$$c' = (x_S g)^{-1} c = N_0\, g^{-1}(k_{\mathbb{A}} \mid i_{\mathbb{A}})\, \mathrm{diag}(1_p, x_{S_0}^{-1}), \qquad c'_f = N_0\, c_g\, \mathrm{diag}(1_p, x_{S_0,f}^{-1}). \tag{6.41}$$

Moreover $c^* J_S k = N_0 \begin{pmatrix} k^* J_S k \\ i^* J_S k \end{pmatrix} = 0$ by (MX1).

Step 4: invariance along the frame. Let $d \in \mathrm{M}_{n'\times 1}(E)$, $\mathcal{X} \subset \mathrm{M}_{n'\times p}(E)$ finite and $u_x \in \mathbb{C}$ $(x \in \mathcal{X})$; let $\ell = \sum_{x\in\mathcal{X}} u_x\, \theta_0(\,\cdot\,[x_T^{-1}x])$, a bounded linear functional on $\mathcal{M}_{S,T}$. We show $\ell(\rho(z)F) = \ell(F)$ for $F \in \mathcal{M}_{S,T}$ and $z = x_T^{-1} y x_S$, $y = dY c^* J_S$, $Y \in \mathrm{M}_{1\times(p\sqcup n_0)}(E)$, i.e. $z \in Z_{d,c}(E)$ in the notation of Lemma 6.2.31. By Step 3, $yk = 0$. By (MX1) every adelic vector is $l_{\mathbb{A}}a + i_{\mathbb{A}}w + k_{\mathbb{A}}b$ with (a,w,b) its coordinates, so $1 = l_{\mathbb{A}}\mathrm{pr}_l + i_{\mathbb{A}}\mathrm{pr}_i + k_{\mathbb{A}}\mathrm{pr}_k$, and $z k_{\mathbb{A}} = x_T^{-1} y k = 0$ gives

$$z = Y_1 \mathrm{pr}_i + x_T^{-1}(yl)\mathrm{pr}_l = i'_{\mathbb{A}} Y_1 + k'_{\mathbb{A}} X', \qquad Y_1 = x_T^{-1}(yi)x_{S_0}, \quad X' = J_T\, yl \in \mathrm{M}_{n'\times p}(E).$$

By the mixed law ((1) of Lemma 6.2.44) for D_T, at the slice point x, with $a = 0$, $w = Y_1$, $b = X'$,

$$(\rho(z)F)[x_T^{-1}x] = \psi_E\big(\jmath\,\mathrm{tr}(X'^* x)\big)\, \rho(Y_1)\, F[x_T^{-1}x] = \rho(Y_1)\, F[x_T^{-1}x],$$

as $\jmath\,\mathrm{tr}(X'^{*}x) \in E$ and ψ_E is trivial on E. Since Y_1 is the rational vector of $\mathrm{Hom}(S_0, T)$ attached to $yi \in \mathrm{M}_{n'\times n_0}(E)$, $\theta_0(\rho(Y_1)G) = \theta_0(G)$, and the claim follows term by term.

Step 5: (1). Let $f_0 = \Psi \otimes_A v^0$, so $f = v \otimes f_0$. Let C' be the constant of (2) of Lemma 6.2.31 for S, T, α, β, A, Ψ, the index sets $\{1\}$ (columns of d) and $p \sqcup n_0$ (columns of c), $N = 0$, $Y_0 = C_1$, $Z_0 = Z$ and $A_0 = B$. Fix h, $H = \mathrm{ht}_T(h) \geq 1$ and a finite $\mathcal{X} \subset \mathrm{M}_{n'\times p}(E)$; choose u_x with $|u_x| = 1$ and $u_x\,\mathrm{term}_x(f)(h) = |\mathrm{term}_x(f)(h)|$, and let ℓ be as in Step 4. Then $\ell(\omega(g,h)\varphi) = \sum_{x\in\mathcal{X}} u_x\,\mathrm{term}_x(\varphi)(h)$, so by (6.40) $|\ell(\omega(g,h)\varphi)| \leq C_1\|\varphi\|H^B$ for all φ: the growth hypothesis of (2) of Lemma 6.2.31 holds with $r = 1$. Let $H > 2$. By Lemma 6.2.30 there is a nonzero d in the lattice of T_h with $d^*J_Td = 0$ and length at most $2/H$. We check that (d, c) is a short pair for $(g, h, \ell, 2/H, Z)$: (i) holds by the choices of d and c; (ii) as $d^*J_Td = 0$; (iii) is Step 4. For (iv), first alternative, let $d' = (x_Th)^{-1}d$ and η with $\Psi(\eta) \neq 0$; take $w \in A$ and a right inverse R of $(\eta c_g)_w$ as in the hypothesis. The entries of the row $(d'^{*}_f)_w$ are the conjugates of those of $(d'_f)_{\bar w} = ((x_Th)^{-1})_{\bar w}\,d \neq 0$, so $(d'^{*}_f)_w \neq 0$, and $(d'^{*}_f)_w(\eta c_g)_wR = (d'^{*}_f)_w$ shows $(d'^{*}_f)_w(\eta c_g)_w \neq 0$. By (6.41), $(d'^{*}_f\eta c'_f)_w = N_0\,(d'^{*}_f)_w(\eta c_g)_w\,\mathrm{diag}(1_p, (x^{-1}_{S_0,f})_w) \neq 0$. The product of the lengths is $2Z/H = 2Z_0r/H$. Hence (2) of Lemma 6.2.31 (with $\mathrm{mom}_B(v) < \infty$, v being a Schwartz vector) gives, for every $H \geq 1$,

$$\sum_{x\in\mathcal{X}} |\mathrm{term}_x(f)(h)| = \ell(\omega(g,h)f) \leq C'\,\mathrm{mom}_B(v).$$

The bound does not depend on $\mathcal{X}$ or h; taking the supremum over $\mathcal{X}$ proves (1) with $C = C'\mathrm{mom}_B(v)$.

Step 6: (2). Each $h \mapsto \mathrm{term}_x(f)(h)$ is continuous ((2) of Lemma 4.1.1, the Hom slice and θ_0 being bounded linear), so $h \mapsto \sum_x |\mathrm{term}_x(f)(h)|$ is Borel. Let $R \subset \mathrm{G}(t)$ be a measurable set of representatives of $\Gamma_T\backslash\mathrm{G}(t)$. By the defining property of the quotient measure ($\sum_{\gamma\in\Gamma_T} \mathbf{1}_R(\gamma h) = 1$), the measure of R is the volume of $[\mathrm{U}(T)]$, which is finite by Theorem 4.2.18 (n' is nonempty and the measure of $\mathrm{G}(t)$ corresponds to a Haar measure of $\mathrm{U}(T)(\mathbb{A}_F)$). By (1), $\int_R \sum_x |\mathrm{term}_x(f)(h)|\,dh \leq C\,\mathrm{vol}([\mathrm{U}(T)]) < \infty$, which is (2) (weight 1). □

Lemma 6.3.27. *Let X, Y, Z be spaces with points with signs r on m, s on n, t on a, let b be a nonempty finite index set and D a splitting of X over Z along b. Let $\mu\colon \Phi \to \mathbb{Z}$ with $\mu(\tau) < \#\{j \in a : t_j = 1\}$ for every $\tau \in \Phi$, and assume that $s_i = 1$ for some $i \in n$ and $\#b + \#\{j \in a : t_j = -1\} = \#\{k \in n : s_k = -1\}$. Let ν be an automorphic character of $\mathrm{U}(1)$ of weight μ and $\delta = \nu\upsilon^{\#b}$. Let $T \in \mathrm{M}_b(E)$ be invertible and, read as an adelic matrix, not represented by the signs -1 on b. Let $f \in \mathcal{M}_{X,Y}$ and $g \in \mathrm{G}(r)$ be such that f has integrable terms at g (for D, Y, δ, δ), and put $\Theta(g') = \int_{[\mathrm{U}(Y)]} \theta^{X,Y}_{\delta,\delta}(f)(g', h)\,dh$. Then*

$$\mathrm{coef}(\jmath T; \Theta)(g) = 0.$$

Proof. Write $\omega = \omega_{\delta,\delta}$ on $\mathcal{M}_{X,Y}$, $\omega' = \omega_{\nu,\delta}$ on $\mathcal{M}_{Z,Y}$, and $\mathrm{term}_x = \mathrm{term}_x(f)$ for the theta terms of (MX6) (for D, Y, δ, δ).

Step 1: unfolding. By (1) of Lemma 6.3.25 (with $(W, W_0, V) = (X, Z, Y)$, $p = b$, $\alpha = \beta = \delta$, weight $y = 1$; the hypothesis is the integrability of the terms), $\mathrm{coef}(\jmath T; \Theta)(g)$ is the sum over the $x \in \mathrm{M}_{n\times b}(E)$ with $x^*J_Yx = T$ of $\int \mathrm{term}_x(g, h)\,dh$ over a set of representatives of $[\mathrm{U}(Y)]$. If there is no such x the coefficient is 0. Otherwise fix one, x_0; as T is invertible, (2) of Lemma 6.3.25 gives

$$\mathrm{coef}(\jmath T; \Theta)(g) = \int_{\Gamma_{x_0}\backslash\mathrm{G}(s)} \mathrm{term}_{x_0}(g, h)\,dh, \tag{6.42}$$

$h \mapsto \mathrm{term}_{x_0}(g,h)$ being left Γ_{x_0}-invariant and integrable on the quotient, $\Gamma_{x_0} = \{x_Y^{-1}\gamma x_Y : \gamma \in \mathrm{U}(Y)(F),\ \gamma x_0 = x_0\}$. Put $x' = x_Y^{-1}x_0$ and $S = \{h \in \mathrm{G}(s) : hx' = x'\}$, a closed subgroup containing Γ_{x_0}.

Step 2: the stabiliser acts through the smaller pair. Let $k \in S$, $h \in \mathrm{G}(s)$, and $\varphi_h = (\omega(g,h)f)[x'] \in \mathcal{M}_{Z,Y}$. Then

$$\mathrm{term}_{x_0}(g,kh) = \theta_{\mathrm{Hom}(Z,Y)}\big(\omega'(1,k)\varphi_h\big). \tag{6.43}$$

Indeed, (2) of Lemma 6.2.45 for $(V,V_0,T) = (X,Z,Y)$, the element 1 of $\mathrm{G}(r)$ (so $m=1$, $g_0=1$, $W=0$, $B=0$), the characters (ν,δ) (so $\nu\upsilon^{\#b} = \delta$) and $h=k$ gives $(\omega(1,k)F)[x] = \omega'(1,k)F[k^{-1}x]$ for every $F \in \mathcal{M}_{X,Y}$ and adelic x; take $F = \omega(g,h)f$, $x = x'$, and use $\omega(1,k)\omega(g,h) = \omega(g,kh)$ ((2) of Lemma 4.1.1) and $k^{-1}x' = x'$.

Step 3: a compact subgroup of S. We have $x'^{*}\varepsilon_s x' = x_0^{*}J_Y x_0 = T$. As T is not represented by the signs -1, there is $\tau \in \Phi$ such that the complex matrix x'_τ has Gram matrix $x'^{*}_\tau \mathrm{diag}(s) x'_\tau = T_\tau$ not of the form $-c^{*}c$, i.e. not negative semidefinite. Lemma 6.3.28 (for the pair (Z,Y), μ, τ, b and $x = x'_\tau$; its hypotheses are those of the statement) gives $u \in \mathrm{U}(\mathrm{diag}\, s)$ such that every continuous linear form on $\mathcal{F}_{Z,Y}$ invariant under $\Omega_{\mu,0}(1,c_{[\tau]})$ for all $c \in K_s$ with $cux'_\tau = ux'_\tau$ is zero. Let $C_0 = \{c \in K_s : cux'_\tau = ux'_\tau\}$, compact, and $C = \{(u^{-1}cu)_{[\tau]} : c \in C_0\}$; its elements fix x', so C is a compact subgroup of S. Let dc be its Haar probability measure (Theorem A.5.1) and $w = (u^{-1})_{[\tau]} \in \mathrm{G}(s)$.

Step 4: the mean over C vanishes. Let $k \in S$ and $A(\varphi) = \int_C \theta_{\mathrm{Hom}(Z,Y)}(\omega'(1,kc)\varphi)\,dc$ for $\varphi \in \mathcal{M}_{Z,Y}$. The integrand is continuous in c ((2) of Lemma 4.1.1), and $\sup_{c\in C}\|\omega'(1,kc)\| < \infty$ by the uniform boundedness principle on the Banach space $\mathcal{M}_{Z,Y}$, so A is a bounded linear functional; by invariance of dc, $A(\omega'(1,p)\varphi) = A(\varphi)$ for $p \in C$. Fix $f' \in \mathcal{M}_{Z,Y}$ and put $\ell(v) = A(\omega'(1,w)(v \otimes f'))$ for $v \in \mathcal{F}_{Z,Y}$. It is continuous: $\|v \otimes f'\| \le \|v\|_{L^1}\|f'\|$, since ρ preserves the L^1 norm. By Lemma 4.1.5 (the real parts act on the Fock factor; ν has weight μ, and the weight of δ does not enter at $(1,y)$), $\omega'(1,y)(v \otimes f') = (\Omega_{\mu,0}(1,y)v) \otimes f'$ for $y \in G_\infty(s)$. For $c \in C_0$, $p = w\,c_{[\tau]}w^{-1} = (u^{-1}cu)_{[\tau]} \in C$, so

$$\ell(\Omega_{\mu,0}(1,c_{[\tau]})v) = A\big(\omega'(1,w)\omega'(1,c_{[\tau]})(v\otimes f')\big) = A\big(\omega'(1,p)\omega'(1,w)(v\otimes f')\big) = \ell(v).$$

Hence $\ell = 0$, i.e. $A\big((\Omega_{\mu,0}(1,w)v)\otimes f'\big) = 0$ for all v, f'; as $\Omega_{\mu,0}(1,w)$ is invertible, $A(v\otimes f') = 0$ for all $v \in \mathcal{F}_{Z,Y}$, $f' \in \mathcal{M}_{Z,Y}$, in particular for $v = v_P$, $f' = \rho_f(y)v^0$. By Lemma 6.3.30, $A = 0$. With (6.43),

$$\int_C \mathrm{term}_{x_0}(g,kch)\,dc = A(\varphi_h) = 0 \qquad (k \in S,\ h \in \mathrm{G}(s)). \tag{6.44}$$

Step 5: the averaging criterion. Apply Lemma 6.2.50 with $G = \mathrm{G}(s)$ and its measure, $H = S$ with a left Haar measure, $\Gamma = \Gamma_{x_0}$ (discrete, contained in S), $F(h) = \mathrm{term}_{x_0}(g,h)$ (continuous, by (2) of Lemma 4.1.1 and the boundedness of the slice map and of the theta functional; left Γ-invariant and integrable on $\Gamma\backslash G$ by Step 1), (C,dc), $t(x,c) = c$, $d = 1$ and $a = 0$: right translation by an element of the compact subgroup C preserves the left Haar measure of S, the modular function of S being a continuous homomorphism to $\mathbb{R}_{>0}$, trivial on compact subgroups; and (6.44) is hypothesis (2) with $a = 0$. As $0 \neq 1$, the integral (6.42) vanishes. □

Lemma 6.3.28. *Let S, T be spaces with points with signs t on a and s on n, let $\mu\colon \Phi \to \mathbb{Z}$, $\tau \in \Phi$ and b a finite index set. Assume $\mu(\tau) < \#\{j \in a : t_j = 1\}$, $s_i = 1$ for some $i \in n$, and $\#b + \#\{j \in a : t_j = -1\} = \#\{k \in n : s_k = -1\}$. Let x be a complex $n \times b$ matrix such that $x^{*}\mathrm{diag}(s)\,x$ is not negative semidefinite. Let $K_s = \{c \in \mathrm{U}(\mathrm{diag}\, s) : c^{*}c = 1\}$, and for $c \in \mathrm{U}(\mathrm{diag}\, s)$ let $c_{[\tau]} \in G_\infty(s)$ have component c at τ and 1 at the other places. Then there is $u \in \mathrm{U}(\mathrm{diag}\, s)$ such that every continuous linear form ℓ on $\mathcal{F}_{S,T}$ with*

$$\ell(\Omega_{\mu,0}(1,c_{[\tau]})w) = \ell(w) \qquad (w \in \mathcal{F}_{S,T},\ c \in K_s,\ cux = ux)$$

is zero.

Proof. Write $D = \operatorname{diag}(s)$, $h(y,y') = y^*Dy'$ on $\mathbb{C}^n$, and $N = \#\{j : t_j = 1\} - \mu(\tau) \geq 1$. The variables of $\mathcal{F}_{S,T}$ are $X_{v,k,j}$ ($v \in \Phi$, $k \in n$, $j \in a$).

Step 1: the isometry u. As x^*Dx is not negative semidefinite, some $v \in \mathbb{C}^b$ has $h(xv,xv) > 0$; rescale so that $h(xv,xv) = 1 = h(e_i,e_i)$. By Witt's theorem A.6.7 (for $\mathbb{C}$ with complex conjugation, the nondegenerate form h, the line $\mathbb{C}xv$ and the isometric map $xv \mapsto e_i$) there is an isometry u of h, i.e. $u \in \mathrm{U}(\operatorname{diag} s)$, with $uxv = e_i$. Put $y = ux$ and $C = \{c \in K_s : cy = y\}$.

Step 2: a negative unit vector for each point. Let $z \in \mathbb{C}^{\Phi\times n\times a}$. There is $r \in \mathbb{C}^n$ with $r_k = 0$ whenever $s_k = 1$, $\sum_k r_k\bar{r}_k = 1$, $\sum_k r_k y_{kl} = 0$ for $l \in b$, and $\sum_k \bar{r}_k z_{\tau,k,j} = 0$ for j with $t_j = -1$. Indeed, the linear map $f\colon r \mapsto ((\sum_k r_k y_{kl})_{l\in b}, (\sum_k r_k \bar{z}_{\tau,k,j})_{t_j=-1}, (r_k)_{s_k=1})$ goes from $\mathbb{C}^n$ to a space of dimension $\#b + \#\{t_j = -1\} + \#\{s_k = 1\} = \#n$. If f were injective it would be onto, and some r would have $f(r) = (0,0,(1)_k)$; then $r_i = 1$, but $\sum_k r_k(yv)_k = \sum_l v_l \sum_k r_k y_{kl} = 0$ while $yv = e_i$ gives $\sum_k r_k(yv)_k = r_i$. So f has a nonzero kernel vector; normalise it, and conjugate the second condition.

Step 3: the rotations. Let r be as in Step 2, $\Pi = \bar{r}r^{\mathsf{T}}$ (entries $\bar{r}_k r_l$) and, for $|\eta| = 1$, $c_\eta = 1 + (\bar{\eta}-1)\Pi$. Then $\Pi^* = \Pi = \Pi^2$ and $D\Pi = \Pi D = -\Pi$ (as r lives on the indices of sign -1), so with $E \in \{1, D\}$ and $E\Pi = \Pi E = \epsilon\Pi$, $c_\eta^* E c_\eta = E + \epsilon\Pi((\bar{\eta}-1) + (\eta-1) + (\eta-1)(\bar{\eta}-1)) = E$. Hence $c_\eta \in K_s$, $c_\eta^{-1} = c_\eta^* = 1 + (\eta-1)\Pi$, and $c_\eta y = y$ since $r^{\mathsf{T}}y = 0$; so $c_\eta \in C$. The block of c_η of sign $+1$ is the identity, and the block of sign -1 is a rank-one perturbation of the identity of determinant $1 + (\bar{\eta}-1)r^{\mathsf{T}}\bar{r} = \bar{\eta} = \eta^{-1}$.

Step 4: the law of the rotations. Every $c \in K_s$ commutes with D ($c^*c = 1$ and $c^*Dc = D$), so $c_{[\tau]}$ is block diagonal for the signs and (5) of Lemma 4.1.1 applies to $\Omega_{\mu,0}(1, c_{[\tau]})$: it maps v_P to a scalar times $v_{P'}$, P' obtained from P by a linear substitution of the variables; in particular it maps Fock vectors of homogeneous polynomials of degree d to such vectors. For $c = c_\eta$:

$$\Omega_{\mu,0}(1, (c_\eta)_{[\tau]})v_P = \eta^N v_{P_\eta},$$

where P_η is P after $X_{\tau,k,j} \mapsto X_{\tau,k,j} + (\bar{\eta}-1)r_k \sum_i \bar{r}_i X_{\tau,i,j}$ for $t_j = -1$ and $X_{\tau,k,j} \mapsto X_{\tau,k,j} + (\eta-1)\bar{r}_k \sum_i r_i X_{\tau,i,j}$ for $t_j = 1$, the variables at $v \neq \tau$ being unchanged.

Step 5: no nonzero fixed polynomial. Let P satisfy $\Omega_{\mu,0}(1, c_{[\tau]})v_P = v_P$ for all $c \in C$. Fix z and choose r by Step 2. For $|\eta| = 1$, $c_\eta \in C$ gives $v_P = \eta^N v_{P_\eta}$, hence $P = \eta^N P_\eta$ ($P \mapsto v_P$ is injective: $v_P(x) = P(\zeta(x))e^{-|x|^2/2}$ with ζ bijective). At z the substitution for $t_j = -1$ adds $(\bar{\eta}-1)r_k \sum_i \bar{r}_i z_{\tau,i,j} = 0$; so $P(z) = \eta^N P(z + (\eta-1)z')$, z' having entries $\bar{r}_k \sum_i r_i z_{\tau,i,j}$ at (τ,k,j) with $t_j = 1$ and 0 elsewhere. The polynomial $g(\eta) = \eta^N P(z + (\eta-1)z')$ equals the constant $P(z)$ on the unit circle, hence everywhere, and $g(0) = 0$ as $N \geq 1$. So $P(z) = 0$ for all z, and $P = 0$.

Step 6: averaging over C. C is a closed subgroup of the compact group K_s, hence compact; let dc be its Haar probability measure (Theorem A.5.1). For $d \geq 0$ let W_d be the finite-dimensional space of Fock vectors of homogeneous polynomials of degree d; by Step 4 it is stable under $\rho(c) = \Omega_{\mu,0}(1, c_{[\tau]})$, $c \in C$, and $c \mapsto \rho(c)|_{W_d}$ is continuous by (2) of Lemma 4.1.1. Let $M = \int_C \rho(c)|_{W_d}\, dc \in \operatorname{End}(W_d)$. For $w \in W_d$, $Mw \in W_d$ is fixed by every $\rho(c')$, $c' \in C$ (invariance of dc), so $Mw = 0$ by Step 5. For ℓ as in the statement and $w \in W_d$, $\ell(w) = \int_C \ell(\rho(c)w)\, dc = \ell(Mw) = 0$.

Step 7. Every polynomial is a finite sum of homogeneous ones, so $\ell(v_P) = 0$ for all P; by Lemma 6.3.29 and the continuity of ℓ, $\ell = 0$. □

Lemma 6.3.29. *Let ε be signs on a finite index set ι. For every polynomial $P \in \mathbb{C}[X_i : i \in \iota]$ the Fock vector v_P lies in $\mathcal{F}_\varepsilon$, and the Fock vectors of polynomials are dense in $\mathcal{F}_\varepsilon$ both for the*

norm of $L^1(\nu_\iota)$ and for the norm of its inner product.

Proof. Write $N = \#\iota$, $\zeta(x) = (\zeta_i(x))_i$ (complex conjugation in the coordinates of sign $+1$), so that ζ is a real-linear bijection of $\mathbb{C}^\iota$ preserving $|x|$ and the measure ν_ι, and let $\mathcal{F}_N$ be the Fock space of entire functions of Theorem A.5.11, with norm $\|f\|^2 = \pi^{-N}\int |f(z)|^2 e^{-|z|^2} d\lambda(z)$.

The kernel in the coordinates ζ. For each index i the exponent of $\beta^\infty_\varepsilon(y,x)e^\infty(x-y)$ contributes $\frac{1}{2}\varepsilon_i(\bar{x}_i y_i - \bar{y}_i x_i) - \frac{1}{2}|x_i - y_i|^2$, which is $\bar{x}_i y_i - \frac{1}{2}|x_i|^2 - \frac{1}{2}|y_i|^2$ if $\varepsilon_i = 1$ and $x_i\bar{y}_i - \frac{1}{2}|x_i|^2 - \frac{1}{2}|y_i|^2$ if $\varepsilon_i = -1$; in both cases it is $\zeta_i(x)\overline{\zeta_i(y)} - \frac{1}{2}|x_i|^2 - \frac{1}{2}|y_i|^2$. Hence, for $c\colon \mathbb{C}^\iota \to \mathbb{C}$ and $f(z) = c(\zeta^{-1}z)e^{|z|^2/2}$, after the substitution $w = \zeta(y)$ the reproducing identity of (WR5) reads

$$f(z) = \int f(w)\, e^{-|w|^2}\, e^{\sum_i z_i \bar{w}_i}\, d\nu_\iota(w) \qquad (z \in \mathbb{C}^\iota), \tag{6.45}$$

and $\int |c|^2 d\nu_\iota = \|f\|^2$, $\int |c|\, d\nu_\iota = \pi^{-N}\int |f| e^{-|z|^2/2} d\lambda$.

Polynomials. For $c = v_P$ we have $f = P$. The integral $\pi^{-N}\int |P| e^{-|z|^2/2} d\lambda$ is finite, and (6.45) holds for $f = P$: expanding $e^{\sum z_i\bar{w}_i} = \sum_\alpha z^\alpha \bar{w}^\alpha/\alpha!$ (absolutely convergent, dominated by $e^{|z||w|}$, which is integrable against $|P(w)|e^{-|w|^2}$), the orthogonality of the monomials in (FK1) of Theorem A.5.11, $\pi^{-N}\int w^\beta \bar{w}^\alpha e^{-|w|^2} d\lambda = \alpha!\,\delta_{\alpha\beta}$, gives $\int w^\beta e^{-|w|^2} e^{\sum z_i\bar{w}_i} d\nu_\iota(w) = z^\beta$. So $v_P \in \mathcal{F}_\varepsilon$.

Density in $L^1(\nu_\iota)$. Let K be the integral operator $(Kg)(x) = \int g(y)\beta^\infty_\varepsilon(y,x)e^\infty(x-y)\, d\nu_\iota(y)$; its kernel has modulus $e^{-|x-y|^2/2}$ and $\int e^{-|x|^2/2} d\nu_\iota = 2^N$, so $\|Kg\|_{L^1} \le 2^N\|g\|_{L^1}$. Let $c \in \mathcal{F}_\varepsilon$, so $c = Kc$, and for $R > 0$ let c_R be c times the indicator of $\{|y| \le R\}$; then $\|c - Kc_R\|_{L^1} = \|K(c - c_R)\|_{L^1} \le 2^N\|c - c_R\|_{L^1} \to 0$. By the computation of the kernel, $(Kc_R)(x) = e^{-|x|^2/2}F_R(\zeta(x))$ with $F_R(z) = \int_{|y|\le R} c(y)e^{-|y|^2/2}e^{\sum_i z_i\overline{\zeta_i(y)}} d\nu_\iota(y) = \sum_\alpha a_\alpha z^\alpha$, where $|a_\alpha| \le \|c\|_{L^1} R^{|\alpha|}/\alpha!$ (expand the exponential; the series converges absolutely, uniformly on $|y| \le R$). Let $P_M = \sum_{|\alpha|\le M} a_\alpha z^\alpha$. Since $\pi^{-1}\int_{\mathbb{C}} |z|^k e^{-|z|^2/2} d\lambda = 2^{1+k/2}\Gamma(1 + k/2)$,

$$\|Kc_R - v_{P_M}\|_{L^1} \le \|c\|_{L^1} \sum_{|\alpha|>M} \prod_{i\in\iota} \frac{R^{\alpha_i}\, 2^{1+\alpha_i/2}\,\Gamma(1+\alpha_i/2)}{\alpha_i!},$$

the tail of a convergent series (the one-variable series $\sum_k R^k 2^{k/2}\Gamma(1 + k/2)/k!$ converges, as $\Gamma(1 + k/2)/k! \le 1/\Gamma(1 + k/2)$ up to a factor 2^k). So $v_{P_M} \to Kc_R$, and the Fock vectors of polynomials are dense in L^1 norm.

Density for the inner product. Let $c \in \mathcal{F}_\varepsilon$ and f as above. By (6.45),

$$f(z) = \int c(y) e^{-|y|^2/2} e^{\sum_i z_i\overline{\zeta_i(y)}} d\nu_\iota(y);$$

the integrand is entire in z and bounded by $|c(y)|e^{|z|^2/2}$ (as $|z||y| - |y|^2/2 \le |z|^2/2$), with c integrable, so f is entire, and $\|f\|^2 = \int |c|^2 d\nu_\iota < \infty$ (c is bounded by $\int |c|\, d\nu_\iota$, the kernel having modulus $e^{-|x-y|^2/2} \le 1$, so c is square integrable). Thus $f \in \mathcal{F}_N$, and by (FK1) of Theorem A.5.11 the partial sums P_M of its expansion in the orthonormal basis $z^\alpha/\sqrt{\alpha!}$ converge to f in $\mathcal{F}_N$. The P_M are polynomials, and $\int |c - v_{P_M}|^2 d\nu_\iota = \|f - P_M\|^2 \to 0$. □

Lemma 6.3.30. *Let s be signs on a finite index set n, Y a Banach space and $L\colon \mathcal{M}_s \to Y$ a bounded linear map with $L(v_P \otimes \rho_f(y)v^0) = 0$ for every polynomial P in the variables indexed by $\Phi \times n$ and every $y \in \mathbb{A}^n_{E,f}$. Then $L = 0$.*

Proof. **Step 1: $v_1 \otimes \rho_f(y)v^0 = \rho_f(y)v^0$.** By (3) and (4) of Lemma 6.2.21, $v_1 \otimes \rho_f(y)v^0 = \rho_f(y)(v_1 \otimes v^0) = \rho_f(y)v^0$.

Step 2: translates of the real vacuum are limits of Fock vectors of polynomials. For each coordinate $c = (w, i)$ of sign σ one computes

$$\beta_\varepsilon^\infty(t_0, t)\, v_1(t - t_0) = e^{-|t_{0,c}|^2/2} e^{-|t_c|^2/2} \exp(\zeta_c(t)\eta_c)$$

with $\eta_c = t_{0,c}$ if $\sigma = 1$ and $\eta_c = \bar{t}_{0,c}$ if $\sigma = -1$ (ζ as in (WR5)). Hence $\rho^\infty(t_0)v_1 = v_1(t_0)\exp(\langle\zeta, \eta\rangle)\, e^\infty$ with $\langle\zeta, \eta\rangle = \sum_c \zeta_c\eta_c$, and with $P_K(X) = \sum_{k\le K}(\sum_c \eta_c X_c)^k/k!$ the Fock vectors $v_1(t_0)v_{P_K}$ converge to $\rho^\infty(t_0)v_1$ in $L^1(\nu)$ by dominated convergence (dominant $e^{|\eta|\,|t|}e^{-|t|^2/2}$).

Step 3: conclusion. Let $z \in \mathbb{A}_E^n$; write $z = \mathrm{rv}(t_0)+\mathrm{fv}(y)$ with t_0 the normalized coordinates of z_∞ and $y = \alpha^{-1}z_f$. By (3) of Lemma 6.2.21 and (WD8), $\rho(z)v^0 = c\,\rho(\mathrm{rv}(t_0))\rho_f(y)v^0$ for a scalar c, and by Step 1, (2) of Lemma 6.2.21 and Step 2, with $F = \rho_f(y)v^0$,

$$L(\rho(z)v^0) = c\,L(\rho(\mathrm{rv}(t_0))(v_1 \otimes F)) = c\,L((\rho^\infty(t_0)v_1) \otimes F) = c\,v_1(t_0)\lim_{K\to\infty} L(v_{P_K} \otimes F) = 0,$$

as $w \mapsto L(w \otimes F)$ is bounded on $L^1(\nu)$. By superposition and boundedness,

$$Lh = \int h(z)L(\rho(z)v^0)\, d\mu_n(z) = 0 \qquad \text{for every } h \in \mathcal{M}_s.$$

□

Lemma 6.3.31. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, a, b, n finite index sets, $\sigma\colon b \sqcup a \to n$ a bijection and $s \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$.*

1. *$\Phi^{\mathrm{st}}_{\sigma,s}$ and Ψ^{st}_s are matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_{\mathfrak{c}})$.*
2. *Ψ^{st}_s is locally constant with compact support on $\mathrm{M}_{n\times b}(E_\Sigma)$ and vanishes at every matrix without a left inverse; $\Phi^{\mathrm{st}}_{\sigma,s}$ is locally constant with compact support on $\mathrm{M}_{a\times n}(E_\Sigma)$ and vanishes at every matrix without a right inverse.*

Proof. Write $\chi = \chi_{\mathfrak{c}}$. For $x \in \mathrm{M}_{a\times n}(E_\Sigma)$ let $M(x)$ be the $n \times n$ matrix whose row $\sigma(j)$ is row j of s ($j \in b$) and whose row $\sigma(i)$ is row i of x ($i \in a$), so that $\Phi^{\mathrm{st}}_{\sigma,s}(x) = \chi^{-1}(\det M(x))$ if $M(x)$ is integral and 0 otherwise. As s is integral, $M(x)$ is integral exactly when x is. Recall that χ^{-1} vanishes off $\mathcal{O}_\Sigma^\times$.

The row datum is supported on the rows of inverses. If $\Phi^{\mathrm{st}}_{\sigma,s}(x) \neq 0$, then $M(x)$ is integral with $\det M(x) \in \mathcal{O}_\Sigma^\times$, so $M(x) \in \mathrm{GL}_n(\mathcal{O}_\Sigma)$; for $k = M(x)^{-1} \in \mathrm{GL}_n(\mathcal{O}_\Sigma)$ the rows $\sigma(a)$ of $k^{-1} = M(x)$ form x, that is $x = (k^{-1})_a$.

The column datum is supported on the columns of $\mathrm{GL}_n(\mathcal{O}_\Sigma)$. If $\Psi^{\mathrm{st}}_s(y) \neq 0$, then y is integral and $sy \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$. Fix $w \in \Sigma$ and let $\bar{y}_w$ be the reduction of y_w modulo ϖ_w. Since $(sy)^{-1}s\,y = 1$ with $(sy)^{-1}s$ integral, $\bar{y}_w$ has rank $\#b$, so its columns extend to a basis of k_w^n by $\#a$ standard basis vectors e_j. Let $g_w \in \mathrm{M}_n(\mathcal{O}_{E,w})$ have the columns of y_w in the positions $\sigma(b)$ and these e_j in the positions $\sigma(a)$; its determinant is a unit, being nonzero modulo ϖ_w. Then $k = (g_w)_{w\in\Sigma} \in \mathrm{GL}_n(\mathcal{O}_\Sigma)$ and $y = k_b$ (k_w is the residue field).

The values. Let $k \in \mathrm{GL}_n(\mathcal{O}_\Sigma)$ and $M = M((k^{-1})_a)$, an integral matrix. The rows $\sigma(a)$ of Mk are the rows $\sigma(a)$ of $k^{-1}k = 1$, that is the standard rows $e^{\mathsf{T}}_{\sigma(i)}$, and its rows $\sigma(b)$ are those of sk. Expanding along the standard rows, $\det(Mk)$ is the determinant of the submatrix of Mk on the rows and columns $\sigma(b)$, which is sk_b. Hence $\det M \cdot \det k = \det(sk_b)$ with $\det k \in \mathcal{O}_\Sigma^\times$, and k_b is integral. If $\det(sk_b)$ is a unit, so is $\det M$, and $\chi^{-1}(\det M) = \chi(\det k)\chi^{-1}(\det(sk_b))$ by multiplicativity of χ on $\mathcal{O}_\Sigma^\times$; otherwise both sides vanish. Thus $\Phi^{\mathrm{st}}_{\sigma,s}((k^{-1})_a) = \chi(\det k)\,\Psi^{\mathrm{st}}_s(k_b)$, which completes the proof of (1).

