gives $\int e(h)\, t_\gamma(g(h,1))\, dh = t_\gamma(g)$ for each γ. By (1),

$$\sum_\gamma \int |e(h)|\, |t_\gamma(g(h,1))|\, dh \leq T \int |e| < \infty,$$

so by Fubini's theorem

$$R(e)F(g) = \sum_\gamma \int e(h) t_\gamma(g(h,1))\, dh = F(g).$$

F is continuous. Let $g, g' \in G^U$ with $g'_f \in g_f J$, an open condition on g'. By the two previous steps and the left invariance of the Haar measure,

$$F(g') = \int e(h) F((g'_\infty h, g'_f))dh = \int e(g'^{-1}_\infty h)\, F((h, g_f))dh,$$

and the same for g; so $|F(g') - F(g)| \leq T \int |e(g'^{-1}_\infty h) - e(g_\infty^{-1}h)|\, dh$, which tends to 0 as $g'_\infty \to g_\infty$ (continuity of left translation in $L^1(G_\infty)$).

F is left invariant under $N_A(E^+)$. Let $\nu \in N_A(E^+) \subseteq \Gamma_U$; ν_0 fixes A pointwise and induces the identity on $A^\perp/A$, and so does ν_0^{-1}. The bijection $\gamma \mapsto \nu^{-1}\gamma$ of Γ_U maps Z onto Z: $\nu_0^{-1}\gamma_0$ keeps A if and only if γ_0 does, and then $\mathrm{charpoly}(\nu_0^{-1}\gamma_0) = \mathrm{charpoly}(\gamma_0)$ by Lemma 5.8.27(ii). Since $t_\gamma(\nu g) = t_{\nu^{-1}\gamma}(g)$ and the sum converges absolutely, $F(\nu g) = F(g)$.

Decay. Proposition 5.8.8, applied to F, T, the subgroup J, δ, A, the point x and $j' = 4fN^3$, gives

$$|F(x)| \leq (\delta/\delta_0)^{4fN^3} T = C_0 \delta_0^{-4fN^3} \delta^{4fN^3} \lambda_U(x)^{-4fN^2} = C\big(\delta^N \lambda_U(x)^{-1}\big)^{4fN^2}.$$

□

Lemma 5.8.27. *Let E be a CM field with maximal totally real subfield E^+, $N \geq 1$, U a nondegenerate hermitian space over E of dimension N with form h, $A \subseteq U$ a nonzero isotropic subspace and $A^\perp = \{w \in U : h(a,w) = 0$ for all $a \in A\}$. Let $\gamma_0 \in \mathrm{U}(U)(E^+)$ with $\gamma_0 A = A$. Then:*

(i) the characteristic polynomial of γ_0 in $E[X]$ is not irreducible;

(ii) if $\nu \in \mathrm{U}(U)(E^+)$ fixes A pointwise and induces the identity on $A^\perp/A$, then $\nu\gamma_0$ and γ_0 have the same characteristic polynomial.

Proof. Let $r = \dim A \geq 1$. As h is nondegenerate, $\dim A^\perp = N - r$, and $A \subseteq A^\perp$ since A is isotropic; so $r \leq N - r$, hence $1 \leq r < N$. For an endomorphism ϕ of U that maps each space of a flag $0 = U_0 \subseteq U_1 \subseteq \cdots \subseteq U_m = U$ into itself, the characteristic polynomial of ϕ is the product of those of the endomorphisms induced on U_i/U_{i-1} (block triangular matrix in an adapted basis).

(i). By the remark, applied to $0 \subseteq A \subseteq U$, the characteristic polynomial of γ_0 is the product of those of $\gamma_0|_A$ and of the map induced on U/A, of degrees $r \geq 1$ and $N - r \geq 1$; so it is not irreducible.

(ii). The isometry γ_0 keeps $A^\perp$: for $w \in A^\perp$ and $a \in A$, $h(a, \gamma_0 w) = h(\gamma_0^{-1}a, w) = 0$, as $\gamma_0^{-1}A = A$. The isometry ν keeps A and $A^\perp$ in the same way, and induces the identity on $U/A^\perp$: for $u \in U$ and $a \in A$, $h(a, \nu u) = h(\nu a, \nu u) = h(a, u)$, so $\nu u - u \in A^\perp$. Hence γ_0, ν and $\nu\gamma_0$ map each space of the flag $0 \subseteq A \subseteq A^\perp \subseteq U$ into itself, and as ν induces the identity on A, on $A^\perp/A$ and on $U/A^\perp$, the maps induced by $\nu\gamma_0$ and by γ_0 on these three quotients coincide. By the remark, $\nu\gamma_0$ and γ_0 have the same characteristic polynomial. □

Proposition 5.8.28. *Let E be a CM field, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$ and Γ_U the image of $\mathrm{U}(U)(E^+)$ under the frames. Fix a Haar measure μ_f on G_f, the product Haar measure on G^U, and on $\Gamma_U\backslash G^U$ the quotient by the counting measure on Γ_U. Let $B > 8N^2$, let e be a cusp kernel of order B on G_∞, and let $K \subseteq \mathrm{K}_f$ be an open subgroup. Assume that the space $\mathcal{A}_K(U, e)$ of forms of type e right invariant under K (FT2) is finite-dimensional, and let $(b_i)_{i\in I}$ be an orthonormal basis for the Petersson product $\langle F, F'\rangle = \int_{\Gamma_U\backslash G^U} \overline{F}F'$ of the measures just fixed. For finitely supported $a = \sum_h a_h h \in \mathbb{C}[G_f]$ put $\phi(y) = \sum_h a_h \mathbf{1}_K(h^{-1}y)$ and $(\rho_U(a)F)(g) = \sum_h a_h F(g(1,h))$. Then for all $g, g' \in G^U$ the series below converges absolutely and*

$$\sum_{\gamma\in\Gamma_U} e((g^{-1}\gamma g')_\infty)\,\phi((g^{-1}\gamma g')_f) = \mu_f(K)\sum_{i\in I}(\rho_U(a)b_i)(g)\,\overline{b_i(g')}.$$

Proof. By Theorem 4.2.18 (through the frames G^U is the adelic unitary group of U and Γ_U its group of rational points) the quotient $\Gamma_U\backslash G^U$ has finite volume, so the inner product is defined on bounded functions; it is positive definite on continuous functions, as a nonzero continuous Γ_U-invariant function is nonzero on the image of a nonempty open set, which has positive measure. For $x \in G^U$ and $\gamma \in \Gamma_U$ write $\kappa_x(\gamma, y) = e((y^{-1}\gamma x)_\infty)\mathbf{1}_K((y^{-1}\gamma x)_f)$.

Step 1: absolute convergence. ϕ is locally constant with compact support, and e has $\sup|e|\,\|\cdot\|_\infty^B < \infty$ with $B \geq 8N^2 + 1$ (EK4)(b). By Proposition 5.8.22(ii) ($j = 0$, $r = 1$, $Z = \Gamma_U$) the left side converges absolutely, and likewise, for every x, $\sum_\gamma |\kappa_x(\gamma, y)| \leq C'\lambda_U(x)^{-4fN^2}$ for all y ($\lambda_U(x)$ the first minimum of (VP4) of Definition 3.2.2), with C' independent of x and y (the test function $\mathbf{1}_K$).

Step 2: the kernel of the level is a form. Fix x and put $P_x(y) = \sum_{\gamma\in\Gamma_U} \kappa_x(\gamma, y)$. By Step 1, P_x is bounded, and it is measurable as a countable sum of measurable functions. For $\delta \in \Gamma_U$, $\kappa_x(\gamma, \delta y) = \kappa_x(\delta^{-1}\gamma, y)$, so P_x is left Γ_U-invariant; for $k \in K$, $(yk)^{-1}\gamma x = k^{-1}(y^{-1}\gamma x)$ has the same real part and finite part in $K(y^{-1}\gamma x)_f$, so P_x is right K-invariant. Moreover $R(e)P_x = P_x$: for $h \in G_\infty$, $(y(h,1))^{-1}\gamma x$ has real part $h^{-1}w_\gamma$, $w_\gamma = (y^{-1}\gamma x)_\infty$, and unchanged finite part, and

$$\int \sum_\gamma |e(h)|\,|\kappa_x(\gamma, y(h,1))|\,dh \leq C'\lambda_U(x)^{-4fN^2}\int |e| < \infty,$$

so summation and integration may be exchanged, and $\int e(h)e(h^{-1}w)\,dh = e(w)$ by (EK3) with $x = 1$. By Lemma 5.8.29, $P_x = R(e)P_x$ is continuous; so $P_x \in \mathcal{A}_K(U, e)$. As $e(z^{-1}) = \overline{e(z)}$ and $\mathbf{1}_K(z^{-1}) = \mathbf{1}_K(z)$, replacing γ by γ^{-1} gives

$$\sum_\gamma e((x^{-1}\gamma g')_\infty)\mathbf{1}_K((x^{-1}\gamma g')_f) = \overline{P_x(g')} \qquad (g' \in G^U). \tag{1}$$

Step 3: $\langle P_x, v\rangle = \mu_f(K)\,v(x)$ for $v \in \mathcal{A}_K(U, e)$. By (1) with $g' = y$, $\overline{P_x(y)}\,v(y) = \sum_\gamma f(\gamma y)$ with $f(y) = e((x^{-1}y)_\infty)\mathbf{1}_K((x^{-1}y)_f)v(y)$, using $v(\gamma y) = v(y)$. The function f is integrable on G^U ($|f| \le \sup|v|\,|e((x^{-1}y)_\infty)|\mathbf{1}_K((x^{-1}y)_f)$), so by the defining property of the quotient measure and left invariance,

$$\langle P_x, v\rangle = \int_{G^U} f = \int_{G_\infty}\int_K e(h)\,v(x(h,k))\,dk\,dh = \mu_f(K)\int_{G_\infty} e(h)v(x(h,1))\,dh = \mu_f(K)\,v(x),$$

since $v(x(h,k)) = v(x(h,1)(1,k)) = v(x(h,1))$ and $R(e)v = v$.

Step 4: one group element. Let $h \in G_f$ and $\phi_h(y) = \mathbf{1}_K(h^{-1}y)$. As $(g(1,h))^{-1}\gamma g' = (1,h^{-1})\,g^{-1}\gamma g'$, (1) with $x = g(1,h)$ gives $\sum_\gamma e((g^{-1}\gamma g')_\infty)\phi_h((g^{-1}\gamma g')_f) = \overline{P_{g(1,h)}(g')}$. Expanding $P = P_{g(1,h)} = \sum_i \langle b_i, P\rangle b_i$ and using Step 3,

$$\overline{P(g')} = \sum_i \langle P, b_i\rangle\,\overline{b_i(g')} = \mu_f(K)\sum_i b_i(g(1,h))\,\overline{b_i(g')} = \mu_f(K)\sum_i (\rho_U(h)b_i)(g)\,\overline{b_i(g')}.$$

Step 5: linearity. $\phi = \sum_h a_h\phi_h$ is a finite sum, each series converges absolutely (Step 1), and both sides are linear in a; Step 4 gives the claim. □

Lemma 5.8.29. *Let E be a CM field, $N \ge 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$ and Γ_U the image of $\mathrm{U}(U)(E^+)$ under the frames. Let e be an idempotent kernel on G_∞, $K \subseteq G_f$ an open subgroup, and F a bounded measurable function on G^U that is left Γ_U-invariant and right K-invariant. Then $\Phi = R(e)F$ is defined everywhere, continuous, bounded by $\sup|F|\int|e|$, left Γ_U-invariant and right K-invariant, and $R(e)\Phi = \Phi$.*

Proof. Let $M = \sup|F|$. For $g \in G^U$ the function $h \mapsto e(h)F(g(h,1))$ is measurable and bounded in modulus by $M|e(h)|$, so $\Phi(g) = \int e(h)F(g(h,1))\,dh$ is defined and $|\Phi(g)| \le M\int|e|$. For $\gamma \in \Gamma_U$, $\Phi(\gamma g) = \Phi(g)$ since $F(\gamma g(h,1)) = F(g(h,1))$; for $k \in K$, $g(1,k)(h,1) = g(h,1)(1,k)$ (the real and finite components commute), so $\Phi(g(1,k)) = \Phi(g)$.

Continuity. Let $g \in G^U$. For $u \in G_\infty$, the substitution $h \mapsto u^{-1}h$ (left invariance of the Haar measure) gives $\Phi(g(u,1)) = \int e(h)F(g(uh,1))\,dh = \int e(u^{-1}h)F(g(h,1))\,dh$, hence

$$|\Phi(g(u,1)) - \Phi(g)| \le M\int_{G_\infty}|e(u^{-1}h) - e(h)|\,dh,$$

which tends to 0 as $u \to 1$, by the continuity of left translation in $L^1(G_\infty)$. For (u,k) with $k \in K$, $\Phi(g(u,k)) = \Phi(g(u,1)(1,k)) = \Phi(g(u,1))$. As $G_\infty \times K$ is a neighbourhood of 1 in G^U, Φ is continuous at g.

Reproduction. For $g \in G^U$, the function $(h,z) \mapsto e(h)e(h^{-1}z)F(g(z,1))$ on $G_\infty \times G_\infty$ is integrable, with $\iint|e(h)|\,|e(h^{-1}z)|\,M\,dz\,dh = M(\int|e|)^2$. By Fubini's theorem and the substitution $z = hh'$,

$$R(e)\Phi(g) = \int e(h)\int e(h')F(g(hh',1))\,dh'\,dh = \int\Big(\int e(h)e(h^{-1}z)\,dh\Big)F(g(z,1))\,dz.$$

The identity (EK3) with $x = 1$ gives $\int e(h)e(h^{-1}z)\,dh = e(1)e(z)/e(1) = e(z)$, so $R(e)\Phi(g) = \Phi(g)$. □

The matching has three clauses, one for each kind of characteristic polynomial. The elliptic clause rests on a description of the elliptic conjugacy classes of a framed space as a product of finite classes, independent of the space, and real classes at each infinite place; this is a local-global statement for hermitian forms [180, 147]. The level cut that follows is linear algebra of Hecke operators at one place, based on the relation $T^+T^- = q^{N-2}(1+(q^N-1)e)$ between the raising operator of a line and its adjoint (Proposition 5.8.52). The group closes with the three statements on the good forms and the definite space announced at the opening of the section.

Theorem 5.8.30. *Let E be a CM field with totally real subfield E^+ and a CM type $(\Phi_v)_v$, let $N \geq 2$, let $K \subseteq \mathrm{K}_f$ be open, let $a \in \mathbb{C}[G_f]$ be finitely supported, and let $\phi(g) = \sum_h a_h \mathbf{1}_K(h^{-1}g)$. Let U be a framed space of rank N over E whose signs do not depend on the infinite place, $s_v = s$ for all v with a fixed $s\colon \{1,\dots,N\} \to \{\pm 1\}$, and let $\lambda = (\lambda_v)_v$, $\lambda_v \in (\frac{N-1}{2} + \mathbb{Z})^N$, have pairwise distinct entries and $|\lambda_{v,i} - \lambda_{v,j}| \geq 500N^3 + 10N^5$ whenever $s_v(i) \neq s_v(j)$. Let $R \in E[X]$.*

(TM1) If R is irreducible and some root of $\Phi_v(R)$, for some infinite place v, has absolute value $\neq 1$, then $I_R^U(\phi) = 0$.

(TM2) Suppose that E contains a primitive 5040-th root of unity and $[E^+ : \mathbb{Q}]$ is even. If R is irreducible and all roots of $\Phi_v(R)$ lie on the unit circle for every v, let $z_v \in \mathrm{U}(N)$ be the diagonal matrix of these roots and χ_{λ_v} the character of the irreducible representation of the compact group $\mathrm{U}(N)$ with Harish-Chandra parameter λ_v. There is $c_R(\phi) \in \mathbb{C}$, depending only on R and ϕ (not on U, s or λ), such that

$$I_R^U(\phi) = c_R(\phi) \prod_v \overline{\chi_{\lambda_v}(z_v)}.$$

(TM3) Suppose that ϕ is cuspidal at a finite place w of E with $w \neq \bar{w}$, and that w' is a finite place of E such that for every $g \in G_f$ with $\phi(g) \neq 0$ the component $g_{w'} \in \mathrm{GL}_N(E_{w'})$ has entries in $\mathcal{O}_{w'}$ and 0 is a simple root of the characteristic polynomial of its reduction modulo w'. If R is not irreducible, then $I_R^U(\phi) = 0$.

Consequently, under the hypotheses of (TM2) and (TM3), for two framed spaces V, V' of rank N with signs s, s', each independent of the infinite place, such that λ satisfies the gap condition for both, $I_R^V(\phi) = I_R^{V'}(\phi)$ for every $R \in E[X]$.

Proof. (TM3) is Proposition 5.8.31.

Normalisations. Replacing the Haar measure dg_v of $\mathrm{U}(\mathrm{diag}(s_v))$ by $\tau\, dg_v$ ($\tau > 0$) divides $d(\lambda_v, s_v)$ by τ and multiplies the quotient measure by τ, so $I_R^U(\phi)$ does not change; a change of μ_f multiplies all $I_R^U(\phi)$ by one positive constant. As (TM1) and (TM3) assert vanishing, for them we take the measures of (FT2) of Definition 3.2.4. Put $e = e_\lambda^U$ and $B = 10N^5$. Since $N \geq 2$, $B \geq 13N^3$. For every v, $2\lambda_v$ has distinct entries congruent to $N-1$ modulo 2 and $|\lambda_{v,i} - \lambda_{v,j}| \geq 500N^3 + B$ whenever $s(i) \neq s(j)$, so by Lemma 5.6.21 e is a cusp kernel of order B on G_∞^U. The subgroup K is open in the compact group K_f, hence compact, so ϕ is locally constant with compact support.

Proof of (TM1). Let R be irreducible and let some root of $\Phi_v(R)$ have absolute value $\neq 1$. Let X_R be the set of $\gamma \in \mathrm{U}(U)(E^+)$ with $\mathrm{charpoly}(\gamma) = R$ and C_R a set of representatives of its conjugacy classes. The function e is continuous with $\sup |e| \, \| \cdot \|_\infty^B < \infty$ by (EK4)(b), so Proposition 5.8.36(ii) with $k = e$ gives

$$I_R^U(\phi) = \sum_{\gamma \in C_R} I_\gamma(e \otimes \phi),$$

the orbital integrals of Definition 5.7.1. Every $\gamma \in C_R$ has the irreducible characteristic polynomial R, a root of whose image under Φ_v lies off the unit circle; so $I_\gamma(e \otimes \phi) = 0$ by Proposition 5.8.38. Hence $I_R^U(\phi) = 0$.

Proof of (TM2). The hypothesis on roots of unity in E is not used. Let R be irreducible with all roots of $\Phi_v(R)$ on the unit circle for every v. If R is not monic of degree N, no $\gamma \in \mathrm{U}(U)(E^+)$ has characteristic polynomial R, so $I_R^U(\phi) = 0$ for every U, and $c_R(\phi) = 0$ works. Let R be monic of degree N; for a framed space U let $X_R(U)$, $\mathcal{C}(U)$, $\mathcal{C}_f(U)$ and $\mathcal{C}_v(s)$ be as in Proposition 5.8.44, and $\mathcal{C}_f$ the set $\mathcal{C}_f(U)$, which by Proposition 5.8.44(i) does not depend on U. For $C \in \mathcal{C}_f$ choose $y_C \in C$; it is the finite component of some $\gamma \in X_R(U)$ for some framed space U, so $Z(y_C)$ is discrete, $I_{y_C}^{\mathrm{fin}}(|\phi|) < \infty$, and $I_{y_C}^{\mathrm{fin}}(\phi)$ does not depend on the choice of y_C (Proposition 5.8.42 (i), (iii) with $k = \|\cdot\|_\infty^{-B}$, (iv)); here I^{fin} is formed with μ_f. Put

$$c_R(\phi) = \sum_{C \in \mathcal{C}_f} I_{y_C}^{\mathrm{fin}}(\phi),$$

which involves only R, ϕ and μ_f; its absolute convergence is shown below.

Fix U, s, λ as in the statement and $e = e_\lambda^U$. The identities of Proposition 5.8.36(ii) and Proposition 5.8.42(ii) are homogeneous under the changes of measure of the first paragraph (replacing dg_v by $\tau\, dg_v$ replaces $d(\lambda_v, s_v)$ by $d(\lambda_v, s_v)/\tau$ and leaves both sides unchanged, and replacing μ_f by $\tau'\mu_f$ multiplies both sides by τ'), so they hold for the measures of the statement. By Proposition 5.8.36(ii) with $k = e$,

$$I_R^U(\phi) = \sum_{[\gamma] \in \mathcal{C}(U)} I_\gamma(e \otimes \phi), \qquad \sum_{[\gamma] \in \mathcal{C}(U)} |I_\gamma(e \otimes \phi)| < \infty.$$

For $\gamma \in X_R(U)$, Proposition 5.8.42(ii), (iii) give $I_\gamma(e \otimes \phi) = I_\gamma^\infty(e)\, I_{\gamma_f}^{\mathrm{fin}}(\phi)$. For an infinite place v and $t \in \mathrm{U}(\operatorname{diag} s)$ with characteristic polynomial $\Phi_v(R)$ put

$$A_v(t) = \int_{\mathrm{U}(\operatorname{diag} s)} d(\lambda_v, s)\, \overline{c_{\lambda_v, s}(h^{-1}th)}\, dh.$$

By Lemma 5.8.43(iv) the class of t contains some $\operatorname{diag}(\zeta_{\sigma(1)}, \dots, \zeta_{\sigma(N)})$, ζ_i the roots of $\Phi_v(R)$, so by Lemma 5.8.49 (applicable: $2\lambda_v$ has gap $500N^3 + 10N^5$ for s, the ζ_i are distinct of absolute value 1) the integral converges absolutely; by invariance of dh under left translation it depends only on the class $[t] \in \mathcal{C}_v(s)$. As e is the product of these kernels over the places, Fubini's theorem gives $I_\gamma^\infty(e) = \prod_v A_v([\gamma_v])$. With Proposition 5.8.44(ii) and Proposition 5.8.42(iv), the classes $[\gamma]$ correspond to the pairs $(C, (\omega_v)_v) \in \mathcal{C}_f \times \prod_v \mathcal{C}_v(s)$, and

$$I_\gamma(e \otimes \phi) = I_{y_C}^{\mathrm{fin}}(\phi) \prod_v A_v(\omega_v).$$

Absolute convergence of $c_R(\phi)$. Let $k_0 = \|\cdot\|_\infty^{-B}$. By Proposition 5.8.36(ii) for (k_0, ϕ) and the Tonelli identity in the proof of Proposition 5.8.42(ii), $\sum_{[\gamma] \in \mathcal{C}(U)} I_\gamma^\infty(k_0)\, I_{\gamma_f}^{\mathrm{fin}}(|\phi|) < \infty$. Fix $(\omega_v^0)_v \in \prod_v \mathcal{C}_v(s)$ (nonempty sets, Proposition 5.8.44(iii)). For the classes $[\gamma]$ corresponding to $(C, (\omega_v^0)_v)$, $C \in \mathcal{C}_f$, the element γ_∞ runs through one conjugacy class of G_∞^U, so $I_\gamma^\infty(k_0)$ is a constant κ, and $\kappa > 0$ (a positive continuous integrand). Hence $\sum_{C \in \mathcal{C}_f} I_{y_C}^{\mathrm{fin}}(|\phi|) < \infty$.

Summation. The sets $\mathcal{C}_v(s)$ are finite and the series over $\mathcal{C}_f$ converges absolutely, so

$$I_R^U(\phi) = \sum_{C \in \mathcal{C}_f} \sum_{(\omega_v) \in \prod_v \mathcal{C}_v(s)} I_{y_C}^{\mathrm{fin}}(\phi) \prod_v A_v(\omega_v) = c_R(\phi) \prod_v S_v, \qquad S_v = \sum_{\omega \in \mathcal{C}_v(s)} A_v(\omega).$$

Let $p = \#\{i : s(i) = 1\}$, $q = N - p$. By Lemma 5.8.43(iv) each class $\omega \in \mathcal{C}_v(s)$ contains $\mathrm{diag}(\zeta_{\sigma(1)}, \dots, \zeta_{\sigma(N)})$ for exactly $p!\,q!$ permutations σ, and every such diagonal matrix lies in one of these classes; so by Lemma 5.8.49

$$S_v = \frac{1}{p!\,q!} \sum_{\sigma \in S_N} A_v(\mathrm{diag}(\zeta_{\sigma(1)}, \dots, \zeta_{\sigma(N)})) = (-1)^{pq}\, \overline{\chi_{\lambda_v}(z_v)}.$$

The signs s are the same at all $[E^+ : \mathbb{Q}]$ infinite places, an even number, so $\prod_v (-1)^{pq} = 1$ and $I_R^U(\phi) = c_R(\phi) \prod_v \overline{\chi_{\lambda_v}(z_v)}$.

Proof of the consequence. Let $R \in E[X]$. If R is irreducible with a root of absolute value $\neq 1$ under some Φ_v, then $I_R^V(\phi) = 0 = I_R^{V'}(\phi)$ by (TM1), applied to $U = V$ and $U = V'$. If R is irreducible with all roots on the unit circle, then by (TM2), with the same $c_R(\phi)$ for both spaces, $I_R^V(\phi) = c_R(\phi) \prod_v \overline{\chi_{\lambda_v}(z_v)} = I_R^{V'}(\phi)$; the right side involves neither the space nor its signs. If R is not irreducible, both terms vanish by (TM3). □

Proposition 5.8.31. *Let E be a CM field with totally real subfield E^+ and a CM type $(\Phi_v)_v$, let $N \geq 2$, and let U be a framed space of rank N over E whose signs do not depend on the infinite place, $s_v = s$ for all v. Let $\lambda = (\lambda_v)_v$, $\lambda_v \in (\frac{N-1}{2} + \mathbb{Z})^N$, have pairwise distinct entries and $|\lambda_{v,i} - \lambda_{v,j}| \geq 500N^3 + 10N^5$ whenever $s(i) \neq s(j)$. Let $K \subseteq \mathrm{K}_f$ be open, $a \in \mathbb{C}[G_f]$ finitely supported and $\phi(g) = \sum_h a_h \mathbf{1}_K(h^{-1}g)$. Suppose that ϕ is cuspidal at a finite place w of E with $w \neq \bar{w}$, and that w' is a finite place of E with $w' \neq \bar{w}'$ such that for every $g \in G_f$ with $\phi(g) \neq 0$ the component $g_{w'} \in \mathrm{GL}_N(E_{w'})$ has entries in $\mathcal{O}_{w'}$ and 0 is a simple root of the characteristic polynomial of its reduction modulo w'. If $R \in E[X]$ is not irreducible, then $I_R^U(\phi) = 0$.*

Proof. Step 1: I_R^U is a linear form on all test functions. Every locally constant compactly supported f on G_f is right invariant under an open subgroup $K' \subseteq \mathrm{K}_f$ and is a finite combination of indicators of cosets hK', that is $f(g) = \sum_h b_h \mathbf{1}_{K'}(h^{-1}g)$ with b finitely supported. By Theorem 5.8.6(ii), applied to K' and b, the sum over γ in $I_R^U(f)$ converges absolutely for every x and is integrable on $\Gamma_U \backslash G^U$. So $I_R^U(f)$ is defined for every such f, and $f \mapsto I_R^U(f)$ is linear.

Step 2: invariance under conjugation. Let $g \in G_f$ and $f^g(z) = f(g^{-1}zg)$. The function $x \mapsto \sum_{\mathrm{charpoly}(\gamma)=R} (e_\lambda^U \otimes f)(x^{-1}\gamma x)$ is left invariant under Γ_U (replacing x by δx permutes the γ by $\gamma \mapsto \delta^{-1}\gamma\delta$, which keeps the characteristic polynomial), and its value for f^g at x is its value for f at $x(1, g)$. The quotient measure on $\Gamma_U \backslash G^U$ is invariant under right translation by G^U, so $I_R^U(f^g) = I_R^U(f)$.

Step 3: support. For $\gamma \in \mathrm{U}(U)(E^+)$ and $x \in G^U$, the image of γ in G_f is conjugate in $\mathrm{GL}_N(\mathbb{A}_{E,f})$, through the finite frame, to the matrix of γ; hence for every finite place u of E at which G_f has the factor $\mathrm{GL}_N(E_u)$, the component $(x^{-1}\gamma x)_{f,u}$ has as characteristic polynomial the image of $\mathrm{charpoly}(\gamma)$ in $E_u[X]$. So if f vanishes at all z with $\mathrm{charpoly}(z_w) = R$, every term of $I_R^U(f)$ vanishes and $I_R^U(f) = 0$.

Step 4: R is a product of two coprime factors. Suppose $I_R^U(\phi) \neq 0$. Then some γ with $\mathrm{charpoly}(\gamma) = R$ and some x give $\phi(g) \neq 0$ for $g = (x^{-1}\gamma x)_f$; so R is monic of degree N, and by Step 3 at w' and the hypothesis, R has coefficients in $\mathcal{O}_{w'}$ and 0 is a simple root of its reduction $\bar{R}$ modulo w'. R is not a proper power: if $R = Q^j$ with $Q \in E[X]$ and $j \geq 2$, we may take Q monic (divide by its leading coefficient, a j-th root of 1); the roots of Q are roots of the monic integral polynomial R, hence integral over $\mathcal{O}_{w'}$, so the coefficients of Q, symmetric functions of them, lie in $\mathcal{O}_{w'}$; then $\bar{R} = \bar{Q}^j$ and $\bar{Q}(0) = 0$, so 0 has multiplicity at least $j \geq 2$ in $\bar{R}$, a contradiction. Let P be a monic irreducible factor of R and $R = P^i C$ with $i \geq 1$ and $P \nmid C$. If $C = 1$, then $R = P$ is irreducible or $R = P^i$ with $i \geq 2$ is a proper power, both excluded. So $A = P^i$ and C are monic of positive degree and coprime, and $R = AC$; their images in $E_w[X]$ are still coprime (a Bezout identity $uA + vC = 1$ maps to $E_w[X]$).

Step 5: conclusion. By Steps 1–3 the linear form $D = I_R^U$ satisfies (i) and (ii) of Proposition 5.8.32 for the images of A and C in $E_w[X]$ (for (i) take $g = \iota_w(g_w)$ in Step 2). Since ϕ is cuspidal at w, Proposition 5.8.32 gives $I_R^U(\phi) = 0$, contradicting the assumption. Hence $I_R^U(\phi) = 0$. □

Proposition 5.8.32. *Let E be a CM field, $N \geq 2$, w a finite place of E with $w \neq \bar{w}$, and $A, C \in E_w[X]$ monic, coprime and of positive degrees with $\deg A + \deg C = N$; let $\Omega = \{z \in G_f : \mathrm{charpoly}(z_w) = AC\}$. Let D be a linear form on the space of locally constant compactly supported functions on G_f such that*

1. *$D\big(f(\iota_w(g)^{-1} \cdot \iota_w(g))\big) = D(f)$ for all f and all $g \in \mathrm{GL}_N(E_w)$, and*
2. *$D(f) = 0$ for every f that vanishes on Ω.*

Let $K \subseteq \mathrm{K}_f$ be open, $b \in \mathbb{C}[G_f]$ finitely supported, and $\phi(g) = \sum_h b_h \mathbf{1}_K(h^{-1}g)$. If ϕ is cuspidal at w, then $D(\phi) = 0$.

Proof. Put $F = E_w$, $G_w = \mathrm{GL}_N(F)$, $K_w = \mathrm{GL}_N(\mathcal{O}_w)$, $a = \deg A$, $c = \deg C$, and let X, M, $g \cdot z = \iota_w(g) z \iota_w(g)^{-1}$ and $\Psi \mapsto \Psi^\flat$ be as in Lemma 5.8.33. Let $N_a \subseteq G_w$ be the group of matrices $n_Z = \begin{pmatrix} 1_a & Z \\ 0 & 1_c \end{pmatrix}$, $Z \in \mathrm{M}_{a\times c}(F)$, with the Haar measure dn that is additive Haar measure in Z, and $P = MN_a$.

Step 1: a form on Ω. Ω is closed in G_f (Lemma 5.8.33(i)), so every locally constant compactly supported f_0 on Ω extends to one on G_f: cover its support by finitely many disjoint sets $V_i \cap \Omega$, $V_i \subseteq G_f$ compact open and pairwise disjoint, on which f_0 is constant, and take $f = \sum_i f_0(V_i \cap \Omega)\mathbf{1}_{V_i}$. By (ii), $D_\Omega(f_0) = D(f)$ does not depend on the extension, and by (i), since Ω is stable under G_w, $D_\Omega(f_0(g^{-1} \cdot \,\cdot)) = D_\Omega(f_0)$.

Step 2: a form on $G_w \times X$. For a locally constant compactly supported Ψ on $G_w \times X$ put $D'(\Psi) = D_\Omega(\Psi^\flat)$ (Lemma 5.8.33(ii)). By the equivariance in Lemma 5.8.33(ii) and Step 1, $D'(\Psi(g_0^{-1}\cdot, \cdot)) = D_\Omega(\Psi^\flat(g_0^{-1} \cdot \,\cdot)) = D'(\Psi)$. X is a closed subset of G_f, hence locally compact, Hausdorff and totally disconnected; so Lemma 5.8.34 applies with $H = G_w$ and $Y = X$: $D'(\Psi) = 0$ whenever $\int_{G_w} \Psi(g, y)\, dg = 0$ for every $y \in X$.

Step 3: the function Ψ. Put $\Psi(g, y) = \mathbf{1}_{K_w N_a}(g)\, \phi(g \cdot y)$. The set $K_w N_a$ is open (a union of translates of K_w) and closed (compact times closed), so Ψ is locally constant. For the support, let $y \in X$ with $y_w = \mathrm{diag}(y_1, y_2)$, and $n = n_Z$. Since products of two matrices of the form $\begin{pmatrix} 0 & * \\ 0 & 0 \end{pmatrix}$ vanish,

$$n_Z y_w n_Z^{-1} = \begin{pmatrix} y_1 & L_y(Z) \\ 0 & y_2 \end{pmatrix}, \qquad L_y(Z) = Zy_2 - y_1 Z. \tag{5.179}$$

L_y is a linear automorphism of $\mathrm{M}_{a\times c}(F)$: $Zy_2 = y_1 Z$ forces $Z = 0$ because y_1, y_2 have no common eigenvalue (their characteristic polynomials A, C are coprime). If $\Psi(g, y) \neq 0$ write $g = k n_Z$ with $k \in K_w$; then $z' = n_Z \cdot y$ lies in the compact set $C' = \bigcup_{k \in K_w} k^{-1} \cdot \mathrm{supp}\, \phi$, and by (5.179) z'_w is block upper triangular, y equals z' away from the place of E^+ below w, y_w is the block diagonal of z'_w, and $Z = L_y^{-1}$ applied to the corner of z'_w. These are continuous functions of z' on the compact set of block upper triangular elements of C', so (g, y) lies in a compact set: Ψ has compact support.

Step 4: the image of Ψ is a multiple of ϕ. Let $z = g \cdot y \in \Omega$ and write $g = kmn$ with $k \in K_w$, $m \in M$, $n \in N_a$ (Iwasawa decomposition $G_w = K_w P$). For $h \in M$, $gh^{-1} = k(mh^{-1})(hnh^{-1})$ with $hnh^{-1} \in N_a$, so $gh^{-1} \in K_w N_a$ iff $mh^{-1} \in K_w N_a \cap M$. This intersection is $K_w \cap M$: if

$mh^{-1} = k'n'$, then $k' \in K_w \cap P$, and an element of $K_w \cap P$ has integral invertible diagonal blocks, so $K_w \cap P = (K_w \cap M)(K_w \cap N_a)$ and $mh^{-1} \in K_w \cap M$. As $\Psi(gh^{-1}, h \cdot y) = \mathbf{1}_{K_w N_a}(gh^{-1})\phi(z)$,

$$\Psi^\flat(z) = \phi(z) \int_M \mathbf{1}_{(K_w \cap M)m}(h)\, dh = c_0\, \phi(z), \qquad c_0 = \mathrm{vol}(K_w \cap M) > 0.$$

Step 5: the fibre integrals vanish. Let $y \in X$. By the integration formula of the Iwasawa decomposition, for suitable Haar measures $\int_{G_w} f(g)\, dg = \int_{K_w} \int_M \int_{N_a} f(kmn)\, dn\, dm\, dk$ for compactly supported continuous f. For $f(g) = \Psi(g, y)$ the integrand vanishes unless $m \in K_w \cap M$ (Step 4 with $h = 1$), and then $km \in K_w$; substituting $k \mapsto km^{-1}$,

$$\int_{G_w} \Psi(g, y)\, dg = c_0 \int_{K_w} \int_{N_a} \phi((kn) \cdot y)\, dn\, dk.$$

Now $n \cdot y = y\, \iota_w(\theta_y(n))$ with $\theta_y(n) = y_w^{-1} n y_w n^{-1} \in N_a$, and by (5.179) $\theta_y(n_Z) = n_{Z'}$ with $Z' = y_1^{-1} L_y(Z)$, a linear automorphism of $\mathrm{M}_{a \times c}(F)$. So

$$\int_{N_a} \phi((kn) \cdot y)\, dn = |\det(y_1^{-1} L_y)|^{-1} \int_{N_a} \phi\big(\iota_w(k)\, y\, \iota_w(n)\, \iota_w(k)^{-1}\big)\, dn = 0$$

by Lemma 5.8.35 with $j = a$ and $x = y$.

Conclusion. By Steps 2, 4 and 5, $c_0 D(\phi) = D_\Omega(c_0 \phi|_\Omega) = D_\Omega(\Psi^\flat) = D'(\Psi) = 0$, so $D(\phi) = 0$. □

Lemma 5.8.33. *Let E be a CM field, $N \geq 2$, and w a finite place of E with $w \neq \bar{w}$; put $F = E_w$ and $G_w = \mathrm{GL}_N(F)$. Let $A, C \in F[X]$ be monic and coprime, of degrees $a, c \geq 1$ with $a + c = N$. Let*

$$\Omega = \{z \in G_f :\ \mathrm{charpoly}(z_w) = AC\},$$
$$X = \{y \in \Omega :\ y_w = \mathrm{diag}(y_1, y_2),\ \mathrm{charpoly}(y_1) = A,\ \mathrm{charpoly}(y_2) = C\},$$

with $y_1 \in \mathrm{GL}_a(F)$, $y_2 \in \mathrm{GL}_c(F)$, and let $M = \mathrm{GL}_a(F) \times \mathrm{GL}_c(F) \subseteq G_w$ (block-diagonal), with a Haar measure dh. Write $g \cdot z = \iota_w(g)\, z\, \iota_w(g)^{-1}$ for $g \in G_w$, $z \in G_f$. Then:

1. *Ω and X are closed in G_f; $\Omega = G_w \cdot X$; and if $g \cdot y = g' \cdot y'$ with $y, y' \in X$, then $h = g'^{-1} g \in M$ and $y' = h \cdot y$.*
2. *For every locally constant compactly supported Ψ on $G_w \times X$ the formula*

$$\Psi^\flat(g \cdot y) = \int_M \Psi(gh^{-1},\, h \cdot y)\, dh \qquad (g \in G_w,\ y \in X)$$

defines a locally constant compactly supported function $\Psi^\flat$ on Ω, and for $g_0 \in G_w$ the function $(g, y) \mapsto \Psi(g_0^{-1} g, y)$ has image $z \mapsto \Psi^\flat(g_0^{-1} \cdot z)$.

Proof. Choose $u, v \in F[X]$ with $uA + vC = 1$. For a matrix $Z \in \mathrm{M}_N(F)$ with $\mathrm{charpoly}(Z) = AC$ put $e(Z) = (vC)(Z)$. By Cayley–Hamilton $(AC)(Z) = 0$, so $e(Z)(1 - e(Z)) = (uv\, AC)(Z) = 0$: $e(Z)$ is an idempotent. Its image is $\ker A(Z)$: $A(Z)e(Z) = (vAC)(Z) = 0$, and if $A(Z)x = 0$ then $x = (uA + vC)(Z)x = e(Z)x$. Likewise $\ker e(Z) = \mathrm{im}(1 - e(Z)) = \ker C(Z)$. So $F^N = \ker A(Z) \oplus \ker C(Z)$, both summands Z-stable. The restriction Z_1 of Z to $\ker A(Z)$ is killed by A, so every root of its characteristic polynomial is a root of A; likewise for the restriction Z_2 to $\ker C(Z)$ and C. Since $\mathrm{charpoly}(Z_1)\mathrm{charpoly}(Z_2) = AC$ and A, C have no common root, $\mathrm{charpoly}(Z_1) = A$ and $\mathrm{charpoly}(Z_2) = C$; in particular $\dim \ker A(Z) = a$. For $y \in X$, $A(y_2)$

is invertible ($uA(y_2) = 1 - vC(y_2) = 1$), so $\ker A(y_w) = F^a \oplus 0$, $\ker C(y_w) = 0 \oplus F^c$, and $e(y_w) = \varepsilon := \operatorname{diag}(1_a, 0_c)$. Also $e(gZg^{-1}) = g\,e(Z)\,g^{-1}$.

(i). The coefficients of $\operatorname{charpoly}(z_w)$ and the blocks of z_w depend continuously on z, so Ω and X are closed. Let $z \in \Omega$ and choose $g \in G_w$ mapping $F^a \oplus 0$ onto $\ker A(z_w)$ and $0 \oplus F^c$ onto $\ker C(z_w)$; then $g^{-1} z_w g$ preserves both coordinate subspaces, and its blocks are conjugate to Z_1, Z_2 for $Z = z_w$, with characteristic polynomials A, C. So $y = g^{-1} \cdot z \in X$ (its components away from the place of E^+ below w are those of z). If $g \cdot y = g' \cdot y'$ with $y, y' \in X$, then $h = g'^{-1} g$ satisfies $h y_w h^{-1} = y'_w$, hence maps $\ker A(y_w) = F^a \oplus 0$ onto $\ker A(y'_w) = F^a \oplus 0$ and $0 \oplus F^c$ onto itself; so $h \in M$, and $y' = h \cdot y$.

Local sections. Let $z_0 = g_0 \cdot y_0 \in \Omega$ with $y_0 \in X$. The map $z \mapsto e(z_w)$ is continuous on Ω and $e(z_{0,w}) = g_0 \varepsilon g_0^{-1}$. Put $x(z) = e(z_w)e(z_{0,w}) + (1 - e(z_w))(1 - e(z_{0,w}))$; it is continuous with $x(z_0) = 1$, so it is invertible on an open neighbourhood U of z_0 in Ω, and $x(z)e(z_{0,w}) = e(z_w)e(z_{0,w}) = e(z_w)x(z)$. For $z \in U$ put $g(z) = x(z) g_0$; then $g(z) \varepsilon g(z)^{-1} = e(z_w)$, so $g(z)^{-1} z_w g(z)$ commutes with ε (as z_w commutes with the polynomial $e(z_w)$ in z_w) and is block diagonal with blocks conjugate to the restrictions of z_w to $\ker A(z_w)$, $\ker C(z_w)$. Hence $y(z) = g(z)^{-1} \cdot z \in X$, and $g \colon U \to G_w$, $y \colon U \to X$ are continuous with $z = g(z) \cdot y(z)$.

(ii), well defined. Let S be the compact support of Ψ and S_1 its projection to G_w. For fixed (g, y) the integrand vanishes unless $gh^{-1} \in S_1$, i.e. $h \in M \cap S_1^{-1} g$, a compact set; the integrand is locally constant, so the integral is finite. If $g \cdot y = g' \cdot y'$, then by (i) $g' = g h_0^{-1}$ and $y' = h_0 \cdot y$ with $h_0 \in M$, and the substitution $h \mapsto h h_0^{-1}$ ($M = \mathrm{GL}_a(F) \times \mathrm{GL}_c(F)$ is unimodular) gives $\int_M \Psi(g' h^{-1}, h \cdot y')\, dh = \int_M \Psi(gh^{-1}, h \cdot y)\, dh$. So $\Psi^\flat$ is well defined on $\Omega = G_w \cdot X$.

(ii), locally constant with compact support. Let $z_0 \in \Omega$, and U, $g(z)$, $y(z)$ as above; shrink U to a compact neighbourhood U_0 of z_0 in Ω. For $z \in U_0$ the integrand $(z, h) \mapsto \Psi(g(z) h^{-1}, h \cdot y(z))$ vanishes unless h lies in the compact set $Q = M \cap S_1^{-1} g(U_0)$, and it is locally constant on $U_0 \times Q$, being a locally constant function composed with a continuous map. Cover $\{z_0\} \times Q$ by finitely many open boxes on which it is constant; on the intersection U_1 of their first factors, $\Psi^\flat(z) = \int_Q \Psi(g(z) h^{-1}, h \cdot y(z))\, dh = \Psi^\flat(z_0)$. The support of $\Psi^\flat$ lies in the image of S under the continuous map $(g, y) \mapsto g \cdot y$, which is compact.

(ii), equivariance. For $z = g \cdot y$, $g_0^{-1} \cdot z = (g_0^{-1} g) \cdot y$, so $\int_M \Psi(g_0^{-1} g h^{-1}, h \cdot y)\, dh = \Psi^\flat((g_0^{-1} g) \cdot y) = \Psi^\flat(g_0^{-1} \cdot z)$. □

Lemma 5.8.34. *Let H be a locally compact totally disconnected group with a left Haar measure μ, and Y a locally compact totally disconnected Hausdorff space. For such a space Z let $C_c^\infty(Z)$ be the space of locally constant complex functions of compact support on Z. Let $D \colon C_c^\infty(H \times Y) \to \mathbb{C}$ be a linear form with*

$$D\big(\Psi(h_0^{-1} \cdot, \cdot)\big) = D(\Psi) \qquad (h_0 \in H,\ \Psi \in C_c^\infty(H \times Y)).$$

Then there is a linear form T on $C_c^\infty(Y)$ with $D(\Psi) = T\big(y \mapsto \int_H \Psi(h, y)\, d\mu(h)\big)$ for every Ψ. In particular $D(\Psi) = 0$ whenever $\int_H \Psi(h, y)\, d\mu(h) = 0$ for every $y \in Y$.

Proof. Product decomposition. Let $\Psi \in C_c^\infty(H \times Y)$. Compact open sets form a basis of both spaces, so every point of the compact support of Ψ has a neighbourhood $U \times V$, with $U \subseteq H$ and $V \subseteq Y$ compact open, on which Ψ is constant; finitely many such boxes $U_1 \times V_1, \dots, U_m \times V_m$ cover the support. Let α run over the nonempty sets $\bigcap_{i \in S} U_i \cap \bigcap_{i \notin S} (H \smallsetminus U_i)$, $S \neq \emptyset$, and β over the analogous sets for the V_i; they are compact open, and the products $\alpha \times \beta$ partition $(\bigcup U_i) \times (\bigcup V_i)$. If a product $\alpha \times \beta$ meets a box $U_i \times V_i$, then $\alpha \subseteq U_i$ and $\beta \subseteq V_i$, so $\alpha \times \beta \subseteq U_i \times V_i$ and Ψ is constant on it; otherwise $\alpha \times \beta$ misses the support. Hence $\Psi = \sum_j c_j\, \mathbf{1}_{\alpha_j} \otimes \mathbf{1}_{\beta_j}$, a finite sum of products $f \otimes \psi$ with $f \in C_c^\infty(H)$, $\psi \in C_c^\infty(Y)$.

Invariant forms on H. Let L be a linear form on $C_c^\infty(H)$ with $L(f(h_0^{-1}\cdot)) = L(f)$, and fix a compact open subgroup K_0. Every $f \in C_c^\infty(H)$ is right invariant under some compact open subgroup $K_1 \subseteq K_0$ (local constancy and compact support), so $f = \sum_j c_j \mathbf{1}_{g_j K_1}$ with finitely many disjoint cosets. By invariance $L(\mathbf{1}_{gK_1}) = L(\mathbf{1}_{K_1})$, and $\mathbf{1}_{K_0}$ is the sum of the $[K_0 : K_1]$ indicators $\mathbf{1}_{kK_1}$, so $L(\mathbf{1}_{K_1}) = L(\mathbf{1}_{K_0})/[K_0 : K_1] = L(\mathbf{1}_{K_0})\mu(K_1)/\mu(K_0)$. Hence $L(f) = \sum_j c_j L(\mathbf{1}_{K_0})\mu(K_1)/\mu(K_0) = \big(L(\mathbf{1}_{K_0})/\mu(K_0)\big)\int_H f\,d\mu$.

Conclusion. For $\psi \in C_c^\infty(Y)$ the form $f \mapsto D(f\otimes\psi)$ is invariant in this sense, so $D(f\otimes\psi) = T(\psi)\int_H f\,d\mu$ with $T(\psi) = D(\mathbf{1}_{K_0}\otimes\psi)/\mu(K_0)$, which is linear in ψ. For $\Psi = \sum_i f_i \otimes \psi_i$,

$$D(\Psi) = \sum_i T(\psi_i)\int_H f_i\,d\mu = T\Big(\sum_i \Big(\int_H f_i\,d\mu\Big)\psi_i\Big) = T\Big(y \mapsto \int_H \Psi(h,y)\,d\mu(h)\Big).$$

□

Lemma 5.8.35. *Let E be a CM field, $N \geq 2$, $K \subseteq \mathrm{K}_f$ open, $a \in \mathbb{C}[G_f]$ finitely supported, $\phi(g) = \sum_h a_h \mathbf{1}_K(h^{-1}g)$, and let w be a finite place of E with $w \neq \bar{w}$ such that ϕ is cuspidal at w. For $1 \leq j \leq N-1$ let $N_j \subseteq \mathrm{GL}_N(E_w)$ be the group of matrices $\begin{pmatrix} 1_j & Z \\ 0 & 1_{N-j}\end{pmatrix}$, with a Haar measure dn. Then for all $k \in \mathrm{GL}_N(\mathcal{O}_w)$ and $x \in G_f$ the function $n \mapsto \phi(\iota_w(k)\,x\,\iota_w(n)\,\iota_w(k)^{-1})$ on N_j is locally constant with compact support, and*

$$\int_{N_j} \phi\big(\iota_w(k)\,x\,\iota_w(n)\,\iota_w(k)^{-1}\big)\,dn = 0.$$

Proof. Write $\bar{m}$ for the reduction modulo w of $m \in \mathrm{GL}_N(\mathcal{O}_w)$, k_w for the residue field, and $K_w(1)$ for the kernel of $m \mapsto \bar{m}$. Take $T = \{1,\dots,j\}$; then $U_T = \{1 + \epsilon Z(1-\epsilon)\} \subseteq \mathrm{GL}_N(k_w)$ is the group of matrices $\begin{pmatrix} 1_j & Z \\ 0 & 1\end{pmatrix}$ over k_w, and reduction maps $N_j(\mathcal{O}_w) = N_j \cap \mathrm{GL}_N(\mathcal{O}_w)$ onto U_T with kernel $N_j \cap K_w(1)$.

Right invariance under $\iota_w(K_w(1))$. Let $g \in G_f$, $t \in \mathrm{GL}_N(k_w)$, and take two families of lifts of the elements ut ($u \in U_T$) that differ only at one u_0, with lifts m, m' there. Subtracting the two vanishing sums of the cuspidality condition gives $\phi(g\,\iota_w(m)) = \phi(g\,\iota_w(m'))$. Every element of $\mathrm{GL}_N(k_w)$ is of the form $u_0 t$ (take $u_0 = 1$), so $\phi(g\,\iota_w(m))$ depends only on $\bar{m}$; with $m = 1$ and $m' \in K_w(1)$ this gives $\phi(g\,\iota_w(m')) = \phi(g)$.

Integrals over $N_j(\mathcal{O}_w)$. Fix k and put $\phi_k(z) = \phi(\iota_w(k) z \iota_w(k)^{-1})$. As $K_w(1)$ is normal in $\mathrm{GL}_N(\mathcal{O}_w)$, ϕ_k is right invariant under $\iota_w(K_w(1))$. For $u \in U_T$ choose $\tilde{n}_u \in N_j(\mathcal{O}_w)$ reducing to u. Then for every $x' \in G_f$

$$\int_{N_j(\mathcal{O}_w)} \phi_k(x'\iota_w(n))\,dn = \mathrm{vol}(N_j \cap K_w(1)) \sum_{u \in U_T} \phi\big(\iota_w(k) x'\,\iota_w(\tilde{n}_u k^{-1})\big) = 0,$$

because $\tilde{n}_u k^{-1} \in \mathrm{GL}_N(\mathcal{O}_w)$ is a lift of $u\bar{k}^{-1}$, so the sum is the cuspidality sum for $g = \iota_w(k)x'$ and $t = \bar{k}^{-1}$.

Integral over N_j. The function $n \mapsto \phi_k(x\iota_w(n))$ is locally constant, and it vanishes unless $\iota_w(n)$ lies in the compact set $x^{-1}\iota_w(k)^{-1}\,\mathrm{supp}(\phi)\iota_w(k)$; since ι_w is a closed embedding and N_j is closed, its support is compact. So it meets only finitely many cosets $n_i N_j(\mathcal{O}_w)$ of the open subgroup $N_j(\mathcal{O}_w)$, and

$$\int_{N_j} \phi_k(x\iota_w(n))\,dn = \sum_i \int_{N_j(\mathcal{O}_w)} \phi_k\big(x\iota_w(n_i)\iota_w(n)\big)\,dn = 0$$

by the previous step with $x' = x\iota_w(n_i)$. □

Proposition 5.8.36. *Let E be a CM field with maximal totally real subfield E^+, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs s, and $G^U = G_\infty \times G_f$. Let $B \geq 13N^3$ be an integer, $k\colon G_\infty \to \mathbb{C}$ measurable with $\sup_{y \in G_\infty} |k(y)|\, \|y\|_\infty^B < \infty$, $\phi\colon G_f \to \mathbb{C}$ locally constant with compact support, and $R \in E[X]$ irreducible. Let X_R be the set of $\gamma \in \mathrm{U}(U)(E^+)$ with* $\mathrm{charpoly}(\gamma) = R$*, and $C_R \subseteq X_R$ a set of representatives of the $\mathrm{U}(U)(E^+)$-conjugacy classes contained in X_R. Then:*

(i) for every $\gamma \in X_R$ the function $x \mapsto (k \otimes \phi)(x^{-1}\gamma x)$ is integrable on $Z_\gamma \backslash G^U$;

(ii) $\sum_{\gamma \in C_R} \int_{Z_\gamma \backslash G^U} |(k \otimes \phi)(x^{-1}\gamma x)|\, dx < \infty$, the series $\sum_{\gamma \in X_R} (k \otimes \phi)(x^{-1}\gamma x)$ converges absolutely for every $x \in G^U$, its sum is integrable on $\Gamma_U \backslash G^U$, and

$$\int_{\Gamma_U \backslash G^U} \sum_{\gamma \in X_R} (k \otimes \phi)(x^{-1}\gamma x)\, dx = \sum_{\gamma \in C_R} I_\gamma(k \otimes \phi).$$

Proof. Write $G = G^U$, $\Gamma_0 = \mathrm{U}(U)(E^+)$, identified with Γ_U through the frames, and $f_\gamma(x) = (k \otimes \phi)(x^{-1}\gamma x)$ for $\gamma \in \Gamma_0$, $x \in G$. These functions are measurable (k is measurable, ϕ is locally constant). For $\delta \in \Gamma_0$, $f_\gamma(\delta x) = f_{\delta^{-1}\gamma\delta}(x)$, and f_γ is left invariant under Z_γ.

Quotient measures. G is a second countable locally compact group, and $\Gamma_0 \subseteq \mathrm{GL}_N(E)$ is countable; every subgroup Δ of Γ_U is a countable discrete subgroup of G, and the quotient measure on $\Delta \backslash G$ is the measure with $\int_{\Delta\backslash G} \sum_{\delta \in \Delta} f(\delta x)\, dx = \int_G f$ for measurable $f \geq 0$ on G. Let $Z \subseteq \Delta$ be subgroups of Γ_U and $F \geq 0$ measurable on G and left Z-invariant. Then

$$\int_{Z\backslash G} F(x)\, dx = \int_{\Delta \backslash G} \sum_{\delta \in Z\backslash\Delta} F(\delta x)\, dx. \tag{5.180}$$

Indeed, a countable discrete subgroup of a second countable locally compact group has a Borel fundamental domain D (a Borel set meeting every orbit Zx in exactly one point). For $f = F\mathbf{1}_D$ we have $\sum_{\zeta \in Z} f(\zeta x) = F(x)$ for all x, hence $\int_{Z\backslash G} F = \int_G f = \int_{\Delta\backslash G} \sum_{\delta\in\Delta} f(\delta x)\, dx$, and grouping Δ into the cosets $Z\delta$ turns the inner sum into $\sum_{\delta \in Z\backslash\Delta} \sum_{\zeta \in Z} f(\zeta\delta x) = \sum_{\delta \in Z\backslash\Delta} F(\delta x)$. By linearity, (5.180) also holds for every complex left Z-invariant measurable F with $\int_{Z\backslash G} |F| < \infty$, the inner series then converging absolutely for almost every x.

A uniform bound. Every $\gamma \in X_R$ has irreducible characteristic polynomial, so Lemma 5.8.37 (applicable: $B \geq 13N^3$, $\sup |k|\, \|\cdot\|_\infty^B < \infty$, ϕ locally constant with compact support) gives $C \geq 0$ with

$$S(x) := \sum_{\gamma \in X_R} |f_\gamma(x)| \leq C \qquad (x \in G).$$

Conjugation by $\delta \in \Gamma_0$ preserves the characteristic polynomial and so permutes X_R; with $f_\gamma(\delta x) = f_{\delta^{-1}\gamma\delta}(x)$ this shows $S(\delta x) = S(x)$. By Theorem 4.2.18, applied to $\mathrm{U}(U)$ over E/E^+ (through the frames $G = \mathrm{U}(U)(\mathbb{A}_{E^+})$ and Γ_U is the image of $\mathrm{U}(U)(E^+)$), $\Gamma_U \backslash G$ has finite volume; so $\int_{\Gamma_U\backslash G} S \leq C \,\mathrm{vol}(\Gamma_U \backslash G) < \infty$.

Orbits. For $\gamma \in C_R$ the map $Z_\gamma \delta \mapsto \delta^{-1}\gamma\delta$ is a bijection from $Z_\gamma \backslash \Gamma_0$ onto the conjugacy class of γ ($\delta^{-1}\gamma\delta = \delta'^{-1}\gamma\delta'$ if and only if $\delta'\delta^{-1} \in Z_\gamma$), and X_R is the disjoint union of these classes. Hence

$$S(x) = \sum_{\gamma \in C_R} \sum_{\delta \in Z_\gamma \backslash \Gamma_0} |f_\gamma(\delta x)|.$$

Integrating over $\Gamma_U \backslash G$, exchanging the integral with the sum over C_R (Tonelli) and applying (5.180) with $Z = Z_\gamma$, $\Delta = \Gamma_U$, $F = |f_\gamma|$ gives

$$\sum_{\gamma \in C_R} \int_{Z_\gamma \backslash G} |f_\gamma| = \int_{\Gamma_U \backslash G} S < \infty.$$

This is the first assertion of (ii), and it gives (i) for $\gamma \in C_R$. For an arbitrary $\gamma \in X_R$ write $\gamma = \delta^{-1}\gamma'\delta$ with $\gamma' \in C_R$, $\delta \in \Gamma_0$; then $Z_\gamma = \delta^{-1}Z_{\gamma'}\delta$, $f_\gamma(x) = f_{\gamma'}(\delta x)$, and $x \mapsto \delta x$ induces a bijection $Z_\gamma\backslash G \to Z_{\gamma'}\backslash G$ which preserves the quotient measures (the measure of G is left invariant, and $\zeta \mapsto \delta\zeta\delta^{-1}$ carries counting measure on Z_γ to that on $Z_{\gamma'}$); so f_γ is integrable on $Z_\gamma\backslash G$. This proves (i).

The identity. As $S \le C$, the series $\sum_{\gamma\in X_R} f_\gamma(x)$ converges absolutely for every x; its sum is measurable, left Γ_U-invariant and bounded by S, hence integrable on $\Gamma_U\backslash G$. Since $\int_{\Gamma_U\backslash G}\sum_{\gamma\in C_R}\sum_{\delta\in Z_\gamma\backslash\Gamma_0}|f_\gamma(\delta x)|\,dx = \int S < \infty$, the integral may be exchanged with the double series (Fubini for the counting measure on the countable index set), and (5.180) for the integrable f_γ gives

$$\int_{\Gamma_U\backslash G}\sum_{\gamma\in X_R} f_\gamma = \sum_{\gamma\in C_R}\int_{\Gamma_U\backslash G}\sum_{\delta\in Z_\gamma\backslash\Gamma_0} f_\gamma(\delta x)\,dx = \sum_{\gamma\in C_R}\int_{Z_\gamma\backslash G} f_\gamma = \sum_{\gamma\in C_R} I_\gamma(k\otimes\phi),$$

the last integrals being absolutely convergent by (i), so that they are the orbital integrals (5.124). □

Lemma 5.8.37. *Let E be a CM field, $N \ge 1$, $s \in \{\pm1\}^N$, U a framed space of rank N over E with signs $s_v = s$ for all v, $G^U = G_\infty \times G_f$, and for $\gamma \in \Gamma_U$ let $\gamma_0 \in \mathrm{U}(U)(E^+)$ be the rational isometry whose image is γ. Let $B \ge 13N^3$ be an integer, $k\colon G_\infty \to \mathbb{C}$ with $\sup_y |k(y)|\,\|y\|_\infty^B < \infty$, and $\varphi\colon G_f \to \mathbb{C}$ locally constant with compact support. There is $C \ge 0$ such that for every $x \in G^U$*

$$\sum_{\substack{\gamma\in\Gamma_U:\ \mathrm{charpoly}(\gamma_0)\\ \textit{irreducible in } E[X]}} |k((x^{-1}\gamma x)_\infty)\,\varphi((x^{-1}\gamma x)_f)| \le C.$$

Proof. Let $f = [E^+ : \mathbb{Q}]$ and Z the set of $\gamma \in \Gamma_U$ with $\mathrm{charpoly}(\gamma_0)$ irreducible. As $\|y\|_\infty \ge 1$ on G_∞ and $B \ge 8N^2 + 1$, Proposition 5.8.22(ii) with $j = 0$, $r = 1$ gives C_0 with

$$\sum_{\gamma\in Z} |k((x^{-1}\gamma x)_\infty)\varphi((x^{-1}\gamma x)_f)| \le C_0\lambda_U(x)^{-4fN^2}$$

for all x ($\lambda_U(x)$ the first minimum of (VP4) of Definition 3.2.2). Let C_1 be the constant of Lemma 5.8.24 for k, φ, and κ that of Proposition 5.8.13(ii) for the open subgroup G_f; put $C = \max(C_0, C_1)\kappa^{4fN^2}$.

Let $x \in G^U$. The first minimum is positive (the nonzero vectors of the lattice $L_{x,\infty}$ of Lemma 5.8.15(iii) have norm bounded below), so there is $\delta > 0$ with $\delta^N = \kappa\lambda_U(x)$. If $\delta > 1$, then $\lambda_U(x)^{-1} < \kappa$ and the sum is at most $C_0\kappa^{4fN^2} \le C$. If $\delta \le 1$, Proposition 5.8.13(ii) gives a nonzero isotropic $A \subseteq U$ and $0 \le a \le b$ with $ab \le \delta$ such that A and $A^\perp$ are spanned by vectors of L_x of lengths at most a and b. By Lemma 5.8.27(i), no $\gamma \in Z$ has $\gamma_0 A = A$. So Lemma 5.8.24 applies to Z and bounds the sum by $C_1(\delta^N\lambda_U(x)^{-1})^{4fN^2} = C_1\kappa^{4fN^2} \le C$. □

Proposition 5.8.38. *Let E be a CM field with maximal totally real subfield E^+ and, for each infinite place v of E^+, the chosen embedding $\Phi_v\colon E \to \mathbb{C}$ above v. Let $N \ge 1$, $s \in \{\pm1\}^N$, U a framed space of rank N over E with signs s, $G^U = G_\infty \times G_f$, $B \ge 13N^3$ an integer, e a cusp kernel of order B on G_∞, and $\phi\colon G_f \to \mathbb{C}$ locally constant with compact support. Let $\gamma \in \mathrm{U}(U)(E^+)$ have irreducible characteristic polynomial $R \in E[X]$, and suppose that for some infinite place v some root of $\Phi_v(R)$ (the polynomial with coefficients mapped by Φ_v) has absolute value $\ne 1$. Then*

$$I_\gamma(e\otimes\phi) = 0.$$

Proof. For $t \in \mathrm{U}(U)(E^+)$ write t_∞ for the real component of its image in Γ_U and $t_v \in \mathrm{U}(\operatorname{diag} s)$ for the component of t_∞ at v: it is the matrix of $t \otimes 1$ on $U \otimes_{E,\Phi_v} \mathbb{C}$ in the frame at v. So $t \mapsto t_v$ is a homomorphism, and $A = \gamma_v$ has characteristic polynomial $\Phi_v(R)$. As R is irreducible over a field of characteristic 0 it is separable, so $\Phi_v(R)$ has N distinct roots $\zeta_1, \dots, \zeta_N$, and $|\zeta_i| \neq 1$ for some i. Hence there is $k \in \mathrm{GL}_N(\mathbb{C})$ with $kAk^{-1} = \operatorname{diag}(\zeta_1, \dots, \zeta_N)$. Let $q \in \mathbb{C}^{1\times N}$ be the i-th row of k, a nonzero row vector, and $|\cdot|$ the standard norm of row vectors; for a matrix b, $|wb| \le |w|\,\|b\|$, $\|b\|$ the operator norm (that of b^{T} is the same).

Rows of the diagonaliser. $qA = \zeta_i q$, the i-th row of $\operatorname{diag}(\zeta)k = kA$. If $t \in \mathrm{GL}_N(\mathbb{C})$ commutes with A, then $M = ktk^{-1}$ commutes with $\operatorname{diag}(\zeta)$; comparing entries, $\zeta_a M_{ab} = M_{ab}\zeta_b$, so $M_{ab} = 0$ for $a \neq b$ and M is diagonal and invertible. Hence $qt = M_{ii}\, q$ with $M_{ii} \neq 0$.

The function H. Put $H(y) = \log|q\, y_v|$ for $y \in G_\infty$; it is well defined (y_v is invertible and $q \neq 0$) and continuous. For $a, b \in G_\infty$, $|qa_v b_v| \le |qa_v|\,\|b_v\|$ and $|qa_v| \le |qa_v b_v|\,\|b_v^{-1}\|$, and $\|b_v^{-1}\| = \|b_v\|$ because $b_v^{-1} = \operatorname{diag}(s)\bar{b}_v^{\mathsf{T}}\operatorname{diag}(s)$; as $\|b_v\| \ge 1$ and $\log r \le r$,

$$|H(ab) - H(a)| \le \log\|b_v\| \le \|b_v\| \le \|b\|_\infty.$$

Moreover $H(\gamma_\infty y) = \log|qAy_v| = \log|\zeta_i| + H(y)$, and for $t \in \mathrm{U}(U)(E^+)$ commuting with γ, t_v commutes with A, so $H(t_\infty y) = \log|M_{ii}| + H(y)$ with $M = kt_v k^{-1}$.

Conclusion. Lemma 5.8.39 applies with $\ell = \log|\zeta_i|$ and gives $\log|\zeta_i| \cdot I_\gamma(e \otimes \phi) = 0$. Since $|\zeta_i| \neq 1$, $\log|\zeta_i| \neq 0$, so $I_\gamma(e \otimes \phi) = 0$. □

Lemma 5.8.39. *Let E be a CM field with maximal totally real subfield E^+, $N \ge 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs s, $G^U = G_\infty \times G_f$, $B \ge 13N^3$ an integer, e a cusp kernel of order B on G_∞, $\phi\colon G_f \to \mathbb{C}$ locally constant with compact support, and $\gamma \in \mathrm{U}(U)(E^+)$ with irreducible characteristic polynomial; for $t \in \mathrm{U}(U)(E^+)$ write $t_\infty \in G_\infty$ for the real component of its image in Γ_U. Let $H\colon G_\infty \to \mathbb{R}$ be measurable with*

$$|H(ab) - H(a)| \le \|b\|_\infty \qquad (a, b \in G_\infty),$$

let $\ell \in \mathbb{R}$ with $H(\gamma_\infty y) = \ell + H(y)$ for all $y \in G_\infty$, and suppose that for every $t \in \mathrm{U}(U)(E^+)$ commuting with γ there is $r_t \in \mathbb{R}$ with $H(t_\infty y) = r_t + H(y)$ for all y. Then

$$\ell \cdot I_\gamma(e \otimes \phi) = 0.$$

Proof. Let m, $c(x) = x^{-1}\gamma x$, the rotation ρ and the kernel $P = P_\gamma$ (for e, ϕ) be as in Lemma 5.8.41 and Lemma 5.8.40; then $c(x)_\infty = x_\infty^{-1}\gamma_\infty x_\infty$. On triples $(x, y, u) \in G^U \times G_\infty \times G_\infty$ put

$$a_1 = H(x_\infty y) - H(x_\infty), \qquad a_2 = H(x_\infty yu) - H(x_\infty y), \qquad a_3 = \ell + H(x_\infty) - H(x_\infty yu),$$

measurable functions with $a_1 + a_2 + a_3 = \ell$. For $\zeta \in Z_\gamma$, $(\zeta x)_\infty = \zeta_\infty x_\infty$ and $H(\zeta_\infty w) = r_\zeta + H(w)$, so each a_i is left invariant under Z_γ in x.

Integrability. By the Lipschitz bound, $|a_1| \le \|y\|_\infty$ and $|a_2| \le \|u\|_\infty$; as $\|\cdot\|_\infty \ge 1$ on G_∞, the weights 1, a_1, a_2 are bounded by $\|y\|_\infty\|u\|_\infty$. So P, a_1P, a_2P are m-integrable by Lemma 5.8.40, and so is $a_3P = \ell P - a_1P - a_2P$.

The rotation moves the weights. Let $(x', y', u') = \rho(x, y, u)$. Then $x'_\infty = x_\infty y$, $y' = u$ and $x_\infty yuu' = x_\infty c(x)_\infty = \gamma_\infty x_\infty$, so $x'_\infty y'u' = \gamma_\infty x_\infty$ and

$$a_1 \circ \rho = H(x_\infty yu) - H(x_\infty y) = a_2, \qquad a_2 \circ \rho = H(\gamma_\infty x_\infty) - H(x_\infty yu) = a_3,$$

using $H(\gamma_\infty x_\infty) = \ell + H(x_\infty)$. Since $P \circ \rho = P$ (Lemma 5.8.41(b)), Lemma 5.8.41(a) applied to $f = a_1 P$ (with $f \circ \rho = a_2 P$) and to $f = a_2 P$ (with $f \circ \rho = a_3 P$) gives

$$\int a_2 P \, dm = \int a_1 P \, dm, \qquad \int a_3 P \, dm = \int a_2 P \, dm.$$

Idempotence kills a_2. Let $b(x,w) = H(x_\infty w) - H(x_\infty)$, measurable and left Z_γ-invariant in x. Then $b(x, yu) = a_1 + a_2$ and $b(x,y) = a_1$, both integrable against P; Lemma 5.8.41(c) gives $\int (a_1 + a_2) P \, dm = \int a_1 P \, dm$, so $\int a_2 P \, dm = 0$, and hence $\int a_1 P \, dm = \int a_3 P \, dm = 0$.

Conclusion. By Lemma 5.8.41(b) (P is m-integrable) $\int P \, dm = I_\gamma(e \otimes \phi)$, so

$$\ell \, I_\gamma(e \otimes \phi) = \int (a_1 + a_2 + a_3) P \, dm = 0.$$

□

Lemma 5.8.40. *Let E be a CM field with maximal totally real subfield E^+, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs s, $G^U = G_\infty \times G_f$, $B \geq 13N^3$ an integer, e a cusp kernel of order B on G_∞, $\phi \colon G_f \to \mathbb{C}$ locally constant with compact support, and $\gamma \in \mathrm{U}(U)(E^+)$ with irreducible characteristic polynomial. For $x \in G^U$ and $y, u \in G_\infty$ put $c = x^{-1}\gamma x$ and*

$$P_\gamma(x,y,u) = e(y)\, e(u)\, e(u^{-1}y^{-1}c_\infty)\, \phi(c_f).$$

Let $a \colon G^U \times G_\infty \times G_\infty \to \mathbb{C}$ be measurable, left invariant under Z_γ in the first variable, with $|a(x,y,u)| \leq \|y\|_\infty \|u\|_\infty$. Then aP_γ is integrable on $(Z_\gamma \backslash G^U) \times G_\infty \times G_\infty$ for the product of the quotient measure and the measures of G_∞.

Proof. Write $\|\cdot\| = \|\cdot\|_\infty$. For $z \in G_\infty$ every component $z_v \in \mathrm{U}(\mathrm{diag}\, s)$ satisfies $z_v^{-1} = \mathrm{diag}(s) \bar{z}_v^{\mathsf{T}} \mathrm{diag}(s)$, so $\|z_v\| = \|z_v^{-1}\| \geq 1$; hence $\|z\| \geq 1$, and $\|zw\| \leq \|z\|\,\|w\|$. The function P_γ is left invariant under Z_γ in x ($x^{-1}\gamma x$ is), and aP_γ is measurable (e is continuous, ϕ locally constant).

Let $C_e = \sup_z |e(z)|\,\|z\|^B$, finite by (EK4)(b), and $M(y) = |e(y)|\,\|y\|^{B+1}$, integrable on G_∞ by (EK4)(a). Fix (x,y,u), put $c = x^{-1}\gamma x$ and $z = u^{-1}y^{-1}c_\infty$. Then $c_\infty = yuz$, so $\|c_\infty\| \leq \|y\|\,\|u\|\,\|z\|$ and

$$|e(z)| \leq C_e \|z\|^{-B} \leq C_e \left(\|y\|\,\|u\|\right)^B \|c_\infty\|^{-B}.$$

Hence

$$|a(x,y,u) P_\gamma(x,y,u)| \leq \|y\|\,\|u\|\,|e(y)|\,|e(u)|\,|e(z)|\,|\phi(c_f)| \leq C_e\, M(y)\, M(u)\, |(k_0 \otimes \phi)(x^{-1}\gamma x)|,$$

with $k_0(w) = \|w\|^{-B}$ on G_∞. The function k_0 is continuous and $\sup |k_0|\,\|\cdot\|^B = 1$, so by Proposition 5.8.36(i) the function $x \mapsto (k_0 \otimes \phi)(x^{-1}\gamma x)$ is integrable on $Z_\gamma \backslash G^U$. By Tonelli's theorem the right side, a product of integrable functions of x, of y and of u, is integrable on $(Z_\gamma \backslash G^U) \times G_\infty \times G_\infty$, and therefore so is aP_γ. □

Lemma 5.8.41. *Let E be a CM field with maximal totally real subfield E^+, $N \geq 1$, $s \in \{\pm 1\}^N$, U a framed space of rank N over E with signs s, $G^U = G_\infty \times G_f$, and $\gamma \in \mathrm{U}(U)(E^+)$. Let m be the product of the quotient measure on $Z_\gamma \backslash G^U$ and the measures of G_∞ on $(Z_\gamma \backslash G^U) \times G_\infty \times G_\infty$. For $x \in G^U$ write $c(x) = x^{-1}\gamma x$, and define*

$$\rho(x,y,u) = \left(x\,(y,1),\ u,\ u^{-1}y^{-1}c(x)_\infty\right) \qquad (x \in G^U,\ y,u \in G_\infty).$$

(a) *Let f be measurable on $G^U \times G_\infty \times G_\infty$, left invariant under Z_γ in the first variable, such that f and $f \circ \rho$ are m-integrable. Then $\int f \circ \rho \, dm = \int f \, dm$.*

Let moreover e be an idempotent kernel on G_∞, $\phi\colon G_f \to \mathbb{C}$ measurable and bounded, and

$$P_\gamma(x,y,u) = e(y)\, e(u)\, e\big(u^{-1}y^{-1}c(x)_\infty\big)\, \phi\big(c(x)_f\big).$$

(b) *$P_\gamma \circ \rho = P_\gamma$; and if P_γ is m-integrable, then $x \mapsto (e \otimes \phi)(x^{-1}\gamma x)$ is integrable on $Z_\gamma\backslash G^U$ and $\int P_\gamma \, dm = I_\gamma(e \otimes \phi)$.*

(c) *Let $b\colon G^U \times G_\infty \to \mathbb{C}$ be measurable and left invariant under Z_γ in the first variable, such that $(x,y,u) \mapsto b(x,yu)P_\gamma(x,y,u)$ and $(x,y,u) \mapsto b(x,y)P_\gamma(x,y,u)$ are m-integrable. Then*

$$\int b(x,yu)\, P_\gamma(x,y,u)\, dm = \int b(x,y)\, P_\gamma(x,y,u)\, dm.$$

Proof. Write ν for the quotient measure on $Z_\gamma\backslash G^U$ and $\mu = dy\, du$ on $G_\infty \times G_\infty$. For $\zeta \in Z_\gamma$, $c(\zeta x) = c(x)$; so $\rho(\zeta x, y, u) = (\zeta x(y,1), u, u^{-1}y^{-1}c(x)_\infty)$, and ρ, $f \circ \rho$, P_γ are compatible with the left action of Z_γ in the first variable. The groups G_∞ and G^U are unimodular (products of reductive groups over local fields, restricted at the finite places); hence the Haar measure of G_∞ is invariant under inversion and under left and right translations, and ν is invariant under right translation by elements of G^U (for measurable $f_0 \ge 0$ on G^U and $g \in G^U$, $\int_{Z_\gamma\backslash G^U} \sum_\zeta f_0(\zeta x g)\, dx = \int f_0(xg)\, dx = \int f_0$).

(a) For $x \in G^U$ let $T_x(y,u) = (u,\ u^{-1}c(x)_\infty y^{-1})$. Then T_x preserves μ: it is $(y,u) \mapsto (c(x)_\infty y^{-1}, u)$, which preserves μ by invariance of dy under inversion and left translation, followed by $(w,u) \mapsto (u, u^{-1}w)$, which preserves μ because $\int\int g(u,u^{-1}w)\, dw\, du = \int\int g(u,w')\, dw'\, du$ by left invariance of dw. Since $c(x(y,1))_\infty = y^{-1}c(x)_\infty y$,

$$\rho(x,y,u) = \big(x(y,1),\ T_{x(y,1)}(y,u)\big).$$

By Fubini's theorem for the integrable $f \circ \rho$,

$$\int f \circ \rho \, dm = \int \Big(\int f(x(y,1), T_{x(y,1)}(y,u))\, d\nu(x) \Big) d\mu(y,u).$$

For fixed (y,u) the function $F(x) = f(x, T_x(y,u))$ is left Z_γ-invariant, and the inner integral is $\int F(x(y,1))\, d\nu(x) = \int F\, d\nu$ by the right invariance of ν. The map $\Theta(x,y,u) = (x, T_x(y,u))$ is a measurable bijection of $(Z_\gamma\backslash G^U) \times G_\infty \times G_\infty$ preserving m (for each x, T_x preserves μ; Tonelli), so $f \circ \Theta$ is m-integrable with $\int f \circ \Theta \, dm = \int f \, dm$, and by Fubini $\int\int f(x, T_x(y,u))\, d\nu(x)\, d\mu = \int f \circ \Theta \, dm$. Together, $\int f \circ \rho \, dm = \int f \, dm$.

(b) Let $(x',y',u') = \rho(x,y,u)$. Then $c(x') = (y,1)^{-1}c(x)(y,1)$, so $c(x')_f = c(x)_f$ and $u'^{-1}y'^{-1}c(x')_\infty = \big(c(x)_\infty^{-1}yu\big)u^{-1}y^{-1}c(x)_\infty y = y$. Hence

$$P_\gamma(\rho(x,y,u)) = e(u)\, e\big(u^{-1}y^{-1}c(x)_\infty\big)\, e(y)\, \phi\big(c(x)_f\big) = P_\gamma(x,y,u).$$

By (EK3) with $x = 1$, $\int e(z)e(z^{-1}w)\, dz = e(w)$ for every $w \in G_\infty$; below it is used only at points w where the integrand is integrable, which Fubini's theorem supplies. Suppose P_γ is m-integrable. By Fubini, for ν-almost every x the function $(y,u) \mapsto P_\gamma(x,y,u)$ is μ-integrable, and for such x and almost every y the function $u \mapsto e(u)e(u^{-1}y^{-1}c(x)_\infty)$ is integrable; by (EK3) its integral is $e(y^{-1}c(x)_\infty)$. Then $y \mapsto e(y)e(y^{-1}c(x)_\infty)$ is integrable with integral $e(c(x)_\infty)$, again by (EK3). So for ν-almost every x,

$$\int P_\gamma(x,y,u)\, d\mu(y,u) = e(c(x)_\infty)\, \phi\big(c(x)_f\big) = (e \otimes \phi)(x^{-1}\gamma x),$$

and the left side is a ν-integrable function of x with integral $\int P_\gamma\,dm$. Hence $x \mapsto (e\otimes\phi)(x^{-1}\gamma x)$ is integrable on $Z_\gamma\backslash G^U$ and $\int P_\gamma\,dm = I_\gamma(e\otimes\phi)$.

(c) By Fubini, for ν-almost every x both

$$(y,u)\mapsto b(x,yu)P_\gamma(x,y,u) \quad\text{and}\quad (y,u)\mapsto b(x,y)P_\gamma(x,y,u)$$

are μ-integrable; fix such an x and write $c=c(x)$. In the first, substitute $u=y^{-1}w$ for fixed y (left invariance of du); the resulting function

$$(y,w)\mapsto b(x,w)e(y)e(y^{-1}w)e(w^{-1}c_\infty)\phi(c_f)$$

is the image of an integrable function under a μ-preserving bijection, hence integrable, and Fubini in the order w outside gives

$$\begin{aligned}\int b(x,yu)P_\gamma(x,y,u)\,d\mu &= \int b(x,w)\,e(w^{-1}c_\infty)\,\phi(c_f)\Big(\int e(y)e(y^{-1}w)\,dy\Big)dw\\ &= \int b(x,w)\,e(w)\,e(w^{-1}c_\infty)\,\phi(c_f)\,dw,\end{aligned}$$

the inner integral being $e(w)$ by (EK3) for almost every w. In the second, integrating first over u gives, by (EK3), $\int e(u)e(u^{-1}y^{-1}c_\infty)\,du = e(y^{-1}c_\infty)$ for almost every y, so

$$\int b(x,y)P_\gamma(x,y,u)\,d\mu = \int b(x,y)\,e(y)\,e(y^{-1}c_\infty)\,\phi(c_f)\,dy.$$

The two right sides agree. Integrating over x (Fubini for the two m-integrable functions) gives (c). □

Proposition 5.8.42. *Let E be a CM field with maximal totally real subfield E^+ and chosen embeddings $\Phi_v\colon E\to\mathbb{C}$ at the infinite places v of E^+. Let $N\ge 1$, $s\in\{\pm1\}^N$, U a framed space of rank N over E with signs s, and $G^U = G_\infty\times G_f$. Let $R\in E[X]$ be irreducible such that every root of $\Phi_v(R)$ has absolute value 1 for every v, and let $\gamma\in \mathrm{U}(U)(E^+)$ have characteristic polynomial R; write $\gamma_\infty\in G_\infty$ and $\gamma_f\in G_f$ for the components of its image in Γ_U. For $y\in G_f$ let $E[y]=\{r(y): r\in E[X]\}\subseteq \mathrm{M}_N(\mathbb{A}_{E,f})$ and $Z(y)=E[y]\cap G_f$. For functions k on G_∞ and ϕ on G_f put*

$$I_\gamma^\infty(k)=\int_{G_\infty} k(h^{-1}\gamma_\infty h)\,dh, \qquad I_y^{\mathrm{fin}}(\phi)=\int_{Z(y)\backslash G_f}\phi(v^{-1}yv)\,dv,$$

when $Z(y)$ is discrete and the integrals converge absolutely.

(i) $t\mapsto t_f$ (the finite component of the image in Γ_U) is an isomorphism of Z_γ onto $Z(\gamma_f)$, and $Z(\gamma_f)$ is a discrete subgroup of G_f.

(ii) If k, ϕ are measurable with $I_\gamma^\infty(|k|)<\infty$ and $I_{\gamma_f}^{\mathrm{fin}}(|\phi|)<\infty$, then $x\mapsto(k\otimes\phi)(x^{-1}\gamma x)$ is integrable on $Z_\gamma\backslash G^U$ and $I_\gamma(k\otimes\phi)=I_\gamma^\infty(k)\,I_{\gamma_f}^{\mathrm{fin}}(\phi)$.

(iii) If $B\ge 13N^3$ is an integer, k is measurable with $\sup|k|\,\|\cdot\|_\infty^B<\infty$ and ϕ is locally constant with compact support, then $I_\gamma^\infty(|k|)<\infty$ and $I_{\gamma_f}^{\mathrm{fin}}(|\phi|)<\infty$.

(iv) For $g\in G_f$ and $y=g^{-1}\gamma_f g$, $Z(y)=g^{-1}Z(\gamma_f)g$, and $I_y^{\mathrm{fin}}(|\phi|)=I_{\gamma_f}^{\mathrm{fin}}(|\phi|)$ and $I_y^{\mathrm{fin}}(\phi)=I_{\gamma_f}^{\mathrm{fin}}(\phi)$ for every measurable ϕ for which the latter integral converges absolutely.

Proof. Write $G = G^U$, $Z = Z_\gamma$ and $Z^f = Z(\gamma_f)$. In a basis of U the image of $t \in \mathrm{U}(U)(E^+)$ in G_f is $t_f = x_U^{-1} t x_U$, x_U the finite frame as a matrix (Definition 5.7.1); so $r(t)_f = r(t_f)$ for $r \in E[X]$ whenever $r(t)$ is unitary, and $t \mapsto t_f$ is injective ($\mathrm{M}_N(E) \to \mathrm{M}_N(\mathbb{A}_{E,f})$ is injective).

(i) *The centraliser.* The characteristic polynomial R of γ is irreducible, so it is the minimal polynomial of γ, $L = E[X]/(R)$ is a field, and U is an L-vector space (X acting by γ) of dimension $N/\deg R = 1$. An E-linear map commuting with γ is L-linear, hence multiplication by an element of L, that is $r(\gamma)$ for some $r \in E[X]$. So Z_γ is the image of $E[\gamma] \cap \mathrm{U}(U)(E^+)$, and its finite components lie in $E[\gamma_f] \cap G_f = Z^f$.

Surjectivity. The map $L \to \mathrm{M}_N(\mathbb{A}_{E,f})$, $r \mapsto r(\gamma_f)$, is a well defined E-algebra map ($R(\gamma_f) = x_U^{-1} R(\gamma) x_U = 0$ by Cayley–Hamilton), injective as L is a field. The class α of X is invertible in L; for $r \in E[X]$ let $r^\natural \in E[X]$ represent $\bar{r}(\alpha^{-1})$, where $\bar{r}$ has conjugated coefficients. For the standard form, $g^* = \bar{g}^{\mathsf{T}}$ and $\gamma_f^* = \gamma_f^{-1}$, so $r(\gamma_f)^* = \bar{r}(\gamma_f^{-1}) = r^\natural(\gamma_f)$; likewise, for the adjoint with respect to the form of U (conjugate-linear in scalars), $r(\gamma)^* = \bar{r}(\gamma^{-1}) = r^\natural(\gamma)$. Hence, using the injectivity of $r \mapsto r(\gamma_f)$ and of $r \mapsto r(\gamma)$ on L,

$$r(\gamma_f) \in G_f \iff r^\natural(\alpha) r(\alpha) = 1 \text{ in } L \iff r(\gamma) \in \mathrm{U}(U)(E^+).$$

So every element $r(\gamma_f)$ of Z^f is t_f for $t = r(\gamma) \in Z_\gamma$; with injectivity, $t \mapsto t_f$ is an isomorphism $Z_\gamma \to Z^f$.

Discreteness. At an infinite place v, $\gamma_v \in \mathrm{U}(\operatorname{diag} s)$ has characteristic polynomial $\Phi_v(R)$, whose roots are distinct (R is separable) and of absolute value 1. For $t \in Z_\gamma$, t_v commutes with γ_v, so by Lemma 5.8.43(i) t_v lies in the set C_v of elements of $\mathrm{U}(\operatorname{diag} s)$ acting on each eigenline of γ_v by a scalar of absolute value 1; in an eigenbasis these are the diagonal matrices with entries in the unit circle, so C_v is compact. Let $W \subseteq G_f$ be a compact open neighbourhood of 1. As Γ_U is discrete in G, $Z \cap (\prod_v C_v \times W)$ is a discrete subset of a compact set, hence finite; by injectivity $Z^f \cap W$ is finite. A subgroup of a Hausdorff group that meets some neighbourhood of 1 in a finite set is discrete; so Z^f is discrete.

(ii) Z^f is a countable discrete subgroup of the second countable group G_f, so it has a Borel fundamental domain D_f for its action by left multiplication. Then $D = G_\infty \times D_f$ is a Borel fundamental domain for Z acting on G: for $x = (h, v)$, $\zeta x \in D$ if and only if $\zeta_f v \in D_f$, and by (i) exactly one $\zeta \in Z$ has this property. For a measurable left Z-invariant $F \geq 0$ on G, $f = F\mathbf{1}_D$ satisfies $\sum_{\zeta \in Z} f(\zeta x) = F(x)$, so $\int_{Z\backslash G} F = \int_D F$; likewise $\int_{Z^f\backslash G_f} F_f = \int_{D_f} F_f$ for left Z^f-invariant $F_f \geq 0$. For $x = (h, v)$, $x^{-1}\gamma x = (h^{-1}\gamma_\infty h,\, v^{-1}\gamma_f v)$, and $v \mapsto \phi(v^{-1}\gamma_f v)$ is left Z^f-invariant (Z^f commutes with γ_f). By Tonelli,

$$\int_{Z\backslash G} \left|(k \otimes \phi)(x^{-1}\gamma x)\right| dx = \int_{G_\infty} |k(h^{-1}\gamma_\infty h)|\, dh \int_{D_f} |\phi(v^{-1}\gamma_f v)|\, dv = I_\gamma^\infty(|k|)\, I_{\gamma_f}^{\mathrm{fin}}(|\phi|) < \infty,$$

and then Fubini's theorem gives $I_\gamma(k \otimes \phi) = \int_D k(h^{-1}\gamma_\infty h)\phi(v^{-1}\gamma_f v) = I_\gamma^\infty(k)\, I_{\gamma_f}^{\mathrm{fin}}(\phi)$.

(iii) Let $k_0(w) = \|w\|_\infty^{-B}$, continuous with $\sup k_0 \| \cdot \|_\infty^B = 1$, and $C_k = \sup |k| \,\| \cdot \|_\infty^B$, so $|k| \leq C_k k_0$. Let $W = \gamma_f \mathrm{K}_f$, compact and open, and $\phi_0 = \mathbf{1}_W$. By Proposition 5.8.36(i) for (k_0, ϕ_0) and the Tonelli identity of (ii) (valid for nonnegative functions without any finiteness assumption), $I_\gamma^\infty(k_0)\, I_{\gamma_f}^{\mathrm{fin}}(\phi_0) < \infty$. We show $I_{\gamma_f}^{\mathrm{fin}}(\phi_0) > 0$. The set $S = \{v \in G_f : v^{-1}\gamma_f v \in W\}$ is open, contains 1 and is left Z^f-invariant. By (i) there is an open neighbourhood $O \subseteq S$ of 1 with $OO^{-1} \cap Z^f = \{1\}$; then for every v at most one $\zeta \in Z^f$ has $\zeta v \in O$, and if one has, $v \in \zeta^{-1} S = S$. So $\sum_{\zeta \in Z^f} \mathbf{1}_O(\zeta v) \leq \mathbf{1}_S(v)$ and

$$I_{\gamma_f}^{\mathrm{fin}}(\phi_0) = \int_{Z^f\backslash G_f} \mathbf{1}_S \;\geq \int_{Z^f\backslash G_f} \sum_\zeta \mathbf{1}_O(\zeta v)\, dv = \mathrm{vol}(O) > 0.$$

Hence $I^\infty_\gamma(k_0) < \infty$ and $I^\infty_\gamma(|k|) \le C_k I^\infty_\gamma(k_0) < \infty$. Finally Proposition 5.8.36(i) for (k_0, ϕ) and the same Tonelli identity give $I^\infty_\gamma(k_0)\, I^{\mathrm{fin}}_{\gamma_f}(|\phi|) < \infty$, and $I^\infty_\gamma(k_0) > 0$ (a positive continuous integrand), so $I^{\mathrm{fin}}_{\gamma_f}(|\phi|) < \infty$.

(iv) $E[g^{-1}\gamma_f g] = g^{-1}E[\gamma_f]g$ and $g^{-1}G_f g = G_f$, so $Z(y) = g^{-1}Z^f g$, again discrete. The map $w \mapsto g^{-1}w$ induces a bijection $Z^f\backslash G_f \to Z(y)\backslash G_f$ ($Z(y)g^{-1}w = g^{-1}Z^f w$) which preserves the quotient measures (left translation preserves the measure of G_f, and conjugation by g carries counting measure on Z^f to that on $Z(y)$), and $(g^{-1}w)^{-1}y(g^{-1}w) = w^{-1}\gamma_f w$. Both identities follow. □

Lemma 5.8.43. *Let $N \ge 1$, $s \in \{\pm 1\}^N$, $p = \#\{i : s(i) = 1\}$, $q = N - p$, let $h(u,u') = \bar{u}^{\mathsf{T}}\mathrm{diag}(s)\,u'$ on $\mathbb{C}^N$ and $G = \mathrm{U}(\mathrm{diag}\, s) = \{g \in \mathrm{GL}_N(\mathbb{C}) : \bar{g}^{\mathsf{T}}\mathrm{diag}(s)\, g = \mathrm{diag}(s)\}$. Let $\zeta_1, \dots, \zeta_N \in \mathbb{C}$ be distinct with $|\zeta_i| = 1$, and $Q = \prod_i (X - \zeta_i)$. For $\sigma \in S_N$ put $t_\sigma = \mathrm{diag}(\zeta_{\sigma(1)}, \dots, \zeta_{\sigma(N)})$.*

(i) Let $t \in G$ have characteristic polynomial Q. Its ζ_i-eigenspace is a line ℓ_i; $h(u,u') = 0$ for $u \in \ell_i$, $u' \in \ell_j$, $i \ne j$; and $h(u,u)$ is real and nonzero for $u \in \ell_i \smallsetminus 0$, with a sign $\varepsilon_t(i) \in \{\pm 1\}$ independent of u, and $\#\{i : \varepsilon_t(i) = 1\} = p$. Every $g \in G$ commuting with t acts on each ℓ_i by a scalar of absolute value 1.

(ii) Elements $t, t' \in G$ with characteristic polynomial Q are conjugate in G if and only if $\varepsilon_t = \varepsilon_{t'}$.

(iii) For $\sigma \in S_N$, $t_\sigma \in G$ has characteristic polynomial Q and $\varepsilon_{t_\sigma} = s \circ \sigma^{-1}$.

(iv) Every G-conjugacy class C of elements of G with characteristic polynomial Q contains t_σ for exactly $p!\,q!$ permutations $\sigma \in S_N$.

Proof. (i) As the ζ_i are distinct roots of the characteristic polynomial, t is diagonalisable with one-dimensional eigenspaces ℓ_i. For $u \in \ell_i$, $u' \in \ell_j$, $h(u,u') = h(tu, tu') = \bar{\zeta}_i\zeta_j\, h(u,u')$, and $\bar{\zeta}_i\zeta_j = \zeta_j/\zeta_i \ne 1$ for $i \ne j$ (as $|\zeta_i| = 1$); so $h(u,u') = 0$. Choose $f_i \in \ell_i \smallsetminus 0$. Then (f_i) is a basis in which the Gram matrix of h is diagonal with entries $h(f_i, f_i)$; these are real (h is hermitian) and nonzero (h is nondegenerate), and $h(cf_i, cf_i) = |c|^2 h(f_i, f_i)$, so the sign $\varepsilon_t(i)$ does not depend on the choice. By Sylvester's law of inertia the number of positive entries is the number p of positive entries of $\mathrm{diag}(s)$. If $g \in G$ commutes with t, it preserves each eigenspace, $gf_i = \mu_i f_i$, and $h(f_i, f_i) = h(gf_i, gf_i) = |\mu_i|^2 h(f_i, f_i)$ gives $|\mu_i| = 1$.

(ii) If $t' = gtg^{-1}$ with $g \in G$, then $g\ell_i$ is the ζ_i-eigenline of t' and $h(gu, gu) = h(u,u)$, so $\varepsilon_{t'} = \varepsilon_t$. Conversely let $\varepsilon_t = \varepsilon_{t'} = \varepsilon$. Choose eigenvectors f_i of t and f'_i of t' for ζ_i, scaled so that $h(f_i, f_i) = h(f'_i, f'_i) = \varepsilon(i)$. The linear map g with $gf_i = f'_i$ carries a basis with Gram matrix $\mathrm{diag}(\varepsilon)$ to a basis with the same Gram matrix, so it preserves h, that is $g \in G$; and $gtg^{-1}f'_i = \zeta_i f'_i = t' f'_i$ for all i, so $gtg^{-1} = t'$.

(iii) t_σ is diagonal with entries of absolute value 1, so $\bar{t}_\sigma^{\mathsf{T}}\mathrm{diag}(s)t_\sigma = \mathrm{diag}(s)$ and $t_\sigma \in G$, with characteristic polynomial Q. The standard basis vector e_k is an eigenvector for $\zeta_{\sigma(k)}$, so $\ell_i = \mathbb{C}e_{\sigma^{-1}(i)}$ and $\varepsilon_{t_\sigma}(i) = \mathrm{sign}\, h(e_{\sigma^{-1}(i)}, e_{\sigma^{-1}(i)}) = s(\sigma^{-1}(i))$.

(iv) Let C be such a class and $\varepsilon = \varepsilon_t$ for $t \in C$; by (ii), $C = \{t' \in G : \mathrm{charpoly}(t') = Q,\ \varepsilon_{t'} = \varepsilon\}$, and by (iii), $t_\sigma \in C$ if and only if $s \circ \sigma^{-1} = \varepsilon$. By (i), ε and s take the value 1 equally often, so there is σ_0 with $s \circ \sigma_0^{-1} = \varepsilon$. For $\sigma = \sigma_0\tau$, $s \circ \sigma^{-1} = (s \circ \tau^{-1}) \circ \sigma_0^{-1}$, which equals ε if and only if $s \circ \tau^{-1} = s$, that is, τ permutes $\{i : s(i) = 1\}$ and $\{i : s(i) = -1\}$ separately. There are $p!\,q!$ such τ. □

Proposition 5.8.44. *Let E be a CM field with maximal totally real subfield E^+ and chosen embeddings $\Phi_v\colon E \to \mathbb{C}$ at the infinite places v of E^+, let $N \geq 1$, and let $R \in E[X]$ be monic and irreducible of degree N such that every root of $\Phi_v(R)$ has absolute value 1 for every v. For a framed space U of rank N over E, with signs s, let $X_R(U)$ be the set of $\gamma \in \mathrm{U}(U)(E^+)$ with characteristic polynomial R, $\mathcal{C}(U)$ the set of $\mathrm{U}(U)(E^+)$-conjugacy classes contained in $X_R(U)$, and $\mathcal{C}_f(U)$ the set of G_f-conjugacy classes of the finite components $\gamma_f \in G_f$ of the images of the $\gamma \in X_R(U)$ in Γ_U. For an infinite place v let $\mathcal{C}_v(s)$ be the set of $\mathrm{U}(\operatorname{diag} s)$-conjugacy classes of elements of $\mathrm{U}(\operatorname{diag} s)$ with characteristic polynomial $\Phi_v(R)$. Then:*

(i) $\mathcal{C}_f(U)$ is the same set of G_f-conjugacy classes for all framed spaces U of rank N over E (of any signs);

(ii) $[\gamma] \mapsto ([\gamma_f], ([\gamma_v])_v)$, with $\gamma_v \in \mathrm{U}(\operatorname{diag} s)$ the components of the real part of the image of γ, is a bijection $\mathcal{C}(U) \to \mathcal{C}_f(U) \times \prod_v \mathcal{C}_v(s)$;

(iii) every $\mathcal{C}_v(s)$ is finite and nonempty.

Proof. Put $F = E^+$; E/F is a CM extension and all infinite places of F are real. The unitary group of a hermitian form and its isometry classes are unchanged if the form h is replaced by $(u, u') \mapsto h(u', u)$, so the convention of (FT1) (conjugate-linear in the first argument) may be exchanged for the one used for unitary dual pairs and global theta lifts over a CM extension.

R is conjugate-reciprocal. The roots of $\Phi_v(R)$ have absolute value 1, so $R(0) \neq 0$. The polynomial $R^\# = \overline{R(0)}^{-1} X^N \bar{R}(X^{-1})$ is monic of degree N, and since complex conjugation on E is induced by complex conjugation under Φ_v, the roots of $\Phi_v(R^\#)$ are the $1/\bar{\zeta} = \zeta$ for the roots ζ of $\Phi_v(R)$; as these are N distinct numbers (R is separable), $\Phi_v(R^\#) = \Phi_v(R)$, hence $R^\# = R$. So $P := R \in \mathcal{P}_N(E/F)$ in the notation of Definition 5.8.2.

Step 1: local classes. Let $V_0 = E^N$ with the standard form, $\Lambda = \mathcal{O}_E^N$, and for a finite place v let K_v be the stabiliser of Λ_v in $\mathrm{U}(V_0)(F_v)$; then $G_f = \prod_v{}' \mathrm{U}(V_0)(F_v)$ (restricted with respect to the K_v) and $\mathrm{K}_f = \prod_v K_v$. For a finite place v, the component at v of the finite frame x_U is an isometry $V_{0,v} \to U_v = U \otimes_F F_v$; hence $X_P(U, F_v) = X_P(V_0, F_v)$, and for $\gamma \in X_R(U)$ the component $(\gamma_f)_v = x_U^{-1} \gamma x_U \in \mathrm{U}(V_0)(F_v)$ satisfies $c_{F_v}((\gamma_f)_v) = c_{F_v}(\gamma)$ (compose the isometry φ of Lemma 5.8.46(b) for γ with x_U^{-1}). For a real place v, $E \otimes_F F_v = \mathbb{C}$ through Φ_v, and the frame at v identifies $\mathrm{U}(U)(F_v)$ with $\mathrm{U}(\operatorname{diag} s)$, $\gamma \mapsto \gamma_v$, preserving characteristic polynomials up to Φ_v; so by Lemma 5.8.46(c) the map $[\gamma_v] \mapsto c_{F_v}(\gamma)$ is a bijection $\mathcal{C}_v(s) \to X_P(U, F_v)$, and $\mathcal{C}_v(s)$ is finite by Lemma 5.8.46(e). It is nonempty: $\operatorname{diag}(\zeta_1, \ldots, \zeta_N)$, the ζ_i the roots of $\Phi_v(R)$, lies in $\mathrm{U}(\operatorname{diag} s)$ since $|\zeta_i| = 1$. This proves (iii).

Step 2: global classes. By Proposition 5.8.45 (H1)–(H3), $[\gamma] \mapsto (c_{F_v}(\gamma))_v$ is a bijection of $\mathcal{C}(U)$ onto the set $\mathcal{F}(U)$ of families $(c_v)_v$ over all places of F with $c_v \in X_P(U, F_v)$ and $c_v = 1$ for all but finitely many v. By Step 1, $\mathcal{F}(U) = \mathcal{F}_f \times \prod_{v|\infty} X_P(U, F_v)$, where $\mathcal{F}_f$ is the set of families over the finite places with $c_v \in X_P(V_0, F_v)$, almost all equal to 1; $\mathcal{F}_f$ does not depend on U.

Step 3: finite classes. Let $y, y' \in G_f$ have characteristic polynomial P. We claim: y and y' are conjugate in G_f if and only if $c_{F_v}(y_v) = c_{F_v}(y'_v)$ for every finite v. If $y' = g^{-1} y g$ with $g \in G_f$, the classes agree by Lemma 5.8.46(b). Conversely, by Lemma 5.8.46(c) there is $g_v \in \mathrm{U}(V_0)(F_v)$ with $g_v^{-1} y_v g_v = y'_v$ for every finite v. For all but finitely many v, $y_v, y'_v \in K_v$ (as $y, y' \in G_f$) and the conclusion of Lemma 5.8.47(a) for (V_0, Λ) holds: $\{x : x^{-1} y_v x \in K_v\} = T_{y_v} K_v$, T_{y_v} the centraliser of y_v. For such v, $g_v = tk$ with $t \in T_{y_v}$, $k \in K_v$, and $k^{-1} y_v k = y'_v$; replacing g_v by k, the family $(g_v)_v$ lies in G_f and conjugates y to y'.

By Step 1 and the claim, $[y] \mapsto (c_{F_v}(y_v))_{v \text{ finite}}$ is an injective map from the set of G_f-classes of elements of G_f with characteristic polynomial P to the families of local classes, and on $\mathcal{C}_f(U)$

it takes values in $\mathcal{F}_f$. It maps $\mathcal{C}_f(U)$ onto $\mathcal{F}_f$: a family in $\mathcal{F}_f$, completed by any classes at the real places (nonempty sets by (iii)), lies in $\mathcal{F}(U)$ and is the family of some $\gamma \in X_R(U)$ (Step 2), whose finite component has the given finite classes (Step 1). So $\mathcal{C}_f(U)$ is the preimage of $\mathcal{F}_f$ under one injective map that does not depend on U, which proves (i).

Step 4: the bijection. The map of (ii) is the composite of the bijection $\mathcal{C}(U) \to \mathcal{F}_f \times \prod_{v|\infty} X_P(U, F_v)$ of Step 2 with the inverses of the bijections $\mathcal{C}_f(U) \to \mathcal{F}_f$ (Step 3) and $\mathcal{C}_v(s) \to X_P(U, F_v)$ (Step 1): indeed the finite part of the family of γ is the image of $[\gamma_f]$, and its component at a real v is the image of $[\gamma_v]$. So it is a bijection. □

Proposition 5.8.45. *Let E/F be a CM extension, $r \geq 1$, $P \in \mathcal{P}_r(E/F)$ and V a hermitian space over E of rank r. For $\gamma \in \mathrm{U}(V)(F)$ with characteristic polynomial P and a place v of F (finite or real) write $c_v(\gamma) = c_{F_v}(\gamma) \in X_P(V, F_v)$. Then:*

(H1) $c_v(\gamma) = (c_F(\gamma))_{F_v}$ for every v, and $c_v(\gamma) = 1$ for all but finitely many v;

(H2) two elements $\gamma, \gamma' \in \mathrm{U}(V)(F)$ with characteristic polynomial P are conjugate in $\mathrm{U}(V)(F)$ if and only if $c_v(\gamma) = c_v(\gamma')$ for every place v;

(H3) for every family $(c_v)_v$ with $c_v \in X_P(V, F_v)$ for every place v and $c_v = 1$ for all but finitely many v, there is $\gamma \in \mathrm{U}(V)(F)$ with characteristic polynomial P and $c_v(\gamma) = c_v$ for every v.

Proof. Write $L = L_P$, $K = K_P$, $\alpha = \alpha_P$. Since $E \subseteq L$, $E \not\subseteq K$ and $K \cap E = F$, while $[L : K] = 2 = [E : F]$, we have $L = KE \cong K \otimes_F E$; with $E = F(\sqrt{d})$, $d \in F$ totally negative (E/F is CM), $L = K(\sqrt{d})$, $*$ is the nontrivial automorphism of L/K and $N = N_{L/K}$. For a place v of F, $K_{P,F_v} = \prod_{w|v} K_w$ and $L_{P,F_v} = \prod_{w|v} L \otimes_K K_w$ over the places w of K above v. Fix bases and write $\det V \in F^\times$ for the determinant of a Gram matrix of V (well defined up to $N_{E/F}(E^\times)$), and similarly over F_v.

A determinant formula. For $x \in K_{P,k}^\times$ ($k = F$ or F_v), in the E_k-basis $1, \alpha, \dots, \alpha^{r-1}$ of $L_{P,k}$ the Gram matrix of h_x is $G_x = (\mathrm{Tr}(x\alpha^i\alpha^{-j}))_{ij}$, and $h_x(y, y') = h_1(xy, y')$, so $\det G_x = N_{L/E}(x) \det G_1$. As $L = K \otimes_F E$, $N_{L/E}(x) = N_{K/F}(x)$ for $x \in K$. Put $d_P = \det G_1 \in F^\times$ (G_1 is hermitian, so its determinant is fixed by conjugation). Thus

$$\det G_x = N_{K/F}(x)\, d_P. \tag{1}$$

If $[x] \in X_P(V, F_v)$, then $\det G_x \in \det V \cdot N(E_v^\times)$, so with η_v the quadratic character of $F_v^\times$ attached to E_v/F_v:

$$\eta_v(N_{K_{P,F_v}/F_v}(x)) = \eta_v(\det V\, d_P^{-1}). \tag{2}$$

(H1). By Lemma 5.8.46(b) for $k = F$ there are $x \in K^\times$ and an isometry $\varphi\colon (L, h_x) \to V$ with $\varphi m_\alpha = \gamma\varphi$; their base changes to F_v have the same properties, so $c_v(\gamma) = [x]_{F_v}$. For all but finitely many v, x is a unit at every $w \mid v$ and L/K is unramified at every $w \mid v$; then x is a norm from $L \otimes_K K_w$ (units are norms in an unramified quadratic extension, everything is a norm in the split algebra), so $[x]_{F_v} = 1$.

(H2). Conjugate elements have equal classes by Lemma 5.8.46(b) at $k = F_v$. Conversely let $c_v(\gamma) = c_v(\gamma')$ for all v, with global (x, φ), (x', φ') as in (H1). Then $u = x/x' \in K^\times$ lies in $N(L_w^\times)$ for every place w of K, $L_w = L \otimes_K K_w$. At a real place w (embedding σ of K), $\sigma(d) < 0$, $L_w \cong \mathbb{C}$ and $\sigma(u) > 0$, so $\sigma(u) = a^2 - \sigma(d)b^2$ with $a, b \in \mathbb{R}$; at a finite w, $u = a^2 - db^2$ with $a, b \in K_w$ (if L_w is a field this is $u \in N(L_w^\times)$, and if d is a square in K_w the form $a^2 - db^2$ represents every element). The Hasse norm theorem A.2.11 for the field K and $\delta = d$ gives

$u = a^2 - db^2 = N(z)$, $z = a + b\sqrt{d} \in L^\times$. So $x = x'N(z)$, i.e. $c_F(\gamma) = [x] = [x'] = c_F(\gamma')$ in $C_P(F)$, and γ, γ' are conjugate in $\mathrm{U}(V)(F)$ by the injectivity in Lemma 5.8.46(c) for $k = F$.

(H3), a global element of K. Choose $x_v \in K_{P,F_v}^\times$ representing c_v, with $x_v = 1$ whenever $c_v = 1$; write $x_{v,w}$ for its components. The family $(x_{v,w})_w$ is an idele of K (almost all components are 1). For the quadratic extension L/K with local characters ω_w of $K_w^\times$ (trivial exactly on $N(L_w^\times)$), the norm compatibility of local class field theory for $L_w = K_w \otimes_{F_v} E_v$ gives $\prod_{w|v} \omega_w(x_{v,w}) = \eta_v(N_{K_{P,F_v}/F_v}(x_v))$, which equals $\eta_v(\det V\, d_P^{-1})$ by (2). Hence

$$\prod_w \omega_w(x_{v,w}) = \prod_v \eta_v(\det V\, d_P^{-1}) = 1$$

by the product formula for the Hecke character η of E/F on $F^\times$ (Hilbert reciprocity). By global class field theory for L/K (the kernel of $\prod_w \omega_w$ on the ideles of K is $K^\times N(\mathbb{I}_L)$), there are $x \in K^\times$ and an idele b of L with $x_{v,w} = xN(b_w)$ for all w; so $[x]_{F_v} = c_v$ for every v.

(H3), a global isometry. For every v, (L_{P,F_v}, h_x) is isometric to V_{F_v}, since $[x]_{F_v} = c_v \in X_P(V, F_v)$ and $h_{xN(z)} \cong h_x$ through m_z. In particular, at every complex embedding τ of E (above a real place of F) the signatures of h_x and of V agree, and $q = \det G_x / \det V \in F^\times$ is a norm from E_v at every finite v and positive at every real v. By Theorem A.2.11 for F and $\delta = d$, $q = N_{E/F}(z_0)$ with $z_0 \in E^\times$, i.e. $\det G_x = z_0 \bar{z}_0 \det V$. Landherr's theorem A.2.12 (E is a CM field) gives an isometry $\varphi\colon (L, h_x) \to V$. Then $\gamma = \varphi m_\alpha \varphi^{-1} \in \mathrm{U}(V)(F)$ has characteristic polynomial P (Lemma 5.8.46(a)) and $c_F(\gamma) = [x]$, so $c_v(\gamma) = [x]_{F_v} = c_v$ by (H1). □

Lemma 5.8.46. *Let E/F be a quadratic extension of number fields, $r \geq 1$, $P \in \mathcal{P}_r(E/F)$, V a hermitian space over E of rank r, and k either F or a completion of F. Write $L = L_{P,k}$, $\alpha = \alpha_P$.*

(a) For $x \in K_{P,k}^\times$, h_x is a nondegenerate hermitian form on the E_k-module L, and multiplication m_α by α is an isometry of h_x with characteristic polynomial P.

(b) For every $\gamma \in \mathrm{U}(V)(k)$ with characteristic polynomial P there are $x \in K_{P,k}^\times$ and an isometry $\varphi\colon (L, h_x) \to V_k$ with $\varphi \circ m_\alpha = \gamma \circ \varphi$. The class $c_k(\gamma) = [x] \in X_P(V, k)$ depends only on the $\mathrm{U}(V)(k)$-conjugacy class of γ.

(c) $\gamma \mapsto c_k(\gamma)$ induces a bijection from the set of $\mathrm{U}(V)(k)$-conjugacy classes of elements with characteristic polynomial P onto $X_P(V, k)$.

(d) For γ, x, φ as in (b), $z \mapsto \varphi \circ m_z \circ \varphi^{-1}$ is an isomorphism of $T_P(k)$ onto the centraliser of γ in $\mathrm{U}(V)(k)$.

(e) If k is a completion of F, then $C_P(k)$, hence $X_P(V, k)$, is finite.

Proof. Write $\mathrm{Tr} = \mathrm{Tr}_{L/E_k}$. Since P is irreducible over a field of characteristic 0, L_P/E is separable, so the trace form $(y, y') \mapsto \mathrm{Tr}(yy')$ on L is nondegenerate (base change of a nondegenerate form). The involution $*$ is a ring automorphism of L which acts on E_k as $e \mapsto \bar{e}$; computing the trace of m_{z^*} in a basis (b_i^*) when (b_i) is an E_k-basis gives $\mathrm{Tr}(z^*) = \overline{\mathrm{Tr}(z)}$.

(a) h_x is E_k-linear in y and conjugate-linear in y' ($(ey')^* = \bar{e}\, y'^*$). Hermitian: $\overline{h_x(y', y)} = \mathrm{Tr}((xy'y^*)^*) = \mathrm{Tr}(x^*y'^*y) = h_x(y, y')$ as $x^* = x$. Nondegenerate: if $h_x(y, y') = 0$ for all y' then $\mathrm{Tr}(xyw) = 0$ for all $w \in L$ (y'^* runs over L), so $xy = 0$ and $y = 0$, x being a unit. Isometry: $h_x(\alpha y, \alpha y') = \mathrm{Tr}(x\, y\, y'^*\, \alpha\alpha^*) = h_x(y, y')$ since $\alpha^* = \alpha^{-1}$. The characteristic polynomial of m_α on $L = E_k[X]/(P)$ is P (basis $1, \alpha, \ldots, \alpha^{r-1}$, companion matrix).

A lemma on invariant forms. Let h be a nondegenerate hermitian form on L with $h(\alpha y, \alpha y') = h(y, y')$. Then $h = h_x$ for a unique $x \in K_{P,k}^\times$. Indeed $h(\alpha y, y') = h(y, \alpha^{-1} y') = h(y, \alpha^* y')$, and $h(ey, y') = h(y, \bar{e} y')$ for $e \in E_k$; as L is generated as a ring by E_k and $\alpha^{\pm 1}$ ($\alpha^{-1} \in E_k[\alpha]$ because $P(0) \neq 0$), $h(zy, y') = h(y, z^* y')$ for all $z \in L$. The map $w \mapsto h(w, 1)$ is E_k-linear, so by nondegeneracy of the trace form there is a unique $x \in L$ with $h(w, 1) = \mathrm{Tr}(xw)$; then $h(y, y') = h(y'^* y, 1) = \mathrm{Tr}(xyy'^*)$. Comparing $h(y', y) = \overline{h(y, y')}$ gives $\mathrm{Tr}((x - x^*) y' y^*) = 0$ for all y, y', so $x = x^*$; nondegeneracy of h forces $x \in L^\times$. Uniqueness: $h_x = h_{x'}$ gives $\mathrm{Tr}((x - x')w) = 0$ for all w.

(b) Write $E_k = \prod_j E_j$ with fields E_j (one factor, or two if $k \supseteq E$ splits E), $V_k = \prod_j V_j$ and P_j the image of P in $E_j[X]$. On each V_j, γ is E_j-linear with characteristic polynomial P_j, which is separable (image of a separable polynomial); a separable characteristic polynomial equals the minimal polynomial, so $V_j \cong E_j[X]/(P_j)$ as $E_j[X]$-modules (X acting by γ). Hence V_k is a free module of rank one over $E_k[X]/(P) = L$ with α acting by γ; for a generator v_0, $\varphi_0(y) = y \cdot v_0$ is an E_k-linear bijection $L \to V_k$ with $\varphi_0 m_\alpha = \gamma \varphi_0$. The pull-back $h(y, y') = \langle \varphi_0 y, \varphi_0 y' \rangle_V$ is nondegenerate hermitian and m_α-invariant because γ is unitary, so $h = h_x$ with $x \in K_{P,k}^\times$ by the lemma, and $\varphi = \varphi_0$ is an isometry $(L, h_x) \to V_k$. In particular $[x] \in X_P(V, k)$.

Conjugacy and norms. Let (γ, x, φ) and (γ', x', φ') be as in (b). For $g \in \mathrm{U}(V)(k)$ with $\gamma' = g\gamma g^{-1}$, the map $\psi = \varphi'^{-1} g \varphi$ is an E_k-linear bijection $L \to L$ commuting with m_α, hence L-linear, i.e. $\psi = m_z$ with $z \in L^\times$; it is an isometry $h_x \to h_{x'}$, so $\mathrm{Tr}(x' z z^* y y'^*) = \mathrm{Tr}(xyy'^*)$ for all y, y', i.e. $x = x' N(z)$. Conversely, if $x = x' N(z)$ with $z \in L^\times$, then $g = \varphi' m_z \varphi^{-1}$ is an isometry of V_k, so $g \in \mathrm{U}(V)(k)$, and $g\gamma g^{-1} = \gamma'$. Taking $\gamma' = \gamma$ shows that $[x]$ does not depend on the choice of (x, φ), and in general that $c_k(\gamma) = c_k(\gamma')$ if and only if γ, γ' are conjugate. This proves (b) and the injectivity in (c).

(c) If $[x] \in X_P(V, k)$, choose an isometry $\varphi\colon (L, h_x) \to V_k$; $\gamma = \varphi m_\alpha \varphi^{-1}$ is unitary by (a), has characteristic polynomial P, and $c_k(\gamma) = [x]$.

(d) With $\gamma' = \gamma$, $x' = x$, $\varphi' = \varphi$, the computation above shows that g centralises γ if and only if $g = \varphi m_z \varphi^{-1}$ with $N(z) = 1$, and $z \mapsto \varphi m_z \varphi^{-1}$ is an injective homomorphism.