Item (2). The integral matrices form a compact open subset of $\mathrm{M}_{n\times b}(E_\Sigma)$ off which Ψ_s^{st} vanishes. On it, $y \mapsto \det(sy)$ is continuous into $\mathcal{O}_\Sigma$; the units form an open and closed subset of $\mathcal{O}_\Sigma$ (the nonunits are the elements with some component in $\varpi_w \mathcal{O}_{E,w}$), and χ is locally constant on the units by the sidecalc above; so Ψ_s^{st} is locally constant. If $\Psi_s^{\mathrm{st}}(y) \neq 0$, then $(sy)^{-1}s$ is a left inverse of y. The same arguments apply to $x \mapsto \chi^{-1}(\det M(x))$ on the compact open set of integral x; if $\Phi_{\sigma,s}^{\mathrm{st}}(x) \neq 0$, then $M(x)$ is invertible, and the columns $\sigma(a)$ of $M(x)^{-1}$ form a right inverse of x: the rows $\sigma(a)$ of $M(x)M(x)^{-1} = 1$, taken in the columns $\sigma(a)$, read $x\,(M(x)^{-1})_{\cdot,\sigma(a)} = 1$. □

Lemma 6.3.32. *Let W be a space with a point with signs s on n, H a splitting of W over W_0 along p with adelic frame $k_\mathbb{A}$, radical centre elements $z(M)$ and centre coefficients* $\mathrm{coef}(T;\cdot)$*, and let $D, D' \colon \mathrm{G}(s) \to \mathbb{C}$ be continuous and left invariant under Γ_W. Let $T \in \mathrm{M}_p(E)$.*

1. *$z(M)z(M') = z(M+M')$ for adelic M, M', and $z(M) \in \Gamma_W$ for $M \in \mathrm{M}_p(E)$. For every $g \in \mathrm{G}(s)$ the function $M \mapsto D(z(M)g)$ is continuous and $\mathrm{M}_p(E)$-periodic, so* $\mathrm{coef}(T;D)(g)$ *is defined;* $\mathrm{coef}(T;D)$ *is continuous on* $\mathrm{G}(s)$*;* $\mathrm{coef}(T;D+cD') = \mathrm{coef}(T;D) + c\,\mathrm{coef}(T;D')$ *for $c \in \mathbb{C}$; and for $Y \in \mathrm{G}(s)$ the function $D_Y = D(\cdot\, Y)$ satisfies* $\mathrm{coef}(T;D_Y)(g) = \mathrm{coef}(T;D)(gY)$*.*

2. *For every adelic $p \times p$ matrix M and $g \in \mathrm{G}(s)$,*

$$\psi_E(\mathrm{tr}(TM))\,\mathrm{coef}(T;D)(z(M)g) = \mathrm{coef}(T;D)(g).$$

3. *If $g \in \mathrm{G}(s)$ and $c \in \mathrm{GL}_p(\mathbb{A}_E)$ satisfy $gk_\mathbb{A} = k_\mathbb{A} c$, then $g\,z(M) = z(cMc^*)\,g$ for every adelic M.*

4. *If $\gamma \in \Gamma_W$ and $c \in \mathrm{M}_p(E)$ satisfy $\gamma k_\mathbb{A} = k_\mathbb{A} c$, then* $\mathrm{coef}(T;D)(\gamma g) = \mathrm{coef}(c^*Tc;D)(g)$ *for every g; in particular* $\mathrm{coef}(T;D)(\gamma g) = \mathrm{coef}(T;D)(g)$ *when $c = 1$.*

Proof. Write $x = x_W$, $\varepsilon = \varepsilon_s$, and let k be the rational frame of H, so $k_\mathbb{A} = x^{-1}k$ and $\mathrm{pr}_l = k_\mathbb{A}^* \varepsilon = k^* J_W x$ (as $(x^{-1})^*\varepsilon = J_W x$). By (MX1), $\mathrm{pr}_l k_\mathbb{A} = 0$. For $g \in \mathrm{G}(s)$, $\varepsilon g = (g^*)^{-1}\varepsilon$, hence

$$\mathrm{pr}_l\, g = (g^{-1}k_\mathbb{A})^*\varepsilon. \tag{6.46}$$

(1). As $\mathrm{pr}_l k_\mathbb{A} = 0$, $(1 + k_\mathbb{A} X \mathrm{pr}_l)(1 + k_\mathbb{A} X' \mathrm{pr}_l) = 1 + k_\mathbb{A}(X + X')\mathrm{pr}_l$; with $X = M - M^*$ this is $z(M)z(M') = z(M+M')$. For $M \in \mathrm{M}_p(E)$, $x\,z(M)\,x^{-1} = 1 + k(M - M^*)k^* J_W$ has entries in E, and $z(M) \in \mathrm{G}(s)$ (MX2), so $z(M) \in \Gamma_W$. Hence $D(z(M+\gamma)g) = D(z(\gamma)z(M)g) = D(z(M)g)$ for $\gamma \in \mathrm{M}_p(E)$; continuity holds as $(M, g) \mapsto z(M)g$ is continuous. The integrand $\psi_E(\mathrm{tr}(TM))D(z(M)g)$ of (MX3) is then continuous and periodic (ψ_E is trivial on E and $\mathrm{tr}(T\gamma) \in E$), so the coefficient is the integral of a bounded continuous function over a relatively compact Borel fundamental domain Q of $\mathrm{M}_p(E)$ in $\mathrm{M}_p(\mathbb{A}_E)$ (e.g. the product of the domains $P \times \widehat{\mathcal{O}}_E$, P a half-open fundamental parallelepiped of $\mathcal{O}_E$). For g in a compact neighbourhood K_g the integrand is bounded on $\bar{Q} \times K_g$, and dominated convergence gives continuity of $\mathrm{coef}(T;D)$. Linearity is linearity of the integral, and $\mathrm{coef}(T;D_Y)(g) = \int \psi_E(\mathrm{tr}(TM))D(z(M)gY)\,dM = \mathrm{coef}(T;D)(gY)$.

(2). By (1), $\mathrm{coef}(T;D)(z(M_0)g) = \int \psi_E(\mathrm{tr}(TM))D(z(M+M_0)g)\,dM$, and the invariance of the Haar measure of the quotient under translation by M_0 turns this into $\int \psi_E(\mathrm{tr}(T(M - M_0)))D(z(M)g)\,dM = \psi_E(\mathrm{tr}(TM_0))^{-1}\mathrm{coef}(T;D)(g)$.

(3). By (6.46) applied to g^{-1}, $\mathrm{pr}_l g^{-1} = (gk_\mathbb{A})^*\varepsilon = c^*\mathrm{pr}_l$. Hence $g\,z(M)\,g^{-1} = 1 + gk_\mathbb{A}(M - M^*)\mathrm{pr}_l g^{-1} = 1 + k_\mathbb{A} c(M - M^*)c^*\mathrm{pr}_l = z(cMc^*)$.

(4). Since γ is invertible, so is c. The map $\phi(N) = cNc^*$ is a continuous additive automorphism of $\mathrm{M}_p(\mathbb{A}_E)$ with $\phi(\mathrm{M}_p(E)) = \mathrm{M}_p(E)$; it induces an automorphism of the compact group $\mathrm{M}_p(\mathbb{A}_E)/\mathrm{M}_p(E)$, which preserves its Haar probability measure by uniqueness. By (3) and the invariance of D, $D(z(cNc^*)\gamma g) = D(\gamma z(N) g) = D(z(N)g)$, and $\mathrm{tr}(TcNc^*) = \mathrm{tr}(c^*TcN)$. Substituting $M = \phi(N)$ in (MX3),

$$\mathrm{coef}(T; D)(\gamma g) = \int \psi_E\big(\mathrm{tr}(c^*TcN)\big) D(z(N)g)\, dN = \mathrm{coef}(c^*Tc; D)(g).$$

□

Proposition 6.3.33. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, X a space with signs r on m, W_1 a space with signs s on n, W a space, b an index set and $(\mathcal{L}, \mathcal{D})$ an equivariant lift for $(\mathfrak{c}, X, b)$. Let D be a base-adapted splitting of X over W_1 along b and D_1 a base-adapted splitting of W_1 over W along a one-element set; radical elements, Levi elements and centre coefficients are those of D. Let $\Psi_0 = \Psi^{\mathrm{st}}_{(\mathrm{pr}_l)_\Sigma}$ be the standard column datum, for $\chi_{\mathfrak{c}}$, of the matrix $(\mathrm{pr}_l)_\Sigma \in \mathrm{M}_{b\times m}(\mathcal{O}_\Sigma)$ of the coordinate pr_l of D, and assume $\Psi_0 \in \mathcal{L}$. Let V' be a space with signs t' on b, and let $\kappa_\alpha \in \mathbb{A}_E^\times$ be the idele with components κ_v at $v \in \Phi$ and finite part α. Assume*

(VL) (vanishing at self-dual lattices) $\mathrm{coef}(\jmath T; \mathcal{D}\Psi_0)\big(\mathrm{rad}(c,z)\,\mathrm{lev}(q,g)\big) = 0$ *for all $T \in \mathrm{M}_b(E)$, $c \in \mathrm{M}_{n\times b}(\mathbb{A}_E)$, $z \in \mathrm{M}_b(\mathbb{A}_E)$, $q \in \mathrm{GL}_b(\mathbb{A}_E)$ and $g \in \mathrm{G}(s)$ such that either*

- *(a) $T = J_{V'}$ and $q = \kappa_\alpha\, x_{V'} Y$ for some $Y \in \mathrm{GL}_b(\mathbb{A}_E)$ for which there is $k \in \mathrm{GL}_b(\widehat{\mathcal{O}}_E)$ with $(Y_f k)^*(Y_f k) = 1$; or*
- *(b) $\det T \neq 0$ and T, read as an adelic matrix, is not represented by the signs t'.*

Then $\mathcal{D}\Psi = 0$ for every locally constant function Ψ on $\mathrm{M}_{m\times b}(E_\Sigma)$ for which there are an index set a, a bijection $\sigma\colon b \sqcup a \to m$ and a function Φ on $\mathrm{M}_{a\times m}(E_\Sigma)$ such that Φ and Ψ are matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_{\mathfrak{c}})$.

Proof. Write $f = \mathcal{D}\Psi_0$, a continuous, left Γ_X-invariant function on $\mathrm{G}(r)$ ((XD11)(b)), and $(1, g)$ for the point with infinite component 1 and finite component g.

Step 1: reduction. By Lemma 6.3.34 it suffices to show $\mathrm{coef}(T; f)((1, g_0)) = 0$ for every $T \in \mathrm{M}_b(E)$ with $T^* = -T$ and $\tau = ((\jmath\alpha\bar{\alpha})^{-1}T)_\Sigma \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$ and every $g_0 \in G_f(m)$ with components 1 at the places of Σ. Fix such T and g_0; $\det T \neq 0$ since $\det \tau$ is a unit.

Step 2: a line and the remaining planes. Write $D = (k, l, i)$ and $D_1 = (k_1, l_1, i_1)$, with W on the index set n_W. Let $W_0 = \mathbb{H}_b \oplus W$, with index set $(b \sqcup b) \sqcup n_W$ and point $x_{W_0} = \mathrm{diag}(x_{\mathbb{H}_b}, x_W)$, and let B be its tautological splitting over W along b: l_B, k_B are the identity blocks of the first and second copy of b, so that k_B is the block of signs -1. Put

$$A = (ik_1,\ il_1,\ (l \mid k \mid ii_1)),$$

the embedding sending the first copy of b to l, the second to k and n_W to ii_1. The relations (MX1) of D and D_1 give $(ik_1)^* J_X (ik_1) = k_1^* J_{W_1} k_1 = 0$, likewise for il_1, $(il_1)^* J_X (ik_1) = 1$, $(l \mid k \mid ii_1)^* J_X (l \mid k \mid ii_1) = \mathrm{diag}(\begin{pmatrix} 0 & 1 \\ 1 & 0 \end{pmatrix}, J_W) = J_{W_0}$, $(l \mid k \mid ii_1)^* J_X\, ik_1 = (0; 0; i_1^* J_{W_1} k_1) = 0$ and likewise for il_1; and $\#m = 2\#b + \#n = (2\#b + \#n_W) + 2$. So A is a splitting of X over W_0 along a one-element set, and $i_A k_B = k = k_D$. Its matrix of adelic frames is, up to the order of the columns, $(l_{D,\mathbb{A}} \mid k_{D,\mathbb{A}} \mid i_{D,\mathbb{A}}) \cdot \mathrm{diag}\big(x_{\mathbb{H}_b}, (l_{1,\mathbb{A}} \mid k_{1,\mathbb{A}} \mid i_{1,\mathbb{A}})\big)$ (as $x_X^{-1} i x_{W_1} = i_{D,\mathbb{A}}$ and $x_X^{-1}(l \mid k) = (l_{D,\mathbb{A}} \mid k_{D,\mathbb{A}})$); both factors are unitary at the infinite places (D, D_1 are base-adapted, and $x_{\mathbb{H}_b}$ is $\frac{1}{\sqrt{2}}\begin{pmatrix} 1 & -1 \\ 1 & 1 \end{pmatrix}$ there) and integral at the finite places (the finite component

of $x_{\mathbb{H}_b}$ is $\begin{pmatrix} 1 & -c \\ c_0 & c\bar{c}_0 \end{pmatrix}$). So A is base-adapted. The matrix of adelic frames of B is $\mathrm{diag}(x_{\mathbb{H}_b}^{-1}, 1)$, unitary at the infinite places and integral at the finite places, since $\det x_{\mathbb{H}_b}$ has finite part $(c\bar{c}_0 + cc_0)^{\#b} = c^{\#b}$, a unit ($c_0 + \bar{c}_0 = 1$). So B is base-adapted.

Step 3: Freitag's lemma. Let S be the set of finite places w with $w \notin \Sigma \cup \bar{\Sigma}$ (so $S = \bar{S}$), $\mathrm{e} = \mathrm{e}_{S \cup \bar{S}}$, $U = \bar{\Sigma}$ (nonempty) and H the frame stabiliser of D off S. We apply (2) of Proposition 6.3.36 to X, A, B, D, the index set b, T, S, U and f. The function f is continuous and left Γ_X-invariant, and right invariant under every $k \in \mathbf{K}_0(m)$ with components 1 at the places outside S, i.e. at $\Sigma \cup \bar{\Sigma}$, by (XD11)(d). The partial means of f are invariant under the A-shears, resp. the $\bar{A}$-shears, for $\bar{\Sigma}$ at every point of H by Lemma 6.3.47 (with $k_D = i_A k_B$ and $\Psi_0 \in \mathcal{L}$).

It remains to check the last hypothesis. Let $x \in \mathrm{G}(r)$ and $\gamma \in \mathrm{M}_b(\mathbb{A}_E)$ with $x k_{D,\mathbb{A}} = k_{D,\mathbb{A}} q_0$, $q_0 = \mathrm{e}\gamma + (1 - \mathrm{e})$, and $T\{\gamma\}$ unimodular on $S \cup \bar{S}$. The matrix q_0 is invertible: by unitarity of x and $l_{D,\mathbb{A}}^* \varepsilon_r k_{D,\mathbb{A}} = 1$, $(x l_{D,\mathbb{A}})^* \varepsilon_r k_{D,\mathbb{A}} q_0 = 1$, so q_0 has a left inverse over the commutative ring $\mathbb{A}_E$. By (3) of Lemma 6.3.48, $x = \mathrm{rad}(c, z)\,\mathrm{lev}(q_0, g)$ for some adelic c, z and some $g \in \mathrm{G}(s)$. Put $\beta = \jmath^{-1} T \in \mathrm{M}_b(E)$, $\det \beta \neq 0$, and $q = \kappa_\alpha^{-1} q_0$. Since $\delta_\jmath = \jmath \kappa_\alpha \bar{\kappa}_\alpha$ ((MX9): components $\jmath_v \kappa_v^2$ at $v \in \Phi$, finite part $\jmath\alpha\bar{\alpha}$),

$$q^* \beta q = \delta_\jmath^{-1} q_0^* T q_0 = T\{q_0\}.$$

Its finite part is unimodular at every finite place: at $w \in S$ it is the component of $T\{\gamma\}$ ($q_0 = \gamma$ at $S = \bar{S}$); at $w \in \Sigma$ it is τ_w ($q_0 = 1$ at $\Sigma \cup \bar{\Sigma}$); at $w \in \bar{\Sigma}$ it is the component of $\delta_\jmath^{-1} T$, which is hermitian ($T^* = -T$, $\bar{\jmath} = -\jmath$), hence the conjugate transpose of its component $\tau_{\bar{w}}$ at $\bar{w} \in \Sigma$. And $T\{q_0\}$ is hermitian for the same reason. By (1) of Lemma 3.2.6 (E contains a primitive 5040th root of unity) there is $k \in \mathrm{GL}_b(\widehat{\mathcal{O}}_E)$ with $k^*(q^* \beta q)_f k = 1$. The hypothesis (VL) is the hypothesis of Lemma 6.3.49 for f, D, V'; that lemma gives

$$\mathrm{coef}(T; f)(x) = \mathrm{coef}(\jmath\beta; f)\big(\mathrm{rad}(c, z)\,\mathrm{lev}(\kappa_\alpha q, g)\big) = 0.$$

So Proposition 6.3.36 gives $\mathrm{coef}(T; f) = 0$ on H.

Step 4: conclusion. The point $(1, g_0)$ lies in H: its infinite component is 1, its components at Σ are 1, and so are those at $\bar{\Sigma}$, since $g_0^* g_0 = 1$ and the component of g_0^* at $\bar{w}$ is the conjugate transpose of the component of g_0 at w. So $\mathrm{coef}(T; f)((1, g_0)) = 0$, and Step 1 concludes. □

Lemma 6.3.34. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, X a space with a point with signs r on m, b an index set, $(\mathcal{L}, \mathcal{D})$ an equivariant lift for $(\mathfrak{c}, X, b)$, and D a base-adapted splitting of X over a space with a point along b, with coordinate pr_l and centre coefficients* coef*. Assume $\Psi_0 = \Psi^{\mathrm{st}}_{(\mathrm{pr}_l)_\Sigma} \in \mathcal{L}$ and*

$$\mathrm{coef}(T; \mathcal{D}\Psi_0)((1, g)) = 0$$

for every $T \in \mathrm{M}_b(E)$ with $T^* = -T$ and $\big((\jmath\alpha\bar{\alpha})^{-1} T\big)_\Sigma \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$ and every $g \in G_f(m)$ whose components at the places of Σ are 1. Then $\mathcal{D}\Psi = 0$ for every locally constant function Ψ on $\mathrm{M}_{m \times b}(E_\Sigma)$ for which there are an index set a, a bijection $\sigma \colon b \sqcup a \to m$ and a function Φ such that Φ and Ψ are matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_\mathfrak{c})$.

Proof. Let $k_\mathbb{A}, l_\mathbb{A}, i_\mathbb{A}$ be the adelic frames of D and $\mathrm{pr}_k, \mathrm{pr}_l, \mathrm{pr}_i$ its coordinates, $\varepsilon = \varepsilon_r$, and $\psi_0(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$ for finite adeles t; a matrix z over E_Σ is read as the finite adelic matrix $\tilde{z}$ with components z at Σ and 0 elsewhere.

Step 1: the frame at Σ. As D is base-adapted, $(l_\mathbb{A} \mid k_\mathbb{A} \mid i_\mathbb{A})$ has integral finite part; its inverse is the matrix of the rows $\mathrm{pr}_l = k_\mathbb{A}^* \varepsilon$, $\mathrm{pr}_k = l_\mathbb{A}^* \varepsilon$, $\mathrm{pr}_i = \varepsilon_{s_0} i_\mathbb{A}^* \varepsilon$ ((MX1)), whose finite parts are conjugate transposes of integral matrices, hence integral. So $Q_\Sigma = (l_\mathbb{A} \mid k_\mathbb{A} \mid i_\mathbb{A})_\Sigma \in$

$\mathrm{GL}_m(\mathcal{O}_\Sigma)$; take $K = (l_\mathbb{A})_\Sigma$ and $L = (k_\mathbb{A})_\Sigma$, two disjoint blocks of $\#b$ columns of Q_Σ, so that the corresponding rows of Q_Σ^{-1} are $K' = (\mathrm{pr}_l)_\Sigma$ and $L' = (\mathrm{pr}_k)_\Sigma$, and $\Psi_0 = \Psi^{\mathrm{st}}_{K'}$. For $z \in \mathrm{M}_b(E_\Sigma)$ put $S_z(y) = \Psi_0(y + LzK'y)$.

Step 2: the additive character. By Lemma 4.1.3, $\widehat{\mathcal{O}}_E$ is its own annihilator under $(u,v) \mapsto \psi_0(\bar{u}v)$. Hence $e(t) = \psi_0(\tilde{t})$ is a continuous additive character of E_Σ with conductor $\mathcal{O}_\Sigma$: if $t \in \mathcal{O}_\Sigma$ then $\tilde{t}\mathcal{O}_\Sigma \subseteq \widehat{\mathcal{O}}_E$ and $e(t\mathcal{O}_\Sigma) = 1$; if $e(t\mathcal{O}_\Sigma) = 1$ then $\psi_0(\tilde{t}v) = \psi_0(\tilde{t}v_\Sigma) = 1$ for every $v \in \widehat{\mathcal{O}}_E$ ($\tilde{t}$ vanishes off Σ), so $\bar{\tilde{t}}$ annihilates $\widehat{\mathcal{O}}_E$, hence is integral, and $t \in \mathcal{O}_\Sigma$.

Step 3: the coefficient functionals are admissible. Let $T \in \mathrm{M}_b(E)$ and $g \in G_f(m)$ with components 1 at Σ, and $x = (1,g)$; then $x_\Sigma = 1$, $(x^{-1}k_\mathbb{A})_\Sigma = L$ and $(\mathrm{pr}_l x)_\Sigma = K'$. By (2) of Lemma 6.3.14 there is a linear functional $\Lambda_{T,g}$ with $\Lambda_{T,g}(\Psi) = \mathrm{coef}(T; \mathcal{D}\Psi)(x)$ for $\Psi \in \mathcal{L}$; moreover $S_z \in \mathcal{L}$ for every z (the functions Ψ_z there, for $\Psi = \Psi_0$), and

$$\Lambda_{T,g}(S_z) = \psi_{E,f}\big(\mathrm{tr}(T\tilde{z})\big)\Lambda_{T,g}(S_0) = e\big(\mathrm{tr}(\tau z)\big)\Lambda_{T,g}(S_0), \qquad \tau = \big((\jmath\alpha\bar{\alpha})^{-1}T\big)_\Sigma,$$

since $\psi_{E,f}(\mathrm{tr}(T\tilde{z})) = \psi_0(\mathrm{tr}((\jmath\alpha\bar{\alpha})^{-1}T\tilde{z}))$ and $\tilde{z}$ vanishes off Σ. If $T^* = -T$ and $\tau \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$, then $\Lambda_{T,g}(S_0) = \mathrm{coef}(T; \mathcal{D}\Psi_0)(x) = 0$ by hypothesis. So for skew-hermitian T the restriction of $\Lambda_{T,g}$ to $\mathcal{L}$ is admissible in the sense of Lemma 6.3.35 (for e, Q_Σ, K, L).

Step 4: functions killed by the admissible functionals. Let $f \in \mathcal{L}$ be killed by every admissible functional on $\mathcal{L}$; we show $\mathcal{D}f = 0$. By Step 3, $\mathrm{coef}(T; \mathcal{D}f)((1,g)) = 0$ for every skew-hermitian $T \in \mathrm{M}_b(E)$ and every g as there. Fix such a g and let $\varphi(M) = \mathcal{D}f(z(M)(1,g))$ for adelic $b \times b$ matrices M; φ is continuous and $\mathrm{M}_b(E)$-periodic ((1) of Lemma 6.3.32; $\mathcal{D}f$ is continuous and left Γ_X-invariant by (XD11)(b)). Its Fourier coefficient at the character $M \mapsto \psi_E(\mathrm{tr}(TM))$ is $\mathrm{coef}(T; \mathcal{D}f)((1,g))$. These vanish also for T not skew-hermitian: as $z(M) = 1 + k_\mathbb{A}(M - M^*)\mathrm{pr}_l$ depends only on $M - M^*$, $\varphi(M+H) = \varphi(M)$ for adelic $H = H^*$, so the coefficient at T equals $\psi_E(\mathrm{tr}(TH))$ times itself (translation invariance of the measure); if it is nonzero, then $\psi_E(\mathrm{tr}(T(Z+Z^*))) = 1$ for all adelic Z, and since $\psi_E(\bar{y}) = \psi_E(y)$ ((WD4) of Definition 3.2.12: $\mathrm{Re}\,\bar{y}_v = \mathrm{Re}\,y_v$, $\mathrm{Tr}_{E/\mathbb{Q}}\,\bar{a} = \mathrm{Tr}_{E/\mathbb{Q}}\,a$), $\psi_E(\mathrm{tr}(TZ^*)) = \psi_E(\mathrm{tr}(T^*Z))$ and $\psi_E(\mathrm{tr}((T+T^*)Z)) = 1$ for all Z, which forces $T + T^* = 0$ by (a) of Theorem A.5.2 applied to each entry. By (a) of Theorem A.5.2 (on the b^2 entries), the characters $M \mapsto \psi_E(\mathrm{tr}(TM))$, $T \in \mathrm{M}_b(E)$, are all the characters of the compact group $\mathrm{M}_b(\mathbb{A}_E)/\mathrm{M}_b(E)$; a continuous function on a compact abelian group whose Fourier coefficients all vanish is 0 (the characters span a dense subalgebra of the continuous functions, by the Stone–Weierstrass theorem). So $\varphi = 0$, in particular $\mathcal{D}f((1,g)) = 0$. By Lemma 4.2.64 (for $R = \Sigma$) the products $\gamma(1,g)$, $\gamma \in \Gamma_X$, g with components 1 at $\Sigma \cup \bar{\Sigma}$, are dense in $\mathrm{G}(r)$; $\mathcal{D}f$ vanishes on them by left invariance and is continuous, so $\mathcal{D}f = 0$.

Step 5: conclusion. Let $\mathcal{P} = \{\Psi \in \mathcal{L} : \mathcal{D}\Psi = 0\}$. It is a linear space of locally constant, compactly supported functions ((XD11)(a)), and $y \mapsto \Psi(hy)$ lies in $\mathcal{P}$ for $\Psi \in \mathcal{P}$, $h \in \mathrm{GL}_m(E_\Sigma)$ ((3) of Lemma 6.3.14). The space $\mathcal{M} = \mathcal{L}$ contains every S_z (Step 3), and $\mathcal{P}$ contains every $f \in \mathcal{L}$ killed by the admissible functionals (Step 4). The character $\chi_\mathfrak{c}$ has the form required in Lemma 6.3.35: on $\mathcal{O}_\Sigma^\times$, $\chi_\mathfrak{c}(u) = \nu(u/\bar{u}) = \prod_{w\in\Sigma}\psi_w(u_w \bmod w)$ with $\psi_w \neq 1$, ψ the tame part of ν (the idele $u/\bar{u}$ has components u_w at $w \in \Sigma$, $\bar{u}_w^{-1}$ at $\bar{w} \notin \Sigma$, where $\psi_{\bar{w}} = 1$, and 1 elsewhere). By Lemma 6.3.35, $\mathcal{P}$ contains every locally constant Ψ matched over $\mathcal{O}_\Sigma$ for $(\sigma, \chi_\mathfrak{c})$ with some Φ; for these, $\mathcal{D}\Psi = 0$. □

Lemma 6.3.35. *Let Σ be a nonempty finite set of finite places of E and b, n finite sets. Let $\chi\colon \mathcal{O}_\Sigma^\times \to \mathbb{C}^\times$ be a character of the form $\chi(u) = \prod_{w\in\Sigma}\chi_w(u_w \bmod \varpi_w)$ with nontrivial characters χ_w of $k_w^\times$. For $s \in \mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$ let Ψ^{st}_s be the standard column datum of (XD10) formed with χ in place of the semilocal character: $\Psi^{\mathrm{st}}_s(y) = \chi(\det(sy))^{-1}$ if $y \in \mathrm{M}_{n\times b}(\mathcal{O}_\Sigma)$ and $\det(sy) \in \mathcal{O}_\Sigma^\times$, and $\Psi^{\mathrm{st}}_s(y) = 0$ otherwise. Let $e\colon E_\Sigma \to \mathbb{C}^\times$ be a continuous additive character with conductor*

$\mathcal{O}_\Sigma$: for $t \in E_\Sigma$, $e(t\mathcal{O}_\Sigma) = 1$ if and only if $t \in \mathcal{O}_\Sigma$. Let $k \in \mathrm{GL}_n(\mathcal{O}_\Sigma)$, let K and L be the $n \times b$ matrices formed by two disjoint sets of $|b|$ columns of k, and K', L' the $b \times n$ matrices formed by the corresponding rows of k^{-1}. For $z \in \mathrm{M}_b(E_\Sigma)$ let $S_z(y) = \Psi^{\mathrm{st}}_{K'}(y + LzK'y)$.

Let $\mathcal{P}$ be a linear space of locally constant, compactly supported functions on $\mathrm{M}_{n\times b}(E_\Sigma)$ such that $y \mapsto f(gy)$ lies in $\mathcal{P}$ for all $f \in \mathcal{P}$ and $g \in \mathrm{GL}_n(E_\Sigma)$. Let $\mathcal{M}$ be a linear space of functions on $\mathrm{M}_{n\times b}(E_\Sigma)$ that contains every S_z, and assume that $\mathcal{P}$ contains every $f \in \mathcal{M}$ with $\Lambda(f) = 0$ for every linear functional Λ on $\mathcal{M}$ that is admissible*, that is, for which there is $T \in \mathrm{M}_b(E_\Sigma)$ with*

$$\Lambda(S_z) = e(\mathrm{tr}(Tz))\,\Lambda(S_0) \quad (z \in \mathrm{M}_b(E_\Sigma)) \qquad \text{and} \qquad \Lambda(S_0) = 0 \ \text{ if } T \in \mathrm{GL}_b(\mathcal{O}_\Sigma).$$

Then $\mathcal{P}$ contains every locally constant function Ψ on $\mathrm{M}_{n\times b}(E_\Sigma)$ that, for some finite set a, bijection $\sigma\colon b \sqcup a \to n$ and function Φ, is matched with Φ over $\mathcal{O}_\Sigma$ for (σ, χ) in the sense of (XD6) (the words of (XD6) over the ring $\mathcal{O}_\Sigma$, with this χ).

Proof. Let $\bar\chi$ be the function on $\bar R$ equal to $\prod_w \chi_w(t_w)^{-1}$ at units $t = (t_w)_w$ and to 0 at non-units. Then $\bar\chi$ is multiplicative, $\bar\chi(\bar u) = \chi(u)^{-1}$ for $u \in \mathcal{O}^\times$, and $\bar\chi(\bar t) = 0$ for $t \in \mathcal{O} \smallsetminus \mathcal{O}^\times$. Consequently, for $s \in \mathrm{M}_{b\times n}(\mathcal{O})$ and integral y, $\Psi^{\mathrm{st}}_s(y) = \bar\chi(\overline{\det(sy)})$. The block relations are $K'K = L'L = 1$ and $K'L = L'K = 0$, and K, L, K', L' are integral.

Step 1: two properties of a matched Ψ. Let Ψ, Φ, a, σ be as in the statement. For $m \in \mathrm{GL}_n(\mathcal{O})$ and $u \in \mathrm{GL}_b(\mathcal{O})$ let $m' \in \mathrm{GL}_n(\mathcal{O})$ be m times the matrix acting as u on the coordinates $\sigma(b)$ and as the identity on $\sigma(a)$; then $m'_b = m_b u$, the rows $\sigma(a)$ of m'^{-1} and of m^{-1} coincide, and $\det m' = \det m \det u$. The matching identity at m and at m' gives $\chi(\det u)\Psi(m_b u) = \Psi(m_b)$. As Ψ vanishes off the set Prim_b of the m_b, which is stable under right multiplication by $\mathrm{GL}_b(\mathcal{O})$,

$$\Psi(yu) = \chi(\det u)^{-1}\Psi(y) \qquad (u \in \mathrm{GL}_b(\mathcal{O}),\ y \in \mathrm{M}_{n\times b}(E_\Sigma)). \tag{a}$$

Since Prim_b is compact, Ψ is locally constant with compact support, so there is $c \geq 1$ with $\Psi(y + \varpi^c t) = \Psi(y)$ for all y and all integral t.

Step 2: a multiple of a standard datum in $\mathcal{P}$ forces $\Psi \in \mathcal{P}$. Let $p \in \mathcal{P}$, $s \in \mathrm{M}_{b\times n}(\mathcal{O})$, $x \in \mathrm{M}_{n\times b}(\mathcal{O})$ and $r\colon \mathrm{M}_{n\times b}(E_\Sigma) \to \mathbb{Z}_{\geq 0}$ with $sx = 1$, $p = r \cdot \Psi^{\mathrm{st}}_s$ and $r(x) \neq 0$. We show $\Psi \in \mathcal{P}$. Put $Q = xs$, so $Q^2 = Q$, and $d = \varpi^{-c}(1-Q) + Q \in \mathrm{GL}_n(E_\Sigma)$, with inverse $\varpi^c(1-Q) + Q$; then $dx = x$ and $sd = s$.

First, for $h \in \mathrm{GL}_n(\mathcal{O})$ and all y,

$$\Psi(h^{-1}x)\,p(dhy) = |p(dhy)|\,\Psi(y). \tag{b}$$

If $p(dhy) = 0$ both sides vanish. Otherwise $z = dhy$ is integral and $g' = sz$ has a unit determinant, so $g' \in \mathrm{GL}_b(\mathcal{O})$, and $g' = sdhy = shy$. Then $z - xg' = \varpi^{-c}(1-Q)hy$, so $y = \varpi^c h^{-1}(z - xg') + h^{-1}xg'$ with $h^{-1}(z - xg')$ integral. By Step 1 and (a), $\Psi(y) = \Psi(h^{-1}xg') = \chi(\det g')^{-1}\Psi(h^{-1}x)$. Moreover $p(z) = r(z)\chi(\det g')^{-1}$, and $|\chi(\det g')| = 1$ as χ has finite image. Hence both sides of (b) equal $r(z)\Psi(y)$.

Let $F_h(y) = \Psi(h^{-1}x)\,p(dhy)$; each F_h lies in $\mathcal{P}$ by the stability of $\mathcal{P}$. The function $h \mapsto F_h$ is constant on the cosets of an open normal subgroup H of $\mathrm{GL}_n(\mathcal{O})$: $h \mapsto \Psi(h^{-1}x)$ is locally constant; p is invariant under translation by $\varpi^N \mathrm{M}_{n\times b}(\mathcal{O})$ for some N and vanishes off a compact set C_p, the y with $dhy \in C_p$ for some $h \in \mathrm{GL}_n(\mathcal{O})$ form a bounded set B, and for $h' = hh_1$ with $h_1 \equiv 1 \bmod \varpi^{N'}$ and N' large, $dh'y - dhy = dh(h_1 - 1)y \in \varpi^N \mathrm{M}_{n\times b}(\mathcal{O})$ for $y \in B$, while for $y \notin B$ both values vanish. Hence

$$G'(y) = \int_{\mathrm{GL}_n(\mathcal{O})} F_h(y)\,dh$$

is a finite linear combination of the F_h and lies in $\mathcal{P}$. By (b), $G'(y) = I(y)\Psi(y)$ with $I(y) = \int_{\mathrm{GL}_n(\mathcal{O})} |p(dhy)|\, dh$. The matrix x is j_b for some $j \in \mathrm{GL}_n(\mathcal{O})$: $\mathcal{O}^n = x\mathcal{O}^b \oplus (\ker s \cap \mathcal{O}^n)$ (write $v = xsv + (v - xsv)$), the second summand is a direct summand of a free module over the product of discrete valuation rings $\mathcal{O}$, hence free of rank $|n| - |b|$ componentwise, and j has the columns of x at $\sigma(b)$ and a basis of the second summand elsewhere. If $\Psi(y) \neq 0$ then $y = l_b$ with $l \in \mathrm{GL}_n(\mathcal{O})$, and the substitution $h \mapsto hjl^{-1}$, which preserves the Haar measure, gives $I(y) = \int |p(dhjl^{-1}l_b)|\, dh = I(j_b) = I(x)$, as $jl^{-1}l_b = j_b$. So $G' = I(x)\Psi$. Finally $I(x) > 0$: the integrand is continuous and non-negative, and at $h = 1$ it is $|p(x)| = r(x)\,|\chi(\det sx)|^{-1} = r(x) \neq 0$. Therefore $\Psi = I(x)^{-1}G' \in \mathcal{P}$.

Step 3: a Gauss sum over $\bar{R}$. Let $\bar{e}(\bar{t}) = e(\varpi^{-1}t)$ for $t \in \mathcal{O}$; it is well defined, e being trivial on $\mathcal{O}$, and is an additive character of $\bar{R}$. For $\bar{T} \in \mathrm{M}_b(\bar{R})$ put

$$\Gamma(\bar{T}) = \sum_{\bar{r} \in \mathrm{M}_b(\bar{R})} \bar{\chi}(\det \bar{r})\, \bar{e}(\mathrm{tr}(\bar{T}\bar{r})).$$

We show $\Gamma(\bar{T}) = 0$ if $\det \bar{T}$ is not a unit. Write $\bar{e}(t) = \prod_w \bar{e}_w(t_w)$ with $\bar{e}_w(t_w) = \bar{e}$ of the element with component t_w at w and 0 elsewhere, and $\bar{\chi} = \prod_w \bar{\chi}_w$ with $\bar{\chi}_w$ equal to χ_w^{-1} on $k_w^\times$ and 0 at 0. Then $\Gamma(\bar{T}) = \prod_w \Gamma_w(\bar{T}_w)$ with $\Gamma_w(\bar{T}_w) = \sum_{\bar{r} \in \mathrm{M}_b(k_w)} \bar{\chi}_w(\det \bar{r})\bar{e}_w(\mathrm{tr}(\bar{T}_w\bar{r}))$. If $\det \bar{T}$ is not a unit, some $\bar{T}_w$ is singular; choose $0 \neq v \in k_w^b$ with $\bar{T}_w v = 0$, $\gamma \in k_w^\times$ with $\chi_w(\gamma) \neq 1$, and $f \in k_w^b$ with $f^T v = \gamma^{-1} - 1$. Then $u = 1 + vf^T$ has $\det u = \gamma^{-1}$ and $\bar{T}_w u = \bar{T}_w$, and the bijection $\bar{r} \mapsto u\bar{r}$ of $\mathrm{M}_b(k_w)$ gives $\Gamma_w(\bar{T}_w) = \bar{\chi}_w(\gamma^{-1})\Gamma_w(\bar{T}_w) = \chi_w(\gamma)\Gamma_w(\bar{T}_w)$, so $\Gamma_w(\bar{T}_w) = 0$.

Step 4: the Gauss sum of shears lies in $\mathcal{P}$. For $\bar{r} \in \mathrm{M}_b(\bar{R})$ choose an integral lift $l(\bar{r})$, with $l(1) = 1$, and put

$$\Gamma_0 = \sum_{\bar{r} \in \mathrm{M}_b(\bar{R})} \bar{\chi}(\det \bar{r})\, S_{\varpi^{-1}l(\bar{r})} \in \mathcal{M}.$$

Let Λ be admissible, with matrix T; we show $\Lambda(\Gamma_0) = 0$. Suppose not. Then $\Lambda(S_0) \neq 0$. For integral z we have $S_z = S_0$: $K'(y + LzK'y) = K'y$ since $K'L = 0$, and $y + LzK'y$ is integral exactly when y is. So $e(\mathrm{tr}(Tz)) = 1$ for every integral z; taking for z an element $\alpha \in \mathcal{O}$ at the place (j, i) and 0 elsewhere gives $e(\alpha T_{ij}) = 1$ for all $\alpha \in \mathcal{O}$, so $T_{ij} \in \mathcal{O}$ by the conductor property, and T is integral. Then $e(\mathrm{tr}(T\varpi^{-1}l(\bar{r}))) = \bar{e}(\mathrm{tr}(\bar{T}\bar{r}))$, and $\Lambda(\Gamma_0) = \Gamma(\bar{T})\Lambda(S_0)$. By Step 3, $\det \bar{T}$ is a unit, so $T \in \mathrm{GL}_b(\mathcal{O})$, and admissibility gives $\Lambda(S_0) = 0$, a contradiction. Hence every admissible Λ kills Γ_0, and $\Gamma_0 \in \mathcal{P}$ by hypothesis.

Step 5: a translate of Γ_0 is a multiple of a standard datum. Let $g = -\varpi^{-1} \cdot 1_n$ and $G(y) = \Gamma_0(gy)$, which lies in $\mathcal{P}$. First, for integral x' and integral $\rho \in \mathrm{M}_b(\mathcal{O})$,

$$\Psi^{\mathrm{st}}_{L'}(L\rho K'x' - \varpi x') = \bar{\chi}(\det \bar{\rho})\, \Psi^{\mathrm{st}}_{K'}(x'). \tag{c}$$

Indeed the argument $y' = L\rho K'x' - \varpi x'$ is integral and $L'y' = \rho K'x' - \varpi L'x'$, so $\overline{L'y'} = \bar{\rho}\,\overline{K'x'}$; take $\bar{\chi} \circ \det$. Now fix y and $\bar{r}$, and put $x' = gy + L\varpi^{-1}l(\bar{r})K'gy$; the term of $\bar{r}$ in $G(y)$ is $\bar{\chi}(\det \bar{r})\Psi^{\mathrm{st}}_{K'}(x')$. If it is non-zero, x' is integral. Since $K'L = 0$, $K'x' = K'gy = -\varpi^{-1}K'y$, and

$$L\,l(\bar{r})K'x' - \varpi x' = -\varpi^{-1}L\,l(\bar{r})K'y + y + \varpi^{-1}L\,l(\bar{r})K'y = y,$$

so by (c) the term equals $\Psi^{\mathrm{st}}_{L'}(y)$. Hence $G = r \cdot \Psi^{\mathrm{st}}_{L'}$, where $r(y)$ is the number of $\bar{r}$ whose term at y is non-zero. Let $x = L - \varpi K$: it is integral and $L'x = L'L - \varpi L'K = 1$. At $y = x$ the term of $\bar{r} = 1$ has $gx = -\varpi^{-1}L + K$, $K'gx = 1$ and $x' = -\varpi^{-1}L + K + \varpi^{-1}L = K$, so it equals $\Psi^{\mathrm{st}}_{K'}(K) = \chi(\det K'K)^{-1} = 1$, and $r(x) \neq 0$.

Step 6: conclusion. Step 2 applies to $p = G$, $s = L'$, $x = L - \varpi K$ and the function r of Step 5, and gives $\Psi \in \mathcal{P}$. □

This group proves Freitag's lemma (Proposition 6.3.36), the vanishing theorem on which the stable-space step rests (Proposition 6.3.33). If the partial means of a centre coefficient along a line are invariant under the shears at a nonempty set of places, and the coefficient vanishes at the points whose Siegel bracket is unimodular, then it vanishes on the stabiliser of the frame away from S: shear invariance makes the coefficient singular along the line, and a singular coefficient is determined by its values at the unimodular points. The proof spreads shear invariance to the whole radical by strong approximation, reduces every point to a straight point by an Iwasawa decomposition for the flag, and shows that at a straight point of least dual index the periods of the shifted mean force the Siegel bracket and its inverse to be integral. The key is that denominator indices decrease strictly under a non-unimodular integral change of basis (Lemma 6.3.45). In the proof of Proposition 6.3.33, the shear hypothesis is Lemma 6.3.47, and the vanishing hypothesis comes from the self-dual lattices through Lemma 6.3.49.

The rest of the group collects lemmas used earlier in the section, in the order of their first use, among them a smooth local form of Witt's theorem for isotropic vectors (Lemma 6.3.57; [330]). It closes with the explicit matching and its archimedean inputs.

Proposition 6.3.36. *Let W be a space with a point with signs s on n, A a base-adapted splitting of W over a space with a point W_0 along a one-element set, B a base-adapted splitting of W_0 over W_2 along an index set p, and D a splitting of W over W_1 along p whose rational frame is $k_D = i_A k_B$; all centre coefficients below are taken along D. Let $T \in \mathrm{M}_p(E)$ with $\det T \neq 0$, S a set of finite places of E, U a nonempty set of finite places of E, $\mathrm{e} = \mathrm{e}_{S \cup \bar{S}}$, and H the frame stabiliser of D off S. Let $f\colon \mathrm{G}(s) \to \mathbb{C}$ be continuous, left invariant under Γ_W, and right invariant under every $k \in \mathbf{K}_0(n)$ (read in $\mathrm{G}(s)$ with infinite components 1) whose component is 1 at every finite place w with $w \notin S$ and $\bar{w} \notin S$.*

1. *For every $x \in \mathrm{G}(s)$ the coefficient $\mathrm{coef}(T; f)(x)$ is defined, and the functions*

$$b \mapsto \mathrm{coef}(T; f)(z^{\mp}_{A,B}(b)\, x)$$

on $\mathrm{M}_{1\times p}(\mathbb{A}_E)$ are continuous and invariant under $\mathrm{M}_{1\times p}(E)$; so the partial means

$$\mathrm{coef}^{\pm}_{A,B,D}(T; f)(x)$$

are defined.

2. *Assume that $\mathrm{coef}^{+}_{A,B,D}(T; f)$ is invariant under the A-shears for U, and $\mathrm{coef}^{-}_{A,B,D}(T; f)$ under the $\bar{A}$-shears for U, at every point of H. Assume further that $\mathrm{coef}(T; f)(X) = 0$ for every $X \in \mathrm{G}(s)$ and $\gamma \in \mathrm{M}_p(\mathbb{A}_E)$ such that $X k_{D,\mathbb{A}} = k_{D,\mathbb{A}}(\mathrm{e}\gamma + (1 - \mathrm{e}))$ and $T\{\gamma\}$ is unimodular on $S \cup \bar{S}$. Then $\mathrm{coef}(T; f)(g) = 0$ for every $g \in H$.*

Proof. Write $f^{\pm} = \mathrm{coef}^{\pm}_{A,B,D}(T; f)$, $z^{\pm} = z^{\pm}_{A,B}$, $k_D = k_{D,\mathbb{A}}$ (so $k_D = i_{A,\mathbb{A}} k_{B,\mathbb{A}}$), $F_1 = (k_{A,\mathbb{A}} \mid k_D)$, and for a straight point $P = (X, u, t, t', \gamma)$ of (A, B, D) off S put $\varphi^{+}_P(a) = f^{+}(z^{+}(a)X)$, $\varphi^{-}_P(b) = f^{-}(z^{-}(b)X)$. The opposite splitting $\bar{A}$ is base-adapted (the same columns in another order), has the same embedding $i_{\mathbb{A}}$, and its shifts, partial means and shifted means are those of A with the signs exchanged ((MX5), (MX11)); so every result below applied to $\bar{A}$ in place of A concerns f^{-} and the $\bar{A}$-shears.

(1) is (1) of Lemma 6.3.32 (for D) and (2) of Lemma 6.3.37.

(2). Suppose that $\mathrm{coef}(T; f)(g) \neq 0$ for some $g \in H$.

There is a straight point with nonzero shifted mean. By (4) of Lemma 6.3.37 ($\det T \neq 0$), $a \mapsto f^{+}(z^{+}(a)g)$ is not identically zero; choose a with $f^{+}(z^{+}(a)g) \neq 0$. By (1) of Lemma 6.3.38

there are $\kappa \in \mathrm{G}(s)$ with finite part in $\mathbf{K}_0(n)$ and blocks with $z^+(a)g\kappa F_1 = F_1 \begin{pmatrix} \alpha & \beta \\ 0 & \gamma_0 \end{pmatrix}$. The point $z^+(a)g$ lies in H, as $z^+(a)$ fixes k_D ((1) of Lemma 6.3.37). By (2) of Lemma 6.3.39 (with $X = g = z^+(a)g$) there is a straight point P_0 of (A, B, D) off S with $\varphi^+_{P_0}(0) \neq 0$. So the set Σ of straight points P of (A, B, D) off S with $\varphi^+_P \not\equiv 0$ is nonempty. For $P \in \Sigma$ the matrix γ is invertible ((1) of Lemma 6.3.39), so $T\{\gamma\}$ is invertible and the dual index of γ on $S \cup \bar{S}$ for T is a positive integer (MX12). Choose $P = (X, u, t, t', \gamma) \in \Sigma$ with the least dual index.

Supports. By Lemma 6.3.43 (its minimality hypothesis is the choice of P), $\gamma^{-1}a^*t$ is integral on $S \cup \bar{S}$ whenever $\varphi^+_P(a) \neq 0$. The opposite $\bar{P} = (X, u, t', t, \gamma)$ is a straight point of $(\bar{A}, B, D)$ off S, and its first shifted mean for $\bar{A}$ is φ^-_P. Let Q be a straight point of $(\bar{A}, B, D)$ off S whose first shifted mean for $\bar{A}$ is not identically zero. Its opposite $\bar{Q}$ is a straight point of (A, B, D) off S with the same matrix γ_Q, and that first shifted mean is $\varphi^-_{\bar{Q}}$; by (4) of Lemma 6.3.37, $\varphi^+_Q \equiv 0$ would force $\varphi^-_{\bar{Q}} \equiv 0$, so $\bar{Q} \in \Sigma$ and the dual index of γ_Q is at least that of γ. Hence Lemma 6.3.43 applies to $\bar{A}$ and $\bar{P}$ (with the hypothesis on f^- and the $\bar{A}$-shears): $\gamma^{-1}b^*t'$ is integral on $S \cup \bar{S}$ whenever $\varphi^-_P(b) \neq 0$.

Unimodularity. By (1) of Lemma 6.3.39, $T\{\gamma\}$ is integral on $S \cup \bar{S}$; by (2) of Lemma 6.3.46 and the two support statements, $T\{\gamma\}$ is invertible with $T\{\gamma\}^{-1}$ integral on $S \cup \bar{S}$. So $T\{\gamma\}$ is unimodular on $S \cup \bar{S}$ (MX9).

Contradiction. By (1) of Lemma 6.3.39 there are $Y \in H$ and $v \in \mathrm{G}(s)$ with $\mathrm{e}Y = \mathrm{e}v$, $vk_D = k_D\gamma$ and $\mathrm{coef}(T; f)(Y) \neq 0$. As e is a scalar,

$$Yk_D = \mathrm{e}\,Yk_D + Y(1 - \mathrm{e})k_D = \mathrm{e}\,vk_D + (1 - \mathrm{e})k_D = k_D(\mathrm{e}\gamma + (1 - \mathrm{e})),$$

and the hypothesis gives $\mathrm{coef}(T; f)(Y) = 0$, a contradiction. Hence $\mathrm{coef}(T; f)(g) = 0$ for every $g \in H$. □

Lemma 6.3.37. *Let W be a space with a point with signs s on n, A a splitting of W over W_0 along a one-element set, B a splitting of W_0 over W_2 along p, D a splitting of W over W_1 along p with rational frame $k_D = i_A k_B$, and write $z^\pm = z^\pm_{A,B}$, z_D for the radical centre elements of D and $\mathrm{coef}(T; \cdot)$ for the centre coefficients along D. Let $f\colon \mathrm{G}(s) \to \mathbb{C}$ be continuous and left invariant under Γ_W, and $T \in \mathrm{M}_p(E)$.*

1. *For adelic $1 \times p$ matrices a, a', b and adelic $p \times p$ matrices M: $z^\pm(a + a') = z^\pm(a)z^\pm(a')$; $z^\pm(a) \in \Gamma_W$ if a is rational; $z^\pm(a)k_{D,\mathbb{A}} = k_{D,\mathbb{A}}$; $z^\pm(a)z_D(M) = z_D(M)z^\pm(a)$; and $z^+(a)z^-(b) = z_D(-a^*b)\, z^-(b)\, z^+(a)$.*

2. *For $x \in \mathrm{G}(s)$ the functions $b \mapsto \mathrm{coef}(T; f)(z^\mp(b)x)$ are continuous and $\mathrm{M}_{1\times p}(E)$-periodic, and the partial means*

$$f^+(x) = \int \mathrm{coef}(T; f)(z^-(b)x)\, db, \qquad f^-(x) = \int \mathrm{coef}(T; f)(z^+(b)x)\, db$$

   (over $\mathrm{M}_{1\times p}(\mathbb{A}_E)/\mathrm{M}_{1\times p}(E)$) are continuous functions of x, with $f^+(z^-(b)x) = f^+(x)$, $f^-(z^+(b)x) = f^-(x)$ and $\psi_E(\mathrm{tr}(TM))\, f^\pm(z_D(M)x) = f^\pm(x)$.

3. *The shifted means $\varphi^+_x(a) = f^+(z^+(a)x)$ and $\varphi^-_x(b) = f^-(z^-(b)x)$ satisfy $\varphi^+_{z^+(a)x}(y) = \varphi^+_x(y + a)$ and $\varphi^-_{z^+(a)x}(b) = \psi_E(-\mathrm{tr}(Ta^*b))\, \varphi^-_x(b)$.*

4. *Let $\det T \neq 0$, $x, x' \in \mathrm{G}(s)$, $c \in \mathbb{C}$ with $\varphi^+_{x'} = c\,\varphi^+_x$. Then $\mathrm{coef}(T; f)(z^-(b)z^+(a)x') = c\,\mathrm{coef}(T; f)(z^-(b)z^+(a)x)$ for all a, b, and $\varphi^-_{x'} = c\,\varphi^-_x$. In particular, if $\varphi^+_x = 0$, then $\mathrm{coef}(T; f)(x) = 0$ and $\varphi^-_x = 0$.*

5. *All of the above holds with A replaced by its opposite splitting, which exchanges z^+ and z^-, f^+ and f^-, φ^+ and φ^-.*

Proof. Write $k_{\mathbb{A}}, l_{\mathbb{A}}, i_{\mathbb{A}}, \mathrm{pr}_k, \mathrm{pr}_l$ for the adelic frames and coordinates of A, $\varepsilon = \varepsilon_s$, $K = i_{\mathbb{A}} k_{B,\mathbb{A}} = k_{D,\mathbb{A}}$ and $\Lambda = K^* \varepsilon$, which is the coordinate pr_l of D. By (MX1) for A and B: $\Lambda K = k^*_{B,\mathbb{A}} \varepsilon_{W_0} k_{B,\mathbb{A}} = 0$, $\Lambda k_{\mathbb{A}} = \Lambda l_{\mathbb{A}} = 0$, $\mathrm{pr}_k K = \mathrm{pr}_l K = 0$, $\mathrm{pr}_k k_{\mathbb{A}} = \mathrm{pr}_l l_{\mathbb{A}} = 1$, $\mathrm{pr}_k l_{\mathbb{A}} = \mathrm{pr}_l k_{\mathbb{A}} = 0$. The composite $A \circ B$ has adelic frame $(k_{\mathbb{A}} \mid K)$ and coordinate pr_l with rows pr_l, Λ; for $\bar{A} \circ B$ these are $(l_{\mathbb{A}} \mid K)$ and pr_k, Λ. As $M_b - M_b^*$ has the blocks b at (o,p) and $-b^*$ at (p,o),

$$\begin{aligned} z^-(b) &= 1 + N_b, & N_b &= k_{\mathbb{A}} b \Lambda - K b^* \mathrm{pr}_l; \\ z^+(a) &= 1 + P_a, & P_a &= l_{\mathbb{A}} a \Lambda - K a^* \mathrm{pr}_k; \\ z_D(M) &= 1 + K(M - M^*)\Lambda. \end{aligned}$$

(1). Additivity and rationality are (1) of Lemma 6.3.32 for the splittings $A \circ B$ and $\bar{A} \circ B$ ($M_{a+a'} = M_a + M_{a'}$). $P_a K = N_b K = 0$ by the relations, so $z^{\pm}$ fix K; then (3) of Lemma 6.3.32 (with $c = 1$) gives the commutation with $z_D(M)$. From the relations, $P_a N_b = -K a^* b \Lambda$ and $N_b P_a = -K b^* a \Lambda$, so $z^+(a) z^-(b) = 1 + P_a + N_b - K a^* b \Lambda$ and $z^-(b) z^+(a) = 1 + Q$ with $Q = P_a + N_b - K b^* a \Lambda$. Since $\Lambda Q = 0$, $z_D(-a^*b)(1+Q) = 1 + Q + K(-a^*b + b^*a)\Lambda = z^+(a) z^-(b)$.

(2). $\mathrm{coef}(T; f)$ is continuous by (1) of Lemma 6.3.32, hence so are the two functions of b. For rational γ, $z^{\mp}(b+\gamma)x = z^{\mp}(\gamma) z^{\mp}(b) x$ with $z^{\mp}(\gamma) \in \Gamma_W$ fixing $k_{D,\mathbb{A}}$, so (4) of Lemma 6.3.32 with $c = 1$ gives periodicity. The integrals are over a relatively compact fundamental domain of a jointly continuous function, so $f^{\pm}$ are continuous (dominated convergence on compact neighbourhoods). Invariance under $z^{\mp}(b)$ is the translation invariance of the measure with additivity. By (1) and (2) of Lemma 6.3.32, $\mathrm{coef}(T; f)(z^-(b) z_D(M) x) = \mathrm{coef}(T; f)(z_D(M) z^-(b) x) = \psi_E(\mathrm{tr}(TM))^{-1} \mathrm{coef}(T; f)(z^-(b) x)$; integrate over b. Likewise for f^-.

(3). The first law is additivity of z^+. By (1), $z^-(b) z^+(a) = z_D(a^*b) z^+(a) z^-(b)$, so by (2)

$$\begin{aligned} \varphi^-_{z^+(a)x}(b) &= f^-(z_D(a^*b) z^+(a) z^-(b) x) = \psi_E(\mathrm{tr}(Ta^*b))^{-1} f^-(z^+(a) z^-(b) x) \\ &= \psi_E(-\mathrm{tr}(Ta^*b)) \varphi^-_x(b). \end{aligned}$$

(4). Let $a_0 \in \mathrm{M}_{1\times p}(E)$. By (1), $z^-(b) z^+(a_0) = z_D(a_0^* b) z^+(a_0) z^-(b)$; by (2) and (4) of Lemma 6.3.32 ($z^+(a_0)$ is rational and fixes $k_{D,\mathbb{A}}$),

$$\varphi^+_x(a_0 + a) = \int \psi_E(-\mathrm{tr}(Ta_0^* b)) \, \mathrm{coef}(T; f)(z^-(b) z^+(a) x) \, db. \tag{6.47}$$

Fix a and let

$$F(b) = \mathrm{coef}(T; f)(z^-(b) z^+(a) x') - c \, \mathrm{coef}(T; f)(z^-(b) z^+(a) x),$$

continuous and periodic by (2). By (6.47) and the hypothesis, $\int \psi_E(b\,R) F(b)\, db = 0$ for $R = -Ta_0^*$ ($\mathrm{tr}(Ta_0^* b) = bTa_0^*$). As T is invertible, R runs over all of E^p when a_0 runs over $\mathrm{M}_{1\times p}(E)$, and by (a) of Theorem A.5.2 on each coordinate the $b \mapsto \psi_E(bR)$ are all the continuous characters of $(\mathbb{A}_E/E)^p$. Hence $F = 0$, which is the first claim. By (1) and (2) of Lemma 6.3.32, $\mathrm{coef}(T; f)(z^+(a) z^-(b) y) = \psi_E(\mathrm{tr}(Ta^*b)) \, \mathrm{coef}(T; f)(z^-(b) z^+(a) y)$ for every y; so the first claim gives $\mathrm{coef}(T; f)(z^+(a) z^-(b) x') = c \, \mathrm{coef}(T; f)(z^+(a) z^-(b) x)$, and integration over a gives $\varphi^-_{x'}(b) = c \, \varphi^-_x(b)$. With $x' = x$ and $c = 0$: $\mathrm{coef}(T; f)(x)$ (the case $a = b = 0$) and φ^-_x vanish.

(5). By (MX5), $z^{\pm}_{\bar{A},B} = z^{\mp}_{A,B}$, the opposite of $\bar{A}$ is A, and $\bar{A}$ has the same embedding $i_{\mathbb{A}}$, so $k_D = i_{\bar{A}} k_B$; the proof applies verbatim. □

Lemma 6.3.38. *Let W be a space with a point with signs s on n, A a base-adapted splitting of W over W_0 (signs on n_0) along a one-element set, B a base-adapted splitting of W_0 over W_2 along p, $k_D = i_{A,\mathbb{A}} k_{B,\mathbb{A}}$, and let $F_1 = (k_{A,\mathbb{A}} \mid k_D)$ and $F_2 = (l_{A,\mathbb{A}} \mid k_D)$ be the adelic frames k of $A \circ B$ and of $\bar{A} \circ B$. Block matrices below have the blocks 1×1, $1 \times p$, $p \times 1$, $p \times p$.*

1. *For every $g \in \mathrm{G}(s)$ there are $\kappa \in \mathrm{G}(s)$ with finite part in $\mathbf{K}_0(n)$, $a \in \mathbb{A}_E$, $\beta \in \mathrm{M}_{1\times p}(\mathbb{A}_E)$ and $\gamma \in \mathrm{M}_p(\mathbb{A}_E)$ such that*
$$g\kappa\, F_1 = F_1 \begin{pmatrix} a & \beta \\ 0 & \gamma \end{pmatrix}.$$

2. *If $g \in \mathrm{G}(s)$ satisfies $gF_1 = F_1 \begin{pmatrix} a & \beta \\ 0 & \gamma \end{pmatrix}$, then there are $c \in \mathrm{M}_{n_0\times 1}(\mathbb{A}_E)$, $\zeta \in \mathbb{A}_E$, $u \in \mathrm{G}(s)$ and $t, t' \in \mathbb{A}_E$ with $g = \mathrm{rad}_A(c,\zeta)\, u$, $uF_1 = F_1 \,\mathrm{diag}(t,\gamma)$, $uF_2 = F_2 \,\mathrm{diag}(t',\gamma)$ and $\bar{t}'t = 1$.*

Proof. Write $k = k_{A,\mathbb{A}}$, $l = l_{A,\mathbb{A}}$, $i = i_{A,\mathbb{A}}$, $\mathrm{pr}_k, \mathrm{pr}_i$ for the coordinates of A, and $\varepsilon = \varepsilon_s$.

(2). The first column of the hypothesis is $gk = ka$. Since g preserves the form, $(gl)^*\varepsilon ka = (gl)^*\varepsilon gk = l^*\varepsilon k = 1$, so a is a unit and g lies in the group P_X of Lemma 6.2.16 for $X = A$ (base-adapted). By (2) of Lemma 6.2.16, $g = n\,\mathrm{lev}_A(m,h)$ with $n = \mathrm{rad}_A(c,\zeta)$ for some c, ζ, $m = \mathrm{pr}_k gk = a$ and $h = \mathrm{pr}_i gi \in \mathrm{G}(s_0)$. As $\mathrm{pr}_i k = 0$ and $\mathrm{pr}_i i = 1$ (MX1), the second block of the hypothesis, $gk_D = k\beta + k_D\gamma$, gives $hk_{B,\mathbb{A}} = \mathrm{pr}_i gk_D = k_{B,\mathbb{A}}\gamma$. Let $u = \mathrm{lev}_A(m,h)$. By (MX2), $uk = km$, $ul = l\,\bar{m}^{-1}$ and $uk_D = i\,h\,k_{B,\mathbb{A}} = k_D\gamma$; so $uF_1 = F_1\,\mathrm{diag}(m,\gamma)$ and $uF_2 = F_2\,\mathrm{diag}(\bar{m}^{-1},\gamma)$. With $t = m$, $t' = \bar{m}^{-1}$ we have $\bar{t}'t = m^{-1}m = 1$.

(1). Let $C = A \circ B$ (MX5); it has frames $k_C = F_1$, $l_C = (l \mid i\,l_{B,\mathbb{A}})$, $i_C = i\,i_{B,\mathbb{A}}$, and up to the order of the columns $(l_C \mid k_C \mid i_C) = (l \mid k \mid i)\,\mathrm{diag}(1, 1, (l_{B,\mathbb{A}} \mid k_{B,\mathbb{A}} \mid i_{B,\mathbb{A}}))$, a product of two matrices that are unitary at every infinite place and integral at the finite places (A, B base-adapted). The relations of (MX1) for C give, for the form $y^*\varepsilon z$, $k_C^*\varepsilon k_C = l_C^*\varepsilon l_C = 0$, $l_C^*\varepsilon k_C = 1$, $i_C^*\varepsilon k_C = i_C^*\varepsilon l_C = 0$ and $i_C^*\varepsilon i_C = \varepsilon_{s_2}$ (s_2 the signs of W_2). Put $J = 1 + \#p$ and let j be the composition $(1, \#p)$ of J, or (1) if p is empty. Let v be a place of F, G_v the component of $\mathrm{G}(s)$ at v, $K_v \subset G_v$ the component at v of the unitary matrices (if $v \in \Phi$) or of $\mathbf{K}_0(n)$ (if v is finite), and $P_v \subset G_v$ the stabiliser of the flag $W_{1,v} \subset W_{2,v}$ spanned by the first column, resp. all columns, of $(F_1)_v$.

For $v \in \Phi$, $G_v = \mathrm{U}(\mathrm{diag}\, s)$, and the columns $e_1 = k_v$, $(e_2, \dots, e_J) = (k_D)_v$, $(f_1, \dots, f_J) = (l_C)_v$, $(u_c) = (i_C)_v$ form a basis with the relations of (i) of Lemma 6.2.17 for the form $y^*\mathrm{diag}(s)z$, orthonormal for the standard form; so K_v is the stabiliser of the majorant, the signature (p_v, q_v) of $\mathrm{diag}(s)$ has $\min(p_v, q_v) \geq J$ (the span of the e and f has signature (J, J)), and (i) of Lemma 6.2.17 gives $G_v = P_vK_v$. For finite v, $E \otimes_F F_v$ is an unramified quadratic field extension of F_v or $F_v \times F_v$ (Lemma 3.2.9); G_v is the unitary group of y^*z on $(E \otimes_F F_v)^n$ ($\varepsilon = 1$ there), K_v is the stabiliser of the self-dual lattice of integral vectors, and $W_{1,v} \subset W_{2,v}$ is an isotropic flag of free submodules of ranks 1 and J (the columns of $(F_1)_v$ are part of the invertible matrix $(l_C \mid k_C \mid i_C)_v$, and $k_C^*\varepsilon k_C = 0$); (ii) of Lemma 6.2.17 gives $G_v = P_vK_v$.

Let $g \in \mathrm{G}(s)$, and let R be the finite set of finite places v of F at which g_v is not integral. For $v \in \Phi \cup R$ write $g_v = \pi_v\kappa_v$ with $\pi_v \in P_v$, $\kappa_v \in K_v$; for the other v put $\pi_v = 1$, $\kappa_v = g_v \in K_v$. Then $\pi = (\pi_v)$ and $\kappa' = (\kappa_v)$ lie in $\mathrm{G}(s)$, $g = \pi\kappa'$, and $\kappa = \kappa'^{-1}$ has finite part in $\mathbf{K}_0(n)$. At every place π_v preserves $W_{1,v}$ and $W_{2,v}$, so $\pi_v(F_1)_v = (F_1)_v \begin{pmatrix} a_v & \beta_v \\ 0 & \gamma_v \end{pmatrix}$, with $a_v = 1$, $\beta_v = 0$, $\gamma_v = 1$ for $v \notin \Phi \cup R$; hence a, β, γ are adelic and $g\kappa F_1 = \pi F_1 = F_1 \begin{pmatrix} a & \beta \\ 0 & \gamma \end{pmatrix}$. □

Lemma 6.3.39. *Let W be a space with a point with signs s on n, A a base-adapted splitting of W over W_0 along a one-element set, B a base-adapted splitting of W_0 over W_2 along p, and D a splitting of W over W_1 along p with $k_{D,\mathbb{A}} = i_{A,\mathbb{A}} k_{B,\mathbb{A}}$; write $k_D = k_{D,\mathbb{A}}$, $F_1 = k_{A\circ B,\mathbb{A}} = (k_{A,\mathbb{A}} \mid k_D)$, $z^{\pm} = z^{\pm}_{A,B}$. Let S be a set of finite places of E, $\mathrm{e} = \mathrm{e}_{S\cup\bar{S}}$, H the frame stabiliser of D off S, $T \in \mathrm{M}_p(E)$, and $f\colon \mathrm{G}(s) \to \mathbb{C}$ continuous, left invariant under Γ_W, and right invariant under every $k \in \mathbf{K}_0(n)$ (read in $\mathrm{G}(s)$ with infinite components 1) whose component is 1 at every finite place outside $S \cup \bar{S}$. Write $f^+ = \mathrm{coef}^+_{A,B,D}(T; f)$.*

1. *Let (X, u, t, t', γ) be a straight point of (A, B, D) off S. Then γ is invertible and $uk_D = k_D\gamma$. If $f^+(z^+(a)X) \neq 0$ for some $a \in \mathrm{M}_{1\times p}(\mathbb{A}_E)$, then there are $Y \in H$ and $v \in \mathrm{G}(s)$ with $\mathrm{e}Y = \mathrm{e}v$, $vk_D = k_D\gamma$ and $\mathrm{coef}(T; f)(Y) \neq 0$; and $T\{\gamma\}$ is integral on $S \cup \bar{S}$.*

2. *Let U be a nonempty set of finite places of E, and assume that f^+ is invariant under the A-shears for U at every point of H. Let $X \in H$ and $g \in \mathrm{G}(s)$ with $\mathrm{e}X = \mathrm{e}g$, let $\kappa \in \mathrm{G}(s)$ have finite part in $\mathbf{K}_0(n)$, and let*

$$g\kappa F_1 = F_1 \begin{pmatrix} a & \beta \\ 0 & \gamma \end{pmatrix} \qquad (a \in \mathbb{A}_E,\ \beta \in \mathrm{M}_{1\times p}(\mathbb{A}_E),\ \gamma \in \mathrm{M}_p(\mathbb{A}_E)).$$

   If $f^+(X) \neq 0$, then there is a straight point (X', u', t, t', γ) of (A, B, D) off S, with this γ, such that $f^+(X') \neq 0$.

Proof. For $g \in \mathrm{G}(s)$ let $g^{(S)}$ be as in Lemma 6.3.40; then $\mathrm{e}g^{(S)} = \mathrm{e}g$ and $(1-\mathrm{e})g^{(S)} = g^{(S)}(1-\mathrm{e}) = 1 - \mathrm{e}$, since e is a scalar with $\mathrm{e}^2 = \mathrm{e}$. The finite components of $k_D = i_{A,\mathbb{A}} k_{B,\mathbb{A}}$ are integral, A and B being base-adapted. By (1) of Lemma 6.3.37, $z^{\pm}(a)k_D = k_D$ for all a.

(1). Let l_C be the adelic frame l of $C = A \circ B$; by (MX1), $l_C^* \varepsilon_s F_1 = 1$. The frame condition $uF_1 = F_1 \,\mathrm{diag}(t, \gamma)$ gives $uk_D = k_D\gamma$ and $\mathrm{diag}(t, \gamma) = l_C^* \varepsilon_s u F_1$, which is invertible with inverse $l_C^* \varepsilon_s u^{-1} F_1$ (as $u^{-1}F_1 = F_1 \,\mathrm{diag}(t, \gamma)^{-1}$ placewise); so γ is invertible. Let $f^+(z^+(a)X) \neq 0$. By (MX11) $f^+(z^+(a)X)$ is the integral of $b \mapsto \mathrm{coef}(T; f)(z^-(b)z^+(a)X)$, so this function does not vanish at some b. Put $Y = z^-(b)z^+(a)X$ and $v = z^-(b)z^+(a)u$. As $z^{\pm}$ fix k_D and $X \in H$, $Y(1 - \mathrm{e})k_D = (1 - \mathrm{e})k_D$, so $Y \in H$; $\mathrm{e}Y = z^-(b)z^+(a)\,\mathrm{e}X = z^-(b)z^+(a)\,\mathrm{e}u = \mathrm{e}v$; $vk_D = z^-(b)z^+(a)k_D\gamma = k_D\gamma$; and $\mathrm{coef}(T; f)(Y) \neq 0$. By (4) of Lemma 6.3.40 (with $X = Y$, $u = v$), $T\{\gamma\}$ is integral on $S \cup \bar{S}$.