(e) Let $k = F_v$. Since $*$ is a nontrivial involution of L_P (nontrivial on E), $[L_P : K_P] = 2$. Then $K_{P,k} = \prod_w K_{P,w}$ over the places w of K_P above v, and $L_{P,k} = \prod_w L_P \otimes_{K_P} K_{P,w}$, each factor a quadratic field extension of $K_{P,w}$ or $K_{P,w} \times K_{P,w}$ with $*$ the conjugation, resp. the swap; N is the componentwise norm. In the split case the norm is surjective; for a quadratic extension of local fields the norm subgroup has index 2 (local class field theory, [224], Chapter V; for $\mathbb{C}/\mathbb{R}$ the norms are the positive reals, of index 2). So $|C_P(k)| \leq 2^{\#\{w|v\}}$. □

Lemma 5.8.47. *Let E/F be a CM extension, $r \geq 1$, $P \in \mathcal{P}_r(E/F)$, V a hermitian space over E of rank r with an $\mathcal{O}_E$-lattice Λ, and $G = \mathrm{U}(V)$; for a finite place v of F let $\Lambda_v = \Lambda \otimes_{\mathcal{O}_F} \mathcal{O}_{F,v}$ and let $K_v \subseteq G(F_v)$ be its stabiliser. Then:*

(a) for all but finitely many finite places v of F: if $\gamma \in K_v$ has characteristic polynomial P, then $c_{F_v}(\gamma) = 1$ and $\{x \in G(F_v) : x^{-1}\gamma x \in K_v\} = T_\gamma K_v$, where T_γ is the centraliser of γ; consequently, for Haar measures μ_v on $G(F_v)$ and dt_v on T_γ,

$$\int_{T_\gamma \backslash G(F_v)} \mathbf{1}_{K_v}(x^{-1}\gamma x)\, d\dot{x} = \frac{\mu_v(K_v)}{dt_v(T_\gamma \cap K_v)};$$

(b) $T_P(F)\backslash T_P(\mathbb{A}_F)$ is compact;

(c) for all but finitely many finite places v of F: there is $\gamma \in K_v$ with characteristic polynomial P, and every such γ satisfies $\iota_\gamma^{-1}(K_v) = T_P(\mathcal{O}_v)$.

Proof. Write $L = L_P$, $K = K_P$, $\alpha = \alpha_P$; Since $*$ is nontrivial on $E \subseteq L$, $E \not\subseteq K$, $K \cap E = F$ and $[L : K] = 2 = [E : F]$, so $L = KE \cong K \otimes_F E$. For a finite place v let $\mathcal{O}_{L,v}$, $\mathcal{O}_{K,v}$, $\mathcal{O}_{E,v}$ be the integral closures of $\mathcal{O}_{F,v}$ in L_{P,F_v}, K_{P,F_v}, E_v, and $\Lambda_v^\vee = \{y : \langle y, \Lambda_v\rangle \subseteq \mathcal{O}_{E,v}\}$.

Excluded places. Let Σ be the finite set of finite v at which one of the following fails: E_v/F_v is unramified; the coefficients of P are in $\mathcal{O}_{E,v}$, $P(0) \in \mathcal{O}_{E,v}^\times$ and the discriminant of P is in $\mathcal{O}_{E,v}^\times$; $\Lambda_v^\vee = \Lambda_v$. (Each condition fails at finitely many v; for the last, $\Lambda^\vee$ and Λ are two $\mathcal{O}_E$-lattices of V, hence equal at almost all places.) Let $v \notin \Sigma$. Then $\mathcal{O}_{E,v}[X]/(P)$ is finite étale over $\mathcal{O}_{E,v}$, hence equal to $\mathcal{O}_{L,v}$, with $\alpha \in \mathcal{O}_{L,v}^\times$; it is stable under $*$ ($\alpha^* = \alpha^{-1}$); its trace dual for $\mathrm{Tr}_{L/E}$ is itself; and $\mathcal{O}_{L,v}$ is a finite product of discrete valuation rings, each factor of $L_{P,F_v} = \prod_w L \otimes_K K_w$ being unramified over K_w (since $L \otimes_K K_w = K_w \otimes_{F_v} E_v$ and E_v/F_v is unramified).

(a), the class. Let $\gamma \in K_v$ have characteristic polynomial P. Then Λ_v is stable under γ and γ^{-1}, hence a module over $\mathcal{O}_{E,v}[\gamma] \cong \mathcal{O}_{L,v}$ ($\alpha \mapsto \gamma$, the isomorphism of Lemma 5.8.46(b)), finitely generated and torsion free of rank one over each factor; as $\mathcal{O}_{L,v}$ is a product of principal ideal domains, $\Lambda_v = \mathcal{O}_{L,v} w_0$ for some w_0. With $\varphi(y) = y \cdot w_0$, Lemma 5.8.46(b) gives $x \in K_{P,F_v}^\times$ with $\varphi\colon (L_{P,F_v}, h_x) \to V_{F_v}$ an isometry, $\varphi(\mathcal{O}_{L,v}) = \Lambda_v$. The dual of $\mathcal{O}_{L,v}$ for h_x is $\{y : \mathrm{Tr}(xy\mathcal{O}_{L,v}) \subseteq \mathcal{O}_{E,v}\} = x^{-1}\mathcal{O}_{L,v}$ (trace self-duality and $\mathcal{O}_{L,v}^* = \mathcal{O}_{L,v}$); self-duality of Λ_v gives $x \in \mathcal{O}_{L,v}^\times \cap K_{P,F_v} = \mathcal{O}_{K,v}^\times$. A unit is a norm from an unramified quadratic extension of local fields and from a split algebra, so $c_{F_v}(\gamma) = [x] = 1$.

(a), the orbit. Clearly $T_\gamma K_v \subseteq \{x : x^{-1}\gamma x \in K_v\}$. Conversely, if $x^{-1}\gamma x \in K_v$, then γ stabilises the self-dual lattice $x\Lambda_v$, which as above equals $\mathcal{O}_{L,v} w$ with $w = \varphi(z)$, $z \in L_{P,F_v}^\times$; it is self-dual for the form $h_{xN(z)}$ read through $y \mapsto y \cdot w$, so $N(z) \in \mathcal{O}_{K,v}^\times$. In each factor L_w of L_{P,F_v}: if L_w is an unramified field over K_w, $N(z_w)$ a unit forces $z_w \in \mathcal{O}_{L_w}^\times$; if $L_w = K_w \times K_w$ with $*$ the swap, $z_w = (z_1, z_2)$ with $z_1 z_2$ a unit, and $z_w = (z_1, z_1^{-1}) \cdot (1, z_1 z_2)$ with (z_1, z_1^{-1}) of norm 1 and $(1, z_1 z_2)$ a unit. So $z = tu$ with $N(t) = 1$ and $u \in \mathcal{O}_{L,v}^\times$, and $x\Lambda_v = \mathcal{O}_{L,v}\varphi(tu) = t \cdot \Lambda_v$ where t acts as $\varphi m_t \varphi^{-1} \in T_\gamma$ (Lemma 5.8.46(d)). Hence $(\varphi m_t \varphi^{-1})^{-1} x$ stabilises Λ_v, i.e. $x \in T_\gamma K_v$. The integral is then $\int_{T_\gamma \backslash T_\gamma K_v} d\dot{x} = \mu_v(K_v)/dt_v(T_\gamma \cap K_v)$ by the quotient integral formula.

(c) Let $v \notin \Sigma$. If $\gamma \in K_v$ has characteristic polynomial P, take w_0 and $\varphi(y) = y \cdot w_0$ as in the proof of the class in (a), so $\varphi(\mathcal{O}_{L,v}) = \Lambda_v$; for $z = q(\alpha) \in L_{P,F_v}$, $\varphi(zy) = q(\gamma)\varphi(y)$, i.e. $\iota_\gamma(z) = \varphi m_z \varphi^{-1}$ on $T_P(F_v)$. Hence $\iota_\gamma(z) \in K_v$ if and only if $z\mathcal{O}_{L,v} = \mathcal{O}_{L,v}$, i.e. $z \in \mathcal{O}_{L,v}^\times$; so $\iota_\gamma^{-1}(K_v) = T_P(\mathcal{O}_v)$. Existence: the computation of duals in (a) with $x = 1$ shows that $\mathcal{O}_{L,v}$ is self-dual for h_1, and Λ_v is self-dual in V_{F_v}. The Gram matrices of $\mathcal{O}_{E,v}$-bases of these two lattices lie in $\mathrm{GL}_r(\mathcal{O}_{E,v})$, so both determinants are units of $\mathcal{O}_{F,v}$, and units are norms from E_v (E_v/F_v unramified, or split). Nondegenerate hermitian spaces over E_v/F_v of the same rank whose determinants agree modulo norms are isometric (Jacobowitz [147]; in the split case every such space of rank r is isometric to the standard one), so there is an isometry $\psi\colon (L_{P,F_v}, h_1) \to V_{F_v}$. Then $\psi(\mathcal{O}_{L,v})$ is a self-dual lattice of V_{F_v}, and Lemma 5.8.48 gives $g \in G(F_v)$ with $g\psi(\mathcal{O}_{L,v}) = \Lambda_v$. With $\varphi = g\psi$, the element $\gamma = \varphi m_\alpha \varphi^{-1}$ lies in $G(F_v)$ and has characteristic polynomial P (Lemma 5.8.46(a)), and $\gamma\Lambda_v = \varphi(\alpha\mathcal{O}_{L,v}) = \Lambda_v$ since $\alpha \in \mathcal{O}_{L,v}^\times$; so $\gamma \in K_v$.

(b) T_P is the Weil restriction from K to F of the norm-one torus of the quadratic field extension L/K, which has no nontrivial K-rational character; so T_P has no nontrivial F-rational character. It contains no nontrivial F-split torus: if $S \subseteq T_P$ were one, choose $\chi \in X^*(T_P)$ whose restriction to S is nontrivial (restriction $X^*(T_P) \to X^*(S)$ is surjective for a subtorus); the absolute Galois group of F acts on $X^*(T_P)$ through a finite quotient Γ, trivially on $X^*(S)$, and restriction is Γ-equivariant, so $\sum_{g\in\Gamma} g\chi$ is an F-rational character of T_P whose restriction to S is $|\Gamma|\,\chi|_S \neq 0$ ($X^*(S)$ is torsion free), a contradiction. As T_P is a torus, hence connected reductive, the compactness criterion of Borel–Harish-Chandra and Mostow–Tamagawa [37], [216] shows that $T_P(F)\backslash T_P(\mathbb{A}_F)$ is compact. □

Lemma 5.8.48. *Let F be a non-archimedean local field with valuation ring $\mathcal{O}$, and let K be either the unramified quadratic field extension of F or $F \times F$, with its non-trivial F-involution c and maximal order R (R is the valuation ring of K, resp. $\mathcal{O} \times \mathcal{O}$). Let W be a free K-module of finite rank with a non-degenerate form $k\colon W \times W \to K$, K-linear in the first variable, with $k(y,x) = c(k(x,y))$. Call an R-lattice $L \subseteq W$ (a finitely generated R-submodule spanning W over K) **self-dual** if $L = \{x \in W : \ k(x,L) \subseteq R\}$. Then for any two self-dual R-lattices L, L' of W there is a K-linear $g\colon W \to W$ with $k(gx,gy) = k(x,y)$ for all x, y and $gL = L'$.*

Proof. K **a field: a self-dual lattice has an orthonormal basis.** Here R is a discrete valuation ring with uniformiser ϖ (the extension is unramified), every finitely generated torsion-free R-module is free, and $\mathrm{Tr}\colon R \to \mathcal{O}$ and $N\colon R^\times \to \mathcal{O}^\times$ are surjective (unramified extensions of local fields; Serre, *Local fields*, Ch. V, §2). Self-duality of L means $k(L,L) \subseteq R$ and that $x \mapsto k(\cdot, x)$ maps L onto $\mathrm{Hom}_R(L,R)$ (every R-linear $L \to R$ extends to a K-linear form on W, which is $k(\cdot,x)$ for a unique $x \in W$, and then $k(L,x) \subseteq R$ gives $x \in L$). We show by induction on $\mathrm{rk}_R L$ that L has a basis $e_1, \dots, e_r$ with $k(e_i, e_j) = \delta_{ij}$. Let $x \in L \smallsetminus \varpi L$. Then $k(x,\cdot)\colon L \to R$ is onto: otherwise its image lies in ϖR, so the R-linear map $k(\cdot,x) = c \circ k(x,\cdot)$ is ϖ times an element of $\mathrm{Hom}_R(L,R)$, which by self-duality is $k(\cdot,x')$ with $x' \in L$; as $k(\cdot,\varpi x') = \varpi\, k(\cdot,x')$, non-degeneracy gives $x = \varpi x' \in \varpi L$. Choose $y \in L$ with $k(x,y) = 1$. We find $z \in L$ with $u = k(z,z) \in \mathcal{O}^\times$ ($k(z,z)$ is c-invariant, so lies in $R \cap F = \mathcal{O}$): take $z = x$ or $z = y$ if $k(x,x)$ or $k(y,y)$ is a unit; otherwise choose $a \in R$ with $\mathrm{Tr}(a) = 1$ and $z = x + ay$, for which

$$k(z,z) = k(x,x) + \mathrm{Tr}\big(\bar{a}\, k(x,y)\big) + N(a)\, k(y,y) \equiv \mathrm{Tr}(\bar{a}) = 1 \pmod{\varpi}.$$

Then $L = Rz \oplus L_1$ with $L_1 = \{w \in L : \ k(w,z) = 0\}$, via $w = k(w,z)u^{-1}z + (w - k(w,z)u^{-1}z)$; the Gram matrix of L in a basis adapted to this sum is block diagonal with the unit u in one block, so its other block is invertible over R and L_1 is self-dual in $z^\perp$. Choose $t \in R^\times$ with $N(t) = u$ and put $e_1 = t^{-1}z$, so $k(e_1,e_1) = 1$, and apply the induction hypothesis to L_1. Given orthonormal bases (e_i) of L and (e_i') of L', the K-linear g with $ge_i = e_i'$ preserves k and maps L onto L'.

$K = F \times F$**.** Let ϵ_1, ϵ_2 be the idempotents of K (interchanged by c) and $W_i = \epsilon_i W$, so $W = W_1 \oplus W_2$. Writing $k = \epsilon_1 k_1 + \epsilon_2 k_2$ with F-valued k_i, linearity in the first variable and semilinearity in the second give $k_1(x,y) = b(x_1, y_2)$ for an F-bilinear $b\colon W_1 \times W_2 \to F$ ($x = x_1 + x_2$, $x_i \in W_i$), and hermitian symmetry gives $k_2(x,y) = b(y_1, x_2)$; non-degeneracy of k makes b perfect. A K-linear $g = (g_1, g_2)$, $g_i \in \mathrm{GL}(W_i)$, preserves k if and only if $g_2 = (g_1^*)^{-1}$, with g_1^* the adjoint for b. Every R-lattice is $L = L_1 \oplus L_2$ with $L_i = \epsilon_i L$ an $\mathcal{O}$-lattice of W_i, and $\{x : \ k(x,L) \subseteq R\} = \{x_1 : \ b(x_1, L_2) \subseteq \mathcal{O}\} \oplus \{x_2 : \ b(L_1, x_2) \subseteq \mathcal{O}\}$; hence L is self-dual if and only if $L_2 = L_1^\perp := \{x_2 : \ b(L_1, x_2) \subseteq \mathcal{O}\}$ (the condition on L_1 then follows from perfectness of b). For self-dual $L = L_1 \oplus L_1^\perp$ and $L' = L_1' \oplus L_1'^\perp$ choose $g_1 \in \mathrm{GL}(W_1)$ with $g_1 L_1 = L_1'$ (both are free $\mathcal{O}$-modules of rank $\dim W_1$); then $(g_1^*)^{-1} L_1^\perp = (g_1 L_1)^\perp = L_1'^\perp$, and $g = (g_1, (g_1^*)^{-1})$ preserves k and maps L onto L'. □

Lemma 5.8.49. *Let $N \geq 1$, $s \in \{\pm 1\}^N$, $p = \#\{i : s(i) = 1\}$, $q = N - p$, and $G = \mathrm{U}(\mathrm{diag}\, s)$ with a Haar measure dh. Let $\lambda \in (\frac{1}{2}\mathbb{Z})^N$ be such that 2λ has gap $500N^3 + 10N^5$ for s, let d_λ be the formal degree for dh, and $e_\lambda = d_\lambda \overline{c_\lambda}$ on G. Let χ_λ be the character of the irreducible representation of the compact group $\mathrm{U}(N)$ with Harish-Chandra parameter λ. Let $z_1, \dots, z_N \in \mathbb{C}$ be distinct with $|z_i| = 1$, and for $\sigma \in S_N$ let $t_\sigma = \mathrm{diag}(z_{\sigma(1)}, \dots, z_{\sigma(N)})$. Then for every σ the function $h \mapsto e_\lambda(h^{-1} t_\sigma h)$ is integrable on G, and*

$$(-1)^{pq} \sum_{\sigma \in S_N} \int_G e_\lambda(h^{-1} t_\sigma h)\, dh = p!\, q!\, \overline{\chi_\lambda(\mathrm{diag}(z_1, \dots, z_N))}.$$

Proof. Index the basis by $n = \{1, \dots, N\}$, put $l = 2\lambda$ (large gap $10N^5$ for s, (WM8) of Definition 3.2.19), $x = (z_1, \dots, z_N)$, and for $a \in n$ let $p(a) = \#\{a' : l_{a'} > l_a\}$ and a_p the index with $p(a_p) = p$ (l is injective). Let dg be the Cayley measure of G and, for $y \in \mathbb{C}^n$ with distinct entries of modulus one, $\Theta(y) = d_\lambda^{\mathrm{Cay}} \int_G c_\lambda(g^{-1}\mathrm{diag}(y)g)\, dg$, with d_λ^{Cay} the formal degree for dg. If $dh = t\, dg$, then $d_\lambda = d_\lambda^{\mathrm{Cay}}/t$, so $d_\lambda \int_G c_\lambda(h^{-1}\mathrm{diag}(y)h)\, dh = \Theta(y)$, and integrability does not depend on the Haar measure. For $\tau \in S_N$ write $x \circ \tau = (z_{\tau(1)}, \dots, z_{\tau(N)})$, so $t_\tau = \mathrm{diag}(x \circ \tau)$; its entries are distinct.

The identity for one permutation. By Proposition 5.7.5 (ii) (with $\varepsilon = s$), for every τ the function $h \mapsto c_\lambda(h^{-1}t_\tau h)$ is integrable, hence so is $h \mapsto e_\lambda(h^{-1}t_\tau h) = d_\lambda \overline{c_\lambda(h^{-1}t_\tau h)}$, and

$$V_{\mathrm{c}}(x \circ \tau)\, D(x \circ \tau)\, \Theta(x \circ \tau) = A(x \circ \tau),$$

with V_{c}, D, κ and A as there. Let $V(y) = \prod_{(a,b):\, l_b < l_a} (y_a - y_b)$. Each factor of D is $y_a - y_b = -(y_b - y_a)$ for a pair with $s_a \neq s_b$ and $l_a < l_b$, and these pairs correspond to the pq unordered pairs of indices with different signs; so $D(y) = (-1)^{pq} \prod_{s_a \neq s_b,\ l_b < l_a} (y_a - y_b)$ and $V_{\mathrm{c}}(y)D(y) = (-1)^{pq}V(y)$. In the order $a_0, \dots, a_{N-1}$, $V(y) = \prod_{p<q}(y_{a_p} - y_{a_q}) = \det\bigl(y_{a_q}^{N-1-p}\bigr)_{p,q}$ (Vandermonde). Replacing y by $x \circ \tau$ permutes the columns of this matrix by a permutation conjugate to τ, so $V(x \circ \tau) = \mathrm{sgn}(\tau)V(x)$. Hence

$$(-1)^{pq}\, \mathrm{sgn}(\tau)\, V(x)\, \Theta(x \circ \tau) = A(x \circ \tau) \qquad (\tau \in S_N). \tag{5.181}$$

Summation. Let $W = \{w \in S_N : s \circ w = s\}$, so $\#W = p!\, q!$. For $w \in W$, by the Leibniz formula and a permutation of rows,

$$\sum_{\tau \in S_N} \mathrm{sgn}(\tau) \prod_a x_{\tau(a)}^{\kappa_{w(a)}} = \det\bigl(x_b^{\kappa_{w(a)}}\bigr)_{a,b} = \mathrm{sgn}(w)\, \Delta(x), \qquad \Delta(x) = \det\bigl(x_b^{\kappa_a}\bigr)_{a,b}.$$

Multiplying (5.181) by $\mathrm{sgn}(\tau)$ and summing over τ gives

$$(-1)^{pq}\, V(x) \sum_{\tau \in S_N} \Theta(x \circ \tau) = \sum_{w \in W} \mathrm{sgn}(w)^2 \Delta(x) = p!\, q!\, \Delta(x).$$

Weyl's character formula. Reordering rows and columns by the same permutation, $\Delta(x) = \det\bigl(x_{a_q}^{\kappa_{a_p}}\bigr)_{p,q}$, and $\kappa_{a_p} = \lambda_{a_p} + \frac{N-1}{2} = \mu_p + N - 1 - p$ with $\mu_p = \lambda_{a_p} - \frac{N-1}{2} + p$. The μ_p are integers ($\lambda_a \in \frac{N-1}{2} + \mathbb{Z}$) and nonincreasing ($\lambda_{a_p} - \lambda_{a_{p+1}} \geq 1$, the entries of l being distinct of equal parity); μ is the highest weight, for the diagonal torus and the order $a_0, \dots, a_{N-1}$ of the basis, of the irreducible representation of $\mathrm{U}(N)$ with Harish-Chandra parameter λ. Weyl's character formula for $\mathrm{U}(N)$ [91] gives $\chi_\lambda(\mathrm{diag}(x)) = \det\bigl(x_{a_q}^{\mu_p+N-1-p}\bigr) / \det\bigl(x_{a_q}^{N-1-p}\bigr) = \Delta(x)/V(x)$, where $V(x) \neq 0$ as the z_i are distinct. Therefore $(-1)^{pq} \sum_\tau \Theta(x \circ \tau) = p!\, q!\, \chi_\lambda(\mathrm{diag}(x))$.

Conclusion. As d_λ is real, $\int_G e_\lambda(h^{-1}t_\tau h)\, dh = \overline{d_\lambda \int_G c_\lambda(h^{-1}t_\tau h)\, dh} = \overline{\Theta(x \circ \tau)}$, and conjugating the last identity gives

$$(-1)^{pq} \sum_{\sigma \in S_N} \int_G e_\lambda(h^{-1}t_\sigma h)\, dh = p!\, q!\, \overline{\chi_\lambda(\mathrm{diag}(z_1, \dots, z_N))}.$$

□

Theorem 5.8.50. *Let E be a CM field containing a primitive 5040-th root of unity, $N \geq 1$, and $G_f = G_f(\{1, \dots, N\})$, $\mathrm{K}_f = \mathbf{K}_0(\{1, \dots, N\})$ as in (VP1). For a finite place v of E with $v \neq \bar{v}$ let $\iota_v \colon \mathrm{GL}_N(E_v) \to G_f$ be the embedding at the place of E^+ below v (component 1 elsewhere), and for $g \in G_f$ let $g_v \in \mathrm{GL}_N(E_v)$ be its component and $g^{(v)} = g\, \iota_v(g_v)^{-1}$; extend $g \mapsto g^{(v)}$*

linearly to $a \mapsto a^{(v)}$ on $\mathbb{C}[G_f]$. Fix $i \in \{1,\dots,N\}$, let $J_v \subseteq \mathrm{GL}_N(\mathcal{O}_v)$ be the stabiliser of the line of the i-th basis vector modulo v, $t_v = \mathrm{diag}(1,\dots,\varpi_v,\dots,1)$ with a uniformiser ϖ_v at position i, and $T_v^+ \in \mathbb{C}[\mathrm{GL}_N(E_v)]$ the sum of a set of representatives of $J_v t_v J_v / J_v$. For an open subgroup $K \subseteq \mathrm{K}_f$ put $K' = \{k \in K :\ k_v \in J_v\}$, and for $a \in \mathbb{C}[G_f]$ and $l,m \geq 0$ put

$$b_{l,m} = \iota_v(T_v^+)^{m+1}\,(a^{(v)})^{l+1} \in \mathbb{C}[G_f].$$

(CU1) For every open $K \subseteq \mathrm{K}_f$, every finitely supported $a \in \mathbb{C}[G_f]$ and every finite place w of E there is a finite place v of E with $v \neq \bar v$ and $v \notin \{w, \bar w\}$, such that $\iota_v(\mathrm{GL}_N(\mathcal{O}_v)) \subseteq K$ and a is a linear combination of elements g with $g_v \in \mathrm{GL}_N(\mathcal{O}_v)$.

(CU2) Let $K \subseteq \mathrm{K}_f$ be open, let $a \in \mathbb{C}[G_f]$ be finitely supported and map K-fixed vectors to K-fixed vectors in every representation of G_f, and let v be as in (CU1) for K and a. Let ρ, ρ' be unitary representations of G_f on complex inner product spaces X, X' such that $X^{K'}$ and $X'^{K'}$ are finite-dimensional. Then each $b_{l,m}$ maps $X^{K'}$ and $X'^{K'}$ into themselves, and if

$$\mathrm{tr}(\rho(b_{l,m}) \mid X^{K'}) = \mathrm{tr}(\rho'(b_{l,m}) \mid X'^{K'}) \qquad \text{for all } l,m \geq 0,$$

then $\mathrm{tr}(\rho(a) \mid X^K) = \mathrm{tr}(\rho'(a) \mid X'^K)$.

(CU3) In the situation of (CU2), let $\phi(g) = \sum_h a_h \mathbf{1}_K(h^{-1}g)$ be cuspidal at a finite place w with $w \neq \bar w$ and $v \notin \{w, \bar w\}$. Then for all $l,m \geq 0$ the function $\phi_{l,m}(g) = \sum_h (b_{l,m})_h \mathbf{1}_{K'}(h^{-1}g)$ is cuspidal at w, and for every g with $\phi_{l,m}(g) \neq 0$ the component g_v has entries in $\mathcal{O}_v$ and 0 is a simple root of the characteristic polynomial of its reduction modulo v.

Proof. Throughout, for a finite place v of E with $v \neq \bar v$ let u be the place of E^+ below v. Then $E \otimes_{E^+} E_u^+ = E_v \times E_{\bar v}$, the factor of G_f at u is identified with $\mathrm{GL}_N(E_v)$ by the component at v, and ι_v is the inclusion of this factor; the factor of K_f at u is $\iota_v(\mathrm{GL}_N(\mathcal{O}_v))$. For an open subgroup $L \subseteq G_f$ and $c \in \mathbb{C}[G_f]$ write $\phi_c^L(g) = \sum_h c_h \mathbf{1}_L(h^{-1}g)$; then $\phi_{xc}^L(g) = \phi_c^L(x^{-1}g)$ for $x \in G_f$, and $c \mapsto \phi_c^L$ is linear.

Proof of (CU1). Infinitely many rational primes split completely in E (Chebotarev's density theorem), and a place v of E above such a prime has $E_v = \mathbb{Q}_p$ and $v \neq \bar v$, because the place of E^+ below it has two places of E above it. The remaining conditions exclude finitely many v. First, $v \in \{w, \bar w\}$ excludes at most two. Second, K is open in the compact group $K_f = \prod_u K_{f,u}$, so it contains $\prod_{u \notin S} K_{f,u}$ for a finite set S of places of E^+, and then $\iota_v(\mathrm{GL}_N(\mathcal{O}_v)) = K_{f,u} \subseteq K$ whenever $u \notin S$. Third, a has finitely many elements in its support, and each element g of the restricted product G_f has $g_v \in \mathrm{GL}_N(\mathcal{O}_v)$ for all but finitely many v. Any split v outside these finitely many places satisfies (CU1).

Reductions for (CU2) and (CU3). Fix K, a and v as in (CU2), so that $v \neq \bar v$, $\iota_v(\mathrm{GL}_N(\mathcal{O}_v)) \subseteq K$ and every g in the support of a has $g_v \in \mathrm{GL}_N(\mathcal{O}_v)$. Let $G^{(u)} \subseteq G_f$ be the subgroup of elements with component 1 at u. Every element of $G^{(u)}$ commutes with every element of $\iota_v(\mathrm{GL}_N(E_v))$, and $g^{(v)} \in G^{(u)}$. Hence $g \mapsto g^{(v)}$ is a homomorphism: $(gh)^{(v)} = g\,h\,\iota_v(h_v)^{-1}\iota_v(g_v)^{-1} = g\,\iota_v(g_v)^{-1}\,h\,\iota_v(h_v)^{-1} = g^{(v)}h^{(v)}$, using that $h^{(v)}$ commutes with $\iota_v(g_v)^{-1}$. For $k \in K$ we have $\iota_v(k_v) \in K_{f,u} \subseteq K$, so $k^{(v)} \in K$, and $k^{(v)}$ has component $1 \in J_v$ at v, so $k^{(v)} \in K'$; also $\iota_v(J_v) \subseteq K'$. Since $k = k^{(v)}\iota_v(k_v)$, this gives, for a representation ρ of G_f on X and $y \in X$:

$$y \in X^{K'} \iff y \text{ is fixed by } \rho(k^{(v)})\ (k \in K) \text{ and by } \rho(\iota_v(j))\ (j \in J_v), \tag{5.182}$$

and the same with $(K, \mathrm{GL}_N(\mathcal{O}_v))$ in place of (K', J_v). Let $\rho^{(v)}(g) = \rho(g^{(v)})$, a representation of G_f on X by the homomorphism property; the first condition in (5.182) says that y is K-fixed for $\rho^{(v)}$.

The operators at the cut level. Put $A = \rho(a^{(v)}) = \rho^{(v)}(a)$, and let T^+, T^-, e be the operators of Proposition 5.8.52 for the local field E_v, the index i and the representation $\rho \circ \iota_v$ of $\mathrm{GL}_N(E_v)$, acting on the vectors fixed by $\rho(\iota_v(J_v))$; thus T^+ is the action of $\iota_v(T_v^+)$ there. By the hypothesis on a, applied to $\rho^{(v)}$, the operator A maps the K-fixed vectors of $\rho^{(v)}$ to themselves; it commutes with $\rho(\iota_v(\mathrm{GL}_N(E_v)))$, so it maps the $\rho(\iota_v(J_v))$-fixed vectors to themselves. By Proposition 5.8.52(ii), $T^\pm$ and e preserve the $\rho(\iota_v(J_v))$-fixed vectors, and as combinations of elements of $\iota_v(\mathrm{GL}_N(E_v))$ they commute with $\rho^{(v)}(G_f)$, so they preserve the K-fixed vectors of $\rho^{(v)}$. By (5.182), A, $T^\pm$ and e preserve $X^{K'}$, and $\rho(b_{l,m})$ acts on $X^{K'}$ as $(T^+)^{m+1}A^{l+1} = A^{l+1}(T^+)^{m+1}$ (the factors commute); in particular $b_{l,m}$ maps $X^{K'}$ into itself. The same holds for ρ'.

Proof of (CU2). Restrict all operators to $X^{K'}$. By Proposition 5.8.52(iii), (iv) (the representation $\rho \circ \iota_v$ is unitary), $\langle T^+x, y\rangle = \langle x, T^-y\rangle$ and $T^+T^- = d(1 + ce)$ with $d = q_v^{N-2} > 0$ and $c = q_v^N - 1 > 0$, q_v the order of the residue field of v. By Proposition 5.8.52(ii), e maps $X^{K'}$ into the vectors fixed by $\rho(\iota_v(\mathrm{GL}_N(\mathcal{O}_v)))$; it also preserves the K-fixed vectors of $\rho^{(v)}$, so by (5.182) for K it maps $X^{K'}$ into X^K, and it is the identity on X^K, which is fixed by $\iota_v(\mathrm{GL}_N(\mathcal{O}_v)) \subseteq K$. So e is an idempotent of $X^{K'}$ with image X^K. Finally A commutes with $T^\pm$, since $\rho^{(v)}(G_f)$ commutes with $\rho(\iota_v(\mathrm{GL}_N(E_v)))$. Thus A, T^+, T^-, e on $X^{K'}$, and the corresponding operators on $X'^{K'}$, satisfy the hypotheses of Lemma 5.8.51 with the same d and c. The traces in that lemma are those of $\rho(b_{l,m})$ and $\rho'(b_{l,m})$ on $X^{K'}$ and $X'^{K'}$, equal by hypothesis; hence $\mathrm{tr}(Ae \mid X^{K'}) = \mathrm{tr}(A'e' \mid X'^{K'})$.

It remains to identify $\mathrm{tr}(Ae \mid X^{K'})$ with $\mathrm{tr}(\rho(a) \mid X^K)$. For $y \in X^K$ and g in the support of a, $\iota_v(g_v) \in K$, so $\rho(g)y = \rho(g^{(v)})\rho(\iota_v(g_v))y = \rho(g^{(v)})y$; hence $\rho(a)y = Ay$, and A maps X^K into itself. Let $\iota\colon X^K \to X^{K'}$ be the inclusion and $p\colon X^{K'} \to X^K$ the map e, so that $e = \iota \circ p$ and $p \circ \iota = \mathrm{id}$. Then $A\iota = \iota\, \rho(a)|_{X^K}$ and

$$\mathrm{tr}(Ae \mid X^{K'}) = \mathrm{tr}(\iota\, \rho(a)|_{X^K}\, p) = \mathrm{tr}(\rho(a)|_{X^K}\, p\, \iota) = \mathrm{tr}(\rho(a) \mid X^K).$$

The same holds for ρ', which proves (CU2).

Proof of (CU3). First, for $c \in \mathbb{C}[G_f]$ a combination of elements h with $h_v \in \mathrm{GL}_N(\mathcal{O}_v)$,

$$\phi^{K'}_{c^{(v)}}(g) = \mathbf{1}_{J_v}(g_v)\, \phi^K_c(g) \qquad (g \in G_f). \tag{5.183}$$

By linearity it suffices to take $c = h$. Then $(h^{(v)})^{-1}g = \iota_v(h_v)h^{-1}g$ has component $h_v h_v^{-1} g_v = g_v$ at v, and since $\iota_v(h_v) \in K$ it lies in K iff $h^{-1}g \in K$; so it lies in K' iff $h^{-1}g \in K$ and $g_v \in J_v$. The element a^{l+1} is a combination of products of elements of the support of a, which are integral at v, and $(a^{l+1})^{(v)} = (a^{(v)})^{l+1}$; so (5.183) gives $\phi^{K'}_{(a^{(v)})^{l+1}}(g) = \mathbf{1}_{J_v}(g_v)\phi^K_{a^{l+1}}(g)$, and $\phi_{l,m} = \phi^{K'}_{b_{l,m}}$ is the combination $\sum_x \beta_x\, \phi^{K'}_{(a^{(v)})^{l+1}}(x^{-1}\,\cdot\,)$, with $\iota_v(T_v^+)^{m+1} = \sum_x \beta_x x$.

Cuspidality at w. The defining condition, $\sum_{u' \in U_T} \psi(g\, \iota_w(\tilde{u}')) = 0$ for all g, T, t and lifts, is linear in ψ and is preserved by left translations $\psi \mapsto \psi(x^{-1}\,\cdot\,)$, since it is required for every g. Now $\phi^K_{a^{l+1}} = \phi^K_{a^l . a} = \sum_x (a^l)_x\, \phi(x^{-1}\,\cdot\,)$ is cuspidal at w. Since $v \notin \{w, \bar{w}\}$, the places of E^+ below v and w differ, so $(g\, \iota_w(\tilde{u}'))_v = g_v$ and the factor $\mathbf{1}_{J_v}(g_v)$ is constant on each sum of the condition; hence $\phi^{K'}_{(a^{(v)})^{l+1}}$ is cuspidal at w, and so is its combination of left translates $\phi_{l,m}$.

Support at v. By Lemma 5.8.53 for E_v (with $m + 1 \geq 1$), the support of $(T_v^+)^{m+1}$ consists of elements $x' \in \mathrm{GL}_N(E_v)$ such that $x'j$ is integral with 0 a simple root of the characteristic polynomial of its reduction for every $j \in J_v$. The support of $(a^{(v)})^{l+1}$ lies in $G^{(u)}$. If $\phi_{l,m}(g) \neq 0$, there are x' in the first support and h in the second with $(\iota_v(x')h)^{-1}g \in K'$; its component at v is $x'^{-1}g_v$ (as $h_v = 1$), so $g_v = x'j$ with $j \in J_v$, and g_v has the stated property. □

Lemma 5.8.51. *Let $d, c > 0$ be real numbers. Let X be a finite-dimensional complex inner product space with linear operators A, T^+, T^-, e such that $\langle T^+x, y\rangle = \langle x, T^-y\rangle$ for all $x, y \in X$,*

$e^2 = e$,

$$T^+T^- = d\,(1 + c\,e),$$

and A commutes with T^+ and with T^-. Let X', A', T'^+, T'^-, e' satisfy the same conditions with the same d, c. If

$$\operatorname{tr}\big(A^{l+1}(T^+)^{m+1} \mid X\big) = \operatorname{tr}\big(A'^{\,l+1}(T'^+)^{m+1} \mid X'\big) \qquad \text{for all integers } l, m \geq 0,$$

then $\operatorname{tr}(Ae \mid X) = \operatorname{tr}(A'e' \mid X')$.

Proof. For $\mu \in \mathbb{C}$ let $X_\mu = \ker(A - \mu)^{\dim X}$ be the generalised eigenspace of A, so that $X = \bigoplus_\mu X_\mu$ with finitely many nonzero summands, and define X'_μ in the same way for A'. The relation $T^+T^- = d(1+ce)$ gives $e = c^{-1}(d^{-1}T^+T^- - 1)$, so e commutes with A. Every operator commuting with A preserves each X_μ; write B_μ for the restriction of such an operator B to X_μ. The restrictions $T^\pm_\mu$, e_μ satisfy the same three relations on X_μ with its induced inner product; in particular $T^-_\mu = (T^+_\mu)^*$, the adjoint in X_μ. The same holds on X'.

Traces split over the generalised eigenspaces. Let B commute with A and let $l \geq 0$. On X_μ the operator $A_\mu - \mu$ is nilpotent and $A_\mu^l - \mu^l = (A_\mu - \mu)P(A_\mu)$ for a polynomial P, so $(A_\mu^l - \mu^l)B_\mu$ is a product of commuting operators one of which is nilpotent; it is nilpotent and has trace 0. Hence

$$\operatorname{tr}(A^l B \mid X) = \sum_\mu \mu^l \operatorname{tr}(B_\mu \mid X_\mu). \tag{5.184}$$

The traces of the powers of T^+ on each X_μ, $\mu \neq 0$, agree. Let S be the finite set of nonzero μ with $X_\mu \neq 0$ or $X'_\mu \neq 0$. Fix $m \geq 0$ and put $\delta(\mu) = \operatorname{tr}((T^+_\mu)^{m+1}) - \operatorname{tr}((T'^+_\mu)^{m+1})$. By (5.184) with $B = (T^+)^{m+1}$ and exponent $l+1$ (the term $\mu = 0$ vanishes) and the hypothesis, $\sum_{\mu\in S} \mu^{l+1}\delta(\mu) = 0$ for $l = 0, \dots, |S| - 1$. The matrix $(\mu^{l+1})_{l,\mu}$ is a Vandermonde matrix times $\operatorname{diag}(\mu)_{\mu\in S}$, invertible since the $\mu \in S$ are distinct and nonzero. So $\delta(\mu) = 0$ for every $\mu \neq 0$ and every $m \geq 0$.

Determinants. Let $\mu \in S$, $n_\mu = \dim X_\mu$ and $r_\mu = \operatorname{rank} e_\mu$. Since e_μ is idempotent, $X_\mu = \operatorname{im} e_\mu \oplus \ker e_\mu$ and $1 + ce_\mu$ is multiplication by $1 + c$ on the first summand and the identity on the second. Therefore

$$|\det T^+_\mu|^2 = \det\big(T^+_\mu (T^+_\mu)^*\big) = \det\big(d(1 + ce_\mu)\big) = d^{\,n_\mu}(1 + c)^{r_\mu} > 0,$$

so T^+_μ is invertible; likewise $|\det T'^+_\mu|^2 = d^{\,n'_\mu}(1 + c)^{r'_\mu}$ and T'^+_μ is invertible.

The characteristic polynomials of T^+_μ and T'^+_μ agree. For an eigenvalue ν let $a(\nu)$, $a'(\nu)$ be its algebraic multiplicities for T^+_μ and T'^+_μ; all eigenvalues of both are nonzero. Then $\operatorname{tr}((T^+_\mu)^j) = \sum_\nu a(\nu)\nu^j$ and similarly for T'^+_μ, and these agree for every $j \geq 1$ by the previous step. The same Vandermonde argument, over the finite set of nonzero ν that are eigenvalues of either operator, gives $a(\nu) = a'(\nu)$ for all ν. Hence the two characteristic polynomials are equal; comparing degrees gives $n_\mu = n'_\mu$, and comparing constant terms gives $\det T^+_\mu = \det T'^+_\mu$.

Ranks. By the two previous steps $d^{\,n_\mu}(1 + c)^{r_\mu} = d^{\,n_\mu}(1 + c)^{r'_\mu}$, and $1 + c > 1$, so $r_\mu = r'_\mu$ for every $\mu \neq 0$.

Conclusion. By (5.184) with $l = 1$ and $B = e$, and since the trace of an idempotent is its rank,

$$\operatorname{tr}(Ae \mid X) = \sum_\mu \mu \operatorname{tr}(e_\mu) = \sum_{\mu\neq 0} \mu\, r_\mu = \sum_{\mu\neq 0} \mu\, r'_\mu = \operatorname{tr}(A'e' \mid X').$$

□

Proposition 5.8.52. *Let F be a non-archimedean local field with ring of integers $\mathcal{O}$, uniformiser ϖ and residue field k of order q, let $N \geq 1$ and $1 \leq i \leq N$. Let $J \subseteq \mathrm{GL}_N(\mathcal{O})$ be the group of elements whose reduction modulo ϖ maps the line $ke_i \subseteq k^N$ to itself, and let $t = \mathrm{diag}(t_1, \ldots, t_N)$ with $t_i = \varpi$ and $t_j = 1$ for $j \neq i$. Then:*

1. *each of JtJ and $Jt^{-1}J$ is the disjoint union of exactly q^{N-1} left cosets gJ.*

Let ρ be a representation of $\mathrm{GL}_N(F)$ on a complex vector space X, and for $y \in X^J$ put

$$T^+ y = \sum_{gJ \subseteq JtJ} \rho(g) y, \qquad T^- y = \sum_{gJ \subseteq Jt^{-1}J} \rho(g) y, \qquad e\, y = \frac{1}{[\mathrm{GL}_N(\mathcal{O}) : J]} \sum_{kJ \subseteq \mathrm{GL}_N(\mathcal{O})} \rho(k) y,$$

the sums running over the left cosets of J in the indicated sets (each term depends only on the coset). Then:

2. *T^+, T^- and e map X^J into X^J; e maps X^J onto $X^{\mathrm{GL}_N(\mathcal{O})}$ and is the identity on $X^{\mathrm{GL}_N(\mathcal{O})}$;*
3. *for every $y \in X^J$,*
$$T^+ T^- y = q^{N-2}(y + (q^N - 1)\, e\, y);$$
4. *if X carries an inner product with $\langle \rho(g)x, \rho(g)y \rangle = \langle x, y \rangle$ for all g, then $\langle T^+ x, y \rangle = \langle x, T^- y \rangle$ for all $x, y \in X^J$.*

Proof. Write $\bar{g} \in \mathrm{GL}_N(k)$ for the reduction of $g \in \mathrm{GL}_N(\mathcal{O})$; reduction is surjective onto $\mathrm{GL}_N(k)$, and its kernel lies in every group considered below. Let $\ell_0 = ke_i$ and $H_0 = \{x \in k^N : x_i = 0\}$, so $\ell_0 \not\subseteq H_0$. Let $J^\flat \subseteq \mathrm{GL}_N(\mathcal{O})$ be the group of elements whose reduction maps H_0 to itself. An element $g \in \mathrm{GL}_N(\mathcal{O})$ lies in J iff $g_{ai} \in \varpi\mathcal{O}$ for $a \neq i$, and in $J^\flat$ iff $g_{ib} \in \varpi\mathcal{O}$ for $b \neq i$. For a subgroup $J_1 \subseteq \mathrm{GL}_N(\mathcal{O})$ containing the kernel of reduction, $gJ_1 = g'J_1$ for $g, g' \in \mathrm{GL}_N(\mathcal{O})$ iff $\bar{g}^{-1}\bar{g}' \in \bar{J}_1$.

Conjugation by t. $(tgt^{-1})_{ab} = t_a g_{ab} t_b^{-1}$: conjugation by t multiplies row i by ϖ and divides column i by ϖ. For $g \in J$ the entries g_{ai}/ϖ $(a \neq i)$ are integral, so tgt^{-1} is integral with the same unit determinant and with row i off the diagonal in $\varpi\mathcal{O}$; thus $tJt^{-1} \subseteq J^\flat$. The same computation with t^{-1} gives $t^{-1}J^\flat t \subseteq J$. Hence $tJt^{-1} = J^\flat$.

Cosets in JtJ. The map $j \mapsto jtJ$ induces a bijection $J/(J \cap tJt^{-1}) \to JtJ/J$, since $jtJ = j'tJ$ iff $j^{-1}j' \in tJt^{-1}$. Here $J \cap tJt^{-1} = J \cap J^\flat$, and $J/(J \cap J^\flat) \cong \bar{J}/(\bar{J} \cap \bar{J}^\flat)$ is in bijection, by $j \mapsto \bar{j}H_0$, with the orbit of H_0 under $\bar{J}$, the stabiliser of ℓ_0. That orbit is the set of hyperplanes $H \subseteq k^N$ with $\ell_0 \not\subseteq H$: such an H is $\ker \xi$ for a unique linear form ξ with $\xi(e_i) = 1$, and the element $g \in \mathrm{GL}_N(k)$ with $ge_i = e_i$ and $ge_j = e_j - \xi(e_j)e_i$ for $j \neq i$ lies in $\bar{J}$ and maps H_0 into, hence onto, H, since $\xi(ge_j) = 0$; conversely every element of $\bar{J}$ maps H_0 to a hyperplane not containing ℓ_0. There are q^{N-1} such forms. So

$$JtJ = \bigsqcup_{H \not\supseteq \ell_0} j_H t J, \qquad j_H \in J,\ \bar{j}_H H_0 = H, \tag{5.185}$$

with q^{N-1} cosets. Since $\mathrm{GL}_N(F)$ is unimodular and J is compact open, the number of left cosets of J in a double coset equals the number of right cosets, and inversion maps the right cosets in JtJ onto the left cosets in $Jt^{-1}J$; this proves (i).

Cosets in $Jt^{-1}J$. By $tJt^{-1} = J^\flat$ we have $Jt^{-1}J = t^{-1}(J^\flat J)$, and $hJ \mapsto \bar{h}\ell_0$ is a bijection from $J^\flat J/J \cong J^\flat/(J^\flat \cap J)$ onto the orbit of ℓ_0 under $\bar{J}^\flat$, the stabiliser of H_0. That orbit is the set of lines $\ell \not\subseteq H_0$: such a line is kz for a unique z with $z_i = 1$, and the element h with $he_i = z$

and $he_j = e_j$ for $j \neq i$ lies in $\bar{J}^\flat$ and maps ℓ_0 onto ℓ; conversely $\bar{J}^\flat$ maps ℓ_0 to lines not contained in H_0. There are q^{N-1} such lines. So

$$Jt^{-1}J = \bigsqcup_{\ell \not\subseteq H_0} t^{-1} h_\ell J, \qquad h_\ell \in J^\flat,\ \bar{h}_\ell \ell_0 = \ell. \tag{5.186}$$

Proof of (ii). For $j \in J$ left multiplication by j permutes the left cosets of J in JtJ, in $Jt^{-1}J$ and in $\mathrm{GL}_N(\mathcal{O})$, so $\rho(j)T^\pm y = T^\pm y$ and $\rho(j)ey = ey$; the same argument for $j \in \mathrm{GL}_N(\mathcal{O})$ shows that ey is fixed by $\mathrm{GL}_N(\mathcal{O})$. If y is fixed by $\mathrm{GL}_N(\mathcal{O})$, every term of ey is y, so $ey = y$.

Proof of (iii). Let $y \in X^J$. For a line $\ell \subseteq k^N$ put $y[\ell] = \rho(g)y$ for any $g \in \mathrm{GL}_N(\mathcal{O})$ with $\bar{g}\ell_0 = \ell$; this is well defined because two such g differ on the right by an element of J, and $\rho(h)y[\ell] = y[\bar{h}\ell]$ for $h \in \mathrm{GL}_N(\mathcal{O})$, $y[\ell_0] = y$. By (5.186), $\rho(t)T^- y = \sum_{\ell \not\subseteq H_0} y[\ell]$. By (ii) $T^- y \in X^J$, so by (5.185)

$$T^+T^- y = \sum_{H \not\supseteq \ell_0} \rho(j_H)\rho(t)T^- y = \sum_{H \not\supseteq \ell_0} \sum_{\ell \not\subseteq H_0} y[\bar{j}_H \ell] = \sum_{H \not\supseteq \ell_0} \sum_{\ell \not\subseteq H} y[\ell],$$

since $\bar{j}_H$ maps the lines not contained in H_0 bijectively onto those not contained in H. Exchange the sums. The line ℓ_0 lies in no H of the outer sum and is counted q^{N-1} times. A line $\ell = kz \neq \ell_0$ is counted once for each form ξ with $\xi(e_i) = 1$ and $\xi(z) \neq 0$; since e_i, z are linearly independent, q^{N-2} of the q^{N-1} forms with $\xi(e_i) = 1$ have $\xi(z) = 0$, so ℓ is counted $q^{N-1} - q^{N-2}$ times. The number of lines is $[\mathrm{GL}_N(\mathcal{O}) : J] = (q^N - 1)/(q-1)$, and $\sum_\ell y[\ell] = \sum_{kJ \subseteq \mathrm{GL}_N(\mathcal{O})} \rho(k)y = \frac{q^N-1}{q-1}\, ey$. Hence

$$T^+T^- y = q^{N-1}y + q^{N-2}(q-1)\Big(\frac{q^N-1}{q-1}\, ey - y\Big) = q^{N-2}\big(y + (q^N - 1)\, ey\big).$$

Proof of (iv). Let $x, y \in X^J$ and $g = jtj'$ with $j, j' \in J$. Then

$$\langle \rho(g)x, y\rangle = \langle \rho(t)\rho(j')x, \rho(j)^{-1}y\rangle = \langle \rho(t)x, y\rangle$$

by unitarity and the invariance of x and y. Summing over the q^{N-1} cosets of (i), $\langle T^+x, y\rangle = q^{N-1}\langle \rho(t)x, y\rangle$. In the same way, every $g \in Jt^{-1}J$ gives $\langle x, \rho(g)y\rangle = \langle x, \rho(t^{-1})y\rangle$, so

$$\langle x, T^- y\rangle = q^{N-1}\langle x, \rho(t)^{-1}y\rangle = q^{N-1}\langle \rho(t)x, y\rangle.$$

□

Lemma 5.8.53. *Let F be a non-archimedean local field with ring of integers $\mathcal{O}$ and uniformiser ϖ, let $N \geq 1$, $1 \leq i \leq N$, let $J \subseteq \mathrm{GL}_N(\mathcal{O})$ be the stabiliser of the line of e_i modulo ϖ, $t = \mathrm{diag}(1, \ldots, \varpi, \ldots, 1)$ with ϖ at position i, and let $T^+ \in \mathbb{C}[\mathrm{GL}_N(F)]$ be the sum of a set of representatives of the left cosets of J in JtJ. Then for every $m \geq 1$ the element $(T^+)^m$ is a linear combination of elements $x \in \mathrm{GL}_N(F)$ with the following property: for every $j \in J$ the matrix xj has entries in $\mathcal{O}$, and 0 is a simple root of the characteristic polynomial of its reduction modulo ϖ.*

Proof. Let k be the residue field, $\bar{g}$ the reduction of a matrix g with entries in $\mathcal{O}$, and $\ell_0 = ke_i$. Let D' be the set of $g \in \mathrm{GL}_N(F)$ with entries in $\mathcal{O}$ such that $\bar{g}\ell_0 \subseteq \ell_0$ and the map induced by $\bar{g}$ on k^N/ℓ_0 is invertible, and let $D \subseteq D'$ be the subset of those with $\bar{g}e_i = 0$.

Closure properties. Reduction is multiplicative on matrices with entries in $\mathcal{O}$, and the induced maps on k^N/ℓ_0 multiply; hence $D'D' \subseteq D'$. If $g \in D$ and $h \in D'$ then $\overline{gh}\, e_i = \bar{g}(\bar{h}e_i) \in \bar{g}\ell_0 = 0$ and $\overline{hg}\, e_i = \bar{h}(0) = 0$, so $DD' \subseteq D$ and $D'D \subseteq D$; also $DD \subseteq D$.

The generators. $J \subseteq D'$: an element of J is a unit of $\mathrm{M}_N(\mathcal{O})$, its reduction is invertible and preserves ℓ_0, so the induced map on the quotient is invertible. $t \in D$: $\bar{t}$ is diagonal with entry 0 at i and 1 elsewhere, so $\bar{t}e_i = 0$ and $\bar{t}$ induces the identity on k^N/ℓ_0. Hence $JtJ \subseteq D'DD' \subseteq D$, so T^+ is a sum of elements of D, and for $m \geq 1$ the element $(T^+)^m$ is a linear combination of products of m elements of D, which lie in D.

Elements of D. Let $x \in D$ and $j \in J$; then $xj \in DD' \subseteq D$. For $g \in D$, in a basis of k^N beginning with e_i the matrix $\bar{g}$ has the block form $\begin{pmatrix} 0 & * \\ 0 & g' \end{pmatrix}$ with g' the invertible map induced on k^N/ℓ_0. So the characteristic polynomial of $\bar{g}$ is $X \cdot \det(X - g')$, and $\det(0 - g') = \pm \det g' \neq 0$: the root 0 is simple. Applied to $g = xj$ this is the claim. □

Proposition 5.8.54. *Let D be admissible data. Then E satisfies (Um) of Definition 3.2.5,*

$$\dim_{\mathbb{C}} \mathcal{A}_M(W_m) = \#\bar{G} \cdot \mathrm{mass}(I_r) \cdot \prod_{v \in \Phi} \mathrm{d}(\varsigma(v)), \qquad \text{and} \qquad d_{\mathcal{T}} \;\leq\; \#\bar{G} \cdot \mathrm{mass}(I_r) \cdot \prod_{v \in \Phi} \mathrm{d}(\varsigma(v)).$$

Proof. Step 0: (Um). $E = E_s$ satisfies (Um) by (2) of Lemma 3.2.9.

Step 1: the space and its forms. W_m has all signs $+1$ ($k + m - 1 = r$), so it is the standard definite space E^r with lattice $L = \mathcal{O}_E^r$ and the identity frame; $G = \mathrm{U}(W_m) = \mathrm{U}_r$, $\Gamma = G(E^+)$, $G_f = G_f(\{1, \ldots, r\})$ and $\mathrm{K}_f = \mathbf{K}_0(\{1, \ldots, r\})$ (the stabiliser of $\widehat{L}$) as in (VP1) of Definition 3.2.2, and K_M as in (HO1). At $v \in \Phi$ the group is $\mathrm{U}(r)$, compact. The entries of $\varsigma(v)$ are strictly decreasing integers ($\varsigma(v)_{k-2+i} = -\kappa(v) - i\Delta$ for $1 \leq i \leq m$, below the entries $\frac{k}{2} - 1 > \cdots > 1 - \frac{k}{2}$) and r is odd, so Theorem 5.7.41(i) gives a unique irreducible representation τ_v of $\mathrm{U}(r)$ with Harish-Chandra parameter $\varsigma(v)$. For the compact group, with μ^{cd} the Haar probability measure, Schur's orthogonality gives $\int |\langle w, \tau_v(g)v' \rangle|^2 \, dg = \|v'\|^2 \|w\|^2 / \dim \tau_v$, and Theorem 5.7.41(ii) gives the same with $\mathrm{d}(\varsigma(v))$; so $\dim \tau_v = \mathrm{d}(\varsigma(v))$. Let $\tau = \bigotimes_v \tau_v$ on W_τ, $\dim W_\tau = \prod_v \mathrm{d}(\varsigma(v))$. By Lemma 5.8.56(ii), $\mathcal{A}_M(W_m)$ is isomorphic to the space of $\varphi \colon G_f \to W_\tau^\vee$ with $\varphi(\gamma_f g k) = \tau^\vee(\gamma_\infty)\varphi(g)$ for $\gamma \in \Gamma$, $k \in \mathrm{K}_M$, where $\tau^\vee$ is the contragredient of τ and $\dim W_\tau^\vee = \dim W_\tau$.

Step 2: free classes. $\Gamma \backslash G_f / \mathrm{K}_M$ is finite (G_f/K_M is covered by finitely many Γ-orbits since $\Gamma \backslash G_f / \mathrm{K}_f$ is finite and $[\mathrm{K}_f : \mathrm{K}_M] < \infty$). A function in $\mathcal{A}_M(W_m)$ is determined by its values at representatives g_x of the double cosets, and the value at g_x is an arbitrary vector fixed by $\tau^\vee(\gamma_\infty)$ for the $\gamma \in \Gamma$ with $\gamma_f \in g_x \mathrm{K}_M g_x^{-1}$. By Lemma 4.6.2(c) (with any chosen place w; K_M acts trivially on L_w / wL_w) these groups are trivial, so

$$\dim \mathcal{A}_M(W_m) = \#(\Gamma \backslash G_f / \mathrm{K}_M) \cdot \prod_{v \in \Phi} \mathrm{d}(\varsigma(v)).$$

Step 3: counting classes. By Step 1, W_m is E^r with $h(x, y) = \sum_i \bar{x}_i y_i$ and the lattice $L = \mathcal{O}_E^r$, and K_f is the stabiliser of $\widehat{L}$ in G_f; K_M is an open subgroup of K_f, and $\Gamma \cap g\mathrm{K}_M g^{-1} = \{1\}$ for every $g \in G_f$ by Lemma 4.6.2(c), as in Step 2. By Step 0 and Lemma 5.6.7 with $n = r$ and the level K_M,

$$\#(\Gamma \backslash G_f / \mathrm{K}_M) = [\mathrm{K}_f : \mathrm{K}_M] \cdot \mathrm{mass}(I_r).$$

Finally $\mathrm{K}_f / \mathrm{K}_M \cong \bar{G}$: by Lemma 4.6.2(a) each chosen place w lies over a split place of E^+ and distinct chosen places lie over distinct places, where K_f has the factor $\mathrm{GL}_r(\mathcal{O}_w)$, whose reduction onto $\mathrm{GL}_r(k_w)$ is surjective; K_M is the kernel of the product of these reductions. This proves the formula for $\dim \mathcal{A}_M(W_m)$.

Step 4. By Proposition 5.8.4(iii) with $j = m$, $d_{\mathcal{T}} = \dim \mathcal{A}^{\mathrm{good}}(W_m) \leq \dim \mathcal{A}_M(W_m)$.

□

Proposition 5.8.55. *Let D be admissible data and V, V' framed spaces such that ς has gap Δ for both. Let $(\gamma_i)_{i\in I}$ be a countable family in G^M and $(c_i)_{i\in I}$ complex numbers, and for $U \in \{V, V'\}$ let R_U be a linear operator on $\mathcal{A}_M(U)$ such that for all $z, y \in \mathcal{A}_M(U)$ the family $\left(c_i\langle z, \rho_U(\gamma_i)y\rangle\right)_{i\in I}$ is summable with sum $\langle z, R_U y\rangle$. Then there is $a \in \mathcal{H}^M$ with $R_V = T_a(V)$ and $R_{V'} = T_a(V')$. In particular R_U preserves $\mathcal{A}^{\mathrm{good}}(U)$, and the restrictions of R_V and $R_{V'}$ to the good forms have the same characteristic polynomial and the same determinant.*

Proof. Step 1: one translation. Let $\gamma \in G^M$. Put $H' = K_f \cap G^M$, an open compact subgroup contained in K_M, and $H = H' \cap \gamma H'\gamma^{-1}$, of finite index in H'. Let

$$p_\gamma = \frac{1}{[H' : H]} \sum_{k\in H'/H} k\gamma \ \in \mathbb{C}[G^M],$$

which does not depend on the representatives k when applied to H'-fixed vectors (if $h \in H$ then $\gamma^{-1}h\gamma \in H'$). It lies in $\mathcal{H}^M$: let x be fixed by K_M in a representation π. Left multiplication by H' permutes the classes kH, so $\pi(p_\gamma)x$ is H'-fixed. $K_M = K_M^c H'$, where K_M^c is the subgroup of elements of K_M with component 1 at the places not below chosen places; elements of K_M^c commute with G^M and fix x, so they fix $\pi(p_\gamma)x$. Since ρ_U is unitary and $z \in \mathcal{A}_M(U)$ is fixed by $H' \subseteq K_M$,

$$\langle z, \rho_U(p_\gamma)y\rangle = \frac{1}{[H' : H]} \sum_k \langle \rho_U(k)^{-1}z, \rho_U(\gamma)y\rangle = \langle z, \rho_U(\gamma)y\rangle \qquad (z, y \in \mathcal{A}_M(U)),$$

for every framed space U.

Step 2: the series. The spaces $\mathcal{A}_M(V)$, $\mathcal{A}_M(V')$ are finite-dimensional (Proposition 5.8.4). For $a \in \mathcal{H}^M$ let $\Psi(a)$ be the pair of sesquilinear forms $(z, y) \mapsto \langle z, T_a(V)y\rangle$ on $\mathcal{A}_M(V)$ and $(z, y) \mapsto \langle z, T_a(V')y\rangle$ on $\mathcal{A}_M(V')$. Ψ is linear and factors through the finite-dimensional space $\operatorname{End}\mathcal{A}_M(V) \times \operatorname{End}\mathcal{A}_M(V')$, so its image $\mathcal{Z}$ is finite-dimensional, hence closed in the (finite-dimensional) space of pairs of forms. By Step 1 the i-th pair of terms is $\Psi(c_i p_{\gamma_i}) \in \mathcal{Z}$; the pair of sums $\left(\langle z, R_V y\rangle, \langle z, R_{V'} y\rangle\right)$ is a limit of finite partial sums, so it lies in $\mathcal{Z}$: it equals $\Psi(a)$ for some $a \in \mathcal{H}^M$. As the Petersson product is nondegenerate, $R_V = T_a(V)$ and $R_{V'} = T_a(V')$.

Step 3. By Proposition 5.8.4, T_a preserves the good forms and has the same characteristic polynomial and determinant on $\mathcal{A}^{\mathrm{good}}(V)$ and on $\mathcal{A}^{\mathrm{good}}(V')$.

Application. □

Lemma 5.8.56. *Let V be a framed space of rank r all of whose signs are $+1$. Through its frames, $\mathrm{U}(V)(\mathbb{A}_{E^+}) = G_\infty \times G_f$ with $G_\infty = \prod_{v\in\Phi} \mathrm{U}(r)$ compact; let $\Gamma \subseteq G_\infty \times G_f$ be the image of $\mathrm{U}(V)(E^+)$, with elements $\gamma = (\gamma_\infty, \gamma_f)$.*

1. *Let π be an irreducible unitary representation of G_∞ on W, $\pi^\vee$ its contragredient on the dual space $W^\vee$, $u \in W$ a unit vector, and $e(h) = \dim W \cdot \overline{\langle u, \pi(h)u\rangle}$. A function $F\colon G_\infty \times G_f \to \mathbb{C}$ is bounded, continuous, left invariant under Γ, right invariant under an open subgroup of G_f, and satisfies $\int_{G_\infty} e(h)F(xh, g)\,dh = F(x, g)$ for all (x, g), if and only if*

$$F(x, g) = \varphi(g)(\pi(x)u) \qquad (x \in G_\infty,\ g \in G_f)$$

for a function $\varphi\colon G_f \to W^\vee$ that is right invariant under an open subgroup of G_f and satisfies $\varphi(\gamma_f g) = \pi^\vee(\gamma_\infty)\varphi(g)$ for all $\gamma \in \Gamma$. The function φ is unique; for an open subgroup $K \subseteq G_f$, F is right invariant under K if and only if φ is; and $\varphi \mapsto F$ is linear and commutes with right translation by G_f.

2. *Suppose that for every $v \in \Phi$ the entries of $\varsigma(v)$ are strictly decreasing and lie in $\frac{r-1}{2}+\mathbb{Z}$. Let π_v be the irreducible representation of $\mathrm{U}(r)$ with Harish-Chandra parameter $\varsigma(v)$ and $\pi = \bigotimes_v \pi_v$ on $W = \bigotimes_v W_v$. Then $\varphi \mapsto F$ of (i) restricts to a linear isomorphism, commuting with right translation by G_f, from the space of functions $\varphi\colon G_f \to W^\vee$ with*

$$\varphi(\gamma_f g k) = \pi^\vee(\gamma_\infty)\varphi(g) \qquad (\gamma \in \Gamma,\ g \in G_f,\ k \in \mathrm{K}_M)$$

onto $\mathcal{A}_M(V)$; and $\dim W = \prod_v \dim \pi_v$.

Proof. Proof of (i), necessity. Let F have the listed properties and fix g. Since $\overline{\langle u, \pi(h)u\rangle} = \langle \pi(h)u, u\rangle = \langle u, \pi(h^{-1})u\rangle$, the substitution $y = xh$ (Haar measure is invariant) gives

$$\begin{aligned} F(x,g) &= \dim W \int_{G_\infty} \langle u, \pi(y^{-1}x)u\rangle F(y,g)\,dy \\ &= \dim W \int_{G_\infty} \langle \pi(y)u, \pi(x)u\rangle F(y,g)\,dy = \varphi(g)(\pi(x)u), \end{aligned}$$

where $\varphi(g) \in W^\vee$ is the linear form $z \mapsto \dim W \int_{G_\infty} F(y,g)\langle \pi(y)u, z\rangle\,dy$ (the integrand is continuous on a compact group). If F is right invariant under an open K, then $\varphi(gk)(\pi(x)u) = \varphi(g)(\pi(x)u)$ for all x; since π is irreducible and $u \neq 0$, the vectors $\pi(x)u$ span W, so $\varphi(gk) = \varphi(g)$. Left invariance under $\gamma \in \Gamma$ gives $\varphi(\gamma_f g)(\pi(\gamma_\infty)\pi(x)u) = \varphi(g)(\pi(x)u)$ for all x, hence $\varphi(\gamma_f g) \circ \pi(\gamma_\infty) = \varphi(g)$, that is $\varphi(\gamma_f g) = \pi^\vee(\gamma_\infty)\varphi(g)$. Uniqueness of φ follows from the same spanning property.

Proof of (i), sufficiency. Let φ be given, right invariant under an open subgroup L, and $F(x,g) = \varphi(g)(\pi(x)u)$. Then φ is constant on the open cosets gL, so F is continuous; F is right invariant under L and, by the transformation law, left invariant under Γ. Give $W^\vee$ the norm dual to that of W, for which $\pi^\vee$ is unitary. Then $\|\varphi(\gamma_f g)\| = \|\varphi(g)\|$ and $\|\varphi(gl)\| = \|\varphi(g)\|$ for $l \in L$, so $\|\varphi\|$ is a function on $\Gamma_f \backslash G_f / L$, Γ_f the projection of Γ. This set is finite: it is the double coset space $\mathrm{U}(V)(E^+)\backslash \mathrm{U}(V)(\mathbb{A}_{E^+})/(G_\infty \times L)$, finite by Borel's finiteness of class numbers [33]. Hence $|F(x,g)| \leq \|\varphi(g)\|$ is bounded. For the convolution identity fix (x,g) and let $w \in W$ represent the linear form $\varphi(g) \circ \pi(x)$, that is $\varphi(g)(\pi(x)z) = \langle w, z\rangle$. Schur's orthogonality relations for the compact group G_∞ give

$$\begin{aligned} \int_{G_\infty} e(h)F(xh,g)\,dh &= \dim W \int_{G_\infty} \langle w, \pi(h)u\rangle\, \overline{\langle u, \pi(h)u\rangle}\,dh \\ &= \langle u,u\rangle\,\langle w,u\rangle = \varphi(g)(\pi(x)u) = F(x,g). \end{aligned}$$

Linearity of $\varphi \mapsto F$ is clear, and $F(x,gh) = \varphi(gh)(\pi(x)u)$, so right translation of F by $h \in G_f$ corresponds to right translation of φ; the statement about K-invariance was shown in the first part.

Proof of (ii). By Theorem 5.7.41(i), applied to the sign vector $(+,\dots,+)$, for which the group is the compact group $\mathrm{U}(r)$, there is up to equivalence exactly one square-integrable representation π_v with Harish-Chandra parameter $\varsigma(v)$; a square-integrable irreducible unitary representation of a compact group is finite-dimensional. We show that $c_{\varsigma(v)}(h) = \langle u_v, \pi_v(h)u_v\rangle$ for a unit vector $u_v \in W_v$. Write $\lambda = \varsigma(v)$, $l = 2\lambda$, $K = \mathrm{U}(r)$ with its Haar probability measure, and $\mu = \mu_l$, $m = m_\mu$ as in Definition 3.2.3. For the signs $(+,\dots,+)$, $\mathrm{bd}(g) = g$, $\mathrm{bd}(g)^{-1}g = 1$ and $m_{-l^\rho}(k^*k) = m_{-l^\rho}(1) = 1$, so (3.2) gives

$$c_\lambda(g) = \|m\|^{-2} \int_K m(gk)\,\overline{m(k)}\,dk \qquad (g \in K).$$

As λ is strictly decreasing with entries in $\frac{r-1}{2}+\mathbb{Z}$, $2\rho_l(i)=r+1-2i$ and $l_i+2\rho_l(i)$ is even, so $\mu(i)=\lambda_i-\frac{r+1}{2}+i$: $\mu=\lambda-\rho$ is integral and weakly decreasing, and it is the highest weight $\Lambda_\varepsilon(\lambda)$ of (Dp3) of Definition 5.1.1 for $\varepsilon=(+,\dots,+)$ (all roots compact). (a) *m is a highest weight vector for right translation.* If b is invertible and $b_{ij}=0$ whenever $j\in P$, $i\notin P$, the $P\times P$ block of gb is $g_{PP}b_{PP}$, so $\Delta_P(gb)=\Delta_P(g)\Delta_P(b)$. The sets $\{i:\mu_i\ge t\}$ are initial segments of $\{1,\dots,r\}$, so every invertible upper triangular b has this property for all of them, and (3.1) gives $m(gb)=m(g)\prod_i b_{ii}^{\mu_i}$. In particular $m(kt)=t^\mu m(k)$ for diagonal $t\in K$, and $m(g(1+xE_{ij}))=m(g)$ for $i<j$, $x\in\mathbb{C}$. (b) *The right translates of m.* On K, m is a polynomial in the entries of k and $\bar k$ ($\det k^{-1}=\overline{\det k}$), so the functions $R(h)m$, $R(h)f(k)=f(kh)$, span a finite-dimensional space $V\subseteq C(K)$, on which R is a continuous unitary representation for the inner product of $L^2(K)$. The function m and its right translates are restrictions of holomorphic functions on $\mathrm{GL}_r(\mathbb{C})$ (polynomials in the entries and $\det^{-1}$), so the complexified action of $X\in\mathfrak{gl}_r(\mathbb{C})$ on V is $f\mapsto\frac{d}{dx}\big|_{x=0}f(k\exp(xX))$; by (a), E_{ij} ($i<j$) kills m and the diagonal matrices act on m by the weight μ. The $U(\mathfrak{gl}_r(\mathbb{C}))$-module generated by m is spanned by products of the E_{ij} with $i>j$ applied to m, so its weight-μ space is $\mathbb{C}m$; it is a direct sum of irreducible submodules (complete reducibility), the components of m in the summands are of weight μ, hence multiples of m, so m lies in one summand, which therefore is the whole module: it is irreducible. As K is connected, this module is V. So (R,V) is irreducible with highest weight μ; by the theorem of the highest weight it is isomorphic to π_v, which by (Dp3) is irreducible and contains, hence equals, the K-type of highest weight $\Lambda_\varepsilon(\lambda)=\mu$. (c) *$c_\lambda$ is a coefficient.* The linear form $f\mapsto f(1)$ on the finite-dimensional Hilbert space V is $f\mapsto\langle v_0,f\rangle$ for some $v_0\in V$, and $v_0\ne0$ as $m(1)=1$; then $f(k)=(R(k)f)(1)=\langle v_0,R(k)f\rangle$, in particular $m(gk)=\langle R(g^{-1})v_0,R(k)m\rangle$. Schur's orthogonality relations for the irreducible unitary (R,V) of dimension n, $\int_K\langle a,R(k)b\rangle\overline{\langle c,R(k)d\rangle}\,dk=n^{-1}\langle a,c\rangle\langle d,b\rangle$, give $\int_K m(gk)\overline{m(k)}\,dk=n^{-1}\|m\|^2\langle R(g^{-1})v_0,v_0\rangle$ and $\|m\|^2=n^{-1}\|m\|^2\|v_0\|^2$. Hence $c_\lambda(g)=\|v_0\|^{-2}\langle v_0,R(g)v_0\rangle$. Transporting $v_0/\|v_0\|$ by an isomorphism $V\to W_v$ that is unitary (invariant inner products on an irreducible representation are proportional) gives the unit vector u_v. By Schur's orthogonality relations, $\int_{\mathrm{U}(r)}|c_{\varsigma(v)}|^2\,dh=1/\dim W_v$ for the probability measure, so the formal degree is $d_{\varsigma(v)}=\dim W_v$; the convolution condition of Definition 3.2.16 does not depend on the Haar measure, since $d_{\varsigma(v)}\,dh$ does not. Hence, with $u=\bigotimes_v u_v$,

$$e_\varsigma(h)=\prod_v\dim W_v\,\overline{\langle u_v,\pi_v(h_v)u_v\rangle}=\dim W\cdot\overline{\langle u,\pi(h)u\rangle},$$

and $\pi=\bigotimes_v\pi_v$ is an irreducible unitary representation of the product group G_∞. So e_ς is the kernel e of (i), and $\mathcal{A}_M(V)$, the space of functions of archimedean type ς that are right invariant under K_M, corresponds by (i) with $K=\mathrm{K}_M$ to the stated space of functions φ. □

5.9 The main inequality

This section proves the main inequality Theorem 5.9.1, $m\cdot\mathrm{rem}\le f\,a\,(\log b)^5$ for every datum, the one result of a later section that Section 2 uses. It is printed after the last of the results that provide its parameters, and Theorem C is cited forward from Section 6. The proof first checks that the parameters fixed in Section 5.6, the Poincaré map at a Bessel pair with a seesaw constant and a family of divisibility errors, have the properties that Theorems A and B assume: the errors by Proposition 4.2.54, the seesaw identity by Proposition 4.2.25, and the two moments by Lemma 5.6.33 and Proposition 5.6.48. The rest is the comparison of two bounds for the covolume of one family of target forms, sketched in the Introduction: the main amount cancels, and the factor m, the number of lifts, survives.

Theorem 5.9.1. *For admissible data D over a parameter pair P,*

$$m \cdot \mathrm{rem} \;\le\; f\,a\,(\log b)^5.$$

Proof. Put

$$\ell = f\,a\,(\log b)^4, \qquad h = h_{\mathrm{main}} - m\,\mathrm{rem} + \ell, \qquad \iota_0 = 10\log(1+2b^2)\,u_{\mathrm{err}}.$$

Sizes. By Proposition 2.3.5, $\log\log b \ge 10^{12} C_P$, and $C_P \ge q_0 \ge 18480$ since all summands of C_P in Definition 2.3.3 other than q_0 are nonnegative. So $\log b \ge e^{10^{12}}$; in particular $b \ge 3$, $4/b^2 \le \frac{1}{2}$, $\log(1+2b^2) \le \log(b^3) = 3\log b$ and $\log b \ge 128$. Also $f, a, m > 0$.

The parameters. Theorems A and B are applied below to the parameters $(\mathcal{P}, c_{\mathrm{ss}}, \mathrm{err})$ fixed above (the Poincaré map, the seesaw constant and the divisibility errors), and these have every property those theorems assume. By Proposition 4.2.54, the family err is nonnegative, satisfies the error conditions of Definition 3.2.37 and has the uniform local property. By Proposition 4.2.25, applied to $\mathcal{P} = \mathcal{P}_{g_\infty, t_0}$ and its scalar c_{ss}, for every ordinary twist ϑ the datum Ψ_ϑ there is admissible for ϑ (conditions 1–3) and satisfies $\Theta_\vartheta(\mathcal{P}\varphi) = c_{\mathrm{ss}} B_{\vartheta,\Psi_\vartheta}(\varphi)$ for every $\varphi \in \mathcal{S}^{\mathrm{ram}}$ (condition 4): this is the seesaw identity assumed in Theorem 4.3.1 and Theorem 4.4.1. By Lemma 5.6.33 (ii), $\mathcal{P}\varphi = \sum_{a \in \mathcal{C}\times I} \theta(\varphi)_a\, \Pi_a$ for every $\varphi \in \mathcal{S}$, the class Poincaré series being formed with the matrix of Proposition 5.7.3, the sign frame of the Bessel systems of the filling datum: this is the hypothesis of Proposition 5.6.48. By that proposition, $\mathcal{S} \ne 0$ and there are an inner product on $\mathcal{S}$ and a real $c_0 > 0$ for which $c_0\mathcal{P}$ satisfies the two moment bounds (i) and (ii) there; these are the bounds (i) and (ii) assumed in Theorem 5.1.2, word for word (with c_0 for the constant c there), so $\mathcal{P}$ satisfies the hypothesis of Theorem 5.1.2.

Enough translates (Theorem B). By Theorem 5.1.2, $d_{\mathcal{T}} \ge 1$ and there is $t \subseteq \bar{G}$ with $\#t \cdot \dim \mathcal{S}^{\mathrm{ram}} \le 5 d_{\mathcal{T}} \log(1+2b^2)$ and $\dim W \ge (1 - 4/b^2) d_{\mathcal{T}}$, where $W = \sum_{s\in t} s\mathfrak{p}(\mathcal{S}^{\mathrm{ram}})$.

Short forms (Theorem A(a)). Let Sh be the set of $\varphi \in \mathcal{S}^{\mathrm{ram}}$ integral at every prime identification with $\|s\mathfrak{p}\varphi\|_\sigma^2 \le e^h$ for all $s \in \bar{G}$ and all automorphisms σ of $\mathbb{C}$. By Theorem 4.3.1, Sh spans $\mathcal{S}^{\mathrm{ram}}$.

The family. As each $s\mathfrak{p}$ is linear, the set $I = \bigcup_{s\in t} s\mathfrak{p}(\mathrm{Sh})$ spans W. Choose a basis $y_1, \dots, y_n$ of W inside I. Then y is linearly independent, $(1 - 4/b^2) d_{\mathcal{T}} \le n \le d_{\mathcal{T}}$, and $y_i = s_i \mathfrak{p} \varphi_i$ with $s_i \in t$, $\varphi_i \in \mathrm{Sh}$.

Covolume. $\|y_i\|_\sigma^2 \le e^h$ for all i, σ, so by Lemma 3.1.7 the family y has covolume at most nh.

Index (Theorem A(b)). Each φ_i is integral at every prime identification, so by Theorem 4.4.1 the family y has index at most $\#t \cdot \dim \mathcal{S}^{\mathrm{ram}} \cdot 2u_{\mathrm{err}} \le 5 d_{\mathcal{T}} \log(1+2b^2) \cdot 2u_{\mathrm{err}} = d_{\mathcal{T}}\,\iota_0$ (index bounds can be enlarged, as $u_{\mathrm{err}} \ge 0$).

Lower bound (Theorem C). By Theorem 6.1.4 with $c = nh$ and $\delta = d_{\mathcal{T}}\iota_0$,

$$d_{\mathcal{T}}(h_{\mathrm{main}} - 3\ell) \le n(h_{\mathrm{main}} + \ell) - n\,m\,\mathrm{rem} + 2 d_{\mathcal{T}} \iota_0. \tag{5.187}$$

Comparison: the main amount cancels. By Lemma 2.4.8, $h_{\mathrm{main}} + \ell \ge 0$, so $n(h_{\mathrm{main}} + \ell) \le d_{\mathcal{T}}(h_{\mathrm{main}} + \ell)$ as $n \le d_{\mathcal{T}}$. Inserting this in (5.187), the terms $d_{\mathcal{T}} h_{\mathrm{main}}$ cancel and

$$n\,m\,\mathrm{rem} \le d_{\mathcal{T}}\, e_0, \qquad e_0 = 4\ell + 2\iota_0 \ge 0.$$

Division. Since $4/b^2 \le \frac{1}{2}$, $n \ge d_{\mathcal{T}}/2 > 0$. If $m\,\mathrm{rem} \le 0$ the claim holds, as $fa(\log b)^5 > 0$. Otherwise $m\,\mathrm{rem} \le (d_{\mathcal{T}}/n) e_0 \le 2e_0$, and

$$2e_0 = 8fa(\log b)^4 + 40\log(1+2b^2)\, fa(\log b)^3 \le (8 + 120)\, fa(\log b)^4 \le fa(\log b)^5,$$

by $\log(1+2b^2) \le 3\log b$ and $\log b \ge 128$. □

6 Integral forms are long: the lower bound (Theorem C)

This section proves Theorem C (Theorem 6.1.4), the lower half of the comparison: an almost full family of target forms with index at most δ and covolume at most c satisfies $d_{\mathcal{T}}(h_{\mathrm{main}} - 3\eta) \leq c + 2\delta$. The proof (Section 6.1) combines the product formula of Section 3 (Theorem 3.1.5) with four inputs. Auxiliary forms, integral after one scaling for all twists and short at the trivial twist, complete the family to a basis (Lemma 6.4.5). The determinant $Z(\vartheta)$ of the chain factors into those of the m single lifts, up to chain ratios of Hecke L-values (Proposition 6.5.1). Along a regular family of twists, the height of the ratios $Z_j(1)/Z_j(\vartheta_\iota)$ of one lift is bounded by the main amount and the denominator budget (Theorem 6.6.6). Regular families exist by Section 7 (Theorem 7.3.1).

The inputs are statements about theta lifts between unitary groups, with the splittings of Kudla [172], and one identity underlies them: the exchange identity (Theorem 6.3.2). It compares the theta integral from a space W to a space V with an integral, over the unitary group of a smaller space V' with $\operatorname{rk} V = \operatorname{rk} V' + 2e$, of a theta kernel from V' to W, at all finite data matched modulo a modulus $\mathfrak{m}$, with a constant whose squared modulus is a fixed multiple of a product of partial Hecke L-values of the character [128, 294], the multiple not depending on $\mathfrak{m}$ or the character. Its ingredients are classical: Rallis's towers of theta lifts [236], the unfolding of Fourier coefficients of theta integrals [237, 171], the seesaw principle, and the analysis of theta integrals outside Weil's convergent range familiar from the regularised Siegel–Weil formula [323, 176, 139]. The identity is not in the literature in this form, because the lifted objects are characters with ramified data and the constant must be uniform in the character; it is proved in full. In our reading it is an identity of Rallis–Waldspurger type, a period of theta lifts whose square is an L-value, as in the Rallis inner product formula and in the formulas for toric and Gross–Prasad periods [313, 111, 141] (see [96]).

After Theorem C and its notions and the background on the theta correspondence in towers (Section 6.2), the section proves the exchange identity with the one-square identity and the explicit matching of class sums (Section 6.3); that auxiliary forms span, by transferring the chain of lifts across two grids of hermitian spaces to definite spaces (Section 6.4); the norm of the chain, by the Rallis inner product formula (Section 6.5); the cost of one lift, with a comparison operator (Section 6.6); and the bounds for Hecke values along a regular family, with the test forms of the denominator conditions (Section 6.7). The cost of one lift uses Theorem B, for the Poincaré map fixed in Section 5, and the equality of multiplicities (Proposition 5.8.4); from Section 4 the section uses the good projection, the Weil representation and the theta functions with complex multiplication and their jets. For another reading of this part of the argument see [223].

6.1 Theorem C

The section opens with the three definitions that the proof of Theorem C reads besides those of Section 3: auxiliary target forms (Definition 6.1.1), whose lifts become integral for all twists after a scaling and whose conjugate squared norms are at most $\exp(2x_1^2 b^2)$; the volumes $Z_j(\vartheta)$ of the single lifts (Definition 6.1.2); and regular families of twists (Definition 6.1.3), which have small ratios of Hecke L-values and bounded denominators. In our reading the denominators measure congruences between lifts and other forms, as in Ribet's method [241]. The proof also reads the critical pairs and the lift of a character of U(1) to a definite group, defined in Section 4.2 (Definition 4.2.4, Definition 4.2.5); for theta lifts of characters of U(1) see [121], and their squared norms are Hecke L-values (Proposition 6.7.13).

The proof applies the product formula to the target lattice, with one twist of a regular

family at each prime identification. The given family is completed to a basis by auxiliary forms (Lemma 6.4.5); each costs $2x_1^2b^2 + b$, and there are at most $4d_{\mathcal{T}}/b^2$ of them, so that their total cost is at most $d_{\mathcal{T}}b$. The ratio of volumes factors into the ratios of the m single lifts and a power of a product of chain ratios (Proposition 6.5.1). The single lifts are bounded by the cost of one lift (Theorem 6.6.6), whose sum over the m lifts produces h_{main} and the error; the chain ratios and the scaling of the auxiliary forms are of small height along a regular family (Lemma 6.1.5); and the scales of the datum absorb the rest (Lemma 6.1.6). The ratios of Hecke L-values are positive and equal to 1 at the trivial twist (Lemma 6.1.7), by Hecke's theory and the non-vanishing on the line $\operatorname{Re} s = 1$ [128, 294, 182]. For the arithmetic of the values of Hecke L-functions of CM fields at integers see [274, 159]; only their non-vanishing and the heights of their ratios are used here.

Definition 6.1.1. Let γ be a function from the m-fold twists to $\mathbb{C}$. A target form $y \in \mathcal{T}$ is **auxiliary for** γ if

(AF1) $\gamma(\vartheta)\,\Theta_\vartheta y \in \Lambda_\vartheta(\iota)$ for every prime identification $\iota \mid \ell$ and every m-fold twist ϑ with $\ell \nmid \mathrm{N}Q(\vartheta)$;

(AF2) $\|y\|_\sigma^2 \le \exp(2x_1^2b^2)$ for every field automorphism σ of $\mathbb{C}$, the conjugate norm being that of the target lattice (the squared norm of the conjugate $\sigma(\Theta_1 y)$).

Definition 6.1.2. For an m-fold twist ϑ and $1 \le j \le m$ the **volume of the j-th lift** is

$$Z_j(\vartheta) = \det\!\big(\Theta_{j,\vartheta^j}^{*}\,\Theta_{j,\vartheta^j}\big),$$

the Gram determinant of the images under Θ_{j,ϑ^j} of an orthonormal basis of $\mathcal{A}^{\mathrm{good}}(W_j)$; note the power ϑ^j. The volume of the chain is the chain determinant $Z(\vartheta)$ of the target lattice.

Definition 6.1.3. Integral forms. For a descent pair O, with spaces $W = W(O)$ and $V = \mathrm{I}_n$, let $\mathcal{A}(V) = \mathrm{Form}(O)$, a finite-dimensional space of algebraic forms on $\mathrm{U}(V)$. For a field embedding $\eta\colon \mathbb{C} \to \mathbb{C}_\ell$, a form Ξ is **integral at** η if for every $g \in G_f(n)$ all coordinates of $\prod_\tau \det(g_{\ell,\tau})^{-e_O(\tau)}\, S_{\kappa_O}\big((g_{\ell,\tau}^{-1})_\tau\big)\,\eta(\Xi(g))$ have absolute value at most 1, where η is applied coordinatewise, S_{κ_O} is the Schur matrix of (WM2) of Definition 3.2.19, and $g_{\ell,\tau} \in \mathrm{GL}_n(\mathbb{C}_\ell)$ is the image of the component of g at the place of E induced by $x \mapsto \eta(\tau(\bar{x}))$ (the ℓ-adic gauge at η); a form is integral at a prime identification $\iota \mid \ell$ if it is integral at the embedding $\mathbb{C} \xrightarrow{\iota} \overline{\mathbb{Q}}_\ell \subset \mathbb{C}_\ell$, and **integral above** ℓ if it is integral at every embedding $\mathbb{C} \to \mathbb{C}_\ell$.

False lifts. Let e be an idempotent of the group algebra of $\prod_{w \in M_O} \mathrm{GL}_{\mathrm{rk}W}(k_w)$, acting on $\mathcal{A}(V)$ through (DP5), and $Z' \subseteq \mathcal{A}(V)$ a subspace. For a finite place w of E with $w \ne \bar{w}$ and $w, \bar{w}$ not among the places of O, the **false lifts** at w are

$$\mathcal{F}_w(e, Z') = e\,\mathcal{A}(V) \;\cap\; \ker H_w(\lambda_w) \;\cap\; Z',$$

where $H_w(\lambda_w)$ is the Hecke polynomial operator of O at w evaluated at the **test value** $\lambda_w = X_*(w)$, the lift Hecke root. A form $y \in \mathcal{A}(V)$ is **orthogonal to the false lifts** for (e, Z') if $y \perp \mathcal{F}_w(e, Z')$ for every such w.

Test forms. A form $\Xi \in \mathcal{A}(V)$ is a **test form for** ℓ if it is integral above ℓ and orthogonal to the false lifts for $(e_{X-1}, \ker O^*)$, where $e_{X-1} = \bigotimes_{w \in M_O} e_{X-1}$ is the tensor product of the label idempotents of the polynomial $X - 1$ over the residue fields k_w (zero unless $\mathrm{rk}W = 1$; for $\mathrm{rk}W = 1$ it is the projector onto the vectors fixed by $\prod_w k_w^\times$), and $O^* = \mathrm{Th}_O$ is the normalised descent.

L-value lifts. For a main pair $p = (\nu, z)$ and a twist ϑ, $O_{p,\vartheta} = O_{X(p,\vartheta)}$ is the descent pair of the L-value data $X(p,\vartheta)$ (rank $2z$, character $\nu\vartheta$), and $\lambda_{p,\vartheta} = \lambda_{X(p,\vartheta)} \in \mathcal{A}(V)$ its lift; $\mathrm{pr}_{p,\vartheta}$ is the orthogonal projection to the line $\mathbb{C}\lambda_{p,\vartheta}$.

Denominators. Let $\iota \mid \ell$, ϑ a twist, $1 \le j \le m$ and $\beta \in \mathbb{R}$; let pr be the orthogonal projection of $\mathcal{A}_{j,\vartheta}(V^{\mathrm{def}})$ onto $\mathcal{L} = \mathcal{L}_{j,\vartheta}$. The twist ϑ has **denominators at most** β **at** ι **for** j if

(DL1) Clearing. there is $B \in \mathrm{End}_{\mathbb{C}}(\mathcal{L})$ with $\|\iota(\det B)\| \ge \exp(-(\dim \mathcal{L})\, r\, \beta)$ such that $B(\mathrm{pr}\, y)$ is integral at ι for every y that is integral at ι and orthogonal to the false lifts for $(e_0, \mathcal{L}^{\perp})$;

(DL2) Main pairs. for every main pair p for j and all test forms Ξ, Ξ' for ℓ of $O_{p,\vartheta}$,

$$\|\iota\langle \mathrm{pr}_{p,\vartheta}\Xi, \mathrm{pr}_{p,\vartheta}\Xi'\rangle\| \le e^{\beta}.$$

For a family $\theta = (\theta_\iota)$ of m-fold twists, one for each prime identification, and $1 \le j \le m$, a **denominator bound** for (θ, j) is a family of reals (γ_ℓ), one for each prime, with

(DB1) $\sum_{\ell \in T} \gamma_\ell \le \beta_{\mathrm{den}}$ for every finite set T of primes;

(DB2) for every $\iota \mid \ell$ the twist $\theta_\iota^{\,j}$ has denominators at most γ_ℓ at ι for j.

Small ratios and regular families. A family $\theta = (\theta_\iota)$ of m-fold twists, one for each prime identification, has **small ratios** if

(SR1) $\ell \nmid \mathrm{N}Q(\theta_\iota)$ for every $\iota \mid \ell$;

(SR2) for every $1 \le j \le m$, every ramified critical pair p and every $s \in \{\pm 1\}$, the family $\iota \mapsto r_p(\theta_\iota^{\,j}, s)^{-1}$ has height at most x_1.

It is **regular** if it has small ratios and

(RW) for every $1 \le j \le m$ there is a denominator bound for (θ, j).

Theorem 6.1.4. *Let D be admissible data over a parameter pair P, and let $y_1, \dots, y_n \in \mathcal{T}$ be linearly independent target forms with $n \ge (1 - 4/b^2)\, d_{\mathcal{T}}$. Let $\delta, c \in \mathbb{R}$, and suppose that the family $(y_1, \dots, y_n)$ has index at most δ and covolume at most c in the target lattice. Then*

$$d_{\mathcal{T}}\Big(h_{\mathrm{main}} - 3\, f\, a\, (\log b)^4\Big) \;\le\; c + 2\delta.$$

Proof. Write $d = d_{\mathcal{T}}$ and $L = \log b$. The proof applies Theorem 3.1.5 to the target lattice, completing y to a basis by auxiliary forms and taking one twist of a regular family for each prime identification.

Step 1: twists. By Theorem 7.3.1 there is a regular family $\theta = (\theta_\iota)$ of m-fold twists. By (SR1), $\ell \nmid \mathrm{N}Q(\theta_\iota)$ for $\iota \mid \ell$, so θ_ι is allowed at ℓ in the target lattice (TL2).

Step 2: completion by auxiliary forms. Let $e \in \mathbb{Z}$ and γ, with $\gamma(\vartheta) \ne 0$ and $|\gamma(\vartheta)| = \mathrm{N}Q(\vartheta)^{e/2} \prod_{0 \le i,j < m} \tau_{ij}(\vartheta)$, be as in Lemma 6.4.5. Since $\mathcal{T}$ is spanned by the forms auxiliary for γ and $y_1, \dots, y_n$ are linearly independent, the exchange lemma gives auxiliary forms $z_1, \dots, z_{n'}$ such that $y_1, \dots, y_n, z_1, \dots, z_{n'}$ is a basis of $\mathcal{T}$; so $n + n' = d$ and, by $n \ge (1 - 4/b^2)d$, $n' \le 4d/b^2$.

Step 3: the hypotheses of Theorem 3.1.5. The target lattice is a twisted lattice on the finite-dimensional inner product space $\mathcal{T}$ by Lemma 3.2.32. Apply Theorem 3.1.5 to it, with the family y, the completion z, the twists $\xi_\iota = \theta_\iota$ (Step 1), the function γ and the constants

$$b_{\mathrm{sh}} = 2x_1^2 b^2, \qquad b_{\mathrm{den}} = b, \qquad b_{\mathrm{vol}} = d(b + faL^4 - h_{\mathrm{main}}).$$

- Θ_ϑ is injective for every m-fold twist ϑ, by Proposition 6.5.1(iii).
- Hypothesis (1) is the assumption of the theorem.
- Hypothesis (2): for $\iota \mid \ell$ and ϑ allowed at ℓ, i.e. $\ell \nmid \mathrm{N}Q(\vartheta)$, $\gamma(\vartheta)\Theta_\vartheta z_j \in \Lambda_\vartheta(\iota)$ by (AF1).
- Hypothesis (3): $\|z_j\|_\sigma^2 \le \exp(2x_1^2 b^2)$ for every automorphism σ by (AF2).
- Hypothesis (4), the denominators: as $\gamma(\theta_\iota) \neq 0$,

$$|\gamma(\theta_\iota)|^{-2} = \big((\mathrm{N}Q(\theta_\iota)^{e/2} \prod_{0\le i,j<m} \tau_{ij}(\theta_\iota)\big)^{-1}\big)^2.$$

  By Lemma 6.1.5(c) the inner family has height at most $m^2 t x_1$ (θ has small ratios), so by Lemma 3.1.8(e), (a) and Lemma 6.1.6(i) the family $\iota \mapsto |\gamma(\theta_\iota)|^{-2}$ has height at most $2m^2 t x_1 \le b$.
- Hypothesis (4), the volumes: by (Vo) and (TL1) the volume at ϑ is $Z(\vartheta)$. Let $e' \in \mathbb{Z}$ be the integer of Proposition 6.5.1. By its parts (iii) and (iv) all volumes are positive and, for every m-fold twist ϑ,

$$\frac{Z(1)}{Z(\vartheta)} = \Big((\mathrm{N}Q(\vartheta)^{e'/2} \textstyle\prod_{1\le i<j\le m} q_{ij}(\vartheta)\big)^{-1}\Big)^d \prod_{j=1}^{m} \frac{Z_j(1)}{Z_j(\vartheta)},$$

  the bracket being nonzero. By Lemma 6.1.5(c) and Lemma 6.1.6(i) the family

$$\iota \mapsto \big(\mathrm{N}Q(\theta_\iota)^{e'/2} \prod_{i<j} q_{ij}(\theta_\iota)\big)^{-1}$$

  has height at most $m^2 t x_1 \le b$, so its d-th power has height at most db (Lemma 3.1.8(e)). By Theorem 6.6.6, for $1 \le j \le m$ the family $\iota \mapsto Z_j(1)/Z_j(\theta_\iota)$ has height at most $dk(L\beta_{\mathrm{den}} - h_{\mathrm{dir}})$. By Lemma 3.1.8(e) the family $\iota \mapsto Z(1)/Z(\theta_\iota)$ has height at most

$$db + m\,dk\,(L\beta_{\mathrm{den}} - h_{\mathrm{dir}}) = d\big(b + faL^4 - h_{\mathrm{main}}\big) = b_{\mathrm{vol}},$$

  using $mkL\beta_{\mathrm{den}} = faL^4$ (Lemma 6.1.6(vi)) and $mkh_{\mathrm{dir}} = h_{\mathrm{main}}$.

Hence Theorem 3.1.5 gives

$$0 \le c + 2\delta + n'\big(2x_1^2 b^2 + b\big) + d\big(b + faL^4 - h_{\mathrm{main}}\big).$$

Step 4: the completion cost and the conclusion. By Step 2 and Lemma 6.1.6(iii),

$$n'\big(2x_1^2 b^2 + b\big) \le \frac{4d}{b^2}\big(2x_1^2 b^2 + b\big) = d \cdot 4\big(2x_1^2 + b^{-1}\big) \le db,$$

and $db \le d\,faL^4$ by Lemma 6.1.6(iv). Substituting both bounds for the two terms db,

$$0 \le c + 2\delta + 3\,d\,faL^4 - d\,h_{\mathrm{main}}, \qquad \text{that is,} \qquad d\big(h_{\mathrm{main}} - 3faL^4\big) \le c + 2\delta.$$

□

Lemma 6.1.5. *Let D be admissible data.*

(a) For $0 \le i < j \le m$ the chain ratio q_{ij}, and for $0 \le i, j < m$ the turn ratio τ_{ij}, is a ramified ratio. Every ramified ratio takes values in $\mathbb{R}_{\ge 0}$.

(b) Let $\theta = (\theta_\iota)$ be a family of m-fold twists with small ratios, $e \in \mathbb{Z}$, A a finite set and $(F_a)_{a\in A}$ ramified ratios. Then the family

$$\iota \longmapsto \Big(\mathrm{N}Q(\theta_\iota)^{e/2} \prod_{a\in A} F_a(\theta_\iota)\Big)^{-1}$$

has height at most $\#A \cdot t \cdot x_1$.

(c) In particular, for θ and e as in (b), the families

$$\iota \mapsto \Big(\mathrm{N}Q(\theta_\iota)^{e/2} \prod_{1\le i<j\le m} q_{ij}(\theta_\iota)\Big)^{-1}, \qquad \iota \mapsto \Big(\mathrm{N}Q(\theta_\iota)^{e/2} \prod_{0\le i,j<m} \tau_{ij}(\theta_\iota)\Big)^{-1}$$

have height at most $m^2 t\, x_1$.

Proof. **(a)** Write $\eta = \upsilon^{-\Delta}\chi_M$; by (LF2), (LF3) of Definition 3.2.26 it has weight $-\Delta$ and tame part ω, and $\mu_j^0 = \mu^\flat \eta^j$ has weight $-\kappa_j$ and tame part ω^j (weights add and tame parts multiply under products of characters). Recall $t = 5r$, $\Delta = 2r^8$ and $\kappa_j = \kappa + (2j+1)\frac{\Delta}{2}$ with $\kappa(v) \in \{b, a/x_1\}$, $a/x_1 = xb/x_1 \le b$.

Chain ratios. Let $0 \le i < j \le m$, $n = j - i \in [1, m]$, and $\nu = \mu_j^0/\mu_i^0 = \eta^n$, of weight $-n\Delta$ and tame part ω^n. Then (ν, t) is a critical pair: $1 \le t \le t$, and $t = 5r \le \Delta \le n\Delta \le m\Delta \le 4b$. It is ramified, since $\omega_w^n = 1$ off the chosen places and $\omega_w^n \ne 1$ at the chosen places by Lemma 6.7.3 ($1 \le n \le m$). By definition $q_{ij}(\vartheta) = F_{\nu,t}(\vartheta^n)$, so q_{ij} is a ramified ratio. *Turn ratios.* Let $0 \le i, j < m$ and $\nu = \mu_{i+1}^0 \mu_{j+1}^0$, of weight $-(\kappa_{i+1} + \kappa_{j+1})$ and tame part ω^{i+j+2}. Then (ν, t) is a critical pair, since $t \le \Delta \le \kappa_{i+1}(v) + \kappa_{j+1}(v) \le 4b$, and it is ramified by Lemma 6.7.3, as $2 \le i + j + 2 \le 2m$. With $n = j + 1 \in [1, m]$, $\tau_{ij}(\vartheta) = F_{\nu,t}(\vartheta^n)$. Finally, a ramified ratio is a finite product of the ratios $r_{(\nu,z')}$, which are quotients of absolute values, hence ≥ 0.

(b) Fix $a \in A$ and write $F_a(\vartheta) = F_{\nu,z}(\vartheta^n)$ with (ν, z) a ramified critical pair and $1 \le n \le m$. For $1 \le z' \le z$ the lower point (ν, z') is a critical pair with the same tame part, hence ramified, and by (SR2) (with $j = n$, $s = 1$) the family $\iota \mapsto r_{(\nu,z')}(\theta_\iota^n)^{-1}$ has height at most x_1. Under the convention $u^{-1} = 0$ for $u = 0$, inversion is multiplicative on $\mathbb{R}$, so

$$F_a(\theta_\iota)^{-1} = \prod_{z'=1}^{z} r_{(\nu,z')}(\theta_\iota^n)^{-1},$$

and by Lemma 3.1.8(e), (a) the family $\iota \mapsto F_a(\theta_\iota)^{-1}$ has height at most $z\, x_1 \le t\, x_1$ (as $z \le t$ and $x_1 > 0$). By Lemma 3.1.8(e) again, $\iota \mapsto \prod_{a\in A} F_a(\theta_\iota)^{-1}$ has height at most $\#A\, t\, x_1$. By (SR1), $N_\iota = \mathrm{N}Q(\theta_\iota)$ is a positive integer prime to ℓ for $\iota \mid \ell$, so by Lemma 3.1.8(b) with exponent $-e/2$ the family $\iota \mapsto N_\iota^{-e/2} \prod_a F_a(\theta_\iota)^{-1} = \big(N_\iota^{e/2} \prod_a F_a(\theta_\iota)\big)^{-1}$ has height at most $\#A\, t\, x_1$.

(c) Apply (b) with (a) to $A = \{(i, j) : 1 \le i < j \le m\}$, of size $m(m-1)/2 \le m^2$, and to $A = \{(i, j) : 0 \le i, j < m\}$, of size m^2, and use Lemma 3.1.8(a) to raise the bound to $m^2 t\, x_1$. □

Lemma 6.1.6. *For admissible data D, with $A = f\, m\, b\, (\log b)^2$:*

(i) $2m^2 t\, x_1 \le b$;

(ii) $x^{99} + x^{202} b^2 \le 2x_1^2 b^2$;

(iii) $4(2x_1^2 + b^{-1}) \le b$;

(iv) $b \le f\, a\, (\log b)^4$;

(v) $3A + r\,\beta_{\mathrm{den}} + 10\,m\,x_1 + k\,(6\beta_{\mathrm{den}} - h_{\mathrm{dir}}) \le k\,(\log b \cdot \beta_{\mathrm{den}} - h_{\mathrm{dir}})$;

(vi) $k \log b \cdot \beta_{\mathrm{den}} = f\,a\,(\log b)^4/m$.

Proof. **Sizes.** $C_P \ge 6$ by its definition in Definition 2.3.3 (it contains the summand $2d+6$ and the other summands are nonnegative), so by Proposition 2.3.5 $\log\log b \ge 6 \cdot 10^{12}$, hence $L := \log b \ge 13$, $x \ge (\log b)^{100} \ge 10^9$, $x^{10^6} \le x_1$ and $x_1^{10^6} \le b$. By (AD2), $m \le 2\sqrt{x}$ and $x^5 \le r \le 3x^5$, so $m^2 \le 4x$, $t \le 15x^5$, $m \le r/2$ and $k = r + 1 - m \ge r/2$. Finally $f \ge 1$, as E has an infinite place.

(i) $2m^2 t\,x_1 \le 2 \cdot 4x \cdot 15x^5 \cdot x_1 = 120x^6 x_1 \le x_1^2 \le b$.

(ii) $x^{202} \le x_1 \le x_1^2$ and $x^{99} \le x_1^2 \le x_1^2 b^2$, so the left side is at most $x_1^2 b^2 + x_1^2 b^2$.

(iii) $b^{-1} \le 1 \le x_1^2/4$, so $4(2x_1^2 + b^{-1}) \le 9x_1^2 \le b$.

(iv) $f\,a\,(\log b)^4 \ge a = xb \ge b$, since $f \ge 1$, $\log b \ge 1$ and $x \ge 1$.

(vi) $\beta_{\mathrm{den}} = faL^3/(mk)$, so $kL\beta_{\mathrm{den}} = faL^4/m$.

(v) The term $-kh_{\mathrm{dir}}$ appears on both sides; it suffices to show $3A + r\beta_{\mathrm{den}} + 10mx_1 + 6k\beta_{\mathrm{den}} \le kL\beta_{\mathrm{den}}$. Put $u = k\beta_{\mathrm{den}} = faL^3/m$. Since $r \le 2k$, $r\beta_{\mathrm{den}} \le 2u$, and it suffices that $3A + 10mx_1 \le u(L-8)$. Now

$$u(L-8) = \frac{f\,x\,b\,L^3(L-8)}{m} \ge \frac{f\,b\,L^2\sqrt{x}\,L(L-8)}{2} \ge 7\,f\,b\,L^2\sqrt{x},$$

using $m \le 2\sqrt{x}$ and $L(L-8) \ge 65$. On the other side $3A = 3fmbL^2 \le 6fbL^2\sqrt{x}$ and $10mx_1 \le 20\sqrt{x}\,x_1 \le fbL^2\sqrt{x}$, since $b \ge x_1^{10^6} \ge 20x_1$. Adding gives the claim. □

Lemma 6.1.7. *Let D be admissible data.*

(a) Let ν be an automorphic character of $\mathrm{U}(1)$ of weight e and tame part ψ with $e(v_0) \ne 0$ for some $v_0 \in \Phi$, and let S be a finite set of finite places of E with $\psi_w = 1$ for every $w \notin S$. Then $L^S(s,\nu) \ne 0$ for every real $s \ge 1$.

(b) For every critical pair p, every tame character ϑ and every sign $s \in \{\pm 1\}$, $r_p(\vartheta, s) > 0$, and $r_p(1,s) = 1$.

(c) Every ramified ratio F satisfies $F(\vartheta) > 0$ for every m-fold twist ϑ, and $F(1) = 1$. In particular $q_{ij}(1) = 1$ for $0 \le i < j \le m$ and $\tau_{ij}(1) = 1$ for $0 \le i, j < m$.

Proof. **(a) The base change is a unitary Hecke character, not of the form $|\cdot|_{\mathbb{A}}^{i\tau}$.** Let $\chi(x) = \nu(x/\bar{x})$ for $x \in \mathbb{A}_E^\times$. Since $x/\bar{x} \in \mathrm{U}(1)(\mathbb{A})$, $x/\bar{x} \in \mathrm{U}(1)(E)$ for $x \in E^\times$, and ν is continuous with values of modulus 1, χ is a unitary Hecke character of E, and $L^S(s,\nu)$ is the partial L-function of χ without the Euler factors at $S \cup \bar{S}$.

χ is unramified at every finite place w with $w, \bar{w} \notin S$: for $y \in \mathcal{O}_w^\times$, viewed as the idele with component y at w and 1 elsewhere, $y/\bar{y}$ has integral finite components, components 1 at the infinite places and nontrivial reductions only at w and $\bar{w}$, so by the definition of weight and tame part $\chi(y) = \psi_w(y \bmod w)\,\psi_{\bar{w}}(\bar{y}^{-1} \bmod \bar{w}) = 1$ (one factor if $w = \bar{w}$).

At v_0 (a complex place, on which complex conjugation of E acts as $z \mapsto \bar{z}$), the same definition gives, for $z \in E_{v_0}^\times = \mathbb{C}^\times$,

$$\chi_{v_0}(z) = (z/\bar{z})^{e(v_0)} = (z/|z|)^{2e(v_0)},$$

which is nontrivial on the unit circle because $e(v_0) \ne 0$. The component at v_0 of $|\cdot|_{\mathbb{A}}^{i\tau}$ is $z \mapsto |z|^{2i\tau}$, trivial on the unit circle. So $\chi \ne |\cdot|_{\mathbb{A}}^{i\tau}$ for every $\tau \in \mathbb{R}$.

(a) Nonvanishing. By Theorem A.1.12(3) (Hecke [128]; non-vanishing on $\operatorname{Re} s = 1$, [182]), the L-function $L(s,\chi)$ is holomorphic and has no zero in $\operatorname{Re} s \geq 1$. By the previous paragraph every place where χ ramifies lies in $S \cup \bar{S}$, where the local factor of $L(s,\chi)$ is 1, so

$$L^S(s,\nu) = L(s,\chi) \prod_w (1 - \chi(\varpi_w)\,\mathrm{N}w^{-s}),$$

the product over the finitely many $w \in S \cup \bar{S}$ at which χ is unramified, ϖ_w a uniformiser. For real $s \geq 1$, $|\chi(\varpi_w)\mathrm{N}w^{-s}| \leq \mathrm{N}w^{-1} \leq 1/2$, so every factor is nonzero, and $L^S(s,\nu) \neq 0$.

(b) Let $p = (\nu, z)$ with ν of weight $-c$, tame part trivial off the chosen places, and $1 \leq z \leq c(v)$ for every $v \in \Phi$. For a tame character ϑ of weight 0 with tame part trivial off its modulus Q, the character $(\nu\vartheta^s)^{-1}$ has weight c (weights add under products and change sign under inversion, by the definition of weight) and tame part trivial off $S_M \cup Q$; the same holds for ν^{-1} with S_M. As $c(v) \geq z \geq 1 \neq 0$ and $z \geq 1$, part (a) gives

$$L^{S_M \cup Q}(z, (\nu\vartheta^s)^{-1}) \neq 0, \qquad L^{S_M}(z, \nu^{-1}) \neq 0,$$

so $r_p(\vartheta, s)$ is a quotient of two positive numbers, hence > 0. For $\vartheta = 1$ the modulus is empty and $1^s = 1$, so numerator and denominator coincide and $r_p(1,s) = 1$.

(c) Let $F(\vartheta) = F_{\nu,z}(\vartheta^n) = \prod_{z'=1}^{z} r_{(\nu,z')}(\vartheta^n)$, with (ν, z) a ramified critical pair and $1 \leq n \leq m$; each (ν, z') is a critical pair (a lower point), and ϑ^n is a tame character. By (b) every factor is > 0, so $F(\vartheta) > 0$. At $\vartheta = 1$, $1^n = 1$, so every factor is $r_{(\nu,z')}(1) = 1$ and $F(1) = 1$. The chain and turn ratios are ramified ratios by Lemma 6.1.5(a), so $q_{ij}(1) = \tau_{ij}(1) = 1$. □

6.2 Theta correspondence: mixed models, towers and unfolding in stages

This section collects the facts about theta lifts between unitary groups on which the exchange identity rests: the Weil representation in a mixed model, attached to a splitting of a hermitian space along an isotropic frame; the tower property, which computes a constant term of a lift along a new hyperbolic plane; and three principles of integration over adelic quotients. The theta correspondence is classical [322, 134, 136] (for unitary dual pairs and their splittings see [172, 121], for the local theory [206, 98]). Here, however, the lifted objects are characters and ramified data rather than cusp forms, and the constants must be uniform in the tame character, so every statement is proved, from the Weil representation of a unitary pair, Tate's Fourier analysis [294], Witt's theorem, strong approximation and Hecke's theory of L-functions [128]. The section adds two definitions: the line terms along a hyperbolic plane with their cone integrals (Definition 6.2.1), and, during the unfolding, the specification of the exchange data (Definition 6.2.23). The organisation follows [259]; for another reading see [223].

The idea throughout is unfolding. Along a splitting a theta integral separates into theta functions of a smaller pair, and an integral over the larger unitary group unfolds, orbit by orbit, into integrals over stabilisers. The main instance is Rallis's tower property [236], in the form Proposition 6.2.2: for a split tame character $\mathfrak{c}$ and the plane data of the exchange, with $W' = W \oplus \mathbb{H}$, $V' = V \oplus \mathbb{H}$ and $e = \operatorname{rk} V - \operatorname{rk} W/2$, the plane constant term of the large side is γ times the large side of the smaller pair at a cone integral, where $|\gamma| = C\, L^{\sharp}_{\mathfrak{c}}(z_e)$ with C independent of $\mathfrak{c}$ and $z_e = e + 1$ or $-e$; only values at points ≥ 1 occur. It differs from Rallis's statement for cusp forms in that the lifted object is a character, the data are ramified at Σ, and the orbit of isotropic vectors survives as a Tate integral. For constant terms in the regularised Siegel–Weil formula see [176, 139], and for constant terms of automorphic forms [208]. The proof has two halves, an unfolding and the evaluation of a Tate integral, given in the two groups that follow. The norms of the lifts are computed later by the Rallis inner product formula (Section 6.5), for cusp forms the formula of [238, 187].

Definition 6.2.1. Throughout, W', W, V', V are spaces with points with signs s' on n', s on n, t' on r', t on r; $A = (k_A, l_A, i_A)$ is a base-adapted splitting of W' over W and $X = (k_X, l_X, i_X)$ a base-adapted splitting of V' over V, both along the one-element set $\{o\}$. Vectors of $\mathrm{Hom}(W', V')$ are $r' \times n'$ matrices.

(LN1) Splittings induced on the target. For a splitting $D = (k, l, i)$ of a space with a point Y over Y_0 along p and a space with a point T with signs on n_T, the **splitting induced on the target** is the splitting of $\mathrm{Hom}(T, Y)$ over $\mathrm{Hom}(T, Y_0)$ along $p \times n_T$ with frames $k \otimes J_T^{\mathsf{T}}$, $l \otimes 1$ and embedding $i \otimes 1$. Its zero term is written $Z^{\mathrm{tg}}_{D,T} \colon \mathcal{M}_{T,Y} \to \mathcal{M}_{T,Y_0}$, and the zero term along the splitting of $\mathrm{Hom}(Y, T)$ induced by D ((MX1); zero terms as in (MX4) of Definition 4.1.18) is written $Z^{\mathrm{sc}}_{D,T} \colon \mathcal{M}_{Y,T} \to \mathcal{M}_{Y_0,T}$.

(LN2) Line terms. For $a \in \mathbb{A}_E$ the **line terms** at a are the maps $\mathrm{Ln}^{\pm}_{A,X}(a) \colon \mathcal{M}_{W',V'} \to \mathcal{M}_{W,V}$,

$$\mathrm{Ln}^{+}_{A,X}(a) f = Z^{\mathrm{tg}}_{X,W}(f[a\, k_{X,\mathbb{A}}]), \qquad \mathrm{Ln}^{-}_{A,X}(a) f = Z^{\mathrm{sc}}_{A,V}\Big(Z^{\mathrm{tg}}_{X,W'}\big(\rho(a\, l_{X,\mathbb{A}}\, \mathrm{pr}_l) f\big)\Big),$$

where $f[a\, k_{X,\mathbb{A}}] \in \mathcal{M}_{W,V'}$ is the slice of f at the adelic $r' \times 1$ matrix $a\, k_{X,\mathbb{A}}$ along the splitting of $\mathrm{Hom}(W', V')$ induced by A ((MX1); slices as in (MX4) of Definition 4.1.18), pr_l is the coordinate of A, and the adelic $r' \times n'$ matrix $a\, l_{X,\mathbb{A}} \mathrm{pr}_l$ is read as a vector of $\mathrm{Hom}(W', V')$.

(LN3) The plane splitting, the line splittings and real line terms. Put $q = (n \sqcup \{o\}) \sqcup r$ and let $\{*\}$ be a one-element set. The **plane splitting** $D^{\mathrm{pl}}_{A,X}$ is the splitting of $\mathrm{Hom}(W', V')$ over $\mathbb{H}_{\{*\}} \oplus \mathrm{Hom}(W, V)$ along q with frames

$$k = \Big(k_X \otimes \begin{pmatrix} i_A^* J_{W'} \\ k_A^* J_{W'} \end{pmatrix}^{\mathsf{T}} \;\Big|\; (i_X J_V^{-1}) \otimes (k_A^* J_{W'})^{\mathsf{T}}\Big), \qquad l = \Big(l_X \otimes \begin{pmatrix} J_W^{-1} i_A^* J_{W'} \\ l_A^* J_{W'} \end{pmatrix}^{\mathsf{T}} \;\Big|\; i_X \otimes (l_A^* J_{W'})^{\mathsf{T}}\Big)$$

(column blocks indexed by $n \sqcup \{o\}$ and by r) and embedding

$$i = \Big(k_X \otimes (l_A^* J_{W'})^{\mathsf{T}} \;\Big|\; l_X \otimes (k_A^* J_{W'})^{\mathsf{T}} \;\Big|\; i_X \otimes (J_W^{-1} i_A^* J_{W'})^{\mathsf{T}}\Big)$$

(column blocks indexed by the first and the second copy of $\{*\}$ in $\mathbb{H}_{\{*\}}$ and by $r \times n$). Let R^+ be the tautological splitting of $\mathbb{H}_{\{*\}} \oplus \mathrm{Hom}(W, V)$ over $\mathrm{Hom}(W, V)$ along $\{*\}$ and R^- its opposite splitting. The **line splittings** are the composites $D^{\pm}_{A,X} = D^{\mathrm{pl}}_{A,X} \circ R^{\pm}$, splittings of $\mathrm{Hom}(W', V')$ over $\mathrm{Hom}(W, V)$ along $q \sqcup \{*\}$. The **line basis** $m_{A,X} \in \mathrm{GL}_{q \sqcup \{*\}}(\mathbb{A}_E)$ is block diagonal with the blocks $\begin{pmatrix} \bar{x}_W & 0 \\ 0 & 1 \end{pmatrix}$ on $n \sqcup \{o\}$, $(x_V^{-1})^*$ on r and 1 on $\{*\}$. For $a \in \mathbb{C}^{\Phi}$ let $b_a \in \mathbb{C}^{\Phi \times (q \sqcup \{*\})}$ have the entries a_w at $(w, *)$ ($w \in \Phi$) and 0 elsewhere. The **real line terms** at a are the maps $\mathcal{F}_{W',V'} \to \mathcal{F}_{W,V}$

$$\mathrm{Ln}^{\pm,\infty}_{A,X}(a) v = \mathrm{rsl}_{D^{\pm}_{A,X}, m_{A,X}}(b_a; v),$$

the real slice of (MX7) for the space with a point $\mathrm{Hom}(W', V')$, the splitting $D^{\pm}_{A,X}$ and the basis $m_{A,X}$ (the Fock models of (MX7) for $\mathrm{Hom}(W', V')$ and $\mathrm{Hom}(W, V)$ are $\mathcal{F}_{W',V'}$ and $\mathcal{F}_{W,V}$).

(LN4) Cone integrals. Let $\mathrm{K}_{\max}(t')$ be the compact subgroup of the $u \in \mathrm{G}(t')$ with $u_w^* u_w = 1$ at every $w \in \Phi$ and $u_f \in \mathbf{K}_0(r')$, with its Haar probability measure du, and let $(\mathbb{C}^{\times})^{\Phi}$

carry the measure $d^\times a = \prod_{w\in\Phi} |a_w|^{-2}\, d\lambda(a_w)$, λ the Lebesgue measure of $\mathbb{C} = \mathbb{R}^2$. Let $\mu\colon \Phi \to \mathbb{Z}$ and $\gamma_\mu(w) = \lfloor \#n'/2 \rfloor - \mu(w)$. For $z \in \mathbb{R}$ and $v \in \mathcal{F}_{W',V'}$ the **cone integral** $(+)$ and the **dual cone integral** $(-)$ are the Bochner integrals in $\mathcal{F}_{W,V}$

$$\mathrm{Cone}^{\pm}_{A,X,\mu}(z;v) = \int_{\mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi} \prod_{w\in\Phi} \Big(\frac{a_w}{|a_w|}\Big)^{2\mu(w)} |a_w|^{2z}\, \mathrm{Ln}^{\pm,\infty}_{A,X}(a)\big(\Omega_{\gamma_\mu,0}(1,u_\infty)v\big)\, du\, d^\times a,$$

defined when the integrand is Bochner integrable; here $u_\infty = (u_w)_{w\in\Phi} \in G_\infty(t')$ and $\Omega_{\gamma_\mu,0}$ is the real Weil representation of the pair (W',V') with weights $(\gamma_\mu, 0)$.

(LN5) The Tate test vector and the Gamma integral. For $m\colon \Phi \to \mathbb{N}$ the **Tate test vector** of W is the Fock vector $\tau_{W,m} \in \mathcal{F}_{W,W}$ ((WR5), index set $\Phi \times n \times n$) of the polynomial $\prod_{w\in\Phi}\prod_{i\in n} X^{m(w)}_{(w,i,i)}$, and for $x \in \mathbb{R}$ the **Gamma integral** is

$$\Gamma^\infty_m(x) = \int_{(\mathbb{C}^\times)^\Phi} \exp\Big(-\sum_{w\in\Phi} |a_w|^2\Big) \prod_{w\in\Phi} |a_w|^{2m(w)+2x}\, d^\times a \in [0,\infty].$$

(LN6) Line characters and the Tate integrand. Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, with base change $\tilde\nu$ (both as in Definition 3.2.22), and υ the splitting character ((WD3) of Definition 3.2.12). The **line characters** of $\mathfrak{c}$ are the automorphic characters of $\mathrm{U}(1)$

$$\alpha_W = \nu^{-1}\upsilon^{\lfloor \#n/2 \rfloor}, \qquad \alpha_{W'} = \nu^{-1}\upsilon^{\lfloor \#n'/2 \rfloor}.$$

For $f \in \mathcal{M}_{W',V'}$, $u \in \mathbb{A}_E^\times$, $g \in \mathrm{G}(s)$ and real x the **Tate integrand** is the function of $a \in \mathbb{A}_E^\times$, $h \in \mathrm{G}(t)$ and $\kappa \in \mathrm{K}_{\max}(t')$

$$Z_x(f;u,g)(a,h,\kappa) = \tilde\nu(au)\,|au|^x \sum_{\xi\in E^\times} \theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^+_{A,X}(\xi au)\big(\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f\big)\Big)(g,h),$$

$|\cdot|$ the module of $\mathbb{A}_E^\times$, $\theta^{W,V}_{\alpha,\beta}$ the theta kernel of (WC4) of Definition 4.1.15, $\omega_{\alpha,\beta}$ as in (WR4) of Definition 3.2.18, and the sum taken when it converges absolutely (0 otherwise).

Proposition 6.2.2. *Let W', W, V', V, A, X be as above, let b be an index set with bijections $\sigma\colon b\sqcup r \to n$ and $\sigma'\colon b\sqcup r' \to n'$, assume that $\#n$ is even, put $e = \#r - \#n/2$, and let $\mu\colon \Phi \to \mathbb{Z}$. Put $z_e = e+1$ and $\pm = +$ if $e \geq 0$, and $z_e = -e$ and $\pm = -$ if $e < 0$; so $z_e \geq 1$. Then there is $C > 0$ such that for every split tame character $\mathfrak{c} = (\nu,\Sigma)$ of weight μ there is $\gamma \in \mathbb{C}$ with*

$$|\gamma| = C\, L^\sharp_{\mathfrak{c}}(z_e)$$

and the following property: for every Schwartz vector $v' \in \mathcal{F}_{W',V'}$, every $y \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$, and all $u \in \mathbb{A}_E^\times$, $g \in \mathrm{G}(s)$ with $u = 1$ or $\#r = \#n$, the cone integral $\mathrm{Cone}^{\pm}_{A,X,\mu}(z_e;v')$ is defined and

$$\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v',y)(u,g) = \gamma\, \theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^{\pm}_{A,X,\mu}(z_e;v'),\Phi^{\mathrm{st}}_{\sigma,y})(g).$$

Proof. Fix a Haar measure on $\mathbb{A}_E^\times$, and let Y, the characters α_W, $\alpha_{W'}$ and the functions $Z_x(f;u,g)$ on Y be those of Lemma 6.2.3 and Lemma 6.2.36 (the two lemmas use the same formula). Let $c_0 \neq 0$ be the constant of Lemma 6.2.3, and $C_+, C_- > 0$ and the idele α_0 those of Lemma 6.2.36; none depends on the character. Put

$$C = |c_0|\, C_\pm\, |\alpha_0|^{z_e} > 0.$$

Let $\mathfrak{c}=(\nu,\Sigma)$ be a split tame character of weight μ, let $\epsilon_\pm$ be the numbers of Lemma 6.2.36 for $\mathfrak{c}$, put $Q=\prod_{w\in\Sigma}\mathrm{N}w$ and

$$\gamma = c_0\,\epsilon_\pm\,|\alpha_0|^{z_e}\,Q^{z_e-1/2}\,L^\Sigma(z_e,\tilde\nu).$$

By (XD7), $L^\sharp_{\mathfrak{c}}(z_e)=|L^\Sigma(z_e,\tilde\nu)|\,Q^{z_e-1/2}$, so $|\gamma|=|c_0|\,C_\pm\,|\alpha_0|^{z_e}\,Q^{z_e-1/2}|L^\Sigma(z_e,\tilde\nu)|=C\,L^\sharp_{\mathfrak{c}}(z_e)$.

Let v', y, u, g be as in the statement and $f=\varphi^{\mathrm{pl}}_{A,\sigma'}(v',y)$. By Lemma 6.2.36, $Z_x(f;u,g)$ is integrable on Y for every real x, in particular for $x=e+1$, and the cone integrals $\mathrm{Cone}^\pm_{A,X,\mu}(z_e;v')$ are defined as $z_e\geq 1$. By Lemma 6.2.3 (whose hypotheses are those of the statement, y being integral),

$$\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v',y)(u,g)=c_0\int_Y Z_{e+1}(f;u,g).$$

If $e\geq 0$, then $e+1=z_e$ and the first formula of Lemma 6.2.36 at $x=z_e$ gives $\int_Y Z_{z_e}(f;u,g)=\epsilon_+|\alpha_0|^{z_e}Q^{z_e-1/2}L^\Sigma(z_e,\tilde\nu)\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^+_{A,X,\mu}(z_e;v'),\Phi^{\mathrm{st}}_{\sigma,y})(g)$. If $e<0$, then $e+1=1-z_e$ and the second formula at $x=z_e$ gives the same with ϵ_- and Cone^-. In both cases multiplying by c_0 gives the assertion. □

The first half of the proof unfolds (Lemma 6.2.3). The constant term along an isotropic line is a sum over the rational vectors; the zero vector contributes nothing at the plane datum, and the nonzero isotropic lines form one orbit by Witt's theorem, so their terms unfold to a Tate integral along the new line, whose integrand is a sum of theta kernels of the smaller pair at line terms. The unfolding is legitimate because the kernels decay. In Weil's convergent range every theta integral converges [323]; for the pairs of the exchange this need not hold, and the group isolates the target-bounded data, which include the local data of the exchange (Lemma 6.2.26). The analytic input is the decay estimate Lemma 6.2.27: for data supported at a split place on surjective (injective) matrices, the kernel decays faster than any power of the height of the target (source) point. Its proof combines a uniform moderate-growth bound, reduction with heights, short bases by Banaszczyk's transference theorem [12], short isotropic vectors and an estimate for functionals invariant along rank-one maps; estimates of this kind are familiar from the regularised Siegel–Weil formula [176, 139].

The mixed model, standard in the local theory [206, 172, 136], enters through zero terms and slices: a splitting of V along an isotropic frame gives each vector a zero term and slices, which are vectors of the model of the complement, and the zero term intertwines the stabiliser of the frame with the smaller pair up to a determinant character. Locally constant, compactly supported functions lie in the span of the Schrödinger functions (Lemma 6.2.22; for Schwartz–Bruhat functions see [322, 294]), so the local data of the exchange are defined for all of them. Right after this, Definition 6.2.23 specifies the exchange data: from now on, for every space with a point V, the functional θ_V is the canonical theta functional of V (Definition 4.1.15), and every theta kernel and theta integral of the exchange data is formed with it.

Lemma 6.2.3. *Let W',W,V',V, A, X be as above, let b be an index set with a bijection $\sigma'\colon b\sqcup r'\to n'$, assume that $\#n$ is even, and put $e=\#r-\#n/2$. Fix a Haar measure $d^\times a$ on $\mathbb{A}_E^\times$ and give $E^\times\backslash\mathbb{A}_E^\times\times[\mathrm{U}(V)]\times\mathrm{K}_{\max}(t')$ the product of its quotient by counting measure on $E^\times$, the quotient measure of $[\mathrm{U}(V)]$ and the Haar probability measure. For a split tame character $\mathfrak{c}=(\nu,\Sigma)$ put $\alpha_W=\nu^{-1}\upsilon^{\#n/2}$ and $\alpha_{W'}=\nu^{-1}\upsilon^{\#n'/2}$, and for $f\in\mathcal{M}_{W',V'}$, $u\in\mathbb{A}_E^\times$, $g\in\mathrm{G}(s)$ and real x put*

$$Z_x(f;u,g)(a,h,\kappa)=\tilde\nu(au)\,|au|^x\sum_{\xi\in E^\times}\theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^+_{A,X}(\xi au)(\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f)\Big)(g,h)$$

for $a\in\mathbb{A}_E^\times$, $h\in\mathrm{G}(t)$, $\kappa\in\mathrm{K}_{\max}(t')$. Then there is a real number $c_0\neq 0$, depending only on A, X and $d^\times a$, with the following property. Let $\mu\colon\Phi\to\mathbb{Z}$, let $\mathfrak{c}=(\nu,\Sigma)$ be a split tame character

of weight μ, let $v \in \mathcal{F}_{W',V'}$ be a Schwartz vector, $y \in \mathrm{M}_{b\times n}(E_\Sigma)$, $g \in \mathrm{G}(s)$ and $u \in \mathbb{A}_E^\times$ with $u = 1$ or $\#r = \#n$, and $f = \varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)$. Then the series defining $Z_{e+1}(f;u,g)(a,h,\kappa)$ converges absolutely, $Z_{e+1}(f;u,g)$ is a function on $E^\times\backslash\mathbb{A}_E^\times \times [\mathrm{U}(V)] \times \mathrm{K}_{\max}(t')$, and, if it is integrable there,

$$\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v,y)(u,g) = c_0 \int Z_{e+1}(f;u,g)(a,h,\kappa)\, d(a,h,\kappa).$$

Proof. Let $c_0 \neq 0$ be the constant of Lemma 6.2.7 for A, X and $d^\times a$. Fix μ, $\mathfrak{c} = (\nu,\Sigma)$, v, y, g, u as in the statement, $f = \varphi^{\mathrm{pl}}_{A,\sigma'}(v,y) = v \otimes [\Phi']_\Sigma$ with $\Phi' = \Phi^{\mathrm{st}}_{\sigma',y(\mathrm{pr}_i)_\Sigma}$, and $\alpha' = \alpha_{W'} = \nu^{-1}\upsilon^{\#n'/2} = \alpha_W\upsilon$ ($\#n' = \#n + 2$ is even).

Step 1: the constant term as a theta integral. By (XD9), $\theta^{\mathrm{lg}}_{\mathfrak{c}}(W',V';v,\Phi') = I^{W',V'}_{\alpha',\alpha'}(f)$, so by (XD10)

$$\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v,y)(u,g) = \int I^{W',V'}_{\alpha',\alpha'}(f)\big(\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2)\,\mathrm{lev}_A(u,g)\big)\, dq.$$

The datum f is target-bounded by Lemma 6.2.26: v is a Schwartz vector, and Φ' is locally constant with compact support and vanishes at every $r' \times n'$ matrix x without a right inverse (if $\Phi'(x) \neq 0$, the $n' \times n'$ matrix with the rows of $y(\mathrm{pr}_i)_\Sigma$ and of x is invertible, so the rows of x are linearly independent).

Step 2: the sum over the rational vectors. Put $F(h) = \omega_{\alpha',\alpha'}(\mathrm{lev}_A(u,g),h)f$ for $h \in \mathrm{G}(t')$. By Lemma 6.2.4 (target V', the point $\mathrm{lev}_A(u,g)$), the series $\sum_{x\in E^{r'}} \mathrm{ct}_A(x;F(h))$ converge absolutely and

$$\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v,y)(u,g) = \int_{[\mathrm{U}(V')]} \sum_{x\in E^{r'}} \mathrm{ct}_A\big(x;F(h)\big)\, dh.$$

By (2) of Lemma 6.2.18, $\mathrm{ct}_A(0;F(h)) = 0$ for every h.

Step 3: the unfolded integrand is Z_{e+1}. Let $a' \in \mathbb{A}_E^\times$, $h \in \mathrm{G}(t)$, $\kappa \in \mathrm{K}_{\max}(t')$, put $f_\kappa = \omega_{\alpha',\alpha'}(1,\kappa)f$ and $\lambda(q) = \theta^{W,V}_{\alpha_W,\alpha_W}\big(\mathrm{Ln}^+_{A,X}(q)f_\kappa\big)(g,h)$ for $q \in \mathbb{A}_E$. Since $\omega_{\alpha',\alpha'}$ is a representation, $F(\mathrm{lev}^{\mathrm{ln}}_X(a',h)\kappa) = \omega_{\alpha',\alpha'}(\mathrm{lev}_A(u,g),\mathrm{lev}^{\mathrm{ln}}_X(a',h))f_\kappa$, and (2) of Lemma 6.2.9 for the character α_W (with $c = a'$, $x = a'u$) and the definition of theta kernels give, for $\xi \in E$,

$$\theta_{\mathrm{Hom}(W,V)}\Big(\mathrm{Ln}^+_{A,X}(\xi)F\big(\mathrm{lev}^{\mathrm{ln}}_X(a',h)\kappa\big)\Big) = \frac{|u|^{(\#r+2)/2}|a'|^{-\#n/2}}{\alpha_W[\#r](u)\,\alpha_W[\#n](a')}\,\lambda(\xi a'u).$$

Here $\tilde\alpha_W = \tilde\nu^{-1}\upsilon^{\#n}$, so $\alpha_W[\#n] = \tilde\nu^{-1}$ and $\alpha_W[\#r] = \tilde\nu^{-1}\upsilon^{\#n-\#r}$; with $e+1 = \#r - \#n/2 + 1$,

$$|a'|^{\#r+1}\,\frac{|u|^{(\#r+2)/2}|a'|^{-\#n/2}}{\alpha_W[\#r](u)\,\alpha_W[\#n](a')} = \tilde\nu(a'u)\,|a'u|^{e+1}\cdot\upsilon(u)^{\#r-\#n}|u|^{(\#n-\#r)/2} = \tilde\nu(a'u)\,|a'u|^{e+1},$$

because $u = 1$ or $\#r = \#n$. By (2) of Lemma 6.2.24 applied to $F(\mathrm{lev}^{\mathrm{ln}}_X(a',h)\kappa)$, the series over $\xi \in E$ of the left side converges absolutely; hence $\sum_{\xi\in E^\times}\lambda(\xi a'u)$ converges absolutely, which is the absolute convergence of the series defining $Z_{e+1}(f;u,g)(a',h,\kappa)$, and the function Θ of Lemma 6.2.7 for $a = b = \alpha'$, $g' = \mathrm{lev}_A(u,g)$ is

$$\Theta(a',h,\kappa) = \tilde\nu(a'u)\,|a'u|^{e+1}\sum_{\xi\in E^\times}\lambda(\xi a'u) = Z_{e+1}(f;u,g)(a',h,\kappa).$$

It is a function on Y: replacing a' by $\zeta a'$ with $\zeta \in E^\times$ permutes the ξ, and $\tilde\nu(\zeta) = \nu(\zeta/\bar\zeta) = 1$, $|\zeta| = 1$; replacing h by γh with $\gamma \in \Gamma_V$ does not change λ, by Lemma 6.2.5.

Step 4: conclusion. If $Z_{e+1}(f;u,g)$ is integrable on Y, the hypotheses of Lemma 6.2.7 hold for $a=b=\alpha'$, f, $g'=\mathrm{lev}_A(u,g)$ (Steps 2 and 3), and with Step 2

$$\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v,y)(u,g)=c_0\int_Y Z_{e+1}(f;u,g)(a,h,\kappa)\,d(a,h,\kappa).$$

□

Lemma 6.2.4. *Let W', W be spaces with points with signs s' on n', s on n, A a splitting of W' over W along a one-element set, V a space with a point with signs t on r, a,b automorphic characters of $\mathrm{U}(1)$, $f\in\mathcal{M}_{W',V}$ target-bounded and $g\in\mathrm{G}(s')$. Then for every $h\in\mathrm{G}(t)$ the series $\sum_{x\in E^r}\mathrm{ct}_A(x;\omega_{a,b}(g,h)f)$ (x read as an $r\times 1$ matrix) converges absolutely, its sum is a bounded measurable function on $[\mathrm{U}(V)]$, and*

$$\int I^{W',V}_{a,b}(f)(\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2)\,g)\,dq=\int_{[\mathrm{U}(V)]}\sum_{x\in E^r}\mathrm{ct}_A(x;\omega_{a,b}(g,h)f)\,dh.$$

Proof. Write $A=(k,l,i)$ with adelic frames $k_{\mathbb{A}},l_{\mathbb{A}},i_{\mathbb{A}}$ and coordinates $\mathrm{pr}_k,\mathrm{pr}_l,\mathrm{pr}_i$, so that pr_l (resp. pr_i, pr_k) is 1 on $l_{\mathbb{A}}$ (resp. $i_{\mathbb{A}}$, $k_{\mathbb{A}}$) and 0 on the other two frames. Let $\varepsilon_{s'},\varepsilon_s,\varepsilon_t$ be the adelic sign matrices of W',W,V, $\theta_0=\theta_{\mathrm{Hom}(W,V)}$, and for $h\in\mathrm{G}(t)$ put $\varphi_h=\omega_{a,b}(g,h)f$. For $\xi\in E^r$ put $x_\xi=x_V^{-1}\xi$ and $h_V(\xi)=\xi^*J_V\xi$; it lies in F (J_V is hermitian), and $x_\xi^*\varepsilon_t x_\xi=h_V(\xi)$ because $x_V^*J_Vx_V=\varepsilon_t$.

Step 1: radical elements. For an adelic $n\times 1$ matrix c and an adele τ let $r(c,\tau)=\mathrm{rad}_A(c,\tau)$ and $N=r(c,\tau)-1=-i_{\mathbb{A}}c\,\mathrm{pr}_l+k_{\mathbb{A}}c^*\varepsilon_s\mathrm{pr}_i-k_{\mathbb{A}}Y\mathrm{pr}_l$ with $Y=\frac12(\jmath^{-1}(\tau+\bar\tau)+c^*\varepsilon_sc)$. (a) N kills $k_{\mathbb{A}}$, maps $i_{\mathbb{A}}$ into the span of $k_{\mathbb{A}}$ and everything into the span of $i_{\mathbb{A}},k_{\mathbb{A}}$, so it is nilpotent and $\det r(c,\tau)=1$. Moreover $N^2=-k_{\mathbb{A}}c^*\varepsilon_sc\,\mathrm{pr}_l$ and $N^3=0$, so $r(c,\tau)^{-1}=1-N+N^2$ and

$$r(c,\tau)k_{\mathbb{A}}=k_{\mathbb{A}},\qquad \mathrm{pr}_i\,r(c,\tau)\,i_{\mathbb{A}}=1,\qquad r(c,\tau)^{-1}l_{\mathbb{A}}=l_{\mathbb{A}}+i_{\mathbb{A}}c+k_{\mathbb{A}}(Y-c^*\varepsilon_sc).$$

(b) As pr_l kills the image of N, $r(0,\tau)r(c,\tau')=r(c,\tau+\tau')$; hence, for adeles e,

$$\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2+e)=\mathrm{rad}^{\mathrm{ln}}_A(0,e)\,\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2).$$

(c) For $e\in E$, $x_{W'}\mathrm{rad}^{\mathrm{ln}}_A(0,e)x_{W'}^{-1}=1-k\,\jmath^{-1}(e+\bar e)\,k^*J_{W'}$ (as $k_{\mathbb{A}}=x_{W'}^{-1}k$ and $\mathrm{pr}_l=k_{\mathbb{A}}^*\varepsilon_{s'}=k^*J_{W'}x_{W'}$) has entries in E; since $\mathrm{rad}^{\mathrm{ln}}_A(0,e)\in\mathrm{G}(s')$, it lies in $\Gamma_{W'}$.

Step 2: the term of ξ at a radical point. Let $\varphi\in\mathcal{M}_{W',V}$, $\xi\in E^r$, $q=(q_1,q_2)$, $c=x_W^{-1}q_1$. By (MX6) with trivial characters, $\mathrm{term}_\xi(\varphi)(\mathrm{rad}^{\mathrm{ln}}_A(q),1)=\theta_0\big((\omega_{1,1}(r,1)\varphi)[x_\xi]\big)$ with $r=r(c,2q_2)$. Apply (2) of Lemma 6.2.45 to the splitting A along o, the space V, $g:=r$, $h:=1$, $\alpha=\upsilon^{-1}$, $\beta=1$: by Step 1 (a) its hypotheses hold with $m=1$, $g_0=1$, its two coordinates are $\mathrm{pr}_ir^{-1}l_{\mathbb{A}}=c$ and $\mathrm{pr}_kr^{-1}l_{\mathbb{A}}=\jmath^{-1}(q_2+\bar q_2)-\frac12c^*\varepsilon_sc$, and $\chi(\det m)=|\det m|=1$. Hence

$$\mathrm{term}_\xi(\varphi)(\mathrm{rad}^{\mathrm{ln}}_A(q),1)=\psi_E\big(\tfrac12(q_2+\bar q_2)h_V(\xi)\big)\,\psi_E\big(-\tfrac14\jmath\,h_V(\xi)\,c^*\varepsilon_sc\big)\,\theta_0\big(\rho(x_\xi c^*\varepsilon_s)\,\varphi[x_\xi]\big).\quad(6.1)$$

Consequences. (i) $|\mathrm{term}_\xi(\varphi)(\mathrm{rad}^{\mathrm{ln}}_A(q),1)|\le\|\theta_0\|\,\|\varphi[x_\xi]\|$, as $|\psi_E|=1$ and each $\rho(z)$ preserves the norm of $L^1(\mu)$ ($|\beta|=1$, μ translation invariant). (ii) $\mathrm{term}_\xi(\varphi)(\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2),1)=\chi_\xi(q_2)\,\mathrm{term}_\xi(\varphi)(\mathrm{rad}^{\mathrm{ln}}_A(q_1,0),1)$ with $\chi_\xi(q_2)=\psi_E(\frac12(q_2+\bar q_2)h_V(\xi))$. (iii) If $h_V(\xi)=0$, the function $q_1\mapsto\mathrm{term}_\xi(\varphi)(\mathrm{rad}^{\mathrm{ln}}_A(q_1,0),1)=\theta_0(\rho(z)\varphi[x_\xi])$, $z=x_\xi c^*\varepsilon_s$, is continuous ($z\mapsto\rho(z)F$ is continuous, translation being continuous in $L^1(\mu)$ and β continuous of modulus 1) and invariant under $q_1\mapsto q_1+\gamma$, $\gamma\in\mathrm{M}_{n\times1}(E)$. Indeed this adds to z the vector $u=x_\xi\gamma^*(x_W^{-1})^*\varepsilon_s=x_V^{-1}(\xi\gamma^*J_W)x_W$, a rational vector of $\mathrm{Hom}(W,V)$. The bicharacter of $\mathrm{Hom}(W,V)$ (signs $t(i)s(j)$)

is $\beta(z,u)=\psi_E(\frac{1}{2}\operatorname{tr}(u^*\varepsilon_t z\varepsilon_s))$ in matrix form, and $u^*\varepsilon_t z\varepsilon_s = x_W^* J_W \gamma\, h_V(\xi)\, c^* = 0$; by (WD7), $\rho(u)\rho(z)=\beta(z,u)^{-1}\rho(u+z)=\rho(u+z)$, and $\theta_0(\rho(u)F)=\theta_0(F)$ by (WD9), θ_0 being a theta functional by Lemma 4.1.17.

Step 3: theta expansion and a summable bound. Let $h\in \mathrm{G}(t)$, $q=(q_1,q_2)$, $r=\mathrm{rad}_A^{\mathrm{ln}}(q)$. Since $\omega_{a,b}$ is a representation ((2) of Lemma 4.1.1) and $\det r = 1$ (Step 1 (a)), $\omega_{a,b}(rg,h)=\omega_{1,1}(r,1)\,\omega_{a,b}(g,h)$. By the theta expansion along the splitting of $\mathrm{Hom}(W',V)$ over $\mathrm{Hom}(W,V)$ induced by A ((5) of Lemma 6.2.44) and (MX6),

$$\vartheta(q,h) := \theta_{a,b}^{W',V}(f)(rg,h) = \theta_{\mathrm{Hom}(W',V)}\big(\omega_{1,1}(r,1)\varphi_h\big) = \sum_{\xi\in E^r} \mathrm{term}_\xi(\varphi_h)(r,1),$$

absolutely convergent, and by Step 2 (i) the ξ-th term is bounded by $\|\theta_0\|\|\varphi_h[x_\xi]\|$, independently of q, where $\sum_\xi \|\varphi_h[x_\xi]\|<\infty$ by (5) of Lemma 6.2.44. By (MX10) and Step 2 (i), $|\mathrm{ct}_A(\xi;\varphi_h)|\le \|\theta_0\|\|\varphi_h[x_\xi]\|$, so $\sum_\xi \mathrm{ct}_A(\xi;\varphi_h)$ converges absolutely.

Step 4: fundamental domains and boundedness of the kernel. Let $P\subset\prod_{v\in\Phi}E_v$ be a half-open fundamental parallelepiped of $\mathcal{O}_E$; since $\mathbb{A}_{E,f}=E+\widehat{\mathcal{O}}_E$ and $E\cap(\prod_v E_v\times\widehat{\mathcal{O}}_E)=\mathcal{O}_E$, $Q_2=P\times\widehat{\mathcal{O}}_E$ is a relatively compact Borel fundamental domain of E in $\mathbb{A}_E$, and $Q_1=Q_2^n$ one of $\mathrm{M}_{n\times 1}(E)$ in $\mathrm{M}_{n\times 1}(\mathbb{A}_E)$. With the Haar measures giving them mass 1, the integral over a quotient of a periodic function is its integral over Q_1, resp. Q_2. Let $R\subset\mathrm{G}(t)$ be a Borel set of representatives of $\Gamma_V\backslash\mathrm{G}(t)$ (Γ_V is discrete and $\mathrm{G}(t)$ second countable); it has finite measure by Theorem 4.2.18, and the integral over $[\mathrm{U}(V)]$ of a left Γ_V-invariant function is its integral over R. Let $Q\subset\mathrm{M}_{n\times1}(\mathbb{A}_E)\times\mathbb{A}_E$ be relatively compact. The closure of $\{\mathrm{rad}_A^{\mathrm{ln}}(q)g : q\in Q\}$ is compact, so by target-boundedness ($|\theta_{a,b}^{W',V}(f)(x,h)|\le C_0\,\mathrm{ht}_{W'}(x)^{B_0}$) and (3) of Lemma 6.2.6, ϑ is bounded on $Q\times\mathrm{G}(t)$. It is continuous in (q,h), as $(x,F)\mapsto\omega(x)F$ is continuous ((2) of Lemma 4.1.1) and $\theta_{\mathrm{Hom}(W',V)}$ is bounded; so on $Q\times R$ it is bounded, measurable and integrable, and Fubini's theorem applies in any order. By Lemma 6.2.5, $\vartheta(q,\gamma h)=\vartheta(q,h)$ for $\gamma\in\Gamma_V$, so $I_{a,b}^{W',V}(f)(\mathrm{rad}_A^{\mathrm{ln}}(q)g)=\int_R\vartheta(q,h)\,dh$, and by Step 1 (b), (c) and Lemma 6.2.5, $q_2\mapsto\vartheta(q_1,q_2,h)$ and $q_2\mapsto I_{a,b}^{W',V}(f)(\mathrm{rad}_A^{\mathrm{ln}}(q_1,q_2)g)$ are E-periodic.

Step 5: the inner integral. Fix q_1. By Step 4 (with $Q=\{q_1\}\times Q_2$) and Fubini,

$$G(q_1) := \int_{\mathbb{A}_E/E} I_{a,b}^{W',V}(f)\big(\mathrm{rad}_A^{\mathrm{ln}}(q_1,q_2)g\big)\,dq_2 = \int_R\int_{Q_2}\vartheta(q_1,q_2,h)\,dq_2\,dh.$$

For fixed h, dominated convergence (Step 3) and Step 2 (ii) give

$$\int_{Q_2}\vartheta(q_1,q_2,h)\,dq_2 = \sum_\xi \mathrm{term}_\xi(\varphi_h)(\mathrm{rad}_A^{\mathrm{ln}}(q_1,0),1)\int_{Q_2}\chi_\xi.$$

The function χ_ξ is a continuous character of $\mathbb{A}_E$, trivial on E (there $\frac{1}{2}(q_2+\bar{q}_2)h_V(\xi)\in E$, and ψ_E is trivial on E), so $\int_{Q_2}\chi_\xi$ is its mean over the compact group $\mathbb{A}_E/E$: 1 if $\chi_\xi=1$, 0 otherwise. If $h_V(\xi)=0$, $\chi_\xi=1$. If $h_V(\xi)\neq 0$, pick $v\in\Phi$; $h_V(\xi)_v$ is real and nonzero, and for the adele q_2 with component $t\in\mathbb{R}$ at v and 0 elsewhere (WD4) gives $\chi_\xi(q_2)=\exp(-4\pi i\,t\,h_V(\xi)_v)$, which is $-i$ for $t=(8h_V(\xi)_v)^{-1}$. Hence

$$\int_{Q_2}\vartheta(q_1,q_2,h)\,dq_2 = \sigma(q_1,h) := \sum_{\xi\in E^r,\ h_V(\xi)=0}\mathrm{term}_\xi(\varphi_h)\big(\mathrm{rad}_A^{\mathrm{ln}}(q_1,0),1\big),$$

and $G(q_1)=\int_R\sigma(q_1,h)\,dh$. By Step 2 (iii) each term of σ is $\mathrm{M}_{n\times1}(E)$-periodic in q_1, so $\sigma(\cdot,h)$ and G are periodic.

Step 6: the outer integral. By periodicity, the left side of the assertion is $\int_{Q_1}G(q_1)\,dq_1=\int_{Q_1}\int_R\sigma(q_1,h)\,dh\,dq_1$. Here $\sigma=\int_{Q_2}\vartheta\,dq_2$ is measurable and bounded on $Q_1\times R$ (Step 4 with

$Q = Q_1 \times Q_2$), so Fubini gives $\int_R \int_{Q_1} \sigma(q_1, h)\, dq_1\, dh$. For fixed h, dominated convergence (Step 3) and (MX10) (for isotropic ξ the integral over the quotient of the periodic term is the integral over Q_1; for the others $\mathrm{ct}_A = 0$) give

$$\int_{Q_1} \sigma(q_1, h)\, dq_1 = \sum_{\xi \in E^r} \mathrm{ct}_A(\xi; \varphi_h) = \int_{Q_1 \times Q_2} \vartheta(q, h)\, dq.$$

The right side is measurable in h (Fubini), bounded (Step 4), and left Γ_V-invariant (Lemma 6.2.5); so $h \mapsto \sum_\xi \mathrm{ct}_A(\xi; \omega_{a,b}(g,h)f)$ is a bounded measurable function on $[\mathrm{U}(V)]$, and its integral over R, which is the left side of the assertion, is its integral over $[\mathrm{U}(V)]$. □

Lemma 6.2.5. *Let S, T be spaces with points with signs s on n and s' on n', and α, β automorphic characters of* $\mathrm{U}(1)$. *For $\gamma \in \Gamma_S$, $\gamma' \in \Gamma_T$ and $\varphi \in \mathcal{M}_{S,T}$,*

$$\theta_{\mathrm{Hom}(S,T)}(\omega_{\alpha,\beta}(\gamma, \gamma')\varphi) = \theta_{\mathrm{Hom}(S,T)}(\varphi);$$

consequently $\theta^{S,T}_{\alpha,\beta}(\varphi)(\gamma g, \gamma' h) = \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)$ for all $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$.

Proof. Write $\mathcal{M} = \mathcal{M}_{S,T}$, $\theta = \theta_{\mathrm{Hom}(S,T)}$ and $\omega = \omega_{\alpha,\beta}$; let $\mathcal{M}^\infty \subset \mathcal{M}$ be the vectors smooth for ρ (those φ for which $z \mapsto \rho(z)\varphi$ is smooth in the archimedean and locally constant in the finite components of z).

Smooth vectors are preserved and dense. For $q = (g, h)$, (2) of Lemma 4.1.1 gives

$$\rho(z)\omega(q)\varphi = \omega(q)\rho(P^{-1}z)\varphi,$$

P the pair map of q, a continuous linear automorphism of $\mathrm{Hom}(S,T)(\mathbb{A}_E)$ preserving the archimedean and finite components; so $\omega(q)\mathcal{M}^\infty \subset \mathcal{M}^\infty$. Density is Gårding's argument: the Heisenberg operators satisfy

$$\rho(z')\rho(z) = \beta(z', z)\rho(z' + z)$$

with β the bicharacter of the model (a direct computation from (WD6), (WD7)); for κ the product of a smooth compactly supported function of the archimedean components and the normalised indicator of a compact open subgroup of the finite components, $\rho(\kappa)\varphi = \int \kappa(z)\rho(z)\varphi\, dz$ satisfies

$$\rho(z')\rho(\kappa)\varphi = \int \kappa(z - z')\beta(z', z)\rho(z)\varphi\, dz,$$

which is smooth in the archimedean part of z' and, as $\beta(z', z) = 1$ for z in the compact support of κ and z' in a small enough compact open subgroup of the finite part, locally constant in its finite part; and $\rho(\kappa_j)\varphi \to \varphi$ for an approximate identity (κ_j) of this form, by the strong continuity of ρ.

Smooth vectors. By Lemma 4.1.17, applied to the fixed line functionals and transporting elements of (WC1)–(WC3), the canonical functional θ is bounded, rational-Heisenberg invariant and normalized. It is therefore a theta functional in the sense of (WD9), as required for the local theta input of Lemma 4.1.2. Let Φ, $\omega_{\psi_F,\chi}$ and $c \neq 0$ be supplied by the action and theta-distribution comparison of Lemma 4.1.2, so that $\Phi \circ \omega(q) = \omega_{\psi_F,\chi}(q) \circ \Phi$ on $\mathcal{M}^\infty$ and $\theta = c\,\theta_{\mathrm{dist}} \circ \Phi$ there, θ_{dist} the theta distribution; here $\mathrm{G}(s)$, $\mathrm{G}(s')$ are identified with $\mathrm{U}(S)(\mathbb{A}_F)$, $\mathrm{U}(T)(\mathbb{A}_F)$ through the points ((VP2) of Definition 3.2.2), under which Γ_S, Γ_T are the groups of rational points. For $\varphi \in \mathcal{M}^\infty$ and $q = (\gamma, \gamma')$ rational, (ii) of Theorem A.5.4 gives

$$\theta(\omega(q)\varphi) = c\,\theta_{\mathrm{dist}}(\omega_{\psi_F,\chi}(q)\Phi\varphi) = c\,\theta_{\mathrm{dist}}(\Phi\varphi) = \theta(\varphi).$$

All vectors. Both $\varphi \mapsto \theta(\omega(q)\varphi)$ and θ are continuous on $\mathcal{M}$ (θ is bounded and $\omega(q)$ is a bounded operator), and they agree on the dense subspace $\mathcal{M}^\infty$; hence they agree on $\mathcal{M}$. Finally $\theta^{S,T}_{\alpha,\beta}(\varphi)(\gamma g, \gamma' h) = \theta(\omega(\gamma, \gamma')\omega(g,h)\varphi) = \theta(\omega(g,h)\varphi)$, as ω is a representation. □

Lemma 6.2.6. *Let V be a space with a point with signs s on n.*

1. $\mathrm{ht}_V(\gamma g) = \mathrm{ht}_V(g)$ *for all* $\gamma \in \Gamma_V$ *and* $g \in \mathrm{G}(s)$.
2. *For every compact set* $K \subset \mathrm{G}(s)$ *there is* $c_K \geq 1$ *with* $\mathrm{ht}_V(gk) \leq c_K \,\mathrm{ht}_V(g)$ *for all* $g \in \mathrm{G}(s)$ *and* $k \in K$.
3. *For every compact set* $K \subset \mathrm{G}(s)$ *the height* ht_V *is bounded on* $\Gamma_V K$.

Proof. For $g \in \mathrm{G}(s)$ let $L(g) = \{u \in E^n : ((x_V g)^{-1}u)_f \in \widehat{\mathcal{O}}_E^n\}$ be the lattice of V_g and, for $u \in E^n$, $|u|_g = \|((x_V g)^{-1}u)_\infty\|$, the euclidean norm on $\mathbb{C}^{\Phi\times n}$; so $\lambda_V(g)$ is the infimum of 1 and of $|u|_g$ over $u \in L(g) \setminus \{0\}$, and $\mathrm{ht}_V(g) = \lambda_V(g)^{-1}$.

(1). Let $\gamma \in \Gamma_V$, so $\delta = x_V \gamma x_V^{-1} \in \mathrm{U}(V)(F) \subset \mathrm{GL}_n(E)$ and $x_V \gamma g = \delta x_V g$. For $u \in E^n$, $(x_V \gamma g)^{-1}u = (x_V g)^{-1}\delta^{-1}u$. Since $u \mapsto \delta^{-1}u$ is a bijection of $E^n \setminus \{0\}$ onto itself, it maps $L(\gamma g) \setminus \{0\}$ bijectively onto $L(g) \setminus \{0\}$ with $|u|_{\gamma g} = |\delta^{-1}u|_g$. Hence $\lambda_V(\gamma g) = \lambda_V(g)$.

(2). Let K be compact. The infinite component $k \mapsto (k_v)_{v\in\Phi}$ is continuous, so $M = \sup_{k\in K} \max_{v\in\Phi} \|k_v\|$ (operator norms) is finite. The finite component $k \mapsto k_f$ is continuous, so the entries of the k_f, $k \in K$, form a compact subset C of $\mathbb{A}_{E,f}$. The open sets $\prod_{w\in R} E_w \times \prod_{w\notin R} \mathcal{O}_{E,w}$, R finite, cover $\mathbb{A}_{E,f}$ and increase with R, so C lies in one of them, and its projection to each E_w, $w \in R$, is compact, hence contained in $\varpi_w^{-m_w}\mathcal{O}_{E,w}$ for some $m_w \geq 0$. Let N be the product of the $p_w^{m_w}$, p_w the residue characteristic of w, over $w \in R$; then $Nc \in \widehat{\mathcal{O}}_E$ for every $c \in C$, so $k_f\widehat{\mathcal{O}}_E^n \subset N^{-1}\widehat{\mathcal{O}}_E^n$ for every $k \in K$. Put $c_K = \max(1, MN)$.

Let $g \in \mathrm{G}(s)$, $k \in K$ and $u \in L(gk) \setminus \{0\}$. At the finite places $(x_V g)^{-1}u = k_f\,(x_V gk)^{-1}u \in k_f\widehat{\mathcal{O}}_E^n \subset N^{-1}\widehat{\mathcal{O}}_E^n$, so $Nu \in L(g) \setminus \{0\}$. At the infinite places $(x_V g)^{-1}u = k_\infty (x_V gk)^{-1}u$, and k_∞ is block diagonal over Φ with blocks of norm at most M, so $|u|_g \leq M|u|_{gk}$. Therefore

$$|u|_{gk} \geq M^{-1}|u|_g = (MN)^{-1}|Nu|_g \geq (MN)^{-1}\lambda_V(g) \geq c_K^{-1}\lambda_V(g).$$

Taking the infimum over u, and using $1 \geq \lambda_V(g) \geq c_K^{-1}\lambda_V(g)$, gives $\lambda_V(gk) \geq c_K^{-1}\lambda_V(g)$, that is $\mathrm{ht}_V(gk) \leq c_K\,\mathrm{ht}_V(g)$.

(3). For $\gamma \in \Gamma_V$ and $k \in K$, (1) and (2) with $g = 1$ give $\mathrm{ht}_V(\gamma k) = \mathrm{ht}_V(k) \leq c_K\,\mathrm{ht}_V(1)$, and $\mathrm{ht}_V(1)$ is finite by (VP4) of Definition 3.2.2. □

Lemma 6.2.7. *Let W', W, V', V, A, X be as above, fix a Haar measure $d^\times a$ on $\mathbb{A}_E^\times$, and give $Y = E^\times\backslash\mathbb{A}_E^\times \times [\mathrm{U}(V)] \times \mathrm{K}_{\max}(t')$ the product of the quotient of $d^\times a$ by counting measure on $E^\times$, the quotient measure of $[\mathrm{U}(V)]$ and the Haar probability measure. There is a real number $c_0 \neq 0$, depending only on A, X and $d^\times a$, with the following property. Let a, b be automorphic characters of $\mathrm{U}(1)$, $f \in \mathcal{M}_{W',V'}$, $g \in \mathrm{G}(s')$, and $F(h) = \omega_{a,b}(g,h)f$ for $h \in \mathrm{G}(t')$. Assume that $\sum_{x\in E^{r'}} \mathrm{ct}_A(x; F(h))$ converges absolutely for every h, that $\mathrm{ct}_A(0; F(h)) = 0$ for every h, and that the function*

$$\Theta(a', h, \kappa) = |a'|^{\#r+1} \sum_{\xi\in E^\times} \theta_{\mathrm{Hom}(W,V)}\Big(\mathrm{Ln}_{A,X}^+(\xi)\, F\big(\mathrm{lev}_X^{\mathrm{ln}}(a', h)\,\kappa\big)\Big)$$

(the series converging absolutely) is a function on Y that is integrable on Y. Then

$$\int_{[\mathrm{U}(V')]} \sum_{x\in E^{r'}} \mathrm{ct}_A(x; F(h))\, dh = c_0 \int_Y \Theta.$$

Proof. Write $G' = \mathrm{G}(t')$, $\Gamma = \Gamma_{V'}$, $\Gamma_P = \Gamma_{P,X}$, $x = x_{V'}$, $\theta_0 = \theta_{\mathrm{Hom}(W,V)}$, and for a line (one-dimensional subspace) $\ell \subset E^{r'}$ and $h \in G'$ put $S_\ell(h) = \sum_{y \in \ell \setminus \{0\}} \mathrm{ct}_A(y; F(h))$ and $S(h) = \sum_{y \in E^{r'}} \mathrm{ct}_A(y; F(h))$; all these series converge absolutely by hypothesis. Let $\mathcal{L}$ be the set of isotropic lines ($h_{V'}$ vanishes on them) and $\ell_0 = Ek_X$, which lies in $\mathcal{L}$ by (MX1).

Step 1: grouping by lines. By (MX10), $\mathrm{ct}_A(y; \cdot) = 0$ unless y is isotropic, and $\mathrm{ct}_A(0; F(h)) = 0$ by hypothesis. Every nonzero isotropic y lies in exactly one line, which is isotropic, so rearranging the absolutely convergent series gives $S(h) = \sum_{\ell \in \mathcal{L}} S_\ell(h)$, with $\sum_\ell |S_\ell(h)| < \infty$.

Step 2: equivariance. Let $\gamma \in \Gamma$, $\delta = x\gamma x^{-1} \in \mathrm{U}(V')(F)$, $y \in E^{r'}$ and $h \in G'$; we show $\mathrm{ct}_A(\delta y; F(\gamma h)) = \mathrm{ct}_A(y; F(h))$. Both vanish unless y is isotropic, as δ preserves $h_{V'}$. Since $\det \gamma = \det \delta$ has norm 1 and lies in E, $a(\det \gamma) = 1$, so $F(\gamma h) = \omega_{a,b}(1, \gamma)F(h) = \omega_{1,1}(1, \gamma)F(h)$ ((2) of Lemma 4.1.1), and $\omega_{1,1}(r, 1)\omega_{1,1}(1, \gamma) = \omega_{1,1}(1, \gamma)\omega_{1,1}(r, 1)$ for every $r \in \mathrm{G}(s')$. Moreover $x^{-1}\delta y = \gamma\,(x^{-1}y)$. By (2) of Lemma 6.2.45 for $g = 1$ (so $m = 1$, $g_0 = 1$ and both coordinates vanish), with the characters $(\upsilon^{-1}, 1)$, $(\omega_{1,1}(1, \gamma)G)[\gamma z] = \omega_{\upsilon^{-1},1}(1, \gamma)(G[z])$ for $G \in \mathcal{M}_{W',V'}$ and adelic z; and $\theta_0 \circ \omega_{\upsilon^{-1},1}(1, \gamma) = \theta_0$ by Lemma 6.2.5. Applying this to $G = \omega_{1,1}(r, 1)F(h)$, $z = x^{-1}y$, $r = \mathrm{rad}_A^{\mathrm{ln}}(q_1, 0)$ and integrating over q_1 in (MX10) gives the claim. Summing over the nonzero vectors of ℓ, $S_{\delta\ell}(\gamma h) = S_\ell(h)$.

Step 3: one orbit, and the unfolded sum. If $\ell = Ey \in \mathcal{L}$, the map $\sigma\colon \ell \to E^{r'}$, $y \mapsto k_X$, is injective and isometric ($h_{V'}(y, y) = 0 = h_{V'}(k_X, k_X)$), so by Witt's theorem (Theorem A.6.7) there is $\delta \in \mathrm{U}(V')(F)$ with $\delta y = k_X$, i.e. $\delta\ell = \ell_0$. The stabiliser of ℓ_0 corresponds to Γ_P by its definition. Let $R \subset \Gamma$ be a set of representatives of $\Gamma_P \backslash \Gamma$; then $\gamma \mapsto (x\gamma x^{-1})^{-1}\ell_0$ is a bijection $R \to \mathcal{L}$, and Step 2 (with $\ell = (x\gamma x^{-1})^{-1}\ell_0$) gives $S_{(x\gamma x^{-1})^{-1}\ell_0}(h) = \Phi(\gamma h)$, $\Phi := S_{\ell_0}$. Hence

$$S(h) = \sum_{\gamma \in R} \Phi(\gamma h), \qquad \sum_{\gamma \in R} |\Phi(\gamma h)| < \infty \qquad (h \in G').$$

Taking $\gamma \in \Gamma_P$ in Step 2 shows that Φ is left Γ_P-invariant.

Step 4: Φ on the line. By (1) of Lemma 6.2.8, $\Phi(h) = \sum_{\xi \in E^\times} \theta_0(\mathrm{Ln}^+_{A,X}(\xi)F(h))$. For $n = \mathrm{rad}_X(c, d) \in N_X$, $F(nh) = \omega_{a,b}(1, n)F(h)$, and by (2) of Lemma 6.2.8 each term is unchanged; so Φ is left N_X-invariant, and $\Theta(a', h, \kappa) = |a'|^{\#r+1}\Phi(\mathrm{lev}_X^{\mathrm{ln}}(a', h)\kappa)$. Each $h \mapsto \mathrm{ct}_A(y; F(h))$ is continuous: its integrand $(q_1, h) \mapsto \theta_0((\omega_{1,1}(\mathrm{rad}_A^{\mathrm{ln}}(q_1, 0)g, h)f)[x^{-1}y])$ is continuous ((2) of Lemma 4.1.1; the Hom slice map is bounded, being a zero term, (7) of Lemma 4.1.1, after an isometric Heisenberg operator) and so bounded on compact sets, and the integral may be taken over a relatively compact fundamental domain; dominated convergence applies. So S, the S_ℓ and Φ are Borel.

Step 5: integration. Φ is Borel and left invariant under N_X and Γ_P, and $\Theta = \Theta_\Phi$ is integrable on Y by hypothesis; by Lemma 6.2.15, Φ is integrable on $\Gamma_P \backslash G'$ and $\int_{\Gamma_P \backslash G'} \Phi = c_1 \int_Y \Theta$, with $c_1 > 0$ depending only on X and $d^\times a$. Let D be a Borel fundamental domain of Γ in G'; then $D_P = \bigsqcup_{\gamma \in R} \gamma D$ is one of Γ_P (as $G' = \bigsqcup_{\pi \in \Gamma_P} \bigsqcup_{\gamma \in R} \pi\gamma D$), and by the left invariance of the measure, for every left Γ_P-invariant Borel $f \geq 0$, $\int_{D_P} f = \int_D \sum_{\gamma \in R} f(\gamma h)\, dh$. With $f = |\Phi|$ this shows that $\sum_{\gamma \in R} |\Phi(\gamma \cdot)|$ is integrable on D, so by dominated convergence and Step 3

$$\int_{[\mathrm{U}(V')]} S = \int_D \sum_{\gamma \in R} \Phi(\gamma h)\, dh = \sum_{\gamma \in R} \int_{\gamma D} \Phi = \int_{D_P} \Phi = \int_{\Gamma_P \backslash G'} \Phi = c_1 \int_Y \Theta.$$

This is the assertion with $c_0 = c_1$. □

Lemma 6.2.8. *Let W', W, V', V, A, X be as above, let $k_X \in \mathrm{M}_{r' \times 1}(E)$ be the rational frame k of X, and $f \in \mathcal{M}_{W',V'}$.*

1. *For every $\xi \in E^\times$, $\mathrm{ct}_A(\xi k_X; f) = \theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^+_{A,X}(\xi)f)$.*

2. For all automorphic characters a, b of $\mathrm{U}(1)$, $c \in \mathrm{M}_{r\times 1}(\mathbb{A}_E)$, $d \in \mathbb{A}_E$ and $\xi \in \mathbb{A}_E$, with $\mathrm{rad}_X(c,d)$ the radical element of X,

$$\mathrm{Ln}^+_{A,X}(\xi)\Big(\omega_{a,b}(1,\mathrm{rad}_X(c,d))\,f\Big) = \mathrm{Ln}^+_{A,X}(\xi)f.$$

Proof. For a splitting (k,l,i) and $c' \in \mathrm{M}_{n_0\times p}(\mathbb{A}_E)$, (MX2) gives $\mathrm{rad}(c',0)k_{\mathbb{A}} = k_{\mathbb{A}}$, $\mathrm{rad}(c',0)i_{\mathbb{A}}w = i_{\mathbb{A}}w + k_{\mathbb{A}}c'^{*}\varepsilon w$ and $\mathrm{rad}(c',0)l_{\mathbb{A}} = l_{\mathbb{A}} - i_{\mathbb{A}}c' - \frac{1}{2}k_{\mathbb{A}}c'^{*}\varepsilon c'$; multiplying out, $\mathrm{rad}(c',0)\mathrm{rad}(-c',0) = 1$, so $\mathrm{pr}_i\,\mathrm{rad}(c',0)^{-1}l_{\mathbb{A}} = c'$. Likewise every $\mathrm{rad}(c',d')$ fixes $k_{\mathbb{A}}$ and has $\mathrm{pr}_i\,\mathrm{rad}(c',d')\,i_{\mathbb{A}} = 1$.

Proof of (1). Put $x = \xi k_X$; then $x^*J_{V'}x = |\xi|^2k_X^*J_{V'}k_X = 0$, and $x_{V'}^{-1}x = \xi k_{X,\mathbb{A}}$ is isotropic for $\varepsilon_{t'}$. Let $q \in \mathrm{M}_{n\times 1}(\mathbb{A}_E)$, $c' = x_W^{-1}q$ and $\eta = \mathrm{rad}^{\mathrm{ln}}_A(q,0) = \mathrm{rad}_A(c',0)$. By the first paragraph $\eta k_{A,\mathbb{A}} = k_{A,\mathbb{A}}$, $\mathrm{pr}_i\eta i_{A,\mathbb{A}} = 1$ and $\mathrm{pr}_i\eta^{-1}l_{A,\mathbb{A}} = c'$. So (2) of Lemma 6.2.45 (source W' split by A, target V', $m=1$, $g_0=1$, $h=1$, characters υ^{-1} and 1), whose phase is 1 because $\xi k_{X,\mathbb{A}}$ is isotropic, gives

$$(\omega_{1,1}(\eta,1)f)[\xi k_{X,\mathbb{A}}] = \rho(\xi k_{X,\mathbb{A}}c'^{*}\varepsilon_s)\,G, \qquad G = f[\xi k_{X,\mathbb{A}}] \in \mathcal{M}_{W,V'}.$$

Hence, with $G^\theta(z) = \theta_{\mathrm{Hom}(W,V')}(\rho(z)G)$, the integrand of (MX10) at q is $G^\theta(k_{X,\mathbb{A}}(x_W^{-1}\bar\xi q)^*\varepsilon_s)$. On the other side, the adelic frame k of the splitting induced on the target by X has the columns $x_{V'}^{-1}k_Xe_j^{\mathsf{T}}J_Wx_W = k_{X,\mathbb{A}}(x_W^{-1}e_j)^*\varepsilon_s$ ($j \in n$), so it sends $b \in \mathbb{A}_E^n$ to $k_{X,\mathbb{A}}(x_W^{-1}\bar b)^*\varepsilon_s$, and (MX4) at the point 0 gives

$$\theta_{\mathrm{Hom}(W,V)}(Z^{\mathrm{tg}}_{X,W}G) = \int_{\mathbb{A}_E^n/E^n} G^\theta(k_{X,\mathbb{A}}(x_W^{-1}\bar b)^*\varepsilon_s)\,db.$$

The map $q \mapsto b = \xi\bar q$ is an automorphism of the topological group $\mathbb{A}_E^n$ carrying E^n onto E^n ($\xi \neq 0$), so it preserves the invariant probability measure of the quotient, and $\bar b = \bar\xi q$. Therefore $\mathrm{ct}_A(\xi k_X; f) = \theta_{\mathrm{Hom}(W,V)}(Z^{\mathrm{tg}}_{X,W}(f[\xi k_{X,\mathbb{A}}]))$, which is $\theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^+_{A,X}(\xi)f)$ by (LN2).

Proof of (2). Let $\varrho = \mathrm{rad}_X(c,d)$; it fixes $k_{X,\mathbb{A}}$, so $\varrho^{-1}k_{X,\mathbb{A}} = k_{X,\mathbb{A}}$, and $\mathrm{pr}_i\varrho i_{X,\mathbb{A}} = 1$. By (2) of Lemma 6.2.45 with the source point 1 ($m=1$, $g_0=1$, $W=B=0$; characters $a\upsilon^{-1}$ and b), $(\omega_{a,b}(1,\varrho)f)[\xi k_{X,\mathbb{A}}] = \omega_{a\upsilon^{-1},b}(1,\varrho)(f[\xi k_{X,\mathbb{A}}])$. By (1) of Lemma 6.2.9 (target V' split by X, $m=1$, $h_0=1$, source point 1; characters $a\upsilon^{-1}$ and $b\upsilon^{-1}$), $Z^{\mathrm{tg}}_{X,W}(\omega_{a\upsilon^{-1},b}(1,\varrho)G) = Z^{\mathrm{tg}}_{X,W}(G)$ for every $G \in \mathcal{M}_{W,V'}$. With (LN2) this is the assertion. □

Lemma 6.2.9. *1. Let $D = (k,l,i)$ be a splitting of a space with a point Y (signs σ) over Y_0 (signs σ_0) along p, and T a space with a point with signs τ on n_T. Let $h \in \mathrm{G}(\sigma)$, $m \in \mathrm{GL}_p(\mathbb{A}_E)$ and $h_0 \in \mathrm{G}(\sigma_0)$ with $h\,k_{\mathbb{A}} = k_{\mathbb{A}}m$ and $\mathrm{pr}_i\,h\,i_{\mathbb{A}} = h_0$, let $g \in \mathrm{G}(\tau)$ and α,β automorphic characters of $\mathrm{U}(1)$. Then for $F \in \mathcal{M}_{T,Y}$*

$$Z^{\mathrm{tg}}_{D,T}(\omega_{\alpha,\beta\upsilon^{\#p}}(g,h)F) = \alpha[\#n_T](\det m)\,|\det m|^{\#n_T/2}\,\omega_{\alpha,\beta}(g,h_0)\,Z^{\mathrm{tg}}_{D,T}(F).$$

2. Let W', W, V', V, A, X be as above, a an automorphic character of $\mathrm{U}(1)$, $u, c \in \mathbb{A}_E^\times$, $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(t)$, $\xi \in \mathbb{A}_E$ and $f \in \mathcal{M}_{W',V'}$. Put $\gamma = \mathrm{lev}_A(u,g)$, $\eta = \mathrm{lev}^{\mathrm{ln}}_X(c,h)$ and $x = cu$. Then

$$\mathrm{Ln}^+_{A,X}(\xi)(\omega_{av,av}(\gamma,\eta)f) = \frac{|u|^{(\#r+2)/2}\,|c|^{-\#n/2}}{a[\#r](u)\,a[\#n](c)}\,\omega_{a,a}(g,h)\,\mathrm{Ln}^+_{A,X}(\xi x)f,$$

$$\mathrm{Ln}^-_{A,X}(\xi)(\omega_{av,av}(\gamma,\eta)f) = \frac{|u|^{\#r/2}\,|c|^{-(\#n+2)/2}}{a[\#r](u)\,a[\#n](c)}\,\omega_{a,a}(g,h)\,\mathrm{Ln}^-_{A,X}(\xi\bar x^{-1})f.$$

Proof. For adelic vectors y of T (resp. of Y, of W') and z write $[y,z] = y\,z^*\varepsilon$, an adelic matrix read as a vector of the relevant Hom space, ε the sign matrix of the source. The pair map sends (g,h) to $P_{g,h}\colon X \mapsto hXg^{-1}$, and $\varepsilon g^{-1} = g^*\varepsilon$ gives

$$P_{g,h}[y,z] = [hy, gz]. \tag{$*$}$$

For a splitting $D = (k,l,i)$ and an element h with $hk_{\mathbb{A}} = k_{\mathbb{A}}m$, $\mathrm{pr}_i h i_{\mathbb{A}} = h_0$, the matrix of h in the adelic basis $(k_{\mathbb{A}}, i_{\mathbb{A}}, l_{\mathbb{A}})$ is block upper triangular with diagonal blocks m, h_0, $(m^*)^{-1}$ (the last because h preserves the form, $l^*_{\mathbb{A}}\varepsilon k_{\mathbb{A}} = 1$ and $k^*_{\mathbb{A}}\varepsilon k_{\mathbb{A}} = k^*_{\mathbb{A}}\varepsilon i_{\mathbb{A}} = 0$), so

$$\det h = \det m\,\det h_0\,\overline{\det m}^{\,-1}. \tag{$**$}$$

Proof of (1). The adelic frames of the splitting of $\mathrm{Hom}(T,Y)$ induced on the target are, by (LN1) and the point $x_Y \otimes (x_T^{-1})^{\mathsf{T}}$ (which reads M as $x_Y^{-1}Mx_T$, and $e_j^{\mathsf{T}}J_T x_T = (x_T^{-1}e_j)^*\varepsilon_\tau$): the columns $[k_{\mathbb{A}}e_b, d_j]$ for k, and the embedding $[w,z] \mapsto [i_{\mathbb{A}}w, z]$, where $d_j = x_T^{-1}e_j$ ($b \in p$, $j \in n_T$). Writing $y = l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b$, the vectors $[l_{\mathbb{A}}a, z]$, $[k_{\mathbb{A}}b, z]$ lie in the spans of the frames l and k of the induced splitting, so its coordinate $\mathrm{pr}_i^{\mathrm{tg}}$ sends $[y,z]$ to $[\mathrm{pr}_i y, z]$. Let $P = P_{g,h}$ and $P_0 = P_{g,h_0}$. By $(*)$, $P[k_{\mathbb{A}}e_b, d_j] = [k_{\mathbb{A}}me_b, gd_j]$; as $[\,\cdot\,,\cdot\,]$ is linear in the first and conjugate-linear in the second argument, P maps the frame k of the induced splitting to itself times $M = m \otimes \overline{g'}$, where $gd_j = \sum_{j'} d_{j'}g'_{j'j}$, $g' = x_T g x_T^{-1}$; so $\det M = (\det m)^{\#n_T}\,\overline{\det g}^{\#p}$. By $(*)$ and the formula for $\mathrm{pr}_i^{\mathrm{tg}}$, $\mathrm{pr}_i^{\mathrm{tg}} P i_{\mathbb{A}}^{\mathrm{tg}}[w,z] = [h_0 w, gz] = P_0[w,z]$. So Lemma 6.2.10, applied to the space with a point $\mathrm{Hom}(T,Y)$, the induced splitting and P, gives

$$Z^{\mathrm{tg}}_{D,T}(\omega(P)F) = \upsilon(\det M)^{-1}|\det M|^{1/2}\,\omega(P_0)\,Z^{\mathrm{tg}}_{D,T}(F),$$

with $\upsilon(\det M)^{-1} = \upsilon(\det m)^{-\#n_T}\upsilon(\det g)^{\#p}$ (as $\upsilon(\bar y) = \upsilon(y)^{-1}$) and $|\det M| = |\det m|^{\#n_T}$ ($|\det g| = 1$). By (WR4) and $(**)$, $\omega_{\alpha,\beta\upsilon^{\#p}}(g,h) = \alpha(\det h)(\beta\upsilon^{\#p})(\det g)^{-1}\omega(P)$ with $\alpha(\det h) = \tilde\alpha(\det m)\,\alpha(\det h_0)$. Collecting the scalars,

$$\begin{aligned}&\tilde\alpha(\det m)\,\upsilon(\det m)^{-\#n_T}|\det m|^{\#n_T/2}\cdot\alpha(\det h_0)\beta(\det g)^{-1}\\ &\quad= \alpha[\#n_T](\det m)\,|\det m|^{\#n_T/2}\cdot\alpha(\det h_0)\beta(\det g)^{-1},\end{aligned}$$

which is the assertion since $\omega_{\alpha,\beta}(g,h_0) = \alpha(\det h_0)\beta(\det g)^{-1}\omega(P_0)$.

Proof of (2). By (MX2), $\gamma k_{A,\mathbb{A}} = k_{A,\mathbb{A}}u$, $\gamma l_{A,\mathbb{A}} = l_{A,\mathbb{A}}\bar u^{-1}$, $\gamma i_{A,\mathbb{A}} = i_{A,\mathbb{A}}g$, hence $\mathrm{pr}_k\gamma = u\,\mathrm{pr}_k$, $\mathrm{pr}_l\gamma = \bar u^{-1}\mathrm{pr}_l$, $\mathrm{pr}_i\gamma i_{A,\mathbb{A}} = g$ (coordinates of A); and $\eta = \mathrm{lev}_X(c^{-1},h)$ has $\eta k_{X,\mathbb{A}} = k_{X,\mathbb{A}}c^{-1}$, $\eta l_{X,\mathbb{A}} = l_{X,\mathbb{A}}\bar c$, $\mathrm{pr}_i\eta i_{X,\mathbb{A}} = h$.

Step 1: the translation. By (2) of Lemma 4.1.1, $\omega(P)^{-1}\rho(z)\omega(P) = \rho(P^{-1}z)$, and $\omega_{av,av}(\gamma,\eta)$ is a scalar times $\omega(P_{\gamma,\eta})$; so $\rho(z)\,\omega_{av,av}(\gamma,\eta) = \omega_{av,av}(\gamma,\eta)\,\rho(\eta^{-1}z\gamma)$. For $z = \xi k_{X,\mathbb{A}}\mathrm{pr}_k$ this is $\eta^{-1}z\gamma = \xi cu\,k_{X,\mathbb{A}}\mathrm{pr}_k = \xi x\,k_{X,\mathbb{A}}\mathrm{pr}_k$, and for $z = \xi l_{X,\mathbb{A}}\mathrm{pr}_l$ it is $\xi\bar c^{-1}\bar u^{-1}l_{X,\mathbb{A}}\mathrm{pr}_l = \xi\bar x^{-1}l_{X,\mathbb{A}}\mathrm{pr}_l$.

Step 2: the sign $+$. By (LN2) and (MX4), $\mathrm{Ln}^+_{A,X}(\xi) = Z^{\mathrm{tg}}_{X,W}\circ Z_S\circ\rho(\xi k_{X,\mathbb{A}}\mathrm{pr}_k)$, S the splitting of $\mathrm{Hom}(W',V')$ induced by A ($T = V'$). By Step 1 it suffices to move $\omega_{av,av}(\gamma,\eta)$ past Z_S and $Z^{\mathrm{tg}}_{X,W}$. The zero-term law of (2) of Lemma 6.2.45 at $x = 0$ (source W' split by A, $p = \{o\}$, $m = u$, $g_0 = g$, target V' of rank $\#r' = \#r + 2$; characters $\alpha = a$, $\beta = av$) gives

$$Z_S(\omega_{av,av}(\gamma,\eta)F) = (av)[\#r+2](u)^{-1}|u|^{(\#r+2)/2}\,\omega_{a,av}(g,\eta)Z_S(F),$$

and (1) (target V' split by X, $m = c^{-1}$, $h_0 = h$, source W of rank $\#n$; $\alpha = \beta = a$) gives

$$Z^{\mathrm{tg}}_{X,W}(\omega_{a,av}(g,\eta)F') = a[\#n](c)^{-1}|c|^{-\#n/2}\,\omega_{a,a}(g,h)Z^{\mathrm{tg}}_{X,W}(F').$$

Since $\widetilde{v}(y) = v(y/\bar{y}) = v(y)^2$, $(av)[\#r+2] = \tilde{a}\, v^2 v^{-\#r-2} = a[\#r]$, and the product of the two factors is the one stated.

Step 3: the sign $-$. By (LN2), $\mathrm{Ln}^-_{A,X}(\xi) = Z^{\mathrm{sc}}_{A,V} \circ Z^{\mathrm{tg}}_{X,W'} \circ \rho(\xi l_{X,\mathbb{A}} \mathrm{pr}_l)$. By (1) (target V' split by X, $m = c^{-1}$, source W' of rank $\#n+2$; $\alpha = av$, $\beta = a$),

$$Z^{\mathrm{tg}}_{X,W'}(\omega_{av,av}(\gamma,\eta)F) = (av)[\#n+2](c)^{-1}|c|^{-(\#n+2)/2}\, \omega_{av,a}(\gamma,h) Z^{\mathrm{tg}}_{X,W'}(F),$$

and by (2) of Lemma 6.2.45 at $x = 0$ (source W' split by A, $m = u$, target V of rank $\#r$; $\alpha = \beta = a$)

$$Z^{\mathrm{sc}}_{A,V}(\omega_{av,a}(\gamma,h)F') = a[\#r](u)^{-1}|u|^{\#r/2}\, \omega_{a,a}(g,h) Z^{\mathrm{sc}}_{A,V}(F').$$

As $(av)[\#n+2] = a[\#n]$, the product is the stated factor; with Step 1 this proves the second formula. □

Lemma 6.2.10. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p an index set, and (k,l,i) a splitting of V over V_0 along p with zero term Z. Let $g \in \mathrm{G}(s)$, $m \in \mathrm{GL}_p(\mathbb{A}_E)$ and $g_0 \in \mathrm{G}(s_0)$ satisfy $g\, k_{\mathbb{A}} = k_{\mathbb{A}} m$ and $\mathrm{pr}_i\, g\, i_{\mathbb{A}} = g_0$. Then for every $f \in \mathcal{M}_s$*

$$Z(\omega_s(g)f) = v(\det m)^{-1}\, |\det m|^{1/2}\, \omega_{s_0}(g_0)\, Z(f).$$

Proof. Throughout, an element g *in the stabiliser* means $g \in \mathrm{G}(s)$ with $gk_{\mathbb{A}} = k_{\mathbb{A}} m$, $\mathrm{pr}_i g i_{\mathbb{A}} = g_0$ for some $m \in \mathrm{GL}_p(\mathbb{A}_E)$, $g_0 \in \mathrm{G}(s_0)$.

Step 1: radical elements. (a) For g in the stabiliser, $\varepsilon_s g = g^{-*}\varepsilon_s$ gives $\mathrm{pr}_l g = k^*_{\mathbb{A}}\varepsilon_s g = (g^{-1}k_{\mathbb{A}})^*\varepsilon_s = m^{-*}\mathrm{pr}_l$; so $\mathrm{pr}_l g i_{\mathbb{A}} = 0$ and $g i_{\mathbb{A}} w = i_{\mathbb{A}} g_0 w + k_{\mathbb{A}}(\mathrm{pr}_k g i_{\mathbb{A}} w)$. (b) $r = g\,\mathrm{lev}(m, g_0)^{-1}$ satisfies $rk_{\mathbb{A}} = k_{\mathbb{A}}$ and $\mathrm{pr}_i r i_{\mathbb{A}} = g_0 g_0^{-1} = 1$. (c) Every $r \in \mathrm{G}(s)$ with $rk_{\mathbb{A}} = k_{\mathbb{A}}$ and $\mathrm{pr}_i r i_{\mathbb{A}} = 1$ is a radical element. Write $r(l_{\mathbb{A}}a) = l_{\mathbb{A}}A_1 a + i_{\mathbb{A}}A_2 a + k_{\mathbb{A}}A_3 a$ and $r(i_{\mathbb{A}}w) = l_{\mathbb{A}}B_1 w + i_{\mathbb{A}}w + k_{\mathbb{A}}B_3 w$. As r preserves $z^*\varepsilon_s z'$, pairing with $r(k_{\mathbb{A}}y) = k_{\mathbb{A}}y$ gives $A_1 = 1$, $B_1 = 0$; pairing $r(i_{\mathbb{A}}w)$ with $r(l_{\mathbb{A}}a)$ gives $B_3 = -A_2^*\varepsilon_{s_0}$; pairing $r(l_{\mathbb{A}}a)$ with $r(l_{\mathbb{A}}a')$ gives $A_3 + A_3^* + A_2^*\varepsilon_{s_0}A_2 = 0$. Put $c = -A_2$ and $b = -\jmath(A_3 + \frac{1}{2}c^*\varepsilon_{s_0}c)$; then b is hermitian ($\bar{\jmath} = -\jmath$ and the last relation), $\frac{1}{2}(\jmath^{-1}(b+b^*) + c^*\varepsilon_{s_0}c) = -A_3$, and by (MX2)

$$\mathrm{rad}(c,b)(l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}y) = l_{\mathbb{A}}a + i_{\mathbb{A}}(w - ca) + k_{\mathbb{A}}(y + c^*\varepsilon_{s_0}w - \tfrac{1}{2}(\jmath^{-1}(b+b^*) + c^*\varepsilon_{s_0}c)a)$$

agrees with r; so $r = \mathrm{rad}(c,b)$. Conversely the display shows that $\mathrm{rad}(c,b)$ is in the stabiliser with $m = 1$, $g_0 = 1$, and that it depends on b only through $b + b^*$. (d) From the display, by direct composition,

$$\begin{aligned} \mathrm{rad}(c_1,b_1)\mathrm{rad}(c_2,b_2) &= \mathrm{rad}\big(c_1 + c_2,\ b_1 + b_2 + \jmath c_1^*\varepsilon_{s_0}c_2\big), \\ \mathrm{lev}(t,1)\,\mathrm{rad}(c,b)\,\mathrm{lev}(t,1)^{-1} &= \mathrm{rad}(ct^*, tbt^*). \end{aligned} \tag{6.2}$$

Step 2: a scalar for every element of the stabiliser. Let g be in the stabiliser and $\Pi = \omega_{s_0}(g_0)^{-1} Z \omega_s(g)$, a bounded linear map $\mathcal{M}_s \to \mathcal{M}_{s_0}$. By (1) of Lemma 6.2.44 for Z (at $x = 0$, $a = 0$), $Z\rho(k_{\mathbb{A}}y) = Z$ and $Z\rho(i_{\mathbb{A}}w + k_{\mathbb{A}}y) = \rho(w)Z$. Hence $\Pi\rho(k_{\mathbb{A}}y) = \omega_{s_0}(g_0)^{-1} Z\rho(k_{\mathbb{A}}my)\omega_s(g) = \Pi$, and by Step 1 (a)

$$\Pi\rho(i_{\mathbb{A}}w) = \omega_{s_0}(g_0)^{-1} Z\rho(i_{\mathbb{A}}g_0 w + k_{\mathbb{A}}\mathrm{pr}_k g i_{\mathbb{A}} w)\omega_s(g) = \omega_{s_0}(g_0)^{-1}\rho(g_0 w) Z\omega_s(g) = \rho(w)\Pi.$$

By (1) of Lemma 6.2.44, $\Pi_x = \Pi\rho(l_{\mathbb{A}}x)$ obeys the mixed law in the hypothesis of (2) of Lemma 6.2.46. Let g_D be as in (1) of Lemma 6.2.46 and $u = \omega_s(g_D)v^0$. By (2) there, $\Pi_x u = C'|e_p(x)|^2 v^0$ for some C'; by Lemma 6.2.11, $u[x] = C|e_p(x)|^2 v^0$ with $C \neq 0$. With

$\gamma = C'/C$ we get $\Pi_x u = \gamma\, u[x]$ for all x. For $z = l_{\mathbb{A}} a + i_{\mathbb{A}} w + k_{\mathbb{A}} y$ the mixed law for Π and for Z gives

$$\Pi\rho(z)u = \psi_E(\tfrac{1}{2}\jmath\, y^* a)\rho(w)\Pi_a u = \gamma\,\psi_E(\tfrac{1}{2}\jmath\, y^* a)\rho(w)u[a] = \gamma\, Z\rho(z)u.$$

For $f \in \mathcal{M}_s$ put $h = \omega_s(g_D)^{-1} f$; by the superposition (1) of Lemma 6.2.12 and $\omega_s(g_D)\rho(z) = \rho(g_D z)\omega_s(g_D)$, $f = \int h(z)\rho(g_D z)u\, d\mu_n(z)$, so $\Pi f = \gamma Z f$ as Π, Z are bounded. Thus there is $c(g) \in \mathbb{C}$ with

$$Z\,\omega_s(g) = c(g)\,\omega_{s_0}(g_0)\,Z. \tag{6.3}$$

Since $Zu = u[0] = Cv^0 \neq 0$, $c(g)$ is unique; and $c(gg') = c(g)c(g')$ for g, g' in the stabiliser (apply (6.3) twice; gg' acts by mm' and $g_0 g_0'$), so $c(g)c(g^{-1}) = c(1) = 1$ and $c(g) \neq 0$.

Step 3: radical elements act by 1. Let $r = \mathrm{rad}(c, b)$ and $L = \mathrm{lev}(2\cdot 1_p, 1)$. With $b' = b/3$, (6.2) gives $L\,\mathrm{rad}(c, b')L^{-1} = \mathrm{rad}(2c, 4b')$ and $\mathrm{rad}(c, b')\, r = \mathrm{rad}(2c, b' + b + \jmath c^* \varepsilon_{s_0} c)$; both have hermitian part $\frac{4}{3}(b + b^*)$ in the second argument, so they are equal. Multiplicativity of c gives $c(\mathrm{rad}(c, b')) = c(L)c(\mathrm{rad}(c, b'))c(L)^{-1} = c(\mathrm{rad}(c, b'))\, c(r)$, hence $c(r) = 1$: $Z\omega_s(r) = Z$.

Step 4: the Levi block form at the adapted point. Let $L = \mathrm{lev}(m, g_0)$, $x_{\mathbb{H}}$ the point of $\mathbb{H}_p$, and $g_1 = x_{\mathbb{H}}^{-1}\mathrm{diag}(m^{-*}, m)x_{\mathbb{H}}$. As $L(l_{\mathbb{A}}\ k_{\mathbb{A}}\ i_{\mathbb{A}}) = (l_{\mathbb{A}} m^{-*}\ k_{\mathbb{A}} m\ i_{\mathbb{A}} g_0)$, the matrix F_D of Lemma 6.2.46 satisfies $LF_D = F_D\,\mathrm{diag}(g_1, g_0)$. With the permutation matrix P sending the basis vector j to $\tau(j)$, $g_D P = F_D$ (by (1) of Lemma 6.2.46), so

$$g_D^{-1} L g_D = P\,\mathrm{diag}(g_1, g_0)\,P^{-1},$$

and $\mathrm{diag}(g_1, g_0)$ preserves the sign matrix of $s^{\mathbb{H}} \sqcup s_0$ (as $P^*\varepsilon_s P$ is that matrix); so $g_1 \in \mathrm{G}(s^{\mathbb{H}})$. Its multiplier: at $v \in \Phi$, conjugation by P maps the block of sign -1 for $s^{\mathbb{H}} \sqcup s_0$ onto that for s, and the block of $\mathrm{diag}(g_1, g_0)_v$ of sign -1 is $\mathrm{diag}((g_{1,v})_-, (g_{0,v})_-)$; at the finite places $\Delta(P\,X\,P^{-1}) = \Delta(X)$ and $\Delta(X_1 \oplus X_2) = \Delta(X_1)\Delta(X_2)$ by Lemma 4.1.13, P being integral. Hence

$$\Delta_s(g_D^{-1} L g_D) = \Delta_{s^{\mathbb{H}}}(g_1)\,\Delta_{s_0}(g_0). \tag{6.4}$$

Step 5: the phase of the hyperbolic multiplier. We show $\Delta_{s^{\mathbb{H}}}(g_1)\, \upsilon(\det m) > 0$. At $v \in \Phi$, $x_{\mathbb{H},v} = 2^{-1/2}\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ and $g_{1,v} = \frac{1}{2}\begin{pmatrix} A+B & B-A \\ B-A & A+B \end{pmatrix}$ with $A = m_v^{-*}$, $B = m_v$; its block of sign -1 (the second copy of p) is $\frac{1}{2}(m_v^{-*} + m_v)$, and

$$\overline{\det \tfrac{1}{2}(m_v^{-*} + m_v)} \cdot \frac{\det m_v}{|\det m_v|} = \frac{\det(\frac{1}{2}(m_v^{-1} + m_v^*)\, m_v)}{|\det m_v|} = \frac{\det \frac{1}{2}(1 + m_v^* m_v)}{|\det m_v|} > 0.$$

At the finite places $x_{\mathbb{H},f} = \begin{pmatrix} 1 & -c \\ c_0 & c\bar{c}_0 \end{pmatrix}$ has integral entries and determinant $c(c_0 + \bar{c}_0) = c$, a unit, so $x_{\mathbb{H},f} \in \mathrm{GL}_{2p}(\widehat{\mathcal{O}}_E)$, and the last display of Lemma 4.1.13 (with $A = m_f$, $k = x_{\mathbb{H},f}$) gives $\Delta(g_{1,f})\, \upsilon(\det m_f) = |\Delta(m_f)|^2 |\det m_f|^{-1/2} > 0$, $\det m_f$ read with components 1 at Φ. Splitting the idele $\det m$ into its archimedean part (finite components 1) and $\det m_f$, (WD3) gives $\upsilon(\det m) = \prod_v \frac{\det m_v}{|\det m_v|}\, \upsilon(\det m_f)$; multiplying the factors proves the claim.

Step 6: the Levi scalar. For $f, f' \in \mathcal{M}_s$ put $B(f, f') = \int_{\mathbb{A}_E^p} \langle f[x], f'[x]\rangle\, dx$. Every vector a of $\mathcal{M}_{s_0}$ satisfies $|a(y)| \leq \|a\|$ (reproducing identity (WD7), $|\beta_{s_0}| = 1$, $|e_{n_0}| \leq 1$), so $|\langle a, a'\rangle| \leq \|a\|\,\|a'\|$; moreover $\|f[x]\| \leq \|Z\|\,\|f\|$, and by (1), (2) of Lemma 6.2.44, $\int \|f'[x]\| dx = \int_{\mathbb{A}_E^p/E^p} \sum_\xi \|(\rho(l_{\mathbb{A}}x)f')[\xi]\|\, dx \leq M\|f'\|$. With the continuity in (4) there, B is a bounded sesquilinear form. It is Heisenberg invariant: for $z = l_{\mathbb{A}} a + i_{\mathbb{A}} w + k_{\mathbb{A}} y$, $(\rho(z)f)[x] = \psi_E(\cdot)\rho(w)f[x + a]$ with a phase of modulus 1, $\rho(w)$ preserves the inner product, and dx is translation invariant. By Lemma 6.2.14, $B = K\langle\cdot,\cdot\rangle$ with $K = B(v^0, v^0)$.

Let $u = \omega_s(g_D)v^0$, so $u[x] = C\varphi(x)v^0$ with $\varphi(x) = |e_p(x)|^2$ (continuous, $\varphi \geq 0$, $\varphi(0) = 1$, integrable), and $v = \omega_s(L)u$. Since $L^{-1}l_{\mathbb{A}} = l_{\mathbb{A}}m^*$, (6.3) gives $v[x] = Z\omega_s(L)\rho(l_{\mathbb{A}}m^*x)u = c(L)\,C\,\varphi(m^*x)\,\omega_{s_0}(g_0)v^0$. Put $I = \int \varphi^2 > 0$ and $J = \int \varphi(x)\varphi(m^*x)\,dx \geq 0$; the substitution $x \mapsto m^*x$ multiplies Haar measure by $|\det m^*| = |\det m|$, so $\int \varphi(m^*x)^2 dx = |\det m|^{-1}I$. Recall $\langle v^0, v^0\rangle = 1$ and $\langle v^0, \omega(h)v^0\rangle = \overline{\Delta(h)}^{-1}$ (Lemma 6.2.13), and that ω preserves inner products. Then:

- $B(u,u) = |C|^2 I = K$;
- $B(v,v) = |c(L)|^2|C|^2|\det m|^{-1}I = K$, so $|c(L)|^2 = |\det m|$;
- $B(u,v) = |C|^2 c(L)\,J\,\overline{\Delta_{s_0}(g_0)}^{-1}$ equals

$$K\langle u, v\rangle = K\langle v^0, \omega_s(g_D^{-1}Lg_D)v^0\rangle = |C|^2 I\,\overline{\Delta_{s^{\mathbb{H}}}(g_1)}^{-1}\overline{\Delta_{s_0}(g_0)}^{-1}$$

  by (6.4).

Hence $c(L)\,J\,\overline{\Delta_{s^{\mathbb{H}}}(g_1)} = I > 0$, so $J > 0$ and $c(L)\overline{\Delta_{s^{\mathbb{H}}}(g_1)} > 0$. By Step 5, $\overline{\Delta_{s^{\mathbb{H}}}(g_1)}$ is a positive multiple of $\overline{\upsilon(\det m)}^{-1} = \upsilon(\det m)$, so $c(L)\upsilon(\det m) > 0$, and with $|c(L)| = |\det m|^{1/2}$ we get $c(L) = \upsilon(\det m)^{-1}|\det m|^{1/2}$.

Step 7: conclusion. For g as in the statement, $r = gL^{-1}$ with $L = \mathrm{lev}(m, g_0)$ is a radical element (Step 1), so by Steps 3 and 6,

$$Z\omega_s(g) = Z\omega_s(r)\omega_s(L) = Z\omega_s(L) = \upsilon(\det m)^{-1}|\det m|^{1/2}\,\omega_{s_0}(g_0)Z.$$

□

Lemma 6.2.11. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, (k,l,i) a splitting of V over V_0 along p, $m \in \mathrm{GL}_p(\mathbb{A}_E)$ and $g \in \mathrm{G}(s)$ such that the splitting is adapted at g in the basis m ((MX5) of Definition 3.2.21). Then there is $C_g \in \mathbb{C}$ with $C_g \neq 0$ and $(\omega_s(g)v^0)[x] = C_g|e_p(m^*x)|^2v^0$ for all $x \in \mathbb{A}_E^p$.*

Proof. **The constant exists.** By (1) of Lemma 6.2.44 for $\Pi = Z$, the slice maps $\Pi_x\colon f \mapsto f[x]$ satisfy the hypothesis of (2) of Lemma 6.2.46, which gives $C_g \in \mathbb{C}$ with $(\omega_s(g)v^0)[x] = C_g|e_p(m^*x)|^2v^0$ for all x. Put $u = \omega_s(g)v^0$ and suppose $C_g = 0$, so that $u[x] = 0$ for every $x \in \mathbb{A}_E^p$.

The zero term vanishes. For $z \in \mathbb{A}_E^n$ write $gz = l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b$. By the mixed law ((1) of Lemma 6.2.44)

$$Z(\rho(gz)u) = (\rho(gz)u)[0] = \psi_E(\tfrac{1}{2}\jmath\, b^*a)\rho(w)u[a] = 0.$$

Let $f \in \mathcal{M}_s$ and $h = \omega_s(g^{-1})f$. By the superposition (1) of Lemma 6.2.12, $h = \int h(z)\rho(z)v^0\,d\mu_n(z)$ as a Bochner integral in $\mathcal{M}_s$. Applying the bounded operator $\omega_s(g)$ and $\omega_s(g)\rho(z) = \rho(gz)\omega_s(g)$ ((2) of Lemma 4.1.1),

$$f = \int h(z)\rho(gz)u\,d\mu_n(z),$$

and as Z is bounded and linear,

$$Z(f) = \int h(z)Z(\rho(gz)u)\,d\mu_n(z) = 0.$$

Contradiction. Hence $f[\xi] = Z(\rho(l_{\mathbb{A}}\xi)f) = 0$ for all f and $\xi \in E^p$, and the theta expansion ((3) of Lemma 6.2.44) gives $\theta_V(f) = 0$ for every $f \in \mathcal{M}_s$. But θ_V is a theta functional (Lemma 4.1.17), so $\int_{W_n/V(E)} |\theta_V(\rho(x)v^0)|^2 dx = 1$ (WD9), which is impossible if $\theta_V = 0$. Therefore $C_g \neq 0$. □

Lemma 6.2.12. *Let s be signs on an index set n.*

1. *(Superposition.) For $h \in \mathcal{M}_s$ the map $z \mapsto h(z)\rho(z)v^0$ from $(\mathbb{A}_E^n, \mu_n)$ to $\mathcal{M}_s$ is Bochner integrable, and $h = \int h(z)\,\rho(z)v^0\,d\mu_n(z)$.*

2. *(Twisted self-convolution.) For all $x, y \in \mathbb{A}_E^n$,*

$$\int_{\mathbb{A}_E^n} e_n(z)\,\beta_s(z,y)\,\beta_s(z+y,x)\,e_n(x-z-y)\,d\mu_n(z) = e_n(y)\,e_n(x).$$

3. *(Vacuum projection.) For $f \in \mathcal{M}_s$ the map $z \mapsto e_n(z)\rho(z)f$ is Bochner integrable, and*

$$\int_{\mathbb{A}_E^n} e_n(z)\,\rho(z)f\,d\mu_n(z) = \langle v^0, f\rangle\, v^0.$$

4. *(Partial projections.) Let Σ be a set of places of E, $A_\Sigma = \{z \in \mathbb{A}_E^n : z_w = 0 \text{ for } w \notin \Sigma\}$, and μ_Σ the Haar measure on A_Σ that is the product of the factors of μ_n at the places of Σ (WD6). For $f \in \mathcal{M}_s$ put $P_\Sigma f = \int_{A_\Sigma} e_n(z)\rho(z)f\,d\mu_\Sigma(z)$. Then P_Σ is a bounded operator, $\langle P_\Sigma f, f'\rangle = \langle f, P_\Sigma f'\rangle$, P_Σ commutes with $\rho(y)$ for every y whose components at the places of Σ are 0, and $P_\Sigma\rho(y)v^0 = e_n(y)v^0$ for $y \in A_\Sigma$; in particular $P_\Sigma v^0 = v^0$. For Σ the set of all places, P_Σ is the operator of (3).*

Proof. **Step 0: evaluation and the Heisenberg law.** For $h \in \mathcal{M}_s$ and every x, $|h(x)| \le \|h\|$, by the reproducing identity (WD7), $|\beta_s| = 1$ and $|e_n| \le 1$; so $h \mapsto h(x)$ is a bounded functional and an element of $\mathcal{M}_s$ is determined by its class in $L^1(\mu_n)$. As β_s is additive in each variable and $\beta_s(y,z) = \beta_s(z,y)^{-1}$ ($\psi_E(\bar t) = \psi_E(t)$, $\bar\jmath = -\jmath$), $(\rho(z)\rho(y)h)(x) = \beta_s(z,x)\beta_s(y,x-z)h(x-z-y) = \beta_s(z,y)\,(\rho(z+y)h)(x)$.

Step 1: (1). The map $z \mapsto h(z)\rho(z)v^0$ is strongly measurable (strong continuity) with norm $|h(z)|\,\|v^0\|$, hence Bochner integrable. By Step 0 the value of its integral at x is $\int h(z)\beta_s(z,x)e_n(x-z)\,d\mu_n(z) = h(x)$, by (WD7).

Step 2: (2), reduction. Write $x = (x_\infty, x_f)$. In the coordinates $x_{v,i} = \kappa_v u_{v,i}$ at $v \in \Phi$ and $x_f = \alpha\xi$ at the finite places, μ_n is the product of $\pi^{-1}du_{v,i}$ over (v,i) and the Haar measure $d\xi$ with $\widehat{\mathcal{O}}_E^n$ of mass 1 (WD6), and, as $\jmath_v\kappa_v^2 = i/(2\pi)$, $\pi\,\mathrm{Im}(\jmath_v)\kappa_v^2 = \frac12$ and $(\alpha\eta)^*(\alpha\xi) = \alpha\bar\alpha\,\eta^*\xi$,

$$e_n(x) = \prod_{v,i} e^{-|u_{v,i}|^2/2}\cdot\prod_i \psi_0(\tfrac{c_0}{2}\bar\xi_i\xi_i)\mathbf{1}_{\widehat{\mathcal{O}}_E}(\xi_i), \qquad \beta_s(x,y) = \prod_{v,i} b_{s_i}(u_{v,i},u'_{v,i})\cdot\prod_i \psi_0(\tfrac12\bar\eta_i\xi_i),$$

for y with coordinates u', η, where $b_\sigma(t,t') = \exp(\sigma(\bar t't - \bar t t')/2)$ (the archimedean factor of ψ_E is $\exp(-2\pi i\,2\,\mathrm{Re}(\cdot))$). So the integral in (2) is a product of one-dimensional integrals, and it suffices to prove (R) and (F) below.

Step 3: (R) archimedean, $\sigma = \pm1$: $\pi^{-1}\int_{\mathbb{C}} e(t)\,b_\sigma(t,t')\,b_\sigma(t+t',u)\,e(u-t-t')\,dt = e(t')e(u)$ with $e(t) = e^{-|t|^2/2}$. For $\sigma = 1$, expanding $|u-t'-t|^2$, the exponent of the integrand is

$$-|t|^2 + \bar u t - \bar t t' - \tfrac12|u-t'|^2 + \tfrac12(\bar u t' - \bar t' u).$$

By the Gaussian integral $\pi^{-1}\int_{\mathbb{C}}\exp(-|t|^2 + at + c\bar t)\,dt = e^{ac}$ ($a, c \in \mathbb{C}$; both sides are entire in (a,c) and agree for $c = \bar a$ by the substitution $t \mapsto t + c$), with $a = \bar u$, $c = -t'$, the integral is $\exp(-\bar u t' - \frac12|u-t'|^2 + \frac12(\bar u t' - \bar t' u)) = \exp(-\frac12(|u|^2 + |t'|^2))$. For $\sigma = -1$ substitute $t \mapsto \bar t$: $b_{-1}(t,t') = b_1(\bar t, \bar t')$ and $e(\bar t) = e(t)$, so the integral is the case $\sigma = 1$ at $(\bar u, \bar t')$, again $e(t')e(u)$.

Step 4: (F) finite: $\int_{\mathbb{A}_{E,f}} \varepsilon(\zeta)\,\psi_0(\frac12\bar\eta\zeta)\,\psi_0(\frac12\bar\xi(\zeta+\eta))\,\varepsilon(\xi-\zeta-\eta)\,d\zeta = \varepsilon(\eta)\varepsilon(\xi)$ with $\varepsilon(\zeta) = \psi_0(\frac{c_0}{2}\bar\zeta\zeta)\mathbf{1}_{\widehat{\mathcal{O}}_E}(\zeta)$. We use $\psi_0(\bar t) = \psi_0(t)^{-1}$ (as $\psi_{E,f}(\bar t) = \psi_{E,f}(t)$ and $\overline{\jmath\alpha\bar\alpha} = -\jmath\alpha\bar\alpha$), $\psi_0(\widehat{\mathcal{O}}_E) = 1$, $c_0 \in \mathcal{O}_E$ and $c_0 + \bar c_0 = 1$ (WD1); in particular $\psi_0(\frac12(X-\bar X)) = \psi_0(\frac12 X)^2 = \psi_0(X) = 1$ for $X \in \widehat{\mathcal{O}}_E$. The integrand vanishes unless $\zeta \in \widehat{\mathcal{O}}_E$ and $\xi-\eta-\zeta \in \widehat{\mathcal{O}}_E$, so both sides vanish unless $d = \xi-\eta \in \widehat{\mathcal{O}}_E$ (for the right side: see below). Let $d \in \widehat{\mathcal{O}}_E$ and $\zeta \in \widehat{\mathcal{O}}_E$. Expanding, and replacing $\psi_0(-\frac{c_0}{2}\bar\zeta d)$ by $\psi_0(\frac{\bar c_0}{2}\zeta\bar d)$ and $\psi_0(c_0\bar\zeta\zeta)$ by 1, the integrand is

$$\psi_0(\tfrac{c_0}{2}\bar d d + \tfrac12\bar\xi\eta)\,\psi_0\Big(\tfrac12\zeta(\bar\eta+\bar\xi-c_0\bar d+\bar c_0\bar d)\Big) = \psi_0(\tfrac{c_0}{2}\bar d d + \tfrac12\bar\xi\eta)\,\psi_0(\zeta(\bar c_0\bar\xi + c_0\bar\eta)),$$

since $\bar\eta+\bar\xi-(c_0-\bar c_0)(\bar\xi-\bar\eta) = (1-c_0+\bar c_0)\bar\xi + (1+c_0-\bar c_0)\bar\eta = 2\bar c_0\bar\xi + 2c_0\bar\eta$. By self-duality the mean of $\psi_0(\zeta t)$ over $\zeta \in \widehat{\mathcal{O}}_E$ is $\mathbf{1}_{\widehat{\mathcal{O}}_E}(t)$, and $\bar c_0\bar\xi + c_0\bar\eta = \bar\eta + \bar c_0\bar d$ is integral iff η is. So the left side is $\psi_0(\frac{c_0}{2}\bar d d + \frac12\bar\xi\eta)\mathbf{1}[\xi,\eta \in \widehat{\mathcal{O}}_E]$, and for ξ,η integral its ratio to $\varepsilon(\eta)\varepsilon(\xi)$ is $\psi_0(\frac12(\bar c_0\bar\xi\eta - c_0\bar\eta\xi)) = \psi_0(\frac12(X-\bar X)) = 1$ with $X = \bar c_0\bar\xi\eta$. If $d \notin \widehat{\mathcal{O}}_E$ the right side vanishes too, as then ξ and η are not both integral.

Step 4b: the same at a set of places. Let Σ be a set of places. The identities of Steps 3 and 4 are local: (R) concerns one coordinate at one infinite place, and Step 4 holds verbatim with $\mathbb{A}_{E,f}$ and $\widehat{\mathcal{O}}_E$ replaced by the restricted product of the E_w and by $\prod_w \mathcal{O}_{E,w}$ over the finite $w \in \Sigma$, because ψ_0 is the product of its local components and $\prod_{w\in\Sigma}\mathcal{O}_{E,w}$ is its own annihilator (the annihilator of $\widehat{\mathcal{O}}_E = \prod_w \mathcal{O}_{E,w}$ is the product of the local annihilators). For $y \in A_\Sigma$ the integrand of $(P_\Sigma\rho(y)v^0)(x) = \int_{A_\Sigma} e_n(z)\beta_s(z,y)\beta_s(z+y,x)e_n(x-z-y)\,d\mu_\Sigma(z)$ is, by Step 0, a product over the places: at the places of Σ these local identities give the factor e_n of y times that of x, and at the places outside Σ the factor is that of $e_n(x)$, as z and y vanish there. Hence $P_\Sigma\rho(y)v^0 = e_n(y)v^0$ (the factors of $e_n(y)$ outside Σ being $e_n(0)$-factors, equal to 1). Boundedness: $\|P_\Sigma\| \le \int_{A_\Sigma}|e_n|\,d\mu_\Sigma < \infty$. Symmetry: $\rho(z)$ preserves the inner product and $\rho(z)^{-1} = \rho(-z)$, e_n is real and even and μ_Σ is invariant under $z \mapsto -z$, so $\langle P_\Sigma f, f'\rangle = \int e_n(z)\langle f, \rho(-z)f'\rangle\,d\mu_\Sigma(z) = \langle f, P_\Sigma f'\rangle$. Commutation: if y vanishes at the places of Σ and $z \in A_\Sigma$, then $\beta_s(y,z) = \beta_s(z,y) = 1$, so $\rho(y)\rho(z) = \rho(z)\rho(y)$ by Step 0.

Step 5: (3). The map $z \mapsto e_n(z)\rho(z)f$ is Bochner integrable as in Step 1, and $Pf = \int e_n(z)\rho(z)f\,d\mu_n(z)$ is bounded linear in f with $\|P\| \le \|e_n\|_1$. For $f = \rho(y)v^0$, Step 0 and (2) give, at every x, $(P\rho(y)v^0)(x) = \int e_n(z)\beta_s(z,y)\beta_s(z+y,x)e_n(x-z-y)\,d\mu_n(z) = e_n(y)e_n(x)$, so $P\rho(y)v^0 = e_n(y)v^0$. For general f, (1) and boundedness of P give $Pf = \int f(y)e_n(y)\,d\mu_n(y)\,v^0 = \langle v^0, f\rangle v^0$. □

Lemma 6.2.13. *Let s be signs on an index set n.*

1. *For every $f \in \mathcal{M}_s$, $\langle v^0, f\rangle = f(0)$. In particular $\langle v^0, v^0\rangle = 1$.*
2. *For every $g \in \mathrm{G}(s)$, $\Delta_s(g) \neq 0$,*

$$|\Delta_s(g)|^2 = \prod_{v\in\Phi} |\det(g_v)_-|^2 \cdot |\det u|^{-1} \qquad \textit{and} \qquad \langle v^0, \omega_s(g)v^0\rangle = \overline{\Delta_s(g)}^{-1},$$

where $u \in \mathrm{GL}_n(\mathbb{A}_{E,f})$ is any element with $u\widehat{\mathcal{O}}_E^n = \widehat{\mathcal{O}}_E^n \cap g_f^{-1}\widehat{\mathcal{O}}_E^n$.

Proof. **Step 1: the vacuum is real and even.** Write $x = (x_\infty, x_f) \in \mathbb{A}_E^n$ and $e_n(x) = e_\infty(x_\infty)e_f(x_f)$ with the two factors of (WD5). The factor e_∞ is real and even. If $x_f \notin \alpha\widehat{\mathcal{O}}_E^n$ then $e_f(x_f) = e_f(-x_f) = 0$. If $x_f = \alpha z$ with $z \in \widehat{\mathcal{O}}_E^n$, then $\frac{c_0\jmath}{2}\sum_i \bar x_i x_i = \jmath\alpha\bar\alpha\,\frac{c_0}{2}z^*z$, so

$$e_f(\alpha z) = \psi_0(\tfrac{c_0}{2}z^*z)\mathbf{1}[z \in \widehat{\mathcal{O}}_E^n] \qquad (z \in \mathbb{A}_{E,f}^n). \tag{6.5}$$

This is even in z, and $e_f(\alpha z)\,\overline{e_f(\alpha z)}^{-1} = \psi_0(c_0 z^* z) = 1$ for $z \in \widehat{\mathcal{O}}_E^n$, because $c_0 \in \mathcal{O}_E$ (WD1), so $c_0 z^* z \in \widehat{\mathcal{O}}_E$, and ψ_0 is trivial on $\widehat{\mathcal{O}}_E$. Hence $\overline{e_n(x)} = e_n(x) = e_n(-x)$ for all x.

Step 2: (1). By (WD7) at the point $x = 0$, with $\beta_s(y,0) = \psi_E(0) = 1$, and by Step 1,

$$f(0) = \int f(y)\,\beta_s(y,0)\,e_n(-y)\,d\mu_n(y) = \int \overline{e_n(y)}\,f(y)\,d\mu_n(y) = \langle v^0, f\rangle.$$

For $f = v^0$ this gives $\langle v^0, v^0\rangle = e_n(0) = 1$.

Step 3: the vacuum coefficient as an integral. Let $g \in \mathrm{G}(s)$. By (1) applied to $\omega_s(g)v^0 \in \mathcal{M}_s$, by (WR3) at $x = 0$ and by Step 1,

$$\begin{aligned}\langle v^0, \omega_s(g)v^0\rangle = (\omega_s(g)v^0)(0) &= \Delta_s(g)\int e_n(y)\,\beta_s(gy,0)\,e_n(-gy)\,d\mu_n(y)\\ &= \Delta_s(g)\int e_n(y)\,e_n(gy)\,d\mu_n(y).\end{aligned}$$

The measure μ_n is the product of the image μ_∞ of $\pi^{-fn}du$ under $u \mapsto (\kappa_v u_{v,i})$ and the image μ_f of dz under $z \mapsto \alpha z$ (WD6); the integrand is the product of an archimedean and a finite factor, each bounded by a Gaussian, respectively an indicator of a compact set; so by Fubini the integral is the product $I_\infty I_f$ of the two integrals below.

Step 4: the archimedean integral. Since $\pi\,\mathrm{Im}(\jmath_v)\kappa_v^2 = \frac{1}{2}$, we have $e_\infty((\kappa_v u_v)_v) = \prod_v \exp(-\frac{1}{2}u_v^* u_v)$, and $(g\,(\kappa_v u_v))_v = \kappa_v g_v u_v$. By the Gaussian integral $\int_{\mathbb{C}^n}\exp(-u^*Au)\,du = \pi^{\#n}\det(A)^{-1}$ for positive definite hermitian A,

$$I_\infty = \prod_{v\in\Phi}\pi^{-\#n}\int_{\mathbb{C}^n}\exp(-u^*\tfrac{1}{2}(1+g_v^*g_v)u)\,du = \prod_{v\in\Phi}\det\big(\tfrac{1}{2}(1+g_v^*g_v)\big)^{-1}.$$

Fix v and order the indices with the signs $+1$ first: $g_v = \begin{pmatrix} A & B\\ C & D\end{pmatrix}$, $D = (g_v)_-$. The relation $g_v^*\mathrm{diag}(s)g_v = \mathrm{diag}(s)$ reads $A^*A = 1 + C^*C$, $D^*D = 1 + B^*B$, $A^*B = C^*D$. Hence

$$\tfrac{1}{2}(1+g_v^*g_v) = \begin{pmatrix} A^*A & C^*D\\ D^*C & D^*D\end{pmatrix},$$

$D^*D \geq 1$ is invertible, so D is invertible, and the Schur complement of D^*D is $A^*A - C^*D(D^*D)^{-1}D^*C = A^*A - C^*C = 1$. Therefore $\det\frac{1}{2}(1+g_v^*g_v) = \det(D^*D) = |\det(g_v)_-|^2$ (an empty block has determinant 1), and $I_\infty = \prod_v |\det(g_v)_-|^{-2}$.

Step 5: the finite integral. By (6.5), $g_f\alpha z = \alpha g_f z$ and $(g_f z)^*(g_f z) = z^*z$ (as $g_f^*g_f = 1$),

$$e_f(\alpha z)\,e_f(\alpha g_f z) = \psi_0(c_0 z^* z)\,\mathbf{1}[z \in \widehat{\mathcal{O}}_E^n \cap g_f^{-1}\widehat{\mathcal{O}}_E^n] = \mathbf{1}[z \in u\widehat{\mathcal{O}}_E^n],$$

the phase being 1 as in Step 1. The Haar measure of $u\widehat{\mathcal{O}}_E^n$ is $|\det u|$ times that of $\widehat{\mathcal{O}}_E^n$, which is 1; so $I_f = |\det u|$.

Step 6: (2). The determinants $\det(g_v)_-$ are nonzero (Step 4), $|v| = 1$ and $\det u$ is an idele, so by (WR3) $\Delta_s(g) \neq 0$ and $|\Delta_s(g)|^2 = \prod_v |\det(g_v)_-|^2\,|\det u|^{-1} = (I_\infty I_f)^{-1}$. By Steps 3–5, $\langle v^0, \omega_s(g)v^0\rangle = \Delta_s(g)\,|\Delta_s(g)|^{-2} = \overline{\Delta_s(g)}^{-1}$. □

Lemma 6.2.14. *Let s be signs on an index set n, and let $B\colon \mathcal{M}_s \times \mathcal{M}_s \to \mathbb{C}$ be conjugate-linear in the first and linear in the second argument, with $|B(f,f')| \leq C\,\|f\|\,\|f'\|$ for some C and all f, f', and with*

$$B(\rho(z)f, \rho(z)f') = B(f,f') \qquad (z \in \mathbb{A}_E^n,\ f, f' \in \mathcal{M}_s).$$

Then $B(f,f') = B(v^0,v^0)\,\langle f, f'\rangle$ for all $f, f' \in \mathcal{M}_s$.

Proof. **Step 1: moving Heisenberg operators across B.** For $a, b \in \mathcal{M}_s$ and $z \in \mathbb{A}_E^n$, invariance under $\rho(-z)$ and $\rho(-z)\rho(z) = 1$ give $B(\rho(z)a, b) = B(a, \rho(-z)b)$; the same holds for $\langle\cdot,\cdot\rangle$, which is invariant under ρ ($|\beta_s| = 1$ and μ_n is translation invariant).

Step 2: the projection is symmetric for B. Let $Pf = \int e_n(y)\rho(y)f\, d\mu_n(y)$, so that $Pf = \langle v^0, f\rangle v^0$ by (3) of Lemma 6.2.12. Since B is bounded, $f' \mapsto B(f, f')$ is a bounded linear functional and $f \mapsto B(f, f')$ a bounded conjugate-linear one, so both commute with Bochner integrals (the latter with conjugated scalars). By Step 1, e_n real and even, and the invariance of μ_n under $y \mapsto -y$,

$$\begin{aligned} B(f, Pf') &= \int e_n(y) B(f, \rho(y)f')\, d\mu_n(y) = \int e_n(y) B(\rho(-y)f, f')\, d\mu_n(y) \\ &= B\Big(\int e_n(-y)\rho(-y)f\, d\mu_n(y), f'\Big) = B(Pf, f'). \end{aligned}$$

Step 3: the value at the vacuum. As $Pv^0 = \langle v^0, v^0\rangle v^0 = v^0$, Step 2 gives for every f

$$B(f, v^0) = B(f, Pv^0) = B(Pf, v^0) = B(\langle v^0, f\rangle v^0, v^0) = \langle f, v^0\rangle\, B(v^0, v^0).$$

Step 4: conclusion. By (1) of Lemma 6.2.12, $f' = \int f'(z)\rho(z)v^0\, d\mu_n(z)$. By boundedness, Step 1 and Step 3,

$$\begin{aligned} B(f, f') &= \int f'(z) B(\rho(-z)f, v^0)\, d\mu_n(z) = B(v^0, v^0) \int f'(z)\langle \rho(-z)f, v^0\rangle\, d\mu_n(z) \\ &= B(v^0, v^0) \int f'(z)\langle f, \rho(z)v^0\rangle\, d\mu_n(z), \end{aligned}$$

and the last integral is $\langle f, \int f'(z)\rho(z)v^0\, d\mu_n(z)\rangle = \langle f, f'\rangle$, the inner product being bounded on $\mathcal{M}_s$ ($|g(x)| \le \|g\|$ for $g \in \mathcal{M}_s$, so $|\langle g, g'\rangle| \le \|g\|\,\|g'\|$). □

Lemma 6.2.15. *Let V', V be spaces with points with signs t' on r' and t on r, X a base-adapted splitting of V' over V along a one-element set, and $d^\times a$ a Haar measure on $\mathbb{A}_E^\times$. Let $Y = E^\times\backslash\mathbb{A}_E^\times \times [\mathrm{U}(V)] \times \mathrm{K}_{\max}(t')$ carry the product of the quotient of $d^\times a$ by counting measure on $E^\times$, the quotient measure of $[\mathrm{U}(V)]$ and the Haar probability measure. There is $c_1 > 0$, depending only on X and $d^\times a$, with the following property. Let $\varphi\colon \mathrm{G}(t') \to \mathbb{C}$ be Borel and left invariant under N_X and under $\Gamma_{P,X}$, and*

$$\Theta_\varphi(a, h, \kappa) = |a|^{\#r+1}\, \varphi\big(\mathrm{lev}_X^{\ln}(a, h)\, \kappa\big) \qquad (a \in \mathbb{A}_E^\times,\ h \in \mathrm{G}(t),\ \kappa \in \mathrm{K}_{\max}(t')).$$

Then Θ_φ is left invariant under $E^\times \times \Gamma_V$ in (a, h), so it is a function on Y. If $\varphi \ge 0$, then $\int_{\Gamma_{P,X}\backslash \mathrm{G}(t')} \varphi = c_1 \int_Y \Theta_\varphi$ in $[0, \infty]$. If Θ_φ is integrable on Y, then φ is integrable on $\Gamma_{P,X}\backslash\mathrm{G}(t')$ and $\int_{\Gamma_{P,X}\backslash \mathrm{G}(t')} \varphi = c_1 \int_Y \Theta_\varphi$.

Proof. Write $G' = \mathrm{G}(t')$ with its measure μ (a left Haar measure), $K = \mathrm{K}_{\max}(t')$ with $d\kappa$, $N = N_X$ with a Haar measure dn, $\Gamma_P = \Gamma_{P,X}$, $M = \mathbb{A}_E^\times \times \mathrm{G}(t)$ with $dm = d^\times a\, dh$ (a Haar measure), $L(m) = \mathrm{lev}_X^{\ln}(a, h)$ for $m = (a, h)$, $w(m) = |a|^{\#r+1}$, $M_F = E^\times \times \Gamma_V$ and $N_F = N \cap \Gamma_{V'}$. By (1) of Lemma 6.2.16, L is a continuous injective homomorphism normalising N, and by (3) of Lemma 6.2.16 applied to $\mathrm{lev}_X(a^{-1}, h)$,

$$\int_N f\big(L(m)\, n\, L(m)^{-1}\big)\, dn = w(m) \int_N f(n)\, dn \qquad (m \in M,\ f \ge 0 \text{ Borel}). \tag{6.6}$$

By (4) of Lemma 6.2.16 (with $\xi \mapsto \xi^{-1}$), $(\delta, \nu) \mapsto L(\delta)\nu$ is a bijection $M_F \times N_F \to \Gamma_P$; in particular $L(\delta) \in \Gamma_P$, and $w(\delta) = 1$ for $\delta \in M_F$ by the product formula. Hence $\Theta_\varphi((\xi, \gamma_0)(a, h), \kappa) = w(\xi a, \gamma_0 h)\varphi(L(\xi, \gamma_0)L(a, h)\kappa) = \Theta_\varphi(a, h, \kappa)$.

Step 1: the Iwasawa measure is a multiple of Haar measure. Let $\Pi\colon M\times N\times K\to G'$, $\Pi(m,n,\kappa)=L(m)n\kappa$, and $\Lambda=\Pi_*(dm\,dn\,d\kappa)$. By (6) and (2) of Lemma 6.2.16, $G'=P_XK$ and $P_X=N\,L(M)=L(M)\,N$, so Π is onto. It is proper: if $L(m)n\kappa\in C$, C compact, then $L(m)n\in CK\cap P_X$, a compact set (P_X is closed), and by (2) of Lemma 6.2.16 the components m, n of $p=L(m)n=(L(m)nL(m)^{-1})L(m)$ are continuous functions of $p\in P_X$; so $\Pi^{-1}(C)$ lies in a compact set and $\Lambda(C)<\infty$. Thus Λ is a nonzero Borel measure on the second countable locally compact space G', finite on compact sets, hence a Radon measure. It is invariant under the action $(p,k)\cdot g=pgk^{-1}$ of $H=P_X\times K$: right translation by K preserves $d\kappa$; left translation by $n_0\in N$ sends $L(m)n\kappa$ to $L(m)(L(m)^{-1}n_0L(m))n\kappa$ and dn is left invariant; left translation by $L(m_0)$ sends it to $L(m_0m)n\kappa$ and dm is left invariant; and $P_X=N\,L(M)$. The measure μ is also H-invariant: it is left invariant, and right invariant under the compact group K, on which the modular function of G' is trivial. The action of H on G' is transitive, with the compact stabiliser $\{(\kappa_0,\kappa_0):\kappa_0\in P_X\cap K\}$ of 1, and the orbit map from the quotient of H by it to G' is a continuous bijection between homogeneous spaces of the σ-compact group H, hence a homeomorphism. An H-invariant Radon measure on the quotient of H by a compact subgroup is unique up to a positive factor (Weil's theorem on invariant measures on homogeneous spaces; see Folland, *A Course in Abstract Harmonic Analysis*, Theorem 2.49). Hence there is $d\in(0,\infty)$ with

$$\int_{G'} f\,d\mu=d^{-1}\int_M\int_N\int_K f(L(m)n\kappa)\,d\kappa\,dn\,dm\qquad(f\ge0\text{ Borel}).\tag{6.7}$$

Step 2: fundamental domains. $\Gamma_P\subset\Gamma_{V'}$ is countable and discrete, and so are $N_F\subset N$ and $M_F\subset M$; let $D\subset G'$, $D_N\subset N$ and $D_M=D_1\times D_2\subset M$ be Borel fundamental domains for their left actions (D_1 for $E^\times$ in $\mathbb{A}_E^\times$, D_2 for Γ_V in $\mathrm{G}(t)$). For $f\ge0$ Borel on N, $\int_N f\,dn=\int_{D_N}\sum_{\nu\in N_F}f(\nu n)\,dn$, and likewise on M. Let C be the compact set of (5) of Lemma 6.2.16; then $\sum_\nu\mathbf{1}_C(\nu n)\ge1$ for every n, so $v_N:=dn(D_N)\le\int_{D_N}\sum_\nu\mathbf{1}_C(\nu n)\,dn=dn(C)<\infty$, and $v_N>0$ since the countably many νD_N cover N.

Step 3: the identity for $\varphi\ge0$. By the definition of the quotient measure and (6.7),

$$\int_{\Gamma_P\backslash G'}\varphi=\int_{G'}\varphi\mathbf{1}_D\,d\mu=d^{-1}\int_M\int_N\int_K\varphi(L(m)n\kappa)\mathbf{1}_D\big(L(m)n\kappa\big)\,d\kappa\,dn\,dm.$$

Since $L(m)n=(L(m)nL(m)^{-1})L(m)$ and φ is left N-invariant, $\varphi(L(m)n\kappa)=\varphi(L(m)\kappa)$. By (6.6) with $f(n)=\mathbf{1}_D(nL(m)\kappa)$, $\int_N\mathbf{1}_D(L(m)n\kappa)\,dn=w(m)A(L(m)\kappa)$ with $A(g)=\int_N\mathbf{1}_D(ng)\,dn$. By Tonelli,

$$\int_{\Gamma_P\backslash G'}\varphi=d^{-1}\int_K\int_M H_\kappa(m)\,A\big(L(m)\kappa\big)\,dm\,d\kappa,\qquad H_\kappa(m)=w(m)\varphi\big(L(m)\kappa\big).$$

For $g\in G'$ and $\delta\in M_F$, (6.6) with $w(\delta)=1$ gives $A(L(\delta)g)=\int_N\mathbf{1}_D(L(\delta)ng)\,dn$, so by Tonelli and the bijection $M_F\times N_F\to\Gamma_P$,

$$\sum_{\delta\in M_F}A(L(\delta)g)=\int_{D_N}\sum_{\nu\in N_F}\sum_{\delta\in M_F}\mathbf{1}_D\big(L(\delta)\nu\,ng\big)\,dn=\int_{D_N}\sum_{\gamma\in\Gamma_P}\mathbf{1}_D(\gamma ng)\,dn=v_N.$$

As H_κ is left M_F-invariant (shown above for Θ_φ),

$$\int_M H_\kappa(m)A(L(m)\kappa)\,dm=\int_{D_M}H_\kappa(m)\sum_{\delta\in M_F}A\big(L(\delta)L(m)\kappa\big)\,dm=v_N\int_{D_M}H_\kappa(m)\,dm.$$

Hence $\int_{\Gamma_P\backslash G'}\varphi=c_1\int_K\int_{D_M}\Theta_\varphi(m,\kappa)\,dm\,d\kappa=c_1\int_Y\Theta_\varphi$ with $c_1=v_N/d$. Replacing dn by $t\,dn$ multiplies v_N and d by t, so c_1 depends only on X, $d^\times a$ and the fixed measures of $\mathrm{G}(t')$ and $\mathrm{G}(t)$.

Step 4: integrable φ. $|\varphi|$ is Borel, ≥ 0 and left invariant under N and Γ_P, and $\Theta_{|\varphi|} = |\Theta_\varphi|$; by Step 3, φ is integrable on $\Gamma_P\backslash G'$ when Θ_φ is integrable on Y. Apply Step 3 to the positive and negative parts of $\operatorname{Re}\varphi$ and $\operatorname{Im}\varphi$, which have the same invariance and finite integrals, and use linearity. □

Lemma 6.2.16. *Let V', V be spaces with points with signs t' on r' and t on r, and $X = (k, l, i)$ a base-adapted splitting of V' over V along a one-element set, with adelic frames $k_\mathbb{A}, l_\mathbb{A}, i_\mathbb{A}$, coordinates $\mathrm{pr}_k, \mathrm{pr}_l, \mathrm{pr}_i$, Levi elements $\mathrm{lev} = \mathrm{lev}_X$ and radical elements $\mathrm{rad} = \mathrm{rad}_X$. Put*

$$N_X = \{\mathrm{rad}(c, b) : c \in \mathrm{M}_{r\times 1}(\mathbb{A}_E),\ b \in \mathbb{A}_E\}, \qquad P_X = \{g \in \mathrm{G}(t') : gk_\mathbb{A} \in k_\mathbb{A}\mathbb{A}_E^\times\},$$

and let $\Gamma_{P,X}$ be the set of $\gamma \in \Gamma_{V'}$ with $x_{V'}\gamma x_{V'}^{-1}k \in kE^\times$.

1. *N_X is the set of $g \in \mathrm{G}(t')$ with $gk_\mathbb{A} = k_\mathbb{A}$ and $\mathrm{pr}_i\, g\, i_\mathbb{A} = 1$; it is a closed subgroup of $\mathrm{G}(t')$. The map $(m, h) \mapsto \mathrm{lev}(m, h)$ is a continuous injective homomorphism $\mathbb{A}_E^\times \times \mathrm{G}(t) \to \mathrm{G}(t')$ whose image normalises N_X, and $\mathrm{lev}(m, h) \in N_X$ only for $(m, h) = (1, 1)$.*

2. *P_X is a closed subgroup of $\mathrm{G}(t')$, and every $g \in P_X$ is $g = n\,\mathrm{lev}(m, h)$ with unique $n \in N_X$, $m \in \mathbb{A}_E^\times$, $h \in \mathrm{G}(t)$, namely $m = \mathrm{pr}_k\, g\, k_\mathbb{A}$ and $h = \mathrm{pr}_i\, g\, i_\mathbb{A}$; so n, m, h depend continuously on g.*

3. *N_X is unimodular, and every Haar measure dn of N_X satisfies, for all (m, h) and Borel $f \geq 0$ on N_X,*

$$\int_{N_X} f\big(\mathrm{lev}(m, h)\, n\, \mathrm{lev}(m, h)^{-1}\big)\, dn = |m|^{-(\#r+1)} \int_{N_X} f(n)\, dn.$$

4. *$\Gamma_{P,X} = P_X \cap \Gamma_{V'}$, and the map $((\xi, \gamma_0), \nu) \mapsto \mathrm{lev}(\xi, \gamma_0)\,\nu$ is a bijection from $(E^\times \times \Gamma_V) \times (N_X \cap \Gamma_{V'})$ onto $\Gamma_{P,X}$.*

5. *There is a compact set $C \subset N_X$ with $N_X = (N_X \cap \Gamma_{V'})\, C$.*

6. *$\mathrm{G}(t') = P_X\, \mathrm{K}_{\max}(t')$.*

Proof. Write $x = x_{V'}$, $\varepsilon = \varepsilon_{t'}$, $p_0 = \#r$, and $\mathcal{F} = (l_\mathbb{A} \mid k_\mathbb{A} \mid i_\mathbb{A})$. From (MX1) and $x^*J_{V'}x = \varepsilon$, $x_V^*J_Vx_V = \varepsilon_t$: $k_\mathbb{A}^*\varepsilon k_\mathbb{A} = l_\mathbb{A}^*\varepsilon l_\mathbb{A} = 0$, $l_\mathbb{A}^*\varepsilon k_\mathbb{A} = 1$, $i_\mathbb{A}^*\varepsilon i_\mathbb{A} = \varepsilon_t$, $i_\mathbb{A}^*\varepsilon k_\mathbb{A} = i_\mathbb{A}^*\varepsilon l_\mathbb{A} = 0$, and $\mathrm{pr}_k = l_\mathbb{A}^*\varepsilon$, $\mathrm{pr}_l = k_\mathbb{A}^*\varepsilon$, $\mathrm{pr}_i = \varepsilon_t i_\mathbb{A}^*\varepsilon$. So $\mathcal{F}^*\varepsilon\mathcal{F}$ is invertible, $\mathcal{F}$ is invertible, and $k_\mathbb{A}\mathrm{pr}_k + l_\mathbb{A}\mathrm{pr}_l + i_\mathbb{A}\mathrm{pr}_i = 1$. For $g \in \mathrm{G}(t')$, $\varepsilon g = (g^*)^{-1}\varepsilon$, so $\mathrm{pr}_l\, g = (g^{-1}k_\mathbb{A})^*\varepsilon$.