(2). By (2) of Lemma 6.3.38, $g\kappa = \mathrm{rad}_A(c, \zeta)\, u'$ with $u'F_1 = F_1 \,\mathrm{diag}(t, \gamma)$, $u'k_{\bar{A}\circ B,\mathbb{A}} = k_{\bar{A}\circ B,\mathbb{A}} \,\mathrm{diag}(t', \gamma)$ and $\bar{t}'t = 1$. By (1) of Lemma 6.2.16 (for $X = A$, base-adapted) the radical elements of A form a group, so $h = \mathrm{rad}_A(c, \zeta)^{-1} = \mathrm{rad}_A(c', \zeta')$ for some c', ζ'. By (MX2), $h - 1 = -i_{\mathbb{A}} c' \mathrm{pr}_l + k_{\mathbb{A}} c'^* \varepsilon_{s_0} \mathrm{pr}_i - k_{\mathbb{A}} Y' \mathrm{pr}_l$ with $Y' = \frac{1}{2}(\jmath^{-1}(\zeta' + \bar{\zeta}') + c'^* \varepsilon_{s_0} c')$ (frames and coordinates of A), and as $\bar{\mathrm{e}} = \mathrm{e} = \mathrm{e}^2$ the same formula for $(\mathrm{e}c', \mathrm{e}\zeta')$ gives $\mathrm{e}(h - 1)$; so $h^{(S)} = 1 + \mathrm{e}(h - 1) = \mathrm{rad}_A(\mathrm{e}c', \mathrm{e}\zeta')$. Put

$$X_1 = X\kappa^{(S)}, \qquad X' = h^{(S)} X_1.$$

Then $X_1(1 - \mathrm{e})k_D = X(1 - \mathrm{e})k_D = (1 - \mathrm{e})k_D$ and $X'(1 - \mathrm{e})k_D = h^{(S)}(1 - \mathrm{e})k_D = (1 - \mathrm{e})k_D$, so $X_1, X' \in H$; and $\mathrm{e}X' = h^{(S)}\,\mathrm{e}X\,\kappa^{(S)} = h^{(S)}\,\mathrm{e}g\kappa = \mathrm{e}\,hg\kappa = \mathrm{e}u'$, using $\mathrm{e}X = \mathrm{e}g$, $\mathrm{e}\kappa^{(S)} = \mathrm{e}\kappa$ and $\mathrm{e}h^{(S)} = \mathrm{e}h$. So (X', u', t, t', γ) is a straight point of (A, B, D) off S. By (2) of Lemma 6.3.41 (with $g = X_1 \in H$ and $\mathrm{rad}_A(\mathrm{e}c', \mathrm{e}\zeta')X_1 = X' \in H$), $f^+(X') = f^+(X_1)$. By (3) of Lemma 6.3.40 applied to each point $z^-(b)X$, $\mathrm{coef}(T; f)(z^-(b)X\kappa^{(S)}) = \mathrm{coef}(T; f)(z^-(b)X)$, and integrating over b, $f^+(X_1) = f^+(X) \neq 0$. □

Lemma 6.3.40. *Let W be a space with a point with signs s on n, D a splitting of W over W_1 along p with adelic frame $k_D = k_{D,\mathbb{A}}$, $f\colon \mathrm{G}(s) \to \mathbb{C}$ continuous and left invariant under Γ_W, $T \in \mathrm{M}_p(E)$, S a set of finite places of E and $\mathrm{e} = \mathrm{e}_{S\cup\bar{S}}$; centre coefficients are taken along D. For $g \in \mathrm{G}(s)$ let $g^{(S)}$ be the matrix $\mathrm{e}g + (1-\mathrm{e})$ (the components of g at the places of $S \cup \bar{S}$, and 1 at all other places).*

1. *$g^{(S)} \in \mathrm{G}(s)$, $(gh)^{(S)} = g^{(S)}h^{(S)}$, and $z_D(M)^{(S)} = z_D(\mathrm{e}M)$ for adelic $p \times p$ matrices M.*
2. *Let $X, g \in \mathrm{G}(s)$ with $\mathrm{e}X = \mathrm{e}g$ and $c \in \mathrm{M}_p(\mathbb{A}_E)$ with $gk_D = k_D c$. Then for every adelic $p \times p$ matrix M*
$$\psi_E\big(\mathrm{e}\,\mathrm{tr}(c^*TcM)\big)\,\mathrm{coef}(T;f)\big(X\,z_D(\mathrm{e}M)\big) = \mathrm{coef}(T;f)(X).$$
3. *Assume that f is right invariant under every $k \in \mathbf{K}_0(n)$ (read in $\mathrm{G}(s)$ with infinite components 1) whose component is 1 at every finite place outside $S\cup\bar{S}$. Then $\mathrm{coef}(T;f)(X\kappa^{(S)}) = \mathrm{coef}(T;f)(X)$ for all $X \in \mathrm{G}(s)$ and all $\kappa \in \mathrm{G}(s)$ whose finite part lies in $\mathbf{K}_0(n)$.*
4. *Assume the hypothesis of (3) and that the finite components of k_D have entries in $\widehat{\mathcal{O}}_E$. Let $X, u \in \mathrm{G}(s)$ with $\mathrm{e}X = \mathrm{e}u$, $\gamma \in \mathrm{M}_p(\mathbb{A}_E)$ with $uk_D = k_D\gamma$, and $\mathrm{coef}(T;f)(X) \neq 0$. Then $T\{\gamma\}$ is integral on $S \cup \bar{S}$.*

Proof. Write $\varepsilon = \varepsilon_s$ and $\Lambda = k_D^*\varepsilon$, the coordinate pr_l of D. The adele e satisfies $\mathrm{e}^2 = \mathrm{e}$, $\bar{\mathrm{e}} = \mathrm{e}$ (the set $S\cup\bar{S}$ is stable under conjugation) and commutes with all adelic matrices; for $g \in \mathrm{G}(s)$, $g^{-1} = \varepsilon g^*\varepsilon$.

(1). As $\mathrm{e}(1-\mathrm{e}) = 0$, $(\mathrm{e}g^* + 1 - \mathrm{e})\varepsilon(\mathrm{e}g + 1 - \mathrm{e}) = \mathrm{e}g^*\varepsilon g + (1-\mathrm{e})\varepsilon = \varepsilon$, and $(\mathrm{e}g + 1 - \mathrm{e})$ is invertible with inverse $\mathrm{e}g^{-1} + 1 - \mathrm{e}$; so $g^{(S)} \in \mathrm{G}(s)$, and multiplicativity is the same computation. By (MX2), $z_D(M)^{(S)} = 1 + \mathrm{e}k_D(M - M^*)\Lambda = 1 + k_D(\mathrm{e}M - (\mathrm{e}M)^*)\Lambda = z_D(\mathrm{e}M)$.

(2). From $\mathrm{e}X = \mathrm{e}g$ we get $\mathrm{e}X^* = \mathrm{e}g^*$ and $\mathrm{e}X^{-1} = \varepsilon(\mathrm{e}X^*)\varepsilon = \mathrm{e}g^{-1}$. Hence $\mathrm{e}Xk_D = \mathrm{e}k_Dc$ and $\mathrm{e}X^{-1}k_D = \mathrm{e}k_Dc^{-1}$ (c is invertible: with l_D the adelic frame $l_{D,\mathbb{A}}$, $l_D^*\varepsilon k_D = 1$ by (MX1), and $c = l_D^*\varepsilon g k_D$; at each place g is invertible and k_D has independent columns, so c is invertible there, $g^{-1}k_D = k_Dc^{-1}$, and $c^{-1} = l_D^*\varepsilon g^{-1}k_D$ is adelic), and by (6.46) of Lemma 6.3.32, $\mathrm{e}\Lambda X = \mathrm{e}(X^{-1}k_D)^*\varepsilon = \mathrm{e}(c^{-1})^*\Lambda$. Therefore, with $N = M - M^*$,

$$X\,z_D(\mathrm{e}M) = X + \mathrm{e}Xk_DN\Lambda = X + \mathrm{e}k_DcN\Lambda, \qquad z_D(\mathrm{e}Mc^*)\,X = X + \mathrm{e}k_DcNc^*\Lambda X = X + \mathrm{e}k_DcN\Lambda,$$

so $X\,z_D(\mathrm{e}M) = z_D(\mathrm{e}cMc^*)X$. By (2) of Lemma 6.3.32 for D,

$$\psi_E(\mathrm{tr}(T\mathrm{e}cMc^*))\,\mathrm{coef}(T;f)(z_D(\mathrm{e}cMc^*)X) = \mathrm{coef}(T;f)(X),$$

and $\mathrm{tr}(TcMc^*) = \mathrm{tr}(c^*TcM)$.

(3). $\kappa^{(S)}$ has infinite components 1, finite part in $\mathbf{K}_0(n)$ and component 1 at every finite place outside $S\cup\bar{S}$; so $f(z_D(M)X\kappa^{(S)}) = f(z_D(M)X)$ for every M, and (MX3) gives the claim.

(4). Fix $i, j \in p$ and $a \in \widehat{\mathcal{O}}_E$, read as the adele with infinite components 0, and let $M = aE_{ji}$ (E_{ji} the matrix unit). At the finite places $\varepsilon = 1$, so $\Lambda = k_D^*$ there, and the finite part of $z_D(M) = 1 + k_D(M - M^*)\Lambda$ has entries in $\widehat{\mathcal{O}}_E$; it lies in $G_f(n)$, so its inverse, its conjugate transpose, is integral too, and the finite part of $z_D(M)$ lies in $\mathbf{K}_0(n)$. By (1), (3) and (2) (with $g = u$, $c = \gamma$),

$$\begin{aligned}\mathrm{coef}(T;f)(X) &= \mathrm{coef}(T;f)\big(Xz_D(M)^{(S)}\big) = \mathrm{coef}(T;f)\big(Xz_D(\mathrm{e}M)\big)\\ &= \psi_E\big(\mathrm{e}\,\mathrm{tr}(\gamma^*T\gamma M)\big)^{-1}\mathrm{coef}(T;f)(X),\end{aligned}$$

and as $\mathrm{coef}(T;f)(X) \neq 0$, $\psi_E(\mathrm{e}\,\mathrm{tr}(\gamma^* T\gamma M)) = 1$. Here $\mathrm{tr}(\gamma^* T\gamma M) = a\,(\gamma^* T\gamma)_{ij} = a\,\delta_\jmath T\{\gamma\}_{ij}$. The adele $\mathrm{e}\,\delta_\jmath T\{\gamma\}_{ij} a$ has infinite components 0, and the finite part of $\delta_\jmath$ is $\jmath\alpha\bar{\alpha}$; so by (WD4), with d the finite part of $\mathrm{e}\,T\{\gamma\}_{ij}$, $\psi_0(da) = 1$. This holds for all $a \in \widehat{\mathcal{O}}_E$, so $\bar{d}$ lies in the annihilator of $\widehat{\mathcal{O}}_E$ under $(u,v) \mapsto \psi_0(\bar{u}v)$, which is $\widehat{\mathcal{O}}_E$ by Lemma 4.1.3; hence $d \in \widehat{\mathcal{O}}_E$, that is, $T\{\gamma\}_{ij}$ is integral on $S \cup \bar{S}$. □

Lemma 6.3.41. *Let W be a space with a point with signs s on n, A a splitting of W over W_0 (signs s_0 on n_0) along a one-element set, B a splitting of W_0 over W_2 along p, and D a splitting of W over W_1 along p with $k_{D,\mathbb{A}} = i_{A,\mathbb{A}} k_{B,\mathbb{A}}$. Let $f\colon \mathrm{G}(s) \to \mathbb{C}$ be continuous and left invariant under Γ_W, $T \in \mathrm{M}_p(E)$, S a set of finite places of E, U a nonempty set of finite places of E, and H the frame stabiliser of D off S. Assume that $\mathrm{coef}^+_{A,B,D}(T;f)$ is invariant under the A-shears for U at every point of H. Then:*

1. *for $x \in H$ and $\zeta \in \mathbb{A}_E$,*

$$\mathrm{coef}^+_{A,B,D}(T;f)(z_A(\zeta)x) = \mathrm{coef}^+_{A,B,D}(T;f)(x),$$

   and $\mathrm{coef}^+_{A,B,D}(T;f)(x)$ is the centre coefficient of f along $A \circ B$ at $0 \oplus T$ at x;

2. *for $g \in H$, $c \in \mathrm{M}_{n_0\times 1}(\mathbb{A}_E)$ and $\beta \in \mathbb{A}_E$ with $\mathrm{rad}_A(c,\beta)\,g \in H$,*

$$\mathrm{coef}^+_{A,B,D}(T;f)(\mathrm{rad}_A(c,\beta)\,g) = \mathrm{coef}^+_{A,B,D}(T;f)(g).$$

Proof. Write $f^+ = \mathrm{coef}^+_{A,B,D}(T;f)$, $C(x)$ for the centre coefficient of f along $A \circ B$ at $0 \oplus T$, $z^- = z^-_{A,B}$, $\mathrm{rad} = \mathrm{rad}_A$, $k = k_{A,\mathbb{A}}$, $i = i_{A,\mathbb{A}}$, $k_D = k_{D,\mathbb{A}}$, $k_B = k_{B,\mathbb{A}}$, $\mathrm{pr}_l, \mathrm{pr}_i$ for the coordinates of A, $\varepsilon_0 = \varepsilon_{s_0}$, $\Lambda = k_D^* \varepsilon_s$ and $\mathrm{e} = \mathrm{e}_U$. By (MX1), read adelically: $\mathrm{pr}_l k = \mathrm{pr}_l i = 0$, $\mathrm{pr}_i k = 0$, $\mathrm{pr}_i i = 1$, $\Lambda k = 0$, and $\mathrm{pr}_l k_D = 0$. Every $g \in \mathrm{G}(s)$ with $gk = k$ commutes with every $z_A(\zeta)$ ((3) of Lemma 6.3.32 for A with $c = 1$), and $z_A(\zeta)k_D = k_D$ as $\mathrm{pr}_l k_D = 0$; so $z_A(\zeta) \in H$, H being a group.

Step 1: radical elements. By (MX2), $\mathrm{rad}(c,\beta) = 1 + N(c,\beta)$ with $N(c,\beta) = -ic\,\mathrm{pr}_l + kc^*\varepsilon_0 \mathrm{pr}_i - kY\,\mathrm{pr}_l$, $Y = \frac{1}{2}(\jmath^{-1}(\beta + \bar{\beta}) + c^*\varepsilon_0 c)$. The relations give $\mathrm{rad}(c,\beta)k = k$, $\mathrm{rad}(c,\beta)i = i + kc^*\varepsilon_0$, and $N(c,\beta)N(c',\beta') = -k\,c^*\varepsilon_0 c'\,\mathrm{pr}_l$; comparing with $N(c+c', \beta+\beta'+\jmath t)$ for $t = c^*\varepsilon_0 c'$ (so $c'^*\varepsilon_0 c = \bar{t}$, ε_0 being real diagonal, and $\bar{\jmath} = -\jmath$),

$$\mathrm{rad}(c,\beta)\,\mathrm{rad}(c',\beta') = \mathrm{rad}\big(c + c',\ \beta + \beta' + \jmath\, c^*\varepsilon_0 c'\big). \tag{6.48}$$

Also $\mathrm{rad}(0,\beta) = 1 - k\frac{1}{2}\jmath^{-1}(\beta + \bar{\beta})\mathrm{pr}_l = z_A(-(2\jmath)^{-1}\beta)$, since $M = -(2\jmath)^{-1}\beta$ has $M - \bar{M} = -(2\jmath)^{-1}(\beta + \bar{\beta})$.

Step 2: rational centre elements. Let $\zeta_0 \in E$. Then $z_A(\zeta_0) \in \Gamma_W$ ((1) of Lemma 6.3.32 for A). For adelic b, $z^-(b) = 1 + kb\Lambda - k_D b^* \mathrm{pr}_l$ fixes k, so it commutes with $z_A(\zeta_0)$; as $z_A(\zeta_0)$ fixes k_D, (4) of Lemma 6.3.32 for D with $c = 1$ gives $\mathrm{coef}(T;f)(z^-(b)z_A(\zeta_0)x) = \mathrm{coef}(T;f)(z_A(\zeta_0)z^-(b)x) = \mathrm{coef}(T;f)(z^-(b)x)$ (coefficients along D), and integration over b gives $f^+(z_A(\zeta_0)x) = f^+(x)$ for every $x \in \mathrm{G}(s)$.

Step 3: local centre elements are shears. For $y \in \mathbb{A}_E$, $\overline{\mathrm{e}y} = \mathrm{e}_{\bar{U}}\bar{y}$, so

$$z_A(\mathrm{e}y) = 1 + k(\mathrm{e}y - \overline{\mathrm{e}y})\mathrm{pr}_l = 1 + \mathrm{e}_{\bar{U}}\,k\,(-\bar{y}\,\mathrm{pr}_l) - \mathrm{e}\,(-ky\,\mathrm{pr}_l),$$

and $(-\bar{y}\,\mathrm{pr}_l)k = 0$: $z_A(\mathrm{e}y)$ is an A-shear for U.

Step 4: strong approximation. Fix $w_0 \in U$. By Theorem A.4.7 for the number field E, the additive group $\mathbb{G}_a^m$ and the set $\{w_0\}$, the set $E^m + E^m_{w_0}$ is dense in $\mathbb{A}_E^m$, where $E^m_{w_0}$ is

embedded as the adelic vectors with components 0 outside w_0; these lie in $\mathrm{e}\,\mathbb{A}_E^m$. Hence for any $Z \in \mathrm{GL}_m(\mathbb{A}_E)$ the set $\{Z\gamma + \mathrm{e}y : \gamma \in E^m,\ y \in \mathbb{A}_E^m\}$ is dense in $\mathbb{A}_E^m$, being the image of a dense set under the homeomorphism $v \mapsto Zv$, which commutes with multiplication by e.

Step 5: proof of (1). Let $x \in H$ and $\varphi(\zeta) = f^+(z_A(\zeta)x)$, continuous by (2) of Lemma 6.3.37. For $\zeta_0 \in E$ and $y \in \mathbb{A}_E$, $z_A(\zeta_0 + \mathrm{e}y) = z_A(\zeta_0)z_A(\mathrm{e}y)$, so by Step 2, Step 3 and the hypothesis at x, $\varphi(\zeta_0 + \mathrm{e}y) = f^+(z_A(\mathrm{e}y)x) = f^+(x)$. By Step 4 ($m = 1$, $Z = 1$) and continuity, $\varphi \equiv f^+(x)$. Then (2) of Lemma 6.3.42 gives $C(x) = \int_{\mathbb{A}_E/E} \varphi(\zeta)\, d\zeta = f^+(x)$.

Step 6: $C(\mathrm{rad}(c,\beta)g) = C(g)$ for $g \in H$ and all c, β. (a) C is continuous by (1) of Lemma 6.3.32 for $A \circ B$, and $C(z_A(\zeta)x) = C(x)$ for all x: by (1) of Lemma 6.3.42 with $b = c = N = 0$, $z_A(\zeta) = z_{A\circ B}(\zeta \oplus 0)$, and (2) of Lemma 6.3.32 for $A \circ B$ applies with $\mathrm{tr}((0 \oplus T)(\zeta \oplus 0)) = 0$. (b) Let $Y \in E^{n_0}$ and $Y_0 = x_{W_0}^{-1} Y$. Conjugated by x_W, using $x_W k = k_{\mathrm{rat}}$, $x_W i = i_{\mathrm{rat}} x_{W_0}$, $\mathrm{pr}_l x_W^{-1} = k_{\mathrm{rat}}^* J_W$ and $\mathrm{pr}_i x_W^{-1} = \varepsilon_0 x_{W_0}^* i_{\mathrm{rat}}^* J_W$ (k_{rat}, i_{rat} the rational frames of A), the three terms of $N(Y_0, 0)$ become $-i_{\mathrm{rat}} Y k_{\mathrm{rat}}^* J_W$, $k_{\mathrm{rat}} Y^* i_{\mathrm{rat}}^* J_W$ and $-\frac{1}{2} k_{\mathrm{rat}} (Y^* J_{W_0} Y) k_{\mathrm{rat}}^* J_W$, all over E; so $\mathrm{rad}(Y_0, 0) \in \Gamma_W$. By Step 1 it fixes k and sends $k_D = i k_B$ to $k_D + k\, Y_0^* \varepsilon_0 k_B = k_D + k\, v$ with $v = Y^* J_{W_0} k_{B,\mathrm{rat}} \in \mathrm{M}_{1\times p}(E)$: it acts on the frame $(k \mid k_D)$ of $A \circ B$ by $u = \begin{pmatrix} 1 & v \\ 0 & 1 \end{pmatrix}$, and $u^*(0 \oplus T)u = 0 \oplus T$. By (4) of Lemma 6.3.32 for $A \circ B$, $C(\mathrm{rad}(Y_0, 0)x) = C(x)$ for all x. (c) Let $y \in \mathrm{M}_{n_0 \times 1}(\mathbb{A}_E)$ and $\nu = \mathrm{rad}(\mathrm{e}y, 0)$. As $(\mathrm{e}y)^* = \mathrm{e}_{\bar{U}} y^*$,

$$\nu = 1 + \mathrm{e}_{\bar{U}}\, k\, c_1 - \mathrm{e}\,(i y\, \mathrm{pr}_l), \qquad c_1 = y^* \varepsilon_0 (\mathrm{pr}_i - \tfrac{1}{2} \mathrm{e}\, y\, \mathrm{pr}_l), \qquad c_1 k = 0,$$

an A-shear for U; ν fixes k, so it commutes with every $z_A(\zeta)$. For $g \in H$, $z_A(\zeta)g \in H$, and by (2) of Lemma 6.3.42 and the hypothesis at $z_A(\zeta)g$,

$$C(\nu g) = \int f^+(z_A(\zeta)\nu g) d\zeta = \int f^+(\nu\, z_A(\zeta) g) d\zeta = \int f^+(z_A(\zeta) g) d\zeta = C(g).$$

(d) For $c = Y_0 + \mathrm{e}y$ and $\beta \in \mathbb{A}_E$ put $\beta' = \beta - \jmath\, Y_0^* \varepsilon_0\, \mathrm{e}y$. By (6.48), $\mathrm{rad}(c, \beta) = \mathrm{rad}(Y_0, 0)\, \mathrm{rad}(0, \beta')\, \nu$, and $\mathrm{rad}(0, \beta') = z_A(-(2\jmath)^{-1}\beta')$; by (b), (a) and (c), $C(\mathrm{rad}(c,\beta)g) = C(\nu g) = C(g)$ for $g \in H$. (e) By Step 4 ($m = \#n_0$, $Z = x_{W_0}^{-1}$) such c are dense in $\mathrm{M}_{n_0\times 1}(\mathbb{A}_E)$, and $c \mapsto C(\mathrm{rad}(c,\beta)g)$ is continuous; so the identity holds for all c.

Step 7: proof of (2). Let $g \in H$ and $h = \mathrm{rad}(c, \beta)$ with $hg \in H$. By (1) at hg and at g and by Step 6, $f^+(hg) = C(hg) = C(g) = f^+(g)$. □

Lemma 6.3.42. *Let W be a space with a point with signs s on n, A a splitting of W over W_0 along a one-element set o, B a splitting of W_0 over W_2 along p, and D a splitting of W over W_1 along p with $k_{D,\mathbb{A}} = i_{A,\mathbb{A}} k_{B,\mathbb{A}}$; write $z^- = z^-_{A,B}$. Let $f\colon \mathrm{G}(s) \to \mathbb{C}$ be continuous and left invariant under Γ_W, $T \in \mathrm{M}_p(E)$, and $0 \oplus T$ the block diagonal $(o \sqcup p) \times (o \sqcup p)$ matrix with blocks 0 and T.*

1. *For adelic matrices ζ (1×1), b ($1 \times p$), c ($p \times 1$) and N ($p \times p$),*

$$z_{A\circ B} \begin{pmatrix} \zeta & b \\ c & N \end{pmatrix} = z_D(N)\, z^-(b - c^*)\, z_A(\zeta).$$

2. *For every $g \in \mathrm{G}(s)$ the function $\zeta \mapsto \mathrm{coef}^+_{A,B,D}(T; f)(z_A(\zeta)g)$ on $\mathbb{A}_E$ is continuous and E-periodic, and, the coefficient on the left being taken along $A \circ B$,*

$$\mathrm{coef}(0 \oplus T; f)(g) = \int_{\mathbb{A}_E/E} \mathrm{coef}^+_{A,B,D}(T; f)(z_A(\zeta)g)\, d\zeta.$$

Proof. Write $k = k_{A,\mathbb{A}}$, pr_l for the coordinate pr_l of A, $\varepsilon = \varepsilon_s$, $k_D = k_{D,\mathbb{A}}$ and $\Lambda = k_D^*\varepsilon$, the coordinate pr_l of D. By the relations of (MX1) for A and B (read adelically through x_W, x_{W_0}, as in the proof of Lemma 6.3.37): $\mathrm{pr}_l k = 0$, $\mathrm{pr}_l k_D = 0$, $\Lambda k = 0$, $\Lambda k_D = k_{B,\mathbb{A}}^* \varepsilon_{s_0} k_{B,\mathbb{A}} = 0$. The composite $A \circ B$ has adelic frame $(k \mid k_D)$ and coordinate pr_l with the rows pr_l, Λ (MX5).

(1). Put $\beta = b - c^*$, so that $c - b^* = -\beta^*$. By (MX2) for $A \circ B$,

$$z_{A\circ B}\begin{pmatrix} \zeta & b \\ c & N \end{pmatrix} = 1 + k(\zeta - \bar{\zeta})\mathrm{pr}_l + k\beta\Lambda - k_D\beta^*\mathrm{pr}_l + k_D(N - N^*)\Lambda.$$

On the other side $z_A(\zeta) = 1 + k(\zeta - \bar{\zeta})\mathrm{pr}_l$, $z_D(N) = 1 + k_D(N - N^*)\Lambda$, and $z^-(\beta) = 1 + N_\beta$ with $N_\beta = k\beta\Lambda - k_D\beta^*\mathrm{pr}_l$ (the matrix $M_\beta - M_\beta^*$ of (MX5) has the blocks β at (o,p) and $-\beta^*$ at (p,o)). The relations give $N_\beta k = 0$ and $\Lambda N_\beta = 0$, $\Lambda k = 0$; hence $N_\beta\, k(\zeta - \bar{\zeta})\mathrm{pr}_l = 0$ and $k_D(N - N^*)\Lambda\big(N_\beta + k(\zeta - \bar{\zeta})\mathrm{pr}_l\big) = 0$, so the product $z_D(N)z^-(\beta)z_A(\zeta)$ is $1 + k_D(N - N^*)\Lambda + N_\beta + k(\zeta - \bar{\zeta})\mathrm{pr}_l$, which is the display.

(2). Write Q_X for the quotient of the adelic matrices of a shape X by the rational ones, with its Haar probability measure. By (1) of Lemma 6.3.32 for the splitting $A \circ B$, the function $\Phi(M) = \psi_E(\mathrm{tr}((0 \oplus T)M))\, f(z_{A\circ B}(M)g)$ is continuous and periodic under the rational $(o \sqcup p) \times (o \sqcup p)$ matrices, and $\mathrm{coef}(0 \oplus T; f)(g)$ is its integral over $Q_{o\sqcup p}$. The decomposition into the four blocks identifies $Q_{o\sqcup p}$ with $Q_{1\times 1} \times Q_{1\times p} \times Q_{p\times 1} \times Q_{p\times p}$ as compact groups, so its Haar probability measure is the product of the four (uniqueness of Haar measure), and by Fubini for the bounded continuous Φ the integral may be taken in the order N, then (b,c), then ζ. As $\mathrm{tr}((0 \oplus T)M) = \mathrm{tr}(TN)$, (1) gives

$$\Phi\begin{pmatrix} \zeta & b \\ c & N \end{pmatrix} = \psi_E(\mathrm{tr}(TN))\, f(z_D(N)\, y), \qquad y = z^-(b - c^*)\, z_A(\zeta)\, g,$$

whose integral over $N \in Q_{p\times p}$ is $\mathrm{coef}(T; f)(y)$, the coefficient along D (MX3). By (2) of Lemma 6.3.37 the function $F_\zeta(\beta) = \mathrm{coef}(T; f)(z^-(\beta)z_A(\zeta)g)$ is continuous and periodic under $\mathrm{M}_{1\times p}(E)$. The map $(b,c) \mapsto b - c^*$ is a continuous surjective homomorphism $\mathrm{M}_{1\times p}(\mathbb{A}_E) \times \mathrm{M}_{p\times 1}(\mathbb{A}_E) \to \mathrm{M}_{1\times p}(\mathbb{A}_E)$ carrying rational points onto rational points, so it induces a continuous surjective homomorphism $\pi\colon Q_{1\times p} \times Q_{p\times 1} \to Q_{1\times p}$ of compact groups; the image of the Haar probability measure under π is a probability measure invariant under all translations (each is π of a translation), hence the Haar probability measure. Therefore

$$\int_{Q_{1\times p}\times Q_{p\times 1}} F_\zeta(b - c^*)\, db\, dc = \int_{Q_{1\times p}} F_\zeta(\beta)\, d\beta = \mathrm{coef}^+_{A,B,D}(T; f)(z_A(\zeta)g)$$

by (MX11). This is, for every adelic ζ, the integral of $\Phi(\zeta, \cdot)$ over the last three blocks, so it is continuous in ζ (dominated convergence for the bounded continuous Φ on the compact quotients) and E-periodic (as Φ is periodic in the block ζ); integrating over $\zeta \in Q_{1\times 1} = \mathbb{A}_E/E$ gives the identity of (2). □

Lemma 6.3.43. *Let W, A, B, D, S, H, T and f be as in Lemma 6.3.39, with $\det T \neq 0$, write $f^+ = \mathrm{coef}^+_{A,B,D}(T; f)$ and $z^+ = z^+_{A,B}$, let U be a nonempty set of finite places of E, and assume that f^+ is invariant under the A-shears for U at every point of H. Let (X, u, t, t', γ) be a straight point of (A, B, D) off S such that every straight point $(X_1, u_1, t_1, t_1', \gamma_1)$ of (A, B, D) off S for which $a \mapsto f^+(z^+(a)X_1)$ is not identically zero has a dual index of γ_1 on $S \cup \bar{S}$ for T at least that of γ. Then $\gamma^{-1}a^*t$ is integral on $S \cup \bar{S}$ for every $a \in \mathrm{M}_{1\times p}(\mathbb{A}_E)$ with $f^+(z^+(a)X) \neq 0$.*

Proof. Write $k = k_{A,\mathbb{A}}$, $l = l_{A,\mathbb{A}}$, $k_D = k_{D,\mathbb{A}}$, pr_k for the coordinate of A, $\Lambda = k_D^* \varepsilon_s$, $F_1 = (k \mid k_D)$, $\mathrm{e} = \mathrm{e}_{S \cup \bar{S}}$. By (1) of Lemma 6.3.39, γ is invertible, and so is $T\{\gamma\}$ ($\det T \neq 0$), so the dual indices are defined; the same holds for every straight point. By (MX2) and (MX5) for $\bar{A} \circ B$, whose adelic frame k is $(l \mid k_D)$ with coordinate pr_l given by the rows $l^* \varepsilon_s = \mathrm{pr}_k$ and Λ, $z^+(a) = 1 + la\Lambda - k_D a^* \mathrm{pr}_k$, and by (MX1) $\Lambda k = 0$, $\Lambda k_D = 0$, $\mathrm{pr}_k k = 1$, $\mathrm{pr}_k k_D = 0$; hence $z^+(a)k = k - k_D a^*$ and $z^+(a)k_D = k_D$, that is

$$z^+(a) F_1 = F_1 \begin{pmatrix} 1 & 0 \\ -a^* & 1 \end{pmatrix}.$$

Suppose $f^+(z^+(a)X) \neq 0$ and $\gamma^{-1} a^* t$ is not integral on $S \cup \bar{S}$. Let $h = z^+(a)u$; then

$$hF_1 = z^+(a) F_1 \operatorname{diag}(t, \gamma) = F_1 \begin{pmatrix} t & 0 \\ -a^* t & \gamma \end{pmatrix}.$$

By (1) of Lemma 6.3.38 there are $\kappa \in \mathrm{G}(s)$ with finite part in $\mathbf{K}_0(n)$ and a', β', γ' with $h\kappa F_1 = F_1 \begin{pmatrix} a' & \beta' \\ 0 & \gamma' \end{pmatrix}$. The point $X_a = z^+(a)X$ lies in H ($z^+(a)$ fixes k_D), satisfies $\mathrm{e} X_a = z^+(a)\,\mathrm{e}u = \mathrm{e}h$, and $f^+(X_a) \neq 0$. By (2) of Lemma 6.3.39 (with $X = X_a$, $g = h$) there is a straight point $(X', u', t'', t''', \gamma')$ of (A, B, D) off S with $f^+(X') \neq 0$, that is, $a'' \mapsto f^+(z^+(a'')X')$ does not vanish at $a'' = 0$; by (1) of Lemma 6.3.39, $T\{\gamma'\}$ is integral on $S \cup \bar{S}$. Since $\gamma^{-1}(-a^* t) = -\gamma^{-1} a^* t$ is not integral on $S \cup \bar{S}$, Lemma 6.3.44 (with $\tau = t$, $x = -a^* t$) shows that the dual index of γ' is smaller than that of γ, contrary to the minimality of (X, u, t, t', γ). □

Lemma 6.3.44. *Let W be a space with a point with signs s on n, A a base-adapted splitting of W over W_0 along a one-element set, B a base-adapted splitting of W_0 over W_2 along p, $F_1 = (k_{A,\mathbb{A}} \mid i_{A,\mathbb{A}} k_{B,\mathbb{A}})$, $T \in \mathrm{M}_p(E)$ with $\det T \neq 0$, and S a set of finite places of E. Let $h, \kappa \in \mathrm{G}(s)$, the finite part of κ in $\mathbf{K}_0(n)$, with*

$$hF_1 = F_1 \begin{pmatrix} \tau & 0 \\ x & \gamma \end{pmatrix}, \qquad h\kappa F_1 = F_1 \begin{pmatrix} a & \beta \\ 0 & \gamma' \end{pmatrix}$$

(blocks 1×1, $1 \times p$, $p \times 1$, $p \times p$ over $\mathbb{A}_E$), where γ is invertible, $T\{\gamma'\}$ is integral on $S \cup \bar{S}$, and $\gamma^{-1} x$ is not integral on $S \cup \bar{S}$. Then γ', $T\{\gamma\}$ and $T\{\gamma'\}$ are invertible, and the dual index of γ' on $S \cup \bar{S}$ for T is smaller than that of γ.

Proof. Let $C = A \circ B$, with frames $k_C = F_1$ and l_C (MX5), and $\varepsilon = \varepsilon_s$; by (MX1), $l_C^* \varepsilon F_1 = 1$. Write B_0, B_1 for the two block matrices of the hypothesis. As $hF_1 = F_1 B_0$ and $h\kappa F_1 = F_1 B_1$ with h, $h\kappa$ invertible, $B_1 = l_C^* \varepsilon h \kappa F_1$ is invertible at every place, with inverse $l_C^* \varepsilon (h\kappa)^{-1} F_1$, and $(h\kappa)^{-1} F_1 = F_1 B_1^{-1}$. Hence

$$\kappa^{-1} F_1 = (h\kappa)^{-1} h F_1 = (h\kappa)^{-1} F_1 B_0 = F_1\, a_0, \qquad a_0 = B_1^{-1} B_0 = l_C^* \varepsilon\, \kappa^{-1} F_1.$$

At the finite places $\varepsilon = 1$, and $l_C = (l_{A,\mathbb{A}} \mid i_{A,\mathbb{A}} l_{B,\mathbb{A}})$, F_1 and κ^{-1} are integral there (A, B are base-adapted, and κ^{-1} has finite part in $\mathbf{K}_0(n)$); so a_0 is integral at all finite places, in particular on $S \cup \bar{S}$. Write $a_0 = \begin{pmatrix} a_{11} & a_{12} \\ a_{21} & a_{22} \end{pmatrix}$. The lower block row of $B_0 = B_1 a_0$ reads $x = \gamma' a_{21}$, $\gamma = \gamma' a_{22}$. As γ is invertible, so are γ' and a_{22}, and $T\{\gamma\}$, $T\{\gamma'\}$ are invertible since $\det T \neq 0$ and δ_J is an idele. Moreover $\gamma^{-1} x = a_{22}^{-1} a_{21}$. If $(\det a_{22})^{-1}$ were integral on $S \cup \bar{S}$, then so would be $a_{22}^{-1} = (\det a_{22})^{-1} \operatorname{adj}(a_{22})$ and $\gamma^{-1} x$, contrary to the hypothesis. Finally $T\{\gamma\} = T\{\gamma' a_{22}\} = a_{22}^*\, T\{\gamma'\}\, a_{22}$, δ_J being a scalar. With d_S as in Lemma 6.3.45, the two dual indices are $d_S(T\{\gamma'\})$ and $d_S(T\{\gamma\})$. By (2) of Lemma 6.3.45 with $C = T\{\gamma'\}$ and $r = a_{22}$, both integral on $S \cup \bar{S}$, $d_S(T\{\gamma'\}) < d_S(a_{22}^* T\{\gamma'\} a_{22}) = d_S(T\{\gamma\})$. □

Lemma 6.3.45. *For a finite adele a of E let $\mathrm{den}(a)$ be its denominator index, the index in $\widehat{\mathcal{O}}_E$ of $H(a) = \{y \in \widehat{\mathcal{O}}_E : ay \in \widehat{\mathcal{O}}_E\}$. For a set S of finite places of E, an adele x and an invertible adelic square matrix C, let x_S be the finite part of $\mathrm{e}_{S\cup\bar{S}}\, x$ and $d_S(C) = \mathrm{den}\big((\det C)_S^{-1}\big)$; so for $T \in \mathrm{M}_p(E)$ and $\gamma \in \mathrm{M}_p(\mathbb{A}_E)$ with $T\{\gamma\}$ invertible, $d_S(T\{\gamma\})$ is the dual index of γ on $S \cup \bar{S}$ for T.*

1. *$\mathrm{den}(a)$ is finite for every finite adele a. If $a = ub$ with $u \in \widehat{\mathcal{O}}_E$, and some $y \in \widehat{\mathcal{O}}_E$ has $ay \in \widehat{\mathcal{O}}_E$ and by $\notin \widehat{\mathcal{O}}_E$, then $\mathrm{den}(a) < \mathrm{den}(b)$.*
2. *Let C, r be adelic $p\times p$ matrices, integral on $S\cup\bar{S}$, such that r^*Cr is invertible and $(\det r)^{-1}$ is not integral on $S \cup \bar{S}$. Then $d_S(C) < d_S(r^*Cr)$.*

Proof. **(1).** $\widehat{\mathcal{O}}_E$ is a compact open subring of the finite adeles, and $H(a)$ is the intersection of $\widehat{\mathcal{O}}_E$ with the preimage of the open set $\widehat{\mathcal{O}}_E$ under the continuous map $y \mapsto ay$; so $H(a)$ is an open subgroup of the compact group $\widehat{\mathcal{O}}_E$, of finite index. If $by \in \widehat{\mathcal{O}}_E$ then $ay = u(by) \in \widehat{\mathcal{O}}_E$, so $H(b) \subset H(a)$; the given y lies in $H(a) \setminus H(b)$. Hence $[H(a) : H(b)] \geq 2$ and $\mathrm{den}(b) = \mathrm{den}(a)\,[H(a) : H(b)] > \mathrm{den}(a)$.