Step 1: radical elements. Let $N = \mathrm{rad}(c, b) - 1 = -i_\mathbb{A}c\,\mathrm{pr}_l + k_\mathbb{A}c^*\varepsilon_t\mathrm{pr}_i - k_\mathbb{A}Y\mathrm{pr}_l$, $Y = \frac{1}{2}(\jmath^{-1}(b+\bar{b})+c^*\varepsilon_t c)$. Then $\mathrm{rad}(c, b)k_\mathbb{A} = k_\mathbb{A}$, $\mathrm{rad}(c, b)i_\mathbb{A} = i_\mathbb{A}+k_\mathbb{A}c^*\varepsilon_t$, $\mathrm{rad}(c, b)l_\mathbb{A} = l_\mathbb{A}-i_\mathbb{A}c-k_\mathbb{A}Y$. As pr_l kills the image of N, $\mathrm{rad}(0, b)\mathrm{rad}(c, b') = \mathrm{rad}(c, b+b')$; and with $z = c_1^*\varepsilon_t c_2$ (so $c_2^*\varepsilon_t c_1 = \bar{z}$), multiplying out gives $\mathrm{rad}(c_1, 0)\mathrm{rad}(c_2, 0) = \mathrm{rad}(c_1+c_2, \frac{1}{2}\jmath(z-\bar{z}))$. Hence, as b enters only through $b + \bar{b} \in \mathbb{A}_F$,

$$\begin{gathered}\Psi(c_1, \beta_1)\Psi(c_2, \beta_2) = \Psi\big(c_1 + c_2,\ \beta_1 + \beta_2 + \jmath(z - \bar{z})\big),\\ \Psi(c, \beta) := \mathrm{rad}(c, \beta/2) \quad (c \in \mathrm{M}_{r\times 1}(\mathbb{A}_E),\ \beta \in \mathbb{A}_F),\end{gathered} \tag{6.8}$$

with $\jmath(z - \bar{z}) \in \mathbb{A}_F$. Ψ maps onto N_X, and it is injective with continuous inverse: $c = -\mathrm{pr}_i\, n\, l_\mathbb{A}$ and $\jmath^{-1}\beta = -2\,\mathrm{pr}_k\, n\, l_\mathbb{A} - c^*\varepsilon_t c$.

Step 2: (1). Let N' be the set of $g \in \mathrm{G}(t')$ with $gk_\mathbb{A} = k_\mathbb{A}$, $\mathrm{pr}_i g i_\mathbb{A} = 1$. For $g \in N'$, $\mathrm{pr}_l g i_\mathbb{A} = k_\mathbb{A}^*\varepsilon i_\mathbb{A} = 0$, so $gi_\mathbb{A} = i_\mathbb{A}+k_\mathbb{A}y$ with $y = \mathrm{pr}_k g i_\mathbb{A}$; from this N' is closed under products and inverses. By Step 1, $N_X \subset N'$. Conversely let $q \in N'$, $qi_\mathbb{A} = i_\mathbb{A}+k_\mathbb{A}y$, $ql_\mathbb{A} = l_\mathbb{A}+i_\mathbb{A}c'+k_\mathbb{A}z'$ (here $\mathrm{pr}_l ql_\mathbb{A} = k_\mathbb{A}^*\varepsilon l_\mathbb{A} = 1$). Since q preserves the form, $(qi_\mathbb{A})^*\varepsilon(ql_\mathbb{A}) = 0$ gives $\varepsilon_t c' + y^* = 0$ and $(ql_\mathbb{A})^*\varepsilon(ql_\mathbb{A}) = 0$

gives $z'+\bar z'=-c'^{*}\varepsilon_t c'$. With $c=-c'$ and $b=-\jmath(z'+\frac12 c^{*}\varepsilon_t c)$ one has $y=c^{*}\varepsilon_t$ and $-Y=z'$, so q and $\mathrm{rad}(c,b)$ agree on the columns of the invertible $\mathcal F$; $q=\mathrm{rad}(c,b)$. So $N_X=N'$, closed. The Levi elements satisfy $\mathrm{lev}(m,h)k_{\mathbb A}=k_{\mathbb A}m$, $\mathrm{lev}(m,h)i_{\mathbb A}=i_{\mathbb A}h$, $\mathrm{lev}(m,h)l_{\mathbb A}=l_{\mathbb A}\bar m^{-1}$, whence lev is a continuous homomorphism, $\mathrm{pr}_k\mathrm{lev}(m,h)k_{\mathbb A}=m$, $\mathrm{pr}_i\mathrm{lev}(m,h)i_{\mathbb A}=h$ (injectivity), and $\mathrm{lev}(m,h)\in N'$ forces $m=1$, $h=1$. Finally, using $h^{*}\varepsilon_t=\varepsilon_t h^{-1}$, a direct computation on the three terms of N gives

$$\mathrm{lev}(m,h)\,\Psi(c,\beta)\,\mathrm{lev}(m,h)^{-1}=\Psi(hc\bar m,\ m\bar m\beta). \tag{6.9}$$

Step 3: (2). $g\in \mathrm{G}(t')$ lies in P_X iff $\mathrm{pr}_l gk_{\mathbb A}=0$ and $\mathrm{pr}_i gk_{\mathbb A}=0$: then $gk_{\mathbb A}=k_{\mathbb A}m$, $m=\mathrm{pr}_k gk_{\mathbb A}$, and m is a unit since $(gl_{\mathbb A})^{*}\varepsilon k_{\mathbb A}m=l_{\mathbb A}^{*}\varepsilon k_{\mathbb A}=1$. So P_X is closed, and a subgroup. For $g\in P_X$, $\mathrm{pr}_l gi_{\mathbb A}=(k_{\mathbb A}m^{-1})^{*}\varepsilon i_{\mathbb A}=0$, so $gi_{\mathbb A}=i_{\mathbb A}h+k_{\mathbb A}y$ with $h=\mathrm{pr}_i gi_{\mathbb A}$, and $\varepsilon_t=(gi_{\mathbb A})^{*}\varepsilon(gi_{\mathbb A})=h^{*}\varepsilon_t h$: $h\in \mathrm{G}(t)$. Then $n=g\,\mathrm{lev}(m,h)^{-1}$ fixes $k_{\mathbb A}$ and $ni_{\mathbb A}=i_{\mathbb A}+k_{\mathbb A}yh^{-1}$, so $n\in N_X$ by (1). If $n\,\mathrm{lev}(m,h)=n'\mathrm{lev}(m',h')$, then $\mathrm{lev}(m'^{-1}m,h'^{-1}h)\in N_X$, so $(m,h)=(m',h')$ and $n=n'$.

Step 4: (3). Let dc, $d\beta$ be Haar measures of $\mathrm{M}_{r\times 1}(\mathbb A_E)=\mathbb A_E^{p_0}$ and $\mathbb A_F$, and dn the image of $dc\,d\beta$ under the homeomorphism Ψ. By (6.8), a left (or right) translation is, in the coordinates, a translation in c followed, for each c, by a translation in β; it preserves $dc\,d\beta$ by Fubini. So dn is a left and right Haar measure, N_X is unimodular, and every Haar measure is a multiple of dn. By (6.9) conjugation by $\mathrm{lev}(m,h)$ is, in the coordinates, $(c,\beta)\mapsto(hc\bar m,m\bar m\beta)$. The first map is given by the matrix $h\bar m\in \mathrm{GL}_{p_0}(\mathbb A_E)$ and multiplies dc by $|\det h|\,|\bar m|^{p_0}=|m|^{p_0}$, since $\det h\overline{\det h}=1$ and conjugation preserves the module; the second multiplies $d\beta$ by $|m\bar m|_{\mathbb A_F}=|m|$. Hence $\int f(\mathrm{lev}\,n\,\mathrm{lev}^{-1})\,dn=|m|^{-(p_0+1)}\int f\,dn$.

Step 5: (4). Let $\gamma\in\Gamma_{V'}$, $\delta=x\gamma x^{-1}\in \mathrm{U}(V')(F)$. Then $\gamma k_{\mathbb A}=x^{-1}\delta k$, and as δk and $k\neq 0$ are rational, $\delta k\in k\mathbb A_E^{\times}$ iff $\delta k\in kE^{\times}$; so $\Gamma_{P,X}=P_X\cap\Gamma_{V'}$. Using $xk_{\mathbb A}=k$, $\mathrm{pr}_k x^{-1}=l^{*}J_{V'}$, $\mathrm{pr}_l x^{-1}=k^{*}J_{V'}$, $xi_{\mathbb A}=ix_V$, $\mathrm{pr}_i x^{-1}=x_V^{-1}J_V^{-1}i^{*}J_{V'}$ (from $\varepsilon_t x_V^{*}=x_V^{-1}J_V^{-1}$), one gets for $\xi\in E^{\times}$, $\gamma_0\in\Gamma_V$

$$x\,\mathrm{lev}(\xi,\gamma_0)\,x^{-1}=k\xi l^{*}J_{V'}+i\,(x_V\gamma_0x_V^{-1})\,J_V^{-1}i^{*}J_{V'}+l\bar\xi^{-1}k^{*}J_{V'}\in \mathrm{GL}_{r'}(E),$$

which lies in $\mathrm{U}(V')(F)$ because $\mathrm{lev}(\xi,\gamma_0)\in \mathrm{G}(t')$; so $\mathrm{lev}(\xi,\gamma_0)\in\Gamma_{P,X}$, and the map lands in $\Gamma_{P,X}$. Conversely, for $\gamma\in\Gamma_{P,X}$, (2) gives $\gamma=n\,\mathrm{lev}(\xi,h)$ with $\xi=\mathrm{pr}_k\gamma k_{\mathbb A}\in E^{\times}$ and $h=\mathrm{pr}_i\gamma i_{\mathbb A}=x_V^{-1}(J_V^{-1}i^{*}J_{V'}\delta i)x_V$, so $x_Vhx_V^{-1}$ has entries in E and, h lying in $\mathrm{G}(t)$, $h\in\Gamma_V$; then $\nu=\mathrm{lev}(\xi,h)^{-1}\gamma=\mathrm{lev}(\xi,h)^{-1}n\,\mathrm{lev}(\xi,h)\in N_X\cap\Gamma_{V'}$. Injectivity: $\mathrm{lev}(\xi,\gamma_0)\nu=\mathrm{lev}(\xi',\gamma_0')\nu'$ gives $\mathrm{lev}(\xi'^{-1}\xi,\gamma_0'^{-1}\gamma_0)\in N_X$, so $(\xi,\gamma_0)=(\xi',\gamma_0')$ by (1).

Step 6: (5). For $u\in E^{p_0}$ and $\beta_0\in F$, $\Psi(x_V^{-1}u,\beta_0)\in\Gamma_{V'}$: conjugated by x, the three terms of N become $-iuk^{*}J_{V'}$, $ku^{*}i^{*}J_{V'}$ and $-k\frac12(\jmath^{-1}\beta_0+u^{*}J_Vu)k^{*}J_{V'}$, all rational. As $\mathbb A_E/E$ and $\mathbb A_F/F$ are compact, there are compact $C_0\subset\mathbb A_E^{p_0}$ and $C_F\subset\mathbb A_F$ with $\mathbb A_E^{p_0}=E^{p_0}+C_0$ and $\mathbb A_F=F+C_F$. Let $n=\Psi(c,\beta)$; choose u with $c-x_V^{-1}u\in C_1:=x_V^{-1}C_0$. By (6.8), $\Psi(c',0)^{-1}=\Psi(-c',0)$ (z is then real) and $\Psi(-x_V^{-1}u,0)\,n=\Psi(c-x_V^{-1}u,\beta+\varrho)$ for some $\varrho\in\mathbb A_F$; choose $\beta_0\in F$ with $\beta+\varrho-\beta_0\in C_F$; then $\Psi(0,-\beta_0)\Psi(-x_V^{-1}u,0)\,n\in\Psi(C_1\times C_F)=:C$, compact.

Step 7: (6). Let v be a place of F; write G_v, K_v for the components at v of $\mathrm{G}(t')$ and $\mathrm{K}_{\max}(t')$, and P_v for the stabiliser in G_v of the line spanned by $(k_{\mathbb A})_v$. For $v\in\Phi$, $G_v=\mathrm{U}(\mathrm{diag}\,t')$, the basis $e_1=(k_{\mathbb A})_v$, $f_1=(l_{\mathbb A})_v$, $u_c=$ the columns of $(i_{\mathbb A})_v$ has the relations of (i) of Lemma 6.2.17 for the form $z^{*}\mathrm{diag}(t')y$ (first paragraph), it is orthonormal for the standard form (base-adapted), so $K_v=\{u\in G_v:u^{*}u=1\}$ is the stabiliser of the majorant, and the signature (p,q) has $\min(p,q)\geq 1$ (the span of e_1,f_1 has signature $(1,1)$); (i) with $J=1$ gives $G_v=P_vK_v$. For finite v, $E\otimes F_v$ is an unramified field or $F_v\times F_v$ (Lemma 3.2.9), G_v is the unitary group of $z^{*}y$ on $(E\otimes F_v)^{r'}$, $K_v=G_v\cap\mathrm{GL}_{r'}(\mathcal O_{E,v})$ is the stabiliser of the self-dual lattice $\mathcal O_{E,v}^{r'}$, and the line of $(k_{\mathbb A})_v$ is free of rank one and isotropic ($a(k_{\mathbb A})_v=0$ implies $a=a\,(l_{\mathbb A})_v^{*}(k_{\mathbb A})_v=0$); (ii)

gives $G_v = P_v K_v$. Let $g \in \mathrm{G}(t')$ and R the finite set of finite v with $g_v \notin \mathrm{GL}_{r'}(\mathcal{O}_{E,v})$. Write $g_v = p_v \kappa_v$ for $v \in \Phi \cup R$, and put $p_v = 1$, $\kappa_v = g_v \in K_v$ otherwise. Then $p = (p_v) \in \mathrm{G}(t')$, $\kappa = (\kappa_v) \in \mathrm{K}_{\max}(t')$, $g = p\kappa$, and $p_v (k_{\mathbb{A}})_v = (k_{\mathbb{A}})_v m_v$ with $m_v \in (E \otimes F_v)^\times$, $m_v = 1$ for $v \notin \Phi \cup R$; so $m \in \mathbb{A}_E^\times$ and $p \in P_X$. □

Lemma 6.2.17. *All symbols introduced here are local to this statement and to the results that cite it. Let $j = (j_1, \dots, j_a)$ be a composition of $J \geq 1$.*

(i) Real place. *Let $V_v = \mathbb{C}^n$ carry a hermitian form h_v of signature (p, q) with $J \leq \min(p, q)$, and let $(e_1, \dots, e_J, u_1, \dots, u_{n-2J}, f_1, \dots, f_J)$ be a basis with $h_v(e_s, f_t) = \delta_{st}$, $h_v(e_s, e_t) = h_v(f_s, f_t) = 0$, $h_v(e_s, u_c) = h_v(f_s, u_c) = 0$, $h_v(u_c, u_d) = \pm\delta_{cd}$. Let h_v^+ be the positive definite hermitian form for which this basis is orthonormal (it is a majorant of h_v), $G_v = \mathrm{U}(V_v, h_v)$, K_v the stabiliser of h_v^+ in G_v, W_i the span of $e_1, \dots, e_{j_1 + \cdots + j_i}$, and P_v the stabiliser of $W_\bullet$ in G_v. Let dg be the Haar measure of G_v and $d_l p$ the left Haar measure of P_v of density 1 at 1 with respect to the Lebesgue measures of $\langle Y, Z \rangle = \mathrm{Re}\,\mathrm{tr}(Y Z^*)$ (Z^* the h_v^+-adjoint) on their Lie algebras, and dk the Haar probability measure of K_v. Then $G_v = P_v K_v$ and for every Borel $\varphi \colon G_v \to [0, \infty]$*

$$\int_{G_v} \varphi \, dg = c_{\mathrm{Iw}} \int_{P_v} \int_{K_v} \varphi(pk) \, dk \, d_l p, \qquad c_{\mathrm{Iw}} = \frac{2^{-d(j)/2} \operatorname{vol} \mathrm{U}(p) \operatorname{vol} \mathrm{U}(q)}{\operatorname{vol} \mathrm{U}(p - J) \operatorname{vol} \mathrm{U}(q - J) \prod_{i=1}^{a} 2^{j_i^2/2} \operatorname{vol} \mathrm{U}(j_i)}.$$

(ii) Finite place. *Let F_v be a nonarchimedean local field, E_v an unramified quadratic extension of F_v or $F_v \times F_v$, V_v a free E_v-module of rank n with a nondegenerate hermitian form h_v, L_v a self-dual lattice, $G_v = \mathrm{U}(V_v, h_v)$, K_v the stabiliser of L_v, $W_\bullet$ an isotropic flag of type j in V_v (free submodules, $\operatorname{rank} W_i - \operatorname{rank} W_{i-1} = j_i$, $h_v(W_a, W_a) = 0$), and P_v its stabiliser. Let dg be the Haar measure of G_v with $\int_{K_v} dg = 1$, $d_l p$ the left Haar measure of P_v with $\int_{P_v \cap K_v} d_l p = 1$, and dk the Haar probability measure of K_v. Then $G_v = P_v K_v$ and $\int_{G_v} \varphi \, dg = \int_{P_v} \int_{K_v} \varphi(pk) \, dk \, d_l p$ for every Borel $\varphi \geq 0$.*

Proof. **A general principle.** Let G be a unimodular locally compact group, $K \subseteq G$ a compact subgroup and $P \subseteq G$ a closed subgroup with $G = PK$; put $K_P = P \cap K$ (compact). By Weil's integration formula there is a G-invariant Radon measure dy on G/K with $\int_G \varphi \, dg = \int_{G/K} \int_K \varphi(gk) \, dk \, dy(gK)$, dk the Haar probability measure; likewise $\int_P \psi \, d_l p = \int_{P/K_P} \int_{K_P} \psi(pl) \, dl \, dz(pK_P)$ for a P-invariant Radon measure dz on P/K_P (dl the Haar probability measure; the modular function of P is trivial on the compact K_P). The map $\iota \colon P/K_P \to G/K$, $pK_P \mapsto pK$, is a P-equivariant homeomorphism ($G = PK$, $P \cap K = K_P$, and $P/K_P \to G/K$ is a continuous bijection of homogeneous spaces of the σ-compact group P, hence open). A P-invariant Radon measure on P/K_P is unique up to a positive factor, so $\iota^* dy = c \, dz$ for some $c > 0$. For $\varphi \geq 0$ put $\Psi(p) = \int_K \varphi(pk) \, dk$, which is right K_P-invariant; then

$$\int_G \varphi \, dg = \int_{G/K} \Psi \, dy = c \int_{P/K_P} \Psi \, dz = c \int_P \Psi \, d_l p = c \int_P \int_K \varphi(pk) \, dk \, d_l p. \tag{$*$}$$

(ii). K_v is a special (indeed hyperspecial) maximal compact subgroup of G_v, so $G_v = P_v K_v$ for every parabolic subgroup P_v by the Iwasawa decomposition of Bruhat–Tits ([309], 3.3.2); P_v, the stabiliser of an isotropic flag, is parabolic. Apply $(*)$ to $\varphi = \mathbf{1}_{K_v}$: the left side is 1 and the right side is $c \int_{P_v} \int_{K_v} \mathbf{1}_{K_v}(pk) \, dk \, d_l p = c \int_{P_v \cap K_v} d_l p = c$. So $c = 1$.

(i): the Lie algebras. Order the basis as $(E_1, \dots, E_a, U, F_a, \dots, F_1)$, where E_i, F_i are the spans of the e_s, f_s with $j_1 + \cdots + j_{i-1} < s \leq j_1 + \cdots + j_i$ and U the span of the u_c. The h_v-orthogonal of W_i is $E_1 \oplus \cdots \oplus E_a \oplus U \oplus F_a \oplus \cdots \oplus F_{i+1}$, so P_v is the group of block upper triangular elements of G_v. Let H be the matrix of h_v in this basis; it is the matrix

of the involution σ with $h_v(y,z) = h_v^+(\sigma y, z)$, $H = H^* = H^{-1}$, and $\sigma(e_s) = f_s$, $\sigma(f_s) = e_s$, $\sigma(u_c) = \pm u_c$. The Lie algebra is $\mathfrak{g} = \{X : X^*H + HX = 0\}$; it is stable under $\theta(X) = -X^*$ (if $X^*H = -HX$ then $HX^*H = -X$, i.e. $XH + HX^* = 0$) and under the projections of $\mathfrak{gl}_n$ onto the strictly block upper, block diagonal and strictly block lower parts (the condition is $X = -HX^*H$, and $X \mapsto -HX^*H$ respects the three parts since H reverses the order of the blocks). Hence $\mathfrak{g} = \mathfrak{n} \oplus \mathfrak{m} \oplus \bar{\mathfrak{n}}$ with $\mathfrak{p} = \mathfrak{n} \oplus \mathfrak{m}$ the Lie algebra of P_v, $\mathfrak{m}$ the block diagonal elements, $\theta(\mathfrak{n}) = \bar{\mathfrak{n}}$, and the three parts are pairwise orthogonal for $\langle \cdot, \cdot \rangle$ (disjoint supports of matrix entries). Further $\mathfrak{g} = \mathfrak{k} \oplus \mathfrak{s}$, $\mathfrak{k} = \{\theta X = X\}$ the Lie algebra of K_v, $\mathfrak{s} = \{\theta X = -X\}$, orthogonal, and $\mathfrak{m} = \mathfrak{k}_M \oplus \mathfrak{s}_M$ with $\mathfrak{k}_M = \mathfrak{m} \cap \mathfrak{k}$, $\mathfrak{s}_M = \mathfrak{m} \cap \mathfrak{s}$. Counting dimensions, $\dim \mathfrak{m} = 2\sum_i j_i^2 + (n-2J)^2$ and $\dim \mathfrak{n} = (n^2 - \dim \mathfrak{m})/2 = d(j)$.

(i): the compact groups. K_v commutes with σ, so it is $\mathrm{U}(V_v^+) \times \mathrm{U}(V_v^-)$ for the ± 1 eigenspaces of σ, of dimensions p, q, and its Lie algebra carries the Frobenius metric on each factor: in the metric of $\langle \cdot, \cdot \rangle$ it has volume $\mathrm{vol}\,\mathrm{U}(p)\,\mathrm{vol}\,\mathrm{U}(q)$. An element $k \in K_v \cap P_v$ preserves $W_{i-1} \subseteq W_i$ and is h_v^+-unitary, so it preserves E_i, hence $\sigma(E_i) = F_i$, hence U; so $K_M := K_v \cap P_v$ consists of the block diagonal elements $(k_1, \dots, k_a, k_0, k_a', \dots, k_1')$ with $k_i \in \mathrm{U}(j_i)$, $k_i' = (k_i^*)^{-1} = k_i$ in the f-basis, and $k_0 \in \mathrm{U}(p-J) \times \mathrm{U}(q-J)$. The element $X \in \mathfrak{u}(j_i)$ occurs twice, so its norm is $\sqrt{2}$ times its Frobenius norm; hence in the metric of $\langle \cdot, \cdot \rangle$, $\mathrm{vol}(K_M) = \mathrm{vol}\,\mathrm{U}(p-J)\,\mathrm{vol}\,\mathrm{U}(q-J) \prod_i 2^{j_i^2/2} \mathrm{vol}\,\mathrm{U}(j_i)$.

(i): the constant. $G_v = P_v K_v$ by the Iwasawa decomposition of the real reductive group G_v ([163], Chapter V): the stabiliser $P_{\min}$ of a maximal isotropic flag refining $W_\bullet$ is a minimal parabolic subgroup contained in P_v, the Iwasawa decomposition gives $G_v = K_v P_{\min}$ for the maximal compact subgroup K_v, and taking inverses $G_v = P_{\min} K_v \subseteq P_v K_v$. Give G_v the left-invariant Riemannian metric equal to $\langle \cdot, \cdot \rangle$ at 1; as $\mathrm{Ad}(K_v)$ preserves $\langle \cdot, \cdot \rangle$ it is also right K_v-invariant, and its volume measure is dg. Give G_v/K_v the G_v-invariant metric equal to $\langle \cdot, \cdot \rangle|_{\mathfrak{s}}$ at the base point. Then $G_v \to G_v/K_v$ is a Riemannian submersion whose fibres gK_v are isometric (by left translation) to K_v with its bi-invariant metric, and the coarea formula gives $(*)$'s first identity with dy the Riemannian measure of G_v/K_v times $\mathrm{vol}(K_v)$. In the same way ($\mathrm{Ad}(K_M)$ preserves $\mathfrak{p}$ and the inner product) dz is $\mathrm{vol}(K_M)$ times the Riemannian measure of P_v/K_M for the metric $\langle \cdot, \cdot \rangle|_{\mathfrak{p} \ominus \mathfrak{k}_M}$. Both Riemannian measures are P_v-invariant, so the ratio of ι^* of the first to the second is the constant $|\det d\iota|$ at the base point. There $d\iota$ is the restriction to $\mathfrak{p} \ominus \mathfrak{k}_M = \mathfrak{n} \oplus \mathfrak{s}_M$ of the orthogonal projection onto $\mathfrak{s}$: it is the identity on $\mathfrak{s}_M$, and $Y \in \mathfrak{n}$ goes to $(Y - \theta Y)/2$ (as $Y = \frac{1}{2}(Y + \theta Y) + \frac{1}{2}(Y - \theta Y)$ with the parts in $\mathfrak{k}$, $\mathfrak{s}$). For an orthonormal basis $Y_1, \dots, Y_d$ of $\mathfrak{n}$,

$$\left\langle \tfrac{Y_s - \theta Y_s}{2}, \tfrac{Y_t - \theta Y_t}{2} \right\rangle = \tfrac{1}{4}\big(\langle Y_s, Y_t \rangle + \langle \theta Y_s, \theta Y_t \rangle\big) = \tfrac{1}{2}\delta_{st},$$

since $\mathfrak{n} \perp \bar{\mathfrak{n}}$ and θ is an isometry, and these images are orthogonal to $\mathfrak{s}_M \subseteq \mathfrak{m}$. Hence $|\det d\iota| = 2^{-d(j)/2}$, and

$$\iota^* dy = \mathrm{vol}(K_v) \cdot 2^{-d(j)/2} \cdot \frac{dz}{\mathrm{vol}(K_M)},$$

so $c = 2^{-d(j)/2} \mathrm{vol}(K_v)/\mathrm{vol}(K_M) = c_{\mathrm{Iw}}$ by the two volumes above, and $(*)$ is the claim. □

Lemma 6.2.18. *Let W', W, V' and A be as above, $\mathfrak{c} = (\nu, \Sigma)$ a split tame character, b an index set with a bijection $\sigma' \colon b \sqcup r' \to n'$, $v \in \mathcal{F}_{W',V'}$, $y \in \mathrm{M}_{b \times n}(E_\Sigma)$, and Z_S the zero term along the splitting S of $\mathrm{Hom}(W', V')$ over $\mathrm{Hom}(W, V')$ induced by A. Then:*

1. *$Z_S(\varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)) = 0$;*
2. *for all automorphic characters a, b of $\mathrm{U}(1)$, $u \in \mathbb{A}_E^\times$, $g \in \mathrm{G}(s)$ and $h \in \mathrm{G}(t')$,*

$$\mathrm{ct}_A\Big(0;\ \omega_{a,b}\big(\mathrm{lev}_A(u,g), h\big)\varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)\Big) = 0.$$

Proof. The function $\Phi = \Phi^{\mathrm{st}}_{\sigma',y(\mathrm{pr}_i)_\Sigma}$ is locally constant with compact support (it vanishes unless the stacked matrix is integral, and is then a function of its reduction modulo the uniformisers), so the plane datum $f = v \otimes [\Phi]_\Sigma$ is defined by Lemma 6.2.22. For adelic vectors y' of V' and z of W' write $\langle y', z\rangle = y'z^*\varepsilon_{s'}$, and let k_A, l_A, i_A be the adelic frames of A.

Step 1: S is adapted. By (MX4), the rational frames of S have the columns $J_{V'}^{-1} e_m\, k^* J_{W'}$, $e_m\, l^* J_{W'}$ ($m \in r'$, k, l the rational frames of A), and its embedding sends M_0 to $M_0 J_W^{-1} i^* J_{W'}$. In adelic coordinates, using $x^{-1}J^{-1} = \varepsilon x^*$ and $J_{W'}x_{W'} = (x_{W'}^{-1})^*\varepsilon_{s'}$, they are $\langle \varepsilon_{t'} x_{V'}^* e_m, k_A\rangle$, $\langle x_{V'}^{-1} e_m, l_A\rangle$, and the embedding sends the adelic unit matrix $e_m e_j^{\mathsf{T}}$ of $\mathrm{Hom}(W, V')$ to $\varepsilon_s(j)\langle e_m, i_A e_j\rangle$. Let $m_S = (\varepsilon_{t'} x_{V'}^*)^{-1} \in \mathrm{GL}_{r'}(\mathbb{A}_E)$ (the index set $r' \times \{o\}$ of S read as r'). Then $k_{\mathbb{A}} m_S$ has the columns $\langle e_m, k_A\rangle$ and $l_{\mathbb{A}} m_S^{-*} = l_{\mathbb{A}} x_{V'} \varepsilon_{t'}$ the columns $\varepsilon_{t'}(m)\langle e_m, l_A\rangle$. As in (MX5), these columns and the $\langle e_m, i_A e_j\rangle$ are, up to signs, the vectorised products of the orthonormal (at ∞) and integral (at the finite places) columns e_m and the columns of $(l_A \mid k_A \mid i_A)$, A being base-adapted; so S is adapted at 1 in the basis m_S.

Step 2: the standard datum vanishes on the frame at $x = 0$. At the finite places $\langle y', z\rangle = y'z^*$, and with $d_K = (\mathrm{pr}_k)_\Sigma = (l_A^*)_\Sigma$, $d_L = (\mathrm{pr}_l)_\Sigma = (k_A^*)_\Sigma$, $d_I = (\mathrm{pr}_i)_\Sigma = (i_A^*)_\Sigma$, the frame $\mathcal{F}_\Sigma$ of S in the basis m_S sends $(0, z, Y)$ ($z \in E_\Sigma^{r'}$, $Y \in \mathrm{M}_{r'\times n}(E_\Sigma)$) to $z\, d_L + Y\, d_I$. The matrix of (XD10) for Φ at this point has rows $y\, d_I$ and $z\, d_L + Y\, d_I$; it equals, up to a permutation of rows, $\begin{pmatrix} 0 & y & 0 \\ 0 & Y & z \end{pmatrix} R$ with $R = (d_K; d_I; d_L)$, whose first column is zero. Its determinant is 0, not a unit, so $\Phi(\mathcal{F}_\Sigma(0, z, Y)) = 0$ for all z, Y.

Step 3: proof of (1). Apply Lemma 6.2.19 to S, the basis m_S, the point $x = 0$, Φ, $\Psi = 0$ and $f_i = 1$: its hypothesis holds by Step 2, and the slice at $m_S^{-*}(\alpha_0 \cdot 0) = 0$ is $Z_S(\rho(0)f) = Z_S(f)$. So $Z_S(f)$ is a multiple of $\mathrm{rsl}_{S,m_S}(0; v) \otimes [0]_\Sigma = 0$ ($\Psi \mapsto \Psi \otimes_\Sigma v^0$ is linear).

Step 4: proof of (2). Let $F = \omega_{a,b}(\mathrm{lev}_A(u, g), h)f$. By (MX2), $\gamma = \mathrm{lev}_A(u, g)$ satisfies $\gamma k_A = k_A u$ and $\mathrm{pr}_i \gamma i_A = g$, so (2) of Lemma 6.2.45 at $x = 0$ (characters $a\upsilon^{-1}$ and b) gives $Z_S(F) = b[\#r'](u)^{-1}|u|^{\#r'/2}\omega_{a\upsilon^{-1},b}(g, h)Z_S(f) = 0$ by (1). For $q \in \mathrm{M}_{n\times 1}(\mathbb{A}_E)$ the element $\eta = \mathrm{rad}_A^{\mathrm{ln}}(q, 0) = \mathrm{rad}_A(x_W^{-1}q, 0)$ satisfies $\eta k_A = k_A$ and $\mathrm{pr}_i \eta i_A = 1$ ((MX2): $\mathrm{pr}_l k_A = \mathrm{pr}_i k_A = 0$, $\mathrm{pr}_l i_A = 0$, $\mathrm{pr}_i i_A = 1$), so (2) of Lemma 6.2.45 at $x = 0$ with the characters υ^{-1} and 1 gives $Z_S(\omega_{1,1}(\eta, 1)F) = Z_S(F) = 0$. The theta term of (MX6) at $x = 0$ is $\theta_{\mathrm{Hom}(W,V')}((\omega_{1,1}(\eta, 1)F)[0]) = \theta_{\mathrm{Hom}(W,V')}(Z_S(\omega_{1,1}(\eta, 1)F)) = 0$, so the integrand of (MX10) vanishes and $\mathrm{ct}_A(0; F) = 0$. □

Lemma 6.2.19. *Let W', T', W, T be spaces with points with signs on n', r', n, r, and D a splitting of $\mathrm{Hom}(W', T')$ over $\mathrm{Hom}(W, T)$ along a nonempty index set p which is adapted at 1 in the basis $m \in \mathrm{GL}_p(\mathbb{A}_E)$. Let $\mathcal{F} = (l_{\mathbb{A}} m^{-*} \mid k_{\mathbb{A}} m \mid i_{\mathbb{A}})$ be its frame, with column blocks indexed by p, p and $r \times n$, and let Σ be a nonempty finite set of finite places of E containing the conjugate of none of its members. Let $\mathcal{F}_\Sigma$ be the matrix of the components at Σ of the finite part of $\mathcal{F}$, $\psi_\Sigma(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$ for $t \in E_\Sigma$ (read as a finite adele), dt the Haar probability measure on $\mathcal{O}_\Sigma$, and $\alpha_0 \in \mathbb{A}_E^\times$ the idele with components κ_v at $v \in \Phi$ and finite part α. Let $v \in \mathcal{F}_{W',T'}$, let $x \in \mathbb{A}_E^p$ have infinite part $x_\infty \in \mathbb{C}^{\Phi\times p}$ and finite part x_f, let Φ and Ψ be functions on the $r' \times n'$, resp. $r \times n$, matrices over E_Σ with $\Phi^\sharp, \Psi^\sharp \in \mathcal{T}_\Sigma$, and let $f_i \colon E_\Sigma \to \mathbb{C}$ ($i \in p$) be continuous on $\mathcal{O}_\Sigma$, such that*

$$\Phi(\mathcal{F}_\Sigma(x_{f,\Sigma}, z, Y)) = \prod_{i\in p} \mathbf{1}_{\mathcal{O}_\Sigma}(z_i)\, f_i(z_i) \cdot \Psi(Y) \qquad (z \in E_\Sigma^p,\ Y \in \mathrm{M}_{r\times n}(E_\Sigma)),$$

where $x_{f,\Sigma}$ is the vector of the components of x_f at Σ and the value of $\mathcal{F}_\Sigma$ is read as an $r' \times n'$

matrix. Then

$$(v\otimes[\Phi]_\Sigma)\big[m^{-*}(\alpha_0 x)\big] = c\,\mathrm{rsl}_{D,m}(x_\infty;v)\otimes[\Psi]_\Sigma,$$
$$c = \mathbf{1}\big[x_f \text{ integral outside } \Sigma\cup\bar\Sigma\big]\,\mathrm{vf}(D)\prod_{i\in p}\int_{\mathcal{O}_\Sigma}\psi_\Sigma\big((\bar x_{f,i})_\Sigma\, t\big)f_i(t)\,dt,$$

where $(\bar x_{f,i})_\Sigma$ is the vector of the components at Σ of the conjugate of the adele $x_{f,i}$.

Proof. Write $V=\mathrm{Hom}(W',T')$, $V_0=\mathrm{Hom}(W,T)$, Z for the zero term and $h[x']$ for the slices of D; $\mathcal{F}_f$ is the finite part of $\mathcal{F}$. Put $\psi_0(t)=\psi_{E,f}(\jmath\alpha\bar\alpha t)$ for finite adeles t (so $\psi_\Sigma=\psi_0$ on E_Σ). For a finite adelic vector u and a set S of places, u_S keeps the components at S and sets the others to 0; $u^*u'=\sum_j \bar u_j u'_j$ (a finite adele). Recall that $\Sigma\cap\bar\Sigma=\emptyset$.

Step 1: three facts on the finite frame and on ψ_0. (a) At the finite places $\varepsilon_s=1$, so $x^*_{V,f}J_V x_{V,f}=1$ and $(x^{-1}_{V,f}u)^*(x^{-1}_{V,f}u')=u^*J_V u'$; with the relations of (MX1) and $x^*_{V_0,f}J_{V_0}x_{V_0,f}=1$ this gives $\mathcal{F}_f^*\mathcal{F}_f=Q_0$, the matrix of the form $(a,b,w;a',b',w')\mapsto a^*b'+b^*a'+w^*w'$. Since D is adapted at 1 in the basis m, $\mathcal{F}_f$ has entries in $\widehat{\mathcal{O}}_E$, and so has $\mathcal{F}_f^{-1}=Q_0\mathcal{F}_f^*$. Hence, placewise, $u\mapsto\mathcal{F}_f u$ is a bijection of the vectors supported on a set S of finite places that preserves integrality at every place, and for $u=(a,b,w)$, $u'=(a',b',w')$,

$$(\mathcal{F}_f u)^*(\mathcal{F}_f u') = a^*b'+b^*a'+w^*w'. \tag{1}$$

(b) $\psi_0(t+\bar t)=1$ for every finite adele t: with $u=\jmath\alpha\bar\alpha t$ we have $\jmath\alpha\bar\alpha\bar t=-\bar u$ ($\bar\jmath=-\jmath$), and $\psi_{E,f}(\bar u)=\psi_{E,f}(u)$ because $\widehat{\mathcal{O}}_E$ is stable under conjugation and $\mathrm{Tr}_{E/\mathbb{Q}}(\bar a)=\mathrm{Tr}_{E/\mathbb{Q}}(a)$. (c) By Lemma 4.1.3, $\widehat{\mathcal{O}}_E^{\,p}$ is its own annihilator under $(u,u')\mapsto\psi_0(u^*u')$. Hence for a finite adelic vector c, $\int_{\mathcal{O}_\Sigma^p}\psi_0(c^*t)\,dt$ is 1 if c is integral at $\bar\Sigma$ and 0 otherwise: c^*t for t supported on Σ only involves $c_{\bar\Sigma}$, the character $t\mapsto\psi_0(c^*_{\bar\Sigma}t)$ is trivial on $\mathcal{O}_\Sigma^p$ exactly when it is trivial on $\widehat{\mathcal{O}}_E^{\,p}$ (the pairing with $c_{\bar\Sigma}$ only sees the components at Σ), that is when $c_{\bar\Sigma}$ is integral, and the integral of a nontrivial character over a compact group is 0.

Step 2: the real part. Since $\alpha_0 x=\mathrm{rv}(x_\infty)+\mathrm{fv}(x_f)$, the point $m^{-*}(\alpha_0 x)$ is $m^{-*}\mathrm{rv}(x_\infty)+y_f$ with $y_f=\alpha m^{-*}x_f$, whose infinite components are 0. Let $h=\Phi^\sharp\otimes_\Sigma v^0$. By (3) of Lemma 6.2.20 (applicable: $p\neq\emptyset$, D adapted at 1 in the basis m),

$$(v\otimes[\Phi]_\Sigma)\big[m^{-*}(\alpha_0x)\big]=\mathrm{rsl}_{D,m}(x_\infty;v)\otimes(v_1\otimes h)[y_f].$$

By (3) of Lemma 4.1.3, h is a finite combination of vectors $\rho(\mathrm{fv}(y))v^0$, and $v_1\otimes\rho(\mathrm{fv}(y))v^0=\rho(\mathrm{fv}(y))(v_1\otimes v^0)=\rho(\mathrm{fv}(y))v^0$ by (3), (4) of Lemma 6.2.21; so $v_1\otimes h=h$. It remains to show

$$h[y_f]=c\;\Psi^\sharp\otimes_\Sigma v^0, \tag{2}$$

because then the right side above is $c\,\mathrm{rsl}_{D,m}(x_\infty;v)\otimes(\Psi^\sharp\otimes_\Sigma v^0)=c\,\mathrm{rsl}_{D,m}(x_\infty;v)\otimes[\Psi]_\Sigma$.

Step 3: the slice of one finite translate of the vacuum. Let y be a finite adelic vector of V supported on $\Sigma\cup\bar\Sigma$ and $(a,b,w)=\mathcal{F}_f^{-1}y$, so $y=l_{\mathbb{A}}m^{-*}a+k_{\mathbb{A}}mb+i_{\mathbb{A}}w$ at the finite places and a,b,w are supported on $\Sigma\cup\bar\Sigma$. Then $\mathrm{fv}(y)=l_{\mathbb{A}}A+k_{\mathbb{A}}B+i_{\mathbb{A}}\mathrm{fv}(w)$ with $A=\alpha m^{-*}a$, $B=\alpha mb$. The mixed law ((1) of Lemma 6.2.44 for $\Pi=Z$) at $y_f=\alpha m^{-*}x_f$ gives, since $B^*(2y_f+A)=\alpha\bar\alpha\,b^*(2x_f+a)$ and $\psi_E=\psi_{E,f}$ on finite adeles,

$$(\rho(\mathrm{fv}(y))v^0)[y_f]=\psi_0\big(\tfrac12 b^*(2x_f+a)\big)\,\rho(\mathrm{fv}(w))\,v^0\big[\alpha m^{-*}(x_f+a)\big].$$

By Lemma 6.2.11 at $g=1$, $v^0[x']=C_1|e_p(m^*x')|^2v^0$, and $C_1=\mathrm{vf}(D)$ by (4) of Lemma 6.2.20 (take $x'=0$). At a finite adelic point $|e_p(\alpha u)|^2=\mathbf{1}[u\in\widehat{\mathcal{O}}_E^{\,p}]$ by (WD5). Hence

$$(\rho(\mathrm{fv}(y))v^0)[y_f]=\mathrm{vf}(D)\,\mathbf{1}\big[x_f+a\in\widehat{\mathcal{O}}_E^{\,p}\big]\,\psi_0\big(b^*x_f+\tfrac12 b^*a\big)\,\rho(\mathrm{fv}(w))v^0. \tag{3}$$

Step 4: the partial Fourier integral of one translate. For a function Θ on $r' \times n'$ matrices over E_Σ with $\Theta^\sharp \in \mathcal{T}_\Sigma$ (a smooth compactly supported function, (1) of Lemma 4.1.3) put

$$\Theta_{x_f}(Y) = \int_{E_\Sigma^p} \psi_0(x_f^* t)\, \Theta\big(\mathcal{F}_\Sigma(x_{f,\Sigma}, t, Y)\big)\, dt \qquad (Y \in \mathrm{M}_{r\times n}(E_\Sigma)),$$

dt the Haar measure of E_Σ^p giving $\mathcal{O}_\Sigma^p$ mass 1; $\Theta \mapsto \Theta_{x_f}$ is linear, and $\psi_0(x_f^* t) = \prod_i \psi_\Sigma((\bar{x}_{f,i})_\Sigma t_i)$. Let y, a, b, w be as in Step 3 and $\Theta^\sharp = \tau_y$, that is $\Theta(X) = \psi_0(\frac{1}{2} y^*(2X + y_\Sigma))\, \mathbf{1}[X + y_\Sigma \text{ integral}]$ for X supported on Σ. For $X = \mathcal{F}_\Sigma(x_{f,\Sigma}, t, Y)$ we have $X + y_\Sigma = \mathcal{F}_f((x_f + a)_\Sigma, t + b_\Sigma, Y + w_\Sigma)$, which by Step 1 (a) is integral exactly when its three coordinates are, and by (1)

$$y^*(2X + y_\Sigma) = a^*(2t + b_\Sigma) + b^*(2x_{f,\Sigma} + a_\Sigma) + w^*(2Y + w_\Sigma).$$

The terms in t of the integrand are $\psi_0((x_f + a)^* t)\, \mathbf{1}[t + b_\Sigma \in \mathcal{O}_\Sigma^p]$; substituting $t = t' - b_\Sigma$ and applying Step 1 (c) to $c = x_f + a$,

$$\Theta_{x_f}(Y) = \mathbf{1}\big[(x_f + a)_{\Sigma\cup\bar{\Sigma}} \text{ integral}\big]\, \psi_0(-x_f^* b_\Sigma - \tfrac{1}{2} a^* b_\Sigma + b^* x_{f,\Sigma} + \tfrac{1}{2} b^* a_\Sigma)\, \tau_w(Y),$$

where $\tau_w(Y) = \psi_0(w^* Y + \frac{1}{2} w^* w_\Sigma)\mathbf{1}[Y + w_\Sigma \text{ integral}]$ is the function τ_w of (WR6) for V_0, so that $(\Theta_{x_f})^\sharp \otimes_\Sigma v^0$ is the same scalar times $\tau_w \otimes_\Sigma v^0 = \rho(\mathrm{fv}(w)) P^\Sigma v^0 = \rho(\mathrm{fv}(w)) v^0$ ((1), (3) of Lemma 4.1.3).

Step 5: comparison. Since a is supported on $\Sigma \cup \bar{\Sigma}$,

$$\mathbf{1}[x_f + a \in \widehat{\mathcal{O}}_E^p] = \mathbf{1}[x_f \text{ integral outside } \Sigma \cup \bar{\Sigma}] \cdot \mathbf{1}[(x_f + a)_{\Sigma\cup\bar{\Sigma}} \text{ integral}].$$

The two phases, that of (3) and that of Step 4, differ by ψ_0 of

$$b^*(x_f - x_{f,\Sigma}) + x_f^* b_\Sigma + \tfrac{1}{2}(b^*(a - a_\Sigma) + a^* b_\Sigma) = (z + \bar{z}) + \tfrac{1}{2}(z' + \bar{z}'), \qquad z = x_{f,\bar{\Sigma}}^* b_\Sigma,\ z' = a_{\bar{\Sigma}}^* b_\Sigma,$$

because b is supported on $\Sigma \cup \bar{\Sigma}$ (so $b^*(x_f - x_{f,\Sigma}) = b_{\bar{\Sigma}}^* x_{f,\bar{\Sigma}} = \bar{z}$, and likewise for a), and by Step 1 (b) this is 1. Comparing (3) with Step 4,

$$(\tau_y \otimes_\Sigma v^0)[y_f] = (\rho(\mathrm{fv}(y)) v^0)[y_f] = \mathrm{vf}(D)\, \mathbf{1}[x_f \text{ integral outside } \Sigma\cup\bar{\Sigma}]\, (\Theta_{x_f})^\sharp \otimes_\Sigma v^0 \qquad (\Theta^\sharp = \tau_y),$$

the first equality by (WR6) with $P^\Sigma v^0 = v^0$ and the independence of the section ((1) of Lemma 4.1.3).

Step 6: proof of (2). Write $\Phi^\sharp = \sum_y c_y \tau_y$ (finitely many y supported on $\Sigma \cup \bar{\Sigma}$), so that $\Phi = \sum_y c_y \Theta_y$ with $\Theta_y^\sharp = \tau_y$. The zero term is linear and $\Theta \mapsto \Theta^\sharp \otimes_\Sigma v^0$ and $\Theta \mapsto \Theta_{x_f}$ are linear, so Step 5 gives $h[y_f] = \mathrm{vf}(D)\, \mathbf{1}[x_f \text{ integral outside } \Sigma \cup \bar{\Sigma}]\, (\Phi_{x_f})^\sharp \otimes_\Sigma v^0$. By the hypothesis on Φ, for $t \in E_\Sigma^p$ the integrand of $\Phi_{x_f}(Y)$ is $\prod_i \psi_\Sigma((\bar{x}_{f,i})_\Sigma t_i) \mathbf{1}_{\mathcal{O}_\Sigma}(t_i) f_i(t_i) \cdot \Psi(Y)$, so by Fubini $\Phi_{x_f} = \prod_i \int_{\mathcal{O}_\Sigma} \psi_\Sigma((\bar{x}_{f,i})_\Sigma t) f_i(t)\, dt \cdot \Psi$. This is (2). □

Lemma 6.2.20. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, $D = (k, l, i)$ a splitting of V over V_0 along p with zero term Z, and $m \in \mathrm{GL}_p(\mathbb{A}_E)$ such that D is adapted at 1 in the basis m. Let $f \in \mathcal{M}_s$.*

1. *For $x \in \mathbb{A}_E^p$ with components 0 at the finite places, $(v_1 \otimes f)[x] = |e_p(m^* x)|^2\, (v_1 \otimes f)[0]$, and $v_1 \otimes ((v_1 \otimes f)[0]) = (v_1 \otimes f)[0]$ (the outer datum formed in $\mathcal{M}_{s_0}$).*
2. *For $v \in \mathcal{F}_s$, $Z(v \otimes f) = Z_{D,m}^\infty(v) \otimes Z(v_1 \otimes f)$.*
3. *For $v \in \mathcal{F}_s$, $b \in \mathbb{C}^{\Phi\times p}$ and $y \in \mathbb{A}_E^p$ with components 0 at the infinite places, $(v \otimes f)[m^{-*}\mathrm{rv}(b) + y] = \mathrm{rsl}_{D,m}(b; v) \otimes (v_1 \otimes f)[y]$.*

4. $Z(v^0) = \mathrm{vf}(D)\, v^0$ *and* $\mathrm{vf}(D) \neq 0$.

Proof. **Step 1: the real adapted frame.** Let $G_\infty = (l_{\mathbb{A}} m^{-*}\ k_{\mathbb{A}} m\ i_{\mathbb{A}})_\infty$, block diagonal over Φ; by adaptedness at 1 each block is square with orthonormal columns, hence unitary. Write $y \in \mathbb{C}^{\Phi\times n}$ as $y = G_\infty(a; b; w)$ with $a, b \in \mathbb{C}^{\Phi\times p}$, $w \in \mathbb{C}^{\Phi\times n_0}$. Then $\mathrm{rv}(y) = l_{\mathbb{A}} m^{-*}\mathrm{rv}(a) + k_{\mathbb{A}} m\,\mathrm{rv}(b) + i_{\mathbb{A}}\mathrm{rv}(w)$ (κ_w is a scalar), ν is invariant under G_∞, and $v_1(y) = v_1(a)v_1(b)v_1(w)$. For real vectors, $\psi_E(\frac{1}{2}\jmath\,\mathrm{rv}(b)^*\mathrm{rv}(c)) = \exp((b^*c - c^*b)/2)$ (all signs +1).

Step 2: (1). Let x be as in (1) and $X \in \mathbb{C}^{\Phi\times p}$ with $m^*x = \mathrm{rv}(X)$. By Step 1 and the mixed law with $A = m^{-*}\mathrm{rv}(a)$, $B = m\,\mathrm{rv}(b)$, $W = \mathrm{rv}(w)$, for which $B^*(2x + A) = \mathrm{rv}(b)^*\mathrm{rv}(2X + a)$,

$$\begin{aligned}(v_1 \otimes f)[x] &= \int v_1(y)\,(\rho(\mathrm{rv}(y))f)[x]\,d\nu(y)\\ &= \iint v_1(a)v_1(b)\,e^{(b^*(2X+a)-(2X+a)^*b)/2}\,P_0\Big(f\big[m^{-*}\mathrm{rv}(X+a)\big]\Big)\,d\nu(a)\,d\nu(b),\end{aligned}$$

where $P_0 h = v_1 \otimes h = \int v_1(w)\rho(\mathrm{rv}(w))h\,d\nu(w)$ on $\mathcal{M}_{s_0}$; Fubini applies, the integrand being bounded by $v_1(y)\|Z\|\|f\|$. The Fourier transform of the Gaussian gives $\int v_1(b)e^{(b^*c-c^*b)/2}d\nu(b) = 2^N e^{-|c|^2/2}$, $N = \#\Phi\,\#p$, and $|a|^2 + |2X + a|^2 = 2|X|^2 + 2|X + a|^2$; substituting $a \mapsto a - X$,

$$(v_1 \otimes f)[x] = 2^N e^{-|X|^2} K, \qquad K = \int e^{-|a|^2} P_0(f[m^{-*}\mathrm{rv}(a)])\,d\nu(a).$$

At $x = 0$ this is $2^N K$. Since P_0 is bounded and $P_0P_0 = P_0$ ((5) of Lemma 6.2.21 for s_0), $P_0K = K$. As $e^{-|X|^2} = |e_p(m^*x)|^2$ for x with finite components 0 ((WD5), $2\pi\,\mathrm{Im}(\jmath_w)\kappa_w^2 = 1$), (1) follows.

Step 3: (2). Let $F = v_1 \otimes f$; then $v \otimes f = v \otimes F$. For $y \in \mathbb{C}^{\Phi\times n}$ put $A = \mathrm{pr}_l\mathrm{rv}(y)$, $W = \mathrm{pr}_i\mathrm{rv}(y) = \mathrm{rv}(w(y))$, $B = \mathrm{pr}_k\mathrm{rv}(y)$, with $a(y)$, $w(y)$, $\chi(y)$ as in (MX7); then $m^*A = \mathrm{rv}(a(y))$ and $\psi_E(\frac{1}{2}\jmath B^*A) = \chi(y)$. By the mixed law at $x = 0$ and (1),

$$Z(v \otimes F) = \int v(y)\,\chi(y)\,\rho(W)F[A]\,d\nu(y) = \int v(y)\,\chi(y)\,e^{-a(y)^*a(y)}\,\rho(\mathrm{rv}(w(y)))F[0]\,d\nu(y).$$

On the other side, $h \mapsto h \otimes F[0]$ is bounded on $L^1(\nu_{\Phi\times n_0})$, which contains $\mathcal{F}_{s_0}$ with the same norm, so it commutes with the Bochner integral defining $Z^\infty_{D,m}(v)$, and

$$\begin{aligned}Z^\infty_{D,m}(v) \otimes F[0] &= \int v(y)\chi(y)e^{-a(y)^*a(y)}\,(\rho^\infty(w(y))v_1) \otimes F[0]\,d\nu(y)\\ &= \int v(y)\chi(y)e^{-a(y)^*a(y)}\,\rho(\mathrm{rv}(w(y)))\,(v_1 \otimes F[0])\,d\nu(y),\end{aligned}$$

and $v_1 \otimes F[0] = F[0]$ by (1). Since $F[0] = Z(v_1 \otimes f)$, (2) follows.

Step 4: (3). The vectors $l_{\mathbb{A}} m^{-*}\mathrm{rv}(b) = \mathrm{rv}((l_{\mathbb{A}} m^{-*})_\infty b)$ and $l_{\mathbb{A}} y$ have disjoint supports, so $\rho(l_{\mathbb{A}}(m^{-*}\mathrm{rv}(b) + y)) = \rho(\mathrm{rv}((l_{\mathbb{A}} m^{-*})_\infty b))\rho(l_{\mathbb{A}} y)$, and by the calculus of data

$$\rho\big(l_{\mathbb{A}}(m^{-*}\mathrm{rv}(b) + y)\big)(v \otimes f) = \big(\rho^\infty((l_{\mathbb{A}} m^{-*})_\infty b)v\big) \otimes \rho(l_{\mathbb{A}} y)f.$$

Applying Z and (2) to the Fock vector $\rho^\infty((l_{\mathbb{A}} m^{-*})_\infty b)v$ gives $\mathrm{rsl}_{D,m}(b; v) \otimes Z(v_1 \otimes \rho(l_{\mathbb{A}} y)f)$, and $v_1 \otimes \rho(l_{\mathbb{A}} y)f = \rho(l_{\mathbb{A}} y)(v_1 \otimes f)$, whose zero term is $(v_1 \otimes f)[y]$.

Step 5: (4). The splitting is adapted at $1 \in \mathrm{G}(s)$ in the basis m, so Lemma 6.2.11 gives $C \neq 0$ with $(v^0)[x] = C|e_p(m^*x)|^2 v^0$; at $x = 0$, $Z(v^0) = Cv^0$, and by (MX8) $\mathrm{vf}(D) = \langle v^0, Cv^0\rangle / \langle v^0, v^0\rangle = C$. □

Lemma 6.2.21. *Let s be signs on an index set n. For $w \in L^1(\nu)$ and $f \in \mathcal{M}_s$ put $w \otimes f = \int w(t)\,\rho(\mathrm{rv}(t))f\,d\nu(t)$.*

1. *This is a Bochner integral in $\mathcal{M}_s$, $\|w \otimes f\| \le \|w\|_{L^1(\nu)}\|f\|$, and for $w \in \mathcal{F}_\varepsilon$ it is the datum of (WR6).*
2. *For $t_0 \in \mathbb{C}^\iota$, $(\rho^\infty(t_0)w) \otimes f = \rho(\mathrm{rv}(t_0))(w \otimes f)$.*
3. *If $z \in \mathbb{A}_E^n$ has components 0 at the infinite places, then $\rho(\mathrm{rv}(t))\rho(z) = \rho(z)\rho(\mathrm{rv}(t)) = \rho(\mathrm{rv}(t)+z)$; consequently $w \otimes (Xf) = X(w \otimes f)$ for $X = \rho(z)$, for $X = \rho_f(y)$ ($y \in \mathbb{A}_{E,f}^n$) and for $X = P^A$.*
4. *$\int v_1(t)\,\beta_\varepsilon^\infty(t,u)\,v_1(u-t)\,d\nu(t) = v_1(u)$ for every $u \in \mathbb{C}^\iota$; so $v_1 \in \mathcal{F}_\varepsilon$. Moreover $v_1 \otimes v^0 = v^0$.*
5. *For $v \in \mathcal{F}_\varepsilon$ and $f \in \mathcal{M}_s$, $v \otimes (v_1 \otimes f) = v \otimes f$; in particular $v_1 \otimes (v_1 \otimes f) = v_1 \otimes f$.*

Proof. **Step 0: rules for ρ.** $\rho(z)\rho(z') = \beta_s(z,z')\rho(z+z')$, as β_s is additive in each variable and $\beta_s(z',z) = \beta_s(z,z')^{-1}$. If z has components only at the infinite and z' only at the finite places, $\beta_s(z,z') = \beta_s(z',z) = 1$. In normalized coordinates the archimedean factor of $\beta_s(\mathrm{rv}(t),\mathrm{rv}(t'))$ is $\prod_{(v,i)} \exp(s_i(\bar{t}'_{v,i}t_{v,i} - \bar{t}_{v,i}t'_{v,i})/2) = \beta_\varepsilon^\infty(t,t')$, because $\jmath_v\kappa_v^2 = i/(2\pi)$ and the archimedean factor of ψ_E is $\exp(-2\pi i\,2\,\mathrm{Re}(\cdot))$.

(1) The integrand is strongly measurable (strong continuity) with norm $|w(t)|\,\|f\|$; (WR6) is the same integral.

(2) Substitute $t = t' + t_0$ (ν is translation invariant). By additivity and $\beta_\varepsilon^\infty(t_0,t_0) = 1$, $\beta_\varepsilon^\infty(t_0,t'+t_0) = \beta_\varepsilon^\infty(t_0,t')$, and by Step 0, $\rho(\mathrm{rv}(t')+\mathrm{rv}(t_0)) = \beta_\varepsilon^\infty(t_0,t')^{-1}\rho(\mathrm{rv}(t_0))\rho(\mathrm{rv}(t'))$. So $(\rho^\infty(t_0)w) \otimes f = \int \beta_\varepsilon^\infty(t_0,t)w(t-t_0)\rho(\mathrm{rv}(t))f\,d\nu(t) = \rho(\mathrm{rv}(t_0))\int w(t')\rho(\mathrm{rv}(t'))f\,d\nu(t')$.

(3) The first part is Step 0. Hence $\rho(\mathrm{rv}(t))$ commutes with $\rho(z)$, with $\rho_f(y)$, a scalar multiple of $\rho(\mathrm{fv}(y))$ (WD8), and with P^A, a Bochner mean of such operators (WR6); a bounded operator commuting with every $\rho(\mathrm{rv}(t))$ commutes with $w \otimes \cdot$.

(4) The integrand is a product over the coordinates $c = (v,i)$. For a coordinate of sign $+1$, expanding $|u-t|^2$, the exponent of $e^{-|t|^2/2}\exp((\bar{u}t - \bar{t}u)/2)e^{-|u-t|^2/2}$ is $-|t|^2 + \bar{u}t - \frac{1}{2}|u|^2$, and the Gaussian integral $\pi^{-1}\int_{\mathbb{C}} \exp(-|t|^2 + at)\,dt = 1$ ($a \in \mathbb{C}$; entire in a, and 1 for $a = 0$ by rotation invariance, the integral of $\exp(-|t|^2)t^k$ vanishing for $k \ge 1$) gives $e^{-|u|^2/2}$. For sign -1 substitute $t \mapsto \bar{t}$. This is the reproducing identity of (WR5), and v_1 is integrable. For $v_1 \otimes v^0$: its value at x (normalized archimedean coordinates u) is $\int v_1(t)\beta_s(\mathrm{rv}(t),x)e_n(x-\mathrm{rv}(t))\,d\nu(t)$; by Step 0 and the product form of e_n (WD5) this is $e_f(x_f)\int v_1(t)\beta_\varepsilon^\infty(t,u)v_1(u-t)\,d\nu(t) = e_f(x_f)v_1(u) = e_n(x)$.

(5) By Fubini (all functions integrable, the operators isometric) and Step 0,

$$\begin{aligned} v \otimes (v_1 \otimes f) &= \iint v(t)v_1(t')\beta_\varepsilon^\infty(t,t')\rho(\mathrm{rv}(t+t'))f\,d\nu\,d\nu \\ &= \int \Big(\int v(t)\beta_\varepsilon^\infty(t,\tau)v_1(\tau-t)\,d\nu(t)\Big)\rho(\mathrm{rv}(\tau))f\,d\nu(\tau), \end{aligned}$$

substituting $t' = \tau - t$ and using $\beta_\varepsilon^\infty(t,\tau-t) = \beta_\varepsilon^\infty(t,\tau)$. The inner integral is $v(\tau)$ by the reproducing identity of $v \in \mathcal{F}_\varepsilon$ (WR5). By (4) this applies to $v = v_1$. □

Lemma 6.2.22. *Let A be a finite set of finite places of E containing the conjugate of none of its members, N a finite index set and $E_A = \prod_{w\in A} E_w$. For every locally constant, compactly supported $\Phi\colon E_A^N \to \mathbb{C}$, the function $x \mapsto \Phi(x_A)$ of finite adelic vectors $x \in \mathbb{A}_{E,f}^N$ lies in $\mathcal{T}_A$. In particular, for a split tame character (ν,Σ), spaces S, T and a locally constant, compactly supported function Φ on $n_T \times n_S$ matrices over E_Σ, $\Phi^\sharp \in \mathcal{T}_\Sigma$ and $\Phi^\flat \in \mathcal{T}_{\bar{\Sigma}}$, so the local datum $v \otimes [\Phi]_\Sigma$ and the conjugate local datum $v \otimes [\Phi]_{\bar{\Sigma}}$ are defined for every $v \in \mathcal{F}_{S,T}$.*

Proof. For $z \in E_A^N$ read as the finite adelic vector with components z_w at $w \in A$ and 0 elsewhere, and $\beta \in E_A^N$, put $e_\beta(z) = \psi_{E,f}(\beta^{\mathsf{T}} z)$. Let $\mathcal{O}_A = \prod_{w \in A} \mathcal{O}_{E,w}$.

Step 1: the functions τ_y. Let y be supported at $A \cup \bar{A}$, $y = a + b$ with a supported at A and b at $\bar{A}$. Then $(2x + y)_A = 2x_A + a$, and the components of $\bar{y}$ at A are $\bar{b}$ (complex conjugation carries the components at $\bar{A}$ to A), while those of $\bar{a}$ sit at $\bar{A}$ and meet the zero components of $(2x + y)_A$. Hence

$$\tau_y(x) = \psi_{E,f}\big(\tfrac{1}{2}\jmath\alpha\bar{\alpha}\,\bar{b}^{\mathsf{T}} a\big)\; e_\beta(x_A)\; \mathbf{1}\big[x_A + a \in \mathcal{O}_A^N\big], \qquad \beta = \jmath\alpha\bar{\alpha}\,\bar{b} \in E_A^N.$$

The components of $\jmath\alpha\bar{\alpha}$ at A are nonzero, so as b runs over the vectors supported at $\bar{A}$, β runs over all of E_A^N; the first factor is a nonzero constant. So $\mathcal{T}_A$ contains every function $x \mapsto e_\beta(x_A)\mathbf{1}_{c+\mathcal{O}_A^N}(x_A)$, $\beta, c \in E_A^N$.

Step 2: indicators of small cosets. Let $k \geq 0$ and $L_k = \prod_{w \in A} \varpi_w^k \mathcal{O}_{E,w}^N$, ϖ_w uniformisers. The local components of the nontrivial character $\psi_{E,f}$ of $\mathbb{A}_{E,f}/(\text{the image of } E)$ are nontrivial, so $\beta \mapsto e_\beta$ identifies E_A^N with its group of characters (self-duality of local fields, Tate's thesis), and every character of the compact open subgroup $\mathcal{O}_A^N$ extends to E_A^N (Pontryagin duality); hence every character χ of the finite group $\mathcal{O}_A^N / L_k$ is $z \mapsto e_\beta(z)$ on $\mathcal{O}_A^N$ for some $\beta = \beta_\chi$. By orthogonality of characters, for $c \in E_A^N$ and $z \in E_A^N$,

$$\mathbf{1}_{c+L_k}(z) = \mathbf{1}_{c+\mathcal{O}_A^N}(z)\,\mathbf{1}_{L_k}(z-c) = \frac{1}{[\mathcal{O}_A^N : L_k]} \sum_\chi e_{\beta_\chi}(-c)\, e_{\beta_\chi}(z)\, \mathbf{1}_{c+\mathcal{O}_A^N}(z),$$

so $x \mapsto \mathbf{1}_{c+L_k}(x_A)$ lies in $\mathcal{T}_A$ by Step 1.

Step 3: Schwartz-Bruhat functions. Φ is locally constant with compact support, so for some $k \geq 0$ it is constant on the cosets of the open subgroup L_k, and its support meets finitely many of them; thus $\Phi = \sum_c \Phi(c)\mathbf{1}_{c+L_k}$ (finite sum over representatives) and $x \mapsto \Phi(x_A)$ lies in $\mathcal{T}_A$ by Step 2.

Local data. With $N = n_T \times n_S$ and $A = \Sigma$ this gives $\Phi^\sharp \in \mathcal{T}_\Sigma$. Since $(\bar{y})_\Sigma$ is the complex conjugate of the matrix of components of y at $\bar{\Sigma}$, $\Phi^\flat(y) = \Phi'(y_{\bar{\Sigma}})$ with $\Phi'(z) = \Phi(\bar{z})$ locally constant with compact support on matrices over $E_{\bar{\Sigma}}$, and $\bar{\Sigma}$ contains the conjugate of none of its members; so $\Phi^\flat \in \mathcal{T}_{\bar{\Sigma}}$. □

Definition 6.2.23. Let $E = E_s$ be the field of a parameter pair P and an index $s \geq 0$, as in Definition 3.2.22.

(XA1) The functionals of the exchange data. From now on, for every space with a point V, the functional θ_V of (XD2) of Definition 3.2.22 is the canonical theta functional of V ((WC3) of Definition 4.1.15), which is a bounded linear functional on the theta model of the signs of V, as (XD2) requires. Theta kernels, theta integrals, target-bounded data, equal-rank ratios, the large and small sides, plane constant terms and the row-column exchange identity of Definition 3.2.22, and every object defined from them, are formed with these functionals; in particular the theta kernel $\theta_{\alpha,\beta}^{S,T}$ of (XD2) is the theta kernel of (WC4) of Definition 4.1.15.

Lemma 6.2.24. *Let W', W, V', V, A, X be as above. Let $Z^{\mathrm{pl}} \colon \mathcal{M}_{W',V'} \to \mathcal{M}_{s_{\mathbb{H}}}$ be the zero term along $D_{A,X}^{\mathrm{pl}}$, $s_{\mathbb{H}}$ the signs of $\mathbb{H}_{\{*\}} \oplus \mathrm{Hom}(W,V)$, and for $F \in \mathcal{M}_{s_{\mathbb{H}}}$ and $a \in \mathbb{A}_E$ let $F[a]_\pm \in \mathcal{M}_{W,V}$ be the slice of F at a along $R^\pm$. Then for every $f \in \mathcal{M}_{W',V'}$:*

1. $\mathrm{Ln}_{A,X}^+(a)f = (Z^{\mathrm{pl}}f)[a]_+$ *and* $\mathrm{Ln}_{A,X}^-(a)f = (Z^{\mathrm{pl}}f)[a]_-$ *for every $a \in \mathbb{A}_E$;*

2. *the series* $\sum_{\xi\in E}\theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^{+}_{A,X}(\xi)f)$ *and* $\sum_{\xi\in E}\theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^{-}_{A,X}(\xi)f)$ *converge absolutely, and both sums equal* $\theta_{\mathbb{H}_{\{*\}}\oplus\mathrm{Hom}(W,V)}(Z^{\mathrm{pl}}f)$.

Proof. For $y\in E^{r'}$ and $z\in E^{n'}$ write $[y,z]=y\,z^{*}J_{W'}\in\mathrm{Hom}(W',V')$, and for $z\in E^{n}$ write $[y,z]_{W}=y\,z^{*}J_{W}\in\mathrm{Hom}(W,V')$. By the computation in (LN3), the form of $\mathrm{Hom}(W',V')$ satisfies $h([y,z],[y',z'])=h_{V'}(y,y')\,h_{W'}(z',z)$. The point of $\mathrm{Hom}(W',V')$ reads a rational vector M as the adelic matrix $x_{V'}^{-1}Mx_{W'}$; since $x_{W'}^{*}J_{W'}x_{W'}=\varepsilon_{s'}$, the coordinates of A are $\mathrm{pr}_k=l_{A,\mathbb{A}}^{*}\varepsilon_{s'}=l_A^{*}J_{W'}x_{W'}$ and $\mathrm{pr}_l=k_A^{*}J_{W'}x_{W'}$. Hence

$$x_{V'}^{-1}[k_X,l_A]x_{W'}=k_{X,\mathbb{A}}\,\mathrm{pr}_k,\qquad x_{V'}^{-1}[l_X,k_A]x_{W'}=l_{X,\mathbb{A}}\,\mathrm{pr}_l. \tag{$*$}$$

Step 1: the frames. Reading the Kronecker products of (LN3), (LN1) and (MX4) column by column:

- $D^{\mathrm{pl}}_{A,X}$ has the frame k with columns $[k_X,i_Ae_j]$ $(j\in n)$, $[k_X,k_A]$, $[i_XJ_V^{-1}e_m,k_A]$ $(m\in r)$, and the embedding i^{pl} with columns $[k_X,l_A]$, $[l_X,k_A]$ (the two copies of $*$) and $[i_Xe_m,i_AJ_W^{-1}e_j]$ $((m,j)\in r\times n)$. The tautological R^{+} has l, k the first and second copy of $*$ and i the block of $\mathrm{Hom}(W,V)$; R^{-} exchanges l and k. By (MX5), $D^{\mathrm{pl}}\circ R^{\pm}$ has the embedding with columns $[i_Xe_m,i_AJ_W^{-1}e_j]$ and the frame k consisting of the columns of k of D^{pl} together with $[l_X,k_A]$ (for $+$), resp. $[k_X,l_A]$ (for $-$); and $i^{\mathrm{pl}}l^{R^{+}}=[k_X,l_A]$, $i^{\mathrm{pl}}l^{R^{-}}=[l_X,k_A]$.
- The splitting S of $\mathrm{Hom}(W',V')$ over $\mathrm{Hom}(W,V')$ induced by A ((MX4), $T=V'$) has k with columns $[J_{V'}^{-1}e_{m'},k_A]$ $(m'\in r')$ and embedding $M\mapsto MJ_W^{-1}i_A^{*}J_{W'}$, which sends $[y,z]_W$ to $[y,i_Az]$. The splitting S^{tg} of $\mathrm{Hom}(W,V')$ over $\mathrm{Hom}(W,V)$ induced on the target by X ((LN1), $T=W$) has k with columns $[k_X,e_j]_W$ and embedding with columns $[i_Xe_m,J_W^{-1}e_j]_W$. So $S\circ S^{\mathrm{tg}}$ has the frame k with columns $[J_{V'}^{-1}e_{m'},k_A]$, $[k_X,i_Ae_j]$ and the embedding with columns $[i_Xe_m,i_AJ_W^{-1}e_j]$.
- The splitting S' of $\mathrm{Hom}(W',V')$ over $\mathrm{Hom}(W',V)$ induced on the target by X $(T=W')$ has k with columns $[k_X,e_{j'}]$ $(j'\in n')$ and embedding $M\mapsto i_XM$, sending $[y,z]$ to $[i_Xy,z]$; the splitting S'^{sc} of $\mathrm{Hom}(W',V)$ over $\mathrm{Hom}(W,V)$ induced by A $(T=V)$ has k with columns $[J_V^{-1}e_m,k_A]$ and embedding with columns $[e_m,i_AJ_W^{-1}e_j]$. So $S'\circ S'^{\mathrm{sc}}$ has the frame k with columns $[k_X,e_{j'}]$, $[i_XJ_V^{-1}e_m,k_A]$ and the embedding with columns $[i_Xe_m,i_AJ_W^{-1}e_j]$.

Step 2: the zero terms agree. Let U^{+} be the span of the $[y,k_A]$ $(y\in E^{r'})$ and the $[k_X,z]$ with $z\in i_AE^{n}$, and U^{-} the span of the $[k_X,z]$ $(z\in E^{n'})$ and the $[i_Xy,k_A]$ $(y\in E^{r})$. By the product formula for h and $h_{W'}(k_A,k_A)=0$, $h_{W'}(i_Az,k_A)=0$, $h_{V'}(k_X,k_X)=0$, $h_{V'}(k_X,i_Xy)=0$, both are totally isotropic. Every column of the frames k of $D^{\mathrm{pl}}\circ R^{+}$ and of $S\circ S^{\mathrm{tg}}$ lies in U^{+}, and every column of those of $D^{\mathrm{pl}}\circ R^{-}$ and of $S'\circ S'^{\mathrm{sc}}$ lies in U^{-}; so in each pair $k^{*}Jk'=0$, and the embeddings agree by Step 1. By (2) of Lemma 6.2.25 and then (1) of Lemma 6.2.25,

$$Z_{D^{\mathrm{pl}}\circ R^{+}}=Z_{S\circ S^{\mathrm{tg}}}=Z_{S^{\mathrm{tg}}}\circ Z_S,\qquad Z_{D^{\mathrm{pl}}\circ R^{-}}=Z_{S'\circ S'^{\mathrm{sc}}}=Z_{S'^{\mathrm{sc}}}\circ Z_{S'},$$

and also $Z_{D^{\mathrm{pl}}\circ R^{\pm}}=Z_{R^{\pm}}\circ Z^{\mathrm{pl}}$.

Step 3: proof of (1). The adelic frames multiply as $i^{\mathrm{pl}}_{\mathbb{A}}l^{R^{\pm}}_{\mathbb{A}}=x^{-1}i^{\mathrm{pl}}l^{R^{\pm}}$, x the point of $\mathrm{Hom}(W',V')$, so by Step 1 and $(*)$, $i^{\mathrm{pl}}_{\mathbb{A}}l^{R^{+}}_{\mathbb{A}}a=a\,k_{X,\mathbb{A}}\mathrm{pr}_k$ and $i^{\mathrm{pl}}_{\mathbb{A}}l^{R^{-}}_{\mathbb{A}}a=a\,l_{X,\mathbb{A}}\mathrm{pr}_l$. By (1) of Lemma 6.2.44, $Z^{\mathrm{pl}}\rho(i^{\mathrm{pl}}_{\mathbb{A}}w)=\rho(w)Z^{\mathrm{pl}}$. Hence, with Step 2,

$$\begin{aligned}(Z^{\mathrm{pl}}f)[a]_{+}&=Z_{R^{+}}\big(\rho(l^{R^{+}}_{\mathbb{A}}a)Z^{\mathrm{pl}}f\big)=Z_{R^{+}}Z^{\mathrm{pl}}\big(\rho(a\,k_{X,\mathbb{A}}\mathrm{pr}_k)f\big)\\&=Z_{S^{\mathrm{tg}}}\Big(Z_S\big(\rho(a\,k_{X,\mathbb{A}}\mathrm{pr}_k)f\big)\Big)=Z^{\mathrm{tg}}_{X,W}\big(f[a\,k_{X,\mathbb{A}}]\big),\end{aligned}$$

the last step by the definition of the Hom slice in (MX4) for S; this is $\mathrm{Ln}^+_{A,X}(a)f$ by (LN2). In the same way $(Z^{\mathrm{pl}}f)[a]_- = Z_{S'^{\mathrm{sc}}}(Z_{S'}(\rho(a\,l_{X,\mathbb{A}}\mathrm{pr}_l)f)) = Z^{\mathrm{sc}}_{A,V}(Z^{\mathrm{tg}}_{X,W'}(\rho(a\,l_{X,\mathbb{A}}\mathrm{pr}_l)f)) = \mathrm{Ln}^-_{A,X}(a)f$.

Step 4: proof of (2). Apply (3) of Lemma 6.2.44 to $F = Z^{\mathrm{pl}}f$ and to the splittings R^+ and R^- of $\mathbb{H}_{\{*\}} \oplus \mathrm{Hom}(W,V)$ over $\mathrm{Hom}(W,V)$ along the nonempty set $\{*\}$: $\theta_{\mathbb{H}_{\{*\}}\oplus\mathrm{Hom}(W,V)}(F) = \sum_{\xi\in E}\theta_{\mathrm{Hom}(W,V)}(F[\xi]_\pm)$ for both signs, the series converging absolutely. By (1), $F[\xi]_\pm = \mathrm{Ln}^\pm_{A,X}(\xi)f$. □

Lemma 6.2.25. *Let V, V_0, V_1 be spaces with points.*

1. *Let D be a splitting of V over V_0 along p and D' a splitting of V_0 over V_1 along q, with zero terms Z_D, $Z_{D'}$. Then the zero term along the composite $D\circ D'$ is $Z_{D\circ D'} = Z_{D'}\circ Z_D$.*
2. *Let $D = (k,l,i)$ and $D' = (k',l',i')$ be splittings of V over V_0 along p and q with $i' = i$ and $k^*J_Vk' = 0$. Then $k' = kc$ for a matrix $c \in \mathrm{M}_{p\times q}(E)$ with a two-sided inverse, and $Z_{D'} = Z_D$.*

Proof. For $f \in \mathcal{M}_s$ write $f^\theta(x) = \theta_V(\rho(x)f)$. The function f^θ is continuous on $\mathbb{A}^n_E$: θ_V is bounded, and $z \mapsto \rho(z)f$ is continuous into $\mathcal{M}_s$, because $\|\rho(z)f - \rho(z')f\|_1 \le \int |\beta_s(z,x+z) - \beta_s(z',x+z)|\,|f(x)|\,d\mu_n(x) + \int |f(x-z)-f(x-z')|\,d\mu_n(x)$ (μ_n is a Haar measure of $\mathbb{A}^n_E$), the first term tends to 0 as $z' \to z$ by dominated convergence (β_s is continuous of modulus 1) and the second by continuity of translation in $L^1(\mu_n)$. By (7) of Lemma 4.1.1 the integrand of (MX4) is a function on the compact group $\mathbb{A}^p_E/E^p$, and the zero term is the unique vector with the property (MX4).

Proof of (1). Write $D = (k,l,i)$, $D' = (k',l',i')$. By (MX5) the composite has frames $(k \mid ik')$ and embedding ii', so its adelic frames are $(k_\mathbb{A} \mid x_V^{-1}ik') = (k_\mathbb{A} \mid i_\mathbb{A}k'_\mathbb{A})$ and $x_V^{-1}ii'x_{V_1} = i_\mathbb{A}i'_\mathbb{A}$, using $x_V^{-1}ik' = (x_V^{-1}ix_{V_0})(x_{V_0}^{-1}k')$. Let $f \in \mathcal{M}_s$ and $y \in \mathbb{A}^{n_1}_E$. The function

$$F(b,b') = f^\theta(i_\mathbb{A}i'_\mathbb{A}y + i_\mathbb{A}k'_\mathbb{A}b' + k_\mathbb{A}b) \qquad (b \in \mathbb{A}^p_E,\ b' \in \mathbb{A}^q_E)$$

is the integrand of (MX4) for $D\circ D'$ at y, hence continuous and a function on $\mathbb{A}^p_E/E^p \times \mathbb{A}^q_E/E^q$, whose invariant probability measure is the product of those of the factors. By (MX4) for D at the point $i'_\mathbb{A}y + k'_\mathbb{A}b'$ and then for D' at y,

$$\theta_{V_1}(\rho(y)Z_{D'}(Z_Df)) = \int_{\mathbb{A}^q_E/E^q}\theta_{V_0}(\rho(i'_\mathbb{A}y + k'_\mathbb{A}b')Z_Df)\,db' = \int_{\mathbb{A}^q_E/E^q}\int_{\mathbb{A}^p_E/E^p} F(b,b')\,db\,db',$$

which by Fubini (a continuous function on a compact group) is $\int F$ over the product, the right side of (MX4) for $D\circ D'$ at y. So $Z_{D'}(Z_Df)$ has the defining property of the zero term of f along $D\circ D'$, and equals it by uniqueness.

Proof of (2). By (MX1), $l^*J_Vk = 1$, $k^*J_Vk = 0$, $i^*J_Vk = i^*J_Vl = 0$, $i^*J_Vi = J_{V_0}$ and $E^n = lE^p \oplus kE^p \oplus iE^{n_0}$. Write $k' = la + kc + iw$ with $a \in \mathrm{M}_{p\times q}(E)$, $c \in \mathrm{M}_{p\times q}(E)$, $w \in \mathrm{M}_{n_0\times q}(E)$. Then $0 = k^*J_Vk' = (l^*J_Vk)^*a = a$ and $0 = i'^*J_Vk' = i^*J_Vk' = J_{V_0}w$, so $a = 0$, $w = 0$ and $k' = kc$. As $k'^*J_Vk = (k^*J_Vk')^* = 0$ and $i = i'$, the same argument gives $k = k'c'$ with $c' \in \mathrm{M}_{q\times p}(E)$. Then $k = kcc'$ and $k' = k'c'c$; since $l^*J_Vk = 1$ and $l'^*J_Vk' = 1$, the columns of k and of k' are linearly independent, so $cc' = 1$ and $c'c = 1$. Hence $k'_\mathbb{A} = x_V^{-1}kc = k_\mathbb{A}c$ and $i'_\mathbb{A} = i_\mathbb{A}$. The map $b \mapsto cb$ is an isomorphism of topological groups $\mathbb{A}^q_E \to \mathbb{A}^p_E$ carrying E^q onto E^p; it induces an isomorphism of the compact quotients, which carries the invariant probability measure to the invariant probability measure (uniqueness of Haar measure). Therefore, for $f \in \mathcal{M}_s$ and $y \in \mathbb{A}^{n_0}_E$,

$$\int_{\mathbb{A}^q_E/E^q} f^\theta(i'_\mathbb{A}y + k'_\mathbb{A}b)\,db = \int_{\mathbb{A}^q_E/E^q} f^\theta(i_\mathbb{A}y + k_\mathbb{A}cb)\,db = \int_{\mathbb{A}^p_E/E^p} f^\theta(i_\mathbb{A}y + k_\mathbb{A}b'')\,db''.$$

So $Z_D(f)$ has the defining property of the zero term of f along D', and $Z_{D'}(f) = Z_D(f)$ by uniqueness. □

Lemma 6.2.26. *Let S, T be spaces with index sets n_S, n_T, let A be a nonempty finite set of finite places of E containing the conjugate of none of its members, $E_A = \prod_{w\in A} E_w$, let v be a Schwartz vector for (S,T), and let φ be a locally constant, compactly supported function on $\mathrm{M}_{n_T\times n_S}(E_A)$ vanishing at every matrix without a right inverse. Put $\varphi^\sharp(y) = \varphi(y_A)$ for finite adelic $n_T \times n_S$ matrices y (an element of $\mathcal{T}_A$ by Lemma 6.2.22). Then the datum $v \otimes (\varphi^\sharp \otimes_A v^0) \in \mathcal{M}_{S,T}$ is target-bounded.*

Proof. By Lemma 6.2.22, $\varphi^\sharp \in \mathcal{T}_A$. A matrix over $E_A = \prod_{w\in A} E_w$ has a right inverse if and only if each of its components x_w ($w \in A$) has one. Fix $w \in A$ (A is nonempty). If $\varphi^\sharp(\eta) = \varphi(\eta_A) \neq 0$ for a finite adelic $n_T \times n_S$ matrix η, then η_A has a right inverse, hence so has η_w. So (1) of Lemma 6.2.27 applies to S, T, A, $\Psi = \varphi^\sharp$ and w; with $N = 0$ it gives $B, M \in \mathbb{N}$ and $C \geq 0$ such that

$$|\theta^{S,T}_{\alpha,\beta}(v \otimes (\varphi^\sharp \otimes_A v^0))(g,h)| \leq C \,\mathrm{mom}_M(v)\,\mathrm{ht}_S(g)^B$$

for all automorphic characters α, β of $\mathrm{U}(1)$ and all $g \in \mathrm{U}(S)(\mathbb{A}_F)$, $h \in \mathrm{U}(T)(\mathbb{A}_F)$. As v is a Schwartz vector, $\mathrm{mom}_M(v) < \infty$, and the datum is target-bounded with the exponent B and the constant $C\,\mathrm{mom}_M(v)$. □

Lemma 6.2.27. *Let S, T be spaces with points with signs s on n and s' on n', A a finite set of finite places of E containing the conjugate of none of its members, $\Psi \in \mathcal{T}_A$ a function of finite adelic $n' \times n$ matrices, and $w \in A$. Write $\Theta(v)(g,h) = \theta^{S,T}_{\alpha,\beta}(v \otimes (\Psi \otimes_A v^0))(g,h)$.*

1. *If η_w has a right inverse in $\mathrm{M}_{n\times n'}(E_w)$ for every η with $\Psi(\eta) \neq 0$, then for every $N \in \mathbb{N}$ there are $B, M \in \mathbb{N}$ and $C \geq 0$ such that*

   $$|\Theta(v)(g,h)|\,\mathrm{ht}_T(h)^N \leq C\,\mathrm{mom}_M(v)\,\mathrm{ht}_S(g)^B$$

   for all automorphic characters α, β of $\mathrm{U}(1)$, all $v \in \mathcal{F}_{S,T}$ with $\mathrm{mom}_M(v) < \infty$, and all $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$.

2. *If η_w has a left inverse in $\mathrm{M}_{n\times n'}(E_w)$ for every η with $\Psi(\eta) \neq 0$, then for every N there are B, M, C with $|\Theta(v)(g,h)|\,\mathrm{ht}_S(g)^N \leq C\,\mathrm{mom}_M(v)\,\mathrm{ht}_T(h)^B$ for the same α, β, v, g, h.*

Proof. Let $\Theta_0 = \theta_{\mathrm{Hom}(S,T)}$ and $f_0 = \Psi \otimes_A v^0$. Since $|\alpha(\det h)\beta(\det g)^{-1}| = 1$, $|\Theta(v)(g,h)| = |\Theta_0(\omega_{1,1}(g,h)(v \otimes f_0))|$, so we work with $\alpha = \beta = 1$ and the functional $\ell = \Theta_0$; the constants below do not depend on α, β.

Inputs. (a) By Lemma 6.2.28 there are $Y_0 \geq 0$, $A_0 \in \mathbb{N}$ with

$$|\Theta_0(\omega_{1,1}(g,h)f)| \leq Y_0\|f\|(\mathrm{ht}_S(g)\mathrm{ht}_T(h))^{A_0}$$

for all g, h, f. (b) By (VP3) of Definition 3.2.2 S and T are framed hermitian spaces and $\lambda_S(g) = \mathrm{ht}_S(g)^{-1}$, $\lambda_T(h) = \mathrm{ht}_T(h)^{-1}$ are the first minima of (VP4) for both readings; by (VP4) their lattices at g, resp. h, are those of S_g, T_h and their lengths are the euclidean norms of the real components; so by Lemma 5.8.21, for $c_S = f\,\#n\,|d_E|$ every g has $c \in \mathrm{GL}_n(E)$ whose columns lie in the lattice of S_g with lengths at most $c_S\mathrm{ht}_S(g)$; likewise $c_T = f\,\#n'\,|d_E|$ for T. (c) By Lemma 6.2.30, if $\mathrm{ht}_T(h) > 2$ there is a nonzero $d \in E^{n'}$ in the lattice of T_h with $d^* J_T d = 0$ and length at most $2/\mathrm{ht}_T(h)$; likewise for S. (d) By Lemma 4.1.17, Θ_0 is invariant under $\rho(\gamma)$ for every rational vector $\gamma = x_T^{-1} X x_S$ ($X \in \mathrm{M}_{n'\times n}(E)$) of $\mathrm{Hom}(S,T)$; in particular under $\rho(z)$, $z \in Z_{d,c}(E)$, for all d, c (notation of Lemma 6.2.31).

(1). Let g, h with $H = \mathrm{ht}_T(h) > 2$, c as in (b) for g and d as in (c) for h (p a one-element set, $q = n$). We check that (d, c) is a short pair for (g, h, Θ_0, x, y) with $x = 2/H$, $y = c_S \mathrm{ht}_S(g)$. Conditions (i) and (ii) hold by (b), (c); (iii) by (d). For (iv), first alternative, let $\Psi(\eta) \neq 0$, $d' = (x_T h)^{-1} d$, $c' = (x_S g)^{-1} c$. The component of d'^*_f at w is the row $a = \overline{d'_{\bar{w}}}^{\mathsf{T}}$, which is nonzero because $d \neq 0$ and $((x_T h)^{-1})_{\bar{w}}$ is invertible; if R is a right inverse of η_w, then $a\eta_w \neq 0$ (else $a = a\eta_w R = 0$); and c'_w is invertible since c is. Hence $(d'^*_f \eta c'_f)_w = a\eta_w c'_w \neq 0$. Moreover $xy = 2c_S \mathrm{ht}_S(g)/H$. Now apply (2) of Lemma 6.2.31 with $\ell = \Theta_0$, N, Y_0, A_0, $Z_0 = c_S$, $r = \mathrm{ht}_S(g) \geq 1$ and $H = \mathrm{ht}_T(h) > 0$: its growth hypothesis is (a), and for $H > 2$ the short pair just built has $xy \leq 2Z_0 r/H$. It gives C', independent of v, g, h, with

$$|\Theta(v)(g,h)| \, \mathrm{ht}_T(h)^N \leq C' \, \mathrm{mom}_{N+A_0}(v) \, \mathrm{ht}_S(g)^{N+2A_0},$$

which is (1) with $M = N + A_0$, $B = N + 2A_0$, $C = C'$.

(2). Exchange the roles: for $H = \mathrm{ht}_S(g) > 2$ take $c \in E^n$ as in (c) for S at g (q a one-element set, $c^* J_S c = 0$, length at most $2/H$) and $d \in \mathrm{GL}_{n'}(E)$ as in (b) for T at h ($p = n'$, lengths at most $c_T \mathrm{ht}_T(h)$). Condition (iv): the component a of d'^*_f at w is the invertible matrix $\overline{d'_{\bar{w}}}^{\mathsf{T}}$, $c'_w \neq 0$ since $c \neq 0$, and $\eta_w c'_w \neq 0$ because η_w has a left inverse; so $a\eta_w c'_w \neq 0$. Then (2) of Lemma 6.2.31 with $Z_0 = c_T$, $r = \mathrm{ht}_T(h)$, $H = \mathrm{ht}_S(g)$ (and (a), which is symmetric in the two heights) gives (2) with the same M, B. □

Lemma 6.2.28. *Let S, T be spaces with points with signs s on n and s' on n'. There are $Y \geq 0$ and $A \in \mathbb{N}$ such that:*

1. *for all automorphic characters α, β of $\mathrm{U}(1)$, all $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$ and $\varphi \in \mathcal{M}_{S,T}$,*

$$|\theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)| \leq Y \, \|\varphi\| \, (\mathrm{ht}_S(g) \, \mathrm{ht}_T(h))^A;$$

2. *for every $g \in \mathrm{G}(s)$ there is $\gamma \in \Gamma_S$ such that $\|\omega_{\alpha,\beta}(\gamma g, 1)\varphi\| \leq Y \, \mathrm{ht}_S(g)^A \, \|\varphi\|$ for all automorphic characters α, β of $\mathrm{U}(1)$ and all $\varphi \in \mathcal{M}_{S,T}$.*

Proof. **Reduction to $\alpha = \beta = 1$.** By (WC4) and (WR4),

$$\theta^{S,T}_{\alpha,\beta}(\varphi)(g,h) = \alpha(\det h)\beta(\det g)^{-1} \theta^{S,T}_{1,1}(\varphi)(g,h),$$

and automorphic characters of $\mathrm{U}(1)$ take values of modulus 1. So it suffices to treat $\omega = \omega_{1,1}$. By (2) of Lemma 4.1.1, ω is a representation of $\mathrm{G}(s) \times \mathrm{G}(s')$ by bounded operators of $\mathcal{M}_{S,T}$ and $(k, \varphi) \mapsto \omega(k)\varphi$ is continuous (the pair map of (VP5) of Definition 3.2.2 is a continuous homomorphism).

Operators on a compact set. Let $\Omega_S \subseteq \mathrm{G}(s)$ and $\Omega_T \subseteq \mathrm{G}(s')$ be the compact sets of Lemma 6.2.29 for S and T. The set $B_S = \{(x, 1) : x \in G_\infty(s), \ \|x_v\| \leq 2 \ (v \in \Phi)\}$ is compact: $\mathrm{U}(\mathrm{diag}\, s)$ is closed in $\mathrm{M}_n(\mathbb{C})$, and on it $\|x^{-1}\| = \|\mathrm{diag}(s) x^* \mathrm{diag}(s)\| = \|x\|$, so $\{x \in \mathrm{U}(\mathrm{diag}\, s) : \|x\| \leq 2\}$ is a compact subset of $\mathrm{GL}_n(\mathbb{C})$. Likewise B_T. Let $K = (\Omega_S \cup B_S \cup \{1\}) \times (\Omega_T \cup B_T \cup \{1\})$, a compact set. For each φ the map $k \mapsto \omega(k)\varphi$ is continuous, hence bounded on K; since $\mathcal{M}_{S,T}$ is a Banach space ((1) of Lemma 4.1.10), the uniform boundedness principle gives $C_0 = \max(1, \sup_{k \in K} \|\omega(k)\|) < \infty$. Choose $A \in \mathbb{N}$ with $2^A \geq C_0$.

The bound. Let $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$. By Lemma 6.2.29, $g = \gamma z (x_1 \cdots x_k, 1)$ and $h = \delta z' (y_1 \cdots y_l, 1)$ with $\gamma \in \Gamma_S$, $\delta \in \Gamma_T$, $z \in \Omega_S$, $z' \in \Omega_T$, all $(x_i, 1) \in B_S$, $(y_j, 1) \in B_T$, $2^k \leq$

$\mathrm{ht}_S(g)$ and $2^l \le \mathrm{ht}_T(h)$. By Lemma 6.2.5, $\Theta(\omega(g,h)\varphi) = \Theta(\omega(\gamma^{-1}g, \delta^{-1}h)\varphi)$, and since ω is a representation of the product group,

$$\omega(\gamma^{-1}g, \delta^{-1}h) = \omega(z,1) \prod_{i=1}^{k} \omega((x_i,1),1) \cdot \omega(1,z') \prod_{j=1}^{l} \omega(1,(y_j,1)),$$

a product of $k+l+2$ operators $\omega(\kappa)$ with $\kappa \in K$. Hence

$$|\Theta(\omega(g,h)\varphi)| \le \|\Theta\|\, 2^{A(k+l+2)}\, \|\varphi\| \le 4^A \|\Theta\| \left(\mathrm{ht}_S(g)\, \mathrm{ht}_T(h)\right)^A \|\varphi\|,$$

so (1) holds with $Y = 4^A \max(1, \|\Theta\|)$. For (2), the same decomposition of g gives $\omega(\gamma^{-1}g, 1) = \omega(z,1) \prod_{i=1}^{k} \omega((x_i,1),1)$, a product of $k+1$ operators $\omega(\kappa)$ with $\kappa \in K$, so $\|\omega(\gamma^{-1}g,1)\varphi\| \le 2^{A(k+1)}\|\varphi\| \le 2^A \mathrm{ht}_S(g)^A \|\varphi\| \le Y\, \mathrm{ht}_S(g)^A \|\varphi\|$; the element $\gamma^{-1} \in \Gamma_S$ works for all α, β, since $\omega_{\alpha,\beta}(\gamma^{-1}g, 1)$ is $\beta(\det(\gamma^{-1}g))^{-1}$, of modulus 1, times $\omega(\gamma^{-1}g,1)$ (WR4). □

Lemma 6.2.29. *Let V be a space with a point with signs s on n.*

1. *There is a compact set $\Omega \subseteq \mathrm{G}(s)$ such that every $g \in \mathrm{G}(s)$ can be written*

$$g = \gamma\, z\, (x_1 x_2 \cdots x_k, 1) \qquad (\gamma \in \Gamma_V,\ z \in \Omega,\ k \in \mathbb{N},\ x_1, \ldots, x_k \in G_\infty(s))$$

   with $\|x_{i,v}\| \le 2$ for all i and all $v \in \Phi$, and $2^k \le \mathrm{ht}_V(g)$.

2. *By (VP3) of Definition 3.2.2, V is the framed hermitian space (E^n, h_V) with signs s on n, its frame at $v \in \Phi$ being the columns of $x_{V,v}$ and its isometry $z \mapsto x_{V,f} z$ (for $n \ne \emptyset$, a framed space of rank $\#n$ in the sense of (FT1) of Definition 3.2.4); its coordinate map is $c_V(u) = x_V^{-1} u$ and its rational points are Γ_V; and by (VP4) of Definition 3.2.2, for $g \in \mathrm{G}(s)$, $L_g(V)$ is the lattice of V_g, $|u|_g = \|((x_V g)^{-1}u)_\infty\|$, and the first minimum $\lambda_V(g) = \mathrm{ht}_V(g)^{-1}$ is the same for both readings.*

Proof. Write $D = \mathrm{diag}(s)$ and, for $g \in \mathrm{G}(s)$ and u in the lattice $L(g)$ of V_g, $w_g(u) = ((x_V g)^{-1}u)_\infty \in \mathbb{C}^{\Phi \times n}$, with components $w_g(u)_v \in \mathbb{C}^n$, and $N_g(u) = \|w_g(u)\|$; so $\lambda_V(g) = \min(1, \inf\{N_g(u) : 0 \ne u \in L(g)\})$.

Step 1: one halving step. We show: for every $g \in \mathrm{G}(s)$ there is $y \in G_\infty(s)$ with $\|y_v\| \le 2$ for all $v \in \Phi$ and $\mathrm{ht}_V(g(y,1)^{-1}) \le \max(\mathrm{ht}_V(g)/2,\, 2)$.

(a) The short vectors span isotropic subspaces. Let $u, u' \in L(g)$ with $N_g(u) < 1$, $N_g(u') < 1$, and $q = u'^* J_V u \in E$. Since $(x_V g)^* J_V (x_V g) = \varepsilon_s$, $q = w^* \varepsilon_s w'$ componentwise with $w = (x_V g)^{-1}u'$, $w' = (x_V g)^{-1}u$. At the finite places $\varepsilon_s = 1$ and w_f, w'_f are integral, so $q \in \mathcal{O}_E$. At $v \in \Phi$, by the Cauchy–Schwarz inequality, $|q_v| = |w_g(u')_v^* D w_g(u)_v| \le N_g(u') N_g(u) < 1$, and $|\bar{q}_v| = |q_v|$. Hence $|N_{E/\mathbb{Q}}(q)| < 1$ and $q = 0$. So for each $v \in \Phi$ the span $W_v \subseteq \mathbb{C}^n$ of the vectors $w_g(u)_v$, $u \in L(g)$, $N_g(u) < 1$, satisfies $a^* D b = 0$ for $a, b \in W_v$.

(b) A dilation of an isotropic subspace. Let $W \subseteq \mathbb{C}^n$ satisfy $a^* D b = 0$ for $a, b \in W$, and put $W' = DW$. For $a, b \in W$, $\langle a, Db\rangle = a^* D b = 0$ and $\langle Da, Db\rangle = a^* b$, $\langle \cdot, \cdot \rangle$ the standard inner product; so $W \perp W'$ and $W \cap W' = 0$. Let $R = (W + W')^\perp$. For $r \in R$ and $a \in W$, $\langle Dr, a\rangle = \langle r, Da\rangle = 0$ and $\langle Dr, Da\rangle = \langle r, a\rangle = 0$, so $DR = R$. Let y act by 2 on W, by $\frac{1}{2}$ on W' and by 1 on R. These three subspaces are mutually orthogonal, so y is self-adjoint with $\|y\| \le 2$ and $\|y^{-1}\| \le 2$. Moreover $Dy = y^{-1}D$: on $a \in W$ both sides give $2Da$; on $Da \in W'$ both give $\frac{1}{2}a$ (as $D^2 = 1$); on R both are D. Hence $y^* D y = y D y = y\, y^{-1} D = D$, i.e. $y \in \mathrm{U}(\mathrm{diag}\, s)$.

(c) Apply (b) to W_v at each $v \in \Phi$, obtaining $y = (y_v) \in G_\infty(s)$, and put $g' = g(y,1)^{-1}$. Then $(x_V g')^{-1} = (y,1)(x_V g)^{-1}$ has the same finite component as $(x_V g)^{-1}$, so $L(g') = L(g)$, and

$w_{g'}(u)_v = y_v w_g(u)_v$. For $0 \neq u \in L(g)$: if $N_g(u) < 1$, then $w_g(u)_v \in W_v$ for every v, so $N_{g'}(u) = 2N_g(u) \geq 2\lambda_V(g)$ (as $\lambda_V(g) \leq N_g(u)$); if $N_g(u) \geq 1$, then $N_g(u) \leq \max_v \|y_v^{-1}\| \, N_{g'}(u) \leq 2N_{g'}(u)$, so $N_{g'}(u) \geq \frac{1}{2}$. Therefore $\lambda_V(g') \geq \min(2\lambda_V(g), \frac{1}{2})$, which is the claimed bound for $\mathrm{ht}_V(g') = \lambda_V(g')^{-1}$.

Step 2: proof of (2), and bounded height. By (VP3) of Definition 3.2.2 V is a framed hermitian space and $\lambda_V(g)$ is the first minimum of (VP4) for both readings ($g \in \mathrm{G}(s)$); with the coordinate map c_V and the lattice $L_g(V)$ of V_g of (VP4), $|u|_g = N_g(u)$. This is (2). By Lemma 5.8.20 for this framed space with $T = 2$ there is a compact $\Omega \subseteq \mathrm{G}(s)$ such that every g with $\mathrm{ht}_V(g) \leq 2$ has some $\gamma_0 \in \Gamma_V$ with $\gamma_0 g \in \Omega$.

Step 3: proof of (1), by induction. We show by induction on $k \in \mathbb{N}$: every g with $\mathrm{ht}_V(g) \leq 2^{k+1}$ is $\gamma z(x_1 \cdots x_k, 1)$ with $\gamma \in \Gamma_V$, $z \in \Omega$ and $x_i \in G_\infty(s)$, $\|x_{i,v}\| \leq 2$. For $k = 0$, Step 2 gives $g = \gamma_0^{-1}(\gamma_0 g)$. If $\mathrm{ht}_V(g) \leq 2^{k+2}$, Step 1 gives y with $\mathrm{ht}_V(g(y,1)^{-1}) \leq \max(2^{k+1}, 2) = 2^{k+1}$; by the induction hypothesis $g(y,1)^{-1} = \gamma z(x_1 \cdots x_k, 1)$, so $g = \gamma z(x_1 \cdots x_k y, 1)$, with $x_{k+1} = y$. Finally, for any g choose $k \in \mathbb{N}$ with $2^k \leq \mathrm{ht}_V(g) < 2^{k+1}$ (possible as $1 \leq \mathrm{ht}_V(g) < \infty$) and apply the claim. □

Lemma 6.2.30. *Let S be a space with a point x_S and signs s on n, and $g \in \mathrm{G}(s)$ with $\mathrm{ht}_S(g) > 2$. Then there is a nonzero u in the lattice of S_g with $u^* J_S u = 0$ and $\|((x_S g)^{-1}u)_\infty\| \leq 2/\mathrm{ht}_S(g)$.*

Proof. Put $L = \{u \in E^n : ((x_S g)^{-1}u)_f \in \widehat{\mathcal{O}}_E^n\}$, the lattice of S_g, and $N(u) = \|((x_S g)^{-1}u)_\infty\|$. The map $u \mapsto ((x_S g)^{-1}u)_\infty$ embeds L as a discrete subgroup of $\mathbb{C}^{\Phi \times n}$ (L is a lattice of E^n and $(x_S g)_\infty$ is invertible), so only finitely many $u \in L$ have $N(u) \leq 1$. As $\lambda_S(g) = \mathrm{ht}_S(g)^{-1} < \frac{1}{2} < 1$, the infimum defining $\lambda_S(g)$ is a minimum over these finitely many nonzero u: there is $u \in L \setminus \{0\}$ with $N(u) = \lambda_S(g) \leq 2/\mathrm{ht}_S(g)$.

It remains to see that $q = u^* J_S u$ vanishes. It lies in F (J_S is hermitian). Put $w = (x_S g)^{-1}u$; since $(x_S g)^* J_S (x_S g) = \varepsilon_s$ ($x_S^* J_S x_S = \varepsilon_s$ and $g^* \varepsilon_s g = \varepsilon_s$), $q = w^* \varepsilon_s w$ componentwise. At a finite place $\varepsilon_s = 1$ and w_f is integral, so q is integral at every finite place: $q \in \mathcal{O}_F$. At a real place σ of F, below the place $v \in \Phi$ of E, $|\sigma(q)| = |\sum_i s_i |w_{i,v}|^2| \leq \|w_\infty\|^2 = N(u)^2 < \frac{1}{4}$. Hence $q \in \mathcal{O}_F$ has $|N_{F/\mathbb{Q}}(q)| < 1$, so $q = 0$. □

Lemma 6.2.31. *Let S, T be spaces with points with signs s on n and s' on n', α, β automorphic characters of $\mathrm{U}(1)$, A a finite set of finite places of E containing the conjugate of none of its members, $\Psi \in \mathcal{T}_A$ (a function of finite adelic $n' \times n$ matrices), $f_0 = \Psi \otimes_A v^0 \in \mathcal{M}_{S,T}$, and p, q finite index sets. For $d \in \mathrm{M}_{n' \times p}(E)$, $c \in \mathrm{M}_{n \times q}(E)$ and a ring $R \supseteq E$ put $Z_{d,c}(R) = \{x_T^{-1} \, dY \, c^* J_S \, x_S : Y \in \mathrm{M}_{p \times q}(R)\}$; $Z_{d,c}(\mathbb{A}_E)/Z_{d,c}(E)$ is a compact group with Haar probability measure dz. Call (d,c) a **short pair** for (g,h,ℓ,x,y), where $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$, ℓ is a bounded linear functional on $\mathcal{M}_{S,T}$ and $x, y \geq 0$, if:*

(i) the columns of d lie in the lattice of T_h and have lengths at most x, and the columns of c lie in the lattice of S_g and have lengths at most y;

(ii) $d^* J_T d = 0$ or $c^* J_S c = 0$;

(iii) $\ell(\rho(z)f) = \ell(f)$ for all $z \in Z_{d,c}(E)$ and $f \in \mathcal{M}_{S,T}$;

(iv) either, with $d' = (x_T h)^{-1} d$ and $c' = (x_S g)^{-1} c$, every finite adelic $n' \times n$ matrix η with $\Psi(\eta) \neq 0$ has some $w \in A$ with $(d_f'^* \, \eta \, c_f')_w \neq 0$; or $\int_{Z_{d,c}(\mathbb{A}_E)/Z_{d,c}(E)} \ell(\rho(z)f) \, dz = 0$ for every $f \in \mathcal{M}_{S,T}$.

Let $N \in \mathbb{N}$.

1. *There is $C \geq 0$ such that for all g, h, ℓ, x, y and every short pair (d, c) for them, and every $v \in \mathcal{F}_{S,T}$ with $\mathrm{mom}_N(v) < \infty$,*

$$\left|\ell(\omega_{\alpha,\beta}(g,h)(v \otimes f_0))\right| \leq C \,\|\ell \circ \omega_{\alpha,\beta}(g,h)\|\,(xy)^N \,\mathrm{mom}_N(v).$$

2. *Let $Y_0, Z_0 \geq 0$ and $A_0 \in \mathbb{N}$. There is $C' \geq 0$ with the following property. Let $v \in \mathcal{F}_{S,T}$ with $\mathrm{mom}_{N+A_0}(v) < \infty$, g, h, ℓ as above and $r \geq 1$, $H > 0$ such that $|\ell(\omega_{\alpha,\beta}(g,h)f)| \leq Y_0 \|f\|(rH)^{A_0}$ for all $f \in \mathcal{M}_{S,T}$ and, if $H > 2$, there is a short pair for (g, h, ℓ, x, y) with $xy \leq 2Z_0 r/H$. Then*

$$\left|\ell(\omega_{\alpha,\beta}(g,h)(v \otimes f_0))\right| H^N \leq C' \,\mathrm{mom}_{N+A_0}(v)\, r^{N+2A_0}.$$

Proof. Let $V = \mathrm{Hom}(S,T)$, signs $s' \otimes s$ on $n' \times n$, point x_V with $x_V^{-1} X = x_T^{-1} X x_S$.

Step 1: the rank-one maps. Let g, h, ℓ, x, y, d, c be as in (1), k the image of (g,h) under the pair map, d_i, c_j the columns, and $X_{ij} = d_i c_j^* J_S \in \mathrm{M}_{n' \times n}(E)$. Since $(x_S g)^* J_S (x_S g) = \varepsilon_s$, $c_j^* J_S x_S g = c_j'^* \varepsilon_s$, so the coordinates of X_{ij} at k are

$$(x_V k)^{-1} X_{ij} = (x_T h)^{-1} X_{ij} (x_S g) = d_i'\, c_j'^* \varepsilon_s.$$

Its finite part $d'_{i,f} c'^*_{j,f}$ is integral by (i), and

$$\sum_{v \in \Phi} \|d'_{i,v} c'^*_{j,v} \varepsilon_s\|^2 = \sum_v \|d'_{i,v}\|^2 \|c'_{j,v}\|^2 \leq \|d'_{i,\infty}\|^2 \|c'_{j,\infty}\|^2 \leq (xy)^2$$

(Frobenius norms). So the X_{ij} ($\#p \cdot \#q$ of them) lie in the lattice of V_k with lengths at most xy. They span $Z = \{dYc^* J_S : Y \in \mathrm{M}_{p\times q}(E)\}$, and for Y, Y' the form of V gives $\mathrm{tr}\big((dY'c^*J_S)^* J_T (dYc^*J_S) J_S^{-1}\big) = \mathrm{tr}\big(Y'^*(d^*J_T d) Y (c^* J_S c)\big) = 0$ by (ii); so Z is isotropic, $x_V^{-1} Z = Z_{d,c}(E)$ and the $\mathbb{A}_E$-span of $x_V^{-1} Z$ is $Z_{d,c}(\mathbb{A}_E)$. In the same way $k^{-1} Z_{d,c}(\mathbb{A}_E) = I$ with $I = \{d' Y c'^* \varepsilon_s : Y \in \mathrm{M}_{p\times q}(\mathbb{A}_E)\}$, an $\mathbb{A}_E$-submodule of $\mathbb{A}_E^{n'\times n}$.

Step 2: (1). Put $\chi = \alpha(\det h)\beta(\det g)^{-1}$ (modulus 1) and $\Lambda = \chi\ell$, so $\Lambda \circ \omega_{s'\otimes s}(k) = \ell \circ \omega_{\alpha,\beta}(g,h)$, and Λ is invariant under $\rho(x_V^{-1}u)$, $u \in Z$, by (iii). Let Λ_Z be its mean as in (1) of Lemma 6.2.32, and $F = \omega_{s'\otimes s}(k)(v \otimes f_0)$. By (2) of Lemma 6.2.32 (for V, A, Ψ, N, $r = \#p \cdot \#q$, $\delta = xy$; constant C),

$$|\Lambda(F) - \Lambda_Z(F)| \leq C \,\|\ell \circ \omega_{\alpha,\beta}(g,h)\|\,(xy)^N \,\mathrm{mom}_N(v),$$

and $|\ell(\omega_{\alpha,\beta}(g,h)(v \otimes f_0))| = |\Lambda(F)|$. It remains to show $\Lambda_Z(F) = 0$. In the second case of (iv), $\Lambda_Z = \chi \int \ell(\rho(z)\cdot)\,dz = 0$. In the first case let $\Lambda' = \Lambda_Z \circ \omega_{s'\otimes s}(k)$. For $z' \in I$, $kz' \in Z_{d,c}(\mathbb{A}_E)$ and $\omega(k)\rho(z') = \rho(kz')\omega(k)$ ((2) of Lemma 4.1.1), so $\Lambda'(\rho(z')f) = \Lambda_Z(\rho(kz')\omega(k)f) = \Lambda'(f)$ by (1) of Lemma 6.2.32. Let η satisfy $\Psi(\eta) \neq 0$ and $w \in A$ with $(d'^*_f \eta c'_f)_w \neq 0$; choose an entry (i,j) with $(d'^*_{i,f}\eta c'_{j,f})_w \neq 0$ and put $z = d'_i c'^*_j \varepsilon_s \in I$. Then $z_f^* \eta = \sum_{a,b} \overline{z_{f,ab}}\eta_{ab} = d'^*_{i,f}\eta c'_{j,f}$, whose component at w is not 0. So Lemma 6.2.35 (signs $s' \otimes s$ on $n' \times n$, the module I, the functional Λ') gives $\Lambda'(\Psi \otimes_A f) = 0$ for every f. Finally, by (3) of Lemma 6.2.21, $v \otimes f_0 = \sum_y c_y(\Psi)\, v \otimes \rho(\mathrm{fv}(y))P^A v^0 = \Psi \otimes_A (v \otimes v^0)$, so $\Lambda_Z(F) = \Lambda'(\Psi \otimes_A (v \otimes v^0)) = 0$.

Step 3: (2). Let C be the constant of (1) for $N + A_0$ in place of N, and $L = \ell \circ \omega_{\alpha,\beta}(g,h)$; then $\|L\| \leq Y_0(rH)^{A_0}$, and $\mathrm{mom}_0(v) = \|v\| \leq \mathrm{mom}_{N+A_0}(v)$. If $H > 2$, (1) applied to the short pair with $xy \leq 2Z_0 r/H$ gives

$$\begin{aligned} |L(v \otimes f_0)| H^N &\leq C\, Y_0 (rH)^{A_0} \Big(\frac{2Z_0 r}{H}\Big)^{N+A_0} H^N \mathrm{mom}_{N+A_0}(v) \\ &= C\, Y_0 (2Z_0)^{N+A_0} r^{N+2A_0}\, \mathrm{mom}_{N+A_0}(v). \end{aligned}$$

If $H \le 2$,

$$|L(v \otimes f_0)|H^N \le \|L\|\,\|f_0\|\,\|v\|\,2^N \le Y_0(2r)^{A_0}2^N\|f_0\|\,\mathrm{mom}_{N+A_0}(v)$$
$$\le 2^{N+A_0}Y_0\|f_0\|\,r^{N+2A_0}\mathrm{mom}_{N+A_0}(v),$$

as $r \ge 1$. So $C' = 2^{N+A_0}Y_0(C\,Z_0^{N+A_0} + \|f_0\|)$ works. □

Lemma 6.2.32. *Let V be a space with a point with signs s on n, $\varepsilon(v,i) = s_i$ on $\iota = \Phi \times n$, A a finite set of finite places of E containing the conjugate of none of its members, $\Psi \in \mathcal{T}_A$, $f_0 = \Psi \otimes_A v^0$, and $N, r \in \mathbb{N}$. For an E-subspace $Z \subseteq E^n$ with $u'^* J_V u = 0$ for all $u, u' \in Z$, let $Z(\mathbb{A}) \subseteq \mathbb{A}_E^n$ be the $\mathbb{A}_E$-span of $x_V^{-1}Z$, $Z(E) = x_V^{-1}Z$, and dz the Haar probability measure of the compact group $Z(\mathbb{A})/Z(E)$.*

1. *Let Z be such a subspace and Λ a bounded linear functional on $\mathcal{M}_s$ with $\Lambda(\rho(x_V^{-1}u)f) = \Lambda(f)$ for all $u \in Z$, $f \in \mathcal{M}_s$. Then for every f the function $z \mapsto \Lambda(\rho(z)f)$ on $Z(\mathbb{A})$ is continuous and $Z(E)$-periodic, $\Lambda_Z(f) = \int_{Z(\mathbb{A})/Z(E)} \Lambda(\rho(z)f)\,dz$ is a bounded linear functional, $\Lambda_Z(\rho(z)f) = \Lambda_Z(f)$ for $z \in Z(\mathbb{A})$, and $\|\Lambda_Z \circ \omega_s(g)\| \le \|\Lambda \circ \omega_s(g)\|$ for every $g \in \mathrm{G}(s)$.*

2. *There is $C \ge 0$ with the following property. Let $g \in \mathrm{G}(s)$, $\delta \ge 0$, and let $u_1, \dots, u_r$ be vectors of the lattice of V_g with $\|((x_V g)^{-1}u_i)_\infty\| \le \delta$ that span a subspace Z as above; let Λ and Λ_Z be as in (1). Then for every $v \in \mathcal{F}_\varepsilon$ with $\mathrm{mom}_N(v) < \infty$,*

$$\big|(\Lambda - \Lambda_Z)(\omega_s(g)(v \otimes f_0))\big| \le C\,\|\Lambda \circ \omega_s(g)\|\,\delta^N\,\mathrm{mom}_N(v).$$

Proof. **Step 1: the Heisenberg operators of $Z(\mathbb{A})$ commute.** Since $x_V^* J_V x_V = \varepsilon_s$, $(x_V^{-1})^* \varepsilon_s x_V^{-1} = J_V$. For $a = \sum_i c_i x_V^{-1}u_i$, $b = \sum_j c'_j x_V^{-1}u'_j$ ($c_i, c'_j \in \mathbb{A}_E$, $u_i, u'_j \in Z$), $\bar{b}^{\mathsf{T}}\varepsilon_s a = \sum_{i,j} \bar{c}'_j c_i\, u'^*_j J_V u_i = 0$, so $\beta_s(a,b) = 1$ (WD6) and $\rho(a)\rho(b) = \rho(a+b)$ on $Z(\mathbb{A})$. Also $Z(\mathbb{A})/Z(E)$ is compact: for a basis $u_1, \dots, u_m$ of Z, $(c_i) \mapsto \sum c_i x_V^{-1}u_i$ maps $\mathbb{A}_E^m$ onto $Z(\mathbb{A})$ and E^m into $Z(E)$, so the quotient is a continuous image of the compact $(\mathbb{A}_E/E)^m$; and $Z(E) \subseteq x_V^{-1}E^n$ is discrete.

Step 2: (1). For $u \in Z$, $\Lambda(\rho(z + x_V^{-1}u)f) = \Lambda(\rho(x_V^{-1}u)\rho(z)f) = \Lambda(\rho(z)f)$ by Step 1; continuity is the strong continuity of ρ. So Λ_Z is defined, linear, and $|\Lambda_Z(f)| \le \|\Lambda\|\|f\|$. For $z' \in Z(\mathbb{A})$, $\Lambda_Z(\rho(z')f) = \int \Lambda(\rho(z+z')f)\,dz = \Lambda_Z(f)$ by Step 1 and invariance of dz. Finally $\rho(z)\omega_s(g) = \omega_s(g)\rho(g^{-1}z)$, so $|\Lambda(\rho(z)\omega_s(g)f)| \le \|\Lambda \circ \omega_s(g)\|\,\|\rho(g^{-1}z)f\| = \|\Lambda \circ \omega_s(g)\|\|f\|$, and integrating gives $\|\Lambda_Z \circ \omega_s(g)\| \le \|\Lambda \circ \omega_s(g)\|$.

Step 3: an integer that fixes f_0. By (WR6) and $P^A v^0 = v^0$, $f_0 = \sum_k c_k \rho(\mathrm{fv}(y_k))v^0$ for finitely many $y_k \in \mathbb{A}_{E,f}^n$. Choose an even integer $M \ge 2$ with $\frac{M}{2}y_k \in \widehat{\mathcal{O}}_E^n$ for all k. For $y \in \widehat{\mathcal{O}}_E^n$, $\beta_s(\mathrm{fv}(My), \mathrm{fv}(y_k)) = \psi_0(\frac{M}{2}\bar{y}_k^{\mathsf{T}}y) = 1$ and $\beta_s(\mathrm{fv}(y_k), \mathrm{fv}(My)) = \psi_0(\frac{M}{2}\bar{y}^{\mathsf{T}}y_k) = 1$, so $\rho(\mathrm{fv}(My))$ commutes with $\rho(\mathrm{fv}(y_k))$; and $\rho(\mathrm{fv}(My))v^0 = \psi_0(\frac{c_0M^2}{2}\bar{y}^{\mathsf{T}}y)^{-1}\rho_f(My)v^0 = v^0$ ($M^2/2$ and c_0 integral). Hence $\rho(\mathrm{fv}(My))f_0 = f_0$ for all $y \in \widehat{\mathcal{O}}_E^n$.

Step 4: rational shifts act on $w \otimes f_0$ as short real translations. By compactness of $\mathbb{A}_E/E$ there is $R > 0$ such that every $c \in \mathbb{A}_E$ is $a + w$ with $a \in E$, $w_f \in \widehat{\mathcal{O}}_E$ and $|w_v| \le R$ for $v \in \Phi$; applied to c/M this writes $c = Ma' + Mw$ with $a' \in E$. Let g, δ, $u_1, \dots, u_r$, Z be as in (2), and $z \in Z(\mathbb{A})$; as the u_i span Z, $z = \sum_i c_i x_V^{-1}u_i$, and writing $c_i = Ma'_i + Mw_i$ we put $u = -M\sum_i a'_i u_i \in Z$, so that $g^{-1}(x_V^{-1}u + z) = Mp$ with $p = \sum_i w_i (x_V g)^{-1}u_i$. The finite part p_f is integral (the u_i lie in the lattice of V_g), and $\|p_\infty\| \le rR\delta$. The archimedean part Mp_∞ and the finite part Mp_f have disjoint supports, so $\beta_s(Mp_\infty, Mp_f) = 1$ and $\rho(Mp) = \rho(Mp_\infty)\rho(Mp_f)$. Now $Mp_f = \mathrm{fv}(M\alpha^{-1}p_f)$ with $\alpha^{-1}p_f$ integral (α^{-1} has integral components, (WD2)), and

$Mp_\infty = \mathrm{rv}(y)$ with $y_{v,i} = \kappa_v^{-1} M p_{v,i}$, $\|y\|_2 \le C_0\delta$, $C_0 = MrR \max_v \kappa_v^{-1}$. By Lemma 6.2.21 and Step 3, for every $w \in \mathcal{F}_\varepsilon$,

$$\rho(g^{-1}(x_V^{-1}u + z))(w \otimes f_0) = \rho(\mathrm{rv}(y))(w \otimes \rho(\mathrm{fv}(M\alpha^{-1}p_f))f_0) = (\rho^\infty(y)w) \otimes f_0. \tag{1}$$

Step 5: (2). Let $\Lambda' = \Lambda - \Lambda_Z$; it is invariant under $\rho(x_V^{-1}u)$, $u \in Z$ (by hypothesis and (1)), and $\int \Lambda'(\rho(z)F)\,dz = \Lambda_Z(F) - \Lambda_Z(F) = 0$ for every F, so

$$\Lambda'(F) = \int_{Z(\mathbb{A})/Z(E)} (\Lambda'(F) - \Lambda'(\rho(z)F))\,dz, \qquad |\Lambda'(F)| \le \sup_{z \in Z(\mathbb{A})} |\Lambda'(F) - \Lambda'(\rho(z)F)|. \tag{2}$$

Define $\ell(w) = \Lambda'(\omega_s(g)(w \otimes f_0))$ on $\mathcal{F}_\varepsilon$; it is bounded with $\|\ell\| \le \|\Lambda' \circ \omega_s(g)\|\,\|f_0\| \le 2\|f_0\|\,\|\Lambda \circ \omega_s(g)\|$ by (1). For $z \in Z(\mathbb{A})$ with u, y as in Step 4, Step 1, invariance and (1) give

$$\begin{aligned}\Lambda'(\rho(z)\omega_s(g)(w \otimes f_0)) &= \Lambda'(\rho(x_V^{-1}u + z)\omega_s(g)(w \otimes f_0)) \\ &= \Lambda'(\omega_s(g)\rho(g^{-1}(x_V^{-1}u + z))(w \otimes f_0)) = \ell(\rho^\infty(y)w).\end{aligned}$$

With (2) for $F = \omega_s(g)(w \otimes f_0)$: $|\ell(w)| \le \sup_{\|y\|_2 \le C_0\delta} |\ell(w) - \ell(\rho^\infty(y)w)|$ for every w. By Lemma 6.2.34 with $t = C_0\delta$ (its constant C_F for ι, ε, N), $|\ell(v)| \le C_F\|\ell\|(C_0\delta)^N \mathrm{mom}_N(v)$, which is (2) with $C = 2C_F C_0^N \|f_0\|$. □

Lemma 6.2.33. *Let s be signs on n, and A a finite set of finite places of E containing the conjugate of none of its members. For functions $\Psi, \Psi' \in \mathcal{T}_A$ put*

$$\langle \Psi, \Psi' \rangle_A = \int_{X_A} \overline{\Psi(x)}\,\Psi'(x)\,dx,$$

where X_A is the set of $x \in \mathbb{A}_{E,f}^n$ whose components at the finite places outside A are integral, and dx is the Haar measure of $\mathbb{A}_{E,f}^n$ giving $\widehat{\mathcal{O}}_E^n$ mass 1. Then:

1. *for $\Psi, \Psi' \in \mathcal{T}_A$ and $f, f' \in \mathcal{M}_s$, $\langle \Psi \otimes_A f, \Psi' \otimes_A f' \rangle = \langle \Psi, \Psi' \rangle_A \langle P^A f, P^A f' \rangle$;*
2. *$P^A v^0 = v^0$;*
3. *if A' is a finite set of finite places containing the conjugate of none of its members, with $(A' \cup \bar{A}') \cap (A \cup \bar{A}) = \emptyset$, then $P^{A'}(\Psi \otimes_A v^0) = \Psi \otimes_A v^0$ for every $\Psi \in \mathcal{T}_A$;*
4. *for $\Psi \in \mathcal{T}_A$, $v_1 \otimes (\Psi \otimes_A v^0) = \Psi \otimes_A v^0$, where v_1 is the real vacuum of (WR5) of Definition 3.2.18 for the signs s on $\Phi \times n$;*
5. *for $\Psi \in \mathcal{T}_A$ and every $y \in \widehat{\mathcal{O}}_E^n$ whose components at the places of $A \cup \bar{A}$ are 0, $\rho_f(y)(\Psi \otimes_A v^0) = \Psi \otimes_A v^0$ (for $A = \emptyset$, $\Psi = 1$: $\rho_f(y)v^0 = v^0$ for every $y \in \widehat{\mathcal{O}}_E^n$);*
6. *for Fock vectors v, v' (signs s on $\Phi \times n$) and $f, f' \in \mathcal{M}_s$, $\langle v \otimes f, v' \otimes f' \rangle = \langle v, v' \rangle \langle v_1 \otimes f, v_1 \otimes f' \rangle$, the first factor the inner product of the Fock model;*
7. *let Σ be a set of finite places of F, and call $f \in \mathcal{M}_s$ a **vacuum above** Σ if $\rho_f(y)f = f$ for every $y \in \widehat{\mathcal{O}}_E^n$ whose components at the finite places not above Σ are 0. If f, f' are vacua above Σ and $\gamma \in \mathrm{G}(s)$ has components 1 at the infinite places and at the finite places not above Σ, then $\langle f', \omega_s(\gamma)f \rangle = \langle v^0, \omega_s(\gamma)v^0 \rangle \langle f', f \rangle$.*

Proof. **Step 1: (1).** Each $\Psi \in \mathcal{T}_A$ depends only on the components at A (Lemma 4.1.3 identifies $\mathcal{T}_A$ with functions on $Q_A = \prod_{w\in A} E_w^n$). The Haar measure of $\mathbb{A}_{E,f}^n$ with $\widehat{\mathcal{O}}_E^n$ of mass 1 is the product of the local ones with $\mathcal{O}_{E,w}^n$ of mass 1, and $X_A = Q_A \times \prod_{w\notin A} \mathcal{O}_{E,w}^n$; so $\langle \Psi, \Psi'\rangle_A = \int_{Q_A} \bar{\Psi}\Psi'$, and (1) is (1) of Lemma 4.1.3.

Step 2: the finite Heisenberg operators of integral vectors. For $y \in \widehat{\mathcal{O}}_E^n$, (WD8) gives $\rho_f(y) = \psi_0(\frac{c_0}{2} y^* y)\rho(\mathrm{fv}(y)) = e_n(\alpha y)\rho(\alpha y)$ (WD5). For $y, y' \in \widehat{\mathcal{O}}_E^n$, $\beta_s(\mathrm{fv}(y), \mathrm{fv}(y')) = \psi_0(\frac{1}{2} y'^* y)$, so

$$\rho_f(y)\rho_f(y')\rho_f(y+y')^{-1} = \psi_0(\tfrac{1}{2} y'^* y - \tfrac{c_0}{2}(y^* y' + y'^* y)) = \psi_0(\tfrac{1}{2}(X - \bar{X})) = 1, \qquad X = \bar{c}_0\, y'^* y \in \widehat{\mathcal{O}}_E,$$

using $1 - c_0 = \bar{c}_0$, $\psi_0(\bar{t}) = \psi_0(t)^{-1}$ and $\psi_0(\widehat{\mathcal{O}}_E) = 1$; so $y \mapsto \rho_f(y)$ is a continuous homomorphism on $\widehat{\mathcal{O}}_E^n$. For a set S of finite places let O_S be the integral vectors with components 0 outside S. With $\Sigma = S$ in (4) of Lemma 6.2.12, $P_S = \int_{O_S} \rho_f(y)\, dy$ (Haar probability measure), so $\rho_f(y) P_S = P_S$ for $y \in O_S$ (translation invariance), and a vector f satisfies $\rho_f(y) f = f$ for all $y \in O_S$ if and only if $P_S f = f$. As $P_S v^0 = v^0$, $\rho_f(y) v^0 = v^0$ for $y \in O_S$; with S all finite places this is the case $A = \emptyset$ of (5). Moreover $P^A = P_{A\cup \bar{A}}$ by (WR6).

Step 3: (5), (2), (3). Let $\Psi \in \mathcal{T}_A$, so $\Psi \otimes_A v^0 = \sum_{y'} c_{y'}(\Psi)\rho(\mathrm{fv}(y'))P^A v^0$ with y' supported at $A \cup \bar{A}$. If $y \in \widehat{\mathcal{O}}_E^n$ has components 0 at $A \cup \bar{A}$, then $\rho_f(y)$ commutes with $\rho(\mathrm{fv}(y'))$ (disjoint supports) and with $P^A = P_{A\cup\bar{A}}$ ((4) of Lemma 6.2.12), so $\rho_f(y)(\Psi \otimes_A v^0) = \sum c_{y'} \rho(\mathrm{fv}(y'))P^A \rho_f(y) v^0 = \Psi \otimes_A v^0$ by Step 2: this is (5). (2) is $P_{A\cup\bar{A}} v^0 = v^0$. For (3), $P^{A'} = P_{A'\cup\bar{A}'}$ is the mean of the $\rho_f(y)$, $y \in O_{A'\cup\bar{A}'}$, and these y vanish at $A \cup \bar{A}$; by (5) each fixes $\Psi \otimes_A v^0$.

Step 4: (4). By (3) and (4) of Lemma 6.2.21, $v_1 \otimes (\Psi \otimes_A v^0) = \sum c_{y'} \rho(\mathrm{fv}(y'))P^A(v_1 \otimes v^0) = \Psi \otimes_A v^0$.

Step 5: (6). Let $P = P_\Phi$ be the partial projection at the infinite places; in normalized coordinates $e_n(\mathrm{rv}(t)) = v_1(t)$ and μ_Φ is the image of ν, so $Pf = v_1 \otimes f$, and $P^2 = P$ by (5) of Lemma 6.2.21. First, $P\rho(\mathrm{rv}(\tau))P = v_1(\tau)P$: for $z = z_\infty + z_f$ (archimedean and finite parts), (4) of Lemma 6.2.12 gives $P\rho(z)v^0 = \rho(z_f)P\rho(z_\infty)v^0 = e_n(z_\infty)\rho(z_f)v^0$, and then $P\rho(\mathrm{rv}(\tau))P\rho(z)v^0 = e_n(z_\infty)\rho(z_f)P\rho(\mathrm{rv}(\tau))v^0 = v_1(\tau)P\rho(z)v^0$; superposition and boundedness extend this to all vectors. Next, for $v \in \mathcal{F}_\varepsilon$ the reproducing identity (WR5) says $v = \int v(\tau)\rho^\infty(\tau) v_1\, d\nu(\tau)$ as a Bochner integral in $L^1(\nu)$ (strong continuity, Fubini), so by (1), (2), (5) of Lemma 6.2.21, $v \otimes f = v \otimes Pf = \int v(\tau)\rho(\mathrm{rv}(\tau))Pf\, d\nu(\tau)$. Hence, with $\rho(\mathrm{rv}(\tau))^{-1}\rho(\mathrm{rv}(\tau')) = \beta_\varepsilon^\infty(-\tau, \tau')\rho(\mathrm{rv}(\tau'-\tau))$ and $\langle Pf, X\rangle = \langle Pf, PX\rangle$ (P symmetric, $P^2 = P$),

$$\langle v \otimes f, v' \otimes f'\rangle = \iint \overline{v(\tau)} v'(\tau') \beta_\varepsilon^\infty(-\tau, \tau')\, v_1(\tau' - \tau)\, d\nu\, d\nu \cdot \langle Pf, Pf'\rangle.$$

Since $\overline{\beta_\varepsilon^\infty(-\tau, \tau')} = \beta_\varepsilon^\infty(\tau, \tau')$ and v_1 is real, the τ-integral is the conjugate of $\int v(\tau)\beta_\varepsilon^\infty(\tau, \tau') v_1(\tau' - \tau)\, d\nu(\tau) = v(\tau')$, by (WR5); so the double integral is $\langle v, v'\rangle$, and $\langle Pf, Pf'\rangle = \langle v_1 \otimes f, v_1 \otimes f'\rangle$.

Step 6: (7). Let S be the set of places of E above Σ, R its complement in the set of all places, $c = \langle v^0, \omega_s(\gamma) v^0\rangle$, and $B(h, h') = \langle P_S h, \omega_s(\gamma) P_S h'\rangle - c\langle P_S h, P_S h'\rangle$, a bounded sesquilinear form. For $y \in A_R$, $\gamma y = y$, so $\omega_s(\gamma)$ commutes with $\rho(y)$, hence with P_R, and $P_R \omega_s(\gamma) v^0 = \omega_s(\gamma) v^0$. For $z = z_S + z_R$, $z' = z'_S + z'_R$ (parts in A_S, A_R), Step 2 and (4) of Lemma 6.2.12 give $P_S \rho(z) v^0 = e_n(z_S)\rho(z_R)v^0$, and with $Z = z'_R - z_R \in A_R$,

$$\begin{aligned}\langle P_S\rho(z)v^0, \omega_s(\gamma) P_S \rho(z')v^0\rangle &= \overline{e_n(z_S)} e_n(z'_S)\beta_s(-z_R, z'_R)\langle \rho(-Z)v^0, P_R\omega_s(\gamma)v^0\rangle \\ &= \overline{e_n(z_S)} e_n(z'_S)\beta_s(-z_R, z'_R)\, e_n(Z)\, c,\end{aligned}$$

by the symmetry of P_R and $P_R\rho(-Z)v^0 = e_n(-Z)v^0 = e_n(Z)v^0$. The case $\gamma = 1$ gives the same expression with c replaced by $\langle v^0, v^0\rangle = 1$. So B vanishes on pairs of Heisenberg translates of

v^0, hence, by superposition in both arguments, everywhere. If f, f' are vacua above Σ, then $P_S f = f$, $P_S f' = f'$ by Step 2, and $B(f', f) = 0$ is (7). $\square$

Lemma 6.2.34. *Let ε be signs on a finite index set ι and $N \in \mathbb{N}$. There is $C \geq 0$ with the following property. Let $t \geq 0$ and let ℓ be a bounded linear functional on $\mathcal{F}_\varepsilon$ such that, if $t < 1$,*

$$|\ell(f)| \leq \sup_{y \in \mathbb{C}^\iota,\ \|y\|_2 \leq t} \big|\ell(f) - \ell(\rho^\infty(y) f)\big| \qquad \text{for every } f \in \mathcal{F}_\varepsilon.$$

Then $|\ell(v)| \leq C\,\|\ell\|\,t^N \operatorname{mom}_N(v)$ for every $v \in \mathcal{F}_\varepsilon$ with $\operatorname{mom}_N(v) < \infty$.

Proof. Write $D = \operatorname{diag}(\varepsilon)$, $\nu = \nu_\iota$, $\rho = \rho^\infty$, $\beta = \beta^\infty_\varepsilon$, $e = e^\infty$, and $\|\cdot\|$ for the norm of (XD3); let $c_\iota \geq 1$ with $1 + \|z\|_2 \leq c_\iota(1 + \|z\|)$ for all z (equivalence of norms on $\mathbb{C}^\iota$). Note $|\beta| = 1$, $\beta(x, y) = \exp(i \operatorname{Im} y^* D x)$ is additive in each variable, and $(\rho(z)v_1)(x) = \beta(z, x) e(x - z)$.

Superposition. For $v \in \mathcal{F}_\varepsilon$, the map $z \mapsto v(z)\rho(z)v_1$ is Bochner integrable in $\mathcal{F}_\varepsilon$ (continuous, with norm $|v(z)|\,\|v_1\|$), and its integral is v: evaluated at x (Fubini) it is $\int v(z)\beta(z, x)e(x - z)\,d\nu(z) = v(x)$, the reproducing identity of (WR5). Hence $\ell(v) = \int v(z)\,\ell(\rho(z)v_1)\,d\nu(z)$ and

$$|\ell(v)| \leq \int |v(z)|\,|\ell(\rho(z)v_1)|\,d\nu(z). \tag{1}$$

The case $t \geq 1$. Then $|\ell(v)| \leq \|\ell\|\,\|v\| = \|\ell\|\operatorname{mom}_0(v) \leq \|\ell\|\,t^N \operatorname{mom}_N(v)$.

The case $t < 1$; iteration. Put $\Delta_y = 1 - \rho(y)$. We show by induction on k that $|\ell(f)| \leq \sup|\ell(\Delta_{y_k} \cdots \Delta_{y_1} f)|$ for every f, the supremum over $y_1, \ldots, y_k$ with $\|y_i\|_2 \leq t$ (it is at most $2^k \|\ell\| \|f\|$, since $\rho(y)$ is an isometry). For $k = 0$ there is nothing to show. Given the claim for k, apply the hypothesis to $f' = \Delta_{y_k} \cdots \Delta_{y_1} f$: $|\ell(f')| \leq \sup_{\|y\|_2 \leq t} |\ell(\Delta_y f')|$; taking the supremum over $y_1, \ldots, y_k$ gives the claim for $k + 1$. With $k = N$ and $f = \rho(z)v_1$,

$$|\ell(\rho(z)v_1)| \leq \|\ell\| \sup_{\|y_i\|_2 \leq t} \big\|\Delta_{y_N} \cdots \Delta_{y_1} \rho(z) v_1\big\|. \tag{2}$$

An N-th difference of a coherent vector. Fix z and $y_1, \ldots, y_N$ with $\|y_i\|_2 \leq t \leq 1$. For $\sigma = (\sigma_1, \ldots, \sigma_N) \in [0, 1]^N$ let $G_\sigma = \rho(\sigma_N y_N) \cdots \rho(\sigma_1 y_1)\rho(z)v_1$ and $w_\sigma = \sum_j \sigma_j y_j$. Applying $(\rho(a)c)(x) = \beta(a, x)c(x - a)$ repeatedly,

$$G_\sigma(x) = \prod_{i=1}^{N} \beta\Big(\sigma_i y_i,\ x - \sum_{j>i} \sigma_j y_j\Big) \cdot \beta(z, x - w_\sigma)\, e(x - w_\sigma - z) = \exp Q(\sigma, x),$$

where, by additivity of β and $e(u) = \exp(-u^*u/2)$, $Q(\cdot, x)$ is a polynomial of degree at most 2 in σ. Expanding the product,

$$\Delta_{y_N} \cdots \Delta_{y_1} \rho(z) v_1 = \sum_{S \subseteq \{1, \ldots, N\}} (-1)^{\#S} G_{\mathbf{1}_S}$$

($\rho(0) = 1$), and by the fundamental theorem of calculus in each variable this function of x equals

$$(-1)^N \int_{[0,1]^N} \partial_{\sigma_1} \cdots \partial_{\sigma_N} \exp Q(\sigma, x)\,d\sigma.$$

By the formula for mixed derivatives of an exponential,

$$\partial_{\sigma_1} \cdots \partial_{\sigma_N} e^Q = e^Q \sum_\pi \prod_{B \in \pi} \partial_B Q,$$

the sum over the partitions π of $\{1,\dots,N\}$, ∂_B the mixed derivative in the σ_i, $i\in B$; $\partial_B Q=0$ if $\#B\ge 3$. Reading off Q (each term is $\pm\frac12$ or $\pm\frac{i}{2}$ times a^*Db or a^*b with a,b among x, z, the $\sigma_j y_j$, and $|a^*Db|\le\|a\|_2\|b\|_2$): $|\partial_{\sigma_i}Q|\le 3\|y_i\|_2(\|x\|_2+\|z\|_2+N)$ and $|\partial_{\sigma_i}\partial_{\sigma_j}Q|\le 2\|y_i\|_2\|y_j\|_2$ for $i\ne j$, on $[0,1]^N$. Hence, with b_N the number of partitions,

$$|\partial_{\sigma_1}\cdots\partial_{\sigma_N}e^{Q}|\le b_N(3t)^N(1+N+\|x\|_2+\|z\|_2)^N\,e(x-w_\sigma-z),$$

using $|e^Q|=|G_\sigma(x)|=e(x-w_\sigma-z)$. Integrating over x, substituting $x=x'+w_\sigma+z$ and using $\|w_\sigma\|_2\le N$ and $1+2N+2\|z\|_2+\|x'\|_2\le 2(1+N)(1+\|z\|_2)(1+\|x'\|_2)$,

$$\|\Delta_{y_N}\cdots\Delta_{y_1}\rho(z)v_1\|\le C_1\,t^N(1+\|z\|_2)^N,\qquad C_1=b_N6^N(1+N)^N\int(1+\|x'\|_2)^N e(x')\,d\nu(x')<\infty.$$

Conclusion. By (2), $|\ell(\rho(z)v_1)|\le C_1\|\ell\|t^N(1+\|z\|_2)^N\le C_1c_\iota^N\|\ell\|t^N(1+\|z\|)^N$, and (1) gives $|\ell(v)|\le C_1c_\iota^N\|\ell\|t^N\mathrm{mom}_N(v)$. So $C=\max(1,C_1c_\iota^N)$ works in both cases. □

Lemma 6.2.35. *Let s be signs on a finite index set m, A a finite set of finite places of E containing the conjugate of none of its members, $\Psi\in\mathcal{T}_A$, $I\subseteq\mathbb{A}_E^m$ an $\mathbb{A}_E$-submodule, and Λ a bounded linear functional on $\mathcal{M}_s$ with $\Lambda(\rho(z)f)=\Lambda(f)$ for all $z\in I$ and $f\in\mathcal{M}_s$. Suppose that for every $y\in\mathbb{A}_{E,f}^m$ with $\Psi(y)\ne 0$ there are $z\in I$ and $w\in A$ with $(z_f^*y)_w\ne 0$. Then $\Lambda(\Psi\otimes_A f)=0$ for every $f\in\mathcal{M}_s$.*

Proof. Fix f. Functions in $\mathcal{T}_A$ are read on Q_A.

Step 1: a character for each point of the support. Let $x\in Q_A$ with $\Psi(x)\ne 0$ (read as a finite adelic vector with components 0 off A). By hypothesis there are $z\in I$ and $w\in A$ with $b=(z_f^*x)_w=\sum_k\overline{z_{k,\bar w}}\,x_{k,w}\ne 0$ (on adeles, $\bar z_w=\overline{z_{\bar w}}$). The restriction of ψ_0 to E_w is a nontrivial continuous character ($\jmath\alpha\bar\alpha\ne 0$ and $\psi_{E,f}$ is nontrivial on E_w), so there is $t_0\in E_w$ with $\psi_0(t_0)\ne 1$; as $a\mapsto\overline{\alpha_{\bar w}^{-1}}\,a\,b$ is a bijection $E_{\bar w}\to E_w$, there is $a_x\in\mathbb{A}_E$ with components 0 except at $\bar w$ and $\overline{\alpha_{\bar w}^{-1}(a_x)_{\bar w}}\,b=t_0$. Put $z_x=a_xz\in I$, supported at $\bar w\in\bar A$, and $y_x=\alpha^{-1}(z_x)_f$, so $\mathrm{fv}(y_x)=z_x$. Since $(y_x)_A=0$,

$$(R_A(y_x)\Phi)(x')=\chi_x(x')\,\Phi(x'),\qquad \chi_x(x')=\psi_0(\bar y_x^{\mathsf T}x'_A)=\psi_0\Big(\overline{\alpha_{\bar w}^{-1}(a_x)_{\bar w}}\sum_k\overline{z_{k,\bar w}}\,x'_{k,w}\Big),$$

for $\Phi\in\mathcal{T}_A$; χ_x is a continuous character of Q_A with $\chi_x(x)=\psi_0(t_0)\ne 1$.

Step 2: a decomposition of Ψ. Let $U_0\subseteq Q_A$ be an open compact subgroup under which Ψ is invariant (Ψ is locally constant with compact support). For each x in the compact support K of Ψ let $U_x\subseteq U_0$ be an open compact subgroup on which χ_x is trivial (its kernel is open). Finitely many $x_1+U_{x_1},\dots,x_r+U_{x_r}$ cover K; let $U=\bigcap_j U_{x_j}$. Then $\Psi=\sum_c\Psi(c)\mathbf{1}_{c+U}$, the finite sum over the cosets $c+U$ meeting K (Ψ is constant on each, as $U\subseteq U_0$). Each such coset meets some $x_j+U_{x_j}$, hence lies in it, and there χ_{x_j} is constant, equal to $\chi_{x_j}(x_j)\ne 1$.

Step 3: each piece is killed. Let $c+U$ be one of these cosets, j as in Step 2, and $\Phi=\mathbf{1}_{c+U}\in\mathcal{T}_A$. Then $R_A(y_{x_j})\Phi=\chi_{x_j}(x_j)\Phi$, so by invariance of Λ under $\rho(z_{x_j})=\rho(\mathrm{fv}(y_{x_j}))$,

$$\Lambda(\Phi\otimes_A f)=\Lambda\big(\rho(\mathrm{fv}(y_{x_j}))(\Phi\otimes_A f)\big)=\chi_{x_j}(x_j)\,\Lambda(\Phi\otimes_A f),$$

and $\Lambda(\Phi\otimes_A f)=0$. By linearity of $\Psi\mapsto\Psi\otimes_A f$ and Step 2, $\Lambda(\Psi\otimes_A f)=0$. □

The second half evaluates the Tate integral (Lemma 6.2.36). Poisson's formula on the new line and the factorisation of the line values of standard data into a matrix Gauss sum, a finite factor and a kernel of the smaller pair reduce it to Tate's integral at the finite places, which

gives $|\alpha_0|^x Q^{x-1/2} L^\Sigma(x,\tilde\nu)$ as in [294, 128], times real cone integrals, which converge and are again Schwartz vectors.

The group continues with the mixed model in its global form. The Weil representation of a pair of spaces with points is the classical Weil representation of the unitary dual pair, split by a pair of characters of U(1) as in [172], and Lemma 6.2.44 gives the four properties that every unfolding uses. Real slices of Schwartz vectors decay rapidly, and every smooth compactly supported family of unitary translates of a Schwartz vector is a slice family (Lemma 6.2.43); in our reading this is what lets the exchange identity prescribe the real vectors of its data.

The section closes with three principles of integration over quotients by discrete subgroups, used repeatedly in the exchange identity: unfolding in stages (Lemma 6.2.47) and the averaging criterion (Lemma 6.2.50), both consequences of one unfolding formula (Lemma 6.2.48), an instance of Weil's formula for quotient measures [320]; and a constancy criterion for automorphic functions on a unitary group that splits off a hyperbolic plane (Lemma 6.2.49), proved by strong approximation [167, 233]. In our reading the averaging criterion is the measure-theoretic form of the vanishing of a period against a character that is nontrivial on the stabiliser.

Lemma 6.2.36. *Let W', W, V', V, A, X be as above, let b be an index set with bijections $\sigma\colon b \sqcup r \to n$ and $\sigma'\colon b \sqcup r' \to n'$, assume that $\#n$ is even, and let $\mu\colon \Phi \to \mathbb{Z}$. Fix a Haar measure on $\mathbb{A}_E^\times$ and give $Y = E^\times\backslash\mathbb{A}_E^\times \times [\mathrm{U}(V)] \times \mathrm{K}_{\max}(t')$ the measure of Lemma 6.2.3. For a split tame character $\mathfrak{c} = (\nu,\Sigma)$ let α_W, $\alpha_{W'}$ and, for $f \in \mathcal{M}_{W',V'}$, $u \in \mathbb{A}_E^\times$, $g \in \mathrm{G}(s)$ and real x, the function $Z_x(f;u,g)$ on Y be as in Lemma 6.2.3:*

$$Z_x(f;u,g)(a,h,\kappa) = \tilde\nu(au)\,|au|^x \sum_{\xi\in E^\times} \theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^+_{A,X}(\xi au)(\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f)\Big)(g,h),$$
$$\alpha_W = \nu^{-1}\upsilon^{\#n/2},\ \alpha_{W'} = \nu^{-1}\upsilon^{\#n'/2}.$$

Let $\alpha_0 \in \mathbb{A}_E^\times$ be the idele with components κ_v at $v \in \Phi$ and finite part the Weil idele α ((WD2), (WD6) of Definition 3.2.12). Then there are real numbers $C_+, C_- > 0$ such that for every split tame character $\mathfrak{c} = (\nu,\Sigma)$ of weight μ there are $\epsilon_+, \epsilon_- \in \mathbb{C}$ with $|\epsilon_\pm| = C_\pm$ and the following property. Let $Q = \prod_{w\in\Sigma} \mathrm{N}w$, let $v \in \mathcal{F}_{W',V'}$ be a Schwartz vector, $y \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$, $f = \varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)$, and $u \in \mathbb{A}_E^\times$, $g \in \mathrm{G}(s)$ with $u = 1$ or $\#r = \#n$. Then $Z_x(f;u,g)$ is integrable on Y for every real x and $x \mapsto \int_Y Z_x(f;u,g)$ is a real-analytic function on $\mathbb{R}$; for every $x \geq 1$ the cone integrals $\mathrm{Cone}^\pm_{A,X,\mu}(x;v)$ are defined, and

$$\int_Y Z_x(f;u,g) = \epsilon_+\,|\alpha_0|^x\,Q^{x-1/2}L^\Sigma(x,\tilde\nu)\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^+_{A,X,\mu}(x;v),\Phi^{\mathrm{st}}_{\sigma,y})(g),$$
$$\int_Y Z_{1-x}(f;u,g) = \epsilon_-\,|\alpha_0|^x\,Q^{x-1/2}L^\Sigma(x,\tilde\nu)\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^-_{A,X,\mu}(x;v),\Phi^{\mathrm{st}}_{\sigma,y})(g).$$

Proof. Let $l_\pm$ be the constants of Lemma 6.2.37, and let $\Lambda_{\mathfrak{c}}$ denote the finite factor of a split tame character $\mathfrak{c}$, defined by the same formula in Lemma 6.2.37 and Lemma 6.2.41. Write $\mathbb{A}_E^\times = (\mathbb{C}^\times)^\Phi \times \mathbb{A}_{E,f}^\times$; the fixed Haar measure of $\mathbb{A}_E^\times$ is $d^\times a \otimes \rho$ for a Haar measure ρ of $\mathbb{A}_{E,f}^\times$, by uniqueness of Haar measure. The idele α_0 is that of Lemma 6.2.37. Put

$$C_\pm = |l_\pm|\,\rho(\widehat{\mathcal{O}}_E^\times) > 0.$$

Fix a split tame character $\mathfrak{c} = (\nu,\Sigma)$ of weight μ, let γ and the finite idele c (with $|\gamma|^2 = Q^{-1}$, $|c| = Q^{-1}$) be those of Lemma 6.2.37 for $\mathfrak{c}$, put $\delta = c^{-1}\alpha_0$ and

$$\epsilon_\pm = l_\pm\,\gamma\,Q^{1/2}\,\tilde\nu(\delta)\,\rho(\widehat{\mathcal{O}}_E^\times).$$

As $|\tilde\nu(\delta)|=1$ and $|\gamma|Q^{1/2}=1$, $|\epsilon_\pm|=C_\pm$. Fix v, y, u, g as in the statement and $f=\varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)$. For $h\in \mathrm{G}(t)$, $\kappa\in \mathrm{K}_{\max}(t')$ and an adele q let $\lambda^{\pm}_{h,\kappa}(q)$ be the line values of Lemma 6.2.40 for ν, f, g, h, κ, and for $a'\in\mathbb{C}^\Phi$ let $m^{\pm}(h,\kappa,a')=\theta^{W,V}_{\alpha_W,\alpha_W}(\mathrm{Ln}^{\pm,\infty}_{A,X}(a')(\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v)\otimes[\Phi^{\mathrm{st}}_{\sigma,y}]_\Sigma)(g,h)$.

Step 1: factorisation. By Lemma 6.2.37, applied to the adele $q\alpha_0^{-1}$, for every adele q

$$\lambda^{\pm}_{h,\kappa}(q)=l_\pm\,\gamma\,\Lambda_{\mathfrak{c}}((q\alpha_0^{-1})_f c)\,m^{\pm}(h,\kappa,(q\alpha_0^{-1})_\infty).$$

At $q=0$ the finite factor is $\Lambda_{\mathfrak{c}}(0)=0$, as 0 is not a unit; so $\lambda^{+}_{h,\kappa}(0)=\lambda^{-}_{h,\kappa}(0)=0$.

Step 2: Poisson's formula. Let $P_+(q)=q$ and $P_-(q)=\bar q^{-1}$ on $\mathbb{A}_E^\times$, and

$$G^{\pm}_x(q)=\tilde\nu(q)|q|^x\lambda^{\pm}_{h,\kappa}(q).$$

Let $a\in\mathbb{A}_E^\times$ and $q=au$. By Step 1 and Lemma 6.2.40 ($\#n$ even), the series converge absolutely and

$$\sum_\xi \lambda^{+}_{h,\kappa}(\xi q)=|q|^{-1}\sum_\xi\lambda^{-}_{h,\kappa}(\xi\bar q^{-1}),$$

sums over $\xi\in E^\times$. Since $\tilde\nu(\xi)=1$, $|\xi|=1$, $\tilde\nu(\bar q^{-1})=\nu(q/\bar q)=\tilde\nu(q)$ and $|\bar q^{-1}|=|q|^{-1}$, this gives, for every real x,

$$Z_x(f;u,g)(a,h,\kappa)=\sum_{\xi\in E^\times}G^{+}_x\big(\xi P_+(au)\big),\qquad Z_{1-x}(f;u,g)(a,h,\kappa)=\sum_{\xi\in E^\times}G^{-}_x\big(\xi P_-(au)\big).$$

Step 3: product form. For $q'\in\mathbb{A}_E^\times$ the adele $q'\delta\alpha_0^{-1}=q'c^{-1}$ has infinite part q'_∞ and finite part q'_fc^{-1}, so Step 1 gives $\lambda^{\pm}_{h,\kappa}(q'\delta)=l_\pm\gamma\,\Lambda_{\mathfrak{c}}(q'_f)\,m^{\pm}(h,\kappa,q'_\infty)$. Since ν has weight μ, $\tilde\nu(a)=\prod_{w\in\Phi}(a_w/|a_w|)^{2\mu(w)}$ for $a\in(\mathbb{C}^\times)^\Phi$, and $|a|=\prod_{w\in\Phi}|a_w|^2$; hence

$$G^{\pm}_x(q'\delta)=l_\pm\gamma\,\tilde\nu(\delta)|\delta|^x\cdot k^{\pm}_x(h,\kappa,q'_\infty)\cdot\Lambda_{\mathfrak{c}}(q'_f)\tilde\nu(q'_f)|q'_f|^x,$$

with $k^{\pm}_x$ the cone kernel of Lemma 6.2.42 (for σ, y, g and the sign $\pm$).

Step 4: the case $x>1$. The map $a\mapsto q'(a)=P_\pm(au)\delta^{-1}$ is a homeomorphism of $\mathbb{A}_E^\times$ that preserves its Haar measure (translations do, and $q\mapsto\bar q^{-1}$ is a continuous automorphism of order two, so its modulus is 1) and permutes the cosets of $E^\times$ ($P_-(\xi a)=\bar\xi^{-1}P_-(a)$). Let $F^{\pm}_x(q',h,\kappa)=G^{\pm}_x(q'\delta)$. By Step 3, Lemma 6.2.42 ($x>0$) and Lemma 6.2.41 ($x>1$), $F^{\pm}_x$ is integrable on $\mathbb{A}_E^\times\times[\mathrm{U}(V)]\times\mathrm{K}_{\max}(t')$, the integral of $|F^{\pm}_x|$ being a product of two finite integrals by Tonelli. For such a function the quotient integral formula for the discrete subgroup $E^\times$ (counting measure; Tonelli for $|F^{\pm}_x|$, then Fubini) shows that $a\mapsto\sum_{\xi\in E^\times}F^{\pm}_x(\xi q'(a),h,\kappa)$ is integrable on Y with integral $\int F^{\pm}_x$. By Step 2 this function is $Z_x(f;u,g)$, resp. $Z_{1-x}(f;u,g)$, so these are integrable and, by Fubini, Lemma 6.2.42 and Lemma 6.2.41,

$$\int_Y Z_x(f;u,g),\ \int_Y Z_{1-x}(f;u,g)\ =\ l_\pm\gamma\,\tilde\nu(\delta)|\delta|^x\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^{\pm}_{A,X,\mu}(x;v),\Phi^{\mathrm{st}}_{\sigma,y})(g)\,\rho(\widehat{\mathcal{O}}_E^\times)L^\Sigma(x,\tilde\nu)$$

(sign $+$ for Z_x, sign $-$ for Z_{1-x}). As $|\delta|^x=|c|^{-x}|\alpha_0|^x=Q^x|\alpha_0|^x$, the factor is $\epsilon_\pm\,|\alpha_0|^x\,Q^{x-1/2}$: the two formulas hold for $x>1$.

Step 5: integrability for every real x. By definition

$$Z_x(f;u,g)(a,h,\kappa)=Z_0(f;u,g)(a,h,\kappa)\,|au|^x.$$

Given x, let $R=|x|+2>1$, so $1-R<x<R$. Then $|au|^x\le|au|^{1-R}+|au|^R$, so $|Z_{x'}(f;u,g)|\le|Z_{1-R}(f;u,g)|+|Z_R(f;u,g)|$ for all $x'\in[1-R,R]$, and the right side is integrable by Step 4.

Hence $Z_x(f;u,g)$ is integrable, and by dominated convergence $x' \mapsto \int_Y Z_{x'}(f;u,g)$ is continuous on $(1-R,R)$; so it is continuous on $\mathbb{R}$.

Step 6: the point $x = 1$. For $x \geq 1$ the cone integrals are defined by Lemma 6.2.42. Both sides of the two formulas are continuous on $[1,\infty)$: the left sides by Step 5; on the right, $|\alpha_0|^x$ and $Q^{x-1/2}$ are continuous, $L^\Sigma(x,\tilde\nu)$ is continuous by Lemma 6.2.41, and $x \mapsto \theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^{\pm}_{A,X,\mu}(x;v),\Phi^{\mathrm{st}}_{\sigma,y})(g)$ is the integral of $k^{\pm}_x$, continuous by Lemma 6.2.42. They agree on $(1,\infty)$ by Step 4, hence also at $x=1$.

Step 7: analyticity in x. Write $\ell(a) = \log|au|$, a function on Y because $|\xi| = 1$ for $\xi \in E^\times$. Fix $x_0 \in \mathbb{R}$ and let $|x - x_0| < 1$. By Step 5, $Z_x(f;u,g) = Z_{x_0}(f;u,g)\, e^{(x-x_0)\ell} = \sum_{m\geq 0} \frac{(x-x_0)^m}{m!} Z_{x_0}(f;u,g)\,\ell^m$, and

$$\sum_{m\geq 0} \frac{|x-x_0|^m}{m!} \big|Z_{x_0}(f;u,g)\big|\,|\ell|^m = \big|Z_{x_0}(f;u,g)\big|\, e^{|x-x_0||\ell|} \leq \big|Z_{x_0+1}(f;u,g)\big| + \big|Z_{x_0-1}(f;u,g)\big|,$$

which is integrable on Y by Step 5. By Tonelli each $Z_{x_0}(f;u,g)\ell^m$ is integrable and, by Fubini for the sum over m, $\int_Y Z_x(f;u,g) = \sum_{m\geq 0} c_m (x-x_0)^m$ with $c_m = \frac{1}{m!}\int_Y Z_{x_0}(f;u,g)\ell^m$, the series converging for $|x-x_0|<1$. So the function is given by a convergent power series near every point. □

Lemma 6.2.37. *Let W', W, V', V, A, X be as above, let b be an index set with bijections $\sigma\colon b \sqcup r \to n$ and $\sigma'\colon b \sqcup r' \to n'$, assume that $\#n$ is even, let $\mu\colon \Phi \to \mathbb{Z}$, and let $\alpha_0 \in \mathbb{A}_E^\times$ be the idele with components κ_v at $v \in \Phi$ and finite part α. For a split tame character $\mathfrak{c} = (\nu,\Sigma)$ put $\alpha_W = \nu^{-1}\upsilon^{\#n/2}$, $\alpha_{W'} = \nu^{-1}\upsilon^{\#n'/2}$, $Q = \prod_{w\in\Sigma} \mathrm{N}w$, and let $\Lambda_{\mathfrak{c}}(a) = \chi_{\mathfrak{c}}(a_\Sigma)^{-1}\chi_{\mathfrak{c}}((\bar a)_\Sigma)$ for finite adeles a integral at every finite place and units at every place of $\Sigma\cup\bar\Sigma$, and $\Lambda_{\mathfrak{c}}(a) = 0$ for all other finite adeles. Then there are $l_+, l_- \in \mathbb{C}^\times$ with the following property. For every split tame character $\mathfrak{c} = (\nu,\Sigma)$ of weight μ there are $\gamma \in \mathbb{C}$ with $|\gamma|^2 = Q^{-1}$ and a finite idele c with $|c| = Q^{-1}$ such that for every $v \in \mathcal{F}_{W',V'}$, every $y \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$, all $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(t)$, $\kappa \in \mathrm{K}_{\max}(t')$, both signs $\pm$ and every adele x with infinite part $x_\infty \in \mathbb{C}^\Phi$ and finite part x_f,*

$$\begin{aligned}&\theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^{\pm}_{A,X}(x\alpha_0)(\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f)\Big)(g,h)\\ &\qquad = l_\pm\,\gamma\,\Lambda_{\mathfrak{c}}(x_f c)\,\theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^{\pm,\infty}_{A,X}(x_\infty)(\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v)\otimes\big[\Phi^{\mathrm{st}}_{\sigma,y}\big]_\Sigma\Big)(g,h),\end{aligned}$$

where $f = \varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)$ and κ_∞ is the infinite component of κ.

Proof. Fix a split tame character $\mathfrak{c} = (\nu,\Sigma)$ of weight μ with tame part ψ and semilocal character $\chi = \chi_{\mathfrak{c}}$. For $t \in \mathcal{O}_\Sigma^\times$, read as a finite adele, $t/\bar t$ has the components t_w at $w\in\Sigma$, $\bar t_w^{-1}$ at $\bar w$ and 1 elsewhere, and $\psi_{\bar w} = 1$ for $w \in \Sigma$; so the weight formula of Definition 3.1.2 gives $\chi(t) = \prod_{w\in\Sigma}\psi_w(t_w \bmod w)$. Let $\varpi \in \mathcal{O}_\Sigma$ have a uniformiser ϖ_w as component at each $w\in\Sigma$, $R = \mathcal{O}_\Sigma/\varpi\mathcal{O}_\Sigma = \prod_{w\in\Sigma} k_w$, so $\#R = Q$, and $\psi_\Sigma(t) = \psi_{E,f}(\jmath\alpha\bar\alpha t)$ on E_Σ, dt the Haar probability measure of $\mathcal{O}_\Sigma$.

Step 0: a Gauss sum. By Lemma 4.1.3, $\widehat{\mathcal{O}}_E$ is its own annihilator under $(u,v)\mapsto\psi_{E,f}(\jmath\alpha\bar\alpha\bar u v)$; taking $u = \bar d$ for $d \in E_\Sigma$ (read as an adele) and v integral, $t\mapsto\psi_\Sigma(dt)$ is trivial on $\mathcal{O}_\Sigma$ if and only if $d\in\mathcal{O}_\Sigma$. Hence $\psi_R(t \bmod \varpi) = \psi_\Sigma(\varpi^{-1}t)$ is a well defined primitive additive character of R. The character χ^{-1}, read on R through reduction and extended by 0 to the nonunits, is a multiplicative character of R, and it is primitive in the sense of Lemma 6.2.39: if $r\neq 0$, some component $r_w \neq 0$; choose $u\in k_w^\times$ with $\psi_w(u)\neq 1$ and $c\in R$ with $c_w = (u-1)/r_w$, $c_{w'} = 0$ otherwise; then $\chi^{-1}(1+cr) = \psi_w(u)^{-1} \notin \{0,1\}$. Let $G = \sum_{u\in R}\chi^{-1}(u)\psi_R(u)$, so $|G|^2 = Q$ by Lemma 6.2.39 (T a point), and $\gamma_0 = Q^{-1}G$. We claim, for $d\in E_\Sigma$,

$$\int_{\mathcal{O}_\Sigma} \chi^{-1}(t)\,\psi_\Sigma(dt)\,dt = \gamma_0\,\chi(\varpi d) \ \text{ if } \varpi d \in \mathcal{O}_\Sigma^\times, \qquad = 0 \ \text{ otherwise.} \tag{G}$$

Indeed $\mathcal{O}_\Sigma$ is the disjoint union of the cosets $u+\varpi\mathcal{O}_\Sigma$ ($u\in R$), each of measure Q^{-1}, and χ^{-1} is constant on each. So the integral is $\sum_u \chi^{-1}(u)\psi_\Sigma(du)\int_{\varpi\mathcal{O}_\Sigma}\psi_\Sigma(dp)\,dp$; the inner integral of a character of the compact group $\varpi\mathcal{O}_\Sigma$ is Q^{-1} if $\varpi d\in\mathcal{O}_\Sigma$ and 0 otherwise. If $e=\varpi d\in\mathcal{O}_\Sigma$, then $\psi_\Sigma(du)=\psi_R(eu)$ and Lemma 6.2.39 with $S=\chi^{-1}$ gives $\sum_u\chi^{-1}(u)\psi_R(eu)=G\,\chi(e)$ if e is a unit and 0 otherwise.

Step 1: the compact point. Let $\kappa=(\kappa_\infty,\kappa_f)\in \mathrm{K}_{\max}(t')$, $f=\varphi^{\mathrm{pl}}_{A,\sigma'}(v,y)$ and $\Phi'=\Phi^{\mathrm{st}}_{\sigma',y(\mathrm{pr}_i)_\Sigma}$. As y and $(\mathrm{pr}_i)_\Sigma$ are integral (base-adaptedness), Φ' vanishes off the integral matrices and on them depends only on the reduction modulo ϖ; so $\Phi'^\sharp=\Phi_0^\natural$ for the modulus $\prod_{w\in\Sigma}w$ and a function Φ_0 on $r'\times n'$ matrices over R. The character $\alpha_{W'}=\nu^{-1}\upsilon^{\#n'/2}$ has weight γ_μ (υ has weight 1). By (5) and (6) of Lemma 4.1.1 (source point 1),

$$\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f=\alpha_{W'}(\det\kappa_f)\,\big(\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v\big)\otimes\big[\Phi'_\kappa\big]_\Sigma,\qquad \Phi'_\kappa(X)=\Phi'(\kappa_\Sigma^{-1}X),$$

$\kappa_\Sigma\in\mathrm{GL}_{r'}(\mathcal{O}_\Sigma)$ the components of κ_f at Σ. Replacing the rows X by $\kappa_\Sigma^{-1}X$ multiplies the matrix of (XD10) by an integral invertible block matrix of determinant $\det\kappa_\Sigma^{-1}$, so $\Phi'_\kappa=\chi(\det\kappa_\Sigma)\Phi'$. The finite idele $z=\det\kappa_f\in\mathrm{U}(1)(\mathbb{A})$ has infinite components 1 and integral finite components, so $\nu(z)=\prod_{w\in\Sigma}\psi_w(z_w \bmod w)=\chi(\det\kappa_\Sigma)$ and $\upsilon(z)=1$ ((WD3)); hence $\alpha_{W'}(\det\kappa_f)\chi(\det\kappa_\Sigma)=1$ and, with $v_\kappa=\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v$,

$$\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f=v_\kappa\otimes[\Phi']_\Sigma.$$

Step 2: line terms as slices along $D^\pm$. Let $a\in\mathbb{A}_E$ and $F\in\mathcal{M}_{W',V'}$. By (1) of Lemma 6.2.24, (1) of Lemma 6.2.44 for the plane splitting and (1) of Lemma 6.2.25,

$$\mathrm{Ln}^\pm_{A,X}(a)F=Z_{R^\pm}\big(\rho(l_{\mathbb{A}}^{R^\pm}a)Z^{\mathrm{pl}}F\big)=Z_{D^\pm}\big(\rho(i_{\mathbb{A}}^{\mathrm{pl}}l_{\mathbb{A}}^{R^\pm}a)F\big),$$

and $i_{\mathbb{A}}^{\mathrm{pl}}l_{\mathbb{A}}^{R^\pm}a$ is the frame $l_{\mathbb{A}}$ of the composite $D^\pm_{A,X}$ ((MX5)) applied to $ae_*\in\mathbb{A}_E^{q\sqcup\{*\}}$. So $\mathrm{Ln}^\pm_{A,X}(a)F$ is the slice $F[ae_*]$ along $D^\pm_{A,X}$. Since $m=m_{A,X}$ is block diagonal with block 1 at $*$, $ae_*=m^{-*}(ae_*)$; for $a=x\alpha_0$, $ae_*=\alpha_0(xe_*)$.

Step 3: the slice. By (1) of Lemma 6.2.38, $D^\pm_{A,X}$ is adapted at 1 in the basis m. Let ϵ be the number of (2) of Lemma 6.2.38 for $\mathfrak{c}$, σ, σ', and put $f_i=1$ ($i\in q$) and $f_*(t)=\epsilon\,\chi^{-1}(x_{f,\Sigma})\chi^{-1}(t)$, which are locally constant. By (2) of Lemma 6.2.38 with $a=x_{f,\Sigma}$, the hypothesis of Lemma 6.2.19 holds for the point xe_*, Φ' and $\Psi=\Phi^{\mathrm{st}}_{\sigma,y}$; both are locally constant with compact support, so $\Phi'^\sharp,\Psi^\sharp\in\mathcal{T}_\Sigma$ by Lemma 6.2.22. The vector xe_* has finite components 0 off $*$, so the integrals for $i\in q$ equal 1, and by (G) with $d=(\bar x_f)_\Sigma$

$$\int_{\mathcal{O}_\Sigma}\psi_\Sigma((\bar x_f)_\Sigma t)f_*(t)\,dt=\epsilon\,\gamma_0\,\chi^{-1}(x_{f,\Sigma})\,\chi(\varpi(\bar x_f)_\Sigma)\,\mathbf{1}[\varpi(\bar x_f)_\Sigma\in\mathcal{O}_\Sigma^\times].$$

As $\mathrm{rsl}_{D^\pm,m}(b_{x_\infty};\cdot)=\mathrm{Ln}^{\pm,\infty}_{A,X}(x_\infty)$ by (LN3), Lemma 6.2.19 and Steps 1, 2 give

$$\mathrm{Ln}^\pm_{A,X}(x\alpha_0)\big(\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f\big)=\mathrm{vf}(D^\pm_{A,X})\,\epsilon\,\gamma_0\,\Lambda'(x_f)\,\mathrm{Ln}^{\pm,\infty}_{A,X}(x_\infty)v_\kappa\otimes\big[\Phi^{\mathrm{st}}_{\sigma,y}\big]_\Sigma,$$

with $\Lambda'(x_f)=\mathbf{1}[x_f$ integral outside $\Sigma\cup\bar\Sigma]\,\chi^{-1}(x_{f,\Sigma})\,\chi(\varpi(\bar x_f)_\Sigma)\,\mathbf{1}[\varpi(\bar x_f)_\Sigma\in\mathcal{O}_\Sigma^\times]$.

Step 4: the shift and the constants. Let c be the finite idele with component $\overline{\varpi_w}\in E_{\bar w}$ at $\bar w$ for $w\in\Sigma$ and 1 elsewhere; $|c|=\prod_{w\in\Sigma}\mathrm{N}\bar w^{-1}=Q^{-1}$. Then $(x_fc)_\Sigma=x_{f,\Sigma}$, $(\overline{x_fc})_\Sigma=\varpi(\bar x_f)_\Sigma$, and x_fc is integral outside $\Sigma\cup\bar\Sigma$ exactly when x_f is; it is a unit at Σ exactly when $x_{f,\Sigma}$ is and a unit at $\bar\Sigma$ exactly when $\varpi(\bar x_f)_\Sigma$ is. Comparing with the definition of $\Lambda_{\mathfrak{c}}$ (χ^{-1} vanishes off the units), $\Lambda'(x_f)=\Lambda_{\mathfrak{c}}(x_fc)$. Put $l_\pm=\mathrm{vf}(D^\pm_{A,X})$, nonzero by (4) of Lemma 6.2.20 and independent of $\mathfrak{c}$, and $\gamma=\epsilon\gamma_0$, so $|\gamma|^2=Q^{-1}$. Applying the linear functional $\theta^{W,V}_{\alpha_W,\alpha_W}(\cdot)(g,h)$ gives the assertion. □

Lemma 6.2.38. *Let W', W, V', V, A, X be as above.*

1. *For both signs, $D^{\pm}_{A,X}$ is adapted at 1 in the basis $m_{A,X}$.*
2. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character with semilocal character $\chi = \chi_{\mathfrak{c}}$, b an index set and $\sigma\colon b \sqcup r \to n$, $\sigma'\colon b \sqcup r' \to n'$ bijections. Let $\mathcal{F}^{\pm}_{\Sigma}$ be the matrix of the components at Σ of the finite part of the frame $(l_{\mathbb{A}} m^{-*}_{A,X} \mid k_{\mathbb{A}} m_{A,X} \mid i_{\mathbb{A}})$ of $D^{\pm}_{A,X}$ (column blocks indexed by $q \sqcup \{*\}$, $q \sqcup \{*\}$, $r \times n$; values read as $r' \times n'$ matrices), $(\mathrm{pr}_i)_{\Sigma} \in \mathrm{M}_{n \times n'}(E_{\Sigma})$ the components at Σ of the finite part of the coordinate pr_i of A, and $e_* \in E_{\Sigma}^{q \sqcup \{*\}}$ the vector with entry 1 at $*$ and 0 elsewhere. Then there is $\epsilon \in \mathbb{C}$ with $|\epsilon| = 1$, depending only on A, X, σ, σ' and $\mathfrak{c}$, such that for both signs, all $y \in \mathrm{M}_{b \times n}(E_{\Sigma})$, $a \in E_{\Sigma}$, $z \in E_{\Sigma}^{q \sqcup \{*\}}$ and $Y \in \mathrm{M}_{r \times n}(E_{\Sigma})$*

$$\Phi^{\mathrm{st}}_{\sigma',\, y(\mathrm{pr}_i)_{\Sigma}}\big(\mathcal{F}^{\pm}_{\Sigma}\,(a e_*, z, Y)\big) = \epsilon \prod_{i \in q} \mathbf{1}_{\mathcal{O}_{\Sigma}}(z_i) \cdot \mathbf{1}_{\mathcal{O}_{\Sigma}}(z_*)\, \chi^{-1}(a)\, \chi^{-1}(z_*) \cdot \Phi^{\mathrm{st}}_{\sigma, y}(Y).$$

Proof. For adelic vectors y of V' and z of W' write $\langle y, z\rangle = y\, z^* \varepsilon_{s'}$, an adelic $r' \times n'$ matrix; it is linear in y and conjugate-linear in z. For rational $y \in E^{r'}$, $z \in E^{n'}$ the rational vector $y z^* J_{W'}$ of $\mathrm{Hom}(W', V')$ has the adelic coordinate $\langle x^{-1}_{V'} y, x^{-1}_{W'} z\rangle$, because $J_{W'} x_{W'} = (x^{-1}_{W'})^* \varepsilon_{s'}$. Write k_X, l_X, i_X and k_A, l_A, i_A for the adelic frames of X and A; then $x^{-1}_{W'}(\text{rational } i_A) = i_A x^{-1}_{W}$ and likewise for X. Recall $J^{-1}(x^{-1})^* = x\varepsilon$ for every space with a point.

Step 1: the frame. By (LN3) the rational frames of $D^{\pm}_{A,X}$ consist of rank-one maps $y z^* J_{W'}$, and the line basis $m = m_{A,X}$ is block diagonal with blocks $\bar{x}_W$ (n), 1 (o), $(x^{-1}_V)^*$ (r), 1 $(*)$; on the l-block the frame is multiplied by m^{-*}, with blocks $(x^{-1}_W)^{\mathsf{T}}$, 1, x_V, 1. Using the conjugate-linearity in z, $J^{-1}_W (x^{-1}_W)^* = x_W \varepsilon_s$ and $J^{-1}_V (x^{-1}_V)^* = x_V \varepsilon_t$, the columns of the adelic frame $\mathcal{F}^{\pm} = (l_{\mathbb{A}} m^{-*} \mid k_{\mathbb{A}} m \mid i_{\mathbb{A}})$ of $D^{\pm}_{A,X}$ are, with $\varepsilon_s(j)$, $\varepsilon_t(m')$ the diagonal entries (signs at the infinite places, 1 at the finite places):

- l-block: $\varepsilon_s(j)\langle l_X, i_A e_j\rangle$ $(j \in n)$, $\langle l_X, l_A\rangle$ (o), $\langle i_X e_{m'}, l_A\rangle$ $(m' \in r)$, and at $*$: $\langle k_X, l_A\rangle$ for $+$, $\langle l_X, k_A\rangle$ for $-$;
- k-block: $\langle k_X, i_A e_j\rangle$, $\langle k_X, k_A\rangle$, $\varepsilon_t(m')\langle i_X e_{m'}, k_A\rangle$, and at $*$: $\langle l_X, k_A\rangle$ for $+$, $\langle k_X, l_A\rangle$ for $-$;
- i-block: $\varepsilon_s(j)\langle i_X e_{m'}, i_A e_j\rangle$ $((m', j) \in r \times n)$.

So, up to signs, the columns are the $\langle y, z\rangle$ with y running over the columns of $B_X = (l_X \mid k_X \mid i_X)$ and z over those of $B_A = (l_A \mid k_A \mid i_A)$, each pair once (there are $(\#r + 2)(\#n + 2)$ columns).

Step 2: proof of (1). As A and X are base-adapted, B_A and B_X have orthonormal columns at every infinite place and entries in $\widehat{\mathcal{O}}_E$ at the finite places. At an infinite place, the euclidean inner product of the vectorisations of $\langle y, z\rangle$ and $\langle y', z'\rangle$ is $(y'^* y)\,\overline{(z'^* z)}$ ($\varepsilon_{s'}$ is unitary), so the columns of $\mathcal{F}^{\pm}$ are orthonormal; at a finite place $\varepsilon_{s'} = 1$ and the entries $y_a \overline{z_b}$ are integral because complex conjugation preserves $\widehat{\mathcal{O}}_E$. This is adaptedness at 1 in the basis m ((MX5)).

Step 3: the frame at Σ. At the finite places $\langle y, z\rangle = y z^*$. Let K_X, L_X, I_X be the components at Σ of k_X, l_X, i_X, put $P_X = (K_X \mid I_X \mid L_X) \in \mathrm{M}_{r'}(\mathcal{O}_{\Sigma})$, and let $R = (\mathrm{pr}_k; \mathrm{pr}_i; \mathrm{pr}_l)_{\Sigma} \in \mathrm{M}_{n'}(\mathcal{O}_{\Sigma})$ be the rows of the components at Σ of the coordinates of A, so that $(\mathrm{pr}_k)_{\Sigma} = (l^*_A)_{\Sigma}$, $(\mathrm{pr}_l)_{\Sigma} = (k^*_A)_{\Sigma}$, $(\mathrm{pr}_i)_{\Sigma} = (i^*_A)_{\Sigma}$. The identities $\mathrm{pr}_{\bullet}\, \bullet_{\mathbb{A}} = 1$, $\mathrm{pr}_{\bullet}\, \bullet'_{\mathbb{A}} = 0$ and $k_{\mathbb{A}}\mathrm{pr}_k + i_{\mathbb{A}}\mathrm{pr}_i + l_{\mathbb{A}}\mathrm{pr}_l = 1$ of (MX1), for A and for X, hold componentwise; with base-adaptedness they give $R \in \mathrm{GL}_{n'}(\mathcal{O}_{\Sigma})$ and $P_X \in \mathrm{GL}_{r'}(\mathcal{O}_{\Sigma})$. By Step 1, for $a \in E_{\Sigma}$, $z \in E_{\Sigma}^{q \sqcup \{*\}}$, $Y \in \mathrm{M}_{r \times n}(E_{\Sigma})$, with $z_n = (z_j)_{j \in n}$ (a row), z_o, $z_r = (z_{m'})_{m' \in r}$ (a column) and z_*,

$$\mathcal{F}^{\pm}_{\Sigma}(a e_*, z, Y) = P_X\, N^{\pm}\, R, \qquad N^{+} = \begin{pmatrix} a & z_n & z_o \\ 0 & Y & z_r \\ 0 & 0 & z_* \end{pmatrix}, \qquad N^{-} = \begin{pmatrix} z_* & z_n & z_o \\ 0 & Y & z_r \\ 0 & 0 & a \end{pmatrix}$$

(rows of $N^{\pm}$ indexed by o, r, o; columns by o, n, o).

Step 4: proof of (2). Let $M = \mathcal{F}_{\Sigma}^{\pm}(ae_*, z, Y)$ and $\tilde{M} \in \mathrm{M}_{n'}(E_\Sigma)$ the matrix whose row $\sigma'(j)$ is row j of $y(\mathrm{pr}_i)_\Sigma$ ($j \in b$) and whose row $\sigma'(i)$ is row i of M ($i \in r'$). Let $T^{\pm} \in \mathrm{M}_{\{o\}\sqcup n\sqcup\{o\}}(E_\Sigma)$ be $N^{\pm}$ with the middle block row replaced by the n rows of the matrix $\langle y; Y\rangle_\sigma$ whose row $\sigma(j)$ is row j of y and row $\sigma(m')$ is row m' of Y, and with the last column z_r replaced by the column with entries 0 at $\sigma(b)$ and $z_{m'}$ at $\sigma(m')$; let $G \in \mathrm{M}_{n'\times(\{o\}\sqcup n\sqcup\{o\})}(\mathcal{O}_\Sigma)$ have row $\sigma'(j)$ equal to $(0, e_{\sigma(j)}^{\mathsf{T}}, 0)$ ($j \in b$) and row $\sigma'(i)$ equal to row i of (K_X, I_X placed in the columns $\sigma(r)$, L_X) ($i \in r'$). Multiplying out, $GT^{\pm}$ has rows $(0, y_j, 0)$ at $\sigma'(j)$ and the rows of $P_X N^{\pm}$ at $\sigma'(r')$, so by Step 3

$$\tilde{M} = G\,T^{\pm}\,R.$$

Up to permutations of rows and columns, G is the block diagonal matrix with blocks 1_b and P_X, so $G \in \mathrm{GL}_{n'}(\mathcal{O}_\Sigma)$, and $RG \in \mathrm{GL}_{n'}(\mathcal{O}_\Sigma)$. Hence $\tilde{M}$ is integral if and only if $T^{\pm}$ is, and $\det\tilde{M} = \det(RG)\det T^{\pm}$ with $\det(RG) \in \mathcal{O}_\Sigma^\times$. $T^{\pm}$ is block upper triangular with diagonal blocks a, $\langle y; Y\rangle_\sigma$, z_* (in some order), so $\det T^{\pm} = a\,z_*\det\langle y; Y\rangle_\sigma$, and $T^{\pm}$ is integral exactly when a, all z_i and $\langle y; Y\rangle_\sigma$ are. As χ^{-1} is multiplicative on $\mathcal{O}_\Sigma$ (a product of integral elements is a unit only if each factor is) and vanishes on $E_\Sigma \setminus \mathcal{O}_\Sigma^\times$, (XD10) gives

$$\Phi^{\mathrm{st}}_{\sigma', y(\mathrm{pr}_i)_\Sigma}(M) = \chi^{-1}(\det(RG))\prod_{i\in q}\mathbf{1}_{\mathcal{O}_\Sigma}(z_i)\cdot\mathbf{1}_{\mathcal{O}_\Sigma}(z_*)\,\chi^{-1}(a)\chi^{-1}(z_*)\cdot\Phi^{\mathrm{st}}_{\sigma,y}(Y).$$

Put $\epsilon = \chi^{-1}(\det(RG))$; RG depends only on A, X, σ, σ' and Σ, and $|\epsilon| = 1$ because χ is unitary on $\mathcal{O}_\Sigma^\times$ ($\chi(t) = \nu(t/\bar{t})$). □

Lemma 6.2.39. *Let R be a finite commutative ring and T a finite set; $\mathrm{M}_{X\times Y}(R)$ denotes the $X \times Y$ matrices over R, $\mathrm{M}_T(R) = \mathrm{M}_{T\times T}(R)$, and $\mathrm{GL}_T(R)$ its group of units. Let $\psi_R\colon R \to \mathbb{C}^\times$ be an additive character which is **primitive**: for every $r \neq 0$ the character $t \mapsto \psi_R(rt)$ is nontrivial. Let $\chi\colon R \to \mathbb{C}$ be a **multiplicative character** ($\chi(1) = 1$, $\chi(rr') = \chi(r)\chi(r')$, and $\chi(r) = 0$ exactly when r is not a unit) which is **primitive**: for every $r \neq 0$ there is $c \in R$ with $\chi(1 + cr) \notin \{0, 1\}$. Put $\chi^{-1}(r) = \chi(r)^{-1}$ for units r and $\chi^{-1}(r) = 0$ otherwise, and*

$$G = \sum_{u\in\mathrm{M}_T(R)}\chi(\det u)\,\psi_R(\mathrm{tr}\,u).$$

Then $|G|^2 = (\#R)^{|T|^2}$, and every function $S\colon \mathrm{M}_T(R) \to \mathbb{C}$ with $S(gu) = \chi(\det g)\,S(u)$ for all $g \in \mathrm{GL}_T(R)$ and $u \in \mathrm{M}_T(R)$ satisfies

$$\sum_{u\in\mathrm{M}_T(R)} S(u)\,\psi_R(\mathrm{tr}(yu)) = G\,\chi^{-1}(\det y)\,S(1) \qquad (y \in \mathrm{M}_T(R)).$$

In particular the left side vanishes when y is not invertible.

Proof. **Step 1: orthogonality and inversion.** For $\rho \in \mathrm{M}_{Y\times X}(R)$, $\mathrm{tr}(\rho v) = \sum_{i,j}\rho_{ji}v_{ij}$, so $\sum_{v\in\mathrm{M}_{X\times Y}(R)}\psi_R(\mathrm{tr}(\rho v)) = \prod_{i,j}\sum_{t\in R}\psi_R(\rho_{ji}t)$, which is $\#\mathrm{M}_{X\times Y}(R)$ if $\rho = 0$ and 0 otherwise, because a nontrivial character of the finite group $(R, +)$ sums to 0 and $t \mapsto \psi_R(\rho_{ji}t)$ is nontrivial for $\rho_{ji} \neq 0$ by primitivity. Consequently, for f on $\mathrm{M}_{X\times Y}(R)$ and $y \in \mathrm{M}_{X\times Y}(R)$, using $\mathrm{tr}(uv) + \mathrm{tr}(yu) = \mathrm{tr}((v + y)u)$,

$$\hat{\hat{f}}(y) = \sum_v f(v)\sum_u\psi_R(\mathrm{tr}((v + y)u)) = \#\mathrm{M}_{X\times Y}(R)\;f(-y).$$

Step 2: equivariance of $\hat{S}$. For $g \in \mathrm{GL}_T(R)$ and $z \in \mathrm{M}_T(R)$, substituting $u \mapsto gu$ (a bijection of $\mathrm{M}_T(R)$),

$$\chi(\det g)\,\hat{S}(zg) = \sum_u S(gu)\,\psi_R(\mathrm{tr}(zgu)) = \hat{S}(z).$$

Step 3: $\hat{S}$ vanishes off $\mathrm{GL}_T(R)$. Let z be a non-invertible matrix. Left multiplication by z on the finite set $\mathrm{M}_T(R)$ is not injective: otherwise it is bijective, some D has $zD = 1$, so $\det z$ is a unit and z is invertible. Hence there is $D \neq 0$ with $zD = 0$; choose an entry $D_{ij} \neq 0$ and, by primitivity of χ, $c \in R$ with $\chi(1 + cD_{ij}) \notin \{0, 1\}$. Let v be the column j of D, so $zv = 0$, and $g = 1 + c\,v\,e_i^{\mathsf{T}}$ (e_i the i-th unit vector). By the matrix determinant lemma $\det g = 1 + c\,e_i^{\mathsf{T}} v = 1 + cD_{ij}$, which is a unit since its χ-value is nonzero; so $g \in \mathrm{GL}_T(R)$, and $zg = z + c\,(zv)\,e_i^{\mathsf{T}} = z$. Step 2 gives $\chi(1 + cD_{ij})\hat{S}(z) = \hat{S}(z)$, hence $\hat{S}(z) = 0$.

Step 4: the formula up to the constant. For $y = g$ invertible, Step 2 with $z = 1$ gives $\hat{S}(g) = \chi(\det g)^{-1}\hat{S}(1)$; with Step 3, $\hat{S}(y) = \chi^{-1}(\det y)\,\hat{S}(1)$ for all y.

Step 5: the constant. The values of χ on the units are roots of unity (the units form a finite group), so $\chi^{-1} = \overline{\chi}$; and $\psi_R(-t) = \overline{\psi_R(t)}$. By Step 1 and Step 4,

$$\#\mathrm{M}_T(R)\,S(1) = \hat{\hat{S}}(-1) = \hat{S}(1)\sum_y \chi^{-1}(\det y)\,\psi_R(-\mathrm{tr}\,y) = \hat{S}(1)\,\overline{G}.$$

The function $S_0(u) = \chi(\det u)$ satisfies the hypothesis, with $S_0(1) = 1$ and $\hat{S}_0(1) = G$; so $|G|^2 = \#\mathrm{M}_T(R) = (\#R)^{|T|^2}$. In particular $G \neq 0$, and for general S, $\hat{S}(1) = \#\mathrm{M}_T(R)\,S(1)/\overline{G} = G\,S(1)$. With Step 4 this is the assertion. □

Lemma 6.2.40. *Let W', W, V', V, A, X be as above and assume that $\#n$ is even. Let ν be an automorphic character of $\mathrm{U}(1)$, $\alpha_W = \nu^{-1}\upsilon^{\#n/2}$ and $\alpha_{W'} = \nu^{-1}\upsilon^{\#n'/2}$. Let $f \in \mathcal{M}_{W',V'}$, $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(t)$, $\kappa \in \mathrm{K}_{\max}(t')$, and for $\alpha \in \mathbb{A}_E$ put*

$$\lambda^{\pm}(\alpha) = \theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^{\pm}_{A,X}(\alpha)(\omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f)\Big)(g,h).$$

If $\lambda^+(0) = \lambda^-(0) = 0$, then for every $a \in \mathbb{A}_E^\times$ the series $\sum_{\xi\in E^\times}\lambda^+(\xi a)$ and $\sum_{\xi\in E^\times}\lambda^-(\xi\bar{a}^{-1})$ converge absolutely and

$$|a|\sum_{\xi\in E^\times}\lambda^+(\xi a) = \sum_{\xi\in E^\times}\lambda^-(\xi\bar{a}^{-1}).$$

Proof. Fix $a \in \mathbb{A}_E^\times$ and put $\varphi = \omega_{\alpha_{W'},\alpha_{W'}}(1,\kappa)f$, $\gamma = \mathrm{lev}_A(1,g)$, $\eta = \mathrm{lev}^{\mathrm{ln}}_X(a,h)$ and $F = \omega_{\alpha_{W'},\alpha_{W'}}(\gamma,\eta)\varphi \in \mathcal{M}_{W',V'}$. As $\#n' = \#n + 2$, $\alpha_{W'} = \alpha_W\upsilon$. By (2) of Lemma 6.2.9 for the character α_W, with $u = 1$ and $c = a$ (so $x = a$), and by the definition of theta kernels ((WC4) of Definition 4.1.15), for every $\xi \in E$

$$\theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^{+}_{A,X}(\xi)F) = \frac{|a|^{-\#n/2}}{\alpha_W[\#n](a)}\,\lambda^+(\xi a),$$
$$\theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^{-}_{A,X}(\xi)F) = \frac{|a|^{-(\#n+2)/2}}{\alpha_W[\#n](a)}\,\lambda^-(\xi\bar{a}^{-1}).$$

By (2) of Lemma 6.2.24 applied to F, the series $\sum_{\xi\in E}\theta_{\mathrm{Hom}(W,V)}(\mathrm{Ln}^{\pm}_{A,X}(\xi)F)$ converge absolutely and have the same sum. Multiplying by the nonzero number $\alpha_W[\#n](a)\,|a|^{(\#n+2)/2}$, the series $\sum_{\xi\in E}\lambda^+(\xi a)$ and $\sum_{\xi\in E}\lambda^-(\xi\bar{a}^{-1})$ converge absolutely and

$$|a|\sum_{\xi\in E}\lambda^+(\xi a) = \sum_{\xi\in E}\lambda^-(\xi\bar{a}^{-1}).$$

The terms at $\xi = 0$ are $\lambda^+(0) = \lambda^-(0) = 0$, so the same holds for the sums over $\xi \in E^\times$. $\square$

Lemma 6.2.41. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character with semilocal character $\chi = \chi_{\mathfrak{c}}$. For a finite adele a let $a_\Sigma \in E_\Sigma$ be its components at the places of Σ and $\bar{a}$ its conjugate, and put*

$$\Lambda_{\mathfrak{c}}(a) = \chi(a_\Sigma)^{-1}\,\chi\big((\bar{a})_\Sigma\big) \quad \text{if } a \text{ is integral at every finite place and a unit at every place of } \Sigma \cup \bar{\Sigma},$$
$$\Lambda_{\mathfrak{c}}(a) = 0 \quad \text{otherwise.}$$

Let ρ be a Haar measure on $\mathbb{A}_{E,f}^\times$ and $x > 1$. Then the function $a \mapsto \Lambda_{\mathfrak{c}}(a)\,\tilde{\nu}(a)\,|a|^x$ on $\mathbb{A}_{E,f}^\times$ (a read as an idele with infinite components 1) is ρ-integrable, and

$$\int_{\mathbb{A}_{E,f}^\times} \Lambda_{\mathfrak{c}}(a)\,\tilde{\nu}(a)\,|a|^x\,d\rho(a) = \rho(\widehat{\mathcal{O}}_E^\times)\,L^\Sigma(x,\tilde{\nu}).$$

Moreover $x \mapsto L^\Sigma(x,\tilde{\nu})$ is continuous and nowhere zero on $[1,\infty)$.

Proof. Let ψ be the tame part of ν and μ its weight; $\psi_w \neq 1$ exactly for $w \in \Sigma$, and $\Sigma \cap \bar{\Sigma} = \emptyset$, so $\psi_{\bar{w}} = 1$ for $w \in \Sigma$. For a finite adele t write $\bar{t}_{w'} = \overline{t_{\bar{w}'}}$ for the component of $\bar{t}$ at w'.

Step 1: χ and $\tilde{\nu}$ on units. For $z \in \mathrm{U}(1)(\mathbb{A})$ with infinite components 1 and integral finite components, the definition of weight and tame part (Definition 3.1.2) gives $\nu(z) = \prod_w \psi_w(z \bmod w)$. For $t \in \mathcal{O}_\Sigma^\times$, read as a finite adele, $t/\bar{t}$ has components t_w at $w \in \Sigma$, $\overline{t_w}^{-1}$ at $\bar{w}$ and 1 elsewhere, so

$$\chi(t) = \nu(t/\bar{t}) = \prod_{w \in \Sigma} \psi_w(t_w \bmod w).$$

For $u \in \widehat{\mathcal{O}}_E^\times$, likewise $\tilde{\nu}(u) = \nu(u/\bar{u}) = \prod_{w\in\Sigma} \psi_w(u_w \bmod w)\,\psi_w(\bar{u}_w \bmod w)^{-1} = \chi(u_\Sigma)\,\chi((\bar{u})_\Sigma)^{-1}$. Hence

$$\Lambda_{\mathfrak{c}}(u)\,\tilde{\nu}(u) = 1 \qquad (u \in \widehat{\mathcal{O}}_E^\times),$$

and $\tilde{\nu}(u) = 1$ if moreover u has components 1 at $\Sigma \cup \bar{\Sigma}$. The support condition of $\Lambda_{\mathfrak{c}}$ is invariant under multiplication by $\widehat{\mathcal{O}}_E^\times$ and χ is multiplicative, so $\Lambda_{\mathfrak{c}}(au) = \Lambda_{\mathfrak{c}}(a)\Lambda_{\mathfrak{c}}(u)$; with $|u| = 1$ the function $F(a) = \Lambda_{\mathfrak{c}}(a)\tilde{\nu}(a)|a|^x$ satisfies $F(au) = F(a)$ for $u \in \widehat{\mathcal{O}}_E^\times$.

Step 2: the integral. Fix a uniformiser π_w at every finite place w. The support of $\Lambda_{\mathfrak{c}}$ in $\mathbb{A}_{E,f}^\times$ is the disjoint union, over the nonzero integral ideals $\mathfrak{a}$ of $\mathcal{O}_E$ prime to the places of $\Sigma \cup \bar{\Sigma}$, of the cosets $a_{\mathfrak{a}}\widehat{\mathcal{O}}_E^\times$, where $a_{\mathfrak{a}}$ has components $\pi_w^{\mathrm{ord}_w\,\mathfrak{a}}$ at $w \notin \Sigma \cup \bar{\Sigma}$ and 1 at $\Sigma \cup \bar{\Sigma}$. On $a_{\mathfrak{a}}\widehat{\mathcal{O}}_E^\times$ the function F is constant (Step 1) and equal to $F(a_{\mathfrak{a}}) = \tilde{\nu}(a_{\mathfrak{a}})\,\mathrm{N}\mathfrak{a}^{-x}$, as $\Lambda_{\mathfrak{c}}(a_{\mathfrak{a}}) = \chi(1)^{-1}\chi(1) = 1$; by Step 1, $\tilde{\nu}$ is trivial on the units at $w \notin \Sigma \cup \bar{\Sigma}$, so $\tilde{\nu}(a_{\mathfrak{a}}) = \tilde{\nu}(\mathfrak{a})$ is the value of $\tilde{\nu}$ on the ideal $\mathfrak{a}$, independent of the uniformisers. The cosets have measure $\rho(\widehat{\mathcal{O}}_E^\times) \in (0,\infty)$, $\widehat{\mathcal{O}}_E^\times$ being compact and open. By Tonelli, $\int |F|\,d\rho = \rho(\widehat{\mathcal{O}}_E^\times)\sum_{\mathfrak{a}} \mathrm{N}\mathfrak{a}^{-x} < \infty$ (the Dedekind zeta function of E converges for $x > 1$), so F is integrable, and

$$\int F\,d\rho = \rho(\widehat{\mathcal{O}}_E^\times)\sum_{\mathfrak{a}} \tilde{\nu}(\mathfrak{a})\,\mathrm{N}\mathfrak{a}^{-x} = \rho(\widehat{\mathcal{O}}_E^\times)\prod_{w \notin \Sigma\cup\bar{\Sigma}} \big(1 - \tilde{\nu}(\pi_w)\mathrm{N}w^{-x}\big)^{-1} = \rho(\widehat{\mathcal{O}}_E^\times)L^\Sigma(x,\tilde{\nu}),$$

by unique factorisation of ideals and absolute convergence.

Step 3: continuity and nonvanishing. $\tilde{\nu}$ is a unitary Hecke character of E: it is continuous, of modulus 1, and trivial on $E^\times$ because $\xi/\bar{\xi} \in \mathrm{U}(1)(E)$. At the infinite places $\tilde{\nu}(a) = \prod_{v\in\Phi}(a_v/|a_v|)^{2\mu(v)}$ (the weight applied to $a/\bar{a}$), and $\mu(v) > 0$ (XD4), so $\tilde{\nu}$ is not of the form $|\cdot|^{i\tau}$. By Step 1, $\tilde{\nu}$ is ramified at every place of $\Sigma \cup \bar{\Sigma}$ (on units at $w \in \Sigma$ it is $\psi_w(u_w \bmod w) \neq 1$ for suitable u, and at $\bar{w}$ it is $\psi_w(\overline{u_{\bar{w}}} \bmod w)^{-1}$), so the Euler factors of

$L(s,\tilde\nu)$ at these places are 1 and $L^\Sigma(s,\tilde\nu)=L(s,\tilde\nu)$ for $\operatorname{Re}s>1$. By Theorem A.1.12 (3), $L(s,\tilde\nu)$ continues holomorphically to $\operatorname{Re}s\ge 1$ without zeros there; its restriction to $[1,\infty)$ is continuous and nowhere zero, and its value at 1 is the value of (XD7). □

Lemma 6.2.42. *Let W',W,V',V, A, X be as above, let b be an index set with a bijection $\sigma\colon b\sqcup r\to n$, and let $\mu\colon\Phi\to\mathbb{Z}$. Let $\mathfrak{c}=(\nu,\Sigma)$ be a split tame character of weight μ, $\alpha_W=\nu^{-1}\upsilon^{\lfloor\#n/2\rfloor}$, $v\in\mathcal{F}_{W',V'}$ a Schwartz vector, $y\in\mathrm{M}_{b\times n}(E_\Sigma)$, $g\in\mathrm{G}(s)$, and $\pm$ a sign. For real $x>0$ let*

$$k_x(h,\kappa,a)=\prod_{w\in\Phi}\Big(\frac{a_w}{|a_w|}\Big)^{2\mu(w)}|a_w|^{2x}\;\theta^{W,V}_{\alpha_W,\alpha_W}\Big(\mathrm{Ln}^{\pm,\infty}_{A,X}(a)\big(\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v\big)\otimes\big[\Phi^{\mathrm{st}}_{\sigma,y}\big]_\Sigma\Big)(g,h)$$

for $h\in\mathrm{G}(t)$, $\kappa\in\mathrm{K}_{\max}(t')$ with infinite component κ_∞, and $a\in(\mathbb{C}^\times)^\Phi$. Then for every $x>0$: the cone integral $\mathrm{Cone}^{\pm}_{A,X,\mu}(x;v)$ is defined and is a Schwartz vector; k_x is integrable on $[\mathrm{U}(V)]\times\mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi$; and

$$\int_{[\mathrm{U}(V)]\times\mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi}k_x(h,\kappa,a)\,dh\,d\kappa\,d^\times a=\theta^{\mathrm{lg}}_{\mathfrak{c}}\big(W,V;\mathrm{Cone}^{\pm}_{A,X,\mu}(x;v),\Phi^{\mathrm{st}}_{\sigma,y}\big)(g).$$

Moreover this integral is a continuous function of $x\in[1,\infty)$.

Proof. Fix $x>0$ and the sign $\pm$. For $\kappa\in\mathrm{K}_{\max}(t')$ and $a\in(\mathbb{C}^\times)^\Phi$ put

$$e_x(a)=\prod_w(a_w/|a_w|)^{2\mu(w)}|a_w|^{2x},$$

so $|e_x(a)|=\prod_w|a_w|^{2x}$, and

$$c(\kappa,a)=\mathrm{Ln}^{\pm,\infty}_{A,X}(a)\big(\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v\big)\in\mathcal{F}_{W,V},\qquad F_x(\kappa,a)=e_x(a)\,c(\kappa,a),$$

the integrand of $\mathrm{Cone}^{\pm}_{A,X,\mu}(x;v)$ (LN4). Let $f_0=[\Phi^{\mathrm{st}}_{\sigma,y}]^\sharp\otimes_\Sigma v^0$, so that $w\otimes[\Phi^{\mathrm{st}}_{\sigma,y}]_\Sigma=w\otimes f_0$, and for $h\in\mathrm{G}(t)$ let $\Lambda_h(w)=\theta^{W,V}_{\alpha_W,\alpha_W}(w\otimes f_0)(g,h)$ ($w\in\mathcal{F}_{W,V}$); then $k_x(h,\kappa,a)=\Lambda_h(F_x(\kappa,a))$ by linearity.

Step 1: three facts on Fock models. (a) For $c\in\mathcal{F}_\varepsilon$ and every z, $|c(z)|\le\|c\|_1$, by the reproducing identity of (WR5) and $|\beta^\infty_\varepsilon e^\infty|\le 1$. Hence evaluations are bounded functionals, $\mathcal{F}_\varepsilon$ is closed in $L^1(\nu_\iota)$ (the reproducing identity passes to L^1-limits, which converge pointwise), a Bochner integral $\int F\,d\lambda$ of an integrable $\mathcal{F}_\varepsilon$-valued F lies in $\mathcal{F}_\varepsilon$ with $(\int F\,d\lambda)(z)=\int F(p)(z)\,d\lambda(p)$, and by Tonelli $\mathrm{mom}_N(\int F\,d\lambda)\le\int\mathrm{mom}_N(F(p))\,d\lambda(p)$. (b) Let $u\in\mathrm{U}(\operatorname{diag}\varepsilon)$ with $u^*u=1$. Then $\operatorname{diag}(\varepsilon)u=(u^*)^{-1}\operatorname{diag}(\varepsilon)=u\operatorname{diag}(\varepsilon)$, so u is block diagonal for the signs and u_- is unitary; moreover $\beta^\infty_\varepsilon(uy,z)=\beta^\infty_\varepsilon(y,u^{-1}z)$ and $e^\infty(z-uy)=e^\infty(u^{-1}z-y)$, so the reproducing identity at $u^{-1}z$ gives $(\omega^\infty_\varepsilon(u)c)(z)=\overline{\det u_-}\,c(u^{-1}z)$. As $|\det u_-|=1$ and ν_ι and the norm are invariant under u, $\mathrm{mom}_N(\omega^\infty_\varepsilon(u)c)=\mathrm{mom}_N(c)$. (c) For $\kappa\in\mathrm{K}_{\max}(t')$ the element $u=\bigoplus_w\kappa_w\otimes 1$ of (WR5) acting on $\mathbb{C}^{\Phi\times r'\times n'}$ satisfies $u^*u=1$ and preserves the signs $t'\otimes s'$, and $|\det\kappa_w|=1$; by (b), $\mathrm{mom}_N(\Omega_{\gamma_\mu,0}(1,\kappa_\infty)v)=\mathrm{mom}_N(v)$ for every N.

Step 2: decay of the line terms. By (1) of Lemma 6.2.38, $D^{\pm}_{A,X}$ is adapted at 1 in the basis $m_{A,X}$, so (1) of Lemma 6.2.43, applied with the point b_a (whose norm is $\|a\|$) and with Step 1 (c), gives for all $N,L\in\mathbb{N}$ a constant $C_{N,L}$ with

$$(1+\|a\|)^L\,\mathrm{mom}_N\big(c(\kappa,a)\big)\le C_{N,L}\,\mathrm{mom}_{N+L}(v)\qquad(\kappa,a).\tag{6.10}$$

Step 3: an integral in a. For $x_0\in(0,\infty)$, $x_1\ge x_0$ and an integer $L_0>2x_1$, put $L=dL_0$. Since $1+\|a\|\ge 1+|a_w|$ for each w, $(1+\|a\|)^{-L}\le\prod_w(1+|a_w|)^{-L_0}$, and

$$\int_{(\mathbb{C}^\times)^\Phi}\prod_w(|a_w|^{2x_0}+|a_w|^{2x_1})(1+\|a\|)^{-L}\,d^\times a\le\Big(2\pi\int_0^\infty(\varrho^{2x_0}+\varrho^{2x_1})\varrho^{-1}(1+\varrho)^{-L_0}\,d\varrho\Big)^d<\infty.$$

Step 4: measurability. The map $\kappa \mapsto \Omega_{\gamma_\mu,0}(1,\kappa_\infty)v$ is continuous ((2) of Lemma 4.1.1 for $\omega_\varepsilon^\infty$, and the determinant factors are continuous). By (MX7), $\mathrm{rsl}_{D,m}(b;u') = Z_{D,m}^\infty(\rho^\infty(P_0 b)u')$ for the fixed complex matrix $P_0 = (l_{\mathbb{A}}(m^{-1})^*)_\infty$, where $Z_{D,m}^\infty$ is a bounded operator ((1) of Lemma 6.2.43 with $M = N = 0$ at the point 0) and $(y,u') \mapsto \rho^\infty(y)u'$ is continuous (Proposition 4.1.14: strongly continuous and isometric). Hence c and F_x are continuous on $\mathrm{K}_{\max}(t') \times (\mathbb{C}^\times)^\Phi$, a second countable space, and so strongly measurable. Likewise $(h,w) \mapsto \Lambda_h(w)$ is continuous: $w \mapsto w \otimes f_0$ is linear with $\|w \otimes f_0\| \le \|w\|_1 \|f_0\|$ (ρ is isometric), $(h,f) \mapsto \omega_{\alpha_W,\alpha_W}(g,h)f$ is continuous and $\theta_{\mathrm{Hom}(W,V)}$ is bounded; so k_x is continuous on $\mathrm{G}(t) \times \mathrm{K}_{\max}(t') \times (\mathbb{C}^\times)^\Phi$, and it is left Γ_V-invariant in h by Lemma 6.2.5.

Step 5: the cone integral is defined and is a Schwartz vector. By (6.10) with the L of Step 3 for $x_0 = x_1 = x$,

$$\int \mathrm{mom}_N(F_x(\kappa,a))\, d\kappa\, d^\times a \le C_{N,L}\, \mathrm{mom}_{N+L}(v) \int \prod_w |a_w|^{2x}(1+\|a\|)^{-L}\, d^\times a < \infty$$

for every N, v being a Schwartz vector. For $N = 0$ this is $\int \|F_x\|_1 < \infty$: with Step 4, F_x is Bochner integrable and $\mathrm{Cone}^\pm_{A,X,\mu}(x;v) \in \mathcal{F}_{W,V}$ is defined; by Step 1 (a) all its moments are finite.

Step 6: the kernel is integrable. The function f_0 comes from $\Phi^{\mathrm{st}}_{\sigma,y}$, which is locally constant with compact support (it is supported on integral matrices, where it is χ^{-1} of a polynomial, χ^{-1} being locally constant on $\mathcal{O}_\Sigma^\times$ and 0 elsewhere), so $[\Phi^{\mathrm{st}}_{\sigma,y}]^\sharp \in \mathcal{T}_\Sigma$ by Lemma 6.2.22. If $\Phi^{\mathrm{st}}_{\sigma,y}(Y) \ne 0$, the $n \times n$ matrix formed from the rows of y and of Y (XD10) is invertible over $\mathcal{O}_\Sigma$, so the rows of Y_w are linearly independent and Y_w has a right inverse for every $w \in \Sigma$ ($\Sigma \ne \emptyset$). By (1) of Lemma 6.2.27 with $N = 0$ there are $M, B \in \mathbb{N}$, $C_1 \ge 0$ with $|\Lambda_h(w)| \le C_1\, \mathrm{mom}_M(w)\, \mathrm{ht}_W(g)^B$ for all h and all w with $\mathrm{mom}_M(w) < \infty$. With (6.10),

$$|k_x(h,\kappa,a)| \le C_1 C_{M,L}\, \mathrm{ht}_W(g)^B\, \mathrm{mom}_{M+L}(v) \prod_w |a_w|^{2x}(1+\|a\|)^{-L}. \tag{6.11}$$

The right side does not depend on (h,κ) and is integrable in a (Step 3); $[\mathrm{U}(V)]$ has finite volume (Theorem 4.2.18) and $\mathrm{K}_{\max}(t')$ mass 1. So k_x is integrable on $[\mathrm{U}(V)] \times \mathrm{K}_{\max}(t') \times (\mathbb{C}^\times)^\Phi$.

Step 7: the identity. By (XD9) (with $\alpha = \nu^{-1}\upsilon^{\lfloor \#n/2 \rfloor} = \alpha_W$) and (XD2),

$$\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\mathrm{Cone}^\pm_{A,X,\mu}(x;v),\Phi^{\mathrm{st}}_{\sigma,y})(g) = \int_{[\mathrm{U}(V)]} \Lambda_h(\mathrm{Cone}^\pm_{A,X,\mu}(x;v))\, dh.$$

For fixed h, Λ_h is a bounded linear functional on $\mathcal{F}_{W,V}$ (Step 4), so it commutes with the Bochner integral: $\Lambda_h(\mathrm{Cone}^\pm_{A,X,\mu}(x;v)) = \int k_x(h,\kappa,a)\, d\kappa\, d^\times a$. Fubini's theorem (Step 6) turns the iterated integral into the integral over the product, which is the assertion.

Step 8: continuity on $[1,\infty)$. Let $x_1 > 1$ and L as in Step 3 for $x_0 = 1$, x_1. For $x \in [1,x_1]$, $|a_w|^{2x} \le |a_w|^2 + |a_w|^{2x_1}$, so by (6.11) (with $C_{M,L}$ for this L, independent of x) all k_x, $x \in [1,x_1]$, are dominated by one integrable function (Steps 3 and 6). For fixed (h,κ,a), $x \mapsto k_x(h,\kappa,a) = e_x(a)\Lambda_h(c(\kappa,a))$ is continuous. By dominated convergence the integral is continuous on $[1,x_1]$, and x_1 is arbitrary. □

Lemma 6.2.43. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p an index set, D a splitting of V over V_0 along p, and $m \in \mathrm{GL}_p(\mathbb{A}_E)$ such that D is adapted at 1 in the basis m. Let $\iota_0 = \Phi \times n_0$ and $\varepsilon_0(v,i) = s_0(i)$, so that $\mathcal{F}_{s_0} = \mathcal{F}_{\varepsilon_0}$.*

1. *For all $N, M \in \mathbb{N}$ there is $C \ge 0$ such that*

$$(1+\|x\|)^M\, \mathrm{mom}_N(\mathrm{rsl}_{D,m}(x;v)) \le C\, \mathrm{mom}_{N+M}(v) \qquad (x \in \mathbb{C}^{\Phi \times p},\ v \in \mathcal{F}_s).$$

In particular every real slice of a Schwartz vector is a Schwartz vector.

2. *Let τ be a smooth compactly supported function on $\mathbb{C}^{\Phi\times p}$, g a map from $\mathbb{C}^{\Phi\times p}$ to $\mathrm{U}(\operatorname{diag}\varepsilon_0)$ that is smooth as a matrix-valued function, and $v'\in\mathcal{F}_{s_0}$ a Schwartz vector. There is a Schwartz vector $v\in\mathcal{F}_s$ with*

$$\mathrm{rsl}_{D,m}(x;v)=\tau(x)\,\omega^\infty_{\varepsilon_0}(g(x))v' \qquad \textit{for every } x\in\mathbb{C}^{\Phi\times p}.$$

Proof. Let $\iota=\Phi\times n$ and $\varepsilon(v,i)=s(i)$, so $\mathcal{F}_s=\mathcal{F}_\varepsilon$; write ρ^∞, v_1 for the real Heisenberg operators and the real vacuum of $\mathcal{F}_s$, and ρ^∞_0, v_1^0 for those of $\mathcal{F}_{s_0}$. Put $\beta_1(x,x')=\exp((x'^*x-x^*x')/2)$ for $x,x'\in\mathbb{C}^{\Phi\times p}$.

Step 0: four facts on a Fock model $\mathcal{F}_\varepsilon$. (F1) Since $|\beta^\infty_\varepsilon e^\infty|\le 1$, the reproducing identity gives $|c(z)|\le\|c\|_1$ for $c\in\mathcal{F}_\varepsilon$ and every z. Hence each evaluation $c\mapsto c(z)$ is a bounded linear functional, $\mathcal{F}_\varepsilon$ is closed in $L^1(\nu)$ (the reproducing identity passes to L^1-limits), and the Bochner integral of an integrable $\mathcal{F}_\varepsilon$-valued function F lies in $\mathcal{F}_\varepsilon$ and satisfies $(\int F\,d\mu)(z)=\int F(t)(z)\,d\mu(t)$ for every z. By Tonelli,

$$\mathrm{mom}_N\Big(\int F\,d\mu\Big)\le\int\mathrm{mom}_N(F(t))\,d\mu(t). \tag{M1}$$

(F2) Since $|(\rho^\infty(t)c)(z)|=|c(z-t)|$ and $1+|z+t|\le(1+|t|)(1+|z|)$, $\mathrm{mom}_N(\rho^\infty(t)c)\le(1+|t|)^N\mathrm{mom}_N(c)$. (F3) $\rho^\infty(t)\rho^\infty(t')=\beta^\infty_\varepsilon(t,t')\,\rho^\infty(t+t')$. (F4) For $h\in\mathrm{U}(\operatorname{diag}\varepsilon)$ the block h_- is invertible and

$$\omega^\infty_\varepsilon(h)c=\overline{\det h_-}\int c(t)\,\rho^\infty(ht)v_1\,d\nu(t),$$

a Bochner integral of norm at most $|\det h_-|\,\|c\|_1\|v_1\|_1$: the values at z of both sides agree by (WR5) and (F1), since $(\rho^\infty(ht)v_1)(z)=\beta^\infty_\varepsilon(ht,z)e^\infty(z-ht)$. For the invertibility, the block on the indices of sign -1 of $h^*\mathrm{diag}(\varepsilon)h=\mathrm{diag}(\varepsilon)$ reads $h_-^*h_-=1+h_{+-}^*h_{+-}$, h_{+-} the block of rows of sign $+1$ and columns of sign -1; so $h_-^*h_-$ is positive definite.

Step 1: adapted coordinates. Let G be the complex matrix, block diagonal over Φ, with column blocks $(l_{\mathbb{A}}m^{-*})_\infty$, $(k_{\mathbb{A}}m)_\infty$, $(i_{\mathbb{A}})_\infty$. By adaptedness at 1 in the basis m each block G_v is square with orthonormal columns, hence unitary, and we write $y=G(a,b,w)$ with $a,b\in\mathbb{C}^{\Phi\times p}$, $w\in\mathbb{C}^{\iota_0}$. Then $|y|^2=|a|^2+|b|^2+|w|^2$, ν_ι is the image of $\nu_{\Phi\times p}\otimes\nu_{\Phi\times p}\otimes\nu_{\iota_0}$ (as $\#n=2\#p+\#n_0$), and by (MX1) the functions $a(y)$, $w(y)$ of (MX7) are the coordinates a, w. Since $x_V^*J_Vx_V=\varepsilon_s$, at each $v\in\Phi$ we have $(x_V^{-1}u)_v^*\,\mathrm{diag}(s)\,(x_V^{-1}u')_v=u^*J_Vu'$; with the relations of (MX1) ($l^*J_Vk=1$, $k^*J_Vk=l^*J_Vl=0$, $i^*J_Vi=J_{V_0}$, $i^*J_Vk=i^*J_Vl=0$) and $x_{V_0}^*J_{V_0}x_{V_0}=\varepsilon_{s_0}$ this gives, for $y=G(a,b,w)$ and $y'=G(a',b',w')$,

$$y'^*\mathrm{diag}(\varepsilon)\,y=a'^*b+b'^*a+w'^*\mathrm{diag}(\varepsilon_0)\,w. \tag{C1}$$

Further $\mathrm{rv}(y)=l_{\mathbb{A}}m^{-*}\mathrm{rv}(a)+k_{\mathbb{A}}m\,\mathrm{rv}(b)+i_{\mathbb{A}}\mathrm{rv}(w)$, so $\mathrm{pr}_k\mathrm{rv}(y)=m\,\mathrm{rv}(b)$, $\mathrm{pr}_l\mathrm{rv}(y)=m^{-*}\mathrm{rv}(a)$ and $\chi(y)=\psi_E(\frac{1}{2}\mathrm{rv}(b)^*\mathrm{rv}(a))$. The finite components vanish, and at $v\in\Phi$, with $\jmath_v=i\,\mathrm{Im}\,\jmath_v$ and $2\pi\,\mathrm{Im}(\jmath_v)\kappa_v^2=1$, (WD4) gives the factor $\exp(-2\pi i\cdot 2\,\mathrm{Re}(\frac{\jmath_v}{2}\kappa_v^2b_v^*a_v))=\exp(i\,\mathrm{Im}\,b_v^*a_v)$. Hence

$$\chi(y)=\exp\big((b^*a-a^*b)/2\big). \tag{C2}$$

Finally the matrix $(l_{\mathbb{A}}(m^{-1})^*)_\infty$ of (MX7) maps x to $G(x,0,0)$. For a function c on $\mathbb{C}^\iota$ write $\tilde c(a,b,w)=c(G(a,b,w))$.

Step 2: the slice formula. For $v\in\mathcal{F}_s$ and $x\in\mathbb{C}^{\Phi\times p}$,

$$\mathrm{rsl}_{D,m}(x;v)=\int\tilde v(a,b,w)\,\exp\Big(\frac{b^*a-a^*b}{2}+b^*x-x^*b-|a+x|^2\Big)\,\rho^\infty_0(w)v_1^0\,d\nu(a,b,w). \tag{S}$$

Indeed, by (C1) the exponent of $\beta_\varepsilon^\infty(G(x,0,0),G(a,b,w))$ is $(b^*x-x^*b)/2$, so

$$(\rho^\infty(G(x,0,0))v)^\sim(a,b,w)=e^{(b^*x-x^*b)/2}\,\tilde v(a-x,b,w);$$

insert this in the definition of $Z^\infty_{D,m}$ (MX7) with (C2) and $a(y)=a$, $w(y)=w$, and substitute $a\mapsto a+x$: the exponents add to $(b^*a-a^*b)/2+b^*x-x^*b$ and $e^{-|a|^2}$ becomes $e^{-|a+x|^2}$.

Step 3: (1). The integrand of (S) has modulus $|\tilde v(a,b,w)|\,e^{-|a+x|^2}\,|\rho_0^\infty(w)v_1^0|$. By (M1) and (F2) for $\mathcal{F}_{s_0}$,

$$\mathrm{mom}_N(\mathrm{rsl}_{D,m}(x;v))\le \mathrm{mom}_N(v_1^0)\int|\tilde v(a,b,w)|\,e^{-|a+x|^2}(1+|w|)^N\,d\nu.$$

With $c_M=\sup_{t\ge0}(1+t)^Me^{-t^2}$ and $1+|x|\le(1+|a|)(1+|a+x|)$ we get $(1+|x|)^Me^{-|a+x|^2}\le c_M(1+|a|)^M$, and $|a|,|w|\le|y|$. Therefore (1) holds with $C=c_M\,\mathrm{mom}_N(v_1^0)$, which is finite ($v_1^0$ is a Gaussian). Taking $M=0$: the real slices of a Schwartz vector are Schwartz vectors, and $v\mapsto\mathrm{rsl}_{D,m}(x;v)$ is a bounded operator from $\mathcal{F}_s$ to $\mathcal{F}_{s_0}$.

Step 4: the laws of real slices. For $y_0=G(a',b',w')$, $v\in\mathcal{F}_s$ and $x\in\mathbb{C}^{\Phi\times p}$,

$$\mathrm{rsl}_{D,m}(x;\rho^\infty(y_0)v)=\beta_1(2x+a',b')\,\rho_0^\infty(w')\,\mathrm{rsl}_{D,m}(x+a';v),\tag{L1}$$

$$\mathrm{rsl}_{D,m}(x;v_1)=e^{-|x|^2}\,v_1^0.\tag{L2}$$

For (L1): $(\rho^\infty(y_0)v)(y+y_0)=\beta_\varepsilon^\infty(y_0,y)v(y)$, as $\beta_\varepsilon^\infty(y_0,y_0)=1$. Substitute $(a,b,w)\mapsto(a+a',b+b',w+w')$ in (S). By (C1) the factor $\beta_\varepsilon^\infty(y_0,y)$ is $\exp((a^*b'+b^*a'-a'^*b-b'^*a)/2)$ times $\beta_{\varepsilon_0}^\infty(w',w)$, and by (F3) $\rho_0^\infty(w+w')=\beta_{\varepsilon_0}^\infty(w',w)^{-1}\rho_0^\infty(w')\rho_0^\infty(w)$, so the factors in w cancel. The remaining exponent is

$$\frac{a^*b'+b^*a'-a'^*b-b'^*a}{2}+\frac{(b+b')^*(a+a')-(a+a')^*(b+b')}{2}+(b+b')^*x-x^*(b+b')$$
$$=\frac{b^*a-a^*b}{2}+b^*(x+a')-(x+a')^*b+\frac{b'^*(2x+a')-(2x+a')^*b'}{2},$$

and the Gaussian is $e^{-|a+(x+a')|^2}$. The last term is the exponent of $\beta_1(2x+a',b')$, and $\rho_0^\infty(w')$ is bounded, so it leaves the Bochner integral; what remains is (S) at $x+a'$. For (L2): $\tilde v_1(a,b,w)=e^{-(|a|^2+|b|^2+|w|^2)/2}$. The integrand of (S) is absolutely integrable, and by Fubini the integral over w is $\int v_1^0(w)\rho_0^\infty(w)v_1^0\,d\nu(w)=v_1^0$ (its value at u is the reproducing identity of v_1^0). The exponent in b is $b^*x_1-x_1^*b=2i\,\mathrm{Im}(b^*x_1)$ with $x_1=a/2+x$, and coordinatewise $\pi^{-1}\int_{\mathbb{C}}e^{-|u_1|^2/2}e^{2i\,\mathrm{Im}(\bar u_1c_1)}\,du_1=2e^{-2|c_1|^2}$ for $c_1\in\mathbb{C}$ (Fourier transform of a Gaussian), so with $k_0=\#(\Phi\times p)$ the integral over b is $2^{k_0}e^{-|a+2x|^2/2}$. Since $\frac12|a|^2+\frac12|a+2x|^2+|a+x|^2=2|a+x|^2+|x|^2$ and $\int e^{-2|a|^2}d\nu(a)=2^{-k_0}$, the integral over a gives $2^{k_0}\cdot2^{-k_0}e^{-|x|^2}$.

Two cases of (L1) are used below: with $K=(k_{\mathbb{A}}m)_\infty$ and $I=(i_{\mathbb{A}})_\infty$ (so $Kb'=G(0,b',0)$, $Iw'=G(0,0,w')$), and $e(x,b')=\exp(b'^*x-x^*b')=\beta_1(2x,b')$,

$$\mathrm{rsl}_{D,m}(x;\rho^\infty(Kb')v)=e(x,b')\,\mathrm{rsl}_{D,m}(x;v),\qquad \mathrm{rsl}_{D,m}(x;\rho^\infty(Iw')v)=\rho_0^\infty(w')\,\mathrm{rsl}_{D,m}(x;v).\tag{L3}$$

Step 5: a family of coherent states and its Fourier transform. Let τ, g, v' be as in (2). The function $\sigma(x)=\tau(x)\,e^{|x|^2}\,\overline{\det g(x)_-}$ is smooth with compact support $\mathrm{supp}\,\sigma\subseteq\mathrm{supp}\,\tau$. Put $A(x)=I\,g(x)$, a smooth family of complex $\iota\times\iota_0$ matrices, and $B_0=\max_{x\in\mathrm{supp}\,\sigma}\|A(x)\|$. For $t\in\mathbb{C}^{\iota_0}$ and $x\in\mathbb{C}^{\Phi\times p}$ let

$$H(t,x)=\sigma(x)\,\rho^\infty(A(x)t)v_1\in\mathcal{F}_s,\qquad \widehat H(t,b)=\int H(t,x)\,\overline{e(x,b)}\,d\nu(x)\quad(b\in\mathbb{C}^{\Phi\times p}),$$

a Bochner integral of a continuous compactly supported function (Proposition 4.1.14). We show: for every $N \in \mathbb{N}$ and every integer $j \geq 0$ there is $C_{N,j}$ with

$$\operatorname{mom}_N(\widehat{H}(t,b)) \leq C_{N,j}\,(1+4|b|^2)^{-j}(1+|t|)^{4j+N} \qquad (t,b). \tag{E}$$

By (F1), $\widehat{H}(t,b)(z) = \int \phi_{t,z}(x)\,\overline{e(x,b)}\,d\nu(x)$ with $\phi_{t,z}(x) = \sigma(x)\exp(\Upsilon(A(x)t,z))$, where $\Upsilon(y,z) = (z^*\operatorname{diag}(\varepsilon)y - y^*\operatorname{diag}(\varepsilon)z)/2 - |z-y|^2/2$ is the exponent of the coherent state $\rho^\infty(y)v_1$ at z. In the real coordinates of $x \in \mathbb{C}^{\Phi\times p} = \mathbb{R}^{2k_0}$, $\overline{e(x,b)} = \exp(-2i\operatorname{Im}(b^*x))$ and $\operatorname{Im}(b^*x)$ is a real linear form with gradient of length $|b|$, so the Laplacian Δ_x multiplies $\overline{e(x,b)}$ by $-4|b|^2$. Integrating by parts ($\phi_{t,z}$ is smooth with compact support),

$$(1+4|b|^2)^j\,\widehat{H}(t,b)(z) = \int ((1-\Delta_x)^j\phi_{t,z})(x)\,\overline{e(x,b)}\,d\nu(x).$$

Now $\Upsilon(y,z) = i\operatorname{Im}(z^*\operatorname{diag}(\varepsilon)y) + \operatorname{Re}(z^*y) - |z|^2/2 - |y|^2/2$, so for a multi-index $\delta \neq 0$ and $x \in \operatorname{supp}\sigma$ the derivative $\partial_x^\delta(\Upsilon(A(x)t,z))$ is a sum of $i\operatorname{Im}(z^*\operatorname{diag}(\varepsilon)\,\partial^\delta A(x)t) + \operatorname{Re}(z^*\partial^\delta A(x)t)$ and, by Leibniz, of terms $-\frac{1}{2}\binom{\delta}{\delta'}(\partial^{\delta'}A(x)t)^*(\partial^{\delta-\delta'}A(x)t)$; with $|z| \leq |z-A(x)t| + B_0|t|$ it is bounded by $c_\delta(1+|t|)^2(1+|z-A(x)t|)$, c_δ depending on the derivatives of A of order at most $|\delta|$ on $\operatorname{supp}\sigma$. By the chain and Leibniz rules, $(1-\Delta_x)^j\phi_{t,z}$ is a finite sum of terms $\partial^{\delta_0}\sigma\cdot\prod_{i\geq1}\partial^{\delta_i}\Upsilon\cdot e^\Upsilon$ with $\sum_{i\geq0}|\delta_i| \leq 2j$ and $\delta_i \neq 0$ for $i \geq 1$; since $|e^\Upsilon| = e^{-|z-A(x)t|^2/2}$ and $(1+r)^{2j}e^{-r^2/2} \leq c_j' e^{-r^2/4}$ for $r \geq 0$,

$$\big|(1-\Delta_x)^j\phi_{t,z}(x)\big| \leq c_j''\,(1+|t|)^{4j}\,e^{-|z-A(x)t|^2/4}\,\mathbf{1}_{\operatorname{supp}\sigma}(x).$$

Finally $\int(1+|z|)^N e^{-|z-y|^2/4}d\nu(z) \leq c_N'''(1+|y|)^N$ with $c_N''' = \int(1+|r|)^N e^{-|r|^2/4}d\nu(r)$, and $|A(x)t| \leq B_0|t|$ on $\operatorname{supp}\sigma$. Integrating over z (Tonelli) gives (E) with $C_{N,j} = c_j''\,c_N'''\,(1+B_0)^N\nu(\operatorname{supp}\sigma)$.

Step 6: the vector v and its moments. Fix N and choose j with $2j > N + 2k_0$. Since $1+|b|^2\cdot 4 \geq (1+|b|)^2/2$, (E), (F2) (with $|Kb| = |b|$, K having orthonormal columns) give

$$\iint |v'(t)|\operatorname{mom}_N(\rho^\infty(Kb)\widehat{H}(t,b))\,d\nu(b)\,d\nu(t) \leq 2^j C_{N,j}\int(1+|b|)^{N-2j}d\nu(b)\cdot\operatorname{mom}_{4j+N}(v') < \infty.$$

The map $(t,b) \mapsto v'(t)\rho^\infty(Kb)\widehat{H}(t,b)$ is measurable into $\mathcal{F}_s$ ($\widehat{H}$ is continuous by dominated convergence with the bound of Step 5, and ρ^∞ is isometric and strongly continuous), so for $N = 0$ it is Bochner integrable, and by (F1) and (M1)

$$v = \iint v'(t)\,\rho^\infty(Kb)\,\widehat{H}(t,b)\,d\nu(b)\,d\nu(t) \in \mathcal{F}_s$$

has $\operatorname{mom}_N(v) < \infty$ for every N: v is a Schwartz vector.

Step 7: the slices of v. Fix x. By Step 3, $\operatorname{rsl}_{D,m}(x;\cdot)$ is bounded, so it commutes with the Bochner integrals, and by (L3) and Fubini,

$$\operatorname{rsl}_{D,m}(x;v) = \int v'(t)\operatorname{rsl}_{D,m}\Big(x;\int e(x,b)\,\widehat{H}(t,b)\,d\nu(b)\Big)\,d\nu(t).$$

For fixed t the inner integral is $H(t,x)$: by (F1) its value at z is $\int e(x,b)\widehat{\phi_{t,z}}(b)\,d\nu(b)$ with $\widehat{\phi_{t,z}}(b) = \int\phi_{t,z}\overline{e(\cdot,b)}\,d\nu$, and Fourier inversion on $\mathbb{R}^{2k_0}$, in the normalisation $\phi(x) = \int\widehat{\phi}(b)e(x,b)\,d\nu(b)$ for smooth compactly supported ϕ (the character $e(x,b) = \exp(2i\operatorname{Im}(b^*x))$ and the measure π^{-k_0} times Lebesgue measure in both variables), gives $\phi_{t,z}(x) = H(t,x)(z)$. By (L3) and (L2),

$$\operatorname{rsl}_{D,m}(x;H(t,x)) = \sigma(x)\,\rho_0^\infty(g(x)t)\operatorname{rsl}_{D,m}(x;v_1) = \sigma(x)\,e^{-|x|^2}\,\rho_0^\infty(g(x)t)v_1^0.$$

Integrating against $v'(t)$ and using (F4) for $h = g(x)$,

$$\mathrm{rsl}_{D,m}(x;v) = \sigma(x)\, e^{-|x|^2}\, \overline{\det g(x)_-}^{\,-1}\, \omega_{\varepsilon_0}^{\infty}(g(x))v' = \tau(x)\, \omega_{\varepsilon_0}^{\infty}(g(x))v'.$$

This proves (2). □

Lemma 6.2.44. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, and (k,l,i) a splitting of V over V_0 along p, with zero term Z and slices $f[x]$; let $Z^\vee$ be the zero term along the opposite splitting (l,k,i). Give $\mathbb{A}_E^p$ the Haar measure dx for which $\mathbb{A}_E^p/E^p$ has volume 1.*

1. *(Mixed law.) Let $\Pi\colon \mathcal{M}_s \to \mathcal{M}_{s_0}$ be a bounded linear map with $\Pi\rho(k_{\mathbb{A}}b) = \Pi$ and $\Pi\rho(i_{\mathbb{A}}w) = \rho(w)\Pi$ for all $b \in \mathbb{A}_E^p$, $w \in \mathbb{A}_E^{n_0}$. Then for $f \in \mathcal{M}_s$, $x,a,b \in \mathbb{A}_E^p$ and $w \in \mathbb{A}_E^{n_0}$,*

$$\Pi\rho(l_{\mathbb{A}}x)\rho(l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b)f = \psi_E\big(\tfrac{1}{2}\jmath\, b^*(2x+a)\big)\, \rho(w)\, \Pi\rho(l_{\mathbb{A}}(x+a))f.$$

   The zero term Z is such a map; for $\Pi = Z$ the identity reads

$$\big(\rho(l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b)f\big)[x] = \psi_E\big(\tfrac{1}{2}\jmath\, b^*(2x+a)\big)\, \rho(w)\, f[x+a].$$

2. *(Summability.) There is $M \geq 0$ with $\sum_{\xi \in E^p} \|f[\xi]\| \leq M\|f\|$ for every $f \in \mathcal{M}_s$.*

3. *(Theta expansion.) For $f \in \mathcal{M}_s$, $\theta_V(f) = \sum_{\xi \in E^p} \theta_{V_0}(f[\xi])$, the series converging absolutely.*

4. *(Integral of the slices.) For $f \in \mathcal{M}_s$ the map $x \mapsto f[x]$ from $\mathbb{A}_E^p$ to $\mathcal{M}_{s_0}$ is continuous and Bochner integrable, and $\int_{\mathbb{A}_E^p} f[x]\, dx = Z^\vee(f)$.*

5. *(Hom slices.) Let T be a space with a point with signs t on n', give $\mathrm{M}_{n'\times p}(\mathbb{A}_E)$ the Haar measure for which $\mathrm{M}_{n'\times p}(E)$ has covolume 1, and let $Z_T^\vee$ be the zero term along the splitting of $\mathrm{Hom}(V,T)$ over $\mathrm{Hom}(V_0,T)$ induced by (l,k,i). For $f \in \mathcal{M}_{V,T}$ and its Hom slices $f[x]$,*

$$\sum_{\xi \in \mathrm{M}_{n'\times p}(E)} \|f[x_T^{-1}\xi]\| < \infty,$$
$$\theta_{\mathrm{Hom}(V,T)}(f) = \sum_{\xi \in \mathrm{M}_{n'\times p}(E)} \theta_{\mathrm{Hom}(V_0,T)}\big(f[x_T^{-1}\xi]\big),$$
$$\int_{\mathrm{M}_{n'\times p}(\mathbb{A}_E)} f[x_T^{-1}x]\, dx = Z_T^\vee(f).$$

Proof. **Step 0: the Heisenberg operators.** The bicharacter $\beta_s(x,y) = \psi_E(\frac{1}{2}\jmath\, y^*\varepsilon_s x)$ is additive in each variable. We have $\psi_E(\bar z) = \psi_E(z)$ (the archimedean factor reads $\mathrm{Re}\, z_v$, and if $z_f - a \in \widehat{\mathcal{O}}_E$ then $\bar z_f - \bar a \in \widehat{\mathcal{O}}_E$ and $\mathrm{Tr}_{E/\mathbb{Q}}\bar a = \mathrm{Tr}_{E/\mathbb{Q}}\, a$), and $\psi_E(z) = 1$ when $\bar z = -z$ (then $\mathrm{Re}\, z_v = 0$, and $a \in E$ with $z_f - a \in \widehat{\mathcal{O}}_E$ has $a + \bar a = (a - z_f) + (\bar a - \bar z_f) \in \widehat{\mathcal{O}}_E \cap F$, so $\mathrm{Tr}_{E/\mathbb{Q}}\, a = \mathrm{Tr}_{F/\mathbb{Q}}(a + \bar a) \in \mathbb{Z}$). As $\bar\jmath = -\jmath$ and $\overline{y^*\varepsilon_s x} = x^*\varepsilon_s y$, we get $\beta_s(y,x) = \beta_s(x,y)^{-1}$ and $\beta_s(z,z) = 1$. From $(\rho(z)f)(x) = \beta_s(z,x)f(x-z)$ one computes

$$\rho(z)\rho(z') = \beta_s(z,z')\, \rho(z+z'), \qquad \rho(z)\rho(z') = \beta_s(z,z')^2\, \rho(z')\rho(z). \tag{6.12}$$

The measure μ_n is a Haar measure of $\mathbb{A}_E^n$, so each $\rho(z)$ is an isometry for the norm of $L^1(\mu_n)$; it preserves $\mathcal{M}_s$ (substitute $y \mapsto y + z$ in the reproducing integral and use (6.12)), and $z \mapsto \rho(z)f$ is continuous (continuity of translation in L^1 and dominated convergence). The frames

satisfy $k_{\mathbb{A}}^*\varepsilon_s k_{\mathbb{A}} = k^*J_V k = 0$, $l_{\mathbb{A}}^*\varepsilon_s l_{\mathbb{A}} = 0$, $l_{\mathbb{A}}^*\varepsilon_s k_{\mathbb{A}} = 1$, $i_{\mathbb{A}}^*\varepsilon_s i_{\mathbb{A}} = \varepsilon_{s_0}$, $i_{\mathbb{A}}^*\varepsilon_s k_{\mathbb{A}} = i_{\mathbb{A}}^*\varepsilon_s l_{\mathbb{A}} = 0$, because $x_V^{-*}\varepsilon_s x_V^{-1} = J_V$ and by the relations of (MX1); hence, for $y = l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b$ and $y' = l_{\mathbb{A}}a' + i_{\mathbb{A}}w' + k_{\mathbb{A}}b'$,

$$\beta_s(y,y') = \psi_E\big(\tfrac{1}{2}\jmath\,(b'^*a + a'^*b)\big)\,\beta_{s_0}(w,w'). \tag{6.13}$$

Finally $\theta_V(\rho(\gamma)f) = \theta_V(f)$ for $\gamma = x_V^{-1}u$, $u \in E^n$ (the canonical theta functional of (WC3) of Definition 4.1.15 is a theta functional of V, Lemma 4.1.17); in particular for $\gamma = k_{\mathbb{A}}\xi$ and $\gamma = l_{\mathbb{A}}\xi$ with $\xi \in E^p$.