(2). Write $\mathrm{e} = \mathrm{e}_{S\cup\bar{S}}$; as $\mathrm{e}^2 = \mathrm{e}$, $(xy)_S = x_S y_S$, and an adele x is integral on $S \cup \bar{S}$ exactly when $x_S \in \widehat{\mathcal{O}}_E$. Since $S \cup \bar{S}$ is stable under conjugation, $\bar{x}$ is integral on $S \cup \bar{S}$ when x is; so $\det r$, $\det r^* = \overline{\det r}$ and $\det C$ are integral on $S \cup \bar{S}$. As $\det(r^*Cr)$ is a unit, so are $\det r$, $\det r^*$ and $\det C$. Put

$$a = \big((\det C)^{-1}\big)_S, \qquad b = \big(\det(r^*Cr)^{-1}\big)_S, \qquad u = (\det r^* \det r)_S, \qquad y = (\det r^* \det C)_S.$$

Then $u, y \in \widehat{\mathcal{O}}_E$; $(\det C)^{-1} = \det r^* \det r\, \det(r^*Cr)^{-1}$ gives $a = ub$; $ay = (\det r^*)_S \in \widehat{\mathcal{O}}_E$; and $by = ((\det r)^{-1})_S \notin \widehat{\mathcal{O}}_E$ by hypothesis. By (1), $d_S(C) = \mathrm{den}(a) < \mathrm{den}(b) = d_S(r^*Cr)$. □

Lemma 6.3.46. *Let W, A, B, D, S, T and f be as in Lemma 6.3.39, with $\det T \neq 0$; write $\mathrm{e} = \mathrm{e}_{S\cup\bar{S}}$, $z^{\pm} = z^{\pm}_{A,B}$ and $f^{\pm} = \mathrm{coef}^{\pm}_{A,B,D}(T; f)$. Let (X, u, t, t', γ) be a straight point of (A, B, D) off S, and put $\varphi^+(a) = f^+(z^+(a)X)$ and $\varphi^-(b) = f^-(z^-(b)X)$ for $a, b \in \mathrm{M}_{1\times p}(\mathbb{A}_E)$.*

1. *Assume that $\gamma^{-1}b^*t'$ is integral on $S \cup \bar{S}$ whenever $\varphi^-(b) \neq 0$. Let $x \in \mathrm{M}_{p\times 1}(\mathbb{A}_E)$ with $T\{\gamma\}x$ integral on $S \cup \bar{S}$, and $a_x = \mathrm{e}\, t'x^*\gamma^*$. Then $\varphi^+(y + a_x) = \varphi^+(y)$ for every $y \in \mathrm{M}_{1\times p}(\mathbb{A}_E)$.*
2. *Assume that φ^+ is not identically zero, that $\gamma^{-1}a^*t$ is integral on $S\cup\bar{S}$ whenever $\varphi^+(a) \neq 0$, and that $\gamma^{-1}b^*t'$ is integral on $S \cup \bar{S}$ whenever $\varphi^-(b) \neq 0$. Then $T\{\gamma\}$ is invertible and $T\{\gamma\}^{-1}$ is integral on $S \cup \bar{S}$.*

Proof. By (1) of Lemma 6.3.39, γ is invertible, hence so is $T\{\gamma\} = \delta_\jmath^{-1}\gamma^*T\gamma$. The adele e is real, idempotent, and supported on the finite places; integrality on $S \cup \bar{S}$ is preserved by sums, products and conjugate transposes ($S \cup \bar{S}$ is stable under conjugation).

(1). By (3) of Lemma 6.3.37, $f^-(z^-(b)z^+(a)X) = \psi_E(-\mathrm{tr}(Ta^*b))\,\varphi^-(b)$ for all a, b. Take $a = a_x$, so $a_x^* = \mathrm{e}\,\gamma x\bar{t}'$, and put $c_b = (\gamma^{-1}b^*t')^*\,(T\{\gamma\}x) = \delta_\jmath^{-1}\bar{t}'\,bT\gamma x$ (a 1×1 matrix, read as an adele). Then

$$\mathrm{tr}(Ta_x^*b) = \mathrm{e}\,\bar{t}'\,bT\gamma x = \mathrm{e}\,\delta_\jmath\, c_b.$$

If $\varphi^-(b) \neq 0$, then $\gamma^{-1}b^*t'$ and $T\{\gamma\}x$ are integral on $S \cup \bar{S}$, so c_b is, and the adele $-\mathrm{e}\delta_\jmath c_b$ has infinite components 0 and finite part $\jmath\alpha\bar{\alpha}r$ with r the finite part of $-\mathrm{e}c_b$, which lies in $\widehat{\mathcal{O}}_E$; by (WD4), $\psi_E(-\mathrm{e}\delta_\jmath c_b) = \psi_0(r) = 1$. Hence $f^-(z^-(b)z^+(a_x)X) = \varphi^-(b)$ for every b (both

sides vanish where $\varphi^-(b) = 0$). By (5) of Lemma 6.3.37, (4) holds for the opposite splitting $\bar{A}$, for which the roles of f^+, f^- and of the two shifted means are exchanged; applied with $x' = z^+(a_x)X$, $x = X$ and $c = 1$ it gives $f^+(z^+(y)z^+(a_x)X) = f^+(z^+(y)X)$ for every y. As $z^+(y + a_x) = z^+(y)z^+(a_x)$ ((1) of Lemma 6.3.37), this is $\varphi^+(y + a_x) = \varphi^+(y)$.

(2). Fix $j \in p$ and let x be the j-th column of $T\{\gamma\}^{-1}$; then $T\{\gamma\}x$ is the j-th unit column, integral. Choose y with $\varphi^+(y) \neq 0$; by (1), $\varphi^+(y+a_x) = \varphi^+(y) \neq 0$. By hypothesis $\gamma^{-1}(y+a_x)^*t$ and $\gamma^{-1}y^*t$ are integral on $S \cup \bar{S}$, hence so is their difference

$$\gamma^{-1}a_x^*t = \gamma^{-1}\,\mathrm{e}\,\gamma x\,\bar{t}'t = \mathrm{e}\,x,$$

using $\bar{t}'t = 1$. So x is integral on $S \cup \bar{S}$; as j was arbitrary, so is $T\{\gamma\}^{-1}$. □

Lemma 6.3.47. *Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character, X a space with a point with signs r on m, b an index set and $(\mathcal{L}, \mathcal{D})$ an equivariant lift for $(\mathfrak{c}, X, b)$. Let D be a base-adapted splitting of X over a space with a point W_1 along b with coordinate $\mathrm{pr}_{l,D}$, and assume $\Psi_0 = \Psi^{\mathrm{st}}_{(\mathrm{pr}_{l,D})_\Sigma} \in \mathcal{L}$. Let A be a splitting of X over a space with a point W_0 along a one-element set and B a splitting of W_0 over a space with a point along b, with rational frames satisfying $k_D = i_A k_B$. Let S be the set of finite places w of E with $w \notin \Sigma \cup \bar{\Sigma}$, H the frame stabiliser of D off S, and $T \in \mathrm{M}_b(E)$. Then at every point of H, $\mathrm{coef}^+_{A,B,D}(T; \mathcal{D}\Psi_0)$ is invariant under the A-shears for $\bar{\Sigma}$, and $\mathrm{coef}^-_{A,B,D}(T; \mathcal{D}\Psi_0)$ is invariant under the $\bar{A}$-shears for $\bar{\Sigma}$.*

Proof. For $\Psi \in \mathcal{L}$ write $f^\pm_\Psi = \mathrm{coef}^\pm_{A,B,D}(T; \mathcal{D}\Psi)$. As $\mathcal{D}\Psi$ is continuous and left Γ_X-invariant ((XD11)(b)), (2) of Lemma 6.3.37 shows that the partial means of $\mathcal{D}\Psi$ are defined everywhere, with $f^+_\Psi(z^-_{A,B}(a)x) = f^+_\Psi(x)$; and $\Psi \mapsto f^\pm_\Psi(x)$ is linear on $\mathcal{L}$ ($\mathcal{D}$ is linear, and so are the centre coefficients by (1) of Lemma 6.3.32 and the integral). In this proof $k_A = k_{A,\mathbb{A}}$ and $k_D = k_{D,\mathbb{A}}$ denote the adelic frames and k^E_A, k^E_D, i^E_A, k^E_B the rational ones (so $k^E_D = i^E_A k^E_B$); write $\mathrm{pr}_l = \mathrm{pr}_{l,D}$, $\varepsilon = \varepsilon_r$, and $s_0 = (\mathrm{pr}_l)_\Sigma$, so $\Psi_0 = \Psi^{\mathrm{st}}_{s_0}$; s_0 is integral because D is base-adapted and $\mathrm{pr}_l = k^*_D\varepsilon$ has finite part $k^*_{D,f}$.

Step 1: two orthogonality relations. $\mathrm{pr}_l k_A = 0$: indeed $\mathrm{pr}_l k_A = (x_X^{-1}k^E_D)^*\varepsilon\, x_X^{-1}k^E_A = (k^E_D)^* J_X k^E_A$ (as $(x_X^{-1})^*\varepsilon x_X^{-1} = J_X$), and $(k^E_D)^*J_X k^E_A = (k^E_B)^*(i^E_A)^*J_X k^E_A = 0$ by (MX1) for A. Moreover, for $g \in H$ and every place $w \in \Sigma$, $(\mathrm{pr}_l g)_w = (\mathrm{pr}_l)_w$: from $g^*\varepsilon g = \varepsilon$, $\mathrm{pr}_l g = (g^{-1}k_D)^*\varepsilon$, and at w the conjugate transpose reads the component at $\bar{w} \in \bar{\Sigma}$, where $g^{-1}k_D = k_D$ (g fixes the components of k_D at the places of $\Sigma \cup \bar{\Sigma}$, the complement of $S \cup \bar{S}$ among the finite places).

Step 2: a linear form and its invariance. Fix $x \in \mathrm{G}(r)$ with $(\mathrm{pr}_l x)_\Sigma = s_0$, and put $u = (x^{-1}k_A)_\Sigma \in \mathrm{M}_{m\times 1}(E_\Sigma)$. Let $\Lambda(\Psi) = f^+_\Psi(x)$ on $\mathcal{L}$. We claim: for $\Phi \in \mathcal{L}$ and $w \in \mathrm{M}_{1\times b}(E_\Sigma)$, the function $\Phi_w(y) = \Phi(y + u\,w\,s_0\,y)$ lies in $\mathcal{L}$ and $\Lambda(\Phi_w) = \Lambda(\Phi)$. Let $N \in \mathrm{M}_{1\times b}(\mathbb{A}_E)$ have components w at Σ and 0 elsewhere, and $\nu_1 = z^-_{A,B}(N) = z_{A\circ B}(M_N)$. The frames of $A \circ B$ are $k_{A\circ B} = (k_A \mid k_D)$ and its coordinate $\mathrm{pr}_{l,A\circ B} = k^*_{A\circ B}\varepsilon$ has the rows $\mathrm{pr}_{l,A}$ and pr_l ((MX1), (MX5)); with (MX2),

$$\nu_1 = 1 + k_A N\,\mathrm{pr}_l - k_D N^* \mathrm{pr}_{l,A}.$$

At a place $w' \in \Sigma$ the component of N^* is the conjugate transpose of that of N at $\bar{w}' \notin \Sigma$, which is 0; so ν_1 has component $1 + (k_A)_{w'}w_{w'}(\mathrm{pr}_l)_{w'}$ at $w' \in \Sigma$ and 1 at the infinite places and at the finite places outside $\Sigma \cup \bar{\Sigma}$. By Step 1, $C = w(\mathrm{pr}_l)_\Sigma$ and $U = (k_A)_\Sigma$ satisfy $CU = 0$. By (1) of Lemma 6.3.14, $\Phi'(y) = \Phi(y + (x^{-1})_\Sigma UC\,x_\Sigma y)$ lies in $\mathcal{L}$ and $\mathcal{D}\Phi'(y'x) = \mathcal{D}\Phi(y'\nu_1^{-1}x)$ for all y'; and $(x^{-1})_\Sigma UCx_\Sigma = u\,w\,(\mathrm{pr}_l x)_\Sigma = u\,w\,s_0$, so $\Phi' = \Phi_w$. Taking $y' = z_D(M)z^-_{A,B}(a)$, and using $z^-_{A,B}(a)z^-_{A,B}(-N) = z^-_{A,B}(a - N)$ ((1) of Lemma 6.3.37),

$$\mathrm{coef}(T; \mathcal{D}\Phi_w)(z^-_{A,B}(a)x) = \mathrm{coef}(T; \mathcal{D}\Phi)(z^-_{A,B}(a - N)x),$$

and integrating over a modulo $\mathrm{M}_{1\times b}(E)$ (translation invariance of the probability measure) gives $\Lambda(\Phi_w) = \Lambda(\Phi)$.

Step 3: averaging over integral shears. Let u, x be as in Step 2 and $r \in \mathrm{M}_{1\times m}(E_\Sigma)$ with $ru = 0$, and assume $s_0 u = 0$. For $t \in \mathcal{K} = \mathrm{M}_{m\times b}(\mathcal{O}_\Sigma)$ (a compact group with Haar probability dt) let $\tau_t(y) = y + u\,(rt)\,s_0\,y$. For $\Phi \in \mathcal{L}$ put $\bar\Phi(y) = \int_{\mathcal{K}} \Phi(\tau_t y)\,dt$. We claim $\bar\Phi \in \mathcal{L}$ and $\Lambda(\bar\Phi) = \Lambda(\Phi)$. As $s_0 u = 0$, $s_0\tau_t(y) = s_0 y$ and $\tau_{-t}\tau_t = \mathrm{id}$. Φ is locally constant with compact support Q ((XD11)(a)), so there is an open subgroup U_0 of $\mathrm{M}_{m\times b}(E_\Sigma)$ with $\Phi(y+\delta) = \Phi(y)$ for all y and $\delta \in U_0$. If $\Phi(\tau_t y) \neq 0$ then $y = \tau_{-t}(\tau_t y)$ lies in the compact set $Q' = \{\tau_{-t}(q) : t \in \mathcal{K}, q \in Q\}$. Choose an open subgroup $U_1 \subseteq \mathcal{K}$ with $u\,r\,\delta\,s_0\,y \in U_0$ for $\delta \in U_1$, $y \in Q'$. For $t - t' \in U_1$ and $y \in Q'$, $\Phi(\tau_{t'} y) = \Phi(\tau_t y + ur(t'-t)s_0 y) = \Phi(\tau_t y)$, and both vanish for $y \notin Q'$. So $t \mapsto \Phi\circ\tau_t$ is constant on the finitely many cosets $t_1U_1, \dots, t_NU_1$ of U_1 in $\mathcal{K}$, and $\bar\Phi = N^{-1}\sum_j \Phi\circ\tau_{t_j}$. Each $\Phi\circ\tau_{t_j}$ is Φ_w for $w = rt_j$, so it lies in $\mathcal{L}$ with the same value of Λ (Step 2); by linearity the claim follows.

Step 4: the shear of the standard datum. With u, r as in Step 3 let $\Psi'(y) = \Psi_0(y + u\,r\,y)$, and assume $\Psi' \in \mathcal{L}$. We show $\bar\Psi' = \bar\Psi_0$, hence $\Lambda(\Psi') = \Lambda(\Psi_0)$. Fix y. Since $ru = 0$, $\Psi'(\tau_t y) = \Psi_0(y + u(rts_0 y + ry))$ and $\Psi_0(\tau_t y) = \Psi_0(y + u\,rts_0 y)$. If $\Psi_0(y+u\rho) \neq 0$ for some $\rho \in \mathrm{M}_{1\times b}(E_\Sigma)$, then $y+u\rho$ is integral and $s_0(y+u\rho) = s_0 y \in \mathrm{GL}_b(\mathcal{O}_\Sigma)$; then $t_0 = (y+u\rho)(s_0 y)^{-1} \in \mathcal{K}$ satisfies $u\,rt_0 s_0 y = ur(y+u\rho) = ury$, so $\Psi'(\tau_t y) = \Psi_0(\tau_{t+t_0} y)$ and the two means agree by translation invariance of dt. Otherwise all values $\Psi_0(y+u\rho)$ vanish, and so do both integrands.

Step 5: the shears. Let $g \in H$ and ν an A-shear for $\bar\Sigma$: $\nu = 1 + \mathrm{e}_\Sigma k_A c - \mathrm{e}_{\bar\Sigma} a$ with $ck_A = 0$. Its components are $1 + (k_A)_w c_w$ at $w \in \Sigma$ and 1 at the infinite places and at the finite places outside $\Sigma \cup \bar\Sigma$. Put $x = \nu g$. By Step 1, $(\mathrm{pr}_l \nu)_\Sigma = (\mathrm{pr}_l)_\Sigma + (\mathrm{pr}_l k_A)_\Sigma c_\Sigma = s_0$ and $(\mathrm{pr}_l x)_\Sigma = (\mathrm{pr}_l g)_\Sigma = s_0$ (the components at Σ of $\mathrm{pr}_l \nu g$ are products of those of $\mathrm{pr}_l\nu$ and g). Hence $u = (x^{-1}k_A)_\Sigma$ satisfies $s_0 u = (\mathrm{pr}_l x\, x^{-1} k_A)_\Sigma = (\mathrm{pr}_l k_A)_\Sigma = 0$, and $r = (cx)_\Sigma$ satisfies $ru = (ck_A)_\Sigma = 0$. By (1) of Lemma 6.3.14 with $U = (k_A)_\Sigma$, $C = c_\Sigma$ ($CU = 0$), $\nu_0 = \nu$ and the point x: $\Psi'(y) = \Psi_0(y + (x^{-1})_\Sigma (k_A)_\Sigma c_\Sigma x_\Sigma y) = \Psi_0(y + ury)$ lies in $\mathcal{L}$ and $\mathcal{D}\Psi'(y'x) = \mathcal{D}\Psi_0(y'\nu^{-1}x) = \mathcal{D}\Psi_0(y'g)$; taking $y' = z_D(M) z^-_{A,B}(a)$ and integrating, $f^+_{\Psi'}(x) = f^+_{\Psi_0}(g)$. By Step 4, $f^+_{\Psi'}(x) = \Lambda(\Psi') = \Lambda(\Psi_0) = f^+_{\Psi_0}(\nu g)$. So $f^+_{\Psi_0}(\nu g) = f^+_{\Psi_0}(g)$: this is the first assertion.

Step 6: the opposite splitting. The opposite splitting $\bar A$ has the same embedding $i_{\bar A} = i_A$, so $k_D = i_{\bar A} k_B$, and its frame is $k_{\bar A} = l_A$. Steps 1–5 for $\bar A$ in place of A show that $\mathrm{coef}^+_{\bar A,B,D}(T; \mathcal{D}\Psi_0)$ is invariant under the $\bar A$-shears for $\bar\Sigma$ at the points of H; and $\mathrm{coef}^+_{\bar A,B,D} = \mathrm{coef}^-_{A,B,D}$ ((MX11)). □

Lemma 6.3.48. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p an index set and $D = (k,l,i)$ a splitting of V over V_0 along p, with its Levi and radical elements.*

1. *For $m, m' \in \mathrm{GL}_p(\mathbb{A}_E)$ and $g_0, g_0' \in \mathrm{G}(s_0)$, $\mathrm{lev}(m,g_0)\,\mathrm{lev}(m',g_0') = \mathrm{lev}(mm', g_0 g_0')$, and $\mathrm{lev}(m,g_0)\,k_{\mathbb{A}} = k_{\mathbb{A}} m$.*

2. *For $m \in \mathrm{GL}_p(\mathbb{A}_E)$, $g_0 \in \mathrm{G}(s_0)$, an adelic $n_0 \times p$ matrix c and an adelic $p \times p$ matrix b,*

$$\mathrm{lev}(m,g_0)\,\mathrm{rad}(c,b)\,\mathrm{lev}(m,g_0)^{-1} = \mathrm{rad}(g_0 c m^*,\ mbm^*).$$

3. *If $x \in \mathrm{G}(s)$ and $q \in \mathrm{GL}_p(\mathbb{A}_E)$ satisfy $x\,k_{\mathbb{A}} = k_{\mathbb{A}} q$, then $x = \mathrm{rad}(c,b)\,\mathrm{lev}(q,g_0)$ for some adelic c, b and some $g_0 \in \mathrm{G}(s_0)$.*

4. *For $m \in \mathrm{GL}_p(E)$, $\mathrm{lev}(m,1) \in \Gamma_V$.*

Proof. Write $\varepsilon = \varepsilon_s$, $\varepsilon_0 = \varepsilon_{s_0}$. From (MX1): $\mathrm{pr}_k = l_{\mathbb{A}}^*\varepsilon$, $\mathrm{pr}_l = k_{\mathbb{A}}^*\varepsilon$, $\mathrm{pr}_i = \varepsilon_0 i_{\mathbb{A}}^*\varepsilon$, and the frame $(l_{\mathbb{A}} \mid k_{\mathbb{A}} \mid i_{\mathbb{A}})$ is invertible with inverse the matrix of the rows pr_l, pr_k, pr_i; so $\mathrm{pr}_k k_{\mathbb{A}} = 1$, $\mathrm{pr}_l l_{\mathbb{A}} = 1$, $\mathrm{pr}_i i_{\mathbb{A}} = 1$, the other products of a coordinate with a frame vanish, and $k_{\mathbb{A}}\mathrm{pr}_k + l_{\mathbb{A}}\mathrm{pr}_l + i_{\mathbb{A}}\mathrm{pr}_i = 1$. The relations of (MX1) read $k_{\mathbb{A}}^*\varepsilon k_{\mathbb{A}} = l_{\mathbb{A}}^*\varepsilon l_{\mathbb{A}} = 0$, $l_{\mathbb{A}}^*\varepsilon k_{\mathbb{A}} = 1$, $i_{\mathbb{A}}^*\varepsilon i_{\mathbb{A}} = \varepsilon_0$, $i_{\mathbb{A}}^*\varepsilon k_{\mathbb{A}} = i_{\mathbb{A}}^*\varepsilon l_{\mathbb{A}} = 0$, as $x_V^* J_V x_V = \varepsilon$.

(1). By definition $\mathrm{lev}(m, g_0)$ sends $k_{\mathbb{A}}a \mapsto k_{\mathbb{A}}ma$, $l_{\mathbb{A}}a \mapsto l_{\mathbb{A}}(m^{-1})^*a$ and $i_{\mathbb{A}}w \mapsto i_{\mathbb{A}}g_0 w$. Composing on the frame gives $\mathrm{lev}(mm', g_0 g_0')$, since $(m^{-1})^*(m'^{-1})^* = ((mm')^{-1})^*$; and the frame determines the matrix.

(2). Put $\lambda = \mathrm{lev}(m, g_0)$, so $\lambda^{-1} = \mathrm{lev}(m^{-1}, g_0^{-1})$ by (1). From the action on the frame, $\lambda i_{\mathbb{A}} = i_{\mathbb{A}} g_0$, $\lambda k_{\mathbb{A}} = k_{\mathbb{A}} m$, $\mathrm{pr}_l\lambda^{-1} = m^*\mathrm{pr}_l$ and $\mathrm{pr}_i\lambda^{-1} = g_0^{-1}\mathrm{pr}_i$. With $X(c,b) = \frac{1}{2}(\jmath^{-1}(b+b^*) + c^*\varepsilon_0 c)$, conjugating the four terms of $\mathrm{rad}(c,b)$ gives

$$\lambda\,\mathrm{rad}(c,b)\,\lambda^{-1} = 1 - i_{\mathbb{A}}(g_0 c m^*)\mathrm{pr}_l + k_{\mathbb{A}}\, mc^*\varepsilon_0 g_0^{-1}\,\mathrm{pr}_i - k_{\mathbb{A}}\, mX(c,b)m^*\,\mathrm{pr}_l.$$

With $c' = g_0 c m^*$: $g_0^*\varepsilon_0 g_0 = \varepsilon_0$ gives $\varepsilon_0 g_0^{-1} = g_0^*\varepsilon_0$, so $mc^*\varepsilon_0 g_0^{-1} = c'^*\varepsilon_0$, and $c'^*\varepsilon_0 c' = mc^*\varepsilon_0 c m^*$; as $\jmath$ is a scalar, $mX(c,b)m^* = X(c', mbm^*)$. This is $\mathrm{rad}(c', mbm^*)$.

(3). Let $x_1 = \mathrm{lev}(q,1)^{-1}x$; by (1), $x_1 k_{\mathbb{A}} = k_{\mathbb{A}}$. Unitarity $x_1^*\varepsilon x_1 = \varepsilon$ gives $\varepsilon x_1 = (x_1^{-1})^*\varepsilon$, hence $\mathrm{pr}_l x_1 = k_{\mathbb{A}}^*(x_1^{-1})^*\varepsilon = (x_1^{-1}k_{\mathbb{A}})^*\varepsilon = \mathrm{pr}_l$. Therefore $x_1 i_{\mathbb{A}} = i_{\mathbb{A}} g_0 + k_{\mathbb{A}}\varphi$ with $g_0 = \mathrm{pr}_i x_1 i_{\mathbb{A}}$ and $\varphi = \mathrm{pr}_k x_1 i_{\mathbb{A}}$, as $\mathrm{pr}_l x_1 i_{\mathbb{A}} = \mathrm{pr}_l i_{\mathbb{A}} = 0$. Applying $x_1^*\varepsilon x_1 = \varepsilon$ to $i_{\mathbb{A}}$ and using the relations above, $g_0^*\varepsilon_0 g_0 = \varepsilon_0$, so $g_0 \in \mathrm{G}(s_0)$. Let $x_2 = \mathrm{lev}(1, g_0)^{-1}x_1$; then $x_2 k_{\mathbb{A}} = k_{\mathbb{A}}$, $\mathrm{pr}_l x_2 = \mathrm{pr}_l$ (as before), $x_2 i_{\mathbb{A}} = i_{\mathbb{A}} + k_{\mathbb{A}}\varphi$, and $x_2 l_{\mathbb{A}} = l_{\mathbb{A}} + i_{\mathbb{A}}\psi + k_{\mathbb{A}}\chi$ with $\psi = \mathrm{pr}_i x_2 l_{\mathbb{A}}$, $\chi = \mathrm{pr}_k x_2 l_{\mathbb{A}}$. Unitarity of x_2 on the pairs $(i_{\mathbb{A}}, l_{\mathbb{A}})$ and $(l_{\mathbb{A}}, l_{\mathbb{A}})$ gives

$$\varepsilon_0\psi + \varphi^* = 0, \qquad \chi + \chi^* + \psi^*\varepsilon_0\psi = 0.$$

Put $c = -\psi$, so $\varphi = c^*\varepsilon_0$; $S = -\chi - \frac{1}{2}c^*\varepsilon_0 c$ satisfies $S + S^* = 0$, and $b = \jmath S$ satisfies $b + b^* = 2\jmath S$ ($\bar{\jmath} = -\jmath$), i.e. $X(c,b) = S + \frac{1}{2}c^*\varepsilon_0 c = -\chi$. Then $\mathrm{rad}(c,b)$ sends $k_{\mathbb{A}} \mapsto k_{\mathbb{A}}$, $i_{\mathbb{A}} \mapsto i_{\mathbb{A}} + k_{\mathbb{A}}c^*\varepsilon_0$ and $l_{\mathbb{A}} \mapsto l_{\mathbb{A}} - i_{\mathbb{A}}c - k_{\mathbb{A}}X(c,b)$, as does x_2; so $x_2 = \mathrm{rad}(c,b)$ and, by (1) and (2), $x = \mathrm{lev}(q, g_0)\,\mathrm{rad}(c,b) = \mathrm{rad}(g_0 c q^*, qbq^*)\,\mathrm{lev}(q, g_0)$.

(4). By (VP2) of Definition 3.2.2 it suffices that $x_V\,\mathrm{lev}(m,1)\,x_V^{-1}$ is a rational point of $\mathrm{U}(V)$. From $x_V^* J_V x_V = \varepsilon$, $(x_V^{-1})^*\varepsilon x_V^{-1} = J_V$ and $x_{V_0}\varepsilon_0 x_{V_0}^* = J_{V_0}^{-1}$, so

$$x_V\,\mathrm{lev}(m,1)\,x_V^{-1} = km\,l^* J_V + i\,J_{V_0}^{-1} i^* J_V + l\,(m^{-1})^* k^* J_V,$$

a matrix over E; it lies in $\mathrm{U}(V)$ because $\mathrm{lev}(m,1) \in \mathrm{G}(s)$ ((MX2)). □

Lemma 6.3.49. *Let X be a space with a point with signs r on m, D a splitting of X over a space with a point W_1 (signs s on n) along b, V' a space with a point with signs t' on b, $\kappa_\alpha \in \mathbb{A}_E^\times$ the idele with components κ_v at $v \in \Phi$ and finite part α, and $f\colon \mathrm{G}(r) \to \mathbb{C}$ continuous and left invariant under Γ_X. Assume that $\mathrm{coef}(\jmath T; f)(\mathrm{rad}(c,z)\,\mathrm{lev}(q,g)) = 0$ for all $T \in \mathrm{M}_b(E)$, $c \in \mathrm{M}_{n\times b}(\mathbb{A}_E)$, $z \in \mathrm{M}_b(\mathbb{A}_E)$, $q \in \mathrm{GL}_b(\mathbb{A}_E)$, $g \in \mathrm{G}(s)$ such that either (a) $T = J_{V'}$ and $q = \kappa_\alpha x_{V'} Y$ for some $Y \in \mathrm{GL}_b(\mathbb{A}_E)$ for which some $k \in \mathrm{GL}_b(\widehat{\mathcal{O}}_E)$ has $(Y_f k)^*(Y_f k) = 1$, or (b) $\det T \neq 0$ and T is not represented by the signs t' (centre coefficients, radical and Levi elements of D). Let $\beta \in \mathrm{M}_b(E)$ with $\det\beta \neq 0$, $q \in \mathrm{GL}_b(\mathbb{A}_E)$ and $k \in \mathrm{GL}_b(\widehat{\mathcal{O}}_E)$ with $k^*(q^*\beta q)_f k = 1$. Then*

$$\mathrm{coef}(\jmath\beta; f)(\mathrm{rad}(c,z)\,\mathrm{lev}(\kappa_\alpha q, g)) = 0 \qquad (c \in \mathrm{M}_{n\times b}(\mathbb{A}_E),\ z \in \mathrm{M}_b(\mathbb{A}_E),\ g \in \mathrm{G}(s)).$$

Proof. Write $p = \mathrm{rad}(c,z)\,\mathrm{lev}(\kappa_\alpha q, g)$. If β, read as an adelic matrix, is not represented by t', then $T = \beta$ and the point p (with $\kappa_\alpha q$ in the place of q) are as in (b), and the coefficient vanishes. Assume now that β is represented by t': for every $v \in \Phi$ there is $a_v \in \mathrm{M}_b(\mathbb{C})$ with $a_v^* \mathrm{diag}(t') a_v = \beta_v$, and a_v is invertible as $\det \beta \neq 0$. In particular β is hermitian (its images under the embeddings at $v \in \Phi$ are).

A point for β. Let $x_\beta \in \mathrm{GL}_b(\mathbb{A}_E)$ have components a_v^{-1} at $v \in \Phi$ and finite part $q_f k$. Then $x_\beta^* \beta x_\beta$ is $(a_v^{-1})^* a_v^* \mathrm{diag}(t') a_v a_v^{-1} = \mathrm{diag}(t')$ at $v \in \Phi$ and $k^*(q^*\beta q)_f k = 1$ at the finite places, so $V_\beta = (\beta, x_\beta)$ is a space with a point with signs t'. By Lemma 4.1.8 (for V_β and V') there are $\gamma \in \mathrm{GL}_b(E)$ with $\gamma^* J_{V'} \gamma = \beta$ and $w \in \mathrm{G}(t')$ with $x_\beta = \gamma^{-1} x_{V'} w$.

Moving the index to the point. By (1) and (4) of Lemma 6.3.48, $\lambda = \mathrm{lev}(\gamma, 1) \in \Gamma_X$ and $\lambda k_{\mathbb{A}} = k_{\mathbb{A}} \gamma$, $k_{\mathbb{A}}$ the adelic frame of D. By (4) of Lemma 6.3.32 (with the rational matrix γ; $\jmath$ is a scalar, so $\gamma^*(\jmath J_{V'})\gamma = \jmath\beta$),

$$\mathrm{coef}(\jmath\beta; f)(p) = \mathrm{coef}(\jmath J_{V'}; f)(\lambda p).$$

By (2) and (1) of Lemma 6.3.48, $\lambda p = \mathrm{rad}(c\gamma^*, \gamma z \gamma^*)\,\lambda\,\mathrm{lev}(\kappa_\alpha q, g) = \mathrm{rad}(c\gamma^*, \gamma z\gamma^*)\,\mathrm{lev}(\kappa_\alpha \gamma q, g)$, the idele κ_α being a scalar.

The self-dual test. Put $Y = x_{V'}^{-1}\gamma q$, so $\kappa_\alpha \gamma q = \kappa_\alpha x_{V'} Y$. From $x_\beta = \gamma^{-1} x_{V'} w$ we get $x_{V'}^{-1}\gamma = w x_\beta^{-1}$, so $Y = w x_\beta^{-1} q$ and $Y_f k = w_f (q_f k)^{-1} q_f k = w_f$, and $w_f \in G_f(b)$ satisfies $w_f^* w_f = 1$. So $(J_{V'}, \lambda p)$ is as in (a), and $\mathrm{coef}(\jmath J_{V'}; f)(\lambda p) = 0$. □

Lemma 6.3.50. *Let W, V be spaces with signs s on n and t on r, $\mathfrak{c} = (\nu, \Sigma)$ a split tame character, $\gamma = \nu^{-1} \upsilon^{\lfloor \#n/2 \rfloor}$ and $F_\mathfrak{c} = (\Psi_1^{\mathrm{st}})^\sharp \otimes_\Sigma v^0 \in \mathcal{M}_{W,W}$ (1 the identity $n \times n$ matrix). Assume that $\theta_\mathfrak{c}^{\mathrm{lg}}(W, W; v, \Psi_1^{\mathrm{st}})(g) = 0$ for every Schwartz vector $v \in \mathcal{F}_{W,W}$ and every $g \in \mathrm{G}(s)$. Then for every Schwartz vector $w \in \mathcal{F}_{W,V\oplus W}$, every automorphic character β of $\mathrm{U}(1)$, $f \in \mathcal{M}_{W,V}$, $x \in \mathrm{M}_{r\times n}(\mathbb{A}_E)$, $g \in \mathrm{G}(s)$ and $y \in \mathrm{G}(t)$, the function of l below is integrable on $[\mathrm{U}(W)]$ and*

$$\int_{[\mathrm{U}(W)]} \theta_{\mathrm{Hom}(W,V\oplus W)}\Big(\rho((x;0))\,\omega_{\gamma,\gamma\beta}(g, \mathrm{diag}(y,l))\,(w \otimes (f \boxtimes^{\mathrm{tg}} F_\mathfrak{c}))\Big)\,dl = 0.$$

Proof. Let e be the bijection of $(r \times n) \sqcup (n \times n)$ onto $(r \sqcup n) \times n$ that is the identity on each part, and for $u \in \mathbb{C}^{\Phi \times ((r\sqcup n)\times n)}$ let (u_1, u_2) be its two parts. Fix β, f, x, g, y and, for $l \in \mathrm{G}(s)$, let

$$S_l(c) = \theta_{\mathrm{Hom}(W,V\oplus W)}\Big(\rho((x;0))\omega_{\gamma,\gamma\beta}(g, \mathrm{diag}(y,l))(c \otimes (f \boxtimes^{\mathrm{tg}} F_\mathfrak{c}))\Big),$$
$$T(c_1) = \theta_{\mathrm{Hom}(W,V)}(\rho(x)\omega_{\gamma,\beta}(g,y)(c_1 \otimes f)),$$
$$L_l(c_2) = \theta_{\mathrm{Hom}(W,W)}(\omega_{\gamma,\gamma}(g,l)(c_2 \otimes F_\mathfrak{c})) = \theta_{\gamma,\gamma}^{W,W}(c_2 \otimes [\Psi_1^{\mathrm{st}}]_\Sigma)(g,l),$$

bounded linear functionals on $\mathcal{F}_{W,V\oplus W}$, $\mathcal{F}_{W,V}$, $\mathcal{F}_{W,W}$ (composites of $c \mapsto c \otimes F$, bounded by (1) of Lemma 6.2.21, the bounded operators ω and ρ of Proposition 4.1.14, and the bounded theta functionals).