Step 1: two laws of the zero term. For $f \in \mathcal{M}_s$, $b \in \mathbb{A}_E^p$, $w \in \mathbb{A}_E^{n_0}$:

$$Z(\rho(k_{\mathbb{A}}b)f) = Z(f), \qquad Z(\rho(i_{\mathbb{A}}w)f) = \rho(w)Z(f). \tag{6.14}$$

By the uniqueness in (7) of Lemma 4.1.1 it suffices to check that the right sides satisfy the defining identity (MX4) for the vectors on the left. For the first: by (6.12) and (6.13), $(\rho(k_{\mathbb{A}}b)f)^\theta(i_{\mathbb{A}}y + k_{\mathbb{A}}b') = \beta_s(i_{\mathbb{A}}y + k_{\mathbb{A}}b', k_{\mathbb{A}}b)\, f^\theta(i_{\mathbb{A}}y + k_{\mathbb{A}}(b'+b)) = f^\theta(i_{\mathbb{A}}y + k_{\mathbb{A}}(b'+b))$, whose mean over $b' \in \mathbb{A}_E^p/E^p$ is that of $f^\theta(i_{\mathbb{A}}y + k_{\mathbb{A}}b')$ by invariance of the Haar measure. For the second: $(\rho(i_{\mathbb{A}}w)f)^\theta(i_{\mathbb{A}}y + k_{\mathbb{A}}b') = \beta_s(i_{\mathbb{A}}y + k_{\mathbb{A}}b', i_{\mathbb{A}}w) f^\theta(i_{\mathbb{A}}(y+w) + k_{\mathbb{A}}b') = \beta_{s_0}(y,w) f^\theta(i_{\mathbb{A}}(y+w) + k_{\mathbb{A}}b')$, whose mean over b' is $\beta_{s_0}(y,w)\theta_{V_0}(\rho(y+w)Z(f)) = \theta_{V_0}(\rho(y)\rho(w)Z(f))$ by (6.12) for V_0.

Step 2: the mixed law (1). Let $y = l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b$ and $u = i_{\mathbb{A}}w + l_{\mathbb{A}}(x+a)$. By (6.12), $\rho(l_{\mathbb{A}}x)\rho(y) = \beta_s(l_{\mathbb{A}}x, y)\rho(k_{\mathbb{A}}b + u) = \beta_s(l_{\mathbb{A}}x, y)\beta_s(k_{\mathbb{A}}b, u)^{-1}\rho(k_{\mathbb{A}}b)\rho(u)$ and $\rho(u) = \beta_s(i_{\mathbb{A}}w, l_{\mathbb{A}}(x+a))^{-1}\rho(i_{\mathbb{A}}w)\rho(l_{\mathbb{A}}(x+a)) = \rho(i_{\mathbb{A}}w)\rho(l_{\mathbb{A}}(x+a))$. By (6.13), $\beta_s(l_{\mathbb{A}}x, y) = \psi_E(\frac{1}{2}\jmath\, b^*x)$ and $\beta_s(k_{\mathbb{A}}b, u)^{-1} = \beta_s(u, k_{\mathbb{A}}b) = \psi_E(\frac{1}{2}\jmath\, b^*(x+a))$. Let Π be as in (1). Applying Π, which absorbs $\rho(k_{\mathbb{A}}b)$ on its right and turns $\rho(i_{\mathbb{A}}w)$ on its right into $\rho(w)$ on its left,

$$\begin{aligned}\Pi\rho(l_{\mathbb{A}}x)\rho(y)f &= \psi_E\big(\tfrac{1}{2}\jmath\, b^*(2x+a)\big)\,\Pi\rho(k_{\mathbb{A}}b)\rho(i_{\mathbb{A}}w)\rho(l_{\mathbb{A}}(x+a))f\\ &= \psi_E\big(\tfrac{1}{2}\jmath\, b^*(2x+a)\big)\,\rho(w)\,\Pi\rho(l_{\mathbb{A}}(x+a))f,\end{aligned}$$

which is (1). By (6.14) the zero term Z satisfies the hypothesis on Π, and $Z\rho(l_{\mathbb{A}}x)F = F[x]$ by (MX4), which gives the second display of (1). In particular $\|f[x]\|$ is continuous in x, $f \mapsto f[x]$ is bounded and linear, and $(\rho(l_{\mathbb{A}}x)f)[\xi] = f[\xi + x]$.

Step 3: superposition. By (1) of Lemma 6.2.12, for $h \in \mathcal{M}_s$ the map $z \mapsto h(z)\rho(z)v^0$ is Bochner integrable in $\mathcal{M}_s$ and

$$h = \int_{\mathbb{A}_E^n} h(z)\,\rho(z)v^0\,d\mu_n(z). \tag{6.15}$$

Step 4: summability (2). Take $g = g_D$ as in (1) of Lemma 6.2.46, so that the splitting is adapted at g in the basis 1, and $u = \omega_s(g)v^0$. By (1), with $\Pi = Z$, the slice maps $f \mapsto f[x]$ satisfy the hypothesis of (2) of Lemma 6.2.46, which gives $C_g \in \mathbb{C}$ with $u[x] = C_g|e_p(x)|^2v^0$ for all x. For $f \in \mathcal{M}_s$ put $h = \omega_s(g^{-1})f$. Applying the bounded operator $\omega_s(g)$ to (6.15) and using $\omega_s(g)\rho(z) = \rho(gz)\omega_s(g)$,

$$f = \int h(z)\,\rho(gz)u\,d\mu_n(z), \qquad \text{so} \qquad f[\xi] = \int h(z)\,(\rho(gz)u)[\xi]\,d\mu_n(z)$$

as $f \mapsto f[\xi]$ is bounded. Write $gz = l_{\mathbb{A}}a_z + i_{\mathbb{A}}w_z + k_{\mathbb{A}}b_z$. By (1), the unitarity of the phase and the isometry $\rho(w_z)$, $\|(\rho(gz)u)[\xi]\| = \|u[\xi + a_z]\| = |C_g|\,|e_p(\xi + a_z)|^2\,\|v^0\|$. Hence, by Tonelli,

$$\sum_{\xi\in E^p}\|f[\xi]\| \le |C_g|\,\|v^0\|\,K\int|h|\,d\mu_n \le |C_g|\,\|v^0\|\,K\,\|\omega_s(g^{-1})\|\,\|f\|, \qquad K = \sup_{a\in\mathbb{A}_E^p}\sum_{\xi\in E^p}|e_p(\xi+a)|^2.$$

K is finite: by (WD5), $|e_p(x)|^2 = \prod_{j\in p}\exp(-2\pi\sum_{v\in\Phi}\mathrm{Im}(\jmath_v)|x_{j,v}|^2)\mathbf{1}[x_{j,f}\in\alpha\widehat{\mathcal{O}}_E]$, so $K\le K_1^{\#p}$ with $K_1=\sup_{a\in\mathbb{A}_E}\sum_{\xi\in E}\exp(-Q(\xi_\infty+a_\infty))\mathbf{1}[\xi+a_f\in\alpha\widehat{\mathcal{O}}_E]$ and $Q(y)=2\pi\sum_v\mathrm{Im}(\jmath_v)|y_v|^2$, a positive definite quadratic form on $E_\infty=\mathbb{C}^\Phi$. For fixed a the ξ counted form an empty set or a coset $\xi_0+\mathfrak{a}$ of the fractional ideal $\mathfrak{a}=E\cap\alpha\widehat{\mathcal{O}}_E$, a lattice in E_∞; so $K_1\le\sup_{y\in E_\infty}\sum_{\lambda\in\mathfrak{a}}e^{-Q(\lambda+y)}$. This sum is $\mathfrak{a}$-periodic in y; for y in a fundamental parallelotope of $Q^{1/2}$-diameter δ we have $Q(\lambda+y)^{1/2}\ge Q(\lambda)^{1/2}-\delta$, and $\sum_\lambda\exp(-\max(0,Q(\lambda)^{1/2}-\delta)^2)<\infty$ since the number of λ with $Q(\lambda)\le r^2$ is $O(r^{2\#\Phi}+1)$.

Step 5: the theta expansion (3). Let $G(b)=f^\theta(k_\mathbb{A}b)=\theta_V(\rho(k_\mathbb{A}b)f)$ for $b\in\mathbb{A}_E^p$. It is continuous (Step 0) and E^p-periodic: for $\gamma\in E^p$, $\rho(k_\mathbb{A}(b+\gamma))=\rho(k_\mathbb{A}\gamma)\rho(k_\mathbb{A}b)$ by (6.12), (6.13), and θ_V absorbs $\rho(k_\mathbb{A}\gamma)$. For $\xi\in E^p$, by (MX4) at $y=0$, (6.12) and Step 0,

$$\begin{aligned}\theta_{V_0}(f[\xi])&=\int_{\mathbb{A}_E^p/E^p}\theta_V\big(\rho(k_\mathbb{A}b)\rho(l_\mathbb{A}\xi)f\big)db=\int_{\mathbb{A}_E^p/E^p}\beta_s(k_\mathbb{A}b,l_\mathbb{A}\xi)^2\,G(b)\,db\\&=\int_{\mathbb{A}_E^p/E^p}\psi_E(\jmath\,\xi^{\mathsf{T}}b)\,G(b)\,db,\end{aligned}$$

the Fourier coefficient of G at the character $b\mapsto\psi_E(\eta^{\mathsf{T}}b)$, $\eta=\jmath\bar\xi$. By (a) of Theorem A.5.2 these characters, for $\eta\in E^p$, are all the characters of $(\mathbb{A}_E/E)^p$, and $\xi\mapsto\jmath\bar\xi$ is a bijection of E^p. As $|\theta_{V_0}(f[\xi])|\le\|\theta_{V_0}\|\,\|f[\xi]\|$, the coefficients are absolutely summable by (2). Fourier inversion at 0 on the compact abelian group $(\mathbb{A}_E/E)^p$ ((b) of Theorem A.5.2, which holds verbatim for this group with dual E^p; Rudin, Fourier analysis on groups, 1.5) gives $\theta_V(f)=G(0)=\sum_\xi\theta_{V_0}(f[\xi])$.

Step 6: the integral of the slices (4). Continuity of $x\mapsto f[x]=Z(\rho(l_\mathbb{A}x)f)$ follows from Step 0. By Step 2 and (2) applied to $\rho(l_\mathbb{A}x)f$, $\sum_\xi\|f[\xi+x]\|\le M\|f\|$ for every x, so $\int_{\mathbb{A}_E^p}\|f[x]\|dx=\int_{\mathbb{A}_E^p/E^p}\sum_\xi\|f[\xi+x]\|dx\le M\|f\|$, and $W=\int f[x]\,dx$ exists. Fix $y\in\mathbb{A}_E^{n_0}$ and the bounded functional $\Theta_y=\theta_{V_0}\circ\rho(y)$. By (1) with $a=x$, $w=y$, $b=0$, $(\rho(l_\mathbb{A}x+i_\mathbb{A}y)f)[\xi]=\rho(y)f[\xi+x]$; so (3) applied to $\rho(i_\mathbb{A}y+l_\mathbb{A}x)f$ gives $\sum_\xi\Theta_y(f[\xi+x])=f^\theta(i_\mathbb{A}y+l_\mathbb{A}x)$. Therefore

$$\theta_{V_0}(\rho(y)W)=\int_{\mathbb{A}_E^p}\Theta_y(f[x])\,dx=\int_{\mathbb{A}_E^p/E^p}\sum_\xi\Theta_y(f[\xi+x])\,dx=\int_{\mathbb{A}_E^p/E^p}f^\theta(i_\mathbb{A}y+l_\mathbb{A}x)\,dx,$$

which is the defining identity (MX4) of the zero term along (l,k,i). By uniqueness, $W=Z^\vee(f)$.

Step 7: Hom slices (5). Let (k',l',i') be the splitting of $\mathrm{Hom}(V,T)$ induced by (k,l,i) (MX4). The point of $\mathrm{Hom}(V,T)$ is $x_T\otimes(x_V^{-1})^{\mathsf{T}}$ ((VP5) of Definition 3.2.2), and $\mathrm{pr}_k=l_\mathbb{A}^*\varepsilon_s=l^*J_Vx_V$; hence $l'_\mathbb{A}=(x_T^{-1}\otimes x_V^{\mathsf{T}})(1\otimes(l^*J_V)^{\mathsf{T}})=x_T^{-1}\otimes\mathrm{pr}_k^{\mathsf{T}}$, which sends an $n'\times p$ matrix X to $x_T^{-1}X\mathrm{pr}_k$. So the slice of f at X for (k',l',i') is the Hom slice $f[x_T^{-1}X]$, and (2), (3), (4) for (k',l',i') give the summability, the expansion, and $\int f[x_T^{-1}X]\,dX=Z'^\vee(f)$, the zero term along (l',k',i'). The splitting of $\mathrm{Hom}(V,T)$ induced by (l,k,i) has the same third frame i' and first frame $J_T^{-1}\otimes(l^*J_V)^{\mathsf{T}}=l'(J_T^{-1}\otimes1_p)$, with $J_T^{-1}\otimes1_p\in\mathrm{GL}_{n'p}(E)$. Since $b\mapsto(J_T^{-1}\otimes1_p)b$ is a continuous automorphism of $\mathbb{A}_E^{n'\times p}/E^{n'\times p}$, it preserves the Haar probability measure, so the two means in (MX4) coincide and $Z'^\vee=Z_T^\vee$. □

Lemma 6.2.45. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, and (k,l,i) a splitting of V over V_0 along p with zero term Z and slices $f[x]$. Let $g\in\mathrm{G}(s)$, $m\in\mathrm{GL}_p(\mathbb{A}_E)$ and $g_0\in\mathrm{G}(s_0)$ satisfy $g\,k_\mathbb{A}=k_\mathbb{A}m$ and $\mathrm{pr}_i\,g\,i_\mathbb{A}=g_0$, and put $W=\mathrm{pr}_i\,g^{-1}l_\mathbb{A}\in\mathrm{M}_{n_0\times p}(\mathbb{A}_E)$ and $B=\mathrm{pr}_k\,g^{-1}l_\mathbb{A}\in\mathrm{M}_p(\mathbb{A}_E)$.*

1. *For $f\in\mathcal{M}_s$ and $x\in\mathbb{A}_E^p$,*

$$(\omega_s(g)f)[x]=v(\det m)^{-1}|\det m|^{1/2}\,\psi_E(\tfrac12\jmath\,x^*B^*m^*x)\,\omega_{s_0}(g_0)\,\rho(Wx)\,f[m^*x].$$

2. *Let T be a space with a point with signs t on n' and adelic sign matrix ε_t, let α,β be automorphic characters of* $\mathrm{U}(1)$*, $h\in \mathrm{G}(t)$, and put $\chi(y)=\beta(y/\bar y)\,\upsilon(y)^{-\#n'}$ for ideles y of E. For $f\in\mathcal{M}_{V,T}$ and every adelic $n'\times p$ matrix x, the Hom slices satisfy*

$$\begin{aligned}\big(\omega_{\alpha\upsilon^{\#p},\beta}(g,h)f\big)[x]=\chi(\det m)^{-1}|\det m|^{\#n'/2}\,\psi_E\big(\tfrac12 J\,\mathrm{tr}(B\,x^*\varepsilon_t\,x\,m)\big)\\ \omega_{\alpha,\beta}(g_0,h)\,\rho\big(h^{-1}xW^*\varepsilon_{s_0}\big)\,f[h^{-1}xm],\end{aligned}$$

where $\omega_{\alpha,\beta}(g_0,h)$ and ρ act on $\mathcal{M}_{V_0,T}$ and $h^{-1}xW^*\varepsilon_{s_0}$ is read as a vector of $\mathrm{Hom}(V_0,T)$*.*

At $x=0$ these are the laws of the zero terms $Z(\omega_s(g)f)$ and

$$Z_T(\omega_{\alpha\upsilon^{\#p},\beta}(g,h)f)=\chi(\det m)^{-1}|\det m|^{\#n'/2}\omega_{\alpha,\beta}(g_0,h)Z_T(f),$$

Z_T the zero term along the induced splitting of $\mathrm{Hom}(V,T)$*.*

Proof. **Step 1: coordinates of $g^{\pm1}$.** As $g^*\varepsilon_s g=\varepsilon_s$ we have $\varepsilon_s g^{-1}=g^*\varepsilon_s$, so $\mathrm{pr}_l g^{-1}=k_{\mathbb{A}}^*\varepsilon_s g^{-1}=(gk_{\mathbb{A}})^*\varepsilon_s=m^*\mathrm{pr}_l$; likewise $g^{-1}k_{\mathbb{A}}=k_{\mathbb{A}}m^{-1}$ gives $\mathrm{pr}_l g=m^{-*}\mathrm{pr}_l$. Since $\mathrm{pr}_l l_{\mathbb{A}}=1$, $\mathrm{pr}_l i_{\mathbb{A}}=\mathrm{pr}_l k_{\mathbb{A}}=0$, the matrix of g in the adelic basis $(k_{\mathbb{A}},i_{\mathbb{A}},l_{\mathbb{A}})$ is block upper triangular with diagonal blocks m, g_0, m^{-*}; hence

$$\det g=\det m\,\overline{\det m}^{\,-1}\det g_0,\qquad \mathrm{pr}_i\,g^{-1}i_{\mathbb{A}}=g_0^{-1},\tag{6.16}$$

the second because g^{-1} has the inverse block matrix. Moreover $g^{-1}l_{\mathbb{A}}x=l_{\mathbb{A}}m^*x+i_{\mathbb{A}}Wx+k_{\mathbb{A}}Bx$ for $x\in\mathbb{A}_E^p$, as its l-coordinate is $\mathrm{pr}_l g^{-1}l_{\mathbb{A}}x=m^*x$.

Step 2: one space, (1). By (2) of Lemma 4.1.1, $\rho(l_{\mathbb{A}}x)\omega_s(g)=\omega_s(g)\rho(g^{-1}l_{\mathbb{A}}x)$. Hence, by Lemma 6.2.10 and the mixed law,

$$(\omega_s(g)f)[x]=Z(\omega_s(g)\rho(g^{-1}l_{\mathbb{A}}x)f)=\upsilon(\det m)^{-1}|\det m|^{1/2}\,\omega_{s_0}(g_0)(\rho(l_{\mathbb{A}}m^*x+i_{\mathbb{A}}Wx+k_{\mathbb{A}}Bx)f)[0],$$

and $(\rho(l_{\mathbb{A}}m^*x+i_{\mathbb{A}}Wx+k_{\mathbb{A}}Bx)f)[0]=\psi_E(\frac12 J\,(Bx)^*m^*x)\rho(Wx)f[m^*x]$.

Step 3: the pair element on $\mathrm{Hom}(V,T)$**.** Let (k',l',i') be the splitting of $\mathrm{Hom}(V,T)$ induced by (k,l,i). Its adelic frames act on matrices by $l'_{\mathbb{A}}X=x_T^{-1}X\mathrm{pr}_k$, $i'_{\mathbb{A}}Y=Y\mathrm{pr}_i$ and $k'_{\mathbb{A}}X'=\varepsilon_t x_T^*X'\mathrm{pr}_l$ (from (VP5) of Definition 3.2.2, (MX4) and $x_V^{-*}\varepsilon_s=J_V x_V$, $x_T^{-1}J_T^{-1}=\varepsilon_t x_T^*$), and the coordinate $\mathrm{pr}_{i'}$ is $X\mapsto Xi_{\mathbb{A}}$ (as $\mathrm{pr}_k i_{\mathbb{A}}=\mathrm{pr}_l i_{\mathbb{A}}=0$, $\mathrm{pr}_i i_{\mathbb{A}}=1$). The pair map P of (g,h) is $X\mapsto hXg^{-1}$. By Step 1, $Pk'_{\mathbb{A}}X'=h\varepsilon_t x_T^*X'm^*\mathrm{pr}_l=k'_{\mathbb{A}}(MX')$ with $MX'=AX'm^*$, $A=x_T^{-*}\varepsilon_t h\varepsilon_t x_T^*$; so

$$\det M=(\det h)^{\#p}\,\overline{\det m}^{\,\#n'},\qquad |\det M|=|\det m|^{\#n'},$$

as $\det h\,\overline{\det h}=1$. And $\mathrm{pr}_{i'}Pi'_{\mathbb{A}}Y=hY\mathrm{pr}_i g^{-1}i_{\mathbb{A}}=hYg_0^{-1}$ by (6.16), which is the pair map P_0 of (g_0,h) on $\mathrm{Hom}(V_0,T)$.

Step 4: the pair, (2). By (WR4), $\omega_{\alpha\upsilon^{\#p},\beta}(g,h)=\alpha(\det h)\upsilon(\det h)^{\#p}\beta(\det g)^{-1}\omega(P)$ and $\omega_{\alpha,\beta}(g_0,h)=\alpha(\det h)\beta(\det g_0)^{-1}\omega(P_0)$, with ω the Weil representations of $\mathrm{Hom}(V,T)$ and $\mathrm{Hom}(V_0,T)$. Lemma 6.2.10 for (k',l',i'), P, M, P_0 gives $Z_T\omega(P)=\upsilon(\det M)^{-1}|\det M|^{1/2}\omega(P_0)Z_T$. Using (6.16) and $\upsilon(\bar y)=\upsilon(y)^{-1}$ (WD3), the scalar collects to

$$\upsilon(\det h)^{\#p}\,\beta\Big(\frac{\det g}{\det g_0}\Big)^{-1}\upsilon(\det h)^{-\#p}\upsilon(\overline{\det m})^{-\#n'}|\det m|^{\#n'/2}=\chi(\det m)^{-1}|\det m|^{\#n'/2}.$$

So

$$Z_T\,\omega_{\alpha\upsilon^{\#p},\beta}(g,h)=\chi(\det m)^{-1}|\det m|^{\#n'/2}\,\omega_{\alpha,\beta}(g_0,h)\,Z_T.$$

Now the Hom slice at x is $Z_T(\rho(x\mathrm{pr}_k)\cdot)$ (MX4), and $\rho(x\mathrm{pr}_k)\omega(P) = \omega(P)\rho(P^{-1}(x\mathrm{pr}_k))$ with $P^{-1}(x\mathrm{pr}_k) = h^{-1}x\,\mathrm{pr}_k g$. By Step 1, $\mathrm{pr}_k g = l_{\mathbb{A}}^*\varepsilon_s g = (g^{-1}l_{\mathbb{A}})^*\varepsilon_s = m\,\mathrm{pr}_k + W^*\varepsilon_{s_0}\mathrm{pr}_i + B^*\mathrm{pr}_l$ (using $i_{\mathbb{A}}^*\varepsilon_s = \varepsilon_{s_0}\mathrm{pr}_i$ and $k_{\mathbb{A}}^*\varepsilon_s = \mathrm{pr}_l$), so

$$h^{-1}x\,\mathrm{pr}_k g = l'_{\mathbb{A}}X + i'_{\mathbb{A}}Y + k'_{\mathbb{A}}X', \qquad X = x_T h^{-1}xm, \quad Y = h^{-1}xW^*\varepsilon_{s_0}, \quad X' = x_T^{-*}\varepsilon_t h^{-1}xB^*.$$

The mixed law for (k', l', i') (whose slice at X, namely $Z_T(\rho(l'_{\mathbb{A}}X)f) = Z_T(\rho(x_T^{-1}X\mathrm{pr}_k)f)$, is the Hom slice at $x_T^{-1}X = h^{-1}xm$) gives $Z_T(\rho(l'_{\mathbb{A}}X+i'_{\mathbb{A}}Y+k'_{\mathbb{A}}X')f) = \psi_E(\frac{1}{2}\jmath\,\mathrm{tr}(X'^*X))\rho(Y)f[h^{-1}xm]$, and $X'^*X = Bx^*h^{-*}\varepsilon_t h^{-1}xm = Bx^*\varepsilon_t xm$ since $h^{-*}\varepsilon_t h^{-1} = \varepsilon_t$. Combining with the zero-term law proves (2). □

Lemma 6.2.46. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, and (k, l, i) a splitting of V over V_0 along p.*

1. *Let $x_{\mathbb{H}}$ be the point of the hyperbolic space $\mathbb{H}_p$, $s^{\mathbb{H}}$ its signs ($+1$ on the first and -1 on the second copy of p), and $F_D = (l_{\mathbb{A}}\ k_{\mathbb{A}}\ i_{\mathbb{A}})\,\mathrm{diag}(x_{\mathbb{H}}, 1)$, an adelic matrix with rows n and columns $(p \sqcup p) \sqcup n_0$. There are a bijection $\tau\colon (p\sqcup p)\sqcup n_0 \to n$ with $s(\tau(j)) = (s^{\mathbb{H}} \sqcup s_0)(j)$ for all j, and $g_D \in \mathrm{G}(s)$ whose column $\tau(j)$ is the column j of F_D for every j. For every such g_D the splitting is adapted at g_D in the basis 1.*

2. *Let $m \in \mathrm{GL}_p(\mathbb{A}_E)$ and $g \in \mathrm{G}(s)$ be such that the splitting is adapted at g in the basis m, and let $(\Pi_x)_{x\in\mathbb{A}_E^p}$ be bounded linear maps $\mathcal{M}_s \to \mathcal{M}_{s_0}$ with*

$$\Pi_x\,\rho(l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b) = \psi_E\big(\tfrac{1}{2}\jmath\,b^*(2x+a)\big)\,\rho(w)\,\Pi_{x+a} \qquad (x, a, b \in \mathbb{A}_E^p,\ w \in \mathbb{A}_E^{n_0}).$$

Then there is $C \in \mathbb{C}$ with $\Pi_x\,\omega_s(g)v^0 = C\,|e_p(m^*x)|^2\,v^0$ for all $x \in \mathbb{A}_E^p$, where v^0 on the right is the vacuum vector of $\mathcal{M}_{s_0}$.

Proof. **(1).** By the frame relations and the relation for $x_{\mathbb{H}}$, $F_D^*\varepsilon_s F_D = \varepsilon_{s^{\mathbb{H}}\sqcup s_0}$, and F_D is invertible. At one $v \in \Phi$, $F_{D,v}$ is an invertible congruence between $\mathrm{diag}(s)$ and $\mathrm{diag}(s^{\mathbb{H}} \sqcup s_0)$, so by Sylvester's law of inertia both have the same number of entries $+1$, and a bijection τ with $s \circ \tau = s^{\mathbb{H}} \sqcup s_0$ exists. Let P be the permutation matrix with $P\delta_j = \delta_{\tau(j)}$; the matrices with column $\tau(j)$ equal to column j of F_D are exactly $g_D = F_D P^{-1}$, and $g_D^*\varepsilon_s g_D = P\,\varepsilon_{s^{\mathbb{H}}\sqcup s_0}P^{-1} = \varepsilon_s$ (as $P^{-*} = P$ and $s\circ\tau = s^{\mathbb{H}}\sqcup s_0$), so $g_D \in \mathrm{G}(s)$. Moreover $g_D^{-1}(l_{\mathbb{A}}\ k_{\mathbb{A}}\ i_{\mathbb{A}}) = P\,\mathrm{diag}(x_{\mathbb{H}}^{-1}, 1)$. At $v \in \Phi$, $x_{\mathbb{H},v}^{-1} = 2^{-1/2}\begin{pmatrix} 1 & 1 \\ -1 & 1 \end{pmatrix}$ (scalar blocks) is unitary, so the columns are orthonormal. At the finite places $x_{\mathbb{H},f} = \begin{pmatrix} 1 & -c \\ c_0 & c\bar{c}_0 \end{pmatrix}$ has integral entries and determinant $c(c_0 + \bar{c}_0) = c$, a unit, so $x_{\mathbb{H},f}^{-1}$ and $P\,\mathrm{diag}(x_{\mathbb{H},f}^{-1}, 1)$ are integral. Hence the splitting is adapted at g_D in the basis 1.

(2), Step 0: reduction to $m = 1$. Put $l' = l_{\mathbb{A}}m^{-*}$, $k' = k_{\mathbb{A}}m$ and $\Pi'_y = \Pi_{m^{-*}y}$. Then $(l'\ k'\ i_{\mathbb{A}})^*\varepsilon_s(l'\ k'\ i_{\mathbb{A}}) = J_0$, and since $(mb)^*(2m^{-*}y + m^{-*}a) = b^*(2y + a)$ the law reads $\Pi'_y\rho(l'a + i_{\mathbb{A}}w + k'b) = \psi_E(\frac{1}{2}\jmath\,b^*(2y+a))\rho(w)\Pi'_{y+a}$. Steps 1–4 below use only these two facts and the hypothesis that $g^{-1}(l'\ k'\ i_{\mathbb{A}})$ has orthonormal columns at Φ and integral entries; we write them for $m = 1$, and for general m they give $\Pi'_y u = C|e_p(y)|^2 v^0$, that is, $\Pi_x u = C|e_p(m^*x)|^2 v^0$.

(2), Step 1: the adapted frame. Let $G = g^{-1}(l_{\mathbb{A}}\ k_{\mathbb{A}}\ i_{\mathbb{A}})$, with columns indexed by $p \sqcup p \sqcup n_0$, and write $z' = (a; b; w)$ accordingly, so that $gGz' = l_{\mathbb{A}}a + k_{\mathbb{A}}b + i_{\mathbb{A}}w$. As g preserves ε_s, $G^*\varepsilon_s G = J_0$. At $v \in \Phi$, G_v is square with orthonormal columns, hence unitary. At the finite places $\varepsilon_s = 1$ and $J_{0,f} = \begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix} \oplus 1 = J_{0,f}^{-1}$, so $G_f^{-1} = J_{0,f}G_f^*$ is integral and $G_f \in \mathrm{GL}_n(\widehat{\mathcal{O}}_E)$.

Therefore $z' \mapsto Gz'$ preserves μ_n (the scalings of (WD6) are scalars), and, in the coordinates $x_{v,j} = \kappa_v u_{v,j}$ at $v \in \Phi$ and $x_f = \alpha\xi$ at the finite places, with $|x|_\infty^2 = \sum_{v,j} |u_{v,j}|^2$,

$$e_n(Gz') = \epsilon(a,b)\, e_{n_0}(w), \qquad \epsilon(a,b) = e^{-(|a|_\infty^2+|b|_\infty^2)/2}\, \psi_0\big(\tfrac{c_0}{2}(a_f'^* b_f' + b_f'^* a_f')\big)\, \mathbf{1}[a_f', b_f' \in \widehat{\mathcal{O}}_E^p],$$

where $a_f = \alpha a_f'$, $b_f = \alpha b_f'$: at $v \in \Phi$ use $|G_v z_v'| = |z_v'|$, and at the finite places $(G_f z')^*(G_f z') = z'^* J_{0,f} z' = a^* b + b^* a + w^* w$ and $G_f z' \in \alpha \widehat{\mathcal{O}}_E^n$ if and only if $z' \in \alpha \widehat{\mathcal{O}}_E^n$.

Step 2: the values lie on the vacuum line. The law at $x = 0$, $b = 0$, $w = 0$ gives $\Pi_y = \Pi_0 \rho(l_{\mathbb{A}} y)$; so $\|\Pi_y\| \le \|\Pi_0\|$ and $y \mapsto \Pi_y F$ is continuous. Let $u = \omega_s(g) v^0$. By (3) of Lemma 6.2.12, $v^0 = \int e_n(y) \rho(y) v^0 \, d\mu_n(y)$; applying $\omega_s(g)$, then Π_x, substituting $y = Gz'$ and using the law,

$$\begin{aligned} \Pi_x u &= \int e_n(y)\, \Pi_x \rho(gy) u \, d\mu_n(y) \\ &= \iint \epsilon(a,b)\, \psi_E\big(\tfrac{1}{2}\jmath\, b^*(2x+a)\big) \Big(\int e_{n_0}(w) \rho(w)\, d\mu_{n_0}(w) \Big) \Pi_{x+a} u \, da\, db, \end{aligned}$$

Fubini being justified by the bound $|e_n(y)|\, \|\Pi_0\|\, \|u\|$ of the integrand, μ_n being the product of μ_p, μ_p, μ_{n_0} in the coordinates (a, b, w). By (3) of Lemma 6.2.12 for s_0, the inner integral sends X to $\langle v^0, X\rangle v^0$. Hence, with the bounded continuous function $\phi(y) = \langle v^0, \Pi_y u\rangle$, $\Pi_x u = \phi(x) v^0$ and

$$\phi(x) = \iint \epsilon(a,b)\, \psi_E\big(\tfrac{1}{2}\jmath\, b^*(2x+a)\big)\, \phi(x+a)\, da\, db. \tag{6.17}$$

Step 3: the integral over b. The integrand of (6.17) is a product of archimedean and finite factors. At each (v, j) the archimedean factor of $\psi_E(\frac{1}{2}\jmath\, b^* y)$ is $\exp((\bar{b}_{v,j} y_{v,j} - \bar{y}_{v,j} b_{v,j})/2)$ in the normalized coordinates (as $\jmath_v \kappa_v^2 = i/(2\pi)$), whose modulus is 1; the Fourier transform of the Gaussian gives $\pi^{-1} \int_{\mathbb{C}} e^{-|t|^2/2} e^{(\bar{t}y - \bar{y}t)/2} dt = 2e^{-|y|^2/2}$. With $y = 2x + a$ and $|a|^2 + |2x+a|^2 = 2|x|^2 + 2|x+a|^2$, the archimedean b-integral times $e^{-|a|_\infty^2/2}$ is $2^N e^{-|x|_\infty^2} e^{-|x+a|_\infty^2}$, $N = \#\Phi\, \#p$. At the finite places, with $x_f = \alpha\xi$, the factor of $\psi_E(\frac{1}{2}\jmath\, b^*(2x+a))$ is $\psi_0(\frac{1}{2} b_f'^*(2\xi + a_f'))$, and $\psi_0(\frac{c_0}{2} a_f'^* b_f') = \psi_0(-\frac{\bar{c}_0}{2} b_f'^* a_f')$ (as $\psi_0(\bar{t}) = \psi_0(t)^{-1}$); since $1 + c_0 - \bar{c}_0 = 2c_0$, the finite factor depending on b_f' is $\psi_0(b_f'^*(\xi + c_0 a_f'))$, whose mean over $b_f' \in \widehat{\mathcal{O}}_E^p$ is $\mathbf{1}[\xi + c_0 a_f' \in \widehat{\mathcal{O}}_E^p]$ by self-duality; for a_f' integral this is $\mathbf{1}[\xi \in \widehat{\mathcal{O}}_E^p]$. Therefore

$$\phi(x) = 2^N e^{-|x|_\infty^2}\, \mathbf{1}\big[\xi \in \widehat{\mathcal{O}}_E^p\big] \int e^{-|x+a|_\infty^2}\, \mathbf{1}\big[a_f' \in \widehat{\mathcal{O}}_E^p\big]\, \phi(x+a)\, da.$$

Step 4: conclusion. For $\xi \in \widehat{\mathcal{O}}_E^p$ the substitution $a \mapsto a - x$ preserves the measure and the condition $a_f' \in \widehat{\mathcal{O}}_E^p$, so the last integral is $K = \int e^{-|a|_\infty^2} \mathbf{1}[a_f' \in \widehat{\mathcal{O}}_E^p] \phi(a)\, da$, independent of x. As $|e_p(x)|^2 = e^{-|x|_\infty^2} \mathbf{1}[\xi \in \widehat{\mathcal{O}}_E^p]$ by (WD5) ($2\pi \operatorname{Im}(\jmath_v)\kappa_v^2 = 1$), we get $\Pi_x u = \phi(x) v^0 = C |e_p(x)|^2 v^0$ with $C = 2^N K$. □

Lemma 6.2.47. *Let G be a locally compact group with a left Haar measure μ, let L and H be unimodular locally compact groups with Haar measures κ and ν, and let $i\colon L \times H \to G$ be a continuous injective homomorphism that is a homeomorphism onto its image, the image being closed. Let $\Lambda \le H$ be a discrete subgroup such that $\Gamma = i(\{1\} \times \Lambda)$ is discrete in G. Let $\rho\colon G \to \mathbb{C}$ be a function with $\operatorname{Re}\rho(g) \ge 0$ for all $g \in G$ and $\operatorname{Re}\rho \ne 0$ on a neighbourhood of some point of G. Then there is $R \in \mathbb{C} \setminus \{0\}$, depending only on $G, L, H, i, \Lambda, \mu, \kappa, \nu, \rho$, with the following property. Let $F\colon G \to \mathbb{C}$ be continuous, left Γ-invariant and μ_Γ-integrable on $\Gamma\backslash G$, and let $c \in \mathbb{C}$. Suppose that every $g \in G$ has some $k \in L \times H$ such that the iterated integral*

$$\int_L \int_{\Lambda\backslash H} F\big(i(l,a)\, i(k)\, g\big)\, d\nu_\Lambda(a)\, d\kappa(l)$$

exists (the inner integral converging absolutely for κ-almost every l and defining a κ-integrable function of l) and equals $\rho(g)\,c$. Then

$$\int_{\Gamma\backslash G} F\,d\mu_\Gamma = R\,c.$$

Proof. Write $M = i(L\times H)$, a closed subgroup of G. As i is an isomorphism of topological groups $L\times H\to M$, the image dm of $\kappa\otimes\nu$ under i is a left Haar measure of M.

A parametrisation of μ. By the existence of Bruhat functions for closed subgroups (Bourbaki, Intégration, ch. VII, §2, no. 4) there is a continuous $\beta_0\ge 0$ on G with $\int_M \beta_0(xm)\,dm = 1$ for every $x\in G$; put $\beta(g) = \beta_0(g^{-1})$, so that $\int_M \beta(m^{-1}g)\,dm = 1$ for every g. For Borel $f\colon G\to[0,\infty]$, Tonelli's theorem and the left invariance of μ (substitute $y = mx$ for fixed m) give

$$\int_G \beta(x)\int_M f(mx)\,dm\,d\mu(x) = \int_M\int_G \beta(m^{-1}y)f(y)\,d\mu(y)\,dm = \int_G f\,d\mu. \tag{6.18}$$

Since $\int_M f(mx)\,dm = \int_L\int_H f(i(l,1)\,i(1,a)\,x)\,d\nu(a)\,d\kappa(l)$ and $i(1,a)i(l,1) = i(l,a)$, (6.18) says that $((x,l),a)\mapsto i(1,a)\,T(x,l)$, with $T(x,l) = i(l,1)x$, carries $\big((\beta\mu)\otimes\kappa\big)\otimes\nu$ to μ; the measure $(\beta\mu)\otimes\kappa$ on $Z = G\times L$ is σ-finite.

Unfolding. Fix F as in the statement. Apply Lemma 6.2.48 to H, the injective continuous homomorphism $a\mapsto i(1,a)$, Λ, $(Z,(\beta\mu)\otimes\kappa)$ and T: applied to $|F|$ (the version in $[0,\infty]$) and Tonelli on $G\times L$ give, with

$$G' = \Big\{x\in G : \int_L\int_{\Lambda\backslash H} \big|F(i(l,a)x)\big|\,d\nu_\Lambda(a)\,d\kappa(l) < \infty\Big\},$$

that $(\beta\mu)(G\setminus G') = 0$; and, applied to F, with $I(x) = \int_{L\times\Lambda\backslash H} F(i(l,a)x)\,d(\kappa\otimes\nu_\Lambda)$ for $x\in G'$ (Fubini),

$$\int_{\Gamma\backslash G} F\,d\mu_\Gamma = \int_{G'} \beta(x)\,I(x)\,d\mu(x), \tag{6.19}$$

the integrand being μ-integrable on G'.

Invariance under M. The quotient measure ν_Λ is invariant under $\Lambda a\mapsto\Lambda a k_2$ for $k_2\in H$: if $\varphi\ge 0$ is Borel on H with $\sum_{\lambda\in\Lambda}\varphi(\lambda a) = 1$ (the indicator of a Borel set meeting each coset Λa exactly once, which exists as Λ is discrete in the second countable group H), so is $a\mapsto\varphi(ak_2^{-1})$, and for Borel $f\ge 0$ on $\Lambda\backslash H$ the right invariance of ν gives $\int_{\Lambda\backslash H} f(\Lambda a k_2)\,d\nu_\Lambda = \int_H \varphi(a) f(\Lambda a k_2)\,d\nu = \int_H \varphi(ak_2^{-1})f(\Lambda a)\,d\nu = \int_{\Lambda\backslash H} f\,d\nu_\Lambda$. Likewise κ is right invariant. For $k = (k_1,k_2)$ we have $i(l,a)\,i(k)\,x = i(lk_1, ak_2)\,x$; hence G' is invariant under left multiplication by M, and $I(i(k)x) = I(x)$ for $x\in G'$ and $k\in L\times H$. Moreover $\mu(G\setminus G') = 0$: by (6.18) with $f = \mathbf{1}_{G\setminus G'}$, which is left M-invariant, $\mu(G\setminus G') = \int_G \beta(x)\mathbf{1}_{G\setminus G'}(x)\,\mathrm{vol}(M)\,d\mu(x) = 0$, as $\beta\mathbf{1}_{G\setminus G'} = 0$ μ-almost everywhere (with $0\cdot\infty = 0$).

The inner integrals. Let $g\in G'$ and let k be as in the hypothesis. Then $i(k)g\in G'$, so the function $(l,\Lambda a)\mapsto F(i(l,a)i(k)g)$ is $\kappa\otimes\nu_\Lambda$-integrable, and by Fubini's theorem its iterated integral, which is $\rho(g)c$ by hypothesis, equals $I(i(k)g) = I(g)$. Hence

$$I(g) = \rho(g)\,c \qquad (g\in G'). \tag{6.20}$$

The constant. Call a pair (F,c) admissible if it satisfies the hypotheses of the statement. If (F,c) is admissible and $c = 0$, then $I = 0$ on G' by (6.20), and (6.19) gives $\int_{\Gamma\backslash G} F\,d\mu_\Gamma = 0 = Rc$

whatever R is. If no admissible pair with $c \neq 0$ exists, put $R = 1$. Otherwise fix one, (F_1, c_1) with $c_1 \neq 0$, with its set G_1' and function I_1, and put

$$R = \int_{G_1'} \beta(x)\, \frac{I_1(x)}{c_1}\, d\mu(x).$$

On G_1' we have $\rho = I_1/c_1$ by (6.20); in particular ρ is left M-invariant on the M-invariant set G_1'. If (F, c) is admissible with $c \neq 0$, then $\beta I/c = \beta\rho = \beta I_1/c_1$ on the μ-conull set $G' \cap G_1'$, so (6.19) gives $\int_{\Gamma\backslash G} F\, d\mu_\Gamma = c \int_{G'} \beta I/c\, d\mu = cR$. So R has the asserted property, and it does not depend on F or c.

$R \neq 0$. Suppose $R = 0$ for the R of the last case. As $\operatorname{Re}\rho \geq 0$, the function $\beta \operatorname{Re}\rho = \operatorname{Re}(\beta I_1/c_1)$ is nonnegative on G_1' with integral $\operatorname{Re} R = 0$, so it vanishes μ-almost everywhere on G_1'. The set $B = \{x \in G_1' : \operatorname{Re}\rho(x) > 0\}$ is left M-invariant, and $\beta \mathbf{1}_B = 0$ μ-almost everywhere; by (6.18) with $f = \mathbf{1}_B$ as before, $\mu(B) = 0$. Let U be a nonempty open set on which $\operatorname{Re}\rho \neq 0$. Then $U \cap G_1' \subset B$ and $\mu(U \cap G_1') = \mu(U) > 0$, a contradiction. Hence $R \neq 0$. □

Lemma 6.2.48. *Let G and H be locally compact groups with left Haar measures μ and ν, let $i\colon H \to G$ be an injective continuous homomorphism, and let $\Lambda \leq H$ be a discrete subgroup such that $\Gamma = i(\Lambda)$ is discrete in G. Let (Z, m) be a σ-finite measure space and $T\colon Z \to G$ a measurable map such that $(z, a) \mapsto i(a)T(z)$ carries $m \otimes \nu$ to μ. Let $F\colon G \to \mathbb{C}$ be Borel, left Γ-invariant and μ_Γ-integrable on $\Gamma\backslash G$. Then for m-almost every z the function $\Lambda a \mapsto F(i(a)T(z))$ is ν_Λ-integrable on $\Lambda\backslash H$, the function $z \mapsto \int_{\Lambda\backslash H} F(i(a)T(z))\, d\nu_\Lambda(a)$ (defined almost everywhere) is m-integrable, and*

$$\int_{\Gamma\backslash G} F\, d\mu_\Gamma = \int_Z \int_{\Lambda\backslash H} F\big(i(a)T(z)\big)\, d\nu_\Lambda(a)\, dm(z).$$

The same identity holds, in $[0, \infty]$, for every Borel left Γ-invariant $F\colon G \to [0, \infty]$.

Proof. **A cutoff for Γ.** The discrete subgroup Γ of the second countable group G is countable. Choose an open neighbourhood U of 1 with $UU^{-1} \cap \Gamma = \{1\}$ and elements $g_1, g_2, \ldots$ with $G = \bigcup_j U g_j$. Each set Ug_j meets each coset Γg in at most one point (if $\gamma u g_j = u' g_j$ with $u, u' \in U$, then $\gamma = u'u^{-1} \in \Gamma \cap UU^{-1}$, so $\gamma = 1$). Hence

$$D = \bigcup_{j \geq 1} \Big(Ug_j \setminus \Gamma\big(Ug_1 \cup \cdots \cup Ug_{j-1}\big) \Big)$$

is a Borel set (a countable union of Borel sets, Γ being countable) meeting every coset Γg in exactly one point. Put $\varphi = \mathbf{1}_D$; then $\sum_{\gamma \in \Gamma} \varphi(\gamma g) = 1$ for every $g \in G$.

The identity for $F \geq 0$. Let $F\colon G \to [0, \infty]$ be Borel and left Γ-invariant. By the defining property of μ_Γ applied to φF,

$$\int_{\Gamma\backslash G} F\, d\mu_\Gamma = \int_{\Gamma\backslash G} \sum_{\gamma \in \Gamma} \varphi(\gamma g) F(\gamma g)\, d\mu_\Gamma(\Gamma g) = \int_G \varphi F\, d\mu.$$

As $(z, a) \mapsto i(a)T(z)$ carries $m \otimes \nu$ to μ, and m, ν are σ-finite (H is σ-compact), Tonelli's theorem gives

$$\int_G \varphi F\, d\mu = \int_Z \int_H \varphi\big(i(a)T(z)\big) F\big(i(a)T(z)\big)\, d\nu(a)\, dm(z).$$

Fix z and put $\varphi_z(a) = \varphi(i(a)T(z))$, $F_z(a) = F(i(a)T(z))$. Since i is an injective homomorphism, $\lambda \mapsto i(\lambda)$ is a bijection $\Lambda \to \Gamma$ and $i(\lambda a)T(z) = i(\lambda)\, i(a)T(z)$; therefore $\sum_{\lambda \in \Lambda} \varphi_z(\lambda a) =$

$\sum_{\gamma\in\Gamma}\varphi(\gamma\, i(a)T(z))=1$ and $F_z(\lambda a)=F_z(a)$ for $\lambda\in\Lambda$. By the defining property of ν_Λ,

$$\int_H \varphi_z F_z\,d\nu=\int_{\Lambda\backslash H}\sum_{\lambda\in\Lambda}\varphi_z(\lambda a)F_z(\lambda a)\,d\nu_\Lambda(\Lambda a)=\int_{\Lambda\backslash H}F_z\,d\nu_\Lambda.$$

The left side is a measurable function of z by Tonelli's theorem, hence so is the right side, and combining the three displays proves the identity in $[0,\infty]$.

Integrable F. Apply the case just proved to $|F|$:

$$\int_Z\int_{\Lambda\backslash H}|F(i(a)T(z))|\,d\nu_\Lambda\,dm=\int_{\Gamma\backslash G}|F|\,d\mu_\Gamma<\infty.$$

So the inner function is ν_Λ-integrable for m-almost every z, and the almost everywhere defined function $z\mapsto\int_{\Lambda\backslash H}F(i(a)T(z))\,d\nu_\Lambda$ is dominated by an m-integrable function. Write $F=F_0-F_1+\mathrm{i}F_2-\mathrm{i}F_3$ with F_0,F_1 the positive and negative parts of $\operatorname{Re}F$ and F_2,F_3 those of $\operatorname{Im}F$; each F_j is Borel, left Γ-invariant and bounded by $|F|$, so both sides of the identity are finite for F_j. Applying the case $F\ge0$ to each F_j and taking the same linear combination gives the identity for F. □

Lemma 6.2.49. *Let W and W_0 be spaces with points with signs s on n and s_0 on n_0, and let H be a splitting of W over W_0 along a one-element set, with Levi and radical elements lev_H and rad_H. Let S be a nonempty set of finite places of E, and let $D\colon \mathrm{G}(s)\to\mathbb{C}$ be a continuous function with the following properties.*

1. *$D(\gamma g)=D(g)$ for all $\gamma\in\Gamma_W$ and $g\in\mathrm{G}(s)$.*
2. *$D(g\,(1,a))=D(g)$ for all $g\in\mathrm{G}(s)$ and all $a\in G_f(n)$ whose components at the finite places outside $S\cup\bar S$ are 1.*
3. *If $D(\mathrm{rad}_H(c,b)\,g)=D(g)$ for all adelic $n_0\times1$ matrices c, all $b\in\mathbb{A}_E$ and all $g\in\mathrm{G}(s)$, then $D(\mathrm{lev}_H(t,1))=D(1)$ for all $t\in\mathbb{A}_E^\times$.*

Then D is constant on $\mathrm{G}(s)$.

Proof. Write $H=(k,l,i)$ with adelic frames $k_\mathbb{A},l_\mathbb{A},i_\mathbb{A}$ and coordinates $\mathrm{pr}_k,\mathrm{pr}_l,\mathrm{pr}_i$, and let $Q=(l_\mathbb{A}\mid k_\mathbb{A}\mid i_\mathbb{A})\in\mathrm{GL}_n(\mathbb{A}_E)$; by (MX1) the rows of Q^{-1} are pr_l, pr_k, pr_i. Let $\mathrm{SU}\subseteq\mathrm{G}(s)$ be the kernel of det. Through $g\mapsto x_W g x_W^{-1}$, $\mathrm{G}(s)$ is $\mathrm{U}(W)(\mathbb{A}_F)$, SU is $\mathrm{SU}(W)(\mathbb{A}_F)$ for the special unitary group $\mathrm{SU}(W)$ of the hermitian form J_W on E^n, an algebraic group over F, and $\Gamma_W\cap\mathrm{SU}$ is $\mathrm{SU}(W)(F)$; the topologies agree, since $\mathrm{GL}_n(E\otimes_F\mathbb{A}_F)=\mathrm{GL}_n(\mathbb{A}_E)$ and conjugation by x_W is a homeomorphism.

Step 1: radical elements and the place v. For all c, b the element $\mathrm{rad}_H(c,b)$ lies in SU: by (MX2), $N=\mathrm{rad}_H(c,b)-1$ maps the column space of $l_\mathbb{A}$ into that of $(i_\mathbb{A}\mid k_\mathbb{A})$, that of $i_\mathbb{A}$ into that of $k_\mathbb{A}$, and kills $k_\mathbb{A}$ (as $\mathrm{pr}_l k_\mathbb{A}=0$, $\mathrm{pr}_i k_\mathbb{A}=0$, $\mathrm{pr}_l i_\mathbb{A}=0$); so N is nilpotent and $\det\mathrm{rad}_H(c,b)=1$. Fix $w\in S$ and let v be the place of F below w; the places of E above v are w and $\bar w$, both in $S\cup\bar S$. Let $\mathrm{SU}_v\subseteq\mathrm{SU}$ be the subgroup of elements whose components at all places of E not above v are 1; it corresponds to $\mathrm{SU}(W)(F_v)$, and each of its elements is $(1,a)$ with a as in (2). For $y\in F_v$ let y also denote the adele of E with components y at w, $\bar w$ and 0 elsewhere; then $\bar y=y$ and by (MX2)

$$\mathrm{rad}_H(0,y)=1-\jmath^{-1}y\,k_\mathbb{A}\mathrm{pr}_l\in\mathrm{SU}_v.$$

Since $k_\mathbb{A}\mathrm{pr}_l\,l_\mathbb{A}=k_\mathbb{A}$ has nonzero component at w, some entry of $(k_\mathbb{A}\mathrm{pr}_l)_w$ is nonzero, so the entries of $\mathrm{rad}_H(0,y)_w$ are unbounded as $|y|_v\to\infty$; hence $\mathrm{SU}(W)(F_v)$, a closed subgroup of $\mathrm{GL}_n(E\otimes_F F_v)$ containing an unbounded set, is not compact.

Step 2: strong approximation. The group $\mathrm{SU}(W)$ is connected, simply connected and absolutely almost simple over F: over an algebraic closure of F it becomes SL_n, and $n = n_0 + 2 \geq 2$. By Step 1 and strong approximation (Theorem A.4.8, with $K = F$, $H = \mathrm{SU}(W)$ and the finite set $\{v\}$), $\mathrm{SU}(W)(F)$ is dense in $\mathrm{SU}(W)(\mathbb{A}_F^{\{v\}})$. Hence the products γk with $\gamma \in \Gamma_W \cap \mathrm{SU}$ and $k \in \mathrm{SU}_v$ are dense in SU: given $h \in \mathrm{SU}$ and a neighbourhood of h, which contains a product $N_v \times N^v$ of neighbourhoods of the components of h above v and away from v in $\mathrm{SU}(W)(F_v) \times \mathrm{SU}(W)(\mathbb{A}_F^{\{v\}})$, choose γ with components away from v in N^v and let $k \in \mathrm{SU}_v$ have components $\gamma_u^{-1} h_u$ at the places u above v; then γk has the components of h above v and those of γ elsewhere, so it lies in $N_v \times N^v$.

Step 3: $D(hg) = D(g)$ for all $h \in \mathrm{SU}$ and $g \in \mathrm{G}(s)$. Fix g. For $\gamma \in \Gamma_W \cap \mathrm{SU}$ and $k \in \mathrm{SU}_v$, (1) gives $D(\gamma k g) = D(kg)$, and $kg = g\,(g^{-1}kg)$, where $g^{-1}kg$ has component 1 at every place of E not above v, the infinite places included; so $g^{-1}kg = (1, a)$ with a as in (2), and (2) gives $D(kg) = D(g)$. The function $h \mapsto D(hg)$ on SU is continuous and equals $D(g)$ on the dense set of Step 2, hence everywhere.

Step 4: the torus. By Steps 1 and 3, $D(\mathrm{rad}_H(c, b) g) = D(g)$ for all c, b, g, so (3) gives $D(\mathrm{lev}_H(t, 1)) = D(1)$ for every $t \in \mathbb{A}_E^\times$. By (MX2), $\mathrm{lev}_H(t, 1) = Q\,\mathrm{diag}(\bar{t}^{-1}, t, 1)\,Q^{-1}$, so

$$\det \mathrm{lev}_H(t, 1) = t\,\bar{t}^{-1}.$$

Step 5: every $g \in \mathrm{G}(s)$ is $h\,\mathrm{lev}_H(t, 1)$ with $h \in \mathrm{SU}$ and $t \in \mathbb{A}_E^\times$. From $g^* \varepsilon_s g = \varepsilon_s$, $z = \det g$ satisfies $z\bar{z} = 1$. Every such idele is $t\bar{t}^{-1}$ for some $t \in \mathbb{A}_E^\times$: at each place u of F, $E \otimes_F F_u$ is $\mathbb{C}$, a quadratic field extension of F_u or $F_u \times F_u$ with the exchange involution, and Hilbert's Theorem 90 for this quadratic algebra gives t_u with $z_u = t_u \bar{t}_u^{-1}$; at the almost all finite u that are unramified in E and at which z_u is a unit, t_u can be taken a unit, namely $t_u = (z_{u,1}, 1)$ if $z_u = (z_{u,1}, z_{u,1}^{-1})$ in the split case, and the unit part of t_u in the inert case (a uniformiser of F_u is one of $E \otimes_F F_u$ and is fixed by the involution). So $t = (t_u)$ is an idele. Put $h = g\,\mathrm{lev}_H(t, 1)^{-1}$; by Step 4, $\det h = 1$.

Conclusion. For $g = h\,\mathrm{lev}_H(t, 1)$ as in Step 5, Steps 3 and 4 give $D(g) = D(\mathrm{lev}_H(t, 1)) = D(1)$. □

Lemma 6.2.50. *Let G be a locally compact group with a left Haar measure μ, $H \leq G$ a closed subgroup with a left Haar measure ν, and $\Gamma \leq H$ a subgroup that is discrete in G. Let $F\colon G \to \mathbb{C}$ be continuous, left Γ-invariant and μ_Γ-integrable on $\Gamma\backslash G$. Let (C, κ) be a probability space, $d \geq 0$, $a \in \mathbb{C}$, and $t\colon G \times C \to H$ a map with $b \mapsto t(x, b)$ measurable for every $x \in G$, such that:*

1. *for all $x \in G$ and $b \in C$, the right translation $s \mapsto s\,t(x, b)$ of H carries ν to $d\nu$;*
2. *for all $s \in H$ and $x \in G$, the function $b \mapsto F(s\,t(x, b)\,x)$ is κ-integrable and*

$$\int_C F(s\,t(x, b)\,x)\,d\kappa(b) = a\,F(sx).$$

If $a \neq d$, then $\int_{\Gamma\backslash G} F\,d\mu_\Gamma = 0$.

Proof. Suppose $\int_{\Gamma\backslash G} F\,d\mu_\Gamma \neq 0$; we show $a = d$.

Unfolding along H. By the existence of Bruhat functions for closed subgroups (Bourbaki, Intégration, ch. VII, §2, no. 4) there is a continuous $\beta_0 \geq 0$ on G with $\int_H \beta_0(ys)\,d\nu(s) = 1$ for all $y \in G$; put $\beta(g) = \beta_0(g^{-1})$, so $\int_H \beta(s^{-1}g)\,d\nu(s) = 1$ for all g. For Borel $f \geq 0$ on G, Tonelli's theorem and the left invariance of μ give

$$\int_G \beta(x) \int_H f(sx)\,d\nu(s)\,d\mu(x) = \int_H \int_G \beta(s^{-1}y) f(y)\,d\mu(y)\,d\nu(s) = \int_G f\,d\mu,$$

so $(x,s)\mapsto sx$ carries the σ-finite measure $(\beta\mu)\otimes\nu$ to μ. By Lemma 6.2.48 (with H, the inclusion $H\to G$, $\Lambda=\Gamma$, $Z=G$, $m=\beta\mu$, $T(x)=x$), for $\beta\mu$-almost every x the function $\Gamma s\mapsto F(sx)$ is ν_Γ-integrable on $\Gamma\backslash H$, and

$$\int_{\Gamma\backslash G}F\,d\mu_\Gamma=\int_G\beta(x)\int_{\Gamma\backslash H}F(sx)\,d\nu_\Gamma(s)\,d\mu(x).$$

As the left side is nonzero, there is $x\in G$ such that $s\mapsto F(sx)$ is ν_Γ-integrable and $J=\int_{\Gamma\backslash H}F(sx)\,d\nu_\Gamma(s)\neq0$. Fix this x and write $t_b=t(x,b)$.

The effect of one translation. Let φ be the indicator of a Borel subset of H meeting each coset Γs exactly once (it exists as Γ is discrete in the second countable group H), so that $\sum_{\gamma\in\Gamma}\varphi(\gamma s)=1$ and $\int_{\Gamma\backslash H}f\,d\nu_\Gamma=\int_H\varphi f\,d\nu$ for every Borel left Γ-invariant $f\geq0$ on H. Let $f\geq0$ be such a function and $b\in C$. By (1), $\int_H h(st_b)\,d\nu(s)=d\int_H h\,d\nu$ for Borel $h\geq0$; applied to $h(s)=\varphi(st_b^{-1})f(s)$, and as $s\mapsto\varphi(st_b^{-1})$ is again the indicator of a set meeting each coset once,

$$\int_H\varphi(s)f(st_b)\,d\nu(s)=d\int_H\varphi(st_b^{-1})f(s)\,d\nu(s)=d\int_{\Gamma\backslash H}f\,d\nu_\Gamma.\tag{6.21}$$

Since $s\mapsto F(st_bx)$ is left Γ-invariant, (6.21) with $f(s)=|F(sx)|$, and then with the four positive and negative parts of the real and imaginary parts of $F(sx)$, gives

$$\int_H\varphi(s)\big|F(st_bx)\big|\,d\nu(s)=d\int_{\Gamma\backslash H}|F(sx)|\,d\nu_\Gamma<\infty,\qquad\int_H\varphi(s)F(st_bx)\,d\nu(s)=d\,J.$$

Fubini. The function $(s,b)\mapsto\varphi(s)F(st(x,b)x)$ on $H\times C$ is measurable (F is continuous and $b\mapsto t(x,b)$ measurable), and by the first identity and $\kappa(C)=1$ it is $\nu\otimes\kappa$-integrable. By Fubini's theorem, the second identity and (2),

$$\begin{aligned}d\,J&=\int_C\int_H\varphi(s)F(st_bx)\,d\nu(s)\,d\kappa(b)=\int_H\varphi(s)\int_C F(st(x,b)x)\,d\kappa(b)\,d\nu(s)\\&=a\int_H\varphi(s)F(sx)\,d\nu(s)=a\,J.\end{aligned}$$

As $J\neq0$, $a=d$. □

6.3 The exchange identity

This section proves the exchange identity (Theorem 6.3.2), from the facts of Section 6.2; what the later sections use is that its constant is uniform in the character. The identity belongs to the theory of theta lifts in Witt towers: Rallis's tower property [236], the Siegel–Weil formula and its regularised forms [280, 323, 176, 139], and the Rallis inner product formula [238, 231, 187]. The second term identity and the inner product formula at the boundary of the convergent range [94, 331] are related to the equal-rank constant below, but are not used. The organisation follows [259].

The theta integrals converge because the local data are target-bounded, and their centre coefficients along a splitting are computed by unfolding: for an invertible Gram matrix the coefficient is, by Witt's theorem [330], the integral of one theta term over the quotient by the stabiliser of one frame (Lemma 6.3.25). This is the unitary form of the computation of Fourier coefficients of theta lifts that goes back to [237, 171]; for Fourier–Jacobi and Bessel periods in this language see [96].

The proof has two halves. The first is the exchange for matched functions (Lemma 6.3.3), with a constant whose square is L_* times the equal-rank ratio, in four steps. (1) At the top,

for a large triple, the identity follows from an identity of periods whose value is the equal-rank theta integral (Proposition 6.3.22, Proposition 6.3.6). The coefficients at indices that are not negative at some real place vanish, because an invariant Fock functional of that kind is zero, and the remaining coefficients are controlled by an equivariant lift, which vanishes once the standard datum vanishes at self-dual lattices (Proposition 6.3.33). This rests on a vanishing theorem for singular centre coefficients, which we call Freitag's lemma (Proposition 6.3.36) after Freitag's theory of singular modular forms [90]; see also [188]. In our reading, neither contains it in the form needed. (2) The identity descends from the top by removing hyperbolic planes one at a time (Proposition 6.3.10), with the tower property on the large side and only the zero vector on the small side; the change of point uses Landherr's theorem [180] and the Hasse norm theorem [123]. (3) It passes from standard to all matched data (Lemma 6.3.13). (4) The small side at the adjoint datum is a unimodular multiple of the theta integral of the reversed pair (Lemma 6.3.4).

The second half is the equal-rank constant (Lemma 6.3.15): the ratio is one nonzero constant for every modulus and every character. It depends only on the signs of the space, and it does not vanish identically (Lemma 6.3.16), since otherwise the vanishing would descend along hyperbolic planes to rank 0, where the theta integral is 1; the descent needs only Hecke's theory (Lemma 6.3.62).

Before the law for squares that closes the section comes the explicit matching (Proposition 6.3.67), the identity for class sums over a definite group at polynomial data, which the cost of one lift uses (Lemma 6.6.62). Besides the exchange identity it needs the calculus of theta kernels (Lemma 6.3.71) and an archimedean matching (Lemma 6.3.68), which rests on the density of the Fock vectors of polynomials [14] and on a polarisation identity for products of determinants, from Weyl's dimension formula [151, 92].

Definition 6.3.1. Class sums. Let a be a finite index set, I_a the standard definite space, $\mathbf{K}_a = \mathrm{U}(I_a)(\widehat{\mathcal{O}})$ the stabiliser of the standard lattice in $\mathrm{U}(I_a)(\mathbb{A}_{F,f})$, and $\Gamma \subseteq \mathbf{K}_a$ an open subgroup. For a function F on $\mathrm{U}(I_a)(\mathbb{A}_{F,f})$, left invariant under $\mathrm{U}(I_a)(F)$ and right invariant under Γ, the **class sum** is

$$\sum_{h \bmod \Gamma}^{\mathrm{cl}} F(h) = \sum_{\mathfrak{c}} \frac{F(h_{\mathfrak{c}})}{\#\big(\mathrm{U}(I_a)(F) \cap h_{\mathfrak{c}} \Gamma h_{\mathfrak{c}}^{-1}\big)}, \tag{6.22}$$

the (finite) sum over the double cosets $\mathfrak{c}$ of $\mathrm{U}(I_a)(F)\backslash \mathrm{U}(I_a)(\mathbb{A}_{F,f})/\Gamma$ with representatives $h_{\mathfrak{c}}$. For a theta kernel with second space I_a, a finite point h is read as the adelic point with infinite components 1.

Polynomials and their Fock vectors. For finite index sets r (rows) and c (columns), $\mathbb{C}[x]_{r\times c}$ is the polynomial ring in the variables $x_{\tau,i,k}$, $\tau \in \Phi$, $i \in r$, $k \in c$; for spaces S, T with index sets n_S, n_T a polynomial $P \in \mathbb{C}[x]_{n_T \times n_S}$ has a Fock vector v_P for the pair (S,T), and for a modulus $\mathfrak{m}$ and a function Φ on $n_T \times n_S$ matrices over $R_{\mathfrak{m}}$ we write $\theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Phi, P] = \theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}}(\Phi, v_P))$.

Block signs. Let n, m, l, b, p, a be finite index sets with bijections $j\colon m \sqcup l \to n$, $f\colon p \sqcup l \to b$, $e\colon p \sqcup a \to m$. The signs sgn_j on n are $+1$ on $j(m)$ and -1 on $j(l)$; the signs sgn_f on b are $+1$ on $f(p)$ and -1 on $f(l)$.

Stacked determinants. Let $\iota = (\iota_\tau)_{\tau\in\Phi}$ be finite sets and $\eta = (\eta_{\tau k})_{\tau\in\Phi, k\in\iota_\tau}$ complex $p \times m$ matrices. For τ and k let $\Delta_\tau(\eta_{\tau k})$ be the determinant of the $m \times m$ matrix whose row $e(i)$ is the row i of $\eta_{\tau k}$ for $i \in p$, and whose row $e(i)$ is $(x_{\tau,i,j(k')})_{k'\in m}$ for $i \in a$. The **product of stacked determinants** is

$$\Delta^j(e;\eta) = \prod_{\tau\in\Phi} \prod_{k\in\iota_\tau} \Delta_\tau(\eta_{\tau k}) \ \in \mathbb{C}[x]_{a\times n}. \tag{6.23}$$

Matched polynomial. With the same data, let $y_\tau^{--} = (x_{\tau,j(i),f(i')})_{i,i'\in l}$ and $y_\tau^{++} = (x_{\tau,j(i),f(i')})_{i\in m,i'\in p}$. The **matched polynomial** is

$$Q_{f,j}(\eta) = \prod_{\tau\in\Phi} \det(y_\tau^{--})^{\max(0,\,|\iota_\tau|+|n|-2|l|)} \prod_{\tau\in\Phi}\prod_{k\in\iota_\tau} \det(\eta_{\tau k}\, y_\tau^{++}) \ \in \mathbb{C}[x]_{n\times b}. \tag{6.24}$$

Theorem 6.3.2. *Let W, V, V' be spaces with index sets n, a, b and a bijection $\sigma\colon b\sqcup a\to n$, and let $e\in\mathbb{N}$ with*

$$\operatorname{rk} V = \operatorname{rk} V' + 2e, \qquad \operatorname{neg}(W) = \operatorname{neg}(V) + \operatorname{neg}(V'),$$
$$2\operatorname{neg}(W) + 2 \le \operatorname{rk} W \le 2\mu(v) + 2\operatorname{neg}(W) \quad (v\in\Phi),$$

for a function $\mu\colon\Phi\to\mathbb{Z}$. Let v be a Schwartz vector for (V',W). Then there are a real number $C>0$ and a Schwartz vector x for (W,V) such that for every modulus $\mathfrak{m}$, every χ and every ν tame of weight μ for $(\mathfrak{m},\chi)$ there is $c\in\mathbb{C}$ with

$$|c|^2 = C\cdot L_*(\mathfrak{m},\nu;e) \neq 0$$

and, with $\gamma=\nu^{-1}\upsilon^{\operatorname{rk} W/2}$: for all automorphic characters α,α' of $\mathrm{U}(1)$ with $\alpha[\operatorname{rk} V]\,\alpha'[\operatorname{rk} V'] = \tilde\nu^{-1}$, all Φ, Ψ matched for (σ,χ) modulo $\mathfrak{m}$, and all $g\in\mathrm{U}(W)(\mathbb{A}_F)$,

$$I^{W,V}_{\gamma,\alpha}(\mathrm{mod}_{\mathfrak{m}}(\Phi,x))(g) = c\int_{[\mathrm{U}(V')]} \theta^{V',W}_{\alpha',\gamma}(\mathrm{mod}_{\mathfrak{m}}(\Psi,v))(h,g)\,dh.$$

The constant C and the vector x are chosen before $\mathfrak{m}$ and ν; so $|c|^2$ is proportional to $L_*(\mathfrak{m},\nu;e)$ with a factor independent of the character.

Proof. **Step 1: the parameters.** By σ, $\operatorname{rk} W = \operatorname{rk} V + \operatorname{rk} V' = 2\operatorname{rk} V' + 2e$ is even, so $\operatorname{rk} V - \frac12\operatorname{rk} W = e$. Put $k = \frac12\operatorname{rk} W - \operatorname{neg}(W)$. Then $k\ge 1$ by $2\operatorname{neg}(W)+2\le\operatorname{rk} W$, $\operatorname{rk} W = 2k + 2\operatorname{neg}(W)$, and $k\le\mu(v)$ for all v by $\operatorname{rk} W\le 2\mu(v)+2\operatorname{neg}(W)$; in particular $\mu\ge 1$.

Step 2: the constant. By Lemma 6.3.15 there are a Schwartz vector z for $(\mathbb{H}\oplus W,\mathbb{H}\oplus W)$ and $C_0\neq 0$ with $r_{\mathbb{H}\oplus W}(\nu,z) = C_0$ for every tame ν of weight μ. Apply Lemma 6.3.3 to $(W,U,V) = (W,V',V)$, with this z and $y=v$ (the hypotheses on ranks and signs are those of the theorem). It gives $C_1\in\mathbb{R}$ and a Schwartz vector x for (W,V) such that every tame ν has a number c with

$$C_1|c|^2 = L_*(\mathfrak{m},\nu;e)\,C_0,$$

together with the identity of (2) of that lemma for $\alpha=1$, $\alpha'=\gamma$ and matched functions over $\mathcal{O}_{\mathfrak{m}}$. The right side is not zero ($L_*>0$, $C_0\neq 0$), so $C_1\neq 0$, $c\neq 0$ and $|c|^2 = (C_0/C_1)L_*(\mathfrak{m},\nu;e)$. If $C_0/C_1\le 0$ this contradicts $|c|^2>0$, so no tame ν of weight μ exists and the theorem holds with $C=1$. Otherwise put $C = C_0/C_1 > 0$.

Step 3: data modulo $\mathfrak{m}$. Let Φ, Ψ be matched for (σ,χ) modulo $\mathfrak{m}$, and let $\pi\colon\mathcal{O}_{\mathfrak{m}}\to R_{\mathfrak{m}}$ be the reduction. It is onto, it is compatible with the residue maps (so u is a unit if and only if $\pi(u)$ is), and on units the character of ν at the places of $\mathfrak{m}$ is $\chi\circ\pi$, by (XD4). Let Φ', Ψ' be $\Phi\circ\pi$, $\Psi\circ\pi$ on integral matrices and 0 elsewhere. Then Ψ' is locally constant, (Φ',Ψ') is matched over $\mathcal{O}_{\mathfrak{m}}$ (the conditions of (XD6) pass through the surjection $\mathrm{GL}_n(\mathcal{O}_{\mathfrak{m}})\to\mathrm{GL}_n(R_{\mathfrak{m}})$), and by (XD5) $\mathrm{mod}_{\mathfrak{m}}(\Phi,x) = x\otimes\Phi'\otimes\Phi^\circ$ and $\mathrm{mod}_{\mathfrak{m}}(\Psi,v) = v\otimes\Psi'\otimes\Phi^\circ$. So Step 2 gives the identity for $\alpha=1$, $\alpha'=\gamma$.

Step 4: the splitting characters. Space characters multiply, $\alpha[p]\,\alpha'[q] = (\alpha\alpha')[p+q]$, and $\gamma[\operatorname{rk} W] = \tilde\nu^{-1}$.

Since base change is injective, $\alpha[\operatorname{rk} V]\alpha'[\operatorname{rk} V'] = \tilde{\nu}^{-1}$ holds if and only if $\alpha\alpha' = \gamma$. Twisting the second character of the pair (W, V) by α multiplies its theta kernel by $d = \alpha(\det g)^{-1}$, and twisting the first character of the pair (V', W) from γ to $\alpha' = \gamma\alpha^{-1}$ multiplies its kernel by the same d. Indeed, by (WR4), $\omega_{\alpha_1,\beta_1}(g_1, h_1) = \alpha_1(\det h_1)\beta_1(\det g_1)^{-1}\omega_{1,1}(g_1, h_1)$ for every pair and all characters, and the theta functional is linear; hence, for every datum φ of (W, V), every datum φ' of (V', W), $g \in \mathrm{U}(W)(\mathbb{A}_F)$, $h \in \mathrm{U}(V)(\mathbb{A}_F)$ and $h' \in \mathrm{U}(V')(\mathbb{A}_F)$,

$$\theta^{W,V}_{\gamma,\alpha}(\varphi)(g,h) = \alpha(\det g)^{-1}\theta^{W,V}_{\gamma,1}(\varphi)(g,h), \qquad \theta^{V',W}_{\gamma\alpha^{-1},\gamma}(\varphi')(h',g) = \alpha(\det g)^{-1}\theta^{V',W}_{\gamma,\gamma}(\varphi')(h',g),$$

and integrating over h, resp. h', the theta integral and the right side of Step 3 are multiplied by d. Multiplying the identity of Step 3 by d gives the identity for (α, α'). □

Lemma 6.3.3. *Let W, U, V be spaces with index sets n, b, r and a bijection $\sigma\colon b \sqcup r \to n$, so that $\operatorname{rk} W = \operatorname{rk} U + \operatorname{rk} V$; assume $\operatorname{rk} W$ even and $\operatorname{neg}(W) = \operatorname{neg}(V) + \operatorname{neg}(U)$. Let $\mu\colon \Phi \to \mathbb{Z}_{>0}$, let z be a Schwartz vector for $(\mathbb{H} \oplus W, \mathbb{H} \oplus W)$ and y a Schwartz vector for (U, W). Then there are $C \in \mathbb{R}$ and a Schwartz vector v for (W, V) with the following property. For every modulus $\mathfrak{m}$ whose places are split over F and every ν tame of weight μ for $(\mathfrak{m}, \chi)$, put $\gamma = \nu^{-1}\upsilon^{\operatorname{rk} W/2}$; there is $c \in \mathbb{C}$ with*

1. *$C\,|c|^2 = L_*(\mathfrak{m}, \nu; \operatorname{rk} V - \frac{1}{2}\operatorname{rk} W) \cdot r_{\mathbb{H}\oplus W}(\nu, z)$;*
2. *for all functions Φ on $r \times n$ and Ψ on $n \times b$ matrices over $\prod_{w\in\mathfrak{m}} E_w$, with Ψ locally constant and (Φ, Ψ) matched over $\mathcal{O}_\mathfrak{m}$ for (σ, χ), and all $g \in \mathrm{U}(W)(\mathbb{A}_F)$,*

$$I^{W,V}_{\gamma,1}(v \otimes \Phi \otimes \Phi^\circ)(g) = c \int_{[\mathrm{U}(U)]} \theta^{U,W}_{\gamma,\gamma}(y \otimes \Psi \otimes \Phi^\circ)(h, g)\, dh.$$

Proof. Write $W_0 = \mathbb{H} \oplus W$, with index set $n_0 = (\{o\} \sqcup \{o\}) \sqcup n$ and signs s_0, so $\#n_0 = \#n + 2$ is even, and let A be its tautological splitting over W along $\{o\}$. Tautological splittings are base-adapted: the matrix of adelic frames of that of $\mathbb{H}_p \oplus V_0$ is $\operatorname{diag}(x^{-1}_{\mathbb{H}_p}, 1)$, where $x_{\mathbb{H}_p}$ is unitary at the infinite places and at the finite places integral with determinant $(c\bar{c}_0 + cc_0)^{\#p} = c^{\#p}$, a unit. For a split tame character $\mathfrak{c} = (\nu, \Sigma)$ put

$$\ell(\mathfrak{c}) = \frac{\left|\theta^{\mathrm{lg}}_\mathfrak{c}(W_0, W_0; z, \Psi^{\mathrm{st}}_1)(1)\right|^2}{L_*(\Sigma, \nu; \#n_0/2)},$$

1 the identity $n_0 \times n_0$ matrix; $L_*(\Sigma, \nu; e) > 0$ for $e \geq 0$ by (3) of Theorem A.1.12 (as in (XD7): powers of norms times $|L^\Sigma(j, \tilde{\nu})|^2$, $j \geq 1$, with $\tilde{\nu}$ nontrivial). Let $U^\flat$ and $y^{\mathrm{ad}} \in \mathcal{F}_{W,U^\flat}$ be as in Lemma 6.3.4; $U^\flat$ has signs $-u$, and y^{ad} is a Schwartz vector by (1) of that lemma.

Step 0: moduli and split tame characters. Let $\mathfrak{m}$ be a modulus and ν tame of weight μ for $(\mathfrak{m}, \chi)$. As $\Sigma = \Sigma(\mathfrak{m})$ is nonempty and contains the conjugate of none of its members, $\mu > 0$, and the tame part of ν is nontrivial exactly at Σ, $\mathfrak{c} = (\nu, \Sigma)$ is a split tame character of weight μ ((XD4)). Its semilocal character is χ read through the residue maps: for $t \in \mathcal{O}^\times_\Sigma$, $t/\bar{t}$ has components t_w at $w \in \Sigma$, $\bar{t}_w^{-1}$ at $\bar{w} \notin \Sigma$ (where the tame part is trivial) and 1 elsewhere, so $\nu(t/\bar{t}) = \prod_{w\in\Sigma} \psi_w(t_w \bmod w) = \chi(t \bmod \mathfrak{m})$. Hence matched over $\mathcal{O}_\mathfrak{m}$ for (σ, χ) is matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_\mathfrak{c})$, and Φ_χ of (XD8) for W_0 is Ψ^{st}_1 for $\chi_\mathfrak{c}$; with $\gamma_0 = \nu^{-1}\upsilon^{\#n_0/2}$, $I_{W_0}(z) = I^{W_0,W_0}_{\gamma_0,\gamma_0}(z \otimes \Phi_\chi \otimes \Phi^\circ) = \theta^{\mathrm{lg}}_\mathfrak{c}(W_0, W_0; z, \Psi^{\mathrm{st}}_1)$, so $r_{\mathbb{H}\oplus W}(\nu, z) = \ell(\mathfrak{c})$. Finally, for Φ matched with a locally constant Ψ, Φ is locally constant with compact support ((1) of Lemma 6.3.19), so $\Phi^\sharp, \Psi^\sharp \in \mathcal{T}_\Sigma$ ((1) of Lemma 4.1.3) and $v \otimes \Phi \otimes \Phi^\circ = v \otimes [\Phi]_\Sigma$, $y \otimes \Psi \otimes \Phi^\circ = y \otimes [\Psi]_\Sigma$.

Step 1: the exchange identity for $(W, V, U^\flat)$. We show: there is a Schwartz vector $v \in \mathcal{F}_{W,V}$ such that $(\sigma, v, y^{\mathrm{ad}}, \ell)$ satisfy the row-column exchange identity for $(W, V, U^\flat)$ and μ.

Case $b \neq \emptyset$. By (3) of Lemma 6.3.5 (for A and $U^\flat$) there is a Schwartz vector $w \in \mathcal{F}_{W_0,U^\flat}$ with $\mathrm{rsl}_{A,U^\flat}(0; w) = y^{\mathrm{ad}}$. Let $X = \mathbb{H}_b \oplus W_0$, with index set $(b \sqcup b) \sqcup n_0$, D its tautological splitting over W_0 along b, $\bar{D}$ the opposite splitting (base-adapted: the same frame matrix with two blocks exchanged), and $\sigma'\colon b \sqcup (b \sqcup n_0) \to (b \sqcup b) \sqcup n_0$ the associativity bijection. Proposition 6.3.6 for X, $W_1 = W_0$, W, $V' = U^\flat$ (signs $-u$ on the nonempty b), D, $D_1 = A$, σ', μ, w and z gives $\phi_{\mathrm{lg}} \in \mathcal{F}_{X,U^\flat \oplus W_0}$, $\phi_{\mathrm{sm}} \in \mathcal{F}_{X,U^\flat}$ with $\mathrm{rsl}_{\bar{D},U^\flat}(0; \phi_{\mathrm{sm}}) = w$ such that $(\sigma', \phi_{\mathrm{lg}}, \phi_{\mathrm{sm}}, \ell)$ satisfy the row-column exchange identity for $(X, U^\flat \oplus W_0, U^\flat)$ and μ. The composite $A' = \bar{D} \circ A$ is a splitting of X over W along $p = b \sqcup \{o\}$; its matrix of adelic frames is, up to the order of the columns, that of $\bar{D}$ times $\mathrm{diag}(1, 1, M_A)$, M_A that of A, so it is base-adapted. By Lemma 6.3.8, $\mathrm{rsl}_{A',U^\flat}(0; \phi_{\mathrm{sm}}) = \mathrm{rsl}_{A,U^\flat}(0; w) = y^{\mathrm{ad}}$. Apply Proposition 6.3.10 to $W' = X$, W, $V' = U^\flat \oplus W_0$ (index set $b \sqcup n_0$), V, $U^\flat$, p, A', σ, σ': $\#n$ is even, and

$$\mathrm{neg}(U^\flat \oplus W_0) = (\#b - \mathrm{neg}(U)) + (\mathrm{neg}(W) + 1) = \#p + \mathrm{neg}(V)$$

by $\mathrm{neg}(W) = \mathrm{neg}(V) + \mathrm{neg}(U)$. It gives $v \in \mathcal{F}_{W,V}$ with the asserted identity.

Case $b = \emptyset$. Then U and $U^\flat$ are the zero space O, $\mathcal{F}_{W_0,O} = \mathcal{F}_{W,O} = \mathbb{C}$, y and y^{ad} are the same number, and $\mathrm{neg}(W) = \mathrm{neg}(V)$. Let $\sigma_0\colon \emptyset \sqcup n_0 \to n_0$ be the identity. For the empty matrix 0, $\Phi^{\mathrm{st}}_{\sigma_0,0} = \Psi^{\mathrm{st}}_1$ on $n_0 \times n_0$ matrices and $\Psi^{\mathrm{st}}_0 = 1$ on the single $n_0 \times \emptyset$ matrix. By Proposition 6.3.17 ($\#n_0$ even, A base-adapted), $\theta^{\mathrm{lg}}_{\mathfrak{c}}(W_0, W_0; z, \Phi^{\mathrm{st}}_{\sigma_0,0})$ is the constant $c_{\mathfrak{c}} = \theta^{\mathrm{lg}}_{\mathfrak{c}}(W_0, W_0; z, \Psi^{\mathrm{st}}_1)(1)$. In rank 0 the theta model and the Fock model are $\mathbb{C}$, the Weil operators are trivial, $[\mathrm{U}(O)]$ is a point of mass 1 and the characters of the small side, evaluated at determinants of points of $\mathrm{U}(O)$ and v^0, are 1; so $\theta^{\mathrm{sm}}_{\mathfrak{c}}(W_0, O; 1, \Psi^{\mathrm{st}}_0) = 1$. Hence $(\sigma_0, z, 1, \ell)$ satisfy the row-column exchange identity for (W_0, W_0, O) and μ with $C = 1$: $|c_{\mathfrak{c}}|^2 = L_*(\Sigma, \nu; \#n_0 - \#n_0/2)\, \ell(\mathfrak{c})$. By Proposition 6.3.10 for $W' = W_0$, A, $V' = W_0$, V, $U = O$ ($\mathrm{neg}(W_0) = 1 + \mathrm{neg}(V)$) there is $x_0 \in \mathcal{F}_{W,V}$ such that $(\sigma, x_0, \mathrm{rsl}_{A,O}(0; 1), \ell)$ satisfy the identity for (W, V, O); and $\mathrm{rsl}_{A,O}(0; 1) = 1$ by (MX7) (the integral over a point, of mass 1, with the real vacuum 1 of rank 0). Put $v = y\, x_0$. As local data and theta integrals of target-bounded data are linear in the real vector ((WR6) of Definition 3.2.18, (2) of Lemma 6.3.21; the data of (XD9) for the standard data are target-bounded by Lemma 6.2.26 and (2) of Lemma 6.3.31), (σ, v, y, ℓ) satisfy the identity for (W, V, O) with the same constants.

Step 2: all matched functions. Let C be the constant of Step 1, chosen with v before any character. Fix $\mathfrak{m}$, ν, $\mathfrak{c}$ as in Step 0 and let c_0 be the number of (XD12) for $\mathfrak{c}$. Apply Lemma 6.3.18 to $\mathfrak{c}$, W, V, $V' = U^\flat$, σ, v, y^{ad} and c_0: it gives an equivariant lift $(\mathcal{L}, \mathcal{D})$ for $(\mathfrak{c}, W, b)$ with $\Psi \in \mathcal{L}$ and

$$\mathcal{D}\Psi = \theta^{\mathrm{lg}}_{\mathfrak{c}}(W, V; v, \Phi) - c_0\, \theta^{\mathrm{sm}}_{\mathfrak{c}}(W, U^\flat; y^{\mathrm{ad}}, \Psi)$$

whenever Φ and a locally constant Ψ are matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_{\mathfrak{c}})$. Let $s_1 \in \mathrm{M}_{b \times n}(\mathcal{O}_\Sigma)$ consist of the rows $\sigma(b)$ of the identity and x_1 of its columns $\sigma(b)$, so $s_1 x_1 = 1$. By Lemma 6.3.31, $(\Phi^{\mathrm{st}}_{\sigma,s_1}, \Psi^{\mathrm{st}}_{s_1})$ is such a pair, so $\Psi^{\mathrm{st}}_{s_1} \in \mathcal{L}$ and $\mathcal{D}\Psi^{\mathrm{st}}_{s_1} = 0$ by (b) of (XD12). The space $\mathcal{P} = \{\Psi \in \mathcal{L} : \mathcal{D}\Psi = 0\}$ consists of locally constant, compactly supported functions ((XD11)(a)), is stable under $y \mapsto \Psi(gy)$, $g \in \mathrm{GL}_n(E_\Sigma)$ ((3) of Lemma 6.3.14), and contains $\Psi^{\mathrm{st}}_{s_1}$; $\chi_{\mathfrak{c}}$ has the residue form of Lemma 6.3.13 (Step 0). By Lemma 6.3.13, every locally constant Ψ matched with some Φ lies in $\mathcal{P}$:

$$\theta^{\mathrm{lg}}_{\mathfrak{c}}(W, V; v, \Phi) = c_0\, \theta^{\mathrm{sm}}_{\mathfrak{c}}(W, U^\flat; y^{\mathrm{ad}}, \Psi), \tag{6.25}$$

and $\Psi \in \mathcal{L}$ is compactly supported and vanishes at the matrices without a left inverse ((XD11)(a)).

Step 3: back to (U,W). Let d be the number of (2) of Lemma 6.3.4 for $\mathfrak{c}$ and y, and $c = c_0 d$, so $|c| = |c_0|$ and (1) is (a) of (XD12): $C|c|^2 = L_*(\Sigma,\nu;\#r - \#n/2)\,\ell(\mathfrak{c}) = L_*(\mathfrak{m},\nu;\operatorname{rk} V - \frac{1}{2}\operatorname{rk} W)\,r_{\mathbb{H}\oplus W}(\nu,z)$. With $\gamma = \nu^{-1}\upsilon^{\#n/2}$, which is the character of the large side of (W,V), (WR4) gives $\omega_{\gamma,1}(g,h) = \gamma(\det g)\,\omega_{\gamma,\gamma}(g,h)$, hence $I^{W,V}_{\gamma,1}(\upsilon\otimes[\Phi]_\Sigma)(g) = \gamma(\det g)\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;\upsilon,\Phi)(g)$. By (6.25) and Lemma 6.3.4,

$$I^{W,V}_{\gamma,1}(\upsilon\otimes\Phi\otimes\Phi^\circ)(g) = c_0\,\gamma(\det g)\,\theta^{\mathrm{sm}}_{\mathfrak{c}}(W,U^\flat;y^{\mathrm{ad}},\Psi)(g) = c\int_{[\mathrm{U}(U)]}\theta^{U,W}_{\gamma,\gamma}(y\otimes\Psi\otimes\Phi^\circ)(h,g)\,dh,$$

which is (2). □

Lemma 6.3.4. *Let W be a space with signs s on n, $\#n$ even, U a space with signs u on b, r an index set and $\sigma\colon b\sqcup r\to n$ a bijection. Let $\epsilon_\flat\in\mathbb{A}_E^\times$ be the idele with components 1 at the infinite places and finite part $\bar{c}\,\bar{\alpha}/\alpha$, and $U^\flat = (-J_U, x_U\epsilon_\flat)$, a space with signs $-u$ on b, with $\mathrm{G}(-u) = \mathrm{G}(u)$ and $[\mathrm{U}(U^\flat)] = [\mathrm{U}(U)]$. For $y\in\mathcal{F}_{U,W}$ (a function of $z\in\mathbb{C}^{\Phi\times(n\times b)}$) let $y^{\mathrm{ad}}(x) = y(x^\natural)$ for $x\in\mathbb{C}^{\Phi\times(b\times n)}$, where $(x^\natural)_{v,i,j} = u_j\,s_i\,\overline{x_{v,j,i}}$ ($v\in\Phi$, $i\in n$, $j\in b$).*

1. *$y^{\mathrm{ad}}\in\mathcal{F}_{W,U^\flat}$, and y^{ad} is a Schwartz vector if y is one.*
2. *Let $\mathfrak{c} = (\nu,\Sigma)$ be a split tame character and $\gamma = \nu^{-1}\upsilon^{\#n/2}$. There is $d\in\mathbb{C}$ with $|d| = 1$ such that for all functions Φ on $\mathrm{M}_{r\times n}(E_\Sigma)$ and Ψ on $\mathrm{M}_{n\times b}(E_\Sigma)$ that are matched over $\mathcal{O}_\Sigma$ for $(\sigma,\chi_{\mathfrak{c}})$, with Ψ locally constant, compactly supported and vanishing at every matrix without a left inverse, and all $g\in\mathrm{G}(s)$,*

$$\gamma(\det g)\,\theta^{\mathrm{sm}}_{\mathfrak{c}}(W,U^\flat;y^{\mathrm{ad}},\Psi)(g) = d\int_{[\mathrm{U}(U)]}\theta^{U,W}_{\gamma,\gamma}(y\otimes[\Psi]_\Sigma)(h,g)\,dh.$$

Proof. **Step 0: the space $U^\flat$.** Write ε_u, ε_s for the adelic sign matrices. Since $\bar{\epsilon}_\flat\epsilon_\flat$ is 1 at the infinite places and $c\bar{c} = -1$ at the finite ones, $(x_U\epsilon_\flat)^*(-J_U)(x_U\epsilon_\flat) = -\bar{\epsilon}_\flat\epsilon_\flat\,\varepsilon_u = \varepsilon_{-u}$: $U^\flat$ is a space with a point with signs $-u$. The conditions $g^*\varepsilon_u g = \varepsilon_u$ and $g^*\varepsilon_{-u}g = \varepsilon_{-u}$ agree, so $\mathrm{G}(-u) = \mathrm{G}(u)$; $\Gamma_{U^\flat} = (x_U\epsilon_\flat)^{-1}\mathrm{U}(-J_U)(F)(x_U\epsilon_\flat) = \Gamma_U$ ($\epsilon_\flat$ is a central scalar and $\mathrm{U}(-J_U) = \mathrm{U}(J_U)$). The Cayley chart and density of $\mathrm{U}(-\operatorname{diag} u)$ at y are those of $\mathrm{U}(\operatorname{diag} u)$ at $-y$ (in Definition 3.2.1, $-J$ and $S(-y) = -S(y)$ give the same D), and $y\mapsto -y$ preserves Lebesgue measure; so the two measures, and the quotient measures on $[\mathrm{U}(U^\flat)] = [\mathrm{U}(U)]$, agree.

Step 1: the adjoint map and three identities. Let ε be the signs $\varepsilon_{ij} = s_i u_j$ of $\mathrm{Hom}(U,W)$ on $n\times b$, and $\varepsilon'_{ji} = -u_j s_i$ those of $\mathrm{Hom}(W,U^\flat)$ on $b\times n$; $N = \#n\cdot\#b$. Let $\lambda = \epsilon_\flat^{-1}$ (components 1 at the infinite places, finite part $\alpha/(\bar{c}\bar{\alpha}) = -c\alpha/\bar{\alpha}$) and

$$\mathrm{ad}(X) = \lambda\,\varepsilon_u X^*\varepsilon_s \qquad (X\in\mathbb{A}_E^{n\times b}),$$

an additive homeomorphism onto $\mathbb{A}_E^{b\times n}$, with entries $\mathrm{ad}(X)_{ji} = \varepsilon_{ij}\overline{X_{ij}}$ at the infinite places and $\lambda\overline{X_{ij}}$ at the finite ones. Its infinite component is the real-linear map A of $\mathbb{C}^{\Phi\times(n\times b)}$ onto $\mathbb{C}^{\Phi\times(b\times n)}$, $(Ax)_{v,j,i} = u_j s_i\overline{x_{v,i,j}}$, whose inverse is $x\mapsto x^\natural$. Note $\lambda\bar{\lambda} = -1$ at the finite places. For a,b,z:

$$\text{(I1) } \beta_{\varepsilon'}(\mathrm{ad}\,a,\mathrm{ad}\,b) = \beta_\varepsilon(a,b), \qquad \text{(I2) } e_N(\mathrm{ad}\,z) = e_N(z), \qquad \text{(I3) } \mathrm{ad}_*\mu_N = \mu_N.$$

(I1): with $w = \bar{b}^{\mathsf{T}}S_\varepsilon a$, the pairing $\overline{\mathrm{ad}\,b}^{\mathsf{T}}S_{\varepsilon'}\mathrm{ad}\,a$ is $\sum -\varepsilon_{ij}b_{ij}\overline{a_{ij}} = -\bar{w}$ at the infinite places and $\bar{\lambda}\lambda\sum b_{ij}\overline{a_{ij}} = -\bar{w}$ at the finite ones; and $\psi_E(\frac{J}{2}(-\bar{w})) = \psi_E(\overline{\frac{J}{2}w}) = \psi_E(\frac{J}{2}w)$. (I2): the archimedean factor of e_N depends on the $|x_{v,k}|$, which A permutes; at the finite places $\mathrm{ad}\,z\in\alpha\widehat{\mathcal{O}}_E^N$ iff $z\in\alpha\widehat{\mathcal{O}}_E^N$ ($\lambda\bar{\alpha}\alpha^{-1} = -c$ is a unit), and then, with $z = \alpha y$, the phases differ by

$\psi_{E,f}(c_0\jmath\,\bar z^{\mathsf T}z) = \psi_{E,f}(\jmath\alpha\bar\alpha\,c_0\bar y^{\mathsf T}y) = 1$, as $c_0\bar y^{\mathsf T}y$ is integral and $\psi_{E,f}(\jmath\alpha\bar\alpha\,\cdot)$ is trivial on $\widehat{\mathcal O}_E$ (self-duality, Lemma 4.1.3). (I3): A is a signed permutation of coordinates composed with conjugation (preserving Lebesgue measure), and in the coordinates z of (WD6) the finite part is $z\mapsto -c\,\bar z^{\mathsf T}$, which preserves the Haar measure. Moreover:

(I4) ad maps the rational vectors of $\mathrm{Hom}(U,W)$ onto those of $\mathrm{Hom}(W,U^\flat)$: using $\varepsilon_u x_U^* = x_U^{-1}J_U^{-1}$ and $x_W^{-*}\varepsilon_s = J_W x_W$, $\mathrm{ad}(x_W^{-1}\xi x_U) = (x_U\epsilon_\flat)^{-1}(J_U^{-1}\xi^*J_W)x_W$ for $\xi\in \mathrm{M}_{n\times b}(E)$, and $\xi\mapsto J_U^{-1}\xi^*J_W$ is a bijection onto $\mathrm{M}_{b\times n}(E)$.

(I5) For $g\in\mathrm{G}(s)$, $h\in\mathrm{G}(u)$: $\mathrm{ad}(gXh^{-1}) = (\varepsilon_u h^{-*}\varepsilon_u)\,\mathrm{ad}(X)\,(\varepsilon_s g^*\varepsilon_s) = h\,\mathrm{ad}(X)\,g^{-1}$. So with k the pair map of (h,g) for (U,W) and k' that of (g,h) for $(W,U^\flat)$, $\mathrm{ad}\circ k = k'\circ\mathrm{ad}$.

Step 2: transport. For f on $\mathbb{A}_E^{n\times b}$ put $Tf = f\circ\mathrm{ad}^{-1}$. If $f\in\mathcal M_\varepsilon$, then by (I3) Tf is μ_N-integrable with $\|Tf\| = \|f\|$, and the substitution $y = \mathrm{ad}^{-1}y'$ in (WD7) with (I1), (I2) shows $Tf\in\mathcal M_{\varepsilon'}$; the same with ad^{-1} gives the inverse $F\mapsto F\circ\mathrm{ad}$. So T is a linear isometry of $\mathcal M_{U,W}$ onto $\mathcal M_{W,U^\flat}$, $Tv^0 = v^0$ by (I2), and by (I1) $(T\rho(z)f)(x) = \beta_\varepsilon(z,\mathrm{ad}^{-1}x)f(\mathrm{ad}^{-1}x - z) = (\rho(\mathrm{ad}\,z)Tf)(x)$:

$$T\rho(z) = \rho(\mathrm{ad}\,z)\,T. \tag{6.26}$$

Step 3: the Weil representations. Let k, k' be as in (I5). By (WR3), the substitution $y = \mathrm{ad}^{-1}y'$ and (I1)–(I3), $T\omega_\varepsilon(k)f = \Delta_\varepsilon(k)\Delta_{\varepsilon'}(k')^{-1}\omega_{\varepsilon'}(k')Tf$ ($\Delta_{\varepsilon'}(k')\neq 0$ by (2) of Lemma 6.2.13). We show $\Delta_{\varepsilon'}(k') = \upsilon(\det k)\Delta_\varepsilon(k)$. Let R be the transposition $X\mapsto X^{\mathsf T}$ of index sets. At $v\in\Phi$, $\mathrm{ad}_v = R\circ E\circ\bar{\cdot}$ with $E = \mathrm{diag}(\varepsilon)$, so $k'_v = R\,E\,\overline{k_v}\,E\,R^{-1} = R\,(k_v^{-1})^{\mathsf T}R^{-1}$, using $k_v^*Ek_v = E$. The block of k'_v on the indices of sign $\varepsilon' = -1$ is thus the transpose of the block of k_v^{-1} on the indices with $\varepsilon = +1$, whose determinant is $\det(k_v)_-/\det k_v$ by Jacobi's identity for complementary minors of an inverse; as $|\det k_v| = 1$, $\overline{\det(k'_v)_-} = \det k_v\cdot\overline{\det(k_v)_-}$. At the finite places $\mathrm{ad}_f = \lambda R\circ\bar{\cdot}$, so $k'_f = R\,\overline{k_f}\,R^{-1}$; with $L = \widehat{\mathcal O}_E^N$, $L\cap\overline{k_f}^{-1}L = \overline{L\cap k_f^{-1}L}$, so $\bar u$ serves for $\overline{k_f}$ when u serves for k_f, and the finite factor of $\Delta_{\varepsilon'}(k')$ is $\upsilon(\det\bar u)|\det u|^{-1/2} = \overline{\Delta(k_f)}$, the multiplier Δ of Lemma 4.1.13 (invariant under the permutation R); since $k_f^*k_f = 1$, Lemma 4.1.13 gives $\overline{\Delta(k_f)} = \upsilon_f(\det k_f)\Delta(k_f)$, υ_f the restriction of υ to the finite ideles (its hypotheses hold by (WD1), (WD3) and Lemma 4.1.3). With $\upsilon(\det k) = \prod_v \det k_v\cdot\upsilon_f(\det k_f)$ (WD3) the claim follows, and

$$T\omega_\varepsilon(k) = \upsilon(\det k)^{-1}\,\omega_{\varepsilon'}(k')\,T,\qquad \det k = \det(g)^{\#b}\det(h)^{-\#n}\ \text{(VP5)}. \tag{6.27}$$

Step 4: the theta functionals. Put $\theta'(F) = \theta_{\mathrm{Hom}(U,W)}(F\circ\mathrm{ad})$ for $F\in\mathcal M_{W,U^\flat}$: a bounded linear functional. For γ a rational vector of $\mathrm{Hom}(U,W)$, (6.26) gives $\theta'(\rho(\mathrm{ad}\,\gamma)F) = \theta_{\mathrm{Hom}(U,W)}(\rho(\gamma)(F\circ\mathrm{ad})) = \theta'(F)$, so by (I4) θ' is invariant under the rational vectors of $\mathrm{Hom}(W,U^\flat)$; and ad induces an isomorphism of the compact quotients by the rational vectors carrying Haar probability measure to Haar probability measure, so

$$\int|\theta'(\rho(x)v^0)|^2dx = \int|\theta_{\mathrm{Hom}(U,W)}(\rho(y)v^0)|^2dy = 1$$

(Lemma 4.1.17). By Lemma 4.1.17 and Lemma 4.1.7, θ' and $\theta_{\mathrm{Hom}(W,U^\flat)}$ differ by a scalar of modulus one: there is z, $|z| = 1$, depending only on U, W and the fixed choices, with

$$\theta_{\mathrm{Hom}(W,U^\flat)}(Tf) = z\,\theta_{\mathrm{Hom}(U,W)}(f)\qquad (f\in\mathcal M_{U,W}). \tag{6.28}$$

Step 5: the theta kernels. Let α_1,β_1 be automorphic characters of U(1), $\alpha_1' = \beta_1^{-1}\upsilon^{\#n}$, $\beta_1' = \alpha_1^{-1}\upsilon^{\#b}$. By (WR4), (6.28), (6.27),

$$\theta^{U,W}_{\alpha_1,\beta_1}(f)(h,g) = \frac{\alpha_1(\det g)}{\beta_1(\det h)}\,z^{-1}\,\frac{\upsilon(\det h)^{\#n}}{\upsilon(\det g)^{\#b}}\,\theta_{\mathrm{Hom}(W,U^\flat)}\big(\omega_{\varepsilon'}(k')Tf\big) = z^{-1}\,\theta^{W,U^\flat}_{\alpha_1',\beta_1'}(Tf)(g,h).$$

Step 6: data, and (1). *Real part.* By (WR5), $\beta^{\infty}_{\varepsilon'}(Ax,Ay)=\beta^{\infty}_{\varepsilon}(x,y)$ (the exponent $\frac{1}{2}(y^*\varepsilon x - x^*\varepsilon y)$ is purely imaginary and is replaced by the conjugate of its negative), $e^{\infty}\circ A = e^{\infty}$ and $A_*\nu=\nu$; so $y\mapsto y\circ A^{-1}=y^{\mathrm{ad}}$ maps $\mathcal{F}_{U,W}$ onto $\mathcal{F}_{W,U^\flat}$, and as $\|Ax\|=\|x\|$ (maximum norm), $\mathrm{mom}_N(y^{\mathrm{ad}})=\mathrm{mom}_N(y)$: this is (1). As T is bounded linear and $v\otimes f$ is a Bochner integral (Lemma 6.2.21), (6.26), $\mathrm{ad}(\mathrm{rv}(t))=\mathrm{rv}(At)$ (κ_v real, $\lambda_\infty=1$) and the substitution $t=A^{-1}t'$ give $T(v\otimes f)=v^{\mathrm{ad}}\otimes Tf$. *Finite part.* Let A_0 be a finite set of finite places containing the conjugate of none of its members, $\Psi_0\in\mathcal{T}_{A_0}$, and $\phi(y)=-c\,y^*$ for finite adelic $n\times b$ matrices y. Then $\mathrm{ad}(\mathrm{fv}(y))=(0,\lambda\bar\alpha y^*)=\mathrm{fv}(\phi(y))$, as $\lambda\bar\alpha=-c\alpha$. For x and y supported on $A_0\cup\bar A_0$, $\overline{\phi(y)}^{\mathsf{T}}(2\phi(x)+\phi(y))$ restricted to $\bar A_0$ is $\bar c c$ times the conjugate of $\bar y^{\mathsf{T}}(2x+y)$ restricted to A_0, and $\phi(x+y)$ is integral at $\bar A_0$ iff $x+y$ is integral at A_0; with (I1)'s computation of $\psi_{E,f}$ this gives $\tau^{(\bar A_0)}_{\phi(y)}\circ\phi=\tau^{(A_0)}_y$. Write $\Psi_0=\sum_y c_y\tau_y$; as $P^{A_0}v^0=v^0$ ((2) of Lemma 6.2.33), (6.26) and $Tv^0=v^0$ give $T(\Psi_0\otimes_{A_0}v^0)=\sum_y c_y\rho(\mathrm{fv}(\phi(y)))P^{\bar A_0}v^0$, and $\sum_y c_y\tau^{(\bar A_0)}_{\phi(y)}=\Psi_0\circ\phi^{-1}$. By (1) of Lemma 4.1.3 the Schrödinger datum does not depend on the representation of a function by the τ_y (a finite representation of a nonzero function is the value of some linear section, and one of 0 is a difference of two representations of one nonzero function); so

$$T\big(v\otimes(\Psi_0\otimes_{A_0}v^0)\big)=v^{\mathrm{ad}}\otimes\big((\Psi_0\circ\phi^{-1})\otimes_{\bar A_0}v^0\big),\qquad \phi^{-1}(\eta)=c\,\eta^*. \tag{6.29}$$

Step 7: matched functions and (2). Let Φ, Ψ be as in (2); by (1) of Lemma 4.1.3, $\Psi^\sharp\in\mathcal{T}_\Sigma$. Let $c_\Sigma\in\mathcal{O}_\Sigma^\times$ be the components of c at Σ. For $X\in\mathrm{M}_{n\times b}(E_\Sigma)$, $\Psi(X)=\chi_{\mathfrak{c}}(c_\Sigma)^{\#b}\Psi(c_\Sigma X)$: if $X=k_b$ for some $k\in\mathrm{GL}_n(\mathcal{O}_\Sigma)$, let k' be k with its columns b multiplied by c_Σ; then $k'_b=c_\Sigma k_b$, $(k'^{-1})_r=(k^{-1})_r$ and $\det k'=c_\Sigma^{\#b}\det k$, and (XD6) for k and k' gives $\chi_{\mathfrak{c}}(\det k)\Psi(k_b)=\Phi((k^{-1})_r)=\chi_{\mathfrak{c}}(c_\Sigma)^{\#b}\chi_{\mathfrak{c}}(\det k)\Psi(c_\Sigma k_b)$; otherwise neither X nor $c_\Sigma X$ is of this form and both values are 0. Now $(\Psi^\sharp\circ\phi^{-1})(\eta)=\Psi(c_\Sigma((\bar\eta)_\Sigma)^{\mathsf{T}})=\chi_{\mathfrak{c}}(c_\Sigma)^{-\#b}(\Psi^{\mathsf{T}})^\flat(\eta)$, so by (6.29) with $A_0=\Sigma$

$$y^{\mathrm{ad}}\otimes[\Psi^{\mathsf{T}}]_{\bar\Sigma}=\chi_{\mathfrak{c}}(c_\Sigma)^{\#b}\,T(y\otimes[\Psi]_\Sigma).$$

Apply Step 5 with $\alpha_1=\beta_1=\gamma$: $\alpha'_1=\nu\upsilon^{\#n/2}$ is the first character of the small side of $(W,U^\flat)$ (XD9), and $\beta'_1=\nu\upsilon^{\#b-\#n/2}$, while the small side has $\upsilon^{\#b}$; by (WR4), $\theta^{W,U^\flat}_{\alpha'_1,\upsilon^{\#b}}=\gamma(\det g)^{-1}\theta^{W,U^\flat}_{\alpha'_1,\beta'_1}$ at (g,h). Hence, with $d=\chi_{\mathfrak{c}}(c_\Sigma)^{\#b}z$, $|d|=1$,

$$\gamma(\det g)\,\theta^{W,U^\flat}_{\alpha'_1,\upsilon^{\#b}}(y^{\mathrm{ad}}\otimes[\Psi^{\mathsf{T}}]_{\bar\Sigma})(g,h)=d\,\theta^{U,W}_{\gamma,\gamma}(y\otimes[\Psi]_\Sigma)(h,g)\qquad(h\in\mathrm{G}(u)=\mathrm{G}(-u)).$$

Integrating over $h\in[\mathrm{U}(U^\flat)]=[\mathrm{U}(U)]$ (Step 0), the integrands being proportional, gives (2); d depends only on $\mathfrak{c}$, U, W and the fixed choices. □

Lemma 6.3.5. *Let X, W_1, V' be spaces with points with index sets m, n, a, let b be an index set, D a base-adapted splitting of X over W_1 along b and $\bar D$ its opposite splitting, and write $\mathbb{C}^{\Phi\times(a\times b)}$ for the space of the arguments of the real slices along V'.*

1. *For every $\phi\in\mathcal{F}_{X,V'}$ and every z, the function $x\mapsto\mathrm{rsl}_{D,V'}(x;\phi)(z)$ is $\nu_{\Phi\times(a\times b)}$-integrable and*
$$\int_{\mathbb{C}^{\Phi\times(a\times b)}}\mathrm{rsl}_{D,V'}(x;\phi)(z)\,d\nu_{\Phi\times(a\times b)}(x)=\mathrm{rsl}_{\bar D,V'}(0;\phi)(z).$$
2. *Let $\tau\ge0$ be a smooth compactly supported real function on $\mathbb{C}^{\Phi\times(a\times b)}$, not identically 0, and $v\in\mathcal{F}_{W_1,V'}$ a Schwartz vector. There are $\kappa\in\mathbb{C}$ and a Schwartz vector $\phi\in\mathcal{F}_{X,V'}$ with*
$$\mathrm{rsl}_{D,V'}(x;\phi)=\tau(x)\,\kappa\,v\quad\text{for every } x,\qquad \mathrm{rsl}_{\bar D,V'}(0;\phi)=v.$$

3. Every Schwartz vector $v \in \mathcal{F}_{W_1,V'}$ is $\mathrm{rsl}_{D,V'}(0;\phi)$ for some Schwartz vector $\phi \in \mathcal{F}_{X,V'}$.

Proof. Throughout, an element c of a Fock model $\mathcal{F}_\varepsilon$ satisfies $|c(z)| \le \|c\|_1$ for every z, by its reproducing identity and $|\beta_\varepsilon^\infty e^\infty| \le 1$; so evaluation at z is a bounded linear functional and commutes with Bochner integrals.

Step 1: a general identity. Let V, V_0 be spaces with points with signs s on n_1 and s_0 on n_0, p an index set, $D' = (k,l,i)$ a splitting of V over V_0 along p and $m \in \mathrm{GL}_p(\mathbb{A}_E)$ such that D' is adapted at 1 in the basis m. Let $\bar D' = (l,k,i)$ and $\bar m = (m^{-1})^*$. We show, for $u \in \mathcal{F}_s$ and every z,

$$\int \mathrm{rsl}_{D',m}(x;u)(z)\, d\nu(x) = Z^\infty_{\bar D',\bar m}(u)(z), \tag{I}$$

the integrand being integrable. Let G be the complex matrix, block diagonal over Φ, with column blocks $(l_{\mathbb{A}}\bar m)_\infty$, $(k_{\mathbb{A}} m)_\infty$, $(i_{\mathbb{A}})_\infty$; by adaptedness it is unitary, and we write $y = G(a,b,w)$ with $a,b \in \mathbb{C}^{\Phi\times p}$, $w \in \mathbb{C}^{\Phi\times n_0}$; $\nu_{\Phi\times n_1}$ is the image of the product of the measures ν in a,b,w. The relations of (MX1) and $x_V^* J_V x_V = \varepsilon_s$ give $\mathrm{pr}_k l_{\mathbb{A}} = 0$, $\mathrm{pr}_k k_{\mathbb{A}} = 1$, $\mathrm{pr}_k i_{\mathbb{A}} = 0$, $\mathrm{pr}_l l_{\mathbb{A}} = 1$, $\mathrm{pr}_l k_{\mathbb{A}} = 0$, $\mathrm{pr}_l i_{\mathbb{A}} = 0$ (for instance $\mathrm{pr}_k k_{\mathbb{A}} = l^* x_V^{-*} \varepsilon_s x_V^{-1} k = l^* J_V k = 1$), and pr_i is 0 on the first two blocks and 1 on the third. Hence, as rv is linear,

$$\mathrm{pr}_k \mathrm{rv}(y) = m\,\mathrm{rv}(b), \quad \mathrm{pr}_l \mathrm{rv}(y) = \bar m\,\mathrm{rv}(a), \quad a(y) = (m^*\mathrm{pr}_l)_\infty y = a, \quad w(y) = w$$

for D' in the basis m, and, since for $\bar D'$ the roles of pr_k and pr_l are exchanged, $\bar a(y) = (\bar m^* \mathrm{pr}_k)_\infty y = b$ and $\bar w(y) = w$ for $\bar D'$ in the basis $\bar m$. The characters are $\chi(y) = \psi_E(\frac{\jmath}{2}\mathrm{rv}(b)^*\mathrm{rv}(a))$ and $\bar\chi(y) = \psi_E(\frac{\jmath}{2}\mathrm{rv}(a)^*\mathrm{rv}(b))$, as $m^*\bar m = 1$. The argument $\frac{\jmath}{2}\mathrm{rv}(b)^*\mathrm{rv}(a)$ has finite part 0 and component $\frac{\jmath_v}{2}\kappa_v^2 b_v^* a_v$ at $v \in \Phi$; with $\jmath_v \kappa_v^2 = i/(2\pi)$ ($\jmath_v$ purely imaginary, $2\pi\,\mathrm{Im}(\jmath_v)\kappa_v^2 = 1$), (WD4) gives

$$\chi(y) = \prod_{v\in\Phi} \exp(-2\pi i\,\mathrm{Re}(\tfrac{i}{2\pi} b_v^* a_v)) = \exp(i\,\mathrm{Im}\, b^*a) = \exp(\tfrac{b^*a - a^*b}{2}), \qquad \bar\chi(y) = \exp(\tfrac{a^*b - b^*a}{2}).$$

By (C1) below, $\beta_\varepsilon^\infty(G(x,0,0), G(a,b,w)) = \exp((b^*x - x^*b)/2)$, where

$$y'^*\mathrm{diag}(\varepsilon)\, y = a'^* b + b'^* a + w'^* \mathrm{diag}(\varepsilon_0)\, w \qquad (y = G(a,b,w),\ y' = G(a',b',w')), \tag{C1}$$

$\varepsilon(v,j) = s(j)$, $\varepsilon_0(v,j) = s_0(j)$; (C1) holds because $(x_V^{-1}u)^*\varepsilon_s(x_V^{-1}u') = u^* J_V u'$ and the relations of (MX1) give the Gram matrix $\begin{pmatrix} 0 & 1 & 0 \\ 1 & 0 & 0 \\ 0 & 0 & J_{V_0} \end{pmatrix}$ for the columns $l\bar m$, km, i of $x_V\, G$ read rationally, with $x_{V_0}^* J_{V_0} x_{V_0} = \varepsilon_{s_0}$ on the last block. Now $(l_{\mathbb{A}}\bar m)_\infty x = G(x,0,0)$, so by definition $\mathrm{rsl}_{D',m}(x;u) = Z^\infty_{D',m}(\rho^\infty(G(x,0,0))u)$. Evaluating at z, writing $\tilde u(a,b,w) = u(G(a,b,w))$ and substituting $a \mapsto a + x$ (with $\beta_\varepsilon^\infty(t,t) = 1$ and the real linearity of the exponent of β_ε^∞),

$$\mathrm{rsl}_{D',m}(x;u)(z) = \int \tilde u(a,b,w) \exp\Big(\frac{b^*a - a^*b}{2} + b^*x - x^*b - |a+x|^2\Big)\big(\rho_0^\infty(w)v_1\big)(z)\, d\nu(a,b,w),$$

ρ_0^∞, v_1 the real Heisenberg operators and the real vacuum of $\mathcal{F}_{s_0}$. The modulus of the integrand is at most $|\tilde u(a,b,w)| e^{-|a+x|^2}$, as $|(\rho_0^\infty(w)v_1)(z)| = |v_1(z-w)| \le 1$; its integral over (a,b,w,x) is $\|u\|_1 \int e^{-|t|^2} d\nu(t) = \|u\|_1$. So Fubini applies. For fixed a,b, substituting $x = t - a$,

$$\int \exp(b^*x - x^*b - |a+x|^2) d\nu(x) = e^{a^*b - b^*a} \int e^{2i\,\mathrm{Im}(b^*t) - |t|^2} d\nu(t) = e^{a^*b - b^*a} e^{-|b|^2},$$

by the Fourier transform of the Gaussian on each coordinate: $\pi^{-1}\int_{\mathbb{C}} e^{-|t_1|^2} e^{2i\,\mathrm{Im}(\bar{b}_1 t_1)} dt_1 = e^{-|b_1|^2}$ ($2\,\mathrm{Im}(\bar{b}_1 t_1)$ is a real linear form in t_1 with gradient of length $2|b_1|$). Hence

$$\int \mathrm{rsl}_{D',m}(x;u)(z)\,d\nu(x) = \int \tilde{u}(a,b,w)\, e^{(a^*b-b^*a)/2}\, e^{-|b|^2} (\rho_0^\infty(w)v_1)(z)\,d\nu(a,b,w).$$

The right side is $Z^\infty_{\bar{D}',\bar{m}}(u)(z)$: the matrix of (MX5) for $\bar{D}'$ in the basis $\bar{m}$ has the same columns as for D' in m (blocks exchanged), and in its definition $\bar{\chi}(y) = e^{(a^*b-b^*a)/2}$, $e^{-\bar{a}(y)^*\bar{a}(y)} = e^{-|b|^2}$ and $\bar{w}(y) = w$. This proves (I).

Step 2: two invariances of the real zero term. Let $D' = (k,l,i)$ be a splitting and m a basis. (i) If $c \in \mathrm{GL}_p(E)$ and $D'' = (kc, l(c^{-1})^*, i)$ is a splitting, then $Z^\infty_{D'',m} = Z^\infty_{D',cm}$: the coordinates of D'' are $\mathrm{pr}''_l = c^*\mathrm{pr}_l$, $\mathrm{pr}''_k = c^{-1}\mathrm{pr}_k$, $\mathrm{pr}''_i = \mathrm{pr}_i$, so $a''(y) = ((cm)^*\mathrm{pr}_l)_\infty y$, $w'' = w$, and $(\mathrm{pr}''_k\mathrm{rv}(y))^*\mathrm{pr}''_l\mathrm{rv}(y) = (\mathrm{pr}_k\mathrm{rv}(y))^*(c^{-1})^*c^*\mathrm{pr}_l\mathrm{rv}(y) = (\mathrm{pr}_k\mathrm{rv}(y))^*\mathrm{pr}_l\mathrm{rv}(y)$. (ii) If $\delta \in \mathrm{GL}_p(\mathbb{A}_E)$ has unitary infinite components, then $Z^\infty_{D',m\delta} = Z^\infty_{D',m}$: only $a(y)$ changes, to $\delta^*_\infty a(y)$, and $|\delta^*_\infty a(y)| = |a(y)|$.

Step 3: (1). Let $V^X = \mathrm{Hom}(X,V')$, $D' = D_{V'}$ the induced splitting of V^X over $\mathrm{Hom}(W_1,V')$ along $a\times b$ with frames $(K,L,I) = (J_{V'}^{-1}\otimes(k^*J_X)^{\mathsf{T}},\ 1\otimes(l^*J_X)^{\mathsf{T}},\ I)$ by (MX1), $D = (k,l,i)$, and $m = m_{V'} = (x_{V'}^{-1})^*\otimes 1_b$. By Lemma 6.3.53, D' is adapted at 1 in the basis m, so (I) holds for D' with $\bar{D}' = (L,K,I)$ and $\bar{m} = (m^{-1})^* = x_{V'}\otimes 1_b$. The splitting $\bar{D}_{V'}$ induced by $\bar{D} = (l,k,i)$ has frames $J_{V'}^{-1}\otimes(l^*J_X)^{\mathsf{T}} = L\,c$ and $1\otimes(k^*J_X)^{\mathsf{T}} = K\,(c^{-1})^*$ with $c = J_{V'}^{-1}\otimes 1_b \in \mathrm{GL}_{a\times b}(E)$ (as $J_{V'}$ is hermitian) and the same third frame I. By Step 2 (i), $Z^\infty_{\bar{D}_{V'},m} = Z^\infty_{\bar{D}',cm}$. From $x^*_{V'}J_{V'}x_{V'} = \varepsilon_{t'}$ (t' the signs of V') we get $J_{V'}^{-1}(x^*_{V'})^{-1} = x_{V'}\varepsilon_{t'}$, so $cm = \bar{m}\,\delta$ with $\delta = \varepsilon_{t'}\otimes 1_b$, whose infinite components are diagonal with entries ±1; by Step 2 (ii), $Z^\infty_{\bar{D}',cm} = Z^\infty_{\bar{D}',\bar{m}}$. Since $\rho^\infty(0)$ is the identity, $\mathrm{rsl}_{\bar{D},V'}(0;\phi) = Z^\infty_{\bar{D}_{V'},m}(\phi) = Z^\infty_{\bar{D}',\bar{m}}(\phi)$, and (I) for $u = \phi$ is (1).

Step 4: (2). Since τ is continuous, non-negative and not identically 0, $T = \int \tau\,d\nu > 0$; put $\kappa = T^{-1}$. By Lemma 6.3.53, (2) of Lemma 6.2.43 applies to the splitting $D_{V'}$, the basis $m_{V'}$, the smooth compactly supported function $\kappa\tau$, the constant map $x\mapsto 1$ and the Schwartz vector v of $\mathcal{F}_{W_1,V'}$, the Fock model of $\mathrm{Hom}(W_1,V')$ that (MX7) uses. It gives a Schwartz vector ϕ with $\mathrm{rsl}_{D,V'}(x;\phi) = \kappa\tau(x)\,\omega^\infty(1)v = \tau(x)\kappa v$, as $\omega^\infty(1)$ is the identity by the reproducing identity. By (1), $\mathrm{rsl}_{\bar{D},V'}(0;\phi)(z) = \kappa\int\tau\,d\nu\cdot v(z) = v(z)$ for every z.

Step 5: (3). The opposite splitting $\bar{D}$ is base-adapted, its matrix of adelic frames being that of D with two column blocks exchanged, and the opposite splitting of $\bar{D}$ is D. Apply (2) to $\bar{D}$, a smooth compactly supported $\tau\ge 0$ with $\tau(0) > 0$ and v: it gives a Schwartz ϕ with $\mathrm{rsl}_{D,V'}(0;\phi) = v$. □

Proposition 6.3.6. *Let X, W_1, W, V' be spaces with signs r on m, s on n, s_W on n_W, t' on b, with $\#n$ even and b nonempty; let D be a base-adapted splitting of X over W_1 along b and $\bar{D}$ its opposite splitting, D_1 a base-adapted splitting of W_1 over W along a one-element set, $\sigma\colon b\sqcup(b\sqcup n)\to m$ a bijection and $\mu\colon\Phi\to\mathbb{Z}$. Let $v\in\mathcal{F}_{W_1,V'}$ and $v_1\in\mathcal{F}_{W_1,W_1}$ be Schwartz vectors. Then there are $\phi_{\mathrm{lg}}\in\mathcal{F}_{X,V'\oplus W_1}$ and $\phi_{\mathrm{sm}}\in\mathcal{F}_{X,V'}$ with*

$$\mathrm{rsl}_{\bar{D},V'}(0;\phi_{\mathrm{sm}}) = v$$

such that $(\sigma,\phi_{\mathrm{lg}},\phi_{\mathrm{sm}},\ell)$ satisfy the row-column exchange identity for $(X,V'\oplus W_1,V')$ and μ, where

$$\ell(\mathfrak{c}) = \frac{\left|\theta^{\mathrm{lg}}_{\mathfrak{c}}(W_1,W_1;v_1,\Psi_1^{\mathrm{st}})(1)\right|^2}{L_*(\Sigma,\nu;\#n/2)} \qquad (\mathfrak{c} = (\nu,\Sigma)),$$

1 being the identity $n\times n$ matrix in Ψ_1^{st} and the identity of $\mathrm{U}(W_1)(\mathbb{A}_F)$ in the argument.

Proof. Put $j = \#n/2$. If $\mu(w) \le 0$ for some $w \in \Phi$, no split tame character has weight μ ((XD4)); then (3) of Lemma 6.3.5, applied to the base-adapted splitting $\bar{D}$, gives a Schwartz vector ϕ_{sm} with $\mathrm{rsl}_{\bar{D},V'}(0;\phi_{\mathrm{sm}}) = v$, and $\phi_{\mathrm{lg}} = 0$, ϕ_{sm} satisfy the assertion with $C = 0$, the condition on characters being empty. From now on $\mu(w) > 0$ for all w.

Step 1: smooth Witt data. Let $J = \mathrm{diag}(t' \sqcup s)$, a complex $(b \sqcup n) \times (b \sqcup n)$ matrix with $J^* = J = J^{-1}$, $\mathrm{U}(J)$ its unitary group, and $x_0 = (1_b; 0)$, so $x_0^* J x_0 = \mathrm{diag}(t')$ is invertible. By Lemma 6.3.7 there are a smooth map $k\colon \mathrm{M}_{(b\sqcup n)\times b}(\mathbb{C}) \to \mathrm{U}(J)$ and an open neighbourhood $\mathcal{N}_0$ of x_0 such that every $y \in \mathcal{N}_0$ is $k(y)x_0c$ for some $c \in \mathrm{M}_b(\mathbb{C})$. The map $A \mapsto \mathrm{adj}(A)/\det A$ is smooth on the open set of invertible $A \in \mathrm{M}_b(\mathbb{C})$; multiplying it by a smooth function with compact support in that set and equal to 1 on an open neighbourhood $\mathcal{N}_1$ of $\mathrm{diag}(t')$ gives a smooth map $\mathrm{iv}\colon \mathrm{M}_b(\mathbb{C}) \to \mathrm{M}_b(\mathbb{C})$ with $\mathrm{iv}(A) = A^{-1}$ for $A \in \mathcal{N}_1$. Let $\mathcal{N} = \{y \in \mathcal{N}_0 : y^*Jy \in \mathcal{N}_1\}$, an open neighbourhood of x_0. Choose a smooth $\mathrm{bm}\colon \mathrm{M}_{(b\sqcup n)\times b}(\mathbb{C})^\Phi \to [0,1]$ with compact support contained in $\mathcal{N}^\Phi$ and $\mathrm{bm}(x_0,\dots,x_0) = 1$. For $x \in \mathrm{M}_{(b\sqcup n)\times b}(\mathbb{C})$ put

$$\mathrm{pr}(x) = x\,\mathrm{iv}(x^*Jx)\,x^*Jx_0,$$

a smooth map with $\mathrm{pr}(x_0) = x_0$. Three facts are used.

(W1) If $\mathrm{bm}(y) \ne 0$, then for every w: $y_w = k(y_w)x_0c$ for some c, $y_w^*Jy_w$ is invertible and $\mathrm{iv}(y_w^*Jy_w) = (y_w^*Jy_w)^{-1}$. (Indeed $y_w \in \mathcal{N}$.)

(W2) If $C \in \mathrm{GL}_b(\mathbb{C})$ and iv inverts the Gram matrices $G = x^*Jx$ and C^*GC, then $\mathrm{pr}(xC) = xC\,C^{-1}G^{-1}C^{-*}\,C^*x^*Jx_0 = \mathrm{pr}(x)$.

(W3) If $\mathrm{bm}(\mathrm{pr}\circ x) \ne 0$, then for every w there is $c \in \mathrm{M}_b(\mathbb{C})$ with $k(\mathrm{pr}(x_w))\,x_0\,c = x_w$ and $c^*\mathrm{diag}(t')c = x_w^*Jx_w$. Indeed $y = \mathrm{pr}(x_w) = x_wA$ with $A = \mathrm{iv}(x_w^*Jx_w)x_w^*Jx_0$; by (W1), $y = k(y)x_0c_0$ and $\det(A^*x_w^*Jx_wA) = \det(y^*Jy) \ne 0$, so A is invertible; $c = c_0A^{-1}$ gives $k(y)x_0c = x_w$, and $c^*\mathrm{diag}(t')c = (k(y)x_0c)^*J(k(y)x_0c) = x_w^*Jx_w$ as $k(y) \in \mathrm{U}(J)$.

Step 2: the small datum. The arguments of the real slices along V' are families $B = (B_w)_w$ of complex $b\times b$ matrices. Let $\tau_{\mathrm{sm}}(B) = \mathrm{bm}((x_0B_w)_w)\prod_w |\det B_w|^{2(j+\mu(w))}$. It is smooth and non-negative, $\tau_{\mathrm{sm}}(1,\dots,1) = 1$, and it has compact support: $\tau_{\mathrm{sm}}(B) \ne 0$ implies $(x_0B_w)_w \in \mathrm{supp}\,\mathrm{bm}$, and $B_w = x_0^*(x_0B_w)$, so the support lies in the image of a compact set under a continuous map. By (2) of Lemma 6.3.5 there are $\kappa \in \mathbb{C}$ and a Schwartz vector $\phi_{\mathrm{sm}} \in \mathcal{F}_{X,V'}$ with

$$\mathrm{rsl}_{D,V'}(B;\phi_{\mathrm{sm}}) = \tau_{\mathrm{sm}}(B)\,\kappa\,v \quad \text{for all } B, \qquad \mathrm{rsl}_{\bar{D},V'}(0;\phi_{\mathrm{sm}}) = v. \tag{1}$$

Step 3: the large datum. Let e be the bijection of $(b\times n)\sqcup(n\times n)$ onto $(b\sqcup n)\times n$ that is the identity on each part, and $v \boxtimes_e v_1$ the product of Lemma 6.3.51, $z \mapsto v(z_1)v_1(z_2)$; the signs of $\mathrm{Hom}(W_1, V'\oplus W_1)$ restrict to those of $\mathrm{Hom}(W_1,V')$ and $\mathrm{Hom}(W_1,W_1)$ on the two parts, so by (1) of Lemma 6.3.51 $v\boxtimes_e v_1$ is a Schwartz vector of $\mathcal{F}_{W_1,V'\oplus W_1}$. The arguments of the real slices along $V'\oplus W_1$ are families $x = (x_w)_w$ of complex $(b\sqcup n)\times b$ matrices. Put $x'_w = k(\mathrm{pr}(x_w))^{-1}x_w$, let $(x'_w)_1$ be its block of rows b, and

$$\tau_{\mathrm{lg}}(x) = \kappa\,\mathrm{bm}(\mathrm{pr}\circ x)\,\mathrm{bm}(x')\prod_w \overline{\det(x'_w)_1}^{\,2\mu(w)}\prod_w \det k(\mathrm{pr}(x_w))^{j-\mu(w)},$$
$$g(x) = \bigoplus_w k(\mathrm{pr}(x_w))\otimes 1_n.$$

Since $k(y)^{-1} = Jk(y)^*J$ and $|\det k(y)| = 1$ for $k(y) \in \mathrm{U}(J)$ (so negative powers of $\det k(y)$ are powers of its conjugate), τ_{lg} and g are smooth. If $\tau_{\mathrm{lg}}(x) \ne 0$ then $\mathrm{pr}\circ x$ and x' lie in $\mathrm{supp}\,\mathrm{bm}$ and $x_w = k(\mathrm{pr}(x_w))x'_w$, so the support of τ_{lg} lies in the image of $(\mathrm{supp}\,\mathrm{bm})^2$ under the continuous map

$(y,x')\mapsto(k(y_w)x'_w)_w$ and is relatively compact. The matrix $g(x)$ lies in $\mathrm{U}(\mathrm{diag}\,\varepsilon_0)$ for the signs ε_0 of $\mathrm{Hom}(W_1,V'\oplus W_1)$, which are $J\otimes\mathrm{diag}(s)$ at each w: $(k\otimes1)^*(J\otimes\mathrm{diag}\,s)(k\otimes1)=k^*Jk\otimes\mathrm{diag}\,s$. By (WR5), $\Omega_{j-\mu,0}(1,k\circ\mathrm{pr}\circ x)=\prod_w\det k(\mathrm{pr}(x_w))^{j-\mu(w)}\,\omega_{\varepsilon_0}^\infty(g(x))$. By Lemma 6.3.53, (2) of Lemma 6.2.43 applies to the induced splitting of $\mathrm{Hom}(X,V'\oplus W_1)$ and its adapted basis, and gives a Schwartz vector $\phi_{\mathrm{lg}}\in\mathcal{F}_{X,V'\oplus W_1}$ with

$$\mathrm{rsl}_{D,V'\oplus W_1}(x;\phi_{\mathrm{lg}})=\kappa\,\mathrm{bm}(\mathrm{pr}\circ x)\,\mathrm{bm}(x')\prod_w\overline{\det(x'_w)_1}^{2\mu(w)}\,\Omega_{j-\mu,0}(1,k\circ\mathrm{pr}\circ x)(v\boxtimes_e v_1)=:S(x). \tag{2}$$

Step 4: a value of S. Let $x_1=(x_{1,w})_w$ be a family with $x_{1,w}^*Jx_{1,w}=\mathrm{diag}(t')$, $y^1=\mathrm{pr}\circ x_1$, and $C=(C_w)_w$ invertible $b\times b$ matrices. (a) If $\mathrm{bm}(y^1)=0$ then $S(x_1C)=0$. (b) If $u_w\in\mathrm{U}(\mathrm{diag}\,t')$ satisfy $k(y^1_w)x_0u_w=x_{1,w}$ for all w, then with $B_w=u_wC_w$

$$S(x_1C)=\kappa\,\mathrm{bm}(y^1)\,\mathrm{bm}\big((x_0B_w)_w\big)\prod_w\overline{\det B_w}^{2\mu(w)}\,\Omega_{j-\mu,0}(1,k\circ y^1)(v\boxtimes_e v_1).$$

Proof. Let $a=x_1C$. If $\mathrm{bm}((k(y'_w)^{-1}a_w)_w)=0$ for every family y', then $S(a)=0$, its factor $\mathrm{bm}(a')$ being of this form; in (b) the right side vanishes as well, since $k(y^1_w)^{-1}a_w=x_0u_wC_w=x_0B_w$. Otherwise some y' has $\mathrm{bm}((k(y'_w)^{-1}a_w)_w)\neq0$; by (W1) iv inverts the Gram matrix of $k(y'_w)^{-1}a_w$, which is $a_w^*Ja_w=C_w^*\mathrm{diag}(t')C_w$, and it inverts $\mathrm{diag}(t')\in\mathcal{N}_1$; by (W2), $\mathrm{pr}(a_w)=\mathrm{pr}(x_{1,w})=y^1_w$. Then $S(a)$ has the factor $\mathrm{bm}(y^1)$, which gives (a), and in (b) $a'_w=k(y^1_w)^{-1}x_{1,w}C_w=x_0B_w$, $(a'_w)_1=B_w$, which gives the formula.

Step 5: the hypotheses of Proposition 6.3.22. Let $\mathrm{pw}(h)=\mathrm{bm}(\mathrm{pr}\circ(h_w^{-1}x_0)_w)$ for $h\in G_\infty(t'\sqcup s)$, a non-negative continuous function with $\mathrm{pw}(1)=\mathrm{bm}(x_0,\dots,x_0)=1$, hence non-zero near 1; and $I(\mathfrak{c})=\theta^{\mathrm{lg}}_{\mathfrak{c}}(W_1,W_1;v_1,\Psi_1^{\mathrm{st}})(1)$, so that $\ell(\mathfrak{c})=|I(\mathfrak{c})|^2/L_*(\Sigma,\nu;\#n/2)$. The vectors ϕ_{lg}, ϕ_{sm} are Schwartz vectors.

(S), first alternative: if $S(x)\neq0$ then $\mathrm{bm}(\mathrm{pr}\circ x)\neq0$, and (W3) gives c with $x_w^*Jx_w=c^*\mathrm{diag}(t')c$ for every w.

(P): Let $\mathfrak{c}=(\nu,\Sigma)$ have weight μ, $\gamma=\gamma_{\mathfrak{c}}=\nu^{-1}\upsilon^j$, and $h\in G_\infty(t'\sqcup s)$. Let $x_{1,w}=h_w^{-1}x_0$; then $x_{1,w}^*Jx_{1,w}=\mathrm{diag}(t')$, and $y^1=\mathrm{pr}\circ x_1$ has $\mathrm{bm}(y^1)=\mathrm{pw}(h)$.

If $\mathrm{pw}(h)=0$, take $(p_1,p_2)=(1,1)$, so $\hat h=h$. For $B\in\mathrm{GL}_b(\mathbb{A}_E)$ the slice argument is $\hat h^{-1}(B_\infty;0)=(x_{1,w}B_w)_w$, and by Step 4 (a) its slice $S(x_1B_\infty)$ vanishes; both sides of (P) are 0.

If $\mathrm{pw}(h)\neq0$, (W3) applied to x_1 gives u_w with $k(y^1_w)x_0u_w=x_{1,w}$ and $u_w^*\mathrm{diag}(t')u_w=\mathrm{diag}(t')$, i.e. $u_w\in\mathrm{U}(\mathrm{diag}\,t')$. The element $g_w=h_wk(y^1_w)\mathrm{diag}(u_w,1)$ of $\mathrm{U}(J)$ fixes the columns of x_0; writing it in blocks, $g_wx_0=x_0$ gives the first block column $(1;0)$, and the block (b,n) of $g_w^*Jg_w=J$ gives $\mathrm{diag}(t')\,(g_w)_{bn}=0$, so $g_w=\mathrm{diag}(1,q_w)$ with $q_w\in\mathrm{U}(\mathrm{diag}\,s)$. Hence $\mathrm{diag}(u_w,q_w^{-1})\,h_w\,k(y^1_w)=1$. Let $p_1\in\mathrm{G}(t')$, $p_2\in\mathrm{G}(s)$ have infinite components $(u_w)_w$, $(q_w^{-1})_w$ and finite components 1; then $\hat h_wk(y^1_w)=1$ for every w. Fix B,β,f,x,g,y as in (P). The slice argument is $a_w=\hat h_w^{-1}(B_w;0)=h_w^{-1}(u_w^{-1}B_w;0)=x_{1,w}u_w^{-1}B_w$, so Step 4 (b) with $C_w=u_w^{-1}B_w$ and the representation property of $\Omega_{j-\mu,0}$ (Proposition 4.1.14) give

$$w_{\hat h}(B)=\Omega_{j-\mu,0}(1,\hat h)\,S(a)=c_B\,(v\boxtimes_e v_1),\qquad c_B=\kappa\,\mathrm{pw}(h)\,\mathrm{bm}\big((x_0B_w)_w\big)\prod_w\overline{\det B_w}^{2\mu(w)}.$$

By (3) of Lemma 6.3.51, $(v\boxtimes_e v_1)\otimes(f\boxtimes^{\mathrm{tg}}F_{\mathfrak{c}})=(v\otimes f)\boxtimes^{\mathrm{tg}}(v_1\otimes F_{\mathfrak{c}})$; by (b) of Lemma 6.3.52 with the characters γ, β, γ, $\omega_{\gamma,\gamma\beta}(g,\mathrm{diag}(y,u))$ carries it to $\omega_{\gamma,\beta}(g,y)(v\otimes f)\boxtimes^{\mathrm{tg}}\omega_{\gamma,\gamma}(g,u)(v_1\otimes F_{\mathfrak{c}})$; by (2) of Lemma 6.3.51, $\rho((x;0))$ acts by $\rho(x)$ on the first factor and by $\rho(0)=1$ on the second; and by (c) of Lemma 6.3.52 the theta functional of the product is the product of the theta functionals. So the integrand of (P) is

$$c_B\,\theta_{\mathrm{Hom}(W_1,V')}\big(\rho(x)\omega_{\gamma,\beta}(g,y)(v\otimes f)\big)\cdot\theta^{W_1,W_1}_{\gamma,\gamma}\big(v_1\otimes[\Psi_1^{\mathrm{st}}]_\Sigma\big)(g,u).$$

The function Ψ_1^{st} is locally constant with compact support $\mathrm{GL}_n(\mathcal{O}_\Sigma)$ and vanishes off the invertible matrices, so $v_1 \otimes [\Psi_1^{\mathrm{st}}]_\Sigma$ is target-bounded (Lemma 6.2.26) and its theta kernel is integrable over $[\mathrm{U}(W_1)]$ (Lemma 6.3.21). As $\gamma = \nu^{-1}\upsilon^{\lfloor \#n/2 \rfloor}$, its integral is $\theta_{\mathfrak{c}}^{\mathrm{lg}}(W_1, W_1; v_1, \Psi_1^{\mathrm{st}})(g)$, which is $I(\mathfrak{c})$ by Proposition 6.3.17 ($\#n$ even, D_1 base-adapted). Hence the left side of (P) is $c_B\, I(\mathfrak{c})\, \theta_{\mathrm{Hom}(W_1,V')}(\rho(x)\omega_{\gamma,\beta}(g,y)(v\otimes f))$. On the right side, by (1), $\mathrm{rsl}_{D,V'}(B_\infty;\phi_{\mathrm{sm}}) = \mathrm{bm}((x_0B_w)_w)\prod_w |\det B_w|^{2(j+\mu(w))}\kappa v$. With $\zeta_w = \det B_w$, the idele $z_B/\bar{z}_B$ lies in $\mathrm{U}(1)(\mathbb{A})$ with finite components 1 and components $\zeta_w/\bar{\zeta}_w$, so by the weight of ν (Definition 3.1.1) $\tilde{\nu}(z_B) = \prod_w (\zeta_w/\bar{\zeta}_w)^{\mu(w)}$, and

$$\frac{\prod_w |\zeta_w|^{2(j+\mu(w))}}{\tilde{\nu}(z_B)\prod_w |\zeta_w|^{\#n}} = \prod_w (\zeta_w\bar{\zeta}_w)^{\mu(w)}\Big(\frac{\bar{\zeta}_w}{\zeta_w}\Big)^{\mu(w)} = \prod_w \bar{\zeta}_w^{2\mu(w)}.$$

So the right side of (P) is $\kappa\,\mathrm{pw}(h)\, I(\mathfrak{c})\,\mathrm{bm}((x_0B_w)_w)\prod_w \bar{\zeta}_w^{2\mu(w)}\theta_{\mathrm{Hom}(W_1,V')}(\rho(x)\omega_{\gamma,\beta}(g,y)(v\otimes f))$, which is the left side.

Step 6: conclusion. By Proposition 6.3.22, $(\sigma, \phi_{\mathrm{lg}}, \phi_{\mathrm{sm}}, \ell)$ satisfy the row-column exchange identity for $(X, V'\oplus W_1, V')$ and μ, and (1) gives $\mathrm{rsl}_{\bar{D},V'}(0;\phi_{\mathrm{sm}}) = v$. □

Lemma 6.3.7. *Let $m, b \geq 0$, let J be a hermitian $m\times m$ complex matrix, $\mathrm{U}(J) = \{g \in \mathrm{GL}_m(\mathbb{C}) : g^*Jg = J\}$, and let x be an $m \times b$ complex matrix with $\det(x^*Jx) \neq 0$. Then there is a map $k\colon \mathrm{M}_{m\times b}(\mathbb{C}) \to \mathrm{U}(J)$, smooth as a map of real vector spaces into $\mathrm{M}_m(\mathbb{C})$, and a neighbourhood N of x such that for every $y \in N$ there is $c \in \mathrm{M}_b(\mathbb{C})$ with*

$$k(y)\, x\, c = y.$$

Proof. Put $G = x^*Jx$, an invertible hermitian $b\times b$ matrix, $w = G^{-1}x^*$ and $P = xw = xG^{-1}x^*$; then $P^* = P$ and $wJx = 1_b$.

Step 1: a linear map into the Lie algebra of $\mathrm{U}(J)$ that moves x within its span. For $a \in \mathrm{M}_m(\mathbb{C})$ put $L(a) = (aP - Pa^*)J$. The map L is $\mathbb{R}$-linear, $L(1) = 0$, and $L(a)^*J = J(Pa^* - aP)J = -JL(a)$. By induction $(L(a)^*)^jJ = J(-L(a))^j$ for $j \geq 0$, so $\exp(L(a))^*J = J\exp(-L(a))$ and $\exp(L(a))^*J\exp(L(a)) = J$: thus $\exp(L(a)) \in \mathrm{U}(J)$. Moreover $L(a)x = ax - xwa^*Jx$ because $wJx = 1$, so

$$(a - L(a))x = x\,(wa^*Jx). \tag{a}$$

Step 2: a smooth local inverse. Let $T(a) = \exp(L(a))\,(a - L(a))$, a smooth map of the real vector space $\mathrm{M}_m(\mathbb{C})$ to itself with $T(1) = 1$. For $h \in \mathrm{M}_m(\mathbb{C})$, since L is linear, $L(1) = 0$ and the derivative of exp at 0 is the identity,

$$\frac{d}{dt}\Big|_{t=0} T(1+th) = L(h)(1 - L(1)) + \exp(L(1))(h - L(h)) = h,$$

so the derivative of T at 1 is the identity. By the inverse function theorem there are an open neighbourhood U_1 of 1 and a smooth map $A_0\colon U_1 \to \mathrm{M}_m(\mathbb{C})$ with $T(A_0(z)) = z$ for $z \in U_1$. Choose a smooth function $\phi\colon \mathrm{M}_m(\mathbb{C}) \to [0,1]$ with compact support in U_1 and $\phi = 1$ on an open neighbourhood $U_2 \subseteq U_1$ of 1, and let $A(z) = \phi(z)A_0(z)$ for $z \in U_1$ and $A(z) = 0$ otherwise. Then A is smooth on $\mathrm{M}_m(\mathbb{C})$ and $T(A(z)) = z$ for $z \in U_2$.

Step 3: the elements $k(y)$. For $y \in \mathrm{M}_{m\times b}(\mathbb{C})$ put $z(y) = 1 - (x-y)wJ$, an affine function of y with $z(x) = 1$ and, as $wJx = 1$,

$$z(y)\, x = x - (x - y) = y.$$

Let $k(y) = \exp(L(A(z(y))))$. By Step 1, $k(y) \in \mathrm{U}(J)$, and $y \mapsto k(y)$ is smooth as a composite of smooth maps. Let $N = z^{-1}(U_2)$, a neighbourhood of x. For $y \in N$ put $a = A(z(y))$ and $c = wa^*Jx$; by (a) and Step 2,

$$k(y)\,x\,c = \exp(L(a))\,(a - L(a))\,x = T(a)\,x = z(y)\,x = y.$$

□

Lemma 6.3.8. *Let V, V_0, V_1, U be spaces with points, D a base-adapted splitting of V over V_0 along a nonempty index set p and D' a base-adapted splitting of V_0 over V_1 along a nonempty index set q, and let $D \circ D'$ be their composite, a splitting of V over V_1 along $p \sqcup q$. Then for every $\phi \in \mathcal{F}_{V,U}$*

$$\mathrm{rsl}_{D\circ D',U}(0;\phi) = \mathrm{rsl}_{D',U}(0;\mathrm{rsl}_{D,U}(0;\phi)).$$

Proof. Let r be the index set of U. If r is empty, the Fock models of $\mathrm{Hom}(V,U)$, $\mathrm{Hom}(V_0,U)$, $\mathrm{Hom}(V_1,U)$ are $\mathbb{C}$ (functions on a point, ν the unit mass) and each real zero term of (MX7) is the identity (the integral over a point of the value times the real vacuum 1), so there is nothing to prove; let r be nonempty, so that $r \times p$, $r \times q$ are nonempty. By (MX7), $\mathrm{rsl}_{C,U}(0;\phi) = Z^\infty_{C,U}(\phi)$ for every splitting C (the Heisenberg operator at 0 is the identity); so we show $Z^\infty_{D\circ D',U} = Z^\infty_{D',U} \circ Z^\infty_{D,U}$.

Step 1: the induced splittings. Write $D = (k,l,i)$, $D' = (k',l',i')$, so $D \circ D' = ((k \mid ik'),(l \mid il'),ii')$ ((MX5)). By (MX1) the frames induced on $\mathrm{Hom}(V,U)$ are $J_U^{-1} \otimes (k^*J_V)^\mathsf{T}$, $1 \otimes (l^*J_V)^\mathsf{T}$, $1 \otimes (J_{V_0}^{-1}i^*J_V)^\mathsf{T}$, and those induced by D' on $\mathrm{Hom}(V_0,U)$ likewise. Since $(J_{V_0}^{-1}i^*J_V)^\mathsf{T}(k'^*J_{V_0})^\mathsf{T} = (k'^*i^*J_V)^\mathsf{T}$, and similarly for l' and i', the splitting $(D \circ D')_U$ is the composite $D_U \circ D'_U$, once $r \times (p \sqcup q)$ is identified with $(r \times p) \sqcup (r \times q)$; under this identification the adapted basis $(x_U^{-1})^* \otimes 1_{p\sqcup q}$ is the block diagonal matrix of the adapted bases for p and q, and the formulas of (MX7) do not depend on the order of the index set. The composite $D \circ D'$ is base-adapted: its matrix of adelic frames is, up to the order of the columns, that of D times the block diagonal matrix with blocks 1, 1 and the matrix of adelic frames of D' (as $x_V^{-1}ik' = i_{D,\mathbb{A}}x_{V_0}^{-1}k'$ and likewise for l', i'), a product of matrices unitary at the infinite places and integral at the finite places. By Lemma 6.3.53, D_U, D'_U and $(D \circ D')_U$ are adapted at 1 in their adapted bases.

Step 2: the zero terms of the vacuum datum. For each of the three induced splittings C, with zero term Z_C and real zero term Z^∞_C, (2) of Lemma 6.2.20 with $f = v^0$, then $v_1 \otimes v^0 = v^0$ ((4) of Lemma 6.2.21) and $Z_C(v^0) = \mathrm{vf}(C)v^0$ with $\mathrm{vf}(C) \neq 0$ ((4) of Lemma 6.2.20) give, for every Fock vector w of the source of C,

$$Z_C(w \otimes v^0) = Z^\infty_C(w) \otimes Z_C(v_1 \otimes v^0) = \mathrm{vf}(C)\,Z^\infty_C(w) \otimes v^0.$$

By (1) of Lemma 6.2.25, $Z_{D_U \circ D'_U} = Z_{D'_U} \circ Z_{D_U}$. Applied to v^0 this gives $\mathrm{vf}(D_U \circ D'_U) = \mathrm{vf}(D_U)\,\mathrm{vf}(D'_U)$. Applied to $\phi \otimes v^0$, the display (for $C = D_U$, then for $C = D'_U$ and the Fock vector $Z^\infty_{D_U}(\phi)$, and for $C = D_U \circ D'_U$) gives

$$\mathrm{vf}(D_U \circ D'_U)\,Z^\infty_{D_U\circ D'_U}(\phi) \otimes v^0 = \mathrm{vf}(D_U)\,\mathrm{vf}(D'_U)\,Z^\infty_{D'_U}(Z^\infty_{D_U}(\phi)) \otimes v^0.$$

Step 3: conclusion. Dividing by the nonzero vacuum factor,

$$Z^\infty_{D_U\circ D'_U}(\phi) \otimes v^0 = Z^\infty_{D'_U}(Z^\infty_{D_U}(\phi)) \otimes v^0$$

in the theta model of $\mathrm{Hom}(V_1,U)$, and Lemma 6.3.9 gives $Z^\infty_{D\circ D',U}(\phi) = Z^\infty_{D',U}(Z^\infty_{D,U}(\phi))$. □

Lemma 6.3.9. *Let s be signs on an index set n and $\mathcal{F}_\varepsilon$ the Fock model for $\iota = \Phi\times n$, $\varepsilon(v,i) = s_i$. For every $w \in \mathcal{F}_\varepsilon$ and $u \in \mathbb{C}^{\Phi\times n}$,*

$$\big(w \otimes v^0\big)\big(\mathrm{rv}(u)\big) = w(u).$$

In particular, if $w, w' \in \mathcal{F}_\varepsilon$ and $w \otimes v^0 = w' \otimes v^0$, then $w = w'$.

Proof. For $f \in \mathcal{M}_s$ and $x \in \mathbb{A}_E^n$, the identity of (WD7) gives $|f(x)| \le \sup|e_n|\,\|f\|_{L^1(\mu_n)}$, so evaluation at x is a bounded linear functional on $\mathcal{M}_s$ and commutes with the Bochner integral $w \otimes v^0 = \int w(y)\,\rho(\mathrm{rv}(y))v^0\,d\nu_\iota(y)$ ((WR6), (1) of Lemma 6.2.21). With $(\rho(z)f)(x) = \beta_s(z,x)f(x-z)$,

$$\big(w \otimes v^0\big)(\mathrm{rv}(u)) = \int w(y)\,\beta_s\big(\mathrm{rv}(y),\mathrm{rv}(u)\big)\,e_n\big(\mathrm{rv}(u)-\mathrm{rv}(y)\big)\,d\nu_\iota(y).$$

At $v \in \Phi$ the element $\jmath_v$ is purely imaginary with $\operatorname{Im}\jmath_v > 0$ and $\kappa_v^2 = (2\pi\operatorname{Im}\jmath_v)^{-1}$, so $\jmath_v\kappa_v^2 = i/(2\pi)$ and $\operatorname{Im}(\jmath_v)\kappa_v^2 = 1/(2\pi)$. The vectors $\mathrm{rv}(y)$ have components $\kappa_v y_{v,i}$ at the infinite places and 0 at the finite places. Hence, by (WD4) and (WD6),

$$\beta_s\big(\mathrm{rv}(y),\mathrm{rv}(u)\big) = \exp\Big(-2\pi i\sum_{v\in\Phi}\operatorname{Re}\big(\tfrac{i}{2\pi}\,u_v^*\mathrm{diag}(s)\,y_v\big)\Big) = \exp\big(i\operatorname{Im}(u^*\mathrm{diag}(\varepsilon)\,y)\big) = \beta_\varepsilon^\infty(y,u),$$

using $\operatorname{Re}(iz) = -\operatorname{Im} z$ and $\frac{1}{2}(z-\bar z) = i\operatorname{Im} z$ for $z = u^*\mathrm{diag}(\varepsilon)y$; and by (WD5), the finite part 0 lying in $\alpha\widehat{\mathcal{O}}_E^n$,

$$e_n\big(\mathrm{rv}(u-y)\big) = \exp\Big(-\pi\sum_{v,i}\operatorname{Im}(\jmath_v)\kappa_v^2|u_{v,i}-y_{v,i}|^2\Big) = \exp\big(-\tfrac{1}{2}\|u-y\|^2\big) = e^\infty(u-y),$$

$\|\cdot\|$ the euclidean norm. So the integral is $\int w(y)\beta_\varepsilon^\infty(y,u)e^\infty(u-y)\,d\nu_\iota(y)$, which is $w(u)$ by the defining identity of $\mathcal{F}_\varepsilon$ ((WR5)). The last assertion follows by evaluating at the points $\mathrm{rv}(u)$. □

Proposition 6.3.10. *Let W', W, V', V, U be spaces with signs s' on n', s on n, t' on r', t on r, u on b, let p be a nonempty index set and A a base-adapted splitting of W' over W along p. Let $\sigma\colon b\sqcup r \to n$ and $\sigma'\colon b\sqcup r' \to n'$ be bijections, assume $\#n$ even and $\mathrm{neg}(V') = \#p + \mathrm{neg}(V)$, and let $\mu\colon \Phi \to \mathbb{Z}$. If $x \in \mathcal{F}_{W',V'}$, $y \in \mathcal{F}_{W',U}$ and ℓ are such that (σ', x, y, ℓ) satisfy the row-column exchange identity for (W', V', U) and μ, then there is $x_0 \in \mathcal{F}_{W,V}$ such that $(\sigma, x_0, \mathrm{rsl}_{A,U}(0;y), \ell)$ satisfy the row-column exchange identity for (W, V, U) and μ.*

Proof. Since A splits off $\#p$ hyperbolic planes, $\#n' = \#n + 2\#p$, and the bijections give $\#r' = \#n' - \#b = \#r + 2\#p$.

Step 0: reindexing. For a splitting $D = (k, l, i)$ along p and a bijection $e\colon q \to p$ let $D^e = (k\circ e, l\circ e, i)$, the frames with their columns renumbered. It is a splitting along q, base-adapted if D is (its matrix of adelic frames has the same columns), the splitting it induces on $\mathrm{Hom}(V,U)$ and the adapted basis $(x_U^{-1})^*\otimes 1_q$ are those of D renumbered by $1\times e$, and $\mathrm{rsl}_{D^e,U}(0;\cdot) = \mathrm{rsl}_{D,U}(0;\cdot)$: in the formula of (MX7) for the real zero term, $a(y)^*a(y)$ and $(\mathrm{pr}_k\mathrm{rv}(y))^*\mathrm{pr}_l\mathrm{rv}(y)$ are sums over the index set of the splitting, which are unchanged by renumbering, and $w(y)$ does not involve it.

Step 1: one plane. Let $p = \{o\}$, so $\#r' = \#r + 2$ and $\mathrm{neg}(V') = 1 + \mathrm{neg}(V)$. Put $e = \#r - \#n/2$, and $z_e = e+1$, $\pm = +$ if $e \ge 0$, $z_e = -e$, $\pm = -$ if $e < 0$.

(a) *A space with the signs of V' that splits over V.* By (2) of Lemma 6.3.63 (for V, the index set $\{o\}$ and the signs t') there are a space V_1 with signs t' and a base-adapted splitting

X of V_1 over V along $\{o\}$. By (1) of Lemma 6.3.63 there are $\gamma' \in \mathrm{GL}_{r'}(E)$ and $k' \in \mathrm{G}(t')$ with $x_{V'} = \gamma'^{-1} x_{V_1} k'$, and $\mathcal{F}_{W',V'} = \mathcal{F}_{W',V_1}$, $\mathcal{M}_{W',V'} = \mathcal{M}_{W',V_1}$ (same signs).

(b) *The identity for V_1.* Let $(D, (c_\mathfrak{c}))$ be the constants of the hypothesis: $D|c_\mathfrak{c}|^2 = L_*(\Sigma, \nu; e+1)\,\ell(\mathfrak{c})$ (as $\#r' - \#n'/2 = e+1$) and $\theta^{\mathrm{lg}}_\mathfrak{c}(W', V'; x, \Phi^{\mathrm{st}}_{\sigma',z'}) = c_\mathfrak{c}\theta^{\mathrm{sm}}_\mathfrak{c}(W', U; y, \Psi^{\mathrm{st}}_{z'})$ for integral $z' \in \mathrm{M}_{b\times n'}(\mathcal{O}_\Sigma)$. Fix $\mathfrak{c} = (\nu, \Sigma)$ of weight μ and $\alpha = \nu^{-1}\upsilon^{\#n'/2}$. The function $\Phi^{\mathrm{st}}_{\sigma',z'}$ is locally constant, compactly supported and vanishes at the matrices without a right inverse (if it is non-zero at x', the square matrix with the rows of z' and x' is invertible), so $x \otimes [\Phi^{\mathrm{st}}_{\sigma',z'}]_\Sigma$ is target-bounded (Lemma 6.2.26) and its theta kernel is integrable over $[\mathrm{U}(V')]$ (Lemma 6.3.21). By Lemma 6.3.64 (with $W_1 = W'$, $\gamma = 1$, $k = 1$) there is $u_\mathfrak{c} = z\,\alpha(\det k')^{-1}$ with $|u_\mathfrak{c}| = 1$ and $\theta^{\mathrm{lg}}_\mathfrak{c}(W', V'; x, \Phi) = u_\mathfrak{c}\theta^{\mathrm{lg}}_\mathfrak{c}(W', V_1; x, \Phi)$ for these Φ. So with $c_1 = u_\mathfrak{c}^{-1}c_\mathfrak{c}$, $|c_1| = |c_\mathfrak{c}|$ and

$$\theta^{\mathrm{lg}}_\mathfrak{c}(W', V_1; x, \Phi^{\mathrm{st}}_{\sigma',z'}) = c_1\,\theta^{\mathrm{sm}}_\mathfrak{c}(W', U; y, \Psi^{\mathrm{st}}_{z'}) \qquad (z' \in \mathrm{M}_{b\times n'}(\mathcal{O}_\Sigma)). \tag{1}$$

(c) *Constant terms.* Let $C > 0$ be the constant of Proposition 6.2.2 for A, X, σ', σ, μ, and $\gamma_\mathfrak{c}$ its number for $\mathfrak{c}$, $|\gamma_\mathfrak{c}| = C\,L^\sharp_\mathfrak{c}(z_e)$. Put $x_0 = \mathrm{Cone}^\pm_{A,X,\mu}(z_e; x)$, a Schwartz vector of $\mathcal{F}_{W,V}$ by Lemma 6.2.42 ($z_e > 0$); it does not depend on $\mathfrak{c}$. Let $z \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$ and $g \in \mathrm{G}(s)$. The matrix $(\mathrm{pr}_i)_\Sigma$ is integral, the finite part of $\mathrm{pr}_i = \varepsilon_s i^*_{A,\mathbb{A}}\varepsilon_{s'}$ being $i^*_{A,\mathbb{A},f}$ with $i_{A,\mathbb{A},f}$ integral; so $z' = z(\mathrm{pr}_i)_\Sigma$ is integral. By Proposition 6.2.2 at $u = 1$, the definition of $\mathrm{CT}^{\mathrm{pl}}$, (1) at the points $\mathrm{rad}^{\mathrm{ln}}_A(q_1, q_2)\mathrm{lev}_A(1, g)$, and Lemma 6.3.11,

$$\gamma_\mathfrak{c}\,\theta^{\mathrm{lg}}_\mathfrak{c}(W, V; x_0, \Phi^{\mathrm{st}}_{\sigma,z})(g) = \mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(x, z)(1, g) = c_1\,\mathrm{vf}(A_U)\,\theta^{\mathrm{sm}}_\mathfrak{c}(W, U; \mathrm{rsl}_{A,U}(0; y), \Psi^{\mathrm{st}}_z)(g).$$

(d) *The constants are non-zero.* The splitting A_U of $\mathrm{Hom}(W', U)$ over $\mathrm{Hom}(W, U)$ is along $b \times \{o\}$. If $b \neq \varnothing$, $\mathrm{vf}(A_U) \neq 0$ by (4) of Lemma 6.2.20, A_U being adapted at 1 in its adapted basis (Lemma 6.3.53). If $b = \varnothing$, both spaces of homomorphisms have rank 0, so both are the standard space of the empty sign vector; in rank 0 the vacuum measure is the unit point mass, so the theta model is $\mathbb{C}$ with $\rho(0) = 1$, $v^0 = e_0 = 1$ and $\langle f, g\rangle = \bar{f}g$ ((WD5)–(WD7) of Definition 3.2.12, empty sums being 0 and empty products 1), and the canonical theta functional is the identity of $\mathbb{C}$ ((WC1)–(WC3) of Definition 4.1.15: the transporting element of a standard space is 1, and the empty product formula gives $\theta(v^0) = 1$). The quotient $\mathbb{A}^\varnothing_E/E^\varnothing$ in (MX4) is a point of mass 1, so (MX4) reads $\theta(Z(f)) = \theta(f)$, that is $Z(f) = f$, and (MX8) gives $\mathrm{vf}(A_U) = \langle 1, 1\rangle/\langle 1, 1\rangle = 1$. For $w \in \Sigma$ and a unit u_w of $\mathcal{O}_{E,w}$, the idele x_w with component u_w at w and 1 elsewhere has $x_w/\bar{x}_w \in \mathrm{U}(1)(\mathbb{A})$ with components u_w at w, $\bar{u}_w^{-1}$ at $\bar{w} \notin \Sigma$ and 1 elsewhere, so $\tilde{\nu}(x_w) = \psi_w(u_w \bmod w)$, which is not identically 1; hence $\tilde{\nu}$ is ramified at w and not of the form $|\cdot|^{i\tau}$. By (3) of Theorem A.1.12, $L(z, \tilde{\nu}) \neq 0$ for real $z \geq 1$; the Euler factors removed in L^Σ are $(1 - \tilde{\nu}(\varpi_w)\mathrm{N}w^{-z})^{-1}$ at unramified places, finite and non-zero for $z \geq 1$; so $L^\Sigma(z_e, \tilde{\nu}) \neq 0$, $L^\sharp_\mathfrak{c}(z_e) > 0$ and $\gamma_\mathfrak{c} \neq 0$. By (c), $c_0 = c_1\mathrm{vf}(A_U)/\gamma_\mathfrak{c}$ satisfies $\theta^{\mathrm{lg}}_\mathfrak{c}(W, V; x_0, \Phi^{\mathrm{st}}_{\sigma,z}) = c_0\,\theta^{\mathrm{sm}}_\mathfrak{c}(W, U; \mathrm{rsl}_{A,U}(0; y), \Psi^{\mathrm{st}}_z)$ for every integral z.

(e) *The size of c_0.* Put $D_0 = D\,C^2/|\mathrm{vf}(A_U)|^2$, independent of $\mathfrak{c}$. Then

$$D_0|c_0|^2 = D|c_\mathfrak{c}|^2/L^\sharp_\mathfrak{c}(z_e)^2 = L_*(\Sigma, \nu; e+1)\,\ell(\mathfrak{c})/L^\sharp_\mathfrak{c}(z_e)^2,$$

and with $Q = \prod_{w\in\Sigma}\mathrm{N}w$ and $L_j = |L^\Sigma(j, \tilde{\nu})|^2$: if $e \geq 0$, $L_*(e+1) = Q^{(e+1)^2}\prod_{j=1}^{e+1}L_j$ and $L^\sharp(e+1)^2 = L_{e+1}Q^{2e+1}$, so the quotient is $Q^{e^2}\prod_{j=1}^{e}L_j = L_*(e)$; if $e = -k < 0$, $L_*(e+1) = L_*(k-1)^{-1}$, $L^\sharp(k)^2 = L_kQ^{2k-1}$ and $L_*(k) = Q^{k^2}\prod_{j=1}^{k}L_j = L^\sharp(k)^2L_*(k-1)$, so the quotient is $L_*(k)^{-1} = L_*(e)$. Hence $D_0|c_0|^2 = L_*(\Sigma, \nu; \#r - \#n/2)\,\ell(\mathfrak{c})$. Finally $\mathrm{rsl}_{A,U}(0; y)$ is a Schwartz vector by (1) of Lemma 6.2.43 and Lemma 6.3.53. So $(\sigma, x_0, \mathrm{rsl}_{A,U}(0; y), \ell)$ satisfy the row-column exchange identity for (W, V, U) and μ.

Step 2: induction on $\#p$. We prove the statement for all data by strong induction on $\#p \geq 1$. If $\#p = 1$, let $e\colon \{o\} \to p$ be the bijection; A^e is base-adapted, Step 1 applies to

it, and $\mathrm{rsl}_{A^e,U}(0;y) = \mathrm{rsl}_{A,U}(0;y)$ by Step 0. Let $\#p \geq 2$ and write $A = (k,l,i)$. Choose a bijection $e\colon n_1 \sqcup q_1 \to p$ with $q_1 = \{o\}$, so $n_1 \neq \varnothing$ and $\#n_1 < \#p$. Let $Y_0 = \mathbb{H}_{q_1} \oplus W$ (index set $(q_1 \sqcup q_1) \sqcup n$) and R its tautological splitting over W along q_1. Define $B = (k_B, l_B, i_B)$ by $k_B = (k \circ e)|_{n_1}$, $l_B = (l \circ e)|_{n_1}$ and $i_B = ((l \circ e)|_{q_1} \mid (k \circ e)|_{q_1} \mid i)$ (columns indexed by $(q_1 \sqcup q_1) \sqcup n$). The relations of (MX1) for A give those of a splitting of W' over Y_0 along n_1: the Gram matrix of the columns of i_B is $\mathrm{diag}\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}, J_W\right) = J_{Y_0}$, these columns are orthogonal to those of k_B, l_B (as $l^* J_{W'} k = 1_p$, $k^* J_{W'} k = l^* J_{W'} l = 0$ and $i^* J_{W'} k = i^* J_{W'} l = 0$), and $\#n' = \#((q_1 \sqcup q_1) \sqcup n) + 2\#n_1$. Its matrix of adelic frames consists of the columns of that of A, the block of $i_{B,\mathbb{A}}$ on $q_1 \sqcup q_1$ multiplied on the right by the point $x_{\mathbb{H}_{q_1}}$; this point is unitary at the infinite places and, at the finite places, integral with determinant $c\bar{c}_0 + cc_0 = c$ a unit ($c_0 + \bar{c}_0 = 1$), so B is base-adapted. The tautological splitting R has the matrix of adelic frames $\mathrm{diag}(x_{\mathbb{H}_{q_1}}^{-1}, 1)$, unitary at the infinite places and integral at the finite places, so R is base-adapted. The composite $B \circ R$ (MX5) has the frames $(k_B \mid i_B k_R) = k \circ e$, $(l_B \mid i_B l_R) = l \circ e$ and the embedding $i_B i_R = i$, so $B \circ R = A^e$. By Step 0 and Lemma 6.3.8,

$$\mathrm{rsl}_{A,U}(0;y) = \mathrm{rsl}_{B\circ R,U}(0;y) = \mathrm{rsl}_{R,U}\big(0; \mathrm{rsl}_{B,U}(0;y)\big).$$

Let $Y_V = \mathbb{H}_{q_1} \oplus V$, with $\mathrm{neg}(Y_V) = 1 + \mathrm{neg}(V)$, so $\mathrm{neg}(V') = \#n_1 + \mathrm{neg}(Y_V)$, and choose a bijection $\tau\colon b \sqcup ((q_1 \sqcup q_1) \sqcup r) \to (q_1 \sqcup q_1) \sqcup n$ (both sides have $\#b + \#r + 2 = \#n + 2$ elements). The rank of Y_0 is even. By the induction hypothesis for B (along n_1, with Y_0, Y_V, τ, σ') there is $x_1 \in \mathcal{F}_{Y_0,Y_V}$ such that $(\tau, x_1, \mathrm{rsl}_{B,U}(0;y), \ell)$ satisfy the identity for (Y_0, Y_V, U) and μ. By Step 1 for R (along q_1, with W, V, σ, τ) there is $x_0 \in \mathcal{F}_{W,V}$ such that $(\sigma, x_0, \mathrm{rsl}_{R,U}(0; \mathrm{rsl}_{B,U}(0;y)), \ell)$ satisfy the identity for (W,V,U) and μ, which is the assertion. □

Lemma 6.3.11. *Let W', W, U be spaces with signs s' on n', s on n, u on b, and A a base-adapted splitting of W' over W along a one-element set. Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, $y \in \mathcal{F}_{W',U}$ a Schwartz vector, $z \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$, and $(\mathrm{pr}_i)_\Sigma \in \mathrm{M}_{n\times n'}(E_\Sigma)$ the matrix of the components at Σ of the finite part of the coordinate pr_i of A. Then for every $g \in \mathrm{G}(s)$*

$$\begin{aligned}&\int_{\mathrm{M}_{n\times 1}(\mathbb{A}_E)/\mathrm{M}_{n\times 1}(E)} \int_{\mathbb{A}_E/E} \theta^{\mathrm{sm}}_{\mathfrak{c}}\big(W', U; y, \Psi^{\mathrm{st}}_{z(\mathrm{pr}_i)_\Sigma}\big)\big(\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2)\,\mathrm{lev}_A(1,g)\big)\,dq_2\,dq_1 \\ &\qquad = \mathrm{vf}(A_U)\,\theta^{\mathrm{sm}}_{\mathfrak{c}}\big(W, U; \mathrm{rsl}_{A,U}(0;y), \Psi^{\mathrm{st}}_z\big)(g),\end{aligned}$$

the integral being iterated as in the plane constant term of (XD10).

Proof. Write $A = (k,l,i)$ with adelic frames $k_\mathbb{A}, l_\mathbb{A}, i_\mathbb{A}$ and coordinates $\mathrm{pr}_k, \mathrm{pr}_l, \mathrm{pr}_i$; by (MX1) they send $l_\mathbb{A} a + i_\mathbb{A} w + k_\mathbb{A} b$ to b, a, w, so $\mathrm{pr}_k k_\mathbb{A} = \mathrm{pr}_l l_\mathbb{A} = 1$, $\mathrm{pr}_i i_\mathbb{A} = 1$ and the other six products vanish. Put $\Psi' = \Psi^{\mathrm{st}}_{z(\mathrm{pr}_i)_\Sigma}$, $y_0 = \mathrm{rsl}_{A,U}(0;y)$, and let $\lambda_1 = \nu\upsilon^{\lfloor \#n'/2 \rfloor}$, $\lambda_0 = \nu\upsilon^{\lfloor \#n/2 \rfloor}$, $\beta = \upsilon^{\#b}$, so that $\lambda_1 = \lambda_0 \upsilon$ ($\#n' = \#n + 2$). By (XD9) the left side is the iterated integral of $I^{W',U}_{\lambda_1,\beta}(f')(\mathrm{rad}^{\mathrm{ln}}_A(q_1,q_2)\mathrm{lev}_A(1,g))$ with $f' = y \otimes [\Psi'^{\mathsf{T}}]_{\bar{\Sigma}}$, and the right side is $\mathrm{vf}(A_U)\, I^{W,U}_{\lambda_0,\beta}(y_0 \otimes [(\Psi^{\mathrm{st}}_z)^{\mathsf{T}}]_{\bar{\Sigma}})(g)$. The finite part of pr_i is $i^*_{\mathbb{A},f}$, integral since A is base-adapted and $\widehat{\mathcal{O}}_E$ is stable under conjugation; so $z(\mathrm{pr}_i)_\Sigma$ is integral and, by (2) of Lemma 6.3.31, Ψ' and Ψ^{st}_z are locally constant with compact support and vanish at the matrices without a left inverse.

Case $b = \varnothing$. Then $\mathrm{Hom}(W', U)$ and $\mathrm{Hom}(W, U)$ have rank 0: their theta and Fock models are $\mathbb{C}$, the canonical theta functional is the identity of $\mathbb{C}$ (the empty product formula of (WC1)), $\mathrm{G}(\varnothing)$ is trivial with the unit point mass, so $[\mathrm{U}(U)]$ is a point of mass 1, the Weil operators are the identity (in (WR3) the multiplier is an empty product times $\upsilon(1)$ and the integral is over a point), and the characters are evaluated at $\det h = 1$ and, for $\beta = \upsilon^0 = 1$, give 1. In rank 0, $\mathcal{T}_A$ is spanned by $\tau_0 = 1$ and $\Psi \otimes_A f = \Psi(0) f$ (P^A and $\rho(0)$ being the identity), and Ψ'^{T}, $(\Psi^{\mathrm{st}}_z)^{\mathsf{T}}$ take the value $\chi^{-1}(\det(\cdot)) = \chi^{-1}(1) = 1$ at the empty matrix. Hence the integrand of

the left side is the number y at every point, the left side is y, and the right side is $\mathrm{vf}(A_U)\,y_0$; here $\mathrm{vf}(A_U)=1$ ((MX4), (MX8): the zero term along a splitting of the zero space along the empty set is the identity) and $y_0=y$ ((MX7): the real zero term over a point, with real vacuum 1, is the identity). From now on $b\neq\varnothing$, so A_U is along the nonempty set $b\times\{o\}$.

Step 1: the expansion. The function $\phi=\Psi'^{\mathsf T}\circ\bar{\cdot}$ on $\mathrm{M}_{b\times n'}(E_{\bar\Sigma})$, $\phi(w)=\Psi'(\bar w^{\mathsf T})$, is locally constant with compact support, $\phi^\sharp=(\Psi'^{\mathsf T})^\flat$, and it vanishes at every w without a right inverse (if $\phi(w)\neq0$, $\bar w^{\mathsf T}$ has a left inverse). By Lemma 6.2.22 the datum $f'=y\otimes(\phi^\sharp\otimes_{\bar\Sigma}v^0)$ is defined, and it is target-bounded by Lemma 6.2.26 (for the place set $\bar\Sigma$). By Lemma 6.2.4 (for W', W, A, the space U, the characters λ_1,β, f' and the point $\mathrm{lev}_A(1,g)$), the left side equals

$$\int_{[\mathrm U(U)]}\sum_{\xi\in E^b}\mathrm{ct}_A(\xi;F_h)\,dh,\qquad F_h=\omega_{\lambda_1,\beta}\big(\mathrm{lev}_A(1,g),h\big)f',$$

the series converging absolutely. By (MX10), $\mathrm{ct}_A(\xi;F_h)=0$ when $\xi^*J_U\xi\neq0$. We compute the terms of the isotropic ξ.

Step 2: terms of isotropic vectors. Let $\xi\in E^b$ with $\xi^*J_U\xi=0$, $x_\xi=x_U^{-1}\xi$, so $x_\xi^*\varepsilon_u x_\xi=\xi^*J_U\xi=0$ ($x_U^*J_Ux_U=\varepsilon_u$). For an adelic $n\times1$ matrix c let $r=\mathrm{rad}_A(c,0)=1+N$, $N=-i_{\mathbb A}c\,\mathrm{pr}_l+k_{\mathbb A}c^*\varepsilon_s\mathrm{pr}_i-\frac12k_{\mathbb A}c^*\varepsilon_sc\,\mathrm{pr}_l$ (MX2). The relations of the coordinates give $rk_{\mathbb A}=k_{\mathbb A}$, $\mathrm{pr}_ir i_{\mathbb A}=1$ and $\mathrm{rad}_A(c,0)\,\mathrm{rad}_A(-c,0)=1$: with N_- the expression N at $-c$, $N+N_-=-k_{\mathbb A}c^*\varepsilon_sc\,\mathrm{pr}_l$, and in NN_- only the product $k_{\mathbb A}c^*\varepsilon_s\mathrm{pr}_i\cdot i_{\mathbb A}c\,\mathrm{pr}_l=k_{\mathbb A}c^*\varepsilon_sc\,\mathrm{pr}_l$ survives ($\mathrm{pr}_li_{\mathbb A}=\mathrm{pr}_lk_{\mathbb A}=\mathrm{pr}_ik_{\mathbb A}=0$), so $(1+N)(1+N_-)=1$. Hence $r^{-1}=\mathrm{rad}_A(-c,0)$ and $r^{-1}l_{\mathbb A}=l_{\mathbb A}+i_{\mathbb A}c-\frac12k_{\mathbb A}c^*\varepsilon_sc$. By (2) of Lemma 6.2.45 (source W' split by A, target U, the element r with $m=1$, $g_0=1$, $W=\mathrm{pr}_ir^{-1}l_{\mathbb A}=c$, $B=\mathrm{pr}_kr^{-1}l_{\mathbb A}=-\frac12c^*\varepsilon_sc$, the point 1 of $\mathrm G(u)$, characters υ^{-1} and 1), whose phase is 1 because $x_\xi^*\varepsilon_ux_\xi=0$,

$$\big(\omega_{1,1}(r,1)F\big)[x_\xi]=\rho\big(x_\xi c^*\varepsilon_s\big)F[x_\xi]\qquad(F\in\mathcal M_{W',U}).$$

With $c=x_W^{-1}q_1$, (MX6) and (MX10) give, θ_0 the canonical theta functional of $\mathrm{Hom}(W,U)$,

$$\mathrm{ct}_A(\xi;F)=\int_{\mathrm M_{n\times1}(\mathbb A_E)/\mathrm M_{n\times1}(E)}\theta_0\big(\rho(x_\xi(x_W^{-1}q_1)^*\varepsilon_s)\,F[x_\xi]\big)\,dq_1.\tag{1}$$

By (2) of Lemma 6.2.45 for the element $\mathrm{lev}_A(1,g)$ ($m=1$, $g_0=g$; $\mathrm{lev}_A(1,g)^{-1}=\mathrm{lev}_A(1,g^{-1})$ fixes $l_{\mathbb A}$, so $W=B=0$), the point h and the characters λ_0, β (with $\lambda_0\upsilon=\lambda_1$),

$$F_h[x_\xi]=\omega_{\lambda_0,\beta}(g,h)\big(f'[h^{-1}x_\xi]\big).\tag{2}$$

Step 3: Hom slices of f'. Let X be an adelic $b\times1$ matrix. By (1) of Lemma 6.3.12, $f'[X]$ is the slice of f' along A_U at $m_U^{-*}X$, and A_U is adapted at 1 in m_U by Lemma 6.3.53. Its frame $(l_{\mathbb A}m_U^{-*}\mid k_{\mathbb A}m_U\mid i_{\mathbb A})$ for A_U sends (a,b',Y) to $a\,\mathrm{pr}_k+\varepsilon_ub'\mathrm{pr}_l+Y\mathrm{pr}_i$ ($b\times n'$ matrices) ; its finite part at $\bar\Sigma$ sends (a,b',Y) to $w=a\,\mathrm{pr}_k+b'\mathrm{pr}_l+Y\mathrm{pr}_i$ (finite parts at $\bar\Sigma$). Then $\bar w^{\mathsf T}=l_\Sigma\bar a^{\mathsf T}+k_\Sigma\bar b'^{\mathsf T}+i_\Sigma\bar Y^{\mathsf T}$, where $l_\Sigma,k_\Sigma,i_\Sigma$ are the components at Σ of the finite parts of $l_{\mathbb A},k_{\mathbb A},i_{\mathbb A}$ (the finite part of pr_k is $l^*_{\mathbb A,f}$, and so on). The matrix $(l_\Sigma\mid k_\Sigma\mid i_\Sigma)$ is square, integral (base-adapted) and has the integral inverse with block rows $(\mathrm{pr}_l)_\Sigma,(\mathrm{pr}_k)_\Sigma,(\mathrm{pr}_i)_\Sigma$ (finite parts $k^*_{\mathbb A,f}$, $l^*_{\mathbb A,f}$, $i^*_{\mathbb A,f}$); and $(\mathrm{pr}_i)_\Sigma l_\Sigma=(\mathrm{pr}_i)_\Sigma k_\Sigma=0$, $(\mathrm{pr}_i)_\Sigma i_\Sigma=1$. Hence $\bar w^{\mathsf T}$ is integral if and only if a, b', Y are, and then $z(\mathrm{pr}_i)_\Sigma\bar w^{\mathsf T}=z\bar Y^{\mathsf T}$; so

$$\phi(w)=\prod_{j\in b\times\{o\}}\mathbf1_{\mathcal O_{\bar\Sigma}}(a_j)\,\mathbf1_{\mathcal O_{\bar\Sigma}}(b'_j)\cdot\psi_0(Y),\qquad\psi_0(Y)=\Psi^{\mathrm{st}}_z(\bar Y^{\mathsf T}),$$

and $\psi_0^\sharp=((\Psi^{\mathrm{st}}_z)^{\mathsf T})^\flat$. Put $x=\alpha_0^{-1}X$, so that $m_U^{-*}X=m_U^{-*}(\alpha_0x)$, α_0 being the idele of Lemma 6.2.19 (components κ_v at $v\in\Phi$, finite part the Weil idele). By Lemma 6.2.19 (for

$D = A_U$, the place set $\bar\Sigma$, $\Phi = \phi$, $\Psi = \psi_0$, and $f_j \equiv 1$ if the components of x_f at $\bar\Sigma$ are integral, $f_j \equiv 0$ otherwise),

$$f'[X] = c_X \,\mathrm{rsl}_{A,U}(x_\infty; y) \otimes (\psi_0^\sharp \otimes_{\bar\Sigma} v^0) \quad \text{for some } c_X \in \mathbb{C}, \qquad c_0 = \mathrm{vf}(A_U), \tag{3}$$

since at $X = 0$ the indicator is 1 and each $\int_{\mathcal{O}} \psi_{\bar\Sigma}(0)\, dt = 1$.

Step 4: the nonzero isotropic terms vanish. Let $\xi \neq 0$ be isotropic and $h \in \mathrm{G}(u)$. For $H \in \mathcal{M}_{W,U}$ put

$$\Lambda(H) = \int_{\mathrm{M}_{n\times 1}(\mathbb{A}_E)/\mathrm{M}_{n\times 1}(E)} \theta_0\big(\rho(x_\xi(x_W^{-1}q_1)^*\varepsilon_s)\,\omega_{\lambda_0,\beta}(g,h)H\big)\, dq_1.$$

For $z_1 = x_\xi c_1$, $z_2 = x_\xi c_2$ (c_j adelic $1 \times n$) the bicharacter β_{H} of $\mathrm{Hom}(W,U)$ is $\beta_{\mathrm{H}}(z_2, z_1) = \psi_E(\frac{1}{2}\,\mathrm{tr}(z_1^*\varepsilon_u z_2 \varepsilon_s)) = 1$, as $z_1^*\varepsilon_u z_2 = c_1^*(x_\xi^*\varepsilon_u x_\xi)c_2 = 0$; so $\rho(z_1)\rho(z_2) = \rho(z_1 + z_2)$ by (WD7). For $\gamma \in \mathrm{M}_{n\times 1}(E)$, $x_\xi(x_W^{-1}\gamma)^*\varepsilon_s = x_U^{-1}(\xi\gamma^* J_W)x_W$ is a rational vector of $\mathrm{Hom}(W,U)$, under which θ_0 is invariant ((WD9), Lemma 4.1.17). Hence the integrand is periodic; it is continuous ($z \mapsto \rho(z)H'$ is continuous, translation being continuous in L^1 and β_{H} continuous of modulus 1), so Λ is defined, linear, and bounded by $\|\theta_0\|\,\|\omega_{\lambda_0,\beta}(g,h)\|$ times the norm (ρ is isometric; (2) of Lemma 4.1.1). Let $I = \{h^{-1}x_\xi\, c\, g : c \in \mathrm{M}_{1\times n}(\mathbb{A}_E)\}$, an $\mathbb{A}_E$-submodule of $\mathbb{A}_E^{b\times n}$. For $z = h^{-1}x_\xi c g \in I$, (2) of Lemma 4.1.1 and (WR4) give $\omega_{\lambda_0,\beta}(g,h)\rho(z) = \rho(x_\xi c)\,\omega_{\lambda_0,\beta}(g,h)$, and $x_\xi c = x_\xi(x_W^{-1}u_c)^*\varepsilon_s$ with $u_c = x_W\varepsilon_s c^*$; so $\Lambda(\rho(z)H)$ is the integral of the integrand of $\Lambda(H)$ translated by u_c, and $\Lambda(\rho(z)H) = \Lambda(H)$ by invariance of the measure. Next, let y_1 be a finite adelic $b \times n$ matrix with $\psi_0^\sharp(y_1) \neq 0$. Then $\Psi_z^{\mathrm{st}}(\bar y_{1,\Sigma}^{\mathsf{T}}) \neq 0$, so by (2) of Lemma 6.3.31 the matrix $\overline{(y_1)_{\bar w}}^{\mathsf{T}}$ has a left inverse, i.e. $(y_1)_{\bar w}$ has rank $\#b$, for every $w \in \Sigma$. Fix $w \in \Sigma$ and let $a = (h^{-1}x_\xi)_{f,\bar w} \in E_{\bar w}^b$, nonzero as $\xi \neq 0$ and h, x_U are invertible. Then $d = a^*(y_1)_{\bar w}(g_{f,\bar w})^* \neq 0$; take c with component d at $\bar w$ and 0 elsewhere, $z = h^{-1}x_\xi c g$. Then the component at $\bar w$ of $z_f^* y_1 = \mathrm{tr}(z_f^* y_1)$ is $a^*(y_1)_{\bar w} g_{f,\bar w}^* c_{\bar w}^* = dd^* \neq 0$. By Lemma 6.2.35 (signs of $\mathrm{Hom}(W,U)$, the place set $\bar\Sigma$, $\psi_0^\sharp \in \mathcal{T}_{\bar\Sigma}$ by Lemma 6.2.22, I and Λ), $\Lambda(\psi_0^\sharp \otimes_{\bar\Sigma} H) = 0$ for every H. By (1), (2), (3) with $X = h^{-1}x_\xi$, and $y' \otimes (\psi_0^\sharp \otimes_{\bar\Sigma} v^0) = \psi_0^\sharp \otimes_{\bar\Sigma} (y' \otimes v^0)$ ((3) of Lemma 6.2.21: the Schrödinger datum is a finite combination of operators $\rho(\mathrm{fv}(\cdot))P^{\bar\Sigma}$),

$$\mathrm{ct}_A(\xi; F_h) = c_X\, \Lambda(\psi_0^\sharp \otimes_{\bar\Sigma} (\mathrm{rsl}_{A,U}(x_\infty; y) \otimes v^0)) = 0.$$

Step 5: the zero vector. For $\xi = 0$, Step 2 gives $(\omega_{1,1}(r,1)F)[0] = F[0]$ for every q_1, so $\mathrm{ct}_A(0; F_h) = \theta_0(F_h[0])$ (probability measure), and by (2), (3),

$$\mathrm{ct}_A(0; F_h) = \mathrm{vf}(A_U)\,\theta_0\Big(\omega_{\lambda_0,\beta}(g,h)(y_0 \otimes (\psi_0^\sharp \otimes_{\bar\Sigma} v^0))\Big) = \mathrm{vf}(A_U)\,\theta_{\lambda_0,\beta}^{W,U}(y_0 \otimes [(\Psi_z^{\mathrm{st}})^{\mathsf{T}}]_{\bar\Sigma})(g,h).$$

By Steps 1, 4 and 5 the left side of the assertion is $\mathrm{vf}(A_U)\int_{[\mathrm{U}(U)]} \theta_{\lambda_0,\beta}^{W,U}(y_0 \otimes [(\Psi_z^{\mathrm{st}})^{\mathsf{T}}]_{\bar\Sigma})(g,h)\, dh = \mathrm{vf}(A_U)\,\theta_{\mathfrak{c}}^{\mathrm{sm}}(W,U; y_0, \Psi_z^{\mathrm{st}})(g)$, by (XD9). □

Lemma 6.3.12. *Let V, V_0, T be spaces with points with signs s on n, s_0 on n_0 and t on an index set n_T, let p be an index set, D a splitting of V over V_0 along p, and $m_T = (x_T^{-1})^* \otimes 1_p$ its adapted basis along T (MX7).*

1. *For every $f \in \mathcal{M}_{V,T}$ and every adelic $n_T \times p$ matrix X, the Hom slice $f[X]$ is the slice of f along D_T at the vector $m_T^{-*}X$ of $\mathbb{A}_E^{n_T\times p}$.*

2. *If n_T and p are nonempty and D is base-adapted, then $\mathrm{vf}(D_T) \neq 0$, and for every $\phi \in \mathcal{F}_{V,T}$ and $b \in \mathbb{C}^{\Phi\times(n_T\times p)}$*

$$(\phi \otimes v^0)[\mathrm{rv}(b)] = \mathrm{vf}(D_T)\,\mathrm{rsl}_{D,T}(b; \phi) \otimes v^0,$$

the left side being the Hom slice of $\phi \otimes v^0 \in \mathcal{M}_{V,T}$ at the adelic $n_T \times p$ matrix $\mathrm{rv}(b)$*, and the right side a datum of* $\mathcal{M}_{V_0,T}$*.*

Proof. Write $D = (k, l, i)$ and D_T for the induced splitting, along $n_T \times p$.

(1): the Hom slice is a slice along D_T. By (MX1) the frame l of D_T is $1 \otimes (l^* J_V)^{\mathsf{T}}$, so its adelic frame is

$$(x_T^{-1} \otimes x_V^{\mathsf{T}})(1 \otimes (l^* J_V)^{\mathsf{T}}) = x_T^{-1} \otimes (l^* J_V x_V)^{\mathsf{T}} = x_T^{-1} \otimes \mathrm{pr}_k^{\mathsf{T}},$$

since $J_V x_V = (x_V^*)^{-1} \varepsilon_s$ gives $l^* J_V x_V = l_{\mathbb{A}}^* \varepsilon_s = \mathrm{pr}_k$. For an adelic $n_T \times p$ matrix Y this sends Y to $x_T^{-1} Y \mathrm{pr}_k$. As $m_T^{-*} = x_T \otimes 1_p$ sends X to $x_T X$, the slice of $f \in \mathcal{M}_{V,T}$ along D_T at $m_T^{-*} X$ is $Z_{D_T}(\rho(X \mathrm{pr}_k) f)$, which is the Hom slice $f[X]$ of (MX4).

(2). Now $n_T \times p$ is nonempty and D is base-adapted. By Lemma 6.3.53, D_T is adapted at 1 in the basis m_T, and $\mathrm{rsl}_{D,T} = \mathrm{rsl}_{D_T, m_T}$ by (MX7). By (4) of Lemma 6.2.20 for D_T, $Z_{D_T}(v^0) = \mathrm{vf}(D_T)\, v^0$ and $\mathrm{vf}(D_T) \neq 0$. By (1), (3) of Lemma 6.2.20 for D_T, m_T, $f = v^0$ and $y = 0$, then $v_1 \otimes v^0 = v^0$ ((4) of Lemma 6.2.21) and $\rho(0) = 1$,

$$(\phi \otimes v^0)[\mathrm{rv}(b)] = \mathrm{rsl}_{D_T, m_T}(b; \phi) \otimes (v_1 \otimes v^0)[0] = \mathrm{rsl}_{D,T}(b; \phi) \otimes Z_{D_T}(v^0) = \mathrm{vf}(D_T)\, \mathrm{rsl}_{D,T}(b; \phi) \otimes v^0.$$

□

Lemma 6.3.13. *Let Σ be a nonempty finite set of finite places of E, a, b, n finite sets and $\sigma \colon b \sqcup a \to n$ a bijection. Let $\chi \colon \mathcal{O}_\Sigma^\times \to \mathbb{C}^\times$ be a character of the form $\chi(u) = \prod_{w \in \Sigma} \chi_w(u_w \bmod \varpi_w)$ with characters χ_w of $k_w^\times$, extended by 0 to $\mathcal{O}_\Sigma \setminus \mathcal{O}_\Sigma^\times$, and for $s \in \mathrm{M}_{b \times n}(\mathcal{O}_\Sigma)$ let $\Psi_s^{\mathrm{st}}(y) = \chi^{-1}(\det(sy))$ for $y \in \mathrm{M}_{n \times b}(\mathcal{O}_\Sigma)$ (χ^{-1} meaning $u \mapsto \chi(u)^{-1}$ on the units and 0 elsewhere) and $\Psi_s^{\mathrm{st}}(y) = 0$ for the other $y \in \mathrm{M}_{n \times b}(E_\Sigma)$. Let $\mathcal{P}$ be a linear space of locally constant, compactly supported functions on $\mathrm{M}_{n \times b}(E_\Sigma)$ such that $y \mapsto f(gy)$ lies in $\mathcal{P}$ for all $f \in \mathcal{P}$ and $g \in \mathrm{GL}_n(E_\Sigma)$. Let $s \in \mathrm{M}_{b \times n}(\mathcal{O}_\Sigma)$ and $x \in \mathrm{M}_{n \times b}(\mathcal{O}_\Sigma)$ with $sx = 1$, and assume $\Psi_s^{\mathrm{st}} \in \mathcal{P}$. Then $\mathcal{P}$ contains every locally constant function Ψ on $\mathrm{M}_{n \times b}(E_\Sigma)$ that is matched over $\mathcal{O}_\Sigma$ for (σ, χ) with some function Φ.*

Proof. Write $\mathcal{K} = \mathrm{GL}_n(\mathcal{O}_\Sigma)$, a compact group with Haar probability measure dk (left and right invariant), $p = \Psi_s^{\mathrm{st}}$, and $\varpi = (\varpi_w)_{w \in \Sigma}$. Let Ψ be locally constant and matched with Φ.

Step 1: two properties of Ψ. (i) Ψ vanishes off the integral matrices k_b, so it has compact support; being locally constant, it is invariant under an open subgroup of $\mathrm{M}_{n \times b}(E_\Sigma)$, hence there is $c \in \mathbb{N}$ with $\Psi(\varpi^c t + y) = \Psi(y)$ for all y and all integral t. (ii) $\Psi(Yh) = \chi(\det h)^{-1} \Psi(Y)$ for all Y and $h \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$: if $Y = k_b$ with $k \in \mathcal{K}$, let k' be k with the columns $\sigma(b)$ replaced by those of $k_b h$; then $k'_b = Yh$, $(k'^{-1})_a = (k^{-1})_a$ (the rows $\sigma(a)$ of k'^{-1} are those of k^{-1}, as k'^{-1} is k^{-1} with the rows $\sigma(b)$ multiplied by h^{-1}) and $\det k' = \det k \det h$, so $\chi(\det k)\Psi(k_b) = \Phi((k^{-1})_a) = \chi(\det k)\chi(\det h)\Psi(Yh)$; if Y is not of this form, neither is Yh, and both values vanish.

Step 2: an element expanding the kernel of s. The matrix $e = xs$ is idempotent ($sx = 1$). Put $d = \varpi^{-c}(1 - e) + e \in \mathrm{GL}_n(E_\Sigma)$, with inverse $d^{-1} = \varpi^c(1 - e) + e$. Then $dx = x$, so $p(dx) = p(x) = \chi^{-1}(\det(sx)) = 1$.

Step 3: the translates are multiples of Ψ. For $k \in \mathcal{K}$ and y,

$$\Psi(k^{-1}x)\, p(dky) = |p(dky)|\, \Psi(y). \tag{6.30}$$

If $p(dky) = 0$ both sides vanish. Otherwise $z = dky$ is integral and $h = sz \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$, with $|p(z)| = 1$ and $p(z) = \chi(\det h)^{-1}$. Now $y = k^{-1}d^{-1}z = \varpi^c k^{-1}(z - xh) + k^{-1}xh$ with $k^{-1}(z - xh)$ integral, so by Step 1, $\Psi(y) = \Psi(k^{-1}xh) = \chi(\det h)^{-1}\Psi(k^{-1}x) = p(z)\Psi(k^{-1}x)$, which is (6.30).

Step 4: averaging. The map $k \mapsto (y \mapsto p(dky))$ from $\mathcal{K}$ to functions is locally constant: p is invariant under an open subgroup U_0 and supported in a compact set Q, $p(dky) \neq 0$ forces $y \in \bigcup_k k^{-1}d^{-1}Q$, a compact set Q', and for $k'k^{-1} - 1$ in a small enough neighbourhood of 0, $d(k'-k)y = d(k'k^{-1}-1)ky \in U_0$ for all $y \in Q'$. So $k \mapsto \Psi(k^{-1}x)\,p(dk\,\cdot)$ takes finitely many values, each on an open set, and

$$F(y) = \int_{\mathcal{K}} \Psi(k^{-1}x)\,p(dky)\,dk$$

is a finite linear combination of the functions $y \mapsto p(dky)$, which lie in $\mathcal{P}$ by stability; so $F \in \mathcal{P}$. By (6.30), $F(y) = I(y)\Psi(y)$ with $I(y) = \int_{\mathcal{K}} |p(dky)|\,dk$.

Step 5: I is a positive constant on the support of Ψ. If $\Psi(y) \neq 0$, then $y = l_b$ for some $l \in \mathcal{K}$. Also $x = j_b$ for some $j \in \mathcal{K}$: at each $w \in \Sigma$, $sx = 1$ shows that the reduction of x_w modulo ϖ_w has rank $\#b$, so its columns extend to a basis of k_w^n by standard basis vectors; placing the columns of x_w in the positions $\sigma(b)$ and these vectors in the positions $\sigma(a)$ gives j_w with unit determinant. Then $y = lj^{-1}x$, and the substitution $k \mapsto kjl^{-1}$ (right invariance of dk) gives $I(y) = I(x)$. Finally $I(x) > 0$: the integrand $k \mapsto |p(dkx)|$ is locally constant (Step 4), nonnegative, and equal to 1 at $k = 1$ (Step 2), hence positive on an open neighbourhood of 1, which has positive measure.

So $F = I(x)\Psi$ with $I(x) > 0$, and $\Psi = I(x)^{-1}F \in \mathcal{P}$. □

Lemma 6.3.14. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, X a space with signs r on m, b an index set and $(\mathcal{L}, \mathcal{D})$ an equivariant lift for $(\mathfrak{c}, X, b)$; functions are functions on $\mathrm{M}_{m\times b}(E_\Sigma)$.*

1. *Let q be an index set, $U \in \mathrm{M}_{m\times q}(E_\Sigma)$ and $C \in \mathrm{M}_{q\times m}(E_\Sigma)$ with $CU = 0$, and let $\nu_0 \in \mathrm{G}(r)$ have components 1 at the infinite places and at the finite places outside $\Sigma \cup \bar{\Sigma}$, and component $1 + UC$ at Σ. For $\Psi \in \mathcal{L}$ and $x \in \mathrm{G}(r)$ the function $\Psi'(y) = \Psi\big(y + (x^{-1})_\Sigma\, UC\, x_\Sigma\, y\big)$ lies in $\mathcal{L}$, and $\mathcal{D}\Psi'(y'x) = \mathcal{D}\Psi(y'\nu_0^{-1}x)$ for all $y' \in \mathrm{G}(r)$.*

2. *Let D be a splitting of X over a space with a point along p, $T \in \mathrm{M}_p(E)$ and $x \in \mathrm{G}(r)$. For $\Psi \in \mathcal{L}$ the function $M \mapsto \mathcal{D}\Psi(z(M)x)$ is continuous and invariant under $\mathrm{M}_p(E)$, so $\mathrm{coef}(T; \mathcal{D}\Psi)(x)$ is defined. There is a linear functional Λ on the space of all functions with $\Lambda(\Psi) = \mathrm{coef}(T; \mathcal{D}\Psi)(x)$ for $\Psi \in \mathcal{L}$, and for $\Psi \in \mathcal{L}$ and $z \in \mathrm{M}_p(E_\Sigma)$ the function $\Psi_z(y) = \Psi\big(y + (x^{-1}k_{\mathbb{A}})_\Sigma\, z\, (\mathrm{pr}_l x)_\Sigma\, y\big)$ lies in $\mathcal{L}$ and*

$$\Lambda(\Psi_z) = \psi_{E,f}\big(\mathrm{tr}(T\tilde{z})\big)\,\Lambda(\Psi).$$

3. *If $\Psi \in \mathcal{L}$, $\mathcal{D}\Psi = 0$ and $g \in \mathrm{GL}_m(E_\Sigma)$, then $\Phi(y) = \Psi(gy)$ lies in $\mathcal{L}$ and $\mathcal{D}\Phi = 0$.*

Proof. **Step 0: two facts on $\mathrm{G}(r)$.** (a) An element of $\mathrm{G}(r)$ of the form $x_X^{-1}\gamma x_X$ with $\gamma \in \mathrm{GL}_m(E)$ lies in Γ_X: from $x_X^* J_X x_X = \varepsilon_r$ we get $x_X^{-*}\varepsilon_r x_X^{-1} = J_X$, so $(x_X^{-1}\gamma x_X)^*\varepsilon_r(x_X^{-1}\gamma x_X) = \varepsilon_r$ says $\gamma^* J_X \gamma = J_X$, i.e. $\gamma \in \mathrm{U}(X)(F)$. (b) If $g \in \mathrm{G}(r)$ has components 1 at the infinite places, then $g = (1, g_f)$ with $g_f \in G_f(m)$.

Step 1: (1). Let $\Psi \in \mathcal{L}$ and $x \in \mathrm{G}(r)$, and put $g = x^{-1}\nu_0 x \in \mathrm{G}(r)$. Its components at the infinite places and at the finite places outside $\Sigma \cup \bar{\Sigma}$ are 1, so by Step 0 (b) $g = (1, g_f)$ with $g_f \in G_f(m)$ of component 1 at every finite w with $w \notin \Sigma$, $\bar{w} \notin \Sigma$, and

$$(g_f)_\Sigma = (x^{-1})_\Sigma(1+UC)x_\Sigma = 1+(x^{-1})_\Sigma\, UC\, x_\Sigma, \qquad \det(g_f)_\Sigma = \det(1+UC) = \det(1+CU) = 1.$$

So $\Psi'(y) = \Psi((g_f)_\Sigma y)$, and (c) of (XD11) gives $\Psi' \in \mathcal{L}$ and $\mathcal{D}\Psi'(y''g) = \upsilon_{\Sigma,1}(1)^{-\#b}\mathcal{D}\Psi(y'') = \mathcal{D}\Psi(y'')$ for all y''. With $y'' = y'\nu_0^{-1}x$ we have $y''g = y'x$, which is the claim.

Step 2: the coefficient is defined and linear. By (MX2), $z(M) = 1 + k_{\mathbb{A}}(M - M^*)\mathrm{pr}_l$ with $\mathrm{pr}_l k_{\mathbb{A}} = 0$ ((MX1): pr_l reads the coordinate along $l_{\mathbb{A}}$), hence $z(M)z(M') = z(M + M')$, and $M \mapsto z(M)$ is continuous. For $M \in \mathrm{M}_p(E)$, $k_{\mathbb{A}} = x_X^{-1}k$ and $\mathrm{pr}_l = k_{\mathbb{A}}^*\varepsilon_r = k^*J_X x_X$ give $z(M) = x_X^{-1}(1 + k(M - M^*)k^*J_X)x_X$ with a rational matrix in the middle, so $z(M) \in \Gamma_X$ by Step 0 (a). By (b) of (XD11), $\mathcal{D}\Psi$ is continuous and left Γ_X-invariant, so $M \mapsto \mathcal{D}\Psi(z(M)x)$ is continuous and $\mathcal{D}\Psi(z(M + M_0)x) = \mathcal{D}\Psi(z(M_0)z(M)x) = \mathcal{D}\Psi(z(M)x)$ for $M_0 \in \mathrm{M}_p(E)$; it is therefore a continuous function on the compact group $\mathrm{M}_p(\mathbb{A}_E)/\mathrm{M}_p(E)$, and $\mathrm{coef}(T; \mathcal{D}\Psi)(x)$ is an absolutely convergent integral. Since $\mathcal{D}$ is linear, $\Psi \mapsto \mathrm{coef}(T; \mathcal{D}\Psi)(x)$ is a linear functional on the subspace $\mathcal{L}$; extend it (choose a complement of $\mathcal{L}$) to a linear functional Λ on all functions.

Step 3: the shear law of (2). Let $\Psi \in \mathcal{L}$, $z \in \mathrm{M}_p(E_\Sigma)$ and $M' = \tilde{z}$. Since $\tilde{z}$ is supported on Σ and $\tilde{z}^*$ on $\bar{\Sigma}$, and $\Sigma \cap \bar{\Sigma} = \emptyset$, the element $\nu_0 = z(M') \in \mathrm{G}(r)$ has components 1 at the infinite places and outside $\Sigma \cup \bar{\Sigma}$, and component $1 + (k_{\mathbb{A}})_\Sigma z(\mathrm{pr}_l)_\Sigma$ at Σ. Apply (1) with $U = (k_{\mathbb{A}})_\Sigma$, $C = z(\mathrm{pr}_l)_\Sigma$ (so $CU = z(\mathrm{pr}_l k_{\mathbb{A}})_\Sigma = 0$): the function $\Psi'(y) = \Psi(y + (x^{-1}k_{\mathbb{A}})_\Sigma z(\mathrm{pr}_l x)_\Sigma y) = \Psi_z(y)$ lies in $\mathcal{L}$ and $\mathcal{D}\Psi_z(y'x) = \mathcal{D}\Psi(y'z(M')^{-1}x)$. Taking $y' = z(M)$ and substituting $M \mapsto M + M'$ in the invariant measure,

$$\begin{aligned}\Lambda(\Psi_z) &= \int \psi_E(\mathrm{tr}(TM))\,\mathcal{D}\Psi\big(z(M - M')x\big)\,dM \\ &= \psi_E\big(\mathrm{tr}(TM')\big)\int \psi_E(\mathrm{tr}(TM))\,\mathcal{D}\Psi(z(M)x)\,dM = \psi_{E,f}\big(\mathrm{tr}(T\tilde{z})\big)\Lambda(\Psi),\end{aligned}$$

using $z(M)z(M')^{-1} = z(M - M')$, that ψ_E is a character, and that $\mathrm{tr}(T\tilde{z})$ is a finite adele, on which $\psi_E = \psi_{E,f}$.

Step 4: (3). Let $k \in \mathrm{GL}_m(\mathbb{A}_{E,f})$ have component g_w at $w \in \Sigma$, component $(\overline{g_w}^{\mathsf{T}})^{-1}$ at $\bar{w}$ (the conjugation identifying E_w with $E_{\bar{w}}$), and 1 elsewhere; this is well defined as $\Sigma \cap \bar{\Sigma} = \emptyset$. Since $(k^*)_u = \overline{k_{\bar{u}}}^{\mathsf{T}}$, we get $(k^*k)_w = g_w^{-1}g_w = 1$ and $(k^*k)_{\bar{w}} = \overline{g_w^{\mathsf{T}}(g_w^{\mathsf{T}})^{-1}} = 1$, so $k \in G_f(m)$, k has component 1 at the finite w' with $w' \notin \Sigma$, $\bar{w}' \notin \Sigma$, and $k_\Sigma = g$. By (c) of (XD11), $\Phi(y) = \Psi(gy)$ lies in $\mathcal{L}$ and $\mathcal{D}\Phi(y'(1,k)) = \upsilon_{\Sigma,1}(\det g)^{-\#b}\mathcal{D}\Psi(y') = 0$ for all y'; as $y' \mapsto y'(1,k)$ is onto, $\mathcal{D}\Phi = 0$. □

Lemma 6.3.15. *Let W be a space and $k \geq 1$ an integer with $\mathrm{rk}\,W = 2k + 2\,\mathrm{neg}(W)$, and let $\mu\colon \Phi \to \mathbb{Z}$ with $k \leq \mu(v)$ for every $v \in \Phi$. There are a Schwartz vector z for $(\mathbb{H} \oplus W, \mathbb{H} \oplus W)$ and a real number $C \neq 0$ such that*

$$r_{\mathbb{H}\oplus W}(\nu, z) = \frac{|I_{\mathbb{H}\oplus W}(z)(1)|^2}{L_*(\mathfrak{m}, \nu; \frac{1}{2}\,\mathrm{rk}\,W + 1)} = C$$

for every modulus $\mathfrak{m}$, every χ and every ν tame of weight μ for $(\mathfrak{m}, \chi)$.

Proof. **Step 1: for definite J the square of the ratio does not depend on ν.** Let J be a space of rank $2k$ with all signs $+1$, and v a Schwartz vector for $(\mathbb{H} \oplus J, \mathbb{H} \oplus J)$. We show that $r_{\mathbb{H}\oplus J}(\nu, v)^2$ is one number D for all ν.

Apply Lemma 6.3.3 to $(W, U, V) = (J, 0, J)$, with $z = v$ and y the vacuum vector of the one-dimensional Fock space of $\mathrm{Hom}(0, J)$; here $\mathrm{rk}\,V - \frac{1}{2}\,\mathrm{rk}\,W = k$. The pair $(\Phi_\chi, 1)$, with 1 the function on the single $2k \times 0$ matrix, is matched: Φ_χ vanishes off the invertible integral matrices and $\Phi_\chi(\kappa^{-1}) = \chi(\det\kappa)$. On the zero space the theta model is $\mathbb{C}$ with $v^0 = 1$ (the rank-0 case of (WD5)–(WD9) of Definition 3.2.12), its canonical theta functional is the identity of $\mathbb{C}$ ((WC1), and (WC3) with $k_V = 1$, of Definition 4.1.15), and $\omega_{1,1}(g, h)$ is ω of the only element of the trivial group of the empty sign vector, the identity ((WR4) of Definition 3.2.18); so the theta kernel of the characters $(1, 1)$ on the zero space is the value of the datum at 0. This gives $B \in \mathbb{R}$,

a Schwartz vector y' for (J,J) and for each ν a number c_1 with $B|c_1|^2 = L_*(k)\, r_{\mathbb{H}\oplus J}(\nu,v)$ and, writing $\theta = \theta^{J,J}_{\gamma,\gamma}(y'\otimes\Phi_\chi\otimes\Phi^\circ)$,

$$\int_{[\mathrm{U}(J)]} \theta(g,h)\,dh = c_1 \operatorname{vol}_0 \qquad (g\in \mathrm{U}(J)(\mathbb{A}_F)). \tag{a}$$

Here the lemma gives the identity with the characters $(\gamma,1)$ on the pair (J,J) and (γ,γ) on the pair $(0,J)$. By (WR4) of Definition 3.2.18, $\omega_{\alpha,\beta}(g,h) = \alpha(\det h)\beta(\det g)^{-1}\omega_{1,1}(g,h)$ and the theta functional is linear, so $\theta^{J,J}_{\gamma,\gamma}(\varphi)(g,h) = \gamma(\det g)^{-1}\theta^{J,J}_{\gamma,1}(\varphi)(g,h)$, while on the pair $(0,J)$ the kernel of the characters (γ,γ) at (h,g) is $\gamma(\det g)$ times the kernel of $(1,1)$, $\det h = 1$ on $\mathrm{U}(0)$; the latter kernel is the value of the datum at 0. Multiplying the identity of the lemma by $\gamma(\det g)^{-1}$ gives (a).

Apply Lemma 6.3.3 to $(W,U,V) = (J,J,0)$, with $z=v$ and $y=y'$; here $\operatorname{rk} V - \frac{1}{2}\operatorname{rk} W = -k$, and the pair $(1,\Phi_\chi)$ is matched. The Fock space of $\mathrm{Hom}(J,0)$ is one-dimensional, so the theta integral of $(J,0)$ at the vector x that the lemma provides is $\operatorname{vol}_0\xi$ for a number ξ that depends neither on ν nor on g. So there are $C_2\in\mathbb{R}$, $\xi\in\mathbb{C}$ and for each ν a number c_2 with $C_2|c_2|^2 = L_*(-k)\, r_{\mathbb{H}\oplus J}(\nu,v)$ and

$$\operatorname{vol}_0\xi = c_2 \int_{[\mathrm{U}(J)]} \theta(h,g)\,dh \qquad (g\in \mathrm{U}(J)(\mathbb{A}_F)). \tag{b}$$

Integrate (b) over $g\in[\mathrm{U}(J)]$. Since J is definite, $[\mathrm{U}(J)]$ is compact and the kernel is integrable on the product, so by Fubini and (a),

$$\operatorname{vol}_J \operatorname{vol}_0\xi = c_2 \int_{[\mathrm{U}(J)]}\int_{[\mathrm{U}(J)]} \theta(h,g)\,dg\,dh = c_2\, c_1 \operatorname{vol}_0 \operatorname{vol}_J,$$

so $\xi = c_1c_2$. As $L_*(k)L_*(-k)=1$,

$$r_{\mathbb{H}\oplus J}(\nu,v)^2 = \big(L_*(k)\,r\big)\big(L_*(-k)\,r\big) = B\,C_2\,|c_1c_2|^2 = B\,C_2\,|\xi|^2 =: D.$$

Step 2: the first floor. Let J be the standard definite space of rank $2k$. If no tame ν of weight μ exists, any z and $C=1$ serve. Otherwise fix one, ν_0; by Lemma 6.3.16 there is a Schwartz v with $C := r_{\mathbb{H}\oplus J}(\nu_0,v)\neq 0$. By Step 1, $r_{\mathbb{H}\oplus J}(\nu,v)^2 = r_{\mathbb{H}\oplus J}(\nu_0,v)^2$, and both ratios are ≥ 0 by (XD8); so $r_{\mathbb{H}\oplus J}(\nu,v) = C$ for every ν.

Step 3: climbing in the number of negative signs. Induction on $q=\mathrm{neg}(W)$. If $q=0$, then W and J have the same signs, so $\mathbb{H}\oplus W$ has the signs of $\mathbb{H}\oplus J$ (and Fock vectors depend only on the signs). By Lemma 6.3.66(3) there is a space Y with these signs and an adapted decomposition $Y = J\oplus\mathbb{H}$, and Lemma 6.3.66(2), applied to $Y_1 = \mathbb{H}\oplus J$ and to $Y_1 = \mathbb{H}\oplus W$, gives $r_{\mathbb{H}\oplus W}(\nu,v) = r_Y(\nu,v) = r_{\mathbb{H}\oplus J}(\nu,v) = C$ with the v of Step 2. If $q\geq 1$, let $W_0 = \mathbb{H}^{q-1}\oplus J$, so that $\operatorname{rk} W_0 = 2k+2(q-1)$ and $\mathrm{neg}(W_0) = q-1$; the induction hypothesis gives v_0 and $C_0\neq 0$ for $\mathbb{H}\oplus W_0$. By Lemma 6.3.66(3) there is a space Y with the signs of $\mathbb{H}\oplus W$ and an adapted decomposition $Y = (\mathbb{H}\oplus W_0)\oplus\mathbb{H}$ (ranks $2k+2q+2$ on both sides, negative signs $q+1$). By Lemma 6.3.66(1) there are v' and $C'>0$ with $r_Y(\nu,v') = C'\, r_{\mathbb{H}\oplus W_0}(\nu,v_0) = C'C_0$, and by Lemma 6.3.66(2), $r_{\mathbb{H}\oplus W}(\nu,v') = r_Y(\nu,v')$. Take $z=v'$ and $C = C'C_0\neq 0$. □

Lemma 6.3.16. *Let $k\geq 1$, let J be the standard definite space of rank $2k$, and let $\mu\colon\Phi\to\mathbb{Z}$ with $k\leq\mu(v)$ for every $v\in\Phi$. For every ν tame of weight μ for some $(\mathfrak{m},\chi)$ there is a Schwartz vector v for $(\mathbb{H}\oplus J,\mathbb{H}\oplus J)$ with $r_{\mathbb{H}\oplus J}(\nu,v)\neq 0$.*

Proof. Let m be the index set of J ($\#m=2k$), $Y=\mathbb{H}\oplus J$ with index set $n_Y = (\{o\}\sqcup\{o\})\sqcup m$, and let ν be tame of weight μ for $(\mathfrak{m},\chi)$, $\Sigma=\Sigma(\mathfrak{m})$. Since $\mu\geq k\geq 1$, $\mathfrak{c}=(\nu,\Sigma)$ is a split

tame character of weight μ (XD4). Its semilocal character is χ on $\mathcal{O}_\Sigma^\times$: for a unit t of $\mathcal{O}_\Sigma$, read as a finite idele, $t/\bar{t} \in \mathrm{U}(1)(\mathbb{A})$ has components t_w at $w \in \Sigma$, $\bar{t}_w^{-1}$ at $\bar{w} \notin \Sigma$ and 1 elsewhere, so $\nu(t/\bar{t}) = \prod_{w\in\Sigma} \psi_w(t_w \bmod w) = \chi(t)$. Hence the function Φ_χ of (XD8) is Ψ_1^{st} for $\chi_{\mathfrak{c}}$, read through the components at Σ, and $I_Y(z) = \theta_{\mathfrak{c}}^{\mathrm{lg}}(Y, Y; z, \Psi_1^{\mathrm{st}})$ for every Schwartz z (both are $I_{\gamma,\gamma}^{Y,Y}$ of the same datum, $\gamma = \nu^{-1}\upsilon^{k+1}$). Moreover $L_*(\Sigma, \nu; k+1) > 0$: it is a product of powers of norms and of $|L^\Sigma(j, \tilde{\nu})|^2$, $1 \le j \le k+1$, and $L^\Sigma(j, \tilde{\nu}) \neq 0$ for $j \ge 1$ by (3) of Theorem A.1.12, $\tilde{\nu}$ being ramified at the places of Σ (it is ψ_w on the units at $w \in \Sigma$, by the computation above) and the removed Euler factors being finite and non-zero for $\mathrm{Re}\, s \ge 1$.

Suppose, for a contradiction, that $r_Y(\nu, z) = 0$ for every Schwartz z, i.e. $\theta_{\mathfrak{c}}^{\mathrm{lg}}(Y, Y; z, \Psi_1^{\mathrm{st}})(1) = 0$.

Step 1: tautological splittings. For an index set p and a space V_0, the tautological splitting of $\mathbb{H}_p \oplus V_0$ over V_0 is base-adapted: its matrix of adelic frames is $\mathrm{diag}(x_{\mathbb{H}_p}^{-1}, 1)$, where $x_{\mathbb{H}_p}$ is unitary at the infinite places and, at the finite places, integral with determinant $(c\bar{c}_0 + cc_0)^{\#p} = c^{\#p}$, a unit ($c_0 + \bar{c}_0 = 1$). Let R_1 be the tautological splitting of Y over J along $\{o\}$ and R_m that of $X = \mathbb{H}_m \oplus Y$ over Y along m.

Step 2: the equal-rank side vanishes everywhere. By Proposition 6.3.17 ($\#n_Y$ even, R_1 base-adapted), $g \mapsto \theta_{\mathfrak{c}}^{\mathrm{lg}}(Y, Y; z, \Psi_1^{\mathrm{st}})(g)$ is constant, hence 0, for every Schwartz z.

Step 3: vanishing at the top. Let $V_X = J^- \oplus Y$ and $\sigma\colon m \sqcup (m \sqcup n_Y) \to (m \sqcup m) \sqcup n_Y$ the associativity bijection. Let $w \in \mathcal{F}_{X,V_X}$ be a Schwartz vector and v_1 the real vacuum of $\mathcal{F}_{X,J^-}$, a Schwartz vector. We apply Proposition 6.3.22 to X, $W_1 = Y$, $W = J$, $V' = J^-$, $D = R_m$, $D_1 = R_1$, σ, μ, $\phi_{\mathrm{lg}} = w$, $\phi_{\mathrm{sm}} = v_1$ and $\mathrm{pw} \equiv 1$. Condition (S) holds in its second form: the signs of J^- are all -1, Y has a sign $+1$, and $2\,\mathrm{neg}(Y) = 2 \le 2k+2 = \#n_Y$. Condition (P) holds for $(\mathfrak{c}, 0)$ with $(p_1, p_2) = (1, 1)$: the right side is 0, and the left side is 0 by Lemma 6.3.50 (for $W = Y$, $V = J^-$, with Step 2 as its hypothesis), applied to $w_{\hat{h}}(B)$, which is a Schwartz vector. Indeed its real slice factor is Schwartz by (1) of Lemma 6.2.43 and Lemma 6.3.53, and Ω preserves Schwartz vectors: by (WR5), $\omega_\varepsilon^\infty(u)c = \overline{\det u_-} \int c(t)\, \rho^\infty(ut) v_1\, d\nu(t)$, and $\mathrm{mom}_N(\rho^\infty(t)c') \le (1 + \|t\|)^N \mathrm{mom}_N(c')$, so $\mathrm{mom}_N(\omega_\varepsilon^\infty(u)c) \le |\det u_-|\, \mathrm{mom}_N(v_1)(1 + \|u\|)^N \mathrm{mom}_N(c)$, $\|u\|$ the operator norm for the maximum norm. So Proposition 6.3.22 gives c with $|c| = K \cdot 0 = 0$, and therefore $\theta_{\mathfrak{c}}^{\mathrm{lg}}(X, V_X; w, \Phi_{\sigma,z}^{\mathrm{st}}) = 0$ for every Schwartz w and every $z \in \mathrm{M}_{m\times((m\sqcup m)\sqcup n_Y)}(\mathcal{O}_\Sigma)$.

Step 4: descent to $(J, 0)$. Let V_0 be the zero space and $\sigma_0\colon m \sqcup \varnothing \to m$ the identity. Apply Lemma 6.3.54 with $W' = X$, $V' = V_X$, $W = J$, $V = V_0$, $b = m$, $\sigma' = \sigma$, σ_0, $j = 2k+1$ and the given k: the index set of X has $6k+2 = 2k+2j$ elements, $\mathrm{neg}(X) = 2k+1 = j + \mathrm{neg}(J)$, $\mathrm{neg}(V_X) = 2k+1 = j + \mathrm{neg}(V_0)$, $\#m = 2k$ is even, $-k \le 0 - k$ and $k \le \mu$. By Step 3 it gives $\theta_{\mathfrak{c}}^{\mathrm{lg}}(J, V_0; v, \Phi_{\sigma_0,y}^{\mathrm{st}}) = 0$ for every Schwartz $v \in \mathcal{F}_{J,V_0}$ and every integral y.

Step 5: rank 0. $\mathrm{Hom}(J, V_0)$ has the empty index set: its Fock model is $\mathbb{C}$ (functions on a point, ν the unit mass), its theta model is $\mathbb{C}$ with $v^0 = 1$, $\rho(0) = 1$ and Weil operators the identity, and its canonical theta functional is the identity; $\mathrm{U}(V_0)$ is the trivial group and $[\mathrm{U}(V_0)]$ is a point of mass 1. For $y = 1_m$, $\Phi_{\sigma_0,1}^{\mathrm{st}}$ is the function on the single (empty) matrix with value $\chi_{\mathfrak{c}}^{-1}(\det 1_m) = 1$; so $(\Phi_{\sigma_0,1}^{\mathrm{st}})^\sharp = 1 = \tau_0$ in $\mathcal{T}_\Sigma$ ((WR6), $y = 0$ being the only finite adelic vector of rank 0), $(\Phi_{\sigma_0,1}^{\mathrm{st}})^\sharp \otimes_\Sigma v^0 = v^0 = 1$ and $1 \otimes 1 = 1$. Hence $\theta_{\mathfrak{c}}^{\mathrm{lg}}(J, V_0; 1, \Phi_{\sigma_0,1}^{\mathrm{st}})(1) = 1$, contradicting Step 4 for the Schwartz vector $v = 1$. So some Schwartz z has $r_Y(\nu, z) \neq 0$. □

Proposition 6.3.17. *Let W_1 be a space with signs s on n, $\#n$ even, with a base-adapted splitting over a space W along a one-element set. Let $\mathfrak{c}$ be a split tame character and v a Schwartz vector for (W_1, W_1). Then the function $g \mapsto \theta_{\mathfrak{c}}^{\mathrm{lg}}(W_1, W_1; v, \Psi_1^{\mathrm{st}})(g)$ on $\mathrm{G}(s)$, 1 the identity $n \times n$ matrix, is constant.*

Proof. Write $\mathfrak{c} = (\nu, \Sigma)$, $\chi = \chi_{\mathfrak{c}}$, $D_1 = (k, l, i)$ for the splitting and a for the index set of W,

so $\#a = \#n - 2$ is even. Let $\varnothing$ be the empty index set, V_0 the zero space (index set $\varnothing$) and $\sigma\colon \varnothing \sqcup n \to n$ the identity. For the empty matrix $0 \in \mathrm{M}_{\varnothing\times n}(E_\Sigma)$ the standard row datum $\Phi^{\mathrm{st}}_{\sigma,0}$ is the function $x \mapsto \chi^{-1}(\det x)$ on integral $n\times n$ matrices over E_Σ and 0 elsewhere, which is Ψ^{st}_1. Put

$$F = \theta^{\mathrm{lg}}_{\mathfrak{c}}(W_1, W_1; v, \Psi^{\mathrm{st}}_1) = \theta^{\mathrm{lg}}_{\mathfrak{c}}(W_1, W_1; v, \Phi^{\mathrm{st}}_{\sigma,0}),$$

a function on $\mathrm{G}(s)$. We verify the hypotheses of Lemma 6.2.49 for F, the splitting $H = D_1$ and $S = \Sigma$.

Step 1: F is an equivariant lift. Apply Lemma 6.3.18 to $\mathfrak{c}$, the spaces W_1, $V = W_1$ (index set n) and $V' = V_0$ (index set $\varnothing$), the bijection σ, the Schwartz vector v, the real vacuum v_1 of $\mathcal{F}_{W_1,V_0}$ (the Fock vector of the polynomial 1, a Schwartz vector by (XD3)) and $c = 0$. It gives an equivariant lift $(\mathcal{L}, \mathcal{D})$ for $(\mathfrak{c}, W_1, \varnothing)$. Let Ψ_0 be the function with value 1 on the single matrix of $\mathrm{M}_{n\times\varnothing}(E_\Sigma)$. The pair $(\Phi^{\mathrm{st}}_{\sigma,0}, \Psi_0)$ is matched over $\mathcal{O}_\Sigma$ for (σ, χ): $\Phi^{\mathrm{st}}_{\sigma,0}(x) \neq 0$ forces x integral with $\det x \in \mathcal{O}_\Sigma^\times$, i.e. $x = (k^{-1})_n$ for $k = x^{-1} \in \mathrm{GL}_n(\mathcal{O}_\Sigma)$; Ψ_0 vanishes nowhere and every $k_\varnothing$ is the single matrix; and $\Phi^{\mathrm{st}}_{\sigma,0}(k^{-1}) = \chi(\det k^{-1})^{-1} = \chi(\det k) = \chi(\det k)\Psi_0(k_\varnothing)$. So $\Psi_0 \in \mathcal{L}$ and $\mathcal{D}\Psi_0 = F$.

Step 2: hypotheses (1) and (2). By (XD11)(b), F is continuous and left Γ_{W_1}-invariant. Let $g \in G_f(n)$ have component 1 at every finite place w with $w \notin \Sigma$ and $\bar w \notin \Sigma$. By (XD11)(c) the function $\Phi(y) = \Psi_0(g_\Sigma y)$, which is Ψ_0 (there is one matrix), lies in $\mathcal{L}$ and $F(x(1,g)) = \mathcal{D}\Phi(x(1,g)) = \upsilon_{\Sigma,1}(\det g_\Sigma)^{-\#\varnothing}\mathcal{D}\Psi_0(x) = F(x)$. This is (2) of Lemma 6.2.49 for $S = \Sigma$, which is nonempty ((XD4)).

Step 3: hypothesis (3). Apply Proposition 6.2.2 to $W' = V' = W_1$, $W = V = W$, the splittings $A = X = D_1$, the index set $\varnothing$ with the identities $\sigma_0\colon \varnothing \sqcup a \to a$ and $\sigma\colon \varnothing \sqcup n \to n$, and the weight μ of $\mathfrak{c}$: $\#a$ is even and $e = \#a - \#a/2 = \#a/2 \geq 0$, so $z_e = \#a/2 + 1$, the sign is $+$, and $\#r = \#a$ equals the rank of W, so the identity holds at every Levi point. It gives γ with

$$\mathrm{CT}^{\mathrm{pl}}_{D_1,\sigma}(v,0)(u,g) = \gamma\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W, W; \mathrm{Cone}^{+}_{D_1,D_1,\mu}(z_e; v), \Phi^{\mathrm{st}}_{\sigma_0,0})(g) \qquad (u \in \mathbb{A}_E^\times,\ g \in \mathrm{U}(W)(\mathbb{A}_F)),$$

0 the empty matrix in $\mathrm{M}_{\varnothing\times a}(\mathcal{O}_\Sigma)$. The right side does not depend on u. The plane datum at 0 is formed with $\Phi^{\mathrm{st}}_{\sigma,0(\mathrm{pr}_i)_\Sigma} = \Phi^{\mathrm{st}}_{\sigma,0}$ (the matrix $0(\mathrm{pr}_i)_\Sigma$ is empty), so by (XD10)

$$\mathrm{CT}^{\mathrm{pl}}_{D_1,\sigma}(v,0)(u,g) = \int F\big(\mathrm{rad}^{\mathrm{ln}}_{D_1}(q_1,q_2)\,\mathrm{lev}_{D_1}(u,g)\big)\,dq,$$

the integral over the compact quotient with its probability measure. Now assume $F(\mathrm{rad}_{D_1}(c,b)g') = F(g')$ for all adelic c, b and all g'. As $\mathrm{rad}^{\mathrm{ln}}_{D_1}(q_1,q_2) = \mathrm{rad}_{D_1}(x_W^{-1}q_1, 2q_2)$ ((MX10)), the integrand is constant and

$$\mathrm{CT}^{\mathrm{pl}}_{D_1,\sigma}(v,0)(u,g) = F(\mathrm{lev}_{D_1}(u,g)).$$

Hence for $t \in \mathbb{A}_E^\times$,

$$F(\mathrm{lev}_{D_1}(t,1)) = \mathrm{CT}^{\mathrm{pl}}_{D_1,\sigma}(v,0)(t,1) = \mathrm{CT}^{\mathrm{pl}}_{D_1,\sigma}(v,0)(1,1) = F(\mathrm{lev}_{D_1}(1,1)) = F(1),$$

because $\mathrm{lev}_{D_1}(1,1) = k_{\mathbb{A}}\mathrm{pr}_k + i_{\mathbb{A}}\mathrm{pr}_i + l_{\mathbb{A}}\mathrm{pr}_l = 1$ ((MX1), (MX2)). This is (3) of Lemma 6.2.49.

Step 4. By Lemma 6.2.49, F is constant on $\mathrm{G}(s)$. □

Lemma 6.3.18. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character with semilocal character $\chi_{\mathfrak{c}}$, let W, V, V' be spaces with signs s on n and index sets a, b, $\sigma\colon b \sqcup a \to n$ a bijection, $\#n$ even, v, v' Schwartz vectors for (W,V), (W,V'), and $c \in \mathbb{C}$. There is an equivariant lift $(\mathcal{L},\mathcal{D})$ for $(\mathfrak{c}, W, b)$ with the following property: whenever Φ is a function on $\mathrm{M}_{a\times n}(E_\Sigma)$ and Ψ a locally constant*

function on $\mathrm{M}_{n\times b}(E_\Sigma)$ *that are matched over* $\mathcal{O}_\Sigma$ *for* $(\sigma,\chi_{\mathfrak{c}})$ *(*Φ *vanishes off the matrices* $(k^{-1})_a$*,* Ψ *off the* k_b*,* $k\in\mathrm{GL}_n(\mathcal{O}_\Sigma)$*, and* $\Phi((k^{-1})_a)=\chi_{\mathfrak{c}}(\det k)\Psi(k_b)$*), then* $\Psi\in\mathcal{L}$ *and*

$$\mathcal{D}\Psi=\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;v,\Phi)-c\,\theta^{\mathrm{sm}}_{\mathfrak{c}}(W,V';v',\Psi).$$

Proof. Write θ^{lg}, θ^{sm} as in Lemma 6.3.20, and let $\mathcal{B}_a$, $\mathcal{B}_b$ be the spaces of locally constant, compactly supported functions on $\mathrm{M}_{a\times n}(E_\Sigma)$ vanishing off the right invertible matrices, resp. on $\mathrm{M}_{n\times b}(E_\Sigma)$ vanishing off the left invertible ones. By Lemma 6.3.20, θ^{lg} and θ^{sm} are defined on $\mathcal{B}_a$, $\mathcal{B}_b$, linear (they are theta integrals of data depending linearly on the function, (2) of Lemma 6.3.21), and their values are continuous left Γ_W-invariant functions on $\mathrm{G}(s)$.

The space $\mathcal{L}$ *and the map* T*.* Let $\chi=\tilde\nu_{\Sigma,\#n}$, a locally constant homomorphism $E_\Sigma^\times\to\mathbb{C}^\times$ ($\tilde\nu$ is continuous on the totally disconnected group $E_\Sigma^\times$, and so is $|\cdot|$). Apply Lemma 6.3.19 to Σ, χ, a,b,n, σ; it gives a $\mathrm{GL}_n(E_\Sigma)$-stable subspace $\mathcal{Q}\subseteq\mathcal{B}_a\times\mathcal{B}_b$; let $\mathcal{L}$ be the space of second members. By (1) of Lemma 6.3.20, $\Lambda=\theta^{\mathrm{lg}}\colon\mathcal{B}_a\to\{\text{functions on }\mathrm{G}(s)\}$ satisfies $\chi(\det h)\Lambda(\Phi(h\,\cdot))=\Lambda(\Phi)$ for $h\in\mathrm{GL}_a(E_\Sigma)$, so (2) of Lemma 6.3.19 gives a linear $T\colon\mathcal{L}\to\{\text{functions on }\mathrm{G}(s)\}$ with $T\Psi=\theta^{\mathrm{lg}}(\Phi)$ for $(\Phi,\Psi)\in\mathcal{Q}$. Put $\mathcal{D}_0=T-c\,\theta^{\mathrm{sm}}$ on $\mathcal{L}\subseteq\mathcal{B}_b$, and let $\mathcal{D}$ be any linear extension of $\mathcal{D}_0$ to all functions on $\mathrm{M}_{n\times b}(E_\Sigma)$ (extend by 0 on a complement of $\mathcal{L}$).

The four conditions of (XD11). (a) $\mathcal{L}\subseteq\mathcal{B}_b$. (b) For $\Psi\in\mathcal{L}$, $\mathcal{D}\Psi=\theta^{\mathrm{lg}}(\Phi)-c\,\theta^{\mathrm{sm}}(\Psi)$ for some Φ with $(\Phi,\Psi)\in\mathcal{Q}$, continuous and left Γ_W-invariant. (c) Let $g\in G_f(n)$ have components 1 off $\Sigma\cup\bar\Sigma$, $t=\det g_\Sigma$, and $(\Phi,\Psi)\in\mathcal{Q}$. By stability, $g_\Sigma^{-1}\cdot(\Phi,\Psi)=\big(\chi(t)^{-1}\Phi(\cdot\,g_\Sigma^{-1}),\Psi(g_\Sigma\,\cdot)\big)\in\mathcal{Q}$, so $\Psi(g_\Sigma\,\cdot)\in\mathcal{L}$, and by (2) of Lemma 6.3.20

$$\begin{aligned}T\big(\Psi(g_\Sigma\,\cdot)\big)(x(1,g))&=\chi(t)^{-1}\tilde\nu_{\Sigma,\#a}(t)\upsilon(t)^{\#a-\#n}\,T\Psi(x)\\&=\upsilon(t)^{-\#b}|t|^{-\#b/2}\,T\Psi(x)=\upsilon_{\Sigma,1}(t)^{-\#b}\,T\Psi(x),\end{aligned}$$

using $\#n-\#a=\#b$; the small side obeys the same law by (2) of Lemma 6.3.20, hence so does $\mathcal{D}$. (d) is (3) of Lemma 6.3.20.