Step 1: coherent states. For u as above, $(\rho^\infty(u)v_1)(z) = \beta^\infty(u,z)e^\infty(z-u)$ is a product over the coordinates, so $\rho^\infty(u)v_1 = \rho^\infty(u_1)v_1 \boxtimes_e \rho^\infty(u_2)v_1$ in the notation of Lemma 6.3.51. By (3) and (2) of Lemma 6.3.51, (b) and (c) of Lemma 6.3.52 (characters γ, β, γ) and $\rho(0) = 1$,

$$S_l(\rho^\infty(u)v_1) = T(\rho^\infty(u_1)v_1)\,L_l(\rho^\infty(u_2)v_1).$$

Step 2: a Schwartz vector for (W, W). By the reproducing identity,

$$w = \int w(u)\,\rho^\infty(u)v_1\,d\nu(u),$$

a Bochner integral (ρ^∞ is isometric and strongly continuous, w integrable). Put

$$v_w = \int w(u)\, T(\rho^\infty(u_1)v_1)\, \rho^\infty(u_2)v_1\, d\nu(u) \in \mathcal{F}_{W,W},$$

a Bochner integral of norm at most $\|T\|\,\|v_1\|_1^2\|w\|_1$. It is a Schwartz vector: by Tonelli and the evaluation of the integrand,

$$\mathrm{mom}_N(v_w) \le \|T\|\|v_1\|_1 \int |w(u)|\,\mathrm{mom}_N(\rho^\infty(u_2)v_1)\, d\nu(u),$$

and $\mathrm{mom}_N(\rho^\infty(t)c) \le (1+\|t\|)^N \mathrm{mom}_N(c)$ (as $|(\rho^\infty(t)c)(z)| = |c(z-t)|$ and $1+\|z+t\| \le (1+\|t\|)(1+\|z\|)$), so $\mathrm{mom}_N(v_w) \le \|T\|\|v_1\|_1 \mathrm{mom}_N(v_1)\,\mathrm{mom}_N(w) < \infty$, using $\|u_2\| \le \|u\|$.

Step 3: the integral. Bounded linear functionals commute with Bochner integrals, so by Steps 1 and 2, for every l,

$$S_l(w) = \int w(u)\, T(\rho^\infty(u_1)v_1) L_l(\rho^\infty(u_2)v_1)\, d\nu(u) = L_l(v_w) = \theta^{W,W}_{\gamma,\gamma}(v_w \otimes [\Psi_1^{\mathrm{st}}]_\Sigma)(g,l).$$

The function Ψ_1^{st} is locally constant, compactly supported and zero off the invertible matrices, so $v_w \otimes [\Psi_1^{\mathrm{st}}]_\Sigma$ is target-bounded (Lemma 6.2.26) and $l \mapsto S_l(w)$ is integrable on $[\mathrm{U}(W)]$ (Lemma 6.3.21); as $\gamma = \nu^{-1}\upsilon^{\lfloor \#n/2 \rfloor}$, its integral is $\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,W; v_w, \Psi_1^{\mathrm{st}})(g) = 0$ by hypothesis. □

Lemma 6.3.51. *Let s_1, s_2, s be signs on index sets n_1, n_2, n and $e\colon n_1 \sqcup n_2 \to n$ a bijection with $s \circ e = s_1 \sqcup s_2$. Let $\iota_j = \Phi \times n_j$, $\iota = \Phi \times n$ with the signs $\varepsilon_j(v,i) = s_j(i)$, $\varepsilon(v,i) = s(i)$, and for z in $\mathbb{C}^\iota$ or $\mathbb{A}_E^n$ let (z_1, z_2) be the restrictions of $z \circ e$ (of $(v,i) \mapsto z_{v,e(i)}$ in the first case) to n_1 and n_2. For $c_1 \in \mathcal{F}_{\varepsilon_1}$ and $c_2 \in \mathcal{F}_{\varepsilon_2}$ let $c_1 \boxtimes_e c_2$ be the function $z \mapsto c_1(z_1)c_2(z_2)$ on $\mathbb{C}^\iota$.*

1. *$c_1 \boxtimes_e c_2 \in \mathcal{F}_\varepsilon$, $\|c_1 \boxtimes_e c_2\|_1 = \|c_1\|_1\|c_2\|_1$ and $\mathrm{mom}_N(c_1 \boxtimes_e c_2) \le \mathrm{mom}_N(c_1)\,\mathrm{mom}_N(c_2)$ for every N; in particular $c_1 \boxtimes_e c_2$ is a Schwartz vector if c_1 and c_2 are.*
2. *For $z \in \mathbb{A}_E^n$, $f_1 \in \mathcal{M}_{s_1}$ and $f_2 \in \mathcal{M}_{s_2}$, $\rho(z)(f_1 \boxtimes_e f_2) = \rho(z_1)f_1 \boxtimes_e \rho(z_2)f_2$.*
3. *For $f_1 \in \mathcal{M}_{s_1}$ and $f_2 \in \mathcal{M}_{s_2}$, $(c_1 \boxtimes_e c_2) \otimes (f_1 \boxtimes_e f_2) = (c_1 \otimes f_1) \boxtimes_e (c_2 \otimes f_2)$.*

Proof. **(1).** Write $x = (x_1, x_2)$, $y = (y_1, y_2)$ for points of $\mathbb{C}^\iota$ in the coordinates given by e. The exponent of $\beta^\infty_\varepsilon(y,x)$ is $(x^*\mathrm{diag}(\varepsilon)y - y^*\mathrm{diag}(\varepsilon)x)/2$, a sum over the coordinates, and $\varepsilon \circ e = \varepsilon_1 \sqcup \varepsilon_2$; so $\beta^\infty_\varepsilon(y,x) = \beta^\infty_{\varepsilon_1}(y_1,x_1)\beta^\infty_{\varepsilon_2}(y_2,x_2)$, likewise $e^\infty(x-y) = e^\infty(x_1-y_1)e^\infty(x_2-y_2)$, and ν_ι is the image of $\nu_{\iota_1} \otimes \nu_{\iota_2}$ ($\#\iota = \#\iota_1 + \#\iota_2$). By Tonelli $c = c_1 \boxtimes_e c_2$ is ν_ι-integrable with $\|c\|_1 = \|c_1\|_1\|c_2\|_1$. Since $|\beta^\infty e^\infty| \le 1$, the function $y \mapsto c(y)\beta^\infty_\varepsilon(y,x)e^\infty(x-y)$ is integrable, and by Fubini and the reproducing identities of c_1 and c_2

$$\begin{aligned}\int c(y)\beta^\infty_\varepsilon(y,x)e^\infty(x-y)\, d\nu_\iota(y) &= \prod_{j=1,2} \int c_j(y_j)\beta^\infty_{\varepsilon_j}(y_j,x_j)e^\infty(x_j-y_j)\, d\nu_{\iota_j}(y_j)\\ &= c_1(x_1)c_2(x_2) = c(x).\end{aligned}$$

So $c \in \mathcal{F}_\varepsilon$. For the moments, $\|x\| = \max(\|x_1\|, \|x_2\|)$ for the maximum norm, so $1+\|x\| \le (1+\|x_1\|)(1+\|x_2\|)$, and Tonelli gives $\mathrm{mom}_N(c) \le \mathrm{mom}_N(c_1)\mathrm{mom}_N(c_2)$.

(2). By (WD6), $\beta_s(z,x) = \psi_E(\frac{J}{2}\sum_{i\in n} \bar{x}_i S_i z_i)$ with S_i the sign s_i at the infinite places and 1 at the finite places; as ψ_E is additive and $s \circ e = s_1 \sqcup s_2$, $\beta_s(z,x) = \beta_{s_1}(z_1,x_1)\beta_{s_2}(z_2,x_2)$. Hence

$$(\rho(z)(f_1 \boxtimes_e f_2))(x) = \beta_{s_1}(z_1,x_1)f_1(x_1-z_1)\,\beta_{s_2}(z_2,x_2)f_2(x_2-z_2) = (\rho(z_1)f_1 \boxtimes_e \rho(z_2)f_2)(x).$$

(3). The map $(F_1, F_2) \mapsto F_1 \boxtimes_e F_2$ from $\mathcal{M}_{s_1} \times \mathcal{M}_{s_2}$ to $\mathcal{M}_s$ is bilinear with $\|F_1 \boxtimes_e F_2\|_1 = \|F_1\|_1 \|F_2\|_1$, since μ_n is the image of $\mu_{n_1} \otimes \mu_{n_2}$ under e ((WD6); Tonelli). For $y \in \mathbb{C}^\iota$, $\mathrm{rv}(y)$ splits as $(\mathrm{rv}(y_1), \mathrm{rv}(y_2))$, so by (2)

$$(c_1 \boxtimes_e c_2)(y)\, \rho(\mathrm{rv}(y))(f_1 \boxtimes_e f_2) = \big(c_1(y_1)\rho(\mathrm{rv}(y_1))f_1\big) \boxtimes_e \big(c_2(y_2)\rho(\mathrm{rv}(y_2))f_2\big).$$

The two factors are Bochner integrable in y_1, y_2 (the Heisenberg operators are isometric and strongly continuous, Proposition 4.1.14, and c_j is integrable). A bounded bilinear map commutes with Bochner integrals in each variable, and the integral over y is the iterated integral over (y_1, y_2) (Fubini for the Bochner integral of an absolutely integrable function). Hence the integral over y against ν_ι, which is $(c_1 \boxtimes_e c_2) \otimes (f_1 \boxtimes_e f_2)$ by (WR6), equals $(c_1 \otimes f_1) \boxtimes_e (c_2 \otimes f_2)$. □

Lemma 6.3.52. *Let α, β, β' be automorphic characters of $\mathrm{U}(1)$. For $g_1 \in \mathrm{G}(s_1)$, $g_2 \in \mathrm{G}(s_2)$ write $\mathrm{diag}(g_1, g_2) \in \mathrm{G}(s_1 \sqcup s_2)$ for the block diagonal element.*

(a) (Source sums.) Let S_1, S_2, T be spaces with points with signs s_1, s_2, s'. For $f \in \mathcal{M}_{S_1,T}$, $f' \in \mathcal{M}_{S_2,T}$, $g_i \in \mathrm{G}(s_i)$ and $h \in \mathrm{G}(s')$,

$$\omega_{\beta\beta',\alpha}(\mathrm{diag}(g_1, g_2), h)(f \boxtimes^{\mathrm{sc}} f') = \omega_{\beta,\alpha}(g_1, h) f \boxtimes^{\mathrm{sc}} \omega_{\beta',\alpha}(g_2, h) f'.$$

(b) (Target sums.) Let S, T_1, T_2 be spaces with points with signs s, s_1, s_2. For $f \in \mathcal{M}_{S,T_1}$, $f' \in \mathcal{M}_{S,T_2}$, $g \in \mathrm{G}(s)$ and $h_i \in \mathrm{G}(s_i)$,

$$\omega_{\alpha,\beta\beta'}(g, \mathrm{diag}(h_1, h_2))(f \boxtimes^{\mathrm{tg}} f') = \omega_{\alpha,\beta}(g, h_1) f \boxtimes^{\mathrm{tg}} \omega_{\alpha,\beta'}(g, h_2) f'.$$

(c) (Theta values: exact factorisation.) In the situation of (a), respectively (b), for all data

$$\theta_{\mathrm{Hom}(S_1 \oplus S_2, T)}(f \boxtimes^{\mathrm{sc}} f') = \theta_{\mathrm{Hom}(S_1,T)}(f)\, \theta_{\mathrm{Hom}(S_2,T)}(f'),$$
$$\theta_{\mathrm{Hom}(S, T_1 \oplus T_2)}(f \boxtimes^{\mathrm{tg}} f') = \theta_{\mathrm{Hom}(S,T_1)}(f)\, \theta_{\mathrm{Hom}(S,T_2)}(f').$$

(d) (Theta kernels: exact factorisation.) Consequently

$$\theta^{S_1 \oplus S_2, T}_{\beta\beta',\alpha}(f \boxtimes^{\mathrm{sc}} f')(\mathrm{diag}(g_1, g_2), h) = \theta^{S_1,T}_{\beta,\alpha}(f)(g_1, h)\, \theta^{S_2,T}_{\beta',\alpha}(f')(g_2, h),$$

$$\theta^{S, T_1 \oplus T_2}_{\alpha,\beta\beta'}(f \boxtimes^{\mathrm{tg}} f')(g, \mathrm{diag}(h_1, h_2)) = \theta^{S,T_1}_{\alpha,\beta}(f)(g, h_1)\, \theta^{S,T_2}_{\alpha,\beta'}(f')(g, h_2).$$

Proof. **Products for one space.** Let $\sigma_1, \sigma_2, \sigma$ be signs on index sets m_1, m_2, m and $e\colon m_1 \sqcup m_2 \to m$ a bijection with $\sigma \circ e = \sigma_1 \sqcup \sigma_2$; for $p_i \in \mathrm{G}(\sigma_i)$ let $p \in \mathrm{G}(\sigma)$ be the element that is block diagonal with blocks p_1, p_2 through e. We show

$$\omega_\sigma(p)(F_1 \boxtimes_e F_2) = \omega_{\sigma_1}(p_1)F_1 \boxtimes_e \omega_{\sigma_2}(p_2)F_2 \qquad (F_i \in \mathcal{M}_{\sigma_i}). \tag{6.49}$$

The multiplier is multiplicative: at $v \in \Phi$ the block of p_v on the indices of sign -1 is, through e, block diagonal with blocks those of $p_{1,v}$, $p_{2,v}$, so its determinant is the product; if $u_i \in \mathrm{GL}_{m_i}(\mathbb{A}_{E,f})$ satisfy $u_i \widehat{\mathcal{O}}_E^{m_i} = \widehat{\mathcal{O}}_E^{m_i} \cap p_{i,f}^{-1} \widehat{\mathcal{O}}_E^{m_i}$, the block diagonal u (through e) satisfies the same for p, and $\det u = \det u_1 \det u_2$; as υ and $|\cdot|$ are multiplicative, $\Delta_\sigma(p) = \Delta_{\sigma_1}(p_1)\Delta_{\sigma_2}(p_2)$. Writing $x = (x_1, x_2)$, $y = (y_1, y_2)$ through e, we have $py = (p_1 y_1, p_2 y_2)$, and by (WR6) e_m, β_σ, μ_m are $e_{m_1} e_{m_2}$, $\beta_{\sigma_1}\beta_{\sigma_2}$, $\mu_{m_1} \otimes \mu_{m_2}$. The integrand of (WR3) for $\omega_\sigma(p)(F_1 \boxtimes_e F_2)$ at x is therefore the product of the integrands for $\omega_{\sigma_i}(p_i)F_i$ at x_i; it is absolutely integrable, as $|\beta| = 1$, $|e_m| \le 1$ and $F_i \in L^1(\mu_{m_i})$, so Fubini's theorem gives (6.49).

(a). Let $\sigma = s' \otimes (s_1 \sqcup s_2)$ on $n' \times (n_1 \sqcup n_2)$, $\sigma_i = s' \otimes s_i$, and e the bijection of the source product (WR6); $\sigma \circ e = \sigma_1 \sqcup \sigma_2$ by (VP5). The pair map of $(\mathrm{diag}(g_1, g_2), h)$ is $X \mapsto hX\,\mathrm{diag}(g_1, g_2)^{-1}$, which on $X = (X_1 \mid X_2)$ is $(hX_1 g_1^{-1} \mid hX_2 g_2^{-1})$: through e it is block diagonal with the pair maps p_i of (g_i, h). By (WR4) of Definition 3.2.18,

$$\omega_{\beta\beta',\alpha}(\mathrm{diag}(g_1, g_2), h) = \beta(\det h)\beta'(\det h)\,\alpha(\det g_1)^{-1}\alpha(\det g_2)^{-1}\,\omega_\sigma(p),$$

and (6.49) with

$$\omega_{\beta,\alpha}(g_1, h) = \beta(\det h)\alpha(\det g_1)^{-1}\omega_{\sigma_1}(p_1),$$
$$\omega_{\beta',\alpha}(g_2, h) = \beta'(\det h)\alpha(\det g_2)^{-1}\omega_{\sigma_2}(p_2)$$

gives (a).

(b). The same with $\sigma = (s_1 \sqcup s_2) \otimes s$ on $(n_1' \sqcup n_2') \times n$, the bijection of the target product, and the pair map $Y \mapsto \mathrm{diag}(h_1, h_2) Y g^{-1}$, which on Y with row blocks Y_1, Y_2 is $(h_1 Y_1 g^{-1}; h_2 Y_2 g^{-1})$; the characters are $\alpha(\det h_1)\alpha(\det h_2)\,\beta(\det g)^{-1}\beta'(\det g)^{-1}$.

(c). Through the bijection e of (a), $\mathrm{Hom}(S_1 \oplus S_2, T)$ is the block orthogonal sum of $\mathrm{Hom}(S_1, T)$ and $\mathrm{Hom}(S_2, T)$: by (VP5) its matrix $J_T \otimes (J_{S_1 \oplus S_2}^{-1})^{\mathsf{T}}$ and its point $x_T \otimes (x_{S_1 \oplus S_2}^{-1})^{\mathsf{T}}$, with $J_{S_1 \oplus S_2} = \mathrm{diag}(J_{S_1}, J_{S_2})$ and $x_{S_1 \oplus S_2} = \mathrm{diag}(x_{S_1}, x_{S_2})$, are block diagonal with blocks $J_T \otimes (J_{S_i}^{-1})^{\mathsf{T}}$, $x_T \otimes (x_{S_i}^{-1})^{\mathsf{T}}$, and the signs agree; and $f \boxtimes^{\mathrm{sc}} f'$ is the coefficient product through e. The factorisation clause of Lemma 4.1.17, read through the sign-preserving bijection e, gives the first identity. For target sums the bijection of (b) exhibits $\mathrm{Hom}(S, T_1 \oplus T_2)$, with matrix $\mathrm{diag}(J_{T_1}, J_{T_2}) \otimes (J_S^{-1})^{\mathsf{T}}$ and point $\mathrm{diag}(x_{T_1}, x_{T_2}) \otimes (x_S^{-1})^{\mathsf{T}}$, as the block orthogonal sum of $\mathrm{Hom}(S, T_i)$, and the same clause gives the second identity.

(d). By (WC4) of Definition 4.1.15, $\theta^{S,T}_{\alpha,\beta}(\varphi)(g, h) = \theta_{\mathrm{Hom}(S,T)}(\omega_{\alpha,\beta}(g, h)\varphi)$; apply (a), respectively (b), and then (c) to the two factors. □

Lemma 6.3.53. *Let V, V_0, U be spaces with points with signs s on n, s_0 on n_0 and t on r, p an index set, and D a base-adapted splitting of V over V_0 along p. Then the splitting D_U of* $\mathrm{Hom}(V, U)$ *over* $\mathrm{Hom}(V_0, U)$ *along $r \times p$ induced by D is adapted at* 1 *in the adapted basis $m_U = (x_U^{-1})^* \otimes 1_p$.*

Proof. Let $D = (k, l, i)$, with adelic frames $k_{\mathbb{A}} = x_V^{-1} k$, $l_{\mathbb{A}} = x_V^{-1} l$, $i_{\mathbb{A}} = x_V^{-1} i x_{V_0}$, and let $B_D = (l_{\mathbb{A}} \mid k_{\mathbb{A}} \mid i_{\mathbb{A}})$; by hypothesis B_D has orthonormal columns at every infinite place and entries in $\widehat{\mathcal{O}}_E$ at the finite places. Write $V^U = \mathrm{Hom}(V, U)$ and $V_0^U = \mathrm{Hom}(V_0, U)$; their points are $x_{V^U} = x_U \otimes (x_V^{-1})^{\mathsf{T}}$ and $x_{V_0^U} = x_U \otimes (x_{V_0}^{-1})^{\mathsf{T}}$, so $x_{V^U}^{-1} = x_U^{-1} \otimes x_V^{\mathsf{T}}$. By (MX1) the frames of D_U are $K = J_U^{-1} \otimes (k^* J_V)^{\mathsf{T}}$, $L = 1_r \otimes (l^* J_V)^{\mathsf{T}}$ and $I = 1_r \otimes (J_{V_0}^{-1} i^* J_V)^{\mathsf{T}}$, with adelic frames $x_{V^U}^{-1} K$, $x_{V^U}^{-1} L$ and $x_{V^U}^{-1} I x_{V_0^U}$. We have $m_U^{-1} = x_U^* \otimes 1_p$, hence $(m_U^{-1})^* = x_U \otimes 1_p$.

Step 1: three identities. From $x_V^* J_V x_V = \varepsilon_s$, $x_U^* J_U x_U = \varepsilon_t$ and $x_{V_0}^* J_{V_0} x_{V_0} = \varepsilon_{s_0}$ we get $J_V x_V = (x_V^*)^{-1}\varepsilon_s$, $x_U^{-1} J_U^{-1} (x_U^*)^{-1} = \varepsilon_t$ and $x_{V_0}^{-1} J_{V_0}^{-1} = \varepsilon_{s_0} x_{V_0}^*$. Hence

$$k^* J_V x_V = k_{\mathbb{A}}^* \varepsilon_s, \qquad l^* J_V x_V = l_{\mathbb{A}}^* \varepsilon_s, \qquad x_{V_0}^{-1} J_{V_0}^{-1} i^* J_V x_V = \varepsilon_{s_0} (x_V^{-1} i x_{V_0})^* \varepsilon_s = \varepsilon_{s_0} i_{\mathbb{A}}^* \varepsilon_s.$$

Step 2: the three column blocks. By the rules for Kronecker products and Step 1,

$$x_{V^U}^{-1} L\,(m_U^{-1})^* = x_U^{-1} x_U \otimes x_V^{\mathsf{T}} (l^* J_V)^{\mathsf{T}} = 1_r \otimes (l^* J_V x_V)^{\mathsf{T}} = 1_r \otimes \varepsilon_s \bar{l}_{\mathbb{A}},$$

$$x_{V^U}^{-1} K\, m_U = x_U^{-1} J_U^{-1} (x_U^{-1})^* \otimes (k^* J_V x_V)^{\mathsf{T}} = \varepsilon_t \otimes \varepsilon_s \bar{k}_{\mathbb{A}},$$

$$x_{V^U}^{-1} I\, x_{V_0^U} = x_U^{-1} x_U \otimes \left(x_{V_0}^{-1} J_{V_0}^{-1} i^* J_V x_V\right)^{\mathsf{T}} = 1_r \otimes \varepsilon_s \bar{i}_{\mathbb{A}} \varepsilon_{s_0}.$$

So the matrix of (MX5) for D_U at $g=1$ in the basis m_U, with column blocks indexed by $r\times p$, $r\times p$, $r\times n_0$, is

$$Q=\left(1_r\otimes\varepsilon_s\bar{l}_{\mathbb{A}}\;\middle|\;\varepsilon_t\otimes\varepsilon_s\bar{k}_{\mathbb{A}}\;\middle|\;1_r\otimes\varepsilon_s\bar{i}_{\mathbb{A}}\varepsilon_{s_0}\right)=\left(1_r\otimes\varepsilon_s\right)\left(1_r\otimes\bar{B}_D\right)R_{\pm},$$

where the columns of $1_r\otimes\bar{B}_D$ are indexed by $r\times(p\sqcup p\sqcup n_0)=(r\times p)\sqcup(r\times p)\sqcup(r\times n_0)$ and $R_{\pm}$ is the block diagonal matrix with blocks 1, $\varepsilon_t\otimes 1_p$, $1_r\otimes\varepsilon_{s_0}$: a diagonal matrix with entries ±1 at the infinite places and 1 at the finite places.

Step 3: orthonormality and integrality. At an infinite place v the matrices $(1_r\otimes\varepsilon_s)_v$ and $(R_{\pm})_v$ are diagonal with entries ±1, so

$$Q_v^*Q_v=(R_{\pm})_v(1_r\otimes\bar{B}_{D,v}^*\bar{B}_{D,v})(R_{\pm})_v=(R_{\pm})_v(1_r\otimes\overline{B_{D,v}^*B_{D,v}})(R_{\pm})_v=(R_{\pm})_v^2=1,$$

since $B_{D,v}^*B_{D,v}=1$. At the finite places ε_s, ε_t, ε_{s_0} are the identity, so every entry of Q_f is 0 or the conjugate of an entry of $B_{D,f}$; complex conjugation preserves $\widehat{\mathcal{O}}_E$, so Q_f has entries in $\widehat{\mathcal{O}}_E$. Hence D_U is adapted at 1 in the basis m_U. □

Lemma 6.3.54. *Let $k\in\mathbb{N}$ and $\mu\colon\Phi\to\mathbb{Z}$ with $k\le\mu(w)$ for every $w\in\Phi$, and let $\mathfrak{c}=(\nu,\Sigma)$ be a split tame character of weight μ. Let W', V', W, V be spaces with signs s' on n', t' on r', s on n, t on r, let b be an index set with bijections $\sigma\colon b\sqcup r\to n$ and $\sigma'\colon b\sqcup r'\to n'$, and let $j\ge1$ with*

$$\#n'=\#n+2j,\qquad \mathrm{neg}(W')=j+\mathrm{neg}(W),\qquad \mathrm{neg}(V')=j+\mathrm{neg}(V),$$

$\#n$ even and $-k\le\#r-\#n/2$. Suppose that $\theta_{\mathfrak{c}}^{\mathrm{lg}}(W',V';v',\Phi^{\mathrm{st}}_{\sigma',y'})=0$ for every Schwartz vector $v'\in\mathcal{F}_{W',V'}$ and every $y'\in\mathrm{M}_{b\times n'}(\mathcal{O}_\Sigma)$. Then $\theta_{\mathfrak{c}}^{\mathrm{lg}}(W,V;v,\Phi^{\mathrm{st}}_{\sigma,y})=0$ for every Schwartz vector $v\in\mathcal{F}_{W,V}$ and every $y\in\mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$.

Proof. **Step 1: one plane, with splittings.** Let A be a base-adapted splitting of W' over W and X one of V' over V, both along $\{o\}$, and let (W',V',σ') be vanishing; we show that (W,V,σ) is vanishing. Fix a Schwartz vector $v\in\mathcal{F}_{W,V}$, $y\in\mathrm{M}_{b\times n}(\mathcal{O}_\Sigma)$, $g\in\mathrm{G}(s)$, and put $I=\theta_{\mathfrak{c}}^{\mathrm{lg}}(W,V;v,\Phi^{\mathrm{st}}_{\sigma,y})(g)$ and $e=\#r-\#n/2\ge-k$. By Lemma 6.3.55 there are a real-analytic $B\colon\mathbb{R}\to(0,\infty)$ and a Schwartz vector $v'\in\mathcal{F}_{W',V'}$ with $\theta_{\mathfrak{c}}^{\mathrm{lg}}(W,V;\mathrm{Cone}^+_{A,X,\mu}(x;v'),\Phi^{\mathrm{st}}_{\sigma,y})(g)=B(x)I$ for all real $x>0$. By Lemma 6.3.62 there is a real-analytic Λ on $(-k,\infty)$ with $\Lambda(x)=L^\Sigma(x,\tilde{\nu})$ for $x\ge1$ and $\Lambda(i)\ne0$ for every integer $i>-k$. Let $f=\varphi^{\mathrm{pl}}_{A,\sigma'}(v',y)$ and $F(x)=\int_Y Z_x(f;1,g)$, with Y, its measure and Z_x as in Lemma 6.2.36. By Lemma 6.2.36 (with $u=1$), F is real-analytic on $\mathbb{R}$, and with its constants ϵ_+, $|\epsilon_+|=C_+>0$, α_0 and $Q=\prod_{w\in\Sigma}\mathrm{N}w$,

$$F(x)=\epsilon_+\,|\alpha_0|^xQ^{x-1/2}L^\Sigma(x,\tilde{\nu})\,B(x)\,I\qquad(x\ge1).$$

The function $R(x)=\epsilon_+|\alpha_0|^xQ^{x-1/2}\Lambda(x)B(x)I$ is real-analytic on $(-k,\infty)$ ($|\alpha_0|^x=e^{x\log|\alpha_0|}$, $Q^{x-1/2}=e^{(x-1/2)\log Q}$) and agrees with F on $[1,2]$; by the identity theorem for real-analytic functions on the connected interval $(-k,\infty)$, $F=R$ there. On the other hand, the matrix $(\mathrm{pr}_i)_\Sigma$ of A is integral (A is base-adapted), so $y(\mathrm{pr}_i)_\Sigma\in\mathrm{M}_{b\times n'}(\mathcal{O}_\Sigma)$ and, (W',V',σ') being vanishing, the integrand of $\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v',y)(1,g)$ vanishes identically; so $\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v',y)(1,g)=0$. By Lemma 6.2.3 (its integrability hypothesis holds by Lemma 6.2.36), $\mathrm{CT}^{\mathrm{pl}}_{A,\sigma'}(v',y)(1,g)=c_0F(e+1)$ with $c_0\ne0$, so $F(e+1)=0$. As $e+1>-k$, $R(e+1)=0$. Here $\epsilon_+\ne0$, $|\alpha_0|^{e+1}>0$, $Q^{e+1/2}>0$, $\Lambda(e+1)\ne0$ ($e+1$ is an integer $>-k$) and $B(e+1)>0$; hence $I=0$.

Step 2: spaces with the same signs. Let (W',V',σ') be vanishing and W_1', V_1' spaces with the signs of W', V'. By (1) of Lemma 6.3.63 there are $\gamma\in\mathrm{GL}_{n'}(E)$, $k_1\in\mathrm{G}(s')$ with $x_{W_1'}=\gamma^{-1}x_{W'}k_1$, and γ', k_1' likewise for V_1', V'. For a Schwartz v' and integral y', the datum

$v' \otimes [\Phi^{\mathrm{st}}_{\sigma',y'}]_\Sigma$ (the same element of $\mathcal{M}_{W',V'} = \mathcal{M}_{W_1',V_1'}$) is target-bounded by Lemma 6.2.26, $\Phi^{\mathrm{st}}_{\sigma',y'}$ being locally constant, compactly supported and zero off the right-invertible matrices; so its theta kernel is integrable over $[\mathrm{U}(V')]$ (Lemma 6.3.21), and by Lemma 6.3.64 there is u with $|u| = 1$ and $\theta^{\mathrm{lg}}_{\mathfrak{c}}(W_1', V_1'; v', \Phi^{\mathrm{st}}_{\sigma',y'})(g) = u\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W', V'; v', \Phi^{\mathrm{st}}_{\sigma',y'})(k_1 g) = 0$. So (W_1', V_1', σ') is vanishing.

Step 3: induction on j. For $j = 1$: $\#n' = \#n + 2$, $\mathrm{neg}(W') = 1 + \mathrm{neg}(W)$, so (2) of Lemma 6.3.63 gives a space W_1 with the signs s' and a base-adapted splitting A of W_1 over W along $\{o\}$; as $\#r' = \#n' - \#b = \#r + 2$ and $\mathrm{neg}(V') = 1 + \mathrm{neg}(V)$, it gives likewise V_1 with the signs t' and X for V_1 over V. By Step 2, (W_1, V_1, σ') is vanishing, and by Step 1 so is (W, V, σ). Let the assertion hold for j and let the data satisfy the hypotheses for $j+1$. Put $Y_W = \mathbb{H}_{\{o\}} \oplus W$ and $Y_V = \mathbb{H}_{\{o\}} \oplus V$, with index sets $(\{o\} \sqcup \{o\}) \sqcup n$ and $(\{o\} \sqcup \{o\}) \sqcup r$, and choose a bijection $\tau\colon b \sqcup ((\{o\} \sqcup \{o\}) \sqcup r) \to (\{o\} \sqcup \{o\}) \sqcup n$ (both sides have $\#n + 2$ elements). Then $\#n' = (\#n + 2) + 2j$, $\mathrm{neg}(W') = j + \mathrm{neg}(Y_W)$, $\mathrm{neg}(V') = j + \mathrm{neg}(Y_V)$, $\#n + 2$ is even and $(\#r + 2) - (\#n + 2)/2 = e + 1 \geq -k$; by the assertion for j, (Y_W, Y_V, τ) is vanishing. The tautological splittings R_W of Y_W over W and R_V of Y_V over V along $\{o\}$ are base-adapted: their matrices of adelic frames are $\mathrm{diag}(x_{\mathbb{H}}^{-1}, 1)$, where the point $x_{\mathbb{H}}$ of $\mathbb{H}_{\{o\}}$ is unitary at the infinite places and integral at the finite places with determinant $c\bar{c}_0 + cc_0 = c$, a unit ($c_0 + \bar{c}_0 = 1$). By Step 1 for R_W, R_V, (W, V, σ) is vanishing. □

Lemma 6.3.55. *Let W', W, V', V, A, X be as above with $\#n$ even, let b be an index set with a bijection $\sigma\colon b \sqcup r \to n$, and let $\mu\colon \Phi \to \mathbb{Z}$. There is a real analytic function $B\colon \mathbb{R} \to (0, \infty)$ such that every Schwartz vector $v \in \mathcal{F}_{W,V}$ has a Schwartz vector $v' \in \mathcal{F}_{W',V'}$ with*

$$\theta^{\mathrm{lg}}_{\mathfrak{c}}(W, V; \mathrm{Cone}^+_{A,X,\mu}(z; v'), \Phi^{\mathrm{st}}_{\sigma,y})(g) = B(z)\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W, V; v, \Phi^{\mathrm{st}}_{\sigma,y})(g)$$

for all real $z > 0$, all split tame characters $\mathfrak{c} = (\nu, \Sigma)$ of weight μ, all $y \in \mathrm{M}_{b\times n}(E_\Sigma)$ and all $g \in \mathrm{G}(s)$. In particular, for every $z > 0$ every Schwartz vector v has a Schwartz vector v' for which this identity holds with $B(z)$ replaced by 1.

Proof. Put $\gamma(w) = \#n/2 - \mu(w)$ and let ρ be the function of Lemma 6.3.56. For $a \in (\mathbb{C}^\times)^\Phi$ write $|a|^{2z} = \prod_{w\in\Phi} |a_w|^{2z}$ and $\ell(a) = \sum_{w\in\Phi} \log|a_w|$.

Step 1: the factor B. Put $B(z) = \int \rho(u, a)\,|a|^{2z}\,du\,d^\times a$, the integral over $\mathrm{K}_{\max}(t') \times (\mathbb{C}^\times)^\Phi$. On the compact support K_ρ of ρ, $|\ell| \leq L$ for some L. The integrand is continuous, ≥ 0, with compact support, and positive on the nonempty open set where $\rho > 0$, which has positive measure (du is a Haar measure and $d^\times a$ has a positive continuous density); so $0 < B(z) < \infty$. Since $|a|^{2z} = e^{2z\ell(a)} = \sum_{k\geq 0} (2z)^k \ell(a)^k/k!$ and $\sum_k |2z|^k |\ell|^k \rho/k! \leq e^{2|z|L}\rho$ is integrable, $B(z) = \sum_{k\geq 0} c_k z^k$ with $c_k = \frac{2^k}{k!} \int \rho\,\ell^k$, $|c_k| \leq \frac{(2L)^k}{k!} \int \rho$; this power series converges on $\mathbb{R}$, so B is real analytic.

Step 2: real points do not change the large side. Let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character of weight μ and $\alpha = \nu^{-1} \upsilon^{\#n/2}$; α has weight $-\mu + \#n/2 = \gamma$. The function $\Phi = \Phi^{\mathrm{st}}_{\sigma,y}$ on $\mathrm{M}_{r\times n}(E_\Sigma)$ is locally constant ($\chi_{\mathfrak{c}}$ is continuous on the totally disconnected group $\mathcal{O}_\Sigma^\times$), compactly supported (on integral matrices), and vanishes at every matrix x without a right inverse: if $\Phi(x) \neq 0$, the $n \times n$ matrix with the rows of y and of x is invertible, so the rows of x are linearly independent. Let $f = \Phi^\sharp \otimes_\Sigma v^0$. By Lemma 6.2.26, $w \otimes f$ is target-bounded for every Schwartz vector $w \in \mathcal{F}_{W,V}$. For $h \in G_\infty(t)$, (5) of Lemma 4.1.1 gives $\omega_{\alpha,\alpha}((1,1),(h,1))(w \otimes f) = (\Omega_{\gamma,\gamma}(1,h)w) \otimes f = (\Omega_{\gamma,0}(1,h)w) \otimes f$ (the factor of the first argument 1 is 1), and (3) of Lemma 6.3.21 with the points 1 and $(h, 1)$ gives (if $r = \varnothing$, $G_\infty(t)$ is trivial and there is nothing to prove)

$$\theta^{\mathrm{lg}}_{\mathfrak{c}}(W, V; \Omega_{\gamma,0}(1,h)w, \Phi)(g) = I^{W,V}_{\alpha,\alpha}(\omega_{\alpha,\alpha}((1,1),(h,1))(w \otimes f))(g) = \theta^{\mathrm{lg}}_{\mathfrak{c}}(W, V; w, \Phi)(g),$$

the integral converging absolutely ((2) of Lemma 6.3.21).