Matched functions. Let (Φ,Ψ) be matched over $\mathcal{O}_\Sigma$ for $(\sigma,\chi_{\mathfrak{c}})$, Ψ locally constant. For $k\in\mathrm{GL}_n(\mathcal{O}_\Sigma)$, $\det k$ is a unit, so $\chi(\det k)=\tilde\nu(\det k)=\chi_{\mathfrak{c}}(\det k)$; thus (Φ,Ψ) is matched for (σ,χ) in the sense of (1) of Lemma 6.3.19, which gives $(\Phi,\Psi)\in\mathcal{Q}$. So $\Psi\in\mathcal{L}$ and $\mathcal{D}\Psi=T\Psi-c\,\theta^{\mathrm{sm}}(\Psi)=\theta^{\mathrm{lg}}(\Phi)-c\,\theta^{\mathrm{sm}}(\Psi)$. □

Lemma 6.3.19. *Let* Σ *be a finite set of finite places of* E*,* $E_\Sigma=\prod_{w\in\Sigma}E_w$ *and* $\mathcal{O}_\Sigma=\prod_{w\in\Sigma}\mathcal{O}_{E,w}$*, and let* $\chi\colon E_\Sigma^\times\to\mathbb{C}^\times$ *be a locally constant homomorphism. Let* a*,* b*,* n *be finite sets and* $\sigma\colon b\sqcup a\to n$ *a bijection. For* $k\in\mathrm{GL}_n(E_\Sigma)$ *let* k_b *be the* $n\times b$ *matrix formed by the columns* $\sigma(b)$ *of* k*, and* $(k^{-1})_a$ *the* $a\times n$ *matrix formed by the rows* $\sigma(a)$ *of* k^{-1}*. Let* $\mathcal{B}_a$ *be the space of locally constant, compactly supported functions on* $\mathrm{M}_{a\times n}(E_\Sigma)$ *that vanish at every matrix without a right inverse, and* $\mathcal{B}_b$ *the space of locally constant, compactly supported functions on* $\mathrm{M}_{n\times b}(E_\Sigma)$ *that vanish at every matrix without a left inverse. The group* $\mathrm{GL}_n(E_\Sigma)$ *acts on* $\mathcal{B}_a\times\mathcal{B}_b$ *by*

$$g\cdot(\Phi,\Psi)=\big(x\mapsto\chi(\det g)\,\Phi(xg),\ y\mapsto\Psi(g^{-1}y)\big).$$

Then there is a $\mathrm{GL}_n(E_\Sigma)$*-stable linear subspace* $\mathcal{Q}\subseteq\mathcal{B}_a\times\mathcal{B}_b$ *with the following two properties, where* $\mathcal{M}$ *denotes the space of all* Ψ *such that* $(\Phi,\Psi)\in\mathcal{Q}$ *for some* Φ*.*

1. *Let* Φ *be a function on* $\mathrm{M}_{a\times n}(E_\Sigma)$ *and* Ψ *a locally constant function on* $\mathrm{M}_{n\times b}(E_\Sigma)$ *that are matched over* $\mathcal{O}_\Sigma$ *for* (σ,χ)*:* Φ *vanishes off the matrices* $(k^{-1})_a$ *and* Ψ *off the matrices* k_b *with* $k\in\mathrm{GL}_n(\mathcal{O}_\Sigma)$*, and* $\Phi((k^{-1})_a)=\chi(\det k)\,\Psi(k_b)$ *for every* $k\in\mathrm{GL}_n(\mathcal{O}_\Sigma)$*. Then* $(\Phi,\Psi)\in\mathcal{Q}$*.*

2. Let X be a complex vector space and $\Lambda\colon \mathcal{B}_a \to X$ a linear map with

$$\chi(\det h)\,\Lambda(x \mapsto \Phi(hx)) = \Lambda(\Phi) \qquad (h \in \mathrm{GL}_a(E_\Sigma),\ \Phi \in \mathcal{B}_a).$$

Then there is a linear map $T\colon \mathcal{M} \to X$ with $T(\Psi) = \Lambda(\Phi)$ for every $(\Phi, \Psi) \in \mathcal{Q}$.

Proof. For a finite set c, an injection $\iota\colon c \to n$ and $m \in \mathrm{GL}_n(E_\Sigma)$ let m_ι be the $n \times c$ matrix of the columns $\iota(c)$ of m, and let $\mathrm{Prim}(\iota)$ be the set of the m_ι with $m \in \mathrm{GL}_n(\mathcal{O})$. For $u \in \mathrm{GL}_b(E_\Sigma)$ and $v \in \mathrm{GL}_a(E_\Sigma)$ let $d(u,v) \in \mathrm{GL}_n(E_\Sigma)$ act as u on the coordinates $\sigma(b)$ and as v on the coordinates $\sigma(a)$; then $(m\,d(u,v))_b = m_b u$, $((m\,d(u,v))^{-1})_a = v^{-1}(m^{-1})_a$ and $\det(m\,d(u,v)) = \det m \det u \det v$.

Step 1: primitive multiples of a matrix with a left inverse. We show: (1a) $\mathrm{Prim}(\iota)$ is compact and open; (1b) if $y \in \mathrm{M}_{n\times c}(E_\Sigma)$ has a left inverse, there is $g_y \in \mathrm{GL}_c(E_\Sigma)$ with

$$\{g \in \mathrm{GL}_c(E_\Sigma) : yg \in \mathrm{Prim}(\iota)\} = g_y\,\mathrm{GL}_c(\mathcal{O});$$

(1c) the coset $g_y\mathrm{GL}_c(\mathcal{O})$ is a locally constant function of y; (1d) if C is a compact set of matrices with a left inverse and y has a left inverse, then $\{g : yg \in C\}$ lies in a compact subset of $\mathrm{GL}_c(E_\Sigma)$.

(1a) $\mathrm{Prim}(\iota)$ is the image of the compact group $\mathrm{GL}_n(\mathcal{O})$ under a continuous map. If $z = m_\iota$ with $m \in \mathrm{GL}_n(\mathcal{O})$ and $\delta \in \varpi\mathrm{M}_{n\times c}(\mathcal{O})$, the matrix m' obtained from m by adding δ to the columns $\iota(c)$ satisfies $\det m' \in \det m + \varpi\mathcal{O} \subseteq \mathcal{O}^\times$, so $m' \in \mathrm{GL}_n(\mathcal{O})$ and $z + \delta \in \mathrm{Prim}(\iota)$.

(1b) The question is componentwise, so let $\Sigma = \{w\}$ and $\mathcal{O} = \mathcal{O}_{E,w}$. Put $N = yE_w^c \cap \mathcal{O}^n$. The module $\mathcal{O}^n/N$ is finitely generated and torsion-free (if $tv \in N$ with $t \neq 0$ then $v \in yE_w^c$), hence free, so $\mathcal{O}^n = N \oplus N'$ with N, N' free. Every vector of yE_w^c has a nonzero multiple in N, and y is injective, so N has rank $|c|$. Let $m \in \mathrm{GL}_n(\mathcal{O})$ have as columns $\iota(c)$ a basis of N and as its other columns a basis of N'. The columns of m_ι lie in yE_w^c, so $m_\iota = yg_y$ for a matrix g_y, unique as y is injective, and invertible as m_ι has rank $|c|$. If also $yg = m'_\iota$ with $m' \in \mathrm{GL}_n(\mathcal{O})$, put $u = g_y^{-1}g$, so that $m'_\iota = m_\iota u$. The rows $\iota(c)$ of m^{-1} form an integral matrix L with $Lm_\iota = 1$, so $u = Lm'_\iota$ is integral; exchanging m and m', u^{-1} is integral, and $u \in \mathrm{GL}_c(\mathcal{O})$. Conversely, for $u \in \mathrm{GL}_c(\mathcal{O})$ the columns $\iota(c)$ of the product of m with the element of $\mathrm{GL}_n(\mathcal{O})$ that acts as u on the coordinates $\iota(c)$ and as the identity on the others are $m_\iota u = yg_y u$.

(1c) If $yg_y \in \mathrm{Prim}(\iota)$ and y' is close to y, then $y'g_y$ is close to yg_y, hence lies in the open set $\mathrm{Prim}(\iota)$; in particular y' has a left inverse, and $g_{y'}\mathrm{GL}_c(\mathcal{O}) = g_y\mathrm{GL}_c(\mathcal{O})$ by (1b).

(1d) By (1c) and compactness, $z \mapsto g_z\mathrm{GL}_c(\mathcal{O})$ takes finitely many values $g_1\mathrm{GL}_c(\mathcal{O})$, …, $g_r\mathrm{GL}_c(\mathcal{O})$ on C. If $yg \in C$, then $(yg)g_{yg} \in \mathrm{Prim}(\iota)$, so $gg_{yg} \in g_y\mathrm{GL}_c(\mathcal{O})$ by (1b), and g lies in one of the compact sets $g_y\mathrm{GL}_c(\mathcal{O})g_j^{-1}$.

Step 2: the transposed statements for matrices with a right inverse. Let $\mathrm{Prim}_b = \mathrm{Prim}(\sigma|_b)$, the set of the k_b with $k \in \mathrm{GL}_n(\mathcal{O})$, and let Prim_a be the set of the $(k^{-1})_a$ with $k \in \mathrm{GL}_n(\mathcal{O})$, that is, of the rows $\sigma(a)$ of elements of $\mathrm{GL}_n(\mathcal{O})$. Since $m \mapsto m^T$ permutes $\mathrm{GL}_n(\mathcal{O})$, Prim_a consists of the transposes of the elements of $\mathrm{Prim}(\sigma|_a)$, and an $a \times n$ matrix x has a right inverse if and only if x^T has a left inverse. For such x, $hx \in \mathrm{Prim}_a$ if and only if $x^T h^T \in \mathrm{Prim}(\sigma|_a)$, so Step 1 for x^T gives: Prim_a is compact and open; $\{h \in \mathrm{GL}_a(E_\Sigma) : hx \in \mathrm{Prim}_a\} = \mathrm{GL}_a(\mathcal{O})h_x$ with $h_x = g_{x^T}^T$; this coset is a locally constant function of x; and for a compact set C' of matrices with a right inverse, $\{h : hx \in C'\}$ lies in a compact set. Taking $v = 1$ or $u = 1$ in $d(u,v)$ shows that Prim_b is stable under right multiplication by $\mathrm{GL}_b(\mathcal{O})$ and Prim_a under left multiplication by $\mathrm{GL}_a(\mathcal{O})$. The matrix $(k^{-1})_a$ has the right inverse formed by the columns $\sigma(a)$ of k, and k_b has the left inverse formed by the rows $\sigma(b)$ of k^{-1}.

Step 3: the averages $\Psi^\flat$, $\Phi^\flat$. For $\Psi \in \mathcal{B}_b$, y with a left inverse, $\Phi \in \mathcal{B}_a$ and x with a right inverse put

$$\Psi^\flat(y) = \int_{\mathrm{GL}_b(E_\Sigma)} \chi(\det g)\, \Psi(yg)\, dg, \qquad \Phi^\flat(x) = \int_{\mathrm{GL}_a(E_\Sigma)} \chi(\det h)\, \Phi(hx)\, dh.$$

The integrands are continuous, and by (1d) applied to the compact set $C = \{\Psi \neq 0\}$, which consists of matrices with a left inverse, the first vanishes off a compact set; likewise the second by Step 2. So both integrals converge absolutely. Invariance of the Haar measures gives, for $g' \in \mathrm{GL}_b(E_\Sigma)$, $h' \in \mathrm{GL}_a(E_\Sigma)$ and $g \in \mathrm{GL}_n(E_\Sigma)$, with $(\Phi', \Psi') = g \cdot (\Phi, \Psi)$:

$$\begin{aligned} \Psi^\flat(yg') &= \chi(\det g')^{-1}\Psi^\flat(y), & \Phi^\flat(h'x) &= \chi(\det h')^{-1}\Phi^\flat(x), \\ \Psi'^\flat(y) &= \Psi^\flat(g^{-1}y), & \Phi'^\flat(x) &= \chi(\det g)\, \Phi^\flat(xg). \end{aligned} \tag{a}$$

Step 4: the space $\mathcal{Q}$ and its stability. Let $\mathcal{Q}$ be the set of $(\Phi, \Psi) \in \mathcal{B}_a \times \mathcal{B}_b$ with

$$\Phi^\flat((k^{-1})_a) = \chi(\det k)\, \Psi^\flat(k_b) \qquad (k \in \mathrm{GL}_n(E_\Sigma)). \tag{b}$$

The conditions are linear, so $\mathcal{Q}$ is a linear subspace. The spaces $\mathcal{B}_a$, $\mathcal{B}_b$ are stable under the action: $x \mapsto \Phi(xg)$ is locally constant, its support is the image of that of Φ under $x \mapsto xg^{-1}$, and xg^{-1} has a right inverse when x has one; similarly for Ψ. Let $(\Phi, \Psi) \in \mathcal{Q}$, $g \in \mathrm{GL}_n(E_\Sigma)$ and $(\Phi', \Psi') = g \cdot (\Phi, \Psi)$. Since $(k^{-1})_a g = ((g^{-1}k)^{-1})_a$ and $(g^{-1}k)_b = g^{-1}k_b$, (a) and (b) for $g^{-1}k$ give

$$\Phi'^\flat((k^{-1})_a) = \chi(\det g)\, \Phi^\flat(((g^{-1}k)^{-1})_a) = \chi(\det g)\chi(\det g^{-1}k)\, \Psi^\flat(g^{-1}k_b) = \chi(\det k)\, \Psi'^\flat(k_b),$$

so $(\Phi', \Psi') \in \mathcal{Q}$.

Step 5: matched pairs lie in $\mathcal{Q}$ (property 1). Let (Φ, Ψ) be as in property 1. For $m \in \mathrm{GL}_n(\mathcal{O})$, $u \in \mathrm{GL}_b(\mathcal{O})$ and $v \in \mathrm{GL}_a(\mathcal{O})$, the matching identity at $m\, d(u, v)$ and at m gives $\Phi(v^{-1}(m^{-1})_a) = \chi(\det u)\chi(\det v)\, \chi(\det m)\Psi(m_b u)$ and $\Phi((m^{-1})_a) = \chi(\det m)\Psi(m_b)$. With $u = 1$, and with $v = 1$, and since both functions vanish off the stable sets Prim_a, Prim_b,

$$\chi(\det h)\, \Phi(hz) = \Phi(z), \qquad \chi(\det u)\, \Psi(yu) = \Psi(y) \qquad (h \in \mathrm{GL}_a(\mathcal{O}),\ u \in \mathrm{GL}_b(\mathcal{O})) \tag{c}$$

for all z and y.

$\Psi \in \mathcal{B}_b$: it is locally constant, and it vanishes off the compact set Prim_b, whose elements have a left inverse. $\Phi \in \mathcal{B}_a$: it vanishes off the compact open set Prim_a, whose elements have a right inverse, so it suffices to show that Φ is constant near every $z_0 = (k_0^{-1})_a$ with $k_0 \in \mathrm{GL}_n(\mathcal{O})$. Choose $N \geq 1$ with $\chi(1 + \varpi^N\mathcal{O}) = 1$ and Ψ constant on $(k_0)_b + \varpi^N \mathrm{M}_{n\times b}(\mathcal{O})$. For $\varepsilon \in \varpi^N \mathrm{M}_{a\times n}(\mathcal{O})$ let m be k_0^{-1} with ε added to its rows $\sigma(a)$. Then $m \equiv k_0^{-1} \bmod \varpi^N$, so $m \in \mathrm{GL}_n(\mathcal{O})$, $k = m^{-1}$ satisfies $k - k_0 = k(k_0^{-1} - m)k_0 \in \varpi^N \mathrm{M}_n(\mathcal{O})$, $(k^{-1})_a = z_0 + \varepsilon$, and $\det(k_0^{-1}k) \in 1 + \varpi^N\mathcal{O}$. Hence

$$\Phi(z_0 + \varepsilon) = \chi(\det k)\Psi(k_b) = \chi(\det k_0)\, \chi(\det k_0^{-1}k)\, \Psi(k_b) = \chi(\det k_0)\Psi((k_0)_b) = \Phi(z_0).$$

Identity (b): let $k \in \mathrm{GL}_n(E_\Sigma)$, $x = (k^{-1})_a$, $y = k_b$. By Step 2 and (1b) choose h_0, g_0 with $\{h : hx \in \mathrm{Prim}_a\} = \mathrm{GL}_a(\mathcal{O})h_0$ and $\{g : yg \in \mathrm{Prim}_b\} = g_0\mathrm{GL}_b(\mathcal{O})$. As Φ vanishes off Prim_a, right invariance of the Haar measure and (c) give

$$\Phi^\flat(x) = \int_{\mathrm{GL}_a(\mathcal{O})} \chi(\det hh_0)\, \Phi(hh_0x)\, dh = \chi(\det h_0)\, \Phi(h_0x),$$

and likewise $\Psi^\flat(y) = \chi(\det g_0)\Psi(yg_0)$. Put $z = h_0 x \in \mathrm{Prim}_a$ and $y_0 = yg_0 \in \mathrm{Prim}_b$, and choose $m \in \mathrm{GL}_n(\mathcal{O})$ with $(m^{-1})_a = z$. Then $zm_b = 0$ and $zy_0 = h_0(k^{-1})_a k_b g_0 = 0$. The kernel of z has dimension $|b|$ (componentwise), as z has rank $|a|$, and m_b, y_0 have rank $|b|$, so $y_0 = m_b u$ with $u \in \mathrm{GL}_b(E_\Sigma)$. With L the rows $\sigma(b)$ of m^{-1}, $u = Ly_0$ is integral; writing $y_0 = m'_b$ with $m' \in \mathrm{GL}_n(\mathcal{O})$ and L' the rows $\sigma(b)$ of m'^{-1}, $u^{-1} = L'm_b$ is integral; so $u \in \mathrm{GL}_b(\mathcal{O})$. Let $k' = m\,d(u,1)$ and $k'' = k\,d(g_0, h_0^{-1})$. Then $k'_b = m_b u = y_0 = k''_b$ and $(k'^{-1})_a = (m^{-1})_a = z = h_0(k^{-1})_a = (k''^{-1})_a$. So $p = k'^{-1}k''$ has the rows $\sigma(a)$ and the columns $\sigma(b)$ of the identity matrix; in the coordinates ordered by $(\sigma(b), \sigma(a))$ it is block upper unitriangular, and $\det p = 1$. Hence $\det m \det u = \det k' = \det k'' = \det k \det g_0 \det h_0^{-1}$, and by the matching identity at m and by (c),

$$\begin{aligned}\Phi^\flat(x) &= \chi(\det h_0)\chi(\det m)\Psi(m_b) = \chi(\det h_0)\chi(\det m \det u)\Psi(m_b u)\\ &= \chi(\det k)\chi(\det g_0)\Psi(yg_0) = \chi(\det k)\,\Psi^\flat(y).\end{aligned}$$

So $(\Phi, \Psi) \in \mathcal{Q}$.

Step 6: an invariant Λ sees only $\Phi^\flat$ on Prim_a. Let Λ be as in property 2 and $\Phi \in \mathcal{B}_a$. We show that $\mathbf{1}_{\mathrm{Prim}_a}\Phi^\flat \in \mathcal{B}_a$ and

$$\Lambda(\Phi) = \Lambda(\mathbf{1}_{\mathrm{Prim}_a}\Phi^\flat). \tag{d}$$

The set $U = \{\Phi \neq 0\}$ is compact and consists of matrices with a right inverse. By Step 2, $x \mapsto \mathrm{GL}_a(\mathcal{O})h_x$ is locally constant, so it takes finitely many distinct values $\mathrm{GL}_a(\mathcal{O})h_1, \dots, \mathrm{GL}_a(\mathcal{O})h_r$ on U, and for $x \in U$ we have $h_j x \in \mathrm{Prim}_a$ for exactly one j. Let $\Phi_j(x) = \Phi(x)$ if $h_j x \in \mathrm{Prim}_a$ and $\Phi_j(x) = 0$ otherwise; as Prim_a is open and closed, $\Phi_j \in \mathcal{B}_a$, and $\Phi = \sum_j \Phi_j$. The function $\Phi'_j(x) = \Phi_j(h_j^{-1}x)$ lies in $\mathcal{B}_a$ and vanishes off Prim_a, and the invariance of Λ at $h = h_j$ gives $\chi(\det h_j)\Lambda(\Phi_j) = \Lambda(\Phi'_j)$. So $\Lambda(\Phi) = \Lambda(\Phi^\circ)$ with $\Phi^\circ = \sum_j \chi(\det h_j)^{-1}\Phi'_j$, which vanishes off Prim_a.

Choose $N \geq 1$ such that Φ° is invariant under translation by $\varpi^N \mathrm{M}_{a\times n}(\mathcal{O})$, and let H be the group of $h \in \mathrm{GL}_a(\mathcal{O})$ with $h \equiv 1 \bmod \varpi^N$ and $\chi(\det h) = 1$, an open normal subgroup of $\mathrm{GL}_a(\mathcal{O})$ (the intersection of a principal congruence subgroup and the kernel of the locally constant homomorphism $\chi \circ \det$). For $h \in H$ we have $\Phi^\circ(hx) = \Phi^\circ(x)$ for all x: for integral x, $hx - x = (h-1)x \in \varpi^N \mathrm{M}_{a\times n}(\mathcal{O})$; for non-integral x, hx is not integral and both values vanish, Prim_a consisting of integral matrices. Let $h'_1, \dots, h'_s$ represent $\mathrm{GL}_a(\mathcal{O})/H$ and $\Phi^{\circ\circ}(x) = s^{-1}\sum_i \chi(\det h'_i)\Phi^\circ(h'_i x)$. By the invariance of Λ, $\Lambda(\Phi^{\circ\circ}) = \Lambda(\Phi^\circ) = \Lambda(\Phi)$. Since H is normal, $h \mapsto \chi(\det h)\Phi^\circ(hx)$ is constant on the cosets $h'_i H$, each of volume $1/s$, so

$$\Phi^{\circ\circ}(x) = \int_{\mathrm{GL}_a(\mathcal{O})} \chi(\det h)\,\Phi^\circ(hx)\,dh.$$

Let $x \in \mathrm{Prim}_a$; then $\{h' : h'x \in \mathrm{Prim}_a\} = \mathrm{GL}_a(\mathcal{O})$. By left invariance of the Haar measure,

$$\Phi^{\circ\circ}(x) = \sum_j \chi(\det h_j)^{-1} \int_{\mathrm{GL}_a(\mathcal{O})} \chi(\det h)\Phi_j(h_j^{-1}hx)\,dh = \sum_j \int_{h_j^{-1}\mathrm{GL}_a(\mathcal{O})} \chi(\det h')\Phi_j(h'x)\,dh'.$$

If $\Phi_j(h'x) \neq 0$ then $h_j h'x \in \mathrm{Prim}_a$, so $h_j h' \in \mathrm{GL}_a(\mathcal{O})$ and $h' \in h_j^{-1}\mathrm{GL}_a(\mathcal{O})$. Hence the j-th integral is the integral over all of $\mathrm{GL}_a(E_\Sigma)$, and $\Phi^{\circ\circ}(x) = \sum_j \Phi_j^\flat(x) = \Phi^\flat(x)$. For $x \notin \mathrm{Prim}_a$, $hx \notin \mathrm{Prim}_a$ for $h \in \mathrm{GL}_a(\mathcal{O})$, so $\Phi^{\circ\circ}(x) = 0$. Thus $\Phi^{\circ\circ} = \mathbf{1}_{\mathrm{Prim}_a}\Phi^\flat$, which lies in $\mathcal{B}_a$, and (d) holds.

Step 7: the factorisation (property 2). Let (Φ, Ψ) and (Φ', Ψ) lie in $\mathcal{Q}$. Every $x \in \mathrm{Prim}_a$ is $(k^{-1})_a$ for some $k \in \mathrm{GL}_n(\mathcal{O})$, and (b) for both pairs gives $\Phi^\flat(x) = \chi(\det k)\Psi^\flat(k_b) = \Phi'^\flat(x)$.

So $\mathbf{1}_{\mathrm{Prim}_a}\Phi^\flat = \mathbf{1}_{\mathrm{Prim}_a}\Phi'^\flat$, and $\Lambda(\Phi) = \Lambda(\Phi')$ by (d). Hence $T(\Psi) = \Lambda(\Phi)$, for any Φ with $(\Phi,\Psi) \in \mathcal{Q}$, is a well-defined map on $\mathcal{M}$; it is linear because $\mathcal{Q}$ is a linear subspace and Λ is linear. Together with Steps 4 and 5 this proves the lemma. □

Lemma 6.3.20. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character and W, V, V' spaces with index sets n, a, b, $\#n$ even. Let v, v' be Schwartz vectors for (W,V), (W,V'); let Φ be a locally constant, compactly supported function on $\mathrm{M}_{a\times n}(E_\Sigma)$ vanishing off the right invertible matrices, and Ψ one on $\mathrm{M}_{n\times b}(E_\Sigma)$ vanishing off the left invertible matrices. Write $\theta^{\mathrm{lg}}(\Phi) = \theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;v,\Phi)$ and $\theta^{\mathrm{sm}}(\Psi) = \theta^{\mathrm{sm}}_{\mathfrak{c}}(W,V';v',\Psi)$; these theta integrals converge absolutely and are continuous and left Γ_W-invariant. Then for $x \in \mathrm{G}(s)$:*

1. *for $h \in \mathrm{GL}_a(E_\Sigma)$, $\tilde\nu_{\Sigma,\#n}(\det h)\,\theta^{\mathrm{lg}}\big(y \mapsto \Phi(hy)\big) = \theta^{\mathrm{lg}}(\Phi)$;*
2. *for $g \in G_f(n)$ with components 1 at the finite places outside $\Sigma\cup\bar\Sigma$, with $t = \det g_\Sigma$,*

$$\theta^{\mathrm{lg}}\big(y\mapsto\Phi(yg_\Sigma^{-1})\big)\big(x(1,g)\big) = \tilde\nu_{\Sigma,\#a}(t)\,\upsilon(t)^{\#a-\#n}\,\theta^{\mathrm{lg}}(\Phi)(x),$$
$$\theta^{\mathrm{sm}}\big(y\mapsto\Psi(g_\Sigma y)\big)\big(x(1,g)\big) = \upsilon_{\Sigma,1}(t)^{-\#b}\,\theta^{\mathrm{sm}}(\Psi)(x);$$

3. *for $k \in \mathbf{K}_0(n)$ with components 1 at the places of Σ, $\theta^{\mathrm{lg}}(\Phi)(x(1,k)) = \theta^{\mathrm{lg}}(\Phi)(x)$ and $\theta^{\mathrm{sm}}(\Psi)(x(1,k)) = \theta^{\mathrm{sm}}(\Psi)(x)$.*

Proof. Put $\alpha = \nu^{-1}\upsilon^{\#n/2}$ (the characters of the large side), $\alpha' = \nu\upsilon^{\#n/2}$, $\beta' = \upsilon^{\#b}$ (those of the small side). By (WD3), $\upsilon(\bar x) = \upsilon(x)^{-1}$, so $\tilde\upsilon = \upsilon^2$; hence the space characters are $\alpha[\#n] = \tilde\nu^{-1}$, $\alpha[\#a] = \tilde\nu^{-1}\upsilon^{\#n-\#a}$ and $\beta'[\#b] = \upsilon^{\#b}$.

Data and convergence. The large side is the theta integral of $\varphi(\Phi) = v\otimes(\Phi^\sharp\otimes_\Sigma v^0)$ and the small side that of $\varphi'(\Psi) = v'\otimes(F_\Psi\otimes_{\bar\Sigma} v^0)$, $F_\Psi = (\Psi^{\mathsf T})^\flat$, $F_\Psi(y) = \Psi\big(((\bar y)_\Sigma)^{\mathsf T}\big)$, a function of $y_{\bar\Sigma}$; these functions lie in $\mathcal{T}_\Sigma$, $\mathcal{T}_{\bar\Sigma}$ by Lemma 6.2.22. $\Psi^{\mathsf T}$ vanishes off the right invertible matrices, and so does its conjugate, so by Lemma 6.2.26 (for $A=\Sigma$, resp. $A=\bar\Sigma$ and the function $z\mapsto\Psi^{\mathsf T}(\bar z)$) both data are target-bounded, and (2) of Lemma 6.3.21 gives convergence, continuity, left Γ_W-invariance and linearity in the datum; (3) there gives $I(\omega(g',h')\varphi)(x) = I(\varphi)(xg')$ for target-bounded φ. The real part of a datum is not touched by finite points: by Lemma 4.1.5, $\omega((1,k),(1,k'))(v\otimes f) = v\otimes\omega((1,k),(1,k'))f$.

(1). Let $k \in G_f(a)$ have component h_w at $w\in\Sigma$, the component $\overline{(h_w^{-1})^{\mathsf T}}$ at $\bar w$ and 1 elsewhere; it is unitary (w is split), and $k_\Sigma = h$. By (4) of Lemma 4.1.1 for the pair (W,V), the points $(1,k^{-1})$ and $\Psi = \Phi^\sharp$, $\omega_{\alpha,\alpha}((1,1),(1,k^{-1}))(\Phi^\sharp\otimes_\Sigma v^0) = \tilde\nu(\det h)|\det h|^{\#n/2}\,(\Phi(h\,\cdot))^\sharp\otimes_\Sigma v^0$ (the factor is $\alpha[\#n](\det_\Sigma k^{-1})|\det_\Sigma k^{-1}|^{-\#n/2}$, and $\Phi^\sharp(ky) = \Phi(hy_\Sigma)$). So $\omega_{\alpha,\alpha}(1,k^{-1})\varphi(\Phi) = \tilde\nu_{\Sigma,\#n}(\det h)\varphi(\Phi(h\,\cdot))$, and $\theta^{\mathrm{lg}}(\Phi)(x) = I(\omega_{\alpha,\alpha}(1,k^{-1})\varphi(\Phi))(x) = \tilde\nu_{\Sigma,\#n}(\det h)\theta^{\mathrm{lg}}(\Phi(h\,\cdot))(x)$.

(2), large side. By (4) of Lemma 4.1.1 with $(1,g)$ on W, $(1,1)$ on V and the function $\Phi_1 = \Phi(\cdot\,g_\Sigma^{-1})$, $\omega_{\alpha,\alpha}((1,g),1)\varphi(\Phi_1) = \alpha[\#a](t)^{-1}|t|^{\#a/2}\varphi(\Phi_1(\cdot\,g_\Sigma)) = \tilde\nu(t)\upsilon(t)^{\#a-\#n}|t|^{\#a/2}\varphi(\Phi)$, and $\theta^{\mathrm{lg}}(\Phi_1)(x(1,g)) = I(\omega_{\alpha,\alpha}((1,g),1)\varphi(\Phi_1))(x)$ gives the first identity.

(2), small side. At a split place, unitarity gives $g_{\bar w} = \overline{(g_w^{-1})^{\mathsf T}}$, so $\det_{\bar\Sigma} g = \bar t^{-1}$ and the components at Σ of $\bar g$ form the matrix $(g_\Sigma^{-1})^{\mathsf T}$. Hence $F_{\Psi_1}(yg) = \Psi_1\big(((\bar y)_\Sigma(g_\Sigma^{-1})^{\mathsf T})^{\mathsf T}\big) = F_{\Psi_1(g_\Sigma^{-1}\cdot)}(y)$. By (4) of Lemma 4.1.1 for (W,V'), $A=\bar\Sigma$, the factor is $\beta'[\#b](\bar t^{-1})^{-1}|\bar t^{-1}|^{\#b/2} = \upsilon(t)^{-\#b}|t|^{-\#b/2} = \upsilon_{\Sigma,1}(t)^{-\#b}$ (as $\upsilon(\bar t^{-1}) = \upsilon(t)$), so $\omega_{\alpha',\beta'}((1,g),1)\varphi'(\Psi_1) = \upsilon_{\Sigma,1}(t)^{-\#b}\varphi'(\Psi_1(g_\Sigma^{-1}\cdot))$. With $\Psi_1 = \Psi(g_\Sigma\cdot)$ and $\theta^{\mathrm{sm}}(\Psi_1)(x(1,g)) = I(\omega_{\alpha',\beta'}((1,g),1)\varphi'(\Psi_1))(x)$ this is the second identity.

(3). Let $A\in\{\Sigma,\bar\Sigma\}$, $F\in\mathcal{T}_A$, and write $F\otimes_A v^0 = \sum_y c_y(F)\rho(\mathrm{fv}(y))P^A v^0$ with y supported at $A\cup\bar A$ ((WR6)). The vectors $\mathrm{fv}(y)$ and $\mathrm{rv}(z)$ have disjoint supports, so their bicharacter is 1 and $\rho(\mathrm{fv}(y))$, P^A commute with every $\rho(\mathrm{rv}(z))$ (Heisenberg relation, (1) of Lemma 4.1.10);

hence $v \otimes (F \otimes_A v^0) = \sum_y c_y(F)\rho(\mathrm{fv}(y))P^A(v \otimes v^0)$. The point $(1,k)$ acts on vectors of Hom by $X \mapsto Xk^{-1}$, which fixes the vectors supported at $A \cup \bar{A}$ (k is 1 at Σ, hence by unitarity at $\bar{\Sigma}$); by (2) of Lemma 4.1.1 $\omega((1,k),1)$ commutes with $\rho(\mathrm{fv}(y))$ and with P^A, and by (6) there $\omega_{\alpha_1,\beta_1}((1,k),1)(v \otimes v^0) = \beta_1(\det k)^{-1}v \otimes v^0$. For $\beta_1 = \alpha$ or β', $\beta_1(\det k) = 1$: $\det k \in \mathrm{U}(1)(\mathbb{A})$ has infinite components 1, unit finite components and component 1 at $\Sigma \cup \bar{\Sigma}$, so $\nu(\det k) = \prod_w \psi_w(\det k \bmod w) = 1$ (tame part trivial off Σ) and $v(\det k) = 1$ by (WD3). So $\omega((1,k),1)$ fixes both data, and (3) of Lemma 6.3.21 gives the invariance. □

Lemma 6.3.21. *Let S, T be spaces with signs s on n and s' on n', n' nonempty, and α, β automorphic characters of* $\mathrm{U}(1)$.

1. *The target-bounded data form a linear subspace of $\mathcal{M}_{S,T}$, stable under $\omega_{\alpha,\beta}(g',h')$ for all $(g',h') \in \mathrm{G}(s) \times \mathrm{G}(s')$.*
2. *For target-bounded φ and $g \in \mathrm{G}(s)$, the function $h \mapsto \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)$ is continuous, bounded and left Γ_T-invariant, so $I^{S,T}_{\alpha,\beta}(\varphi)(g)$ converges absolutely; the function $I^{S,T}_{\alpha,\beta}(\varphi)$ is continuous on $\mathrm{G}(s)$ and left Γ_S-invariant; and $\varphi \mapsto I^{S,T}_{\alpha,\beta}(\varphi)$ is linear on the target-bounded data.*
3. *For target-bounded φ, $(g',h') \in \mathrm{G}(s) \times \mathrm{G}(s')$ and $g \in \mathrm{G}(s)$,*
$$I^{S,T}_{\alpha,\beta}(\omega_{\alpha,\beta}(g',h')\varphi)(g) = I^{S,T}_{\alpha,\beta}(\varphi)(gg').$$

Proof. Write $\theta(\varphi) = \theta^{S,T}_{\alpha,\beta}(\varphi)$, $I = I^{S,T}_{\alpha,\beta}$, $\omega = \omega_{\alpha,\beta}$, and x_S for the point of S.

Step 1: heights under translation and on compact sets. For $g \in \mathrm{G}(s)$ the lattice of S_g is $L(g) = \{u \in E^n : ((x_S g)^{-1}u)_f \in \widehat{\mathcal{O}}_E^n\}$ and $\lambda_S(g)$ is the infimum of 1 and of $\|((x_S g)^{-1}u)_\infty\|$ over $u \in L(g) \setminus \{0\}$. Let $g' \in \mathrm{G}(s)$ and choose a positive integer N with $g'_f\widehat{\mathcal{O}}_E^n \subset N^{-1}\widehat{\mathcal{O}}_E^n$. If $u \in L(gg')$ then $(x_S g)^{-1}u \in g'_f\widehat{\mathcal{O}}_E^n$ at the finite places, so $Nu \in L(g)$, and $\|((x_S gg')^{-1}u)_\infty\| \geq \|g'_\infty\|^{-1}\|((x_S g)^{-1}u)_\infty\| \geq \|g'_\infty\|^{-1}N^{-1}\lambda_S(g)$ (operator norm). Hence, as $\lambda_S \leq 1$,

$$\mathrm{ht}_S(gg') \leq c(g')\,\mathrm{ht}_S(g), \qquad c(g') = \max(1, N\|g'_\infty\|). \tag{6.31}$$

For a compact $K \subset \mathrm{G}(s)$, c is bounded on K (g'_f ranges over a compact set, so one N serves, and $\|g'_\infty\|$ is bounded), so by (6.31) with $g = 1$ the height is bounded on K.

Step 2: (1). If $|\theta(\varphi)(g,h)| \leq C\,\mathrm{ht}_S(g)^B$ and $|\theta(\varphi')(g,h)| \leq C'\mathrm{ht}_S(g)^{B'}$ for all characters, then, as $\mathrm{ht}_S \geq 1$ and θ is linear in the datum, $|\theta(a\varphi+a'\varphi')(g,h)| \leq (|a|C+|a'|C')\mathrm{ht}_S(g)^{\max(B,B')}$. For (g',h'), $\theta(\omega(g',h')\varphi)(g,h) = \theta(\varphi)(gg',hh')$ (as ω is a representation; the characters in (XD2) are those of ω, and for other characters α',β' the operator $\omega_{\alpha',\beta'}(g',h')$ differs from $\omega(g',h')$ by the scalar $(\alpha'\alpha^{-1})(\det h')(\beta'\beta^{-1})(\det g')^{-1}$ of modulus 1), so by (6.31) $|\theta_{\alpha',\beta'}(\omega(g',h')\varphi)(g,h)| \leq Cc(g')^B\mathrm{ht}_S(g)^B$.

Step 3: (2). The map $(g,h) \mapsto \omega(g,h)\varphi$ is continuous and $\theta_{\mathrm{Hom}(S,T)}$ is bounded, so $\theta(\varphi)$ is continuous on $\mathrm{G}(s) \times \mathrm{G}(s')$; by Lemma 6.2.5 it is invariant under $\Gamma_S \times \Gamma_T$ on the left. For fixed g it is bounded in h by $C\,\mathrm{ht}_S(g)^B$, and $[\mathrm{U}(T)]$ has finite volume (Theorem 4.2.18), so $I(\varphi)(g)$ converges absolutely and $I(\varphi)(\gamma g) = I(\varphi)(g)$ for $\gamma \in \Gamma_S$. For g in a compact neighbourhood K of a point the integrands are bounded by $C\sup_K \mathrm{ht}_S^B < \infty$ (Step 1), a constant integrable on $[\mathrm{U}(T)]$; dominated convergence gives the continuity of $I(\varphi)$. Linearity on the subspace of (1) is linearity of the integral.

Step 4: (3). By Step 2, $\omega(g',h')\varphi$ is target-bounded and

$$I(\omega(g',h')\varphi)(g)=\int_{[\mathrm{U}(T)]}\theta(\varphi)(gg',hh')\,dh.$$

The group $\mathrm{U}(T)(\mathbb{A}_F)$ is unimodular (it is reductive), so the quotient measure on $[\mathrm{U}(T)]$ is invariant under right translation by h', and the integral is $I(\varphi)(gg')$. □

Proposition 6.3.22. *Let X, W_1, W, V' be spaces with signs r on m, s on n, s_W on n_W, t' on b, with $\#n$ even and b nonempty; let D be a base-adapted splitting of X over W_1 along b, D_1 a base-adapted splitting of W_1 over W along a one-element set, $\sigma\colon b\sqcup(b\sqcup n)\to m$ a bijection and $\mu\colon\Phi\to\mathbb{Z}$. Let $\phi_{\mathrm{lg}}\in\mathcal{F}_{X,V'\oplus W_1}$ and $\phi_{\mathrm{sm}}\in\mathcal{F}_{X,V'}$ be Schwartz vectors, $\mathrm{pw}\colon G_\infty(t'\sqcup s)\to[0,\infty)$ a function that does not vanish on a neighbourhood of 1. For a split tame character $\mathfrak{c}=(\nu,\Sigma)$ put $\gamma_{\mathfrak{c}}=\nu^{-1}\upsilon^{\#n/2}$ and $F_{\mathfrak{c}}=(\Psi_1^{\mathrm{st}})^\sharp\otimes_\Sigma v^0\in\mathcal{M}_{W_1,W_1}$, 1 the identity $n\times n$ matrix and Ψ_1^{st} formed with $\chi_{\mathfrak{c}}$; for $B\in\mathrm{GL}_b(\mathbb{A}_E)$ let z_B be the idele with components $\det B_v$ at $v\in\Phi$ and 1 at the finite places. For a split tame character $\mathfrak{c}=(\nu,\Sigma)$ of weight μ and $I_0\in\mathbb{C}$ consider the condition*

(P) (period identity for $(\mathfrak{c},I_0)$) for every $h\in G_\infty(t'\sqcup s)$ there is $(p_1,p_2)\in\mathrm{G}(t')\times\mathrm{G}(s)$ such that, with $\hat h=\mathrm{diag}(p_{1,\infty},p_{2,\infty})\,h\in G_\infty(t'\sqcup s)$, for all $B\in\mathrm{GL}_b(\mathbb{A}_E)$, all automorphic characters β of $\mathrm{U}(1)$, all $f\in\mathcal{M}_{W_1,V'}$, $x\in\mathrm{M}_{b\times n}(\mathbb{A}_E)$, $g\in\mathrm{G}(s)$ and $y\in\mathrm{G}(t')$,

$$\begin{aligned}&\int_{[\mathrm{U}(W_1)]}\theta_{\mathrm{Hom}(W_1,V'\oplus W_1)}\Big(\rho\big((x;0)\big)\,\omega_{\gamma_{\mathfrak{c}},\gamma_{\mathfrak{c}}\beta}\big(g,\mathrm{diag}(y,u)\big)\big(w_{\hat h}(B)\otimes(f\boxtimes^{\mathrm{tg}}F_{\mathfrak{c}})\big)\Big)\,du\\&\quad=\frac{\mathrm{pw}(h)\,I_0}{\tilde\nu(z_B)\prod_{v\in\Phi}|\det B_v|^{\#n}}\,\theta_{\mathrm{Hom}(W_1,V')}\Big(\rho(x)\,\omega_{\gamma_{\mathfrak{c}},\beta}(g,y)\big(\mathrm{rsl}_{D,V'}(B_\infty;\phi_{\mathrm{sm}})\otimes f\big)\Big),\end{aligned}$$

where $w_{\hat h}(B)=\Omega_{\#n/2-\mu,0}(1,\hat h)\,\mathrm{rsl}_{D,V'\oplus W_1}\big(\hat h^{-1}(B_\infty;0);\phi_{\mathrm{lg}}\big)\in\mathcal{F}_{W_1,V'\oplus W_1}$, the argument of the slice having components $\hat h_v^{-1}(B_v;0)$, $v\in\Phi$;

and assume

(S) (support or signs) either every $x=(x_v)_{v\in\Phi}$, x_v complex $(b\sqcup n)\times b$ matrices, with $\mathrm{rsl}_{D,V'\oplus W_1}(x;\phi_{\mathrm{lg}})\neq0$ has, at every $v\in\Phi$, $x_v^*\mathrm{diag}(t'\sqcup s)\,x_v=c^*\mathrm{diag}(t')\,c$ for some $c\in\mathrm{M}_b(\mathbb{C})$; or $t'(i)=-1$ for all $i\in b$, $s(j)=1$ for some $j\in n$, and $2\,\mathrm{neg}(W_1)\le\#n$.

Then there is $K>0$ such that for every split tame character $\mathfrak{c}=(\nu,\Sigma)$ of weight μ and every $I_0\in\mathbb{C}$ for which (P) holds there is $c\in\mathbb{C}$ with $|c|=K|I_0|$ and

$$\theta^{\mathrm{lg}}_{\mathfrak{c}}(X,V'\oplus W_1;\phi_{\mathrm{lg}},\Phi^{\mathrm{st}}_{\sigma,z})=c\,\theta^{\mathrm{sm}}_{\mathfrak{c}}(X,V';\phi_{\mathrm{sm}},\Psi^{\mathrm{st}}_z)\qquad\text{for every } z\in\mathrm{M}_{b\times m}(\mathcal{O}_\Sigma).$$

In particular, if I is a complex function on the split tame characters of weight μ such that (P) holds for $(\mathfrak{c},I(\mathfrak{c}))$ for every $\mathfrak{c}$, then $(\sigma,\phi_{\mathrm{lg}},\phi_{\mathrm{sm}},\ell)$ satisfy the row-column exchange identity for $(X,V'\oplus W_1,V')$ and μ, where $\ell(\mathfrak{c})=|I(\mathfrak{c})|^2/L_*(\Sigma,\nu;\#n/2)$.

Proof. Throughout, $i\colon\mathrm{G}(t')\times\mathrm{G}(s)\to\mathrm{G}(t'\sqcup s)$ is the block diagonal map $(y,y')\mapsto\mathrm{diag}(y,y')$, $\kappa_\alpha\in\mathbb{A}_E^\times$ is the idele with components κ_v at $v\in\Phi$ and finite part α, and, for a split tame character $\mathfrak{c}=(\nu,\Sigma)$, $z_0=(\mathrm{pr}_l)_\Sigma\in\mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$ for the coordinate pr_l of D (integral, D being base-adapted), $\alpha_{\mathfrak{c}}=\nu^{-1}\upsilon^{\lfloor\#m/2\rfloor}$, $\alpha'_{\mathfrak{c}}=\nu\upsilon^{\lfloor\#m/2\rfloor}$, $\beta'=\upsilon^{\#b}$, and for $z\in\mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$

$$\Theta^{\mathrm{lg}}_z=\theta^{\mathrm{lg}}_{\mathfrak{c}}(X,V'\oplus W_1;\phi_{\mathrm{lg}},\Phi^{\mathrm{st}}_{\sigma,z})=I_{\alpha_{\mathfrak{c}},\alpha_{\mathfrak{c}}}(f_z),\qquad\Theta^{\mathrm{sm}}_z=\theta^{\mathrm{sm}}_{\mathfrak{c}}(X,V';\phi_{\mathrm{sm}},\Psi^{\mathrm{st}}_z)=I_{\alpha'_{\mathfrak{c}},\beta'}(f'_z),$$

with $f_z=\phi_{\mathrm{lg}}\otimes[\Phi^{\mathrm{st}}_{\sigma,z}]_\Sigma$ and $f'_z=\phi_{\mathrm{sm}}\otimes[(\Psi^{\mathrm{st}}_z)^{\mathsf T}]_{\bar\Sigma}$. Centre coefficients, radical and Levi elements are those of D.

Step 0: the constants. Put $\varrho(h) = \mathrm{pw}(h_\infty)$ for $h = (h_\infty, u) \in \mathrm{G}(t' \sqcup s)$ if $\mathrm{diag}(u_1, u_2)\, u \in \mathbf{K}_0(b \sqcup n)$ for some $(u_1, u_2) \in G_f(b) \times G_f(n)$, and $\varrho(h) = 0$ otherwise. Then $\varrho \geq 0$, and $\varrho \neq 0$ on the neighbourhood $N \times \mathbf{K}_0(b \sqcup n)$ of 1, N a neighbourhood of 1 in $G_\infty(t' \sqcup s)$ on which $\mathrm{pw} \neq 0$ (take $u_1 = u_2 = 1$). The groups $\mathrm{G}(t')$, $\mathrm{G}(s)$ are unimodular (products of unitary groups of local fields, almost all compact), i is a continuous injective homomorphism and a homeomorphism onto its closed image, Γ_{W_1} is discrete, and $i(\{1\} \times \Gamma_{W_1})$ lies in the discrete group $\Gamma_{V' \oplus W_1}$, the point of $V' \oplus W_1$ being $\mathrm{diag}(x_{V'}, x_{W_1})$. Let $R \neq 0$ be the constant of Lemma 6.2.47 for $G = \mathrm{G}(t' \sqcup s)$, $L = \mathrm{G}(t')$, $H = \mathrm{G}(s)$ with their measures, this i, $\Lambda = \Gamma_{W_1}$ and $\rho = \varrho$. Let $K_1 > 0$ be the constant of Lemma 6.3.23 (whose hypotheses are those of the present statement, (IP) being (P)), and $K = |R| K_1 > 0$. Neither depends on a character.

Fix a split tame character $\mathfrak{c} = (\nu, \Sigma)$ of weight μ and I_0 such that (P) holds; let C_1 be as in Lemma 6.3.23, $|C_1| = K_1 |I_0|$, and $c = RC_1$, so that $|c| = K|I_0|$.

Step 1: the coefficients at self-dual lattices. Let $T \in \mathrm{M}_b(E)$, $p = \mathrm{rad}(c', z)\, \mathrm{lev}(q, g)$ with $c' \in \mathrm{M}_{n \times b}(\mathbb{A}_E)$, $z \in \mathrm{M}_b(\mathbb{A}_E)$, $q \in \mathrm{GL}_b(\mathbb{A}_E)$, $g \in \mathrm{G}(s)$, and assume (a) or (b) of (VL) of Proposition 6.3.33. We show

$$\mathrm{coef}\big(\jmath T; \Theta^{\mathrm{lg}}_{z_0}\big)(p) = c\, \mathrm{coef}\big(\jmath T; \Theta^{\mathrm{sm}}_{z_0}\big)(p). \tag{6.32}$$

By (1) of Lemma 6.3.24, f_{z_0} has integrable terms at p for D, $V' \oplus W_1$, $\alpha_{\mathfrak{c}}, \alpha_{\mathfrak{c}}$, and f'_{z_0} for D, V', $\alpha'_{\mathfrak{c}}, \beta'$; so both coefficients are defined by (1) of Lemma 6.3.25 (weight $y = 1$; the integral over a fundamental domain is the integral over the quotient).

Case (b): $\det T \neq 0$ *and* T *is not represented by* t'. The right side of (6.32) vanishes by (2) of Lemma 6.3.24. Under the first alternative of (S) so does the left side, by the same item. Under the second alternative apply Lemma 6.3.27 to X, $Y = V' \oplus W_1$ (signs $t' \sqcup s$), $Z = W_1$, the nonempty b, D, the character $\nu_0 = \nu^{-1} \upsilon^{\#n/2}$ of weight $\mu_0 = \#n/2 - \mu$ (υ has weight 1, (WD3) of Definition 3.2.12), T and f_{z_0}: $\delta = \nu_0 \upsilon^{\#b} = \alpha_{\mathfrak{c}}$ since $\lfloor \#m/2 \rfloor = \#b + \#n/2$; $s(j) = 1$ for some j; $\#b + \mathrm{neg}(W_1)$ is the number of signs -1 of $t' \sqcup s$ as $t' \equiv -1$; $\mu_0(\tau) = \#n/2 - \mu(\tau) < \#n/2 \leq \#n - \mathrm{neg}(W_1) = \#\{j : s_j = 1\}$ as $\mu(\tau) > 0$ ((XD4)) and $2\,\mathrm{neg}(W_1) \leq \#n$; T is invertible and not represented by $t' = -1$; and the terms are integrable. So the left side vanishes too.

Case (a): $T = J_{V'}$ *and* $q = \kappa_\alpha x_{V'} Y$ *with* $(Y_f k)^* (Y_f k) = 1$ *for some* $k \in \mathrm{GL}_b(\widehat{\mathcal{O}}_E)$. Let $x_0 = (1; 0) \in \mathrm{M}_{(b \sqcup n) \times b}(E)$, with Gram matrix $x_0^* \mathrm{diag}(J_{V'}, J_{W_1}) x_0 = J_{V'}$, invertible. A rational point γ of $\mathrm{U}(V' \oplus W_1)$ with $\gamma x_0 = x_0$ has first block column $(1; 0)$, and the block (b, n) of $\gamma^* \mathrm{diag}(J_{V'}, J_{W_1}) \gamma = \mathrm{diag}(J_{V'}, J_{W_1})$ reads $J_{V'} \gamma_{bn} = 0$; so $\gamma = \mathrm{diag}(1, \gamma_2)$ with γ_2 a rational point of $\mathrm{U}(W_1)$, and conversely. Hence the group Γ_{x_0} of (2) of Lemma 6.3.25 is $i(\{1\} \times \Gamma_{W_1})$, and that lemma gives

$$\mathrm{coef}(\jmath J_{V'}; \Theta^{\mathrm{lg}}_{z_0})(p) = \int_{i(\{1\} \times \Gamma_{W_1}) \backslash \mathrm{G}(t' \sqcup s)} F(h)\, dh, \qquad F(h) = \mathrm{term}^{\mathrm{lg}}_{x_0}(p, h),$$

F being left invariant and integrable on the quotient. For the small side take $x_0 = 1 \in \mathrm{M}_b(E)$: a rational point of $\mathrm{U}(V')$ fixing 1 is 1, so

$$\mathrm{coef}(\jmath J_{V'}; \Theta^{\mathrm{sm}}_{z_0})(p) = \int_{\mathrm{G}(t')} \mathrm{term}^{\mathrm{sm}}_1(p, y)\, dy =: \Sigma_{\mathrm{sm}}.$$

The function F is continuous: $h \mapsto \omega_{\alpha_{\mathfrak{c}}, \alpha_{\mathfrak{c}}}(p, h) f_{z_0}$ is continuous ((2) of Lemma 4.1.1), and the theta term is this vector followed by a Heisenberg operator (an isometry of the theta model), the zero term ((7) of Lemma 4.1.1, bounded) and a theta functional (bounded, (WD9) of Definition 3.2.12). By Lemma 6.3.23, for every $h \in \mathrm{G}(t' \sqcup s)$ there is (k_1, k_2) with

$$\int_{\mathrm{G}(t')} \int_{\Gamma_{W_1} \backslash \mathrm{G}(s)} F\big(i(y, y')\, i(k_1, k_2)\, h\big)\, dy'\, dy = \varrho(h)\, C_1 \Sigma_{\mathrm{sm}},$$

the iterated integral existing. By Lemma 6.2.47 with the constant $C_1\Sigma_{\mathrm{sm}}$, the integral of F over the quotient is $RC_1\Sigma_{\mathrm{sm}} = c\,\Sigma_{\mathrm{sm}}$, which is (6.32).

Step 2: the equivariant lift. The rank $\#m = 2\#b + \#n$ is even. Apply Lemma 6.3.18 to $\mathfrak{c}$, $W = X$ (signs r on m), $V = V' \oplus W_1$ (index set $b \sqcup n$), V' (index set b), σ, $v = \phi_{\mathrm{lg}}$, $v' = \phi_{\mathrm{sm}}$ and the number c: it gives an equivariant lift $(\mathcal{L}, \mathcal{D})$ for $(\mathfrak{c}, X, b)$ with $\Psi \in \mathcal{L}$ and $\mathcal{D}\Psi = \theta^{\mathrm{lg}}_{\mathfrak{c}}(X, V' \oplus W_1; \phi_{\mathrm{lg}}, \Phi) - c\,\theta^{\mathrm{sm}}_{\mathfrak{c}}(X, V'; \phi_{\mathrm{sm}}, \Psi)$ whenever Φ and a locally constant Ψ are matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_{\mathfrak{c}})$. By Lemma 6.3.31, for $z \in \mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$ the pair $(\Phi^{\mathrm{st}}_{\sigma,z}, \Psi^{\mathrm{st}}_z)$ is such a pair; hence

$$\Psi^{\mathrm{st}}_z \in \mathcal{L}, \qquad \mathcal{D}\Psi^{\mathrm{st}}_z = \Theta^{\mathrm{lg}}_z - c\,\Theta^{\mathrm{sm}}_z. \tag{6.33}$$

Step 3: vanishing at self-dual lattices. By (2) of Lemma 6.3.31, $\Phi^{\mathrm{st}}_{\sigma,z}$ and the function $y \mapsto (\Psi^{\mathrm{st}}_z)^{\mathsf{T}}(\bar{y})$ on $\mathrm{M}_{b\times m}(E_{\bar\Sigma})$ (whose transfer to finite adelic matrices is the function of the conjugate local datum, (XD9)) are locally constant with compact support and vanish at the matrices without a right inverse. So f_z and f'_z are target-bounded (Lemma 6.2.26, with $A = \Sigma$, resp. $A = \bar\Sigma$), and Θ^{lg}_z, Θ^{sm}_z are continuous and left Γ_X-invariant ((2) of Lemma 6.3.21; the targets $V' \oplus W_1$, V' have nonempty index sets). By (1) of Lemma 6.3.32, (6.33) and (6.32),

$$\mathrm{coef}(\jmath T; \mathcal{D}\Psi^{\mathrm{st}}_{z_0})(p) = \mathrm{coef}(\jmath T; \Theta^{\mathrm{lg}}_{z_0})(p) - c\,\mathrm{coef}(\jmath T; \Theta^{\mathrm{sm}}_{z_0})(p) = 0$$

for every (T, p) as in (VL) of Proposition 6.3.33. With $\Psi_0 = \Psi^{\mathrm{st}}_{z_0} \in \mathcal{L}$, Proposition 6.3.33 (for D, D_1, V') gives $\mathcal{D}\Psi = 0$ for every locally constant Ψ matched with some function; for $\Psi = \Psi^{\mathrm{st}}_z$ (Lemma 6.3.31) and (6.33), $\Theta^{\mathrm{lg}}_z = c\,\Theta^{\mathrm{sm}}_z$ for every $z \in \mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$. This is the main assertion.

Step 4: the row-column exchange identity. Let I be as in the last assertion and $c(\mathfrak{c})$ the number of Step 3 for $(\mathfrak{c}, I(\mathfrak{c}))$, so $|c(\mathfrak{c})| = K|I(\mathfrak{c})|$. The value $L_*(\Sigma, \nu; \#n/2)$ is positive: it is a power of $\prod_{w\in\Sigma} \mathrm{N}w$ times the numbers $|L^\Sigma(j, \tilde\nu)|^2$, $1 \le j \le \#n/2$, and $L^\Sigma(j, \tilde\nu) \ne 0$ for $j \ge 1$ by (3) of Theorem A.1.12 ($\tilde\nu$ is nontrivial, being $\psi_w \ne 1$ on the units at $w \in \Sigma$; the removed Euler factors are finite and nonzero for $\mathrm{Re}\, s \ge 1$); so ℓ is defined. With $a = b \sqcup n$ the index set of $V' \oplus W_1$, $\#a - \lfloor \#m/2 \rfloor = \#b + \#n - (\#b + \#n/2) = \#n/2$, and with $C = K^{-2}$

$$C\,|c(\mathfrak{c})|^2 = |I(\mathfrak{c})|^2 = L_*(\Sigma, \nu; \#a - \lfloor \#m/2 \rfloor)\,\ell(\mathfrak{c}),$$

which is (a) of (XD12); (b) of (XD12) is the main assertion, and ϕ_{lg}, ϕ_{sm} are Schwartz vectors. □

Lemma 6.3.23. *Let X, W_1, V' be spaces with signs r on m, s on n, t' on b, with $\#n$ even and b nonempty; let D be a base-adapted splitting of X over W_1 along b, $\sigma\colon b \sqcup (b \sqcup n) \to m$ a bijection and $\mu\colon \Phi \to \mathbb{Z}$. Let $\phi_{\mathrm{lg}} \in \mathcal{F}_{X,V'\oplus W_1}$ and $\phi_{\mathrm{sm}} \in \mathcal{F}_{X,V'}$ be Schwartz vectors and $\mathrm{pw}\colon G_\infty(t' \sqcup s) \to [0, \infty)$ a function. For a split tame character $\mathfrak{c} = (\nu, \Sigma)$ put $\gamma_{\mathfrak{c}} = \nu^{-1}\upsilon^{\#n/2}$, $F_{\mathfrak{c}} = (\Psi^{\mathrm{st}}_1)^\sharp \otimes_\Sigma v^0 \in \mathcal{M}_{W_1,W_1}$ (1 the identity $n \times n$ matrix, Ψ^{st}_1 formed with $\chi_{\mathfrak{c}}$), $z_0 = (\mathrm{pr}_l)_\Sigma \in \mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$ for the coordinate pr_l of D, $\alpha_{\mathfrak{c}} = \nu^{-1}\upsilon^{\lfloor \#m/2 \rfloor}$, $\alpha'_{\mathfrak{c}} = \nu\,\upsilon^{\lfloor \#m/2 \rfloor}$, $\beta' = \upsilon^{\#b}$; let $\mathrm{term}^{\mathrm{lg}}_x$ be the theta terms along D of $\phi_{\mathrm{lg}} \otimes [\Phi^{\mathrm{st}}_{\sigma,z_0}]_\Sigma \in \mathcal{M}_{X,V'\oplus W_1}$ for $V' \oplus W_1$ and the characters $(\alpha_{\mathfrak{c}}, \alpha_{\mathfrak{c}})$, and $\mathrm{term}^{\mathrm{sm}}_x$ those of $\phi_{\mathrm{sm}} \otimes [(\Psi^{\mathrm{st}}_{z_0})^{\mathsf{T}}]_{\bar\Sigma} \in \mathcal{M}_{X,V'}$ for V' and $(\alpha'_{\mathfrak{c}}, \beta')$. For $B \in \mathrm{GL}_b(\mathbb{A}_E)$ let z_B be the idele with components $\det B_v$ at $v \in \Phi$ and 1 at the finite places. For a split tame character $\mathfrak{c}$ of weight μ and $I_0 \in \mathbb{C}$ consider the condition*

(IP) for every $h \in G_\infty(t' \sqcup s)$ there is $(p_1, p_2) \in \mathrm{G}(t') \times \mathrm{G}(s)$ such that, with $\hat h = \mathrm{diag}(p_{1,\infty}, p_{2,\infty})\,h$, for all $B \in \mathrm{GL}_b(\mathbb{A}_E)$, all automorphic characters β of $\mathrm{U}(1)$, all $f \in \mathcal{M}_{W_1,V'}$, $x \in \mathrm{M}_{b\times n}(\mathbb{A}_E)$, $g \in \mathrm{G}(s)$ and $y \in \mathrm{G}(t')$,

$$\int_{[\mathrm{U}(W_1)]} \theta_{\mathrm{Hom}(W_1, V'\oplus W_1)}\Big(\rho((x;0))\,\omega_{\gamma_{\mathfrak{c}},\gamma_{\mathfrak{c}}\beta}(g, \mathrm{diag}(y, u))\big(w_{\hat h}(B) \otimes (f \boxtimes^{\mathrm{tg}} F_{\mathfrak{c}})\big)\Big)\,du$$
$$= \frac{\mathrm{pw}(h)\,I_0}{\tilde\nu(z_B)\prod_{v\in\Phi} |\det B_v|^{\#n}}\,\theta_{\mathrm{Hom}(W_1,V')}\Big(\rho(x)\,\omega_{\gamma_{\mathfrak{c}},\beta}(g, y)\big(\mathrm{rsl}_{D,V'}(B_\infty; \phi_{\mathrm{sm}}) \otimes f\big)\Big),$$

where $w_{\hat h}(B) = \Omega_{\#n/2-\mu,0}(1,\hat h)\,\mathrm{rsl}_{D,V'\oplus W_1}(\hat h^{-1}(B_\infty;0);\phi_{\mathrm{lg}})$.

Then there is $K_1>0$ *with the following property. Let* $\mathfrak{c}$ *be a split tame character of weight* μ *and* $I_0\in\mathbb{C}$ *such that (IP) holds. There is* $C_1\in\mathbb{C}$ *with* $|C_1|=K_1|I_0|$ *such that for all* $c\in \mathrm{M}_{n\times b}(\mathbb{A}_E)$, $z\in \mathrm{M}_b(\mathbb{A}_E)$, $g\in \mathrm{G}(s)$, $Y\in \mathrm{GL}_b(\mathbb{A}_E)$ *and* $k\in \mathrm{GL}_b(\widehat{\mathcal{O}}_E)$ *with* $(Y_fk)^*(Y_fk)=1$, *with* $p=\mathrm{rad}(c,z)\,\mathrm{lev}(\kappa_\alpha x_{V'}Y,g)$, κ_α *the idele with components* κ_v *at* $v\in\Phi$ *and finite part* α, $x_0=(1;0)\in \mathrm{M}_{(b\sqcup n)\times b}(E)$ *and* $1\in \mathrm{M}_b(E)$, *and for every* $h=(h_\infty,u)\in \mathrm{G}(t'\sqcup s)$, *there is* $(k_1,k_2)\in \mathrm{G}(t')\times\mathrm{G}(s)$ *such that: for every* $y\in \mathrm{G}(t')$ *the function* $y'\mapsto \mathrm{term}^{\mathrm{lg}}_{x_0}(p,\mathrm{diag}(y,y')\,\mathrm{diag}(k_1,k_2)\,h)$ *is integrable on* $[\mathrm{U}(W_1)]$, *its integral is an integrable function of* $y\in\mathrm{G}(t')$, *and*

$$\int_{\mathrm{G}(t')}\int_{[\mathrm{U}(W_1)]}\mathrm{term}^{\mathrm{lg}}_{x_0}(p,\mathrm{diag}(y,y')\,\mathrm{diag}(k_1,k_2)\,h)\,dy'\,dy=\varrho(h)\,C_1\int_{\mathrm{G}(t')}\mathrm{term}^{\mathrm{sm}}_1(p,y)\,dy,$$

where $\varrho(h)=\mathrm{pw}(h_\infty)$ *if* $\mathrm{diag}(u_1,u_2)\,u\in\mathbf{K}_0(b\sqcup n)$ *for some* $(u_1,u_2)\in G_f(b)\times G_f(n)$, *and* $\varrho(h)=0$ *otherwise.*

Proof. **Step 0: notation and the constant.** Write $D=(k,l,i)$ with adelic frames $k_{\mathbb{A}},l_{\mathbb{A}},i_{\mathbb{A}}$, $U=V'\oplus W_1$ (signs $t'\sqcup s$ on $b\sqcup n$, point $x_U=\mathrm{diag}(x_{V'},x_{W_1})$), D_U, $D_{V'}$ the splittings of $\mathrm{Hom}(X,U)$, $\mathrm{Hom}(X,V')$ induced by D, with adapted bases m_U, $m_{V'}$. The adelic matrix $P_0=(k_{\mathbb{A}}\mid i_{\mathbb{A}}\mid l_{\mathbb{A}})$ has integral entries at the finite places (D is base-adapted), and so has its inverse, whose block rows $\mathrm{pr}_k=l^*_{\mathbb{A}}\varepsilon_r$, $\mathrm{pr}_i=\varepsilon_s i^*_{\mathbb{A}}\varepsilon_r$, $\mathrm{pr}_l=k^*_{\mathbb{A}}\varepsilon_r$ are conjugate transposes of integral matrices there ($\varepsilon=1$ at the finite places); so $P_{0,\Sigma}\in\mathrm{GL}_m(\mathcal{O}_\Sigma)$ and $z_0=(\mathrm{pr}_l)_\Sigma$ is integral. Let $\epsilon_\sigma\in\{\pm1\}$ be the sign such that, for every $b\times m$ matrix z_1 and $(b\sqcup n)\times m$ matrix w, the $m\times m$ matrix with row $\sigma(j)$ equal to row j of z_1 ($j\in b$) and row $\sigma(i')$ equal to row i' of w ($i'\in b\sqcup n$) has determinant $\epsilon_\sigma\det\binom{w}{z_1}$, the rows of w placed first. By (MX2), $\mathrm{rad}(c,z)$ and $\mathrm{lev}(q,g)$ fix and move the frame as follows: $p\,k_{\mathbb{A}}=k_{\mathbb{A}}q$ and $\mathrm{pr}_i\,p\,i_{\mathbb{A}}=g$ for $p=\mathrm{rad}(c,z)\mathrm{lev}(q,g)$, and $\mathrm{pr}_ip^{-1}l_{\mathbb{A}}=g^{-1}c$.

Fix the data c,z,g,Y,k of the statement, $q=\kappa_\alpha x_{V'}Y$, $p=\mathrm{rad}(c,z)\mathrm{lev}(q,g)$, $x_c=x_{V'}^{-1}c^*\varepsilon_s\in \mathrm{M}_{b\times n}(\mathbb{A}_E)$, $d_0=\det(\kappa_\alpha x_{V'})$. Let $\mathfrak{c}=(\nu,\Sigma)$ be split tame of weight μ, $\chi=\chi_{\mathfrak{c}}$, $\mathfrak{m}=\prod_{w\in\Sigma}w$ (a modulus with $\Sigma(\mathfrak{m})=\Sigma$), $f=\phi_{\mathrm{lg}}\otimes[\Phi]_\Sigma$ with $\Phi=\Phi^{\mathrm{st}}_{\sigma,z_0}$, $f'=\phi_{\mathrm{sm}}\otimes[\Phi']_{\bar\Sigma}$ with $\Phi'=(\Psi^{\mathrm{st}}_{z_0})^{\mathsf{T}}$. The vacuum factors $\mathrm{vf}_U=\mathrm{vf}(D_U)$, $\mathrm{vf}_{V'}=\mathrm{vf}(D_{V'})$ are nonzero by (2) of Lemma 6.3.12 (b, $b\sqcup n$ nonempty). Put

$$K_1=\Big|\frac{\mathrm{vf}_U}{\mathrm{vf}_{V'}}\Big|\,|d_0|^{\#n/2}>0,\qquad \varepsilon'=\chi(\epsilon_\sigma\det P_{0,\Sigma}^{-1})^{-1},\qquad C_1=\frac{\mathrm{vf}_U}{\mathrm{vf}_{V'}}\,\varepsilon'\,\tilde\nu(d_0)\,|d_0|^{\#n/2}\,I_0.$$

K_1 depends only on D, V', W_1; as $|\varepsilon'|=|\tilde\nu(d_0)|=1$, $|C_1|=K_1|I_0|$; and C_1 does not depend on c,z,g,Y,k, ϵ_σ, P_0, d_0 being fixed.

Step 1: the semilocal character. By (XD4) and Definition 3.1.1,

$$\nu(u)=\prod_v u_v^{\mu(v)}\prod_{w\in\Sigma}\psi_w(u_w \bmod w)$$

for $u\in\mathrm{U}(1)(\mathbb{A})$ with integral finite components. For $t\in\mathcal{O}_\Sigma^\times$, $t/\bar t$ has components t_w at $w\in\Sigma$, $\overline{t_w}^{-1}$ at $\bar w\notin\Sigma$ and 1 elsewhere, so $\chi(t)=\prod_{w\in\Sigma}\psi_w(t_w \bmod w)$: χ depends on t mod $\mathfrak{m}$. Consequently: (a) for $\kappa\in\mathbf{K}_0(b\sqcup n)$ (infinite components 1), $\nu(\det\kappa)=\chi((\det\kappa)_\Sigma)$ and $\upsilon(\det\kappa)=1$ (WD3); (b) for a finite idele d with unit components, $\tilde\nu(d)=\nu(d/\bar d)=\prod_{w\in\Sigma}\psi_w(d_w)\psi_w(\overline{d_{\bar w}})^{-1}=\chi(d_\Sigma)\,\chi((\bar d)_\Sigma)^{-1}$; (c) for $u\in\mathrm{U}(1)(\mathbb{A})$, $\tilde\nu(u)=\nu(u^2)$ as $\bar u=u^{-1}$.

Step 2: invariance of f under the standard level. The function Φ on integral matrices is $\bar\Phi(x \bmod \mathfrak{m})$, $\bar\Phi(\bar x)=\bar\chi^{-1}(\det\bar M)$ with M formed as in (XD10) and $\bar\chi^{-1}$ the reduction of χ^{-1} (zero at nonunits), by Step 1; so $\Phi^\sharp=\bar\Phi^\natural$. Let $\kappa\in\mathbf{K}_0(b\sqcup n)$. Replacing the rows x by

$\bar\kappa^{-1}x$ multiplies $\det\bar M$ by $\det\bar\kappa^{-1}$, so $\bar\Phi(\bar\kappa^{-1}\bar x)=\chi((\det\kappa)_\Sigma)\bar\Phi(\bar x)$. By (6) of Lemma 4.1.1 (pair (X,U), $k=1$, $k'=\kappa$) and Step 1 (a), as $\alpha_{\mathfrak c}=\nu^{-1}\upsilon^{\lfloor\#m/2\rfloor}$,

$$\omega_{\alpha_{\mathfrak c},\alpha_{\mathfrak c}}(1,(1,\kappa))f=\chi((\det\kappa)_\Sigma)^{-1}\chi((\det\kappa)_\Sigma)\,f=f. \tag{6.34}$$

Step 3: the terms at the parabolic point. By (1) of Lemma 6.3.12, the Hom slice at X is the slice along the induced splitting at $m^{-*}X=x_UX$ (resp. $x_{V'}X$). Apply (2) of Lemma 6.2.45 to $V=X$, $V_0=W_1$, D, the element p ($m=q$, $g_0=g$, $W=g^{-1}c$) and the Hom slice at $x_U^{-1}x_0=(x_{V'}^{-1};0)$, resp. $x_{V'}^{-1}\cdot1$, both with Gram matrix $J_{V'}$ for ε_U, resp. $\varepsilon_{t'}$. Then $\rho(h^{-1}XW^*\varepsilon_s)$ follows $\omega(g,h)$ as $\rho(XW^*\varepsilon_sg^{-1})=\rho((x_c;0))$, resp. $\rho(x_c)$ ((2) of Lemma 4.1.1; $W^*\varepsilon_sg^{-1}=c^*\varepsilon_s$), and $h^{-1}Xq=\kappa_\alpha h^{-1}(Y;0)$, resp. $\kappa_\alpha y^{-1}Y$. With $\gamma_{\mathfrak c}=\alpha_{\mathfrak c}\upsilon^{-\#b}$ (as $\lfloor\#m/2\rfloor=\#b+\#n/2$) and $\alpha'_{\mathfrak c}\upsilon^{-\#b}=\nu\upsilon^{\#n/2}$, this gives, for $h\in\mathrm G(t'\sqcup s)$ and $y\in\mathrm G(t')$,

$$\begin{aligned}\mathrm{term}^{\mathrm{lg}}_{x_0}(p,h)&=\kappa_{\mathrm{lg}}\,\theta_{\mathrm{Hom}(W_1,U)}\Big(\rho((x_c;0))\,\omega_{\gamma_{\mathfrak c},\gamma_{\mathfrak c}\upsilon^{\#b}}(g,h)\\&\qquad f[\kappa_\alpha h^{-1}(Y;0)]\Big),\\ \mathrm{term}^{\mathrm{sm}}_1(p,y)&=\kappa_{\mathrm{sm}}\,\nu(\det y)^2\,\theta_{\mathrm{Hom}(W_1,V')}\Big(\rho(x_c)\,\omega_{\gamma_{\mathfrak c},\upsilon^{\#b}}(g,y)\\&\qquad f'[\kappa_\alpha y^{-1}Y]\Big),\end{aligned}$$

using $\omega_{\nu\upsilon^{\#n/2},\upsilon^{\#b}}(g,y)=\nu(\det y)^2\omega_{\gamma_{\mathfrak c},\upsilon^{\#b}}(g,y)$ (WR4), where, with the same phase

$$\psi=\psi_E(\tfrac12\jmath\,\mathrm{tr}(\mathrm{pr}_kp^{-1}l_{\mathbb A}\,J_{V'}\,q))$$

on both sides and the characters

$$\begin{aligned}\chi_{\mathrm{lg}}(y)&=\alpha_{\mathfrak c}(y/\bar y)\upsilon(y)^{-\#b-\#n}=\tilde\nu(y)^{-1}\upsilon(y)^{\#b},\\ \chi_{\mathrm{sm}}(y)&=\upsilon(y/\bar y)^{\#b}\upsilon(y)^{-\#b}=\upsilon(y)^{\#b}\end{aligned}$$

of that law,

$$\begin{aligned}&\kappa_{\mathrm{lg}}=\chi_{\mathrm{lg}}(\det q)^{-1}|\det q|^{(\#b+\#n)/2}\psi,\qquad \kappa_{\mathrm{sm}}=\chi_{\mathrm{sm}}(\det q)^{-1}|\det q|^{\#b/2}\psi,\\ &\frac{\kappa_{\mathrm{lg}}}{\kappa_{\mathrm{sm}}}=\tilde\nu(\det q)\,|\det q|^{\#n/2}.\end{aligned}$$

Step 4: the slices. The frames of D_U act on coordinates by $l'_{\mathbb A}m_U^{-*}a=a\,\mathrm{pr}_k$, $k'_{\mathbb A}m_Uz'=\varepsilon_Uz'\mathrm{pr}_l$, $i'_{\mathbb A}Y'=Y'\mathrm{pr}_i$ (from (MX1), (VP5) of Definition 3.2.2, $m_U^{-*}a=x_Ua$, $m_Uz'=x_U^{-*}z'$); likewise for $D_{V'}$. At the finite places $\varepsilon=1$, so the frame of Lemma 6.2.19 sends (a,z',Y') to $M'=a\,\mathrm{pr}_k+z'\mathrm{pr}_l+Y'\mathrm{pr}_i$, and $M'P_0=(a\mid Y'\mid z')$.

Large side. For M' over E_Σ the matrix M of (XD10) for $\Phi(M')$ satisfies, as $z_0P_{0,\Sigma}=(0\mid0\mid1_b)$, $\det(MP_{0,\Sigma})=\epsilon_\sigma\det\begin{pmatrix}a&Y'&z'\\0&0&1_b\end{pmatrix}=\epsilon_\sigma\det(a\mid Y')$, so $\det M=\epsilon_\sigma\det P_{0,\Sigma}^{-1}\det(a\mid Y')$; and M is integral exactly when $(a\mid Y'\mid z')$ is ($P_{0,\Sigma}$ unimodular). Hence

$$\Phi(M')=\prod_{i\in(b\sqcup n)\times b}\mathbf1_{\mathcal O_\Sigma}(z'_i)\cdot\Psi_a(Y'),\qquad \Psi_a(Y')=\varepsilon'\,\mathbf1[a,Y'\text{ integral}]\,\chi^{-1}(\det(a\mid Y')),$$

χ^{-1} being multiplicative on $\mathcal O_\Sigma$ (zero at nonunits). By Lemma 6.3.53, D_U is adapted at 1 in the basis m_U, along the nonempty $(b\sqcup n)\times b$. So Lemma 6.2.19 (with $f_i=1$, $\alpha_0=\kappa_\alpha$, and

the character integrals $\int_{\mathcal{O}_\Sigma}\psi_\Sigma(at)\,dt=\mathbf{1}[a\in\mathcal{O}_\Sigma]$) gives, for an adelic $(b\sqcup n)\times b$ matrix a with finite part a_f,

$$f[\kappa_\alpha a]=\mathrm{vf}_U\,\mathbf{1}[a_f\text{ integral at the finite places outside }\Sigma]\,\mathrm{rsl}_{D,U}(a_\infty;\phi_{\mathrm{lg}})\otimes[\Psi_{a_{f,\Sigma}}]_\Sigma.$$

If $a_f=(B_f;0)$ with $B_f\in\mathrm{GL}_b(\widehat{\mathcal{O}}_E)$, then $\det((B_f;0)_\Sigma\mid Y')=\det B_\Sigma\det Y'_2$, Y'_2 the rows n of Y', so $\Psi_{a_{f,\Sigma}}=\varepsilon'\chi^{-1}(\det B_\Sigma)\,(\mathbf{1}\otimes\Psi_1^{\mathrm{st}})$ (the product of the constant 1 on the rows b and Ψ_1^{st} on the rows n, on integral matrices); both factors are functions modulo $\mathfrak{m}$ (Step 1), and by (a) of Lemma 6.3.80 (with $P_1=P_2=1$) and $v_1\otimes F=F$, $[\mathbf{1}\otimes\Psi_1^{\mathrm{st}}]_\Sigma=v^0\boxtimes^{\mathrm{tg}}F_{\mathfrak{c}}$, v^0 the vacuum of $\mathcal{M}_{W_1,V'}$. So

$$f[\kappa_\alpha a]=\mathrm{vf}_U\,\varepsilon'\chi^{-1}(\det B_\Sigma)\,\mathrm{rsl}_{D,U}(a_\infty;\phi_{\mathrm{lg}})\otimes(v^0\boxtimes^{\mathrm{tg}}F_{\mathfrak{c}})\qquad(a_f=(B_f;0),\ B_f\in\mathrm{GL}_b(\widehat{\mathcal{O}}_E)),\tag{6.35}$$

and $f[\kappa_\alpha a]=0$ if a_f is not integral.

Small side. Read $[\Phi']_{\bar\Sigma}$ as the local datum at $\bar\Sigma$ of $G(y_{\bar\Sigma})=\Phi'((\bar y)_\Sigma)$. For M' over $E_{\bar\Sigma}$ and $w\in\Sigma$, $(z_0)_w$ is the conjugate of $((k_{\mathbb{A}})_{\bar w})^{\mathsf{T}}$, so $z_0\,\overline{M'}^{\mathsf{T}}$ has at w the conjugate of $(M'_{\bar w}(k_{\mathbb{A}})_{\bar w})^{\mathsf{T}}=a_{\bar w}^{\mathsf{T}}$ ($M'k_{\mathbb{A}}=a$). Hence $G(M')=\prod_i\mathbf{1}_{\mathcal{O}_{\bar\Sigma}}(z'_i)\cdot\mathbf{1}[a,Y'\text{ integral}]\,\chi^{-1}((\overline{\det a})_\Sigma)$, and Lemma 6.2.19 for $\bar\Sigma$ and $D_{V'}$ (adapted at 1 in $m_{V'}$ by Lemma 6.3.53), with $\mathbf{1}_{\bar\Sigma}\otimes_{\bar\Sigma}v^0=v^0$, gives for an invertible adelic $b\times b$ matrix B

$$f'[\kappa_\alpha B]=\mathrm{vf}_{V'}\,\mathbf{1}[B_f\text{ integral}]\,\chi^{-1}((\overline{\det B_f})_\Sigma)\,\mathrm{rsl}_{D,V'}(B_\infty;\phi_{\mathrm{sm}})\otimes v^0.\tag{6.36}$$

Step 5: the finite part of the point. Let $h_0=(h_\infty,u)\in\mathrm{G}(t'\sqcup s)$. Apply (IP) to h_∞: it gives (p_1,p_2) and $\hat h=\mathrm{diag}(p_{1,\infty},p_{2,\infty})h_\infty$. *Case A: no $(u_1,u_2)\in G_f(b)\times G_f(n)$ has* $\mathrm{diag}(u_1,u_2)u\in\mathbf{K}_0(b\sqcup n)$; then $\varrho(h_0)=0$. Take $(k_1,k_2)=(1,1)$. For $y\in\mathrm{G}(t')$, $y'\in\mathrm{G}(s)$ let $h=\mathrm{diag}(y,y')h_0$, $a=h^{-1}(Y;0)$, so $a_f=h_f^{-1}(Y_f;0)$. Suppose a_f integral. Then $Z=a_fk$ is integral with $Z^*Z=(Y_fk)^*(Y_fk)=1$, and so is $Z_0=(1;0)$; both have the integral left inverses Z^*, Z_0^*. By (2) of Lemma 3.2.6 there is $g_1\in\mathrm{GL}_{b\sqcup n}(\widehat{\mathcal{O}}_E)$ with $g_1^*g_1=1$ and $g_1Z=Z_0$. The unitary matrix $U_0=g_1h_f^{-1}\mathrm{diag}(Y_fk,1)$ fixes $(1;0)$, so $U_0^*=U_0^{-1}$ fixes it too and $U_0=\mathrm{diag}(1,w')$ with $w'\in G_f(n)$. Then $h_f=\mathrm{diag}(Y_fk,w'^{-1})g_1$ and $u=\mathrm{diag}(y_f,y'_f)^{-1}\mathrm{diag}(Y_fk,w'^{-1})g_1$, so $\mathrm{diag}(u_1,u_2)u=g_1\in\mathbf{K}_0(b\sqcup n)$ with $u_1=(y_f^{-1}Y_fk)^{-1}\in G_f(b)$, $u_2=w'y'_f\in G_f(n)$, against the assumption. So a_f is not integral, $f[\kappa_\alpha a]=0$ by Step 4, and $\mathrm{term}^{\mathrm{lg}}_{x_0}(p,h)=0$ by Step 3 for all y,y'. The identity of the statement holds with both sides 0. *Case B:* $\mathrm{diag}(u_1,u_2)u=\kappa\in\mathbf{K}_0(b\sqcup n)$ *for some* (u_1,u_2). Then $\varrho(h_0)=\mathrm{pw}(h_\infty)$. Take $k_1=(p_{1,\infty},u_1)\in\mathrm{G}(t')$, $k_2=(p_{2,\infty},u_2)\in\mathrm{G}(s)$, so that $\mathrm{diag}(k_1,k_2)h_0=(\hat h,1)(1,\kappa)$. By (6.34), for y,y',

$$\mathrm{term}^{\mathrm{lg}}_{x_0}(p,\mathrm{diag}(y,y')\mathrm{diag}(k_1,k_2)h_0)=\mathrm{term}^{\mathrm{lg}}_{x_0}(p,\mathrm{diag}(y,y')(\hat h,1)).$$

Step 6: the inner integral in Case B. Fix $y\in\mathrm{G}(t')$ and put $B=y^{-1}Y\in\mathrm{GL}_b(\mathbb{A}_E)$. For $h=\mathrm{diag}(y,y')(\hat h,1)$, $h^{-1}(Y;0)$ has infinite part $\hat h^{-1}(B_\infty;0)$ and finite part $(B_f;0)$, independent of y'. If B_f is not integral, both $\mathrm{term}^{\mathrm{lg}}_{x_0}(p,h)$ and $\mathrm{term}^{\mathrm{sm}}_1(p,y)$ vanish (Steps 3, 4). Let B_f be integral; as $B_fk=y_f^{-1}Y_fk$ is unitary, $(B_fk)^{-1}=(B_fk)^*$ is integral, $B_f\in\mathrm{GL}_b(\widehat{\mathcal{O}}_E)$ and $\det B_f$ is a unit idele. By (5) of Lemma 4.1.1 ($\gamma_{\mathfrak{c}}$ has weight $\#n/2-\mu$; the finite part of $(\hat h,1)$ is 1), $\omega_{\gamma_{\mathfrak{c}},\gamma_{\mathfrak{c}}\upsilon^{\#b}}(1,(\hat h,1))$ sends $w\otimes F$ to $(\Omega_{\#n/2-\mu,0}(1,\hat h)w)\otimes F$. With Step 3, (6.35) and $\omega(g,h)=\omega(g,\mathrm{diag}(y,y'))\,\omega(1,(\hat h,1))$,

$$\mathrm{term}^{\mathrm{lg}}_{x_0}(p,h)=\kappa_{\mathrm{lg}}\,\mathrm{vf}_U\,\varepsilon'\chi^{-1}(\det B_\Sigma)\,\theta_{\mathrm{Hom}(W_1,U)}\Big(\rho((x_c;0))\,\omega_{\gamma_{\mathfrak{c}},\gamma_{\mathfrak{c}}\upsilon^{\#b}}(g,\mathrm{diag}(y,y'))\\(w_{\hat h}(B)\otimes(v^0\boxtimes^{\mathrm{tg}}F_{\mathfrak{c}}))\Big).$$

This is a continuous function of y', left invariant under Γ_{W_1} (by (2) of Lemma 6.3.25, $\mathrm{diag}(1,\gamma)$ fixing x_0 for $\gamma \in \Gamma_{W_1}$), and bounded by (1) of Lemma 6.3.24; $[\mathrm{U}(W_1)]$ has finite volume (Theorem 4.2.18; a point if n is empty), so it is integrable there. By (IP) with B, $\beta = \upsilon^{\#b}$, the vacuum $v^0 \in \mathcal{M}_{W_1,V'}$, $x = x_c$, g and y, and by (6.36) and Step 3,

$$\int_{[\mathrm{U}(W_1)]} \mathrm{term}^{\mathrm{lg}}_{x_0}(p,h)\,dy' = \frac{\kappa_{\mathrm{lg}}\,\mathrm{vf}_U\,\varepsilon'\chi^{-1}(\det B_\Sigma)\,\mathrm{pw}(h_\infty)\,I_0}{\tilde\nu(z_B)\prod_{v\in\Phi}|\det B_v|^{\#n}} \cdot \frac{\mathrm{term}^{\mathrm{sm}}_1(p,y)}{\kappa_{\mathrm{sm}}\,\nu(\det y)^2\,\mathrm{vf}_{V'}\,\chi^{-1}((\overline{\det B_f})_\Sigma)}.$$

Now $\det q = d_0 \det y \det B$, $\det B = z_B \det B_f$ as ideles, $|\det y| = |\det B_f| = 1$ and $|z_B|^{\#n/2} = \prod_v |\det B_v|^{\#n}$; by Step 3 and Step 1 (b), (c),

$$\frac{\kappa_{\mathrm{lg}}}{\kappa_{\mathrm{sm}}} = \tilde\nu(d_0)\,\nu(\det y)^2\,\tilde\nu(z_B)\,\tilde\nu(\det B_f)\,|d_0|^{\#n/2}\prod_v |\det B_v|^{\#n},$$
$$\chi^{-1}(\det B_\Sigma)\,\tilde\nu(\det B_f) = \chi^{-1}((\overline{\det B_f})_\Sigma).$$

So the scalar is $\frac{\mathrm{vf}_U}{\mathrm{vf}_{V'}}\varepsilon'\tilde\nu(d_0)|d_0|^{\#n/2}\mathrm{pw}(h_\infty)I_0 = \varrho(h_0)\,C_1$, and for every $y \in \mathrm{G}(t')$

$$\int_{[\mathrm{U}(W_1)]} \mathrm{term}^{\mathrm{lg}}_{x_0}(p, \mathrm{diag}(y,y')\mathrm{diag}(k_1,k_2)h_0)\,dy' = \varrho(h_0)\,C_1\,\mathrm{term}^{\mathrm{sm}}_1(p,y), \tag{6.37}$$

also when B_f is not integral (both sides 0).

Step 7: conclusion. By (1) of Lemma 6.3.24, f' has integrable terms at p for D, V', $\alpha'_{\mathfrak{c}}, \beta'$; by (2) of Lemma 6.3.25 for $x_0 = 1 \in \mathrm{M}_b(E)$, whose stabiliser in the rational points of $\mathrm{U}(V')$ is trivial, $y \mapsto \mathrm{term}^{\mathrm{sm}}_1(p,y)$ is integrable on $\mathrm{G}(t')$. In Case B, (6.37) shows that the inner integral exists for every y and is an integrable function of y, and integrating (6.37) over $\mathrm{G}(t')$ gives the identity of the statement; in Case A everything is 0. □

Lemma 6.3.24. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, X a space with signs r on m, W_1 a space with signs s on n, V' a space with signs t' on a nonempty index set b, D a base-adapted splitting of X over W_1 along b with coordinate pr_l, $z_0 = (\mathrm{pr}_l)_\Sigma \in \mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$, and $\sigma\colon b \sqcup (b \sqcup n) \to m$ a bijection. Let $\phi \in \mathcal{F}_{X,V'\oplus W_1}$ and $\phi' \in \mathcal{F}_{X,V'}$ be Schwartz vectors, put $\alpha = \nu^{-1}\upsilon^{\lfloor \#m/2\rfloor}$, $\alpha' = \nu\,\upsilon^{\lfloor \#m/2\rfloor}$, $\beta' = \upsilon^{\#b}$,*

$$f = \phi \otimes \big[\Phi^{\mathrm{st}}_{\sigma,z_0}\big]_\Sigma \in \mathcal{M}_{X,V'\oplus W_1}, \qquad f' = \phi' \otimes \big[(\Psi^{\mathrm{st}}_{z_0})^{\mathsf{T}}\big]_{\bar\Sigma} \in \mathcal{M}_{X,V'},$$

and let $p = \mathrm{rad}(c,z)\,\mathrm{lev}(q,g)$ with $c \in \mathrm{M}_{n\times b}(\mathbb{A}_E)$, $z \in \mathrm{M}_b(\mathbb{A}_E)$, $q \in \mathrm{GL}_b(\mathbb{A}_E)$, $g \in \mathrm{G}(s)$ (elements of D).

1. *f has integrable terms at p for D, $V' \oplus W_1$, α, α, and f' has integrable terms at p for D, V', α', β'; moreover the sums $\sum_x |\mathrm{term}_x(f)(p,h)|$ over $x \in \mathrm{M}_{(b\sqcup n)\times b}(E)$ and $\sum_x |\mathrm{term}_x(f')(p,h')|$ over $x \in \mathrm{M}_b(E)$ (theta terms for the same data) are bounded functions of $h \in \mathrm{G}(t' \sqcup s)$, resp. $h' \in \mathrm{G}(t')$.*

2. *Let $T \in \mathrm{M}_b(E)$ be such that T, read as an adelic matrix, is not represented by the signs t'. Then $\mathrm{coef}\big(\jmath T; \theta^{\mathrm{sm}}_{\mathfrak{c}}(X, V'; \phi', \Psi^{\mathrm{st}}_{z_0})\big)(p) = 0$. If moreover every $x = (x_v)_{v\in\Phi}$, x_v complex $(b \sqcup n) \times b$ matrices, with $\mathrm{rsl}_{D,V'\oplus W_1}(x;\phi) \neq 0$ has, at every $v \in \Phi$, $x_v^*\mathrm{diag}(t' \sqcup s)\,x_v = e^*\mathrm{diag}(t')\,e$ for some $e \in \mathrm{M}_b(\mathbb{C})$, then $\mathrm{coef}\big(\jmath T; \theta^{\mathrm{lg}}_{\mathfrak{c}}(X, V' \oplus W_1; \phi, \Phi^{\mathrm{st}}_{\sigma,z_0})\big)(p) = 0$.*

Proof. Write $D = (k,l,i)$ with adelic frames $k_{\mathbb{A}}, l_{\mathbb{A}}, i_{\mathbb{A}}$, $\Phi = \Phi^{\mathrm{st}}_{\sigma,z_0}$, $\Phi' = (\Psi^{\mathrm{st}}_{z_0})^{\mathsf{T}}$, $U = V' \oplus W_1$ (signs $t' \sqcup s$ on $b \sqcup n$, point $x_U = \mathrm{diag}(x_{V'}, x_{W_1})$), and D_U, $D_{V'}$ for the splittings of $\mathrm{Hom}(X,U)$, $\mathrm{Hom}(X,V')$ induced by D. By (2) of Lemma 6.3.31, Φ and $\Psi^{\mathrm{st}}_{z_0}$ are locally constant with compact

support; so $\Phi^\sharp \in \mathcal{T}_\Sigma$ and $\Phi'^\flat \in \mathcal{T}_{\bar\Sigma}$ ($y \mapsto (\bar y)_\Sigma$ is a homeomorphism from the components at $\bar\Sigma$ to those at Σ), and $f = \phi \otimes (\Phi^\sharp \otimes_\Sigma v^0)$, $f' = \phi' \otimes (\Phi'^\flat \otimes_{\bar\Sigma} v^0)$; $\bar\Sigma$ contains the conjugate of none of its members, as Σ does not.

Step 1: the point on the frame. By (MX2), $\mathrm{lev}(q,g)k_\mathbb{A} = k_\mathbb{A} q$, $\mathrm{lev}(q,g)i_\mathbb{A} = i_\mathbb{A} g$, $\mathrm{rad}(c,z)k_\mathbb{A} = k_\mathbb{A}$ and $\mathrm{rad}(c,z)i_\mathbb{A} = i_\mathbb{A} + k_\mathbb{A} c^* \varepsilon_s$, since $\mathrm{pr}_k k_\mathbb{A} = 1$, $\mathrm{pr}_i k_\mathbb{A} = \mathrm{pr}_l k_\mathbb{A} = 0$, $\mathrm{pr}_i i_\mathbb{A} = 1$, $\mathrm{pr}_k i_\mathbb{A} = \mathrm{pr}_l i_\mathbb{A} = 0$. Hence

$$p\,k_\mathbb{A} = k_\mathbb{A} q, \qquad p\,i_\mathbb{A} = i_\mathbb{A} g + k_\mathbb{A} c^* \varepsilon_s g, \qquad p^{-1}(k_\mathbb{A} \mid i_\mathbb{A}) = (k_\mathbb{A} \mid i_\mathbb{A})\,Q^{-1}, \quad Q = \begin{pmatrix} q & c^*\varepsilon_s g \\ 0 & g \end{pmatrix}, \tag{6.38}$$

Q being invertible. Let c_p be the finite part of $p^{-1}(k_\mathbb{A} \mid i_\mathbb{A})$. The adelic $m \times m$ matrix $P_0 = (k_\mathbb{A} \mid i_\mathbb{A} \mid l_\mathbb{A})$ is invertible, the coordinates pr_k, pr_i, pr_l forming the block rows of its inverse; and $\mathrm{pr}_l P_0 = (0 \mid 0 \mid 1_b)$.

Step 2: the support of $\Phi^\sharp$. Let η be a finite adelic $(b \sqcup n) \times m$ matrix with $\Phi^\sharp(\eta) = \Phi(\eta_\Sigma) \neq 0$, and $w \in \Sigma$. By (XD10) the $m \times m$ matrix M whose row $\sigma(j)$ is row j of z_0 ($j \in b$) and whose row $\sigma(i')$ is row i' of η_Σ ($i' \in b \sqcup n$) has $\det M \in \mathcal{O}_\Sigma^\times$, so $\det M_w \neq 0$. As $(z_0)_w = ((\mathrm{pr}_l)_f)_w$, the rows $\sigma(j)$, $j \in b$, of $M_w(P_0)_w$ are those of $(0 \mid 0 \mid 1_b)$ and its other rows form $(\eta_w(k_\mathbb{A} \mid i_\mathbb{A})_w \mid \eta_w(l_\mathbb{A})_w)$; expanding along the first group of rows, $\det(M_w(P_0)_w) = \pm \det(\eta_w(k_\mathbb{A} \mid i_\mathbb{A})_w)$. Hence $\eta_w(k_\mathbb{A} \mid i_\mathbb{A})_w$ is invertible, and by (6.38) so is the square matrix $(\eta\, c_p)_w = \eta_w(k_\mathbb{A} \mid i_\mathbb{A})_w (Q^{-1})_w$.

Step 3: the support of $\Phi'^\flat$. Let η be a finite adelic $b \times m$ matrix with $\Phi'^\flat(\eta) = \Psi^{\mathrm{st}}_{z_0}(y) \neq 0$, $y = ((\bar\eta)_\Sigma)^\mathsf{T}$, and $w \in \Sigma$. By (XD10), y is integral and $\det(z_0 y) \in \mathcal{O}_\Sigma^\times$. Now $(z_0)_w = ((k_\mathbb{A})_f^*)_w$ is the conjugate of $(((k_\mathbb{A})_f)_{\bar w})^\mathsf{T}$ and y_w that of $(\eta_{\bar w})^\mathsf{T}$, so $(z_0 y)_w$ is the conjugate of $(\eta_{\bar w}((k_\mathbb{A})_f)_{\bar w})^\mathsf{T}$, and $\eta_{\bar w}(k_\mathbb{A})_{\bar w} \in \mathrm{GL}_b(E_{\bar w})$. With R_0 its inverse, $\eta_{\bar w}(k_\mathbb{A} \mid i_\mathbb{A})_{\bar w}$ has the right inverse $\binom{R_0}{0}$, and by (6.38) $(\eta\, c_p)_{\bar w}$ has the right inverse $Q_{\bar w}\binom{R_0}{0}$; here $\bar w \in \bar\Sigma$.

Step 4: (1). By Step 2 the hypothesis of Lemma 6.3.26 holds for $S = X$, $S_0 = W_1$, D (along the nonempty b), $T = U$ (nonempty index set), the characters α, α, $A = \Sigma$, $\Psi = \Phi^\sharp$, the Schwartz vector ϕ and the point p; by Step 3 it holds for $T = V'$, α', β', $A = \bar\Sigma$, $\Psi = \Phi'^\flat$, ϕ' and p. Items (1) and (2) of Lemma 6.3.26 give (1).

Step 5: (2), the small side. Let $\mathfrak{F}$ be a Borel set meeting each coset of $\Gamma_{V'}$ in $\mathrm{G}(t')$ once; the integral over $[\mathrm{U}(V')]$ of a left $\Gamma_{V'}$-invariant integrable function is its integral over $\mathfrak{F}$, so $\theta^{\mathrm{sm}}_{\mathfrak{c}}(X, V'; \phi', \Psi^{\mathrm{st}}_{z_0})$ is the function Θ_1 of Lemma 6.3.25 for $W = X$, $W_0 = W_1$, D, $V = V'$, α', β', f' and the weight $y = 1$ (the kernel is left $\Gamma_{V'}$-invariant in h by Lemma 6.2.5). By (1) and (1) of Lemma 6.3.25 at $g = p$, the coefficient is the sum over the $x \in \mathrm{M}_b(E)$ with $x^* J_{V'} x = T$ of integrals of theta terms. For such x, $J_{V'} = x_{V'}^{-*} \varepsilon_{t'} x_{V'}^{-1}$ (as $x_{V'}^* J_{V'} x_{V'} = \varepsilon_{t'}$) gives $T = e^* \varepsilon_{t'} e$ with $e = x_{V'}^{-1} x$, so $T_v = e_v^* \mathrm{diag}(t') e_v$ at every $v \in \Phi$: T would be represented by t'. The sum is empty, and the coefficient is 0.

Step 6: (2), the large side. As in Step 5, by (1) and (1) of Lemma 6.3.25 for $V = U$, α, α, f and $y = 1$, the coefficient of the large side at p is $\sum_x \int_{\mathfrak{F}} \mathrm{term}_x(f)(p,h)\,dh$ over the $x \in \mathrm{M}_{(b\sqcup n)\times b}(E)$ with $x^* J_U x = T$, $\mathfrak{F}$ now for Γ_U; we show that every such term vanishes. Let $h \in \mathrm{G}(t' \sqcup s)$. By (6.38), $p\,k_\mathbb{A} = k_\mathbb{A} q$ and $\mathrm{pr}_i\, p\, i_\mathbb{A} = g$; so (2) of Lemma 6.2.45 (for $V = X$, $V_0 = W_1$, the element p with $m = q$, $g_0 = g$, the target U, the characters $\alpha \upsilon^{-\#b}, \alpha$ and h) expresses $(\omega_{\alpha,\alpha}(p,h)f)[x_U^{-1}x]$ as a scalar times $\omega_{\alpha\upsilon^{-\#b},\alpha}(g,h)\rho(\cdot)\,f[Y]$, $Y = h^{-1} x_U^{-1} x q$. It suffices to show $f[Y] = 0$.

By (1) of Lemma 6.3.12, $f[Y]$ is the slice of f along D_U at $x_U Y = (x_U \otimes 1_b) Y = m_U^{-*} Y$. Let $\tilde Y \in \mathbb{C}^{\Phi \times ((b\sqcup n)\times b)}$ have components $\tilde Y_v = \kappa_v^{-1} Y_v$ ($v \in \Phi$), and Y_f the finite part of Y; then $m_U^{-*} Y = m_U^{-*} \mathrm{rv}(\tilde Y) + (x_U Y)_f$, the second summand with components 0 at the infinite places. The splitting D_U is adapted at 1 in the basis m_U by Lemma 6.3.53 (D being base-adapted),

along the nonempty $(b \sqcup n) \times b$; so (3) of Lemma 6.2.20 gives

$$f[Y] = \mathrm{rsl}_{D,U}(\tilde{Y};\phi) \otimes (v_1 \otimes (\Phi^\sharp \otimes_\Sigma v^0))[(x_U Y)_f],$$

the outer slice along D_U. Now $h^* \varepsilon_U h = \varepsilon_U$ and $x_U^{-*} \varepsilon_U x_U^{-1} = J_U$ give $Y^* \varepsilon_U Y = q^* x^* J_U x q = q^* T q$, so at every $v \in \Phi$

$$\tilde{Y}_v^* \,\mathrm{diag}(t' \sqcup s)\, \tilde{Y}_v = \kappa_v^{-2}\, q_v^* T_v q_v.$$

If $\mathrm{rsl}_{D,U}(\tilde{Y};\phi) \neq 0$, the hypothesis gives $e_v \in \mathrm{M}_b(\mathbb{C})$ with $\kappa_v^{-2} q_v^* T_v q_v = e_v^* \mathrm{diag}(t') e_v$, i.e. $T_v = (\kappa_v e_v q_v^{-1})^* \mathrm{diag}(t')(\kappa_v e_v q_v^{-1})$, for every $v \in \Phi$, and T would be represented by t'. So the real slice is 0, hence $f[Y] = 0$ (the datum $w \otimes F$ of (WR6) is linear in w), every term vanishes, and the coefficient of the large side at p is 0. □

Lemma 6.3.25. *Let W, W_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, (k,l,i) a splitting of W over W_0 along p, V a space with a point with signs t on m and point x_V, α, β automorphic characters of $\mathrm{U}(1)$ and $f \in \mathcal{M}_{W,V}$, with theta terms $\mathrm{term}_x(g,h) = \mathrm{term}_x(f)(g,h)$ of (MX6) for the splitting (k,l,i) of W, the space V and α, β. Fix a Borel set $\mathfrak{F} \subset \mathrm{G}(t)$ meeting each coset $\Gamma_V h$ exactly once. Let $y\colon \mathrm{G}(t) \to \mathbb{C}$ be continuous and left Γ_V-invariant, let $g \in \mathrm{G}(s)$, and assume that f has integrable terms at g with weight y. Put $\Theta_y(g') = \int_{\mathfrak{F}} \theta_{\alpha,\beta}^{W,V}(f)(g',h)\, y(h)\, dh$ for $g' \in \mathrm{G}(s)$.*

1. *For every $\tau \in \mathrm{M}_p(E)$ the centre coefficient $\mathrm{coef}(\jmath\tau;\Theta_y)(g)$ is defined, and*

$$\mathrm{coef}(\jmath\tau;\Theta_y)(g) = \sum_{x \in \mathrm{M}_{m\times p}(E),\ x^* J_V x = \tau} \int_{\mathfrak{F}} \mathrm{term}_x(g,h)\, y(h)\, dh,$$

   the series converging absolutely.

2. *Let $x_0 \in \mathrm{M}_{m\times p}(E)$ have invertible Gram matrix $\tau_0 = x_0^* J_V x_0$. Let $\Gamma_{x_0} = \{x_V^{-1}\gamma x_V : \gamma \in \mathrm{U}(V)(F),\ \gamma x_0 = x_0\}$. Then $h \mapsto \mathrm{term}_{x_0}(g,h) y(h)$ is left Γ_{x_0}-invariant and integrable on $\Gamma_{x_0}\backslash \mathrm{G}(t)$ for the quotient measure of dh, and*

$$\mathrm{coef}(\jmath\tau_0;\Theta_y)(g) = \int_{\Gamma_{x_0}\backslash \mathrm{G}(t)} \mathrm{term}_{x_0}(g,h)\, y(h)\, dh.$$

Proof. By (MX6) with $R = \mathfrak{F}$, $\int_{\mathfrak{F}} \sum_x |\mathrm{term}_x(g,h) y(h)|\, dh < \infty$; this is the hypothesis used below. Write $\beta(x) = x^* J_V x$ and note $(x_V^{-1}x)^* \varepsilon_t (x_V^{-1}x) = \beta(x)$, as $x_V^{-*}\varepsilon_t x_V^{-1} = J_V$.

Step 1: expansion and the centre. By (5) of Lemma 6.2.44 applied to $\omega_{\alpha,\beta}(g',h)f$, $\theta_{\alpha,\beta}^{W,V}(f)(g',h) = \sum_x \mathrm{term}_x(g',h)$, absolutely. For an adelic $p \times p$ matrix M, the element $z(M)$ of (MX2) satisfies $z(M)k_{\mathbb{A}} = k_{\mathbb{A}}$ and $\mathrm{pr}_i z(M) i_{\mathbb{A}} = 1$ (as $\mathrm{pr}_l k_{\mathbb{A}} = \mathrm{pr}_l i_{\mathbb{A}} = 0$), and $z(M)z(M') = z(M+M')$, so $z(M)^{-1} l_{\mathbb{A}} = l_{\mathbb{A}} - k_{\mathbb{A}}(M - M^*)$: in (2) of Lemma 6.2.45 (with $\alpha\upsilon^{-\#p}$ in place of α, $h = 1$) its data are $m = 1$, $g_0 = 1$, $W = 0$, $B = M^* - M$. As $\omega_{\alpha,\beta}(z(M)g,h) = \omega_{\alpha,\beta}(z(M),1)\,\omega_{\alpha,\beta}(g,h)$, that law at $x_V^{-1}x$ gives

$$\mathrm{term}_x(z(M)g,h) = \psi_E\big(\tfrac{1}{2}\jmath\,\mathrm{tr}((M^* - M)\beta(x))\big)\mathrm{term}_x(g,h) = \psi_E\big(-\mathrm{tr}(\jmath\beta(x)M)\big)\mathrm{term}_x(g,h),$$

because $\mathrm{tr}(M^*\beta(x)) = \overline{\mathrm{tr}(\beta(x)M)}$ for hermitian $\beta(x)$ and $\psi_E(\bar{z}) = \psi_E(z)$, $\bar{\jmath} = -\jmath$.

Step 2: (1). Put $I_x = \int_{\mathfrak{F}} \mathrm{term}_x(g,h) y(h)\, dh$; by the hypothesis $\sum_x |I_x| < \infty$. By Step 1, $|\theta_{\alpha,\beta}^{W,V}(f)(z(M)g,h)y(h)| \le \sum_x |\mathrm{term}_x(g,h)y(h)|$, so $\Theta_y(z(M)g)$ is defined, and by dominated convergence

$$\Theta_y(z(M)g) = \sum_x \psi_E\big(-\mathrm{tr}(\jmath\beta(x)M)\big) I_x,$$

a continuous function of M, bounded by $\sum_x |I_x|$ and invariant under $\mathrm{M}_p(E)$ (ψ_E is trivial on E). Integrating against $\psi_E(\mathrm{tr}(\jmath\tau M))$ over the compact group $\mathrm{M}_p(\mathbb{A}_E)/\mathrm{M}_p(E)$ with its probability measure, and exchanging sum and integral (the sum of the absolute values is $\sum_x |I_x| < \infty$),

$$\mathrm{coef}(\jmath\tau;\Theta_y)(g) = \sum_x I_x \int_{\mathrm{M}_p(\mathbb{A}_E)/\mathrm{M}_p(E)} \psi_E\big(\mathrm{tr}(\jmath(\tau-\beta(x))M)\big)\,dM.$$

For $U \in \mathrm{M}_p(E)$, $M \mapsto \psi_E(\mathrm{tr}(UM))$ is a character of this compact group; if $U_{ab} \neq 0$, its restriction to the matrices with one nonzero entry in place (b,a) is $z \mapsto \psi_E(U_{ab}z)$, nontrivial by (a) of Theorem A.5.2. So the inner integral is 1 if $\jmath(\tau-\beta(x)) = 0$, that is $\beta(x) = \tau$, and 0 otherwise. This is (1).

Step 3: equivariance of the terms. Let $\gamma \in \mathrm{U}(V)(F)$ and $\gamma_{\mathbb{A}} = x_V^{-1}\gamma x_V \in \Gamma_V$. By (2) of Lemma 6.2.45 with $g = 1$ (so $m = 1$, $g_0 = 1$, $W = B = 0$) and $h = \gamma_{\mathbb{A}}$, $(\omega_{\alpha,\beta}(1,\gamma_{\mathbb{A}})F)[X] = \omega_{\alpha\upsilon^{-\#p},\beta}(1,\gamma_{\mathbb{A}})F[\gamma_{\mathbb{A}}^{-1}X]$, and $\gamma_{\mathbb{A}}^{-1}x_V^{-1}\gamma x = x_V^{-1}x$. By Lemma 6.2.5 for $\mathrm{Hom}(W_0,V)$ and the automorphic characters $\alpha\upsilon^{-\#p}$, β,

$$\mathrm{term}_{\gamma x}(g,\gamma_{\mathbb{A}}h) = \mathrm{term}_x(g,h). \tag{6.39}$$

Step 4: (2). Let $X_0 = \{x : \beta(x) = \tau_0\}$. Each $x \in X_0$ is injective (τ_0 is invertible), so $x_0c \mapsto xc$ is an isometry from x_0E^p into (E^m, u'^*J_Vu); by Witt's theorem A.6.7 it extends to some $\gamma \in \mathrm{U}(V)(F)$ with $\gamma x_0 = x$. Conversely $\beta(\gamma x_0) = \tau_0$. So $\gamma_{\mathbb{A}} \mapsto \gamma^{-1}x_0$ is a bijection $\Gamma_{x_0}\backslash\Gamma_V \to X_0$. Put $\Phi_x(h) = \mathrm{term}_x(g,h)y(h)$; as y is Γ_V-invariant, (6.39) gives $\Phi_{\gamma x}(\gamma_{\mathbb{A}}h) = \Phi_x(h)$; in particular Φ_{x_0} is left Γ_{x_0}-invariant and $\Phi_{x_0}(\gamma_{\mathbb{A}}h) = \Phi_{\gamma^{-1}x_0}(h)$, so

$$\sum_{\delta\in\Gamma_{x_0}\backslash\Gamma_V} \Phi_{x_0}(\delta h) = \sum_{x\in X_0} \Phi_x(h),$$

and likewise with absolute values. For Borel $\Psi \geq 0$ on $\mathrm{G}(t)$ left invariant under Γ_{x_0}, the defining properties of the two quotient measures (written with $\Psi = \sum_{\gamma'\in\Gamma_{x_0}}(\varphi\Psi)(\gamma'\,\cdot)$, φ the indicator of a Borel set meeting each coset $\Gamma_{x_0}h$ once) give $\int_{\Gamma_{x_0}\backslash\mathrm{G}(t)}\Psi = \int_{\Gamma_V\backslash\mathrm{G}(t)}\sum_{\delta\in\Gamma_{x_0}\backslash\Gamma_V}\Psi(\delta h)$, and the latter is $\int_{\mathfrak{F}}\sum_\delta \Psi(\delta h)\,dh$. Applied to $|\Phi_{x_0}|$ this shows $\int_{\Gamma_{x_0}\backslash\mathrm{G}(t)}|\Phi_{x_0}| \leq \int_{\mathfrak{F}}\sum_x|\Phi_x| < \infty$; applied to the positive and negative parts of the real and imaginary parts of Φ_{x_0} (each Γ_{x_0}-invariant) it gives $\int_{\Gamma_{x_0}\backslash\mathrm{G}(t)}\Phi_{x_0} = \int_{\mathfrak{F}}\sum_{x\in X_0}\Phi_x\,dh = \sum_{x\in X_0} I_x$, which is $\mathrm{coef}(\jmath\tau_0;\Theta_y)(g)$ by (1). □

Lemma 6.3.26. *Let S, S_0, T be spaces with points with signs s on n, s_0 on n_0 and t on n', with n' nonempty; let p be a nonempty index set and D a splitting of S over S_0 along p with adelic frames $k_{\mathbb{A}}$, $i_{\mathbb{A}}$. Let α,β be automorphic characters of $\mathrm{U}(1)$, A a finite set of finite places of E containing the conjugate of none of its members, $\Psi \in \mathcal{T}_A$, $v \in \mathcal{F}_{S,T}$ a Schwartz vector, $f = v \otimes (\Psi \otimes_A v^0) \in \mathcal{M}_{S,T}$ and $g \in \mathrm{G}(s)$. Let c_g be the finite part of the adelic $n \times (p \sqcup n_0)$ matrix $g^{-1}(k_{\mathbb{A}} \mid i_{\mathbb{A}})$, and assume that for every finite adelic $n' \times n$ matrix η with $\Psi(\eta) \neq 0$ there is $w \in A$ such that the $n' \times (p \sqcup n_0)$ matrix $(\eta\, c_g)_w$ over E_w has a right inverse. Then, with the theta terms of f for D, T, α, β:*

1. *there is $C \geq 0$ with $\sum_{x\in\mathrm{M}_{n'\times p}(E)}|\mathrm{term}_x(f)(g,h)| \leq C$ for every $h \in \mathrm{G}(t)$;*
2. *f has integrable terms at g for D, T, α, β.*

Proof. Write $D = (k,l,i)$, $\mathrm{term}_x(\varphi)(h) = \mathrm{term}_x(\varphi)(g,h)$ for $\varphi \in \mathcal{M}_{S,T}$ (g is fixed), $\omega = \omega_{\alpha,\beta}$, and D_T for the splitting of $\mathrm{Hom}(S,T)$ over $\mathrm{Hom}(S_0,T)$ along $n' \times p$ induced by D (MX1), with adelic frames $k'_{\mathbb{A}}$, $i'_{\mathbb{A}}$. By (1) of Lemma 6.3.12, for $x \in \mathrm{M}_{n'\times p}(E)$ the Hom slice $F[x_T^{-1}x]$ is the slice of F along D_T at $(x_T \otimes 1_p)(x_T^{-1}x) = x$.

Step 1: rational points permute the terms. Let $\gamma \in \Gamma_T$ and $\gamma_0 = x_T \gamma x_T^{-1} \in \mathrm{U}(T)(F)$. We show $\mathrm{term}_{\gamma_0 x}(\varphi)(\gamma h) = \mathrm{term}_x(\varphi)(h)$. By (2) of Lemma 6.2.45 for the element $1 \in \mathrm{G}(s)$ (so $m = 1$, $g_0 = 1$, $W = B = 0$), the characters $\alpha\upsilon^{-\#_p}, \beta$ and the element γ of $\mathrm{G}(t)$, $(\omega(1,\gamma)F)[X] = \omega_{\alpha\upsilon^{-\#_p},\beta}(1,\gamma)\, F[\gamma^{-1}X]$, and $\gamma^{-1}x_T^{-1}\gamma_0 x = x_T^{-1}x$. As $\omega(g,\gamma h) = \omega(1,\gamma)\omega(g,h)$ ((2) of Lemma 4.1.1) and $\theta_0 \circ \omega_{\alpha\upsilon^{-\#_p},\beta}(1,\gamma) = \theta_0$ by Lemma 6.2.5 for (S_0, T),

$$\mathrm{term}_{\gamma_0 x}(\varphi)(\gamma h) = \theta_0\Big(\omega_{\alpha\upsilon^{-\#_p},\beta}(1,\gamma)\big((\omega(g,h)\varphi)[x_T^{-1}x]\big)\Big) = \mathrm{term}_x(\varphi)(h).$$

Step 2: growth in the height. We show that there are $C_1 \geq 0$ and $B \in \mathbb{N}$ with

$$\sum_{x \in \mathrm{M}_{n'\times p}(E)} |\mathrm{term}_x(\varphi)(h)| \leq C_1\, \|\varphi\|\, \mathrm{ht}_T(h)^B \qquad (\varphi \in \mathcal{M}_{S,T},\ h \in \mathrm{G}(t)). \tag{6.40}$$

By (2) of Lemma 6.2.44 for D_T (along the nonempty $n' \times p$) there is $M \geq 0$ with $\sum_x \|F[x_T^{-1}x]\| \leq M\|F\|$ for all $F \in \mathcal{M}_{S,T}$. Let $\Omega_T \subseteq \mathrm{G}(t)$ be the compact set of Lemma 6.2.29 for T, and $B_T = \{(y,1) : y \in G_\infty(t),\ \|y_v\| \leq 2\ (v \in \Phi)\}$, compact since $\mathrm{U}(\mathrm{diag}\, t)$ is closed and $\|y^{-1}\| = \|\mathrm{diag}(t) y^* \mathrm{diag}(t)\| = \|y\|$ on it. The set $K = \{(g,1)\} \cup (\{1\} \times (\Omega_T \cup B_T))$ is compact; for each φ the map $\kappa \mapsto \omega_{1,1}(\kappa)\varphi$ is continuous ((2) of Lemma 4.1.1), hence bounded on K, and the uniform boundedness principle gives $C_0 = \max(1, \sup_{\kappa\in K} \|\omega_{1,1}(\kappa)\|) < \infty$. Choose $B \in \mathbb{N}$ with $2^B \geq C_0$. Given h, Lemma 6.2.29 writes $h = \gamma z (y_1 \cdots y_k, 1)$ with $\gamma \in \Gamma_T$, $z \in \Omega_T$, $(y_j, 1) \in B_T$ and $2^k \leq \mathrm{ht}_T(h)$. Put $h' = \gamma^{-1}h$. By Step 1 applied to $\gamma_0^{-1}x$, $\mathrm{term}_x(\varphi)(h) = \mathrm{term}_{\gamma_0^{-1}x}(\varphi)(h')$, and $x \mapsto \gamma_0^{-1}x$ is a bijection of $\mathrm{M}_{n'\times p}(E)$; so

$$\sum_x |\mathrm{term}_x(\varphi)(h)| = \sum_x |\mathrm{term}_x(\varphi)(h')| \leq \|\theta_0\|\, M\, \|\omega(g,h')\|\, \|\varphi\|.$$

By (WR4), $\|\omega(g,h')\| = \|\omega_{1,1}(g,h')\|$, and $(g,h') = (g,1)(1,z)\prod_j (1,(y_j,1))$ is a product of $k+2$ elements of K; so $\|\omega(g,h')\| \leq C_0^{k+2} \leq 4^B\, \mathrm{ht}_T(h)^B$. This is (6.40) with $C_1 = 4^B\|\theta_0\|M$.

Step 3: a short frame. The finite part of the adelic matrix $(x_S g)^{-1}(k \mid i)$ has finitely many entries, so there is an integer $N_0 \geq 1$ with $N_0\,((x_S g)^{-1}(k \mid i))_f$ integral. Put $c = N_0(k \mid i) \in \mathrm{M}_{n\times(p\sqcup n_0)}(E)$: its columns lie in the lattice of S_g; let $Z \geq 0$ be the largest of their lengths. Since $k_{\mathbb{A}} = x_S^{-1}k$ and $i_{\mathbb{A}} = x_S^{-1} i x_{S_0}$,