Step 3: the identity. Let v be a Schwartz vector and v' the Schwartz vector of Lemma 6.3.56 for v. Fix $z>0$, $\mathfrak{c}$, y, g and let k_z be the integrand of Lemma 6.2.42 for v', the sign $+$ and $x=z$. By Lemma 6.3.56, for each (u,a) there is $h=h(u,a)\in G_\infty(t)$ with

$$\prod_w (a_w/|a_w|)^{2\mu(w)}\mathrm{Ln}^{+,\infty}_{A,X}(a)(\Omega_{\gamma_\mu,0}(1,u_\infty)v')=\rho(u,a)\Omega_{\gamma,0}(1,h)v;$$

as $w\mapsto w\otimes f$ and the theta kernel are linear,

$$k_z(h',u,a)=\rho(u,a)\,|a|^{2z}\,\theta^{W,V}_{\alpha,\alpha}\big((\Omega_{\gamma,0}(1,h)v)\otimes f\big)(g,h')\qquad (h'\in \mathrm{G}(t)).$$

By Lemma 6.2.42, k_z is integrable on $[\mathrm{U}(V)]\times \mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi$ and its integral is the left side of the statement. By Fubini's theorem and Step 2 (for every (u,a) the integral over h' converges absolutely and equals $\rho(u,a)|a|^{2z}\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;v,\Phi)(g)$), the integral is $B(z)\,\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;v,\Phi)(g)$.

Step 4: the normalised form. For $z>0$ apply Step 3 to the Schwartz vector $B(z)^{-1}v$; by the linearity of $w\mapsto\theta^{\mathrm{lg}}_{\mathfrak{c}}(W,V;w,\Phi)(g)$ on Schwartz vectors ((2) of Lemma 6.3.21 and Step 2), its vector v' satisfies the identity with the factor 1. □

Lemma 6.3.56. *Let W',W,V',V, A, X be as above with $\#n$ even, let $\mu\colon\Phi\to\mathbb{Z}$, and put $\gamma(w)=\#n/2-\mu(w)$ for $w\in\Phi$. There is a continuous function $\rho\geq 0$ with compact support on $\mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi$, not identically 0, such that every Schwartz vector $v\in\mathcal{F}_{W,V}$ has a Schwartz vector $v'\in\mathcal{F}_{W',V'}$ with the following property: for every $(u,a)\in\mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi$ there is $h\in G_\infty(t)$ with*

$$\prod_{w\in\Phi}\Big(\frac{a_w}{|a_w|}\Big)^{2\mu(w)}\ \mathrm{Ln}^{+,\infty}_{A,X}(a)(\Omega_{\gamma_\mu,0}(1,u_\infty)v')=\rho(u,a)\ \Omega_{\gamma,0}(1,h)\,v.$$

Proof. Put $\gamma(w)=\#n/2-\mu(w)$. As A splits off one hyperbolic plane, $\#n'=\#n+2$, so $\gamma_\mu(w)=\lfloor\#n'/2\rfloor-\mu(w)=\gamma(w)+1$. Write Z^∞ for $Z^\infty_{X_W,m^{\mathrm{tg}}_W}$, m^{tg}_W the basis of Lemma 6.3.58, and for $w\in\Phi$ let $x_{B,w}\in\mathbb{C}^{r'}$ be the component at w of the adelic frame $k_{X,\mathbb{A}}$ of X; for $a\in\mathbb{C}^\Phi$ and $u\in\mathrm{K}_{\max}(t')$ let $u^{-1}a\,x_B$ be the family $(u_w^{-1}a_wx_{B,w})_w$.

Step 1: the line vector. The relations $k_X^*J_{V'}k_X=0$, $l_X^*J_{V'}k_X=1$ of (MX1) and $x_{V'}^*J_{V'}x_{V'}=\varepsilon_{t'}$ give $k^*_{X,\mathbb{A}}\varepsilon_{t'}k_{X,\mathbb{A}}=0$ and $l^*_{X,\mathbb{A}}\varepsilon_{t'}k_{X,\mathbb{A}}=1$. At $w\in\Phi$: $x^*_{B,w}\mathrm{diag}(t')x_{B,w}=0$, and $x_{B,w}\neq 0$. Put $c_w=|x_{B,w}|^2>0$.

Step 2: a Witt family and a bump. For each w, Lemma 6.3.57 gives a smooth $k_w\colon\mathbb{C}^{r'}\to\mathrm{U}(\mathrm{diag}\,t')$ and an open neighbourhood N_w of $x_{B,w}$ with $k_w(y)x_{B,w}=y$ for isotropic $y\in N_w$. The set $\mathcal{G}$ of families $x=(x_w)_w$ with $x_w\in N_w$ and $\frac12c_w<|x_w|^2<2c_w$ for all w is an open neighbourhood of $x_B=(x_{B,w})_w$; choose a smooth β on $\mathbb{C}^{\Phi\times(r'\times\{o\})}$ with values in $[0,1]$, compact support in $\mathcal{G}$ and $\beta(x_B)=1$, and put $k(x)=(k_w(x_w))_w\in G_\infty(t')$. Then: (B1) if $\beta(x)\neq0$ and every x_w is isotropic, $k_w(x_w)x_{B,w}=x_w$; (B2) if $\beta(x)\neq0$, $\frac12c_w\leq|x_w|^2\leq2c_w$ for all w.

Step 3: the function ρ. Let $\rho(u,a)=\beta(u^{-1}a\,x_B)\prod_w|a_w|^{\#n}$ on $\mathrm{K}_{\max}(t')\times(\mathbb{C}^\times)^\Phi$. It is continuous, non-negative, and $\rho(1,(1)_w)=\beta(x_B)=1$. Since $u_w^*u_w=1$, $|u_w^{-1}a_wx_{B,w}|^2=|a_w|^2c_w$; so by (B2) $\rho(u,a)\neq0$ implies $\frac12\leq|a_w|^2\leq2$ for all w, and the support of ρ lies in the compact set $\mathrm{K}_{\max}(t')\times\prod_w\{a_w:\frac12\leq|a_w|^2\leq2\}$.

Step 4: the vectors v^B and v'. Let $v\in\mathcal{F}_{W,V}$ be a Schwartz vector. By Lemma 6.3.58, (2) of Lemma 6.2.43 applies to X_W and m^{tg}_W (the Fock models of (MX7) for $\mathrm{Hom}(W,V')$ and $\mathrm{Hom}(W,V)$ being $\mathcal{F}_{W,V'}$ and $\mathcal{F}_{W,V}$); with a smooth compactly supported τ with $\tau(0)=1$ and the constant map 1 it gives a Schwartz $v^B\in\mathcal{F}_{W,V'}$ whose real slice at 0 is $\tau(0)\,\omega^\infty(1)v=v$; as

$\rho^\infty(0)=1$, this slice is $Z^\infty(v^B)$, so $Z^\infty(v^B)=v$. Next, let $\tau'(x)=\beta(x)\prod_w \det k_w(x_w)^{\gamma(w)}$ and $g'(x)=\bigoplus_w k_w(x_w)\otimes 1_n$. Since $|\det k_w(y)|=1$ for $k_w(y)\in \mathrm{U}(\mathrm{diag}\, t')$, negative powers of $\det k_w$ are powers of its conjugate, so τ' is smooth with compact support; g' is smooth with values in the unitary group of the signs of $\mathrm{Hom}(W,V')$, as $(k\otimes 1)^*(\mathrm{diag}\, t'\otimes \mathrm{diag}\, s)(k\otimes 1)=\mathrm{diag}\, t'\otimes \mathrm{diag}\, s$. By Lemma 6.3.53 and (2) of Lemma 6.2.43 for the splitting induced by A on $\mathrm{Hom}(W',V')$ there is a Schwartz $v'\in\mathcal{F}_{W',V'}$ with

$$\mathrm{rsl}_{A,V'}(x;v')=\tau'(x)\,\omega^\infty(g'(x))\,v^B=\beta(x)\,\Omega_{\gamma,0}(1,k(x))v^B \qquad \text{for all } x, \tag{1}$$

the last equality by (WR5).

Step 5: the identity. Fix (u,a) and put $y=u^{-1}a\,x_B$, so that $u_\infty^{-1}(a\,x_B)=y$. By Lemma 6.3.59, Lemma 6.3.60 (with the weight γ; $\gamma_\mu=\gamma+1$), (1) and the representation property of $\Omega_{\gamma,0}$ (Proposition 4.1.14),

$$\mathrm{Ln}^{+,\infty}_{A,X}(a)(\Omega_{\gamma_\mu,0}(1,u_\infty)v')=Z^\infty\Big(\Omega_{\gamma,0}(1,u_\infty)\,\mathrm{rsl}_{A,V'}(y;v')\Big)=\beta(y)\,Z^\infty\Big(\Omega_{\gamma,0}(1,u_\infty k(y))v^B\Big).$$

If $\beta(y)=0$ then $\rho(u,a)=0$ and the assertion holds with $h=1$. Otherwise each $y_w=u_w^{-1}a_w x_{B,w}$ is isotropic, u_w preserving the form $\mathrm{diag}(t')$, so by (B1) $k_w(y_w)x_{B,w}=y_w$, and $g=u_\infty k(y)$ satisfies $g_w x_{B,w}=u_w y_w=a_w x_{B,w}$. By Lemma 6.3.61 ($\#n$ even) there is $h\in G_\infty(t)$ with $Z^\infty(\Omega_{\gamma,0}(1,g)v^B)=\prod_w(a_w/|a_w|)^{-2\mu(w)}|a_w|^{\#n}\,\Omega_{\gamma,0}(1,h)Z^\infty(v^B)$, and $Z^\infty(v^B)=v$. Hence

$$\prod_w\Big(\frac{a_w}{|a_w|}\Big)^{2\mu(w)}\mathrm{Ln}^{+,\infty}_{A,X}(a)(\Omega_{\gamma_\mu,0}(1,u_\infty)v')=\beta(y)\prod_w|a_w|^{\#n}\,\Omega_{\gamma,0}(1,h)v=\rho(u,a)\,\Omega_{\gamma,0}(1,h)v.$$

□

Lemma 6.3.57. *Let ε be signs on a finite index set a, $J=\mathrm{diag}(\varepsilon)$ the complex $a\times a$ matrix and $\mathrm{U}(J)=\{g\in \mathrm{GL}_a(\mathbb{C}): g^*Jg=J\}$. Let $x_0\in\mathbb{C}^a$ be nonzero with $x_0^*Jx_0=0$. Then there are a map $k\colon \mathbb{C}^a\to \mathrm{U}(J)$, smooth as a map of real vector spaces into $\mathrm{M}_a(\mathbb{C})$, and a neighbourhood N of x_0 such that*

$$k(x)\,x_0=x \qquad \textit{for every } x\in N \textit{ with } x^*Jx=0.$$

Proof. **Step 1: quasi-reflections.** For $z\in\mathbb{C}^a$ and $c\in\mathbb{C}^\times$ with $c+\bar c=z^*Jz$ put $R_{z,c}=1-c^{-1}zz^*J$. For $v,w\in\mathbb{C}^a$, using $(z^*Jv)^-=v^*Jz$,

$$(R_{z,c}v)^*J(R_{z,c}w)=v^*Jw+(v^*Jz)(z^*Jw)\big(-\bar c^{-1}-c^{-1}+|c|^{-2}z^*Jz\big)=v^*Jw,$$

since $|c|^{-2}(z^*Jz-c-\bar c)=0$. So $R_{z,c}^*JR_{z,c}=J$, and $R_{z,c}\in\mathrm{U}(J)$ (J being invertible, so is $R_{z,c}$).

Step 2: a smooth family carrying $y_0=Jx_0$. Let $y_0=Jx_0$. Then $y_0^*Jy_0=x_0^*J^3x_0=x_0^*Jx_0=0$ and $y_0^*J=x_0^*$. For $x\in\mathbb{C}^a$ put $\sigma(x)=\frac12 x^*Jx-x^*x_0$ and $z(x)=y_0-x$. Then

$$\sigma(x)+\overline{\sigma(x)}=x^*Jx-x^*x_0-x_0^*x=z(x)^*Jz(x),$$

because $z^*Jz=y_0^*Jy_0-y_0^*Jx-x^*Jy_0+x^*Jx$ with $y_0^*Jx=x_0^*x$ and $x^*Jy_0=x^*x_0$. The function σ is smooth (a real polynomial) and $\sigma(x_0)=-|x_0|^2\neq 0$, so there is $\delta>0$ with $\sigma\neq 0$ on the ball $B(x_0,2\delta)$. Let b be a smooth function on $\mathbb{C}^a$ with values in $[0,1]$, equal to 1 on $B(x_0,\delta)$ and 0 off $B(x_0,2\delta)$, and $\pi(x)=x_0+b(x)(x-x_0)$; then π is smooth, $\pi(x)\in B(x_0,2\delta)$ for all x, and $\pi(x)=x$ on $B(x_0,\delta)$. Put $k_1(x)=R_{z(\pi(x)),\sigma(\pi(x))}\in\mathrm{U}(J)$; its entries are polynomials in the real coordinates of $\pi(x)$ divided by the non-vanishing smooth function $\sigma(\pi(x))$, so k_1 is smooth.

If $x \in B(x_0,\delta)$ and $x^*Jx = 0$, then $\pi(x) = x$, $\sigma(x) = -x^*x_0$ and $z(x)^*Jy_0 = y_0^*Jy_0 - x^*Jy_0 = -x^*x_0 = \sigma(x)$, so

$$k_1(x)\,y_0 = y_0 - \sigma(x)^{-1}(z(x)^*Jy_0)z(x) = y_0 - z(x) = x.$$

Step 3: carrying x_0. By Step 2 at $x = x_0$, $k_1(x_0)y_0 = x_0$, so $k_1(x_0)^{-1}x_0 = y_0$. Let $k(x) = k_1(x)k_1(x_0)^{-1}$, smooth with values in $\mathrm{U}(J)$, and $N = B(x_0,\delta)$. For isotropic $x \in N$, $k(x)x_0 = k_1(x)y_0 = x$. □

Lemma 6.3.58. *Let Y, Y_0, T be spaces with points with signs σ on n_Y, σ_0 on n_0 and τ on n_T, p an index set and D a base-adapted splitting of Y over Y_0 along p. Then the splitting of* $\mathrm{Hom}(T,Y)$ *over* $\mathrm{Hom}(T,Y_0)$ *along $p \times n_T$ induced on the target by D is adapted at* 1 *in the basis*

$$m_T^{\mathrm{tg}} = 1_p \otimes \bar{x}_T\,\varepsilon_\tau \in \mathrm{GL}_{p\times n_T}(\mathbb{A}_E).$$

Proof. Let $D = (k,l,i)$ with adelic frames $k_{\mathbb{A}} = x_Y^{-1}k$, $l_{\mathbb{A}} = x_Y^{-1}l$, $i_{\mathbb{A}} = x_Y^{-1}ix_{Y_0}$, and $B_D = (l_{\mathbb{A}} \mid k_{\mathbb{A}} \mid i_{\mathbb{A}})$, with orthonormal columns at the infinite places and entries in $\widehat{\mathcal{O}}_E$ at the finite places. The points of $\mathrm{Hom}(T,Y)$ and $\mathrm{Hom}(T,Y_0)$ are $x_Y \otimes (x_T^{-1})^{\mathsf{T}}$ and $x_{Y_0} \otimes (x_T^{-1})^{\mathsf{T}}$, and by (LN1) the frames of the induced splitting are $k \otimes J_T^{\mathsf{T}}$, $l \otimes 1$, $i \otimes 1$. Its adelic frames are therefore

$$(x_Y^{-1} \otimes x_T^{\mathsf{T}})(k \otimes J_T^{\mathsf{T}}) = k_{\mathbb{A}} \otimes (J_T x_T)^{\mathsf{T}}, \qquad (x_Y^{-1} \otimes x_T^{\mathsf{T}})(l \otimes 1) = l_{\mathbb{A}} \otimes x_T^{\mathsf{T}},$$

$$(x_Y^{-1} \otimes x_T^{\mathsf{T}})(i \otimes 1)(x_{Y_0} \otimes (x_T^{-1})^{\mathsf{T}}) = i_{\mathbb{A}} \otimes 1.$$

Put $m = m_T^{\mathrm{tg}}$. Since $(J_T x_T)^{\mathsf{T}}\bar{x}_T = (x_T^* J_T x_T)^{\mathsf{T}} = \varepsilon_\tau$, we get $(k_{\mathbb{A}} \otimes (J_T x_T)^{\mathsf{T}})\,m = k_{\mathbb{A}} \otimes \varepsilon_\tau^2 = k_{\mathbb{A}} \otimes 1$. Since $m^{-1} = 1 \otimes \varepsilon_\tau \bar{x}_T^{-1}$ and $(\bar{x}_T^{-1})^* = (x_T^{-1})^{\mathsf{T}}$, $(m^{-1})^* = 1 \otimes (x_T^{-1})^{\mathsf{T}}\varepsilon_\tau$, so $(l_{\mathbb{A}} \otimes x_T^{\mathsf{T}})(m^{-1})^* = l_{\mathbb{A}} \otimes \varepsilon_\tau$. Hence the matrix of (MX5) at 1 in the basis m is, with the column blocks indexed by $p \times n_T$, $p \times n_T$ and $n_0 \times n_T$,

$$Q = \left(l_{\mathbb{A}} \otimes \varepsilon_\tau \;\middle|\; k_{\mathbb{A}} \otimes 1 \;\middle|\; i_{\mathbb{A}} \otimes 1\right) = (B_D \otimes 1_{n_T})\,R_\pm,$$

where the columns of $B_D \otimes 1_{n_T}$ are indexed by $(p \sqcup p \sqcup n_0) \times n_T = (p \times n_T) \sqcup (p \times n_T) \sqcup (n_0 \times n_T)$ and $R_\pm$ is block diagonal with the blocks $1_p \otimes \varepsilon_\tau$, 1, 1, diagonal with entries ± 1 at the infinite places and 1 at the finite places. At an infinite place v, $Q_v^*Q_v = (R_\pm)_v(B_{D,v}^* B_{D,v} \otimes 1)(R_\pm)_v = (R_\pm)_v^2 = 1$. At the finite places every entry of Q is an entry of B_D or 0, hence in $\widehat{\mathcal{O}}_E$. So the induced splitting is adapted at 1 in the basis m. □

Lemma 6.3.59. *Let W', W, V', V, A, X be as above, and for $w \in \Phi$ let $x_{B,w} \in \mathbb{C}^{r'}$ be the component at w of the adelic frame $k_{X,\mathbb{A}}$ of X. For $a \in \mathbb{C}^\Phi$ let $a\,x_B \in \mathbb{C}^{\Phi \times (r' \times \{o\})}$ be the family $(a_w x_{B,w})_{w\in\Phi}$. Then for every $v \in \mathcal{F}_{W',V'}$*

$$\mathrm{Ln}_{A,X}^{+,\infty}(a)\,v = Z^\infty_{X_W, m_W^{\mathrm{tg}}}\big(\mathrm{rsl}_{A,V'}(a\,x_B; v)\big).$$

Proof. Fix $a \in \mathbb{C}^\Phi$ and let $\alpha = \mathrm{rv}(a) \in \mathbb{A}_E$, the adele with components $\kappa_w a_w$ at $w \in \Phi$ and 0 at the finite places. Fix $v \in \mathcal{F}_{W',V'}$ and put $F = v \otimes v^0 \in \mathcal{M}_{W',V'}$. Since X splits a hyperbolic plane off V', $\#r' = \#r + 2 \geq 2$. By (LN3), $\mathrm{Ln}_{A,X}^{+,\infty}(a)v = \mathrm{rsl}_{D^+,m}(b_a; v)$, and D^+ is a splitting of $\mathrm{Hom}(W',V')$ over $\mathrm{Hom}(W,V)$ along the nonempty set $q \sqcup \{*\}$.

Step 1: the slice along D^+ in one step. By (1) of Lemma 6.2.38, D^+ is adapted at 1 in the basis m. By (3) of Lemma 6.2.20 (for D^+, m, $f = v^0$, $b = b_a$, $y = 0$), $v_1 \otimes v^0 = v^0$ ((4) of Lemma 6.2.21) and (4) of Lemma 6.2.20,

$$F\big[m^{-*}\mathrm{rv}(b_a)\big]_{D^+} = \mathrm{Ln}^{+,\infty}_{A,X}(a)v \otimes Z_{D^+}(v^0) = \mathrm{vf}(D^+)\,\mathrm{Ln}^{+,\infty}_{A,X}(a)v \otimes v^0, \qquad \mathrm{vf}(D^+) \neq 0, \quad (1)$$

the slice being taken along D^+. The basis m is block diagonal with the block 1 on $\{*\}$, and $\mathrm{rv}(b_a)$ has the entry α at $*$ and 0 elsewhere; so $m^{-*}\mathrm{rv}(b_a) = \alpha e_*$, e_* the unit vector at $*$.

Step 2: slices along D^+ at multiples of e_* are line terms. Let $f \in \mathcal{M}_{W',V'}$ and $c \in \mathbb{A}_E$. Write x for the point of $\mathrm{Hom}(W',V')$, $x_{\mathbb{H}}$ for that of $\mathbb{H}_{\{*\}} \oplus \mathrm{Hom}(W,V)$, and i^{pl}, l^R for the embedding of D^{pl} and the frame l of R^+. By (MX5) the frame l of D^+ has the column $i^{\mathrm{pl}}l^R$ at $*$, so its adelic frame sends ce_* to $x^{-1}i^{\mathrm{pl}}l^Rc = i^{\mathrm{pl}}_{\mathbb{A}}l^R_{\mathbb{A}}c$, with $i^{\mathrm{pl}}_{\mathbb{A}} = x^{-1}i^{\mathrm{pl}}x_{\mathbb{H}}$ and $l^R_{\mathbb{A}} = x^{-1}_{\mathbb{H}}l^R$. By (1) of Lemma 6.2.25, $Z_{D^+} = Z_{R^+} \circ Z^{\mathrm{pl}}$, and by (1) of Lemma 6.2.44 for $\Pi = Z^{\mathrm{pl}}$ (at $x = a = b = 0$; D^{pl} is along the nonempty set q), $Z^{\mathrm{pl}}\rho(i^{\mathrm{pl}}_{\mathbb{A}}w) = \rho(w)Z^{\mathrm{pl}}$. Hence

$$f[ce_*]_{D^+} = Z_{R^+}Z^{\mathrm{pl}}(\rho(i^{\mathrm{pl}}_{\mathbb{A}}l^R_{\mathbb{A}}c)f) = Z_{R^+}(\rho(l^R_{\mathbb{A}}c)Z^{\mathrm{pl}}f) = (Z^{\mathrm{pl}}f)[c]_+ = \mathrm{Ln}^+_{A,X}(c)f,$$

the last step by (1) of Lemma 6.2.24. By (LN2), $\mathrm{Ln}^+_{A,X}(c)f = Z^{\mathrm{tg}}_{X,W}(f[c\,k_{X,\mathbb{A}}])$, the inner slice the Hom slice along the splitting $A_{V'}$ of $\mathrm{Hom}(W',V')$ over $\mathrm{Hom}(W,V')$ induced by A.

Step 3: the zero term on the target of a vacuum datum. We show: for every $\psi \in \mathcal{F}_{W,V'}$,

$$Z^{\mathrm{tg}}_{X,W}(\psi \otimes v^0) = \mathrm{vf}(X_W)\,Z^{\infty}_{X_W,m^{\mathrm{tg}}_W}(\psi) \otimes v^0, \qquad Z^{\mathrm{tg}}_{X,W}(v^0) = \mathrm{vf}(X_W)\,v^0, \qquad \mathrm{vf}(X_W) \neq 0. \quad (2)$$

The splitting X_W is along $\{o\} \times n$. If $n \neq \varnothing$: X_W is adapted at 1 in the basis m^{tg}_W by Lemma 6.3.58, and (2) of Lemma 6.2.20 with $f = v^0$, $v_1 \otimes v^0 = v^0$ and (4) of Lemma 6.2.20 give (2). If $n = \varnothing$: $\mathrm{Hom}(W,V')$ and $\mathrm{Hom}(W,V)$ have rank 0, so both are the standard space of the empty sign vector, with theta model $\mathbb{C}$, $\rho(0) = 1$, $v^0 = 1$, $\langle f,g\rangle = \bar{f}g$ ((WD5)–(WD7), empty sums 0 and empty products 1) and the identity of $\mathbb{C}$ as canonical theta functional ((WC1)–(WC3)); the quotient in (MX4) is a point of mass 1, so (MX4) reads $Z^{\mathrm{tg}}_{X,W}(f) = f$ and $\mathrm{vf}(X_W) = 1$ by (MX8). The Fock models are $\mathbb{C}$ (functions on a point, ν the unit mass, real vacuum 1), the datum $\psi \otimes v^0$ is the number ψ, and the real zero term of (MX7) is the integral over a point of $\psi \cdot 1 \cdot 1 \cdot 1$, so $Z^{\infty}_{X_W,m^{\mathrm{tg}}_W}(\psi) = \psi$; (2) holds.

Step 4: the line term in two steps. The adelic $r' \times 1$ matrix $\alpha\,k_{X,\mathbb{A}}$ has components $\kappa_w a_w x_{B,w}$ at $w \in \Phi$ and 0 at the finite places, so $\alpha\,k_{X,\mathbb{A}} = \mathrm{rv}(a\,x_B)$. By (2) of Lemma 6.3.12 (for W', W, $T = V'$ with the nonempty index set r', and A along $\{o\}$),

$$F[\alpha\,k_{X,\mathbb{A}}] = (v \otimes v^0)[\mathrm{rv}(a\,x_B)] = \mathrm{vf}(A_{V'})\,\mathrm{rsl}_{A,V'}(a\,x_B; v) \otimes v^0, \qquad \mathrm{vf}(A_{V'}) \neq 0.$$

Applying $Z^{\mathrm{tg}}_{X,W}$, Step 2 (with $c = \alpha$) and (2) (with $\psi = \mathrm{rsl}_{A,V'}(a\,x_B; v)$) give

$$F[\alpha e_*]_{D^+} = \mathrm{vf}(A_{V'})\,\mathrm{vf}(X_W)\,Z^{\infty}_{X_W,m^{\mathrm{tg}}_W}\big(\mathrm{rsl}_{A,V'}(a\,x_B; v)\big) \otimes v^0. \quad (3)$$

Step 5: the vacuum factors. Apply Step 2 with $c = 0$ to $f = v^0$: $Z_{D^+}(v^0) = Z^{\mathrm{tg}}_{X,W}(v^0[0])$, and the Hom slice at 0 is $v^0[0] = Z_{A_{V'}}(v^0) = \mathrm{vf}(A_{V'})v^0$ ((4) of Lemma 6.2.20 for $A_{V'}$, which is along the nonempty set $r' \times \{o\}$ and adapted at 1 in its adapted basis by Lemma 6.3.53). By (2) and (MX8), $\mathrm{vf}(D^+) = \mathrm{vf}(A_{V'})\,\mathrm{vf}(X_W)$.

Step 6: conclusion. By (1), Step 1 and (3), with Step 5 and the linearity of $\phi \mapsto \phi \otimes v^0$ ((WR6)),

$$\mathrm{vf}(D^+)\Big(\mathrm{Ln}^{+,\infty}_{A,X}(a)v - Z^{\infty}_{X_W,m^{\mathrm{tg}}_W}\big(\mathrm{rsl}_{A,V'}(a\,x_B; v)\big)\Big) \otimes v^0 = 0.$$

As $\mathrm{vf}(D^+) \neq 0$, Lemma 6.3.9 for the signs of $\mathrm{Hom}(W,V)$ gives the assertion. □

Lemma 6.3.60. *Let W', W, V' and A be as above, $\gamma\colon \Phi \to \mathbb{Z}$, $h \in G_\infty(t')$, $x = (x_w)_{w\in\Phi} \in \mathbb{C}^{\Phi\times(r'\times\{o\})}$ (each x_w a vector of $\mathbb{C}^{r'}$) and $h^{-1}x = (h_w^{-1}x_w)_w$. Then for every $v \in \mathcal{F}_{W',V'}$*

$$\mathrm{rsl}_{A,V'}(x;\Omega_{\gamma+1,0}(1,h)v) = \Omega_{\gamma,0}(1,h)\,\mathrm{rsl}_{A,V'}(h^{-1}x;v),$$

with Ω the real Weil representation of the pair (W',V') on the left and of (W,V') on the right, 1 the identity of $G_\infty(s')$, resp. $G_\infty(s)$.

Proof. If r' is empty, $G_\infty(t')$ is trivial and both sides are $\mathrm{rsl}_{A,V'}(x;v)$; let r' be nonempty, so that $A_{V'}$ is a splitting along the nonempty set $r'\times\{o\}$.

Step 1: reduction to the weights $(1,0)$**.** By (WR5),

$$\Omega_{\gamma+1,0}(1,h) = \prod_w \det(h_w)^{\gamma(w)}\,\Omega_{1,0}(1,h) \quad\text{and}\quad \Omega_{\gamma,0}(1,h) = \prod_w \det(h_w)^{\gamma(w)}\,\Omega_{0,0}(1,h),$$

and $\mathrm{rsl}_{A,V'}(x;\cdot)$ is linear ((MX7), a Bochner integral linear in the vector). So it suffices to prove

$$\mathrm{rsl}_{A,V'}(x;\Omega_{1,0}(1,h)v) = \Omega_{0,0}(1,h)\,\mathrm{rsl}_{A,V'}(h^{-1}x;v).$$

Step 2: real slices as Hom slices. Apply (2) of Lemma 6.3.12 to the base-adapted splitting A of W' over W along $\{o\}$ and $T = V'$; the index sets r' and $\{o\}$ are nonempty. So $\mathrm{vf} = \mathrm{vf}(A_{V'}) \neq 0$, and for every $\phi \in \mathcal{F}_{W',V'}$ and $b \in \mathbb{C}^{\Phi\times(r'\times\{o\})}$

$$(\phi\otimes v^0)[\mathrm{rv}(b)] = \mathrm{vf}\,\mathrm{rsl}_{A,V'}(b;\phi)\otimes v^0, \tag{6.50}$$

the left side a Hom slice.

Step 3: the law of Hom slices. Let $\hat{h} = (h,1) \in \mathrm{G}(t')$. By (5) of Lemma 4.1.1 (the characters υ and 1 have weights 1 and 0), $\omega_{\upsilon,1}(1,\hat{h})(\upsilon\otimes v^0) = (\Omega_{1,0}(1,h)v)\otimes v^0$. Apply (2) of Lemma 6.2.45 to the splitting A along $\{o\}$, $T = V'$, the characters $\alpha = 1$ (so that $\alpha\upsilon^{\#\{o\}} = \upsilon$) and $\beta = 1$, the element $g = 1$ (with $m = 1$, $g_0 = 1$, $W = \mathrm{pr}_i l_{A,\mathbb{A}} = 0$, $B = \mathrm{pr}_k l_{A,\mathbb{A}} = 0$, $\chi(1) = 1$) and $\hat{h}$: for every adelic X,

$$\big(\omega_{\upsilon,1}(1,\hat{h})(\upsilon\otimes v^0)\big)[X] = \omega_{1,1}(1,\hat{h})\big((\upsilon\otimes v^0)[\hat{h}^{-1}X]\big),$$

$\omega_{1,1}$ on the right being that of the pair (W,V'). At $X = \mathrm{rv}(b)$, $\hat{h}^{-1}X = \mathrm{rv}(h^{-1}b)$ ($\hat{h}$ has finite components 1 and κ_υ is a scalar). By (6.50) on both sides and (5) of Lemma 4.1.1 for the pair (W,V') (weights $0,0$),

$$\mathrm{vf}\,\mathrm{rsl}_{A,V'}\big(b;\Omega_{1,0}(1,h)v\big)\otimes v^0 = \mathrm{vf}\,\big(\Omega_{0,0}(1,h)\,\mathrm{rsl}_{A,V'}(h^{-1}b;v)\big)\otimes v^0.$$

As $\mathrm{vf}\neq 0$, Lemma 6.3.9 gives the identity of Step 1 at $x = b$. □

Lemma 6.3.61. *Let W, V', V and X be as above with $\#n$ even, $\mu\colon \Phi\to\mathbb{Z}$ and $\gamma(w) = \#n/2 - \mu(w)$. For $w\in\Phi$ let $x_{B,w}\in\mathbb{C}^{r'}$ be the component at w of $k_{X,\mathbb{A}}$. Let $g\in G_\infty(t')$ and $a\in(\mathbb{C}^\times)^\Phi$ with $g_w x_{B,w} = a_w x_{B,w}$ for every $w\in\Phi$. Then there is $h\in G_\infty(t)$ such that for every $v\in\mathcal{F}_{W,V'}$*

$$Z^\infty_{X_W,m_W^{\mathrm{tg}}}\big(\Omega_{\gamma,0}(1,g)v\big) = \prod_{w\in\Phi}\Big(\frac{a_w}{|a_w|}\Big)^{-2\mu(w)}|a_w|^{\#n}\;\Omega_{\gamma,0}(1,h)\,Z^\infty_{X_W,m_W^{\mathrm{tg}}}(v),$$

with Ω the real Weil representation of the pair (W,V') on the left and of (W,V) on the right.

Proof. Write $Z^\infty = Z^\infty_{X_W, m_W^{\mathrm{tg}}}$ and $\hat g = (g,1) \in \mathrm{G}(t')$, and let $\hat a \in \mathbb{A}_E^\times$ have components a_w at $w \in \Phi$ and 1 at the finite places. Then $\hat g k_{X,\mathbb{A}} = k_{X,\mathbb{A}} \hat a$.

Step 1: the point h. By (3) of Lemma 6.3.48, $\hat g = \mathrm{rad}(c,z)\,\mathrm{lev}(\hat a, h_0)$ with $h_0 \in \mathrm{G}(t)$, and $h_0 = \mathrm{pr}_i \hat g i_{X,\mathbb{A}}$ since $\mathrm{pr}_i \,\mathrm{rad}(c,z)\, i_{X,\mathbb{A}} = 1$ ((MX2)); its finite components are $\mathrm{pr}_i i_{X,\mathbb{A}} = 1$, so $h_0 = (h,1)$ with $h \in G_\infty(t)$. In the frame $(l_{X,\mathbb{A}} \mid k_{X,\mathbb{A}} \mid i_{X,\mathbb{A}})$ the radical element is unipotent (it maps $k_{X,\mathbb{A}}$ to itself, $i_{X,\mathbb{A}}$ into $i_{X,\mathbb{A}} + k_{X,\mathbb{A}}(\cdot)$ and $l_{X,\mathbb{A}}$ into $l_{X,\mathbb{A}}$ + (the span of $i_{X,\mathbb{A}}, k_{X,\mathbb{A}}$)) and the Levi element is block diagonal with blocks $\bar{\hat a}^{-1}$, $\hat a$, h_0; so $\det g_w = (a_w/\bar a_w)\det h_w$ for $w \in \Phi$.

Step 2: reduction to the weights $(0,0)$. By (WR5), $\Omega_{\gamma,0}(1,g) = \prod_w \det(g_w)^{\gamma(w)} \Omega_{0,0}(1,g)$ and $\Omega_{\gamma,0}(1,h) = \prod_w \det(h_w)^{\gamma(w)}\Omega_{0,0}(1,h)$, and Z^∞ is linear. With $a_w/\bar a_w = (a_w/|a_w|)^2$ and $2\gamma(w) - \#n = -2\mu(w)$, the assertion follows from

$$Z^\infty\big(\Omega_{0,0}(1,g)v\big) = \prod_{w\in\Phi} \Big(\frac{a_w}{|a_w|}\Big)^{-\#n} |a_w|^{\#n}\; \Omega_{0,0}(1,h)\, Z^\infty(v). \tag{6.51}$$

If n is empty, all Fock models involved are $\mathbb{C}$, $\Omega_{0,0}$ and Z^∞ are the identity, and (6.51) holds; let n be nonempty, so that X_W is a splitting along the nonempty set $\{o\} \times n$.

Step 3: the adelic law. Apply (1) of Lemma 6.2.9 to $D = X$ (with $Y = V'$, $Y_0 = V$, $p = \{o\}$), $T = W$, the element $\hat g$ with $m = \hat a$ and h_0, the point $1 \in \mathrm{G}(s)$ and the characters $\alpha = \beta = 1$, and to $F = v \otimes v^0 \in \mathcal{M}_{W,V'}$:

$$Z^{\mathrm{tg}}_{X,W}\big(\omega_{1,v}(1,\hat g)(v\otimes v^0)\big) = 1[\#n](\hat a)\,|\hat a|^{\#n/2}\,\omega_{1,1}(1,h_0)\, Z^{\mathrm{tg}}_{X,W}(v\otimes v^0),$$

with $1[\#n](\hat a) = \upsilon(\hat a)^{-\#n} = \prod_w (a_w/|a_w|)^{-\#n}$ and $|\hat a|^{\#n/2} = \prod_w |a_w|^{\#n}$ (the module at a complex place is the square of the absolute value). By (5) of Lemma 4.1.1 (the characters have weight 0 on the target side; the source point is 1), $\omega_{1,\upsilon}(1,\hat g)(v\otimes v^0) = (\Omega_{0,0}(1,g)v)\otimes v^0$ and $\omega_{1,1}(1,h_0)(w'\otimes v^0) = (\Omega_{0,0}(1,h)w')\otimes v^0$. By Lemma 6.3.58, X_W is adapted at 1 in m_W^{tg}; so (2) and (4) of Lemma 6.2.20 and $v_1 \otimes v^0 = v^0$ ((4) of Lemma 6.2.21) give $Z^{\mathrm{tg}}_{X,W}(\phi\otimes v^0) = \mathrm{vf}\, Z^\infty(\phi)\otimes v^0$ for every Fock vector ϕ, with $\mathrm{vf} = \mathrm{vf}(X_W) \neq 0$. Hence

$$\mathrm{vf}\, Z^\infty\big(\Omega_{0,0}(1,g)v\big)\otimes v^0 = \prod_w \Big(\frac{a_w}{|a_w|}\Big)^{-\#n} |a_w|^{\#n}\, \mathrm{vf}\,\big(\Omega_{0,0}(1,h) Z^\infty(v)\big)\otimes v^0,$$

and Lemma 6.3.9 gives (6.51). □

Lemma 6.3.62. *Let $\mu\colon \Phi \to \mathbb{Z}$ and $k \in \mathbb{N}$ with $k \le \mu(v)$ for every $v \in \Phi$, and let $\mathfrak{c} = (\nu, \Sigma)$ be a split tame character of weight μ. Then there is a real-analytic function $\Lambda\colon (-k,\infty) \to \mathbb{C}$ such that $\Lambda(x) = L^\Sigma(x, \tilde\nu)$ for every real $x \ge 1$ and $\Lambda(j) \neq 0$ for every integer $j > -k$.*

Proof. Let $\psi = (\psi_w)_w$ be the tame part of ν, so $\psi_w \neq 1$ exactly for $w \in \Sigma$. Complex conjugation of E extends to $\mathbb{A}_E$; for a place w of E let $\bar w$ be the conjugate place. For a finite place w it induces an isomorphism $\sigma_w\colon E_w \to E_{\bar w}$ with $\sigma_w(\mathcal{O}^\times_{E,w}) = \mathcal{O}^\times_{E,\bar w}$, and hence an isomorphism of residue fields. As F is totally real and E totally imaginary, every infinite place $v \in \Phi$ is complex and fixed by conjugation, which acts on $E_v = \mathbb{C}$ (through the embedding of the CM type) as complex conjugation. For a place w let $\iota_w\colon E_w^\times \to \mathbb{A}_E^\times$ be the inclusion with components 1 at the other places and $\tilde\nu_w = \tilde\nu \circ \iota_w$.

Step 1: $\tilde\nu$ is a unitary Hecke character of E. The map $x \mapsto x/\bar x$ is a continuous homomorphism $\mathbb{A}_E^\times \to \mathrm{U}(1)(\mathbb{A})$ (as $(x/\bar x)\overline{(x/\bar x)} = 1$) that maps $E^\times$ into $\mathrm{U}(1)(E)$. Since ν is continuous, of modulus 1 and trivial on $\mathrm{U}(1)(E)$, $\tilde\nu$ is a continuous character of $\mathbb{A}_E^\times/E^\times$ of modulus 1.

Step 2: the local components. (a) Let $v \in \Phi$ and $a \in \mathbb{C}^\times$. The idele $\iota_v(a)/\overline{\iota_v(a)}$ has the component $a/\bar a$ at v and 1 elsewhere; it lies in $\mathrm{U}(1)(\mathbb{A})$ and its finite components are integral,

so the definition of weight and tame part (Definition 3.1.2) gives

$$\tilde{\nu}_v(a) = \Big(\frac{a}{\bar{a}}\Big)^{\mu(v)} = \Big(\frac{a}{|a|}\Big)^{2\mu(v)}.$$

(b) Let w be a finite place and $u \in \mathcal{O}_{E,w}^\times$. If $\bar{w} = w$, the idele $\iota_w(u)/\overline{\iota_w(u)}$ has the single component $u/\sigma_w(u) \in \mathcal{O}_{E,w}^\times$ at w and 1 elsewhere, so $\tilde{\nu}_w(u) = \psi_w((u/\sigma_w(u)) \bmod w)$. If $\bar{w} \neq w$, it has the components u at w and $\sigma_w(u)^{-1}$ at $\bar{w}$, so

$$\tilde{\nu}_w(u) = \psi_w(u \bmod w)\, \psi_{\bar{w}}(\sigma_w(u)^{-1} \bmod \bar{w}).$$

Since Σ contains the conjugate of none of its members, $w \in \Sigma$ implies $\bar{w} \neq w$ and $\bar{w} \notin \Sigma$. Hence: if $w \notin \Sigma \cup \bar{\Sigma}$, then $\psi_w = \psi_{\bar{w}} = 1$ and $\tilde{\nu}_w$ is trivial on $\mathcal{O}_{E,w}^\times$; if $w \in \Sigma$, then $\tilde{\nu}_w(u) = \psi_w(u \bmod w)$, which is not identically 1 because $\psi_w \neq 1$ and reduction $\mathcal{O}_{E,w}^\times \to k_w^\times$ is onto; if $w = \bar{w}_0$ with $w_0 \in \Sigma$, then $\psi_w = 1$ and $\tilde{\nu}_w(u) = \psi_{w_0}(\sigma_w(u) \bmod w_0)^{-1}$, again not identically 1 since σ_w maps $\mathcal{O}_{E,w}^\times$ onto $\mathcal{O}_{E,w_0}^\times$. So $\tilde{\nu}$ is ramified exactly at the places of $\Sigma \cup \bar{\Sigma}$, the Euler product of $L(s, \tilde{\nu})$ runs over the finite places $w \notin \Sigma \cup \bar{\Sigma}$, and

$$L(s, \tilde{\nu}) = L^\Sigma(s, \tilde{\nu}) \qquad (\operatorname{Re} s > 1).$$

(c) By (a), $\tilde{\nu}_v$ is the character $a \mapsto (a/|a|)^{2\mu(v)}$ of $\mathbb{C}^\times$, whose local L-factor is $\Gamma_{\mathbb{C}}(s + \mu(v))$, $\Gamma_{\mathbb{C}}(s) = 2(2\pi)^{-s}\Gamma(s)$ ([296], Section 2.5: the factor of $a \mapsto (a/|a|)^\ell$ is $\Gamma_{\mathbb{C}}(s + |\ell|/2)$). Hence

$$L_\infty(s, \tilde{\nu}) = L_\infty(s, \tilde{\nu}^{-1}) = \prod_{v \in \Phi} \Gamma_{\mathbb{C}}(s + \mu(v)).$$

Step 3: continuation. $\tilde{\nu}$ is not of the form $|\cdot|_{\mathbb{A}}^{i\tau}$: on the unit circle of $\mathbb{C}^\times$ at $v \in \Phi$ the character $|\iota_v(\cdot)|_{\mathbb{A}}^{i\tau} = |\cdot|^{2i\tau}$ is trivial, whereas $\tilde{\nu}_v(e^{i\vartheta}) = e^{2i\mu(v)\vartheta}$ is not, as $\mu(v) \geq k \geq 0$ and $\mu(v) > 0$ by (XD4). The same holds for $\tilde{\nu}^{-1} = \overline{\tilde{\nu}}$. By Theorem A.1.12 (2), whose poles occur only in the case excluded here (item (1)), $\xi(s, \tilde{\nu})$ continues to an entire function. As Γ has no zeros, $1/L_\infty(s, \tilde{\nu})$ is entire, so

$$L(s, \tilde{\nu}) = \big(|d_E| \operatorname{N}\mathfrak{f}(\tilde{\nu})\big)^{-s/2}\, \xi(s, \tilde{\nu})\, L_\infty(s, \tilde{\nu})^{-1}$$

continues to an entire function, again written $L(s, \tilde{\nu})$; the same argument applies to $\overline{\tilde{\nu}}$. By Step 2 (b) this continuation agrees with $L^\Sigma(s, \tilde{\nu})$ on $\operatorname{Re} s > 1$, so its value at $s = 1$ is the value $L^\Sigma(1, \tilde{\nu})$ of (XD7). Put $\Lambda(x) = L(x, \tilde{\nu})$ for real $x > -k$. The restriction of an entire function to an open interval of $\mathbb{R}$ is real-analytic (at each real point its Taylor series converges on a disc), and $\Lambda(x) = L^\Sigma(x, \tilde{\nu})$ for $x \geq 1$.

Step 4: nonvanishing at the integers $j > -k$. If $j \geq 1$, then $\Lambda(j) = L(j, \tilde{\nu}) \neq 0$ by Theorem A.1.12 (3). Let $j \leq 0$ and $j > -k$. By Theorem A.1.12 (2), $\xi(s, \tilde{\nu}) = W(\tilde{\nu})\, \xi(1 - s, \overline{\tilde{\nu}})$ and $W(\tilde{\nu})W(\overline{\tilde{\nu}}) = 1$, so $W(\tilde{\nu}) \neq 0$. At $s = 1 - j \geq 1$ the three factors of $\xi(s, \overline{\tilde{\nu}})$ are holomorphic: $L(1 - j, \overline{\tilde{\nu}}) \neq 0$ by Theorem A.1.12 (3), $L_\infty(1 - j, \overline{\tilde{\nu}}) = \prod_v \Gamma_{\mathbb{C}}(1 - j + \mu(v))$ is finite and nonzero because $1 - j + \mu(v) \geq 1$, and the power of $|d_E| \operatorname{N}\mathfrak{f}(\overline{\tilde{\nu}})$ is positive. Hence $\xi(j, \tilde{\nu}) = W(\tilde{\nu})\, \xi(1 - j, \overline{\tilde{\nu}}) \neq 0$. On the other side, $j + \mu(v) \geq j + k > 0$ for every $v \in \Phi$, so $L_\infty(s, \tilde{\nu})$ is holomorphic at $s = j$ and $\xi(j, \tilde{\nu}) = (|d_E| \operatorname{N}\mathfrak{f}(\tilde{\nu}))^{j/2} L_\infty(j, \tilde{\nu})\, L(j, \tilde{\nu})$. Therefore $\Lambda(j) = L(j, \tilde{\nu}) \neq 0$. □

Lemma 6.3.63. *1. Let V, V_1 be spaces with points with the same signs s on n. There are $\gamma \in \mathrm{GL}_n(E)$ with $\gamma^* J_{V_1} \gamma = J_V$ and $k \in \mathrm{G}(s)$ with $x_V = \gamma^{-1} x_{V_1} k$; and for every such pair (γ, k), $\Gamma_V = k^{-1} \Gamma_{V_1} k$.*

2. *Let W be a space with a point with signs s on n, let p, r be finite index sets and t signs on r with $\#r = \#n + 2\#p$ and $\#\{\rho : t_\rho = -1\} = \#p + \#\{i : s_i = -1\}$. There are a space with a point W' with signs t and a base-adapted splitting of W' over W along p.*

Proof. (1). This is Lemma 4.1.8.

(2). Let s'' be the signs of $W'' = \mathbb{H}_p \oplus W$ on $(p \sqcup p) \sqcup n$: $+1$ on the first copy of p, -1 on the second, s on n. It has $\#r$ indices and $\#p + \#\{s_i = -1\}$ signs -1, so there is a bijection $\epsilon\colon r \to (p \sqcup p) \sqcup n$ with $s'' \circ \epsilon = t$. For a matrix M indexed by $(p \sqcup p) \sqcup n$ let M^ϵ be the matrix $(M_{\epsilon(\rho),\epsilon(\rho')})_{\rho,\rho' \in r}$, and similarly for one-sided reindexing of rows. Put $W' = (J^\epsilon_{W''}, x^\epsilon_{W''})$; as reindexing is conjugation by a permutation matrix, $(x^\epsilon_{W''})^* J^\epsilon_{W''} x^\epsilon_{W''} = (\varepsilon_{s''})^\epsilon = \varepsilon_t$, so W' is a space with a point with signs t. Let l, k, i be the $r \times p$, $r \times p$, $r \times n$ matrices obtained by reindexing the rows of the column blocks of the identity matrix for the first copy of p, the second copy and n. The conditions of (MX1) are invariant under the simultaneous reindexing, and in the original order they read off the blocks of $J_{W''} = \operatorname{diag}(\left(\begin{smallmatrix} 0 & 1 \\ 1 & 0 \end{smallmatrix}\right), J_W)$: $l^* J l = 0$, $k^* J k = 0$, $l^* J k = 1$, $i^* J i = J_W$, $i^* J k = i^* J l = 0$, and $\#r = \#n + 2\#p$. So (k, l, i) is a splitting of W' over W along p. In the original order the matrix with column blocks $l_{\mathbb{A}} = x^{-1} l$, $k_{\mathbb{A}} = x^{-1} k$, $i_{\mathbb{A}} = x^{-1} i x_W$ ($x = x_{W''}$) is $\operatorname{diag}(x^{-1}_{\mathbb{H}_p}, 1_n)$. At an infinite place $x_{\mathbb{H}_p} = \frac{1}{\sqrt{2}} \left(\begin{smallmatrix} 1 & -1 \\ 1 & 1 \end{smallmatrix}\right)$ (blocks scalar) is real orthogonal, so its inverse has orthonormal columns. At the finite places $x_{\mathbb{H}_p} = \left(\begin{smallmatrix} 1 & -c \\ c_0 & c\bar{c}_0 \end{smallmatrix}\right)$ has integral entries and determinant $c\bar{c}_0 + cc_0 = c$, a unit ($c_0 + \bar{c}_0 = 1$ by (WD1)), so its inverse $c^{-1} \left(\begin{smallmatrix} c\bar{c}_0 & c \\ -c_0 & 1 \end{smallmatrix}\right)$ is integral. Reindexing rows permutes the entries, so the splitting is base-adapted. □

Lemma 6.3.64. *Let W, W_1 be spaces with points with signs s on n and V, V_1 spaces with points with signs t on a. Let $\gamma \in \mathrm{GL}_n(E)$, $k \in \mathrm{G}(s)$, $\gamma' \in \mathrm{GL}_a(E)$, $k' \in \mathrm{G}(t)$ with $x_W = \gamma^{-1} x_{W_1} k$ and $x_V = \gamma'^{-1} x_{V_1} k'$. There is $z \in \mathbb{C}$ with $|z| = 1$ such that for all automorphic characters α, β of $\mathrm{U}(1)$, all $\varphi \in \mathcal{M}_{W,V} = \mathcal{M}_{W_1,V_1}$, $g \in \mathrm{G}(s)$ and $h \in \mathrm{G}(t)$, with $u = z\,\beta(\det k)\,\alpha(\det k')^{-1}$,*

$$\theta^{W,V}_{\alpha,\beta}(\varphi)(g,h) = u\,\theta^{W_1,V_1}_{\alpha,\beta}(\varphi)(kg, k'h);$$

moreover $h \mapsto \theta^{W,V}_{\alpha,\beta}(\varphi)(g,h)$ is integrable on $[\mathrm{U}(V)]$ if and only if $h \mapsto \theta^{W_1,V_1}_{\alpha,\beta}(\varphi)(kg,h)$ is integrable on $[\mathrm{U}(V_1)]$, and then $I^{W,V}_{\alpha,\beta}(\varphi)(g) = u\, I^{W_1,V_1}_{\alpha,\beta}(\varphi)(kg)$.

Proof. Write $H = \mathrm{Hom}(W,V)$, $H_1 = \mathrm{Hom}(W_1,V_1)$ (signs $t \otimes s$ on $a \times n$, the same model $\mathcal{M}$), $N = a \times n$, and $P = k' \otimes (k^{-1})^{\mathsf{T}} \in \mathrm{G}(t \otimes s)$, the image of (k,k') under the pair map.

Rational vectors. The points are $x_H = x_V \otimes (x_W^{-1})^{\mathsf{T}}$ and $x_{H_1} = x_{V_1} \otimes (x_{W_1}^{-1})^{\mathsf{T}}$, and $(x_W^{-1})^{\mathsf{T}} = (k^{-1} x_{W_1}^{-1} \gamma)^{\mathsf{T}}$, so

$$x_H = (\gamma'^{-1} \otimes \gamma^{\mathsf{T}})\, x_{H_1}\, P.$$

As $\gamma'^{-1} \otimes \gamma^{\mathsf{T}} \in \mathrm{GL}_N(E)$ permutes E^N, the rational vectors satisfy $H(E) = \{x_H^{-1} u : u \in E^N\} = P^{-1} H_1(E)$.

Comparison of the theta functionals. Let $\theta' = \theta_{H_1} \circ \omega_{t\otimes s}(P)$. By (2) of Lemma 4.1.1, $\omega_{t\otimes s}(P)$ is a bounded operator of $\mathcal{M}$ preserving the inner product, so $\langle \omega_{t\otimes s}(P) v^0, \omega_{t\otimes s}(P) v^0 \rangle = \langle v^0, v^0 \rangle = 1$ ((1) of Lemma 4.1.10), and $\omega_{t\otimes s}(P) \rho(y) = \rho(Py)\, \omega_{t\otimes s}(P)$ for $y \in \mathbb{A}_E^N$; and $x \mapsto Px$ is an additive homeomorphism of $\mathbb{A}_E^N$ carrying $H(E)$ onto $H_1(E)$. By (3) of Lemma 6.3.65 for $V = H$, $V' = H_1$, $\tau = P$ and $\Pi = \omega_{t\otimes s}(P)$, there is z_1 with $|z_1| = 1$ and $\theta' = z_1 \theta_H$; so $\theta_H = z\,\theta'$ with $z = z_1^{-1}$, $|z| = 1$.

Kernels. By (WR4), $\omega_{\alpha,\beta}(g,h) = \alpha(\det h)\beta(\det g)^{-1}\omega_{t\otimes s}(h\otimes(g^{-1})^{\mathsf{T}})$, and $P\,(h\otimes(g^{-1})^{\mathsf{T}}) = k'h\otimes((kg)^{-1})^{\mathsf{T}}$. Hence

$$\theta^{W,V}_{\alpha,\beta}(\varphi)(g,h) = z\,\alpha(\det h)\beta(\det g)^{-1}\theta_{H_1}\big(\omega_{t\otimes s}(k'h\otimes((kg)^{-1})^{\mathsf{T}})\varphi\big) = z\,\frac{\beta(\det k)}{\alpha(\det k')}\,\theta^{W_1,V_1}_{\alpha,\beta}(\varphi)(kg,k'h).$$

Integrals. By (1) of Lemma 6.3.63, for the pair (γ',k') (it qualifies: $J_V = (x_V^{-1})^*\varepsilon_t x_V^{-1} = \gamma'^*(x_{V_1}^{-1})^*(k'^{-1})^*\varepsilon_t k'^{-1}x_{V_1}^{-1}\gamma' = \gamma'^* J_{V_1}\gamma'$ as $k'\in \mathrm{G}(t)$), $\Gamma_V = k'^{-1}\Gamma_{V_1}k'$. Left translation by k' preserves the measure of $\mathrm{G}(t)$ and carries Γ_V-orbits to Γ_{V_1}-orbits, so $\Gamma_V h\mapsto \Gamma_{V_1}k'h$ carries the quotient measure of $[\mathrm{U}(V)]$ to that of $[\mathrm{U}(V_1)]$. With the identity of the kernels, $|u|=1$, this gives the equivalence of integrability and the identity of the theta integrals. □

Lemma 6.3.65. *Let ι, ι' be index sets with $\#\iota = \#\iota' = N$, ε signs on ι and ε' signs on ι', $W = \mathbb{A}_E^{\iota}$ and $W' = \mathbb{A}_E^{\iota'}$.*

1. *Let $\sigma\colon W\to W'$ be an additive homeomorphism with*

$$\beta_{\varepsilon'}(\sigma x,\sigma y) = \beta_\varepsilon(x,y),\qquad e_N(\sigma x) = e_N(x)\qquad (x,y\in W),\qquad \sigma_*\mu_N = \mu_N.$$

   Then $\Pi f = f\circ\sigma^{-1}$ defines a linear bijection $\Pi\colon \mathcal{M}_\varepsilon\to\mathcal{M}_{\varepsilon'}$ that preserves the norm and the inner product, with $\Pi v^0 = v^0$ and $\Pi\rho(y) = \rho(\sigma y)\Pi$ for $y\in W$.

2. *In (1), let moreover $k\in\mathrm{G}(\varepsilon)$ and $k'\in\mathrm{G}(\varepsilon')$ satisfy $\sigma(kx) = k'\sigma(x)$ for all $x\in W$. Then*

$$\Pi\,\omega_\varepsilon(k) = \frac{\Delta_\varepsilon(k)}{\Delta_{\varepsilon'}(k')}\,\omega_{\varepsilon'}(k')\,\Pi.$$

3. *Let V, V' be spaces with points with signs ε and ε', $\tau\colon W\to W'$ an additive homeomorphism with $\tau(V(E)) = V'(E)$, and $\Pi\colon\mathcal{M}_\varepsilon\to\mathcal{M}_{\varepsilon'}$ a bounded linear map with $\langle\Pi v^0,\Pi v^0\rangle = 1$ and $\Pi\rho(y) = \rho(\tau y)\Pi$ for $y\in W$. Then $\theta'\circ\Pi$ is a theta functional of V for every theta functional θ' of V', and there is $z\in\mathbb{C}$ with $|z|=1$ such that $\theta_{V'}(\Pi f) = z\,\theta_V(f)$ for all $f\in\mathcal{M}_\varepsilon$.*

4. *Let δ be signs on ι and $k\in\mathrm{G}(\delta)$. Then $(k^{-1})^{\mathsf{T}}\in\mathrm{G}(-\delta)$ and*

$$\Delta_{-\delta}\big((k^{-1})^{\mathsf{T}}\big) = \upsilon(\det k)\,\Delta_\delta(k).$$

Proof. **(1).** Let $f\in\mathcal{M}_\varepsilon$. As σ is a homeomorphism, Πf is measurable, and $\sigma_*\mu_N = \mu_N$ gives $\int|\Pi f|\,d\mu_N = \int|f|\,d\mu_N$ and $\int\overline{\Pi f}\,\Pi g\,d\mu_N = \int\bar f g\,d\mu_N$ for $f,g\in\mathcal{M}_\varepsilon$. For $x'\in W'$, the reproducing identity of (WD7) at $\sigma^{-1}x'$, the substitution $y=\sigma^{-1}y'$ (which preserves μ_N) and the two identities of the hypothesis, applied to $\sigma^{-1}y'$, $\sigma^{-1}x'$ and to $\sigma^{-1}x'-\sigma^{-1}y' = \sigma^{-1}(x'-y')$ (additivity), give

$$(\Pi f)(x') = \int f(y)\,\beta_\varepsilon(y,\sigma^{-1}x')\,e_N(\sigma^{-1}x'-y)\,d\mu_N(y) = \int(\Pi f)(y')\,\beta_{\varepsilon'}(y',x')\,e_N(x'-y')\,d\mu_N(y'),$$

so $\Pi f\in\mathcal{M}_{\varepsilon'}$. The map $\sigma^{-1}\colon W'\to W$ is an additive homeomorphism satisfying the same three hypotheses with the roles of ε and ε' exchanged (apply them to $\sigma^{-1}x'$, $\sigma^{-1}y'$; and $(\sigma^{-1})_*\mu_N = \mu_N$), so $f'\mapsto f'\circ\sigma$ maps $\mathcal{M}_{\varepsilon'}$ into $\mathcal{M}_\varepsilon$; it is inverse to Π, and Π is a linear bijection preserving norm and inner product. Next, $\Pi v^0 = e_N\circ\sigma^{-1} = e_N = v^0$. Finally, for $y\in W$,

$$(\Pi\rho(y)f)(x') = \beta_\varepsilon(y,\sigma^{-1}x')\,f(\sigma^{-1}x'-y) = \beta_{\varepsilon'}(\sigma y,x')\,(\Pi f)(x'-\sigma y) = (\rho(\sigma y)\Pi f)(x').$$

(2). By (2) of Lemma 6.2.13, $\Delta_{\varepsilon'}(k') \neq 0$. For $f \in \mathcal{M}_\varepsilon$ and $x' \in W'$, (WR3), the substitution $y = \sigma^{-1}y'$, the identity $k\sigma^{-1}y' = \sigma^{-1}(k'y')$ (from $\sigma(kx) = k'\sigma(x)$ with $x = \sigma^{-1}y'$) and the hypotheses of (1) give

$$\begin{aligned}(\Pi\omega_\varepsilon(k)f)(x') &= \Delta_\varepsilon(k)\int(\Pi f)(y')\,\beta_\varepsilon(\sigma^{-1}(k'y'),\sigma^{-1}x')\,e_N(\sigma^{-1}(x'-k'y'))\,d\mu_N(y')\\ &= \Delta_\varepsilon(k)\int(\Pi f)(y')\,\beta_{\varepsilon'}(k'y',x')\,e_N(x'-k'y')\,d\mu_N(y'),\end{aligned}$$

which is $\Delta_\varepsilon(k)\Delta_{\varepsilon'}(k')^{-1}(\omega_{\varepsilon'}(k')\Pi f)(x')$ by (WR3).

(3). Let θ' be a theta functional of V' and $\theta'' = \theta' \circ \Pi$, a bounded linear functional on $\mathcal{M}_\varepsilon$. For $\gamma \in V(E)$, $\tau\gamma \in V'(E)$, so $\theta''(\rho(\gamma)f) = \theta'(\rho(\tau\gamma)\Pi f) = \theta''(f)$. The quotients $W/V(E)$ and $W'/V'(E)$ are compact (Lemma 4.1.10, (2)). As τ is additive, bijective and $\tau(V(E)) = V'(E)$ (so $\tau^{-1}(V'(E)) = V(E)$), it induces a continuous bijective homomorphism $\bar\tau\colon W/V(E) \to W'/V'(E)$; a continuous bijection of a compact space onto a Hausdorff space is a homeomorphism, and the image under $\bar\tau$ of the invariant probability measure of $W/V(E)$ is an invariant probability measure of $W'/V'(E)$, hence its invariant probability measure. With $\Pi\rho(x)v^0 = \rho(\tau x)\Pi v^0$ and (2) of Lemma 4.1.10 for θ' and $u = v = \Pi v^0$,

$$\begin{aligned}\int_{W/V(E)}\left|\theta''(\rho(x)v^0)\right|^2 dx &= \int_{W/V(E)}\left|\theta'(\rho(\tau x)\Pi v^0)\right|^2 dx\\ &= \int_{W'/V'(E)}\left|\theta'(\rho(y)\Pi v^0)\right|^2 dy = \langle \Pi v^0, \Pi v^0\rangle = 1.\end{aligned}$$

So θ'' is a theta functional of V (WD9). By Lemma 4.1.17, $\theta_{V'}$ is a theta functional of V' and θ_V one of V; so $\theta_{V'} \circ \Pi$ and θ_V are theta functionals of V, and by Lemma 4.1.7 they differ by a scalar z of absolute value one.

(4). Write $k^{-\mathsf{T}} = (k^{-1})^{\mathsf{T}}$, $I_- = \{i \in \iota : \delta_i = -1\}$ and $I_+ = \iota \smallsetminus I_-$. *Membership.* As $\varepsilon_{-\delta} = -\varepsilon_\delta$ at the infinite places and 1 at the finite places, $\mathrm{G}(-\delta) = \mathrm{G}(\delta)$. At $v \in \Phi$, with $D = \mathrm{diag}(\delta)$ ($D = D^{-1}$ real), $k_v^* D k_v = D$ gives $k_v^{-1}D(k_v^{-1})^* = D$, and conjugating entrywise, $\overline{k_v^{-1}}\,D\,(k_v^{-1})^{\mathsf{T}} = D$, that is $(k_v^{-\mathsf{T}})^* D k_v^{-\mathsf{T}} = D$. At the finite places $k_f^* k_f = 1$ gives $k_f^{-\mathsf{T}} = \overline{k_f}$ and $\overline{k_f}^{\,*}\,\overline{k_f} = \overline{k_f^* k_f} = 1$. So $k^{-\mathsf{T}} \in \mathrm{G}(\delta) = \mathrm{G}(-\delta)$.

Infinite places. The indices of sign -1 for $-\delta$ are those of I_+. By Jacobi's theorem on the complementary minors of an inverse matrix, $\det((k_v^{-1})_{I_+}) = \det((k_v)_{I_-})/\det k_v$ (a determinant over the empty set being 1), and $(k_v^{-\mathsf{T}})_{I_+} = \big((k_v^{-1})_{I_+}\big)^{\mathsf{T}}$ has the same determinant. As $|\det k_v| = 1$ ($k_v^* D k_v = D$), $\overline{\det(k_v)}^{-1} = \det k_v$, so

$$\prod_{v\in\Phi}\overline{\det\big((k_v^{-\mathsf{T}})_{I_+}\big)} = \prod_{v\in\Phi}\det k_v \cdot \prod_{v\in\Phi}\overline{\det\big((k_v)_{I_-}\big)}:$$

the archimedean factor of $\Delta_{-\delta}(k^{-\mathsf{T}})$ is $\prod_v \det k_v$ times that of $\Delta_\delta(k)$ (WR3).

Finite places. Let $L = \widehat{\mathcal{O}}_E^{\,\iota}$ and $u \in \mathrm{GL}_N(\mathbb{A}_{E,f})$ with $uL = L \cap k_f^{-1}L$. Conjugation is a ring automorphism of $\mathbb{A}_{E,f}$ preserving $\widehat{\mathcal{O}}_E$, so $\bar u L = L \cap \overline{k_f}^{-1}L$, and $\bar u$ is an admissible choice in (WR3) for $k_f^{-\mathsf{T}} = \overline{k_f}$. Conjugation permutes the finite places, carrying the place w to $\bar w$ of the same norm, so $|\det\bar u| = |\det u|$; and $\upsilon(\bar x) = \upsilon(x)^{-1} = \overline{\upsilon(x)}$ (WD3). Hence the finite factor of $\Delta_{-\delta}(k^{-\mathsf{T}})$ is $\overline{\Delta(k_f)}$, where $\Delta(k_f) = \upsilon_f(\det u)|\det u|^{-1/2}$ is the finite factor of $\Delta_\delta(k)$ and $\upsilon_f(y) = \upsilon((1,y))$ ($(1,y)$ the idele with infinite components 1). This Δ is the one of Lemma 4.1.13 for $\jmath = \jmath$, the Weil idele α and υ_f, whose hypotheses hold: $\bar\jmath = -\jmath$ and $c_0 \in \mathcal{O}_E$ by (WD1), $\widehat{\mathcal{O}}_E$ is self-dual for $(z,w) \mapsto \psi_{E,f}(\jmath\alpha\bar\alpha\bar z w)$ by Lemma 4.1.3, and υ_f is continuous, of absolute value

1, trivial on $\widehat{\mathcal{O}}_E^\times$ and satisfies $\upsilon_f(\bar t) = \upsilon_f(t)^{-1}$ by (WD3). As $k_f^* k_f = 1$, Lemma 4.1.13 gives $\overline{\Delta(k_f)} = \upsilon_f(\det k_f)\,\Delta(k_f)$.

Conclusion. The idele $\det k$ is the product of $((\det k_v)_v, 1)$, whose finite components are units, and of $(1, \det k_f)$; by (WD3), $\upsilon(\det k) = \prod_v \det k_v \cdot \upsilon_f(\det k_f)$, as $|\det k_v| = 1$. Multiplying the two factors, $\Delta_{-\delta}(k^{-\mathsf T}) = \upsilon(\det k)\,\Delta_\delta(k)$. □

Lemma 6.3.66. *Call a decomposition $Y = W \oplus \mathbb{H}$ of a space Y, with $\mathbb{H}$ spanned by isotropic vectors l, l' with $\langle l, l'\rangle = 1$,* adapted *if the frames are orthonormal at the infinite places and integral at the finite places. Let $\mu\colon \Phi \to \mathbb{Z}_{>0}$; ν runs over the characters tame of weight μ for some $(\mathfrak m, \chi)$.*

1. *Let $Y = W \oplus \mathbb{H}$ be adapted with $\operatorname{rk} W$ even. For every Schwartz vector v for (W, W) there are a Schwartz vector v' for (Y, Y) and $C > 0$ with $r_Y(\nu, v') = C\, r_W(\nu, v)$ for all ν.*
2. *Let $Y = W \oplus \mathbb{H}$ be adapted with $\operatorname{rk} Y$ even, and let Y_1 be a space with the signs of Y. Then $r_{Y_1}(\nu, v) = r_Y(\nu, v)$ for every Schwartz vector v for (Y, Y) and all ν.*
3. *For every space W_1 and every sign vector s' of length $\operatorname{rk} W_1 + 2$ with $\operatorname{neg}(s') = \operatorname{neg}(W_1) + 1$ there are a space Y with signs s' and an adapted decomposition $Y = W_1 \oplus \mathbb{H}$.*

Proof. **Step 0: the equal-rank integrals as large sides.** An adapted decomposition $Y = W \oplus \mathbb{H}$ is a base-adapted splitting (k, l, i) of Y over W along a one-element set: $\mathbb{H}$ is spanned by the isotropic vectors l, k with $l^* J_Y k = 1$, and the frames are orthonormal at the infinite and integral at the finite places. Let ν be tame of weight μ for $(\mathfrak m, \chi)$; then $\mathfrak c = (\nu, \Sigma(\mathfrak m))$ is a split tame character of weight μ ($\Sigma(\mathfrak m)$ contains the conjugate of none of its places, $\mu > 0$). For $u \in \mathcal{O}_\Sigma^\times$ the component of $u/\bar u$ at $\bar w$ ($w \in \Sigma$) is the inverse of the conjugate of u_w, and $\psi_{\bar w} = 1$, so by the definition of the tame part (Definition 3.1.2) $\chi_{\mathfrak c}(u) = \nu(u/\bar u) = \prod_{w\in\Sigma} \psi_w(u_w \bmod w) = \chi(u \bmod \mathfrak m)$; hence Φ_χ of (XD8) is the standard column datum Ψ_1^{st} of (XD10), and, for every space Z of even rank, $I_Z(v) = \theta_{\mathfrak c}^{\mathrm{lg}}(Z, Z; v, \Psi_1^{\mathrm{st}})$ (both with the character $\nu^{-1}\upsilon^{\operatorname{rk} Z/2}$). For the empty index set $\varnothing$ and the identity $\sigma_Z\colon \varnothing \sqcup n_Z \to n_Z$ of the index set of Z, the standard row datum at the empty matrix is $\Phi^{\mathrm{st}}_{\sigma_Z, 0} = \Psi_1^{\mathrm{st}}$.

(1) Let n, n' be the index sets of W, Y, $\#n = 2d$, $\#n' = 2d+2$, and A the splitting. By Proposition 6.2.2 for $W' = V' = Y$, $W = V = W$, the splittings $A = X = A$, the index set $\varnothing$ with σ_W, σ_Y and the weight μ ($\#n$ even; $e = 2d - d = d \geq 0$, $z_e = d+1$, the sign $+$; the ranks of V and W agree), there is $C_1 > 0$ such that every split tame character $\mathfrak c$ of weight μ has $\gamma_{\mathfrak c}$ with $|\gamma_{\mathfrak c}| = C_1 L_{\mathfrak c}^\sharp(d+1)$ and $\mathrm{CT}^{\mathrm{pl}}_{A,\sigma_Y}(v', 0)(1,1) = \gamma_{\mathfrak c}\theta_{\mathfrak c}^{\mathrm{lg}}(W, W; \mathrm{Cone}^+_{A,A,\mu}(d+1; v'), \Psi_1^{\mathrm{st}})(1)$ for every Schwartz vector v' for (Y, Y). By Lemma 6.3.55 (normalised form, $z = d+1 > 0$, the index set $\varnothing$, σ_W) there is a Schwartz vector v' for (Y, Y) with $\theta_{\mathfrak c}^{\mathrm{lg}}(W, W; \mathrm{Cone}^+_{A,A,\mu}(d+1; v'), \Psi_1^{\mathrm{st}}) = \theta_{\mathfrak c}^{\mathrm{lg}}(W, W; v, \Psi_1^{\mathrm{st}})$ for all $\mathfrak c$. By Proposition 6.3.17 (Y has even rank and the base-adapted splitting A) the function $F_{\mathfrak c} = \theta_{\mathfrak c}^{\mathrm{lg}}(Y, Y; v', \Psi_1^{\mathrm{st}})$ is constant; the plane datum at the empty matrix is formed with Ψ_1^{st}, so $\mathrm{CT}^{\mathrm{pl}}_{A,\sigma_Y}(v', 0)(1,1)$, the mean of $F_{\mathfrak c}$ over a compact quotient with its probability measure, is $F_{\mathfrak c}(1)$. Hence $I_Y(v')(1) = \gamma_{\mathfrak c} I_W(v)(1)$ by Step 0, and $|I_Y(v')(1)|^2 = C_1^2 L_{\mathfrak c}^\sharp(d+1)^2 |I_W(v)(1)|^2$. With $S = \Sigma(\mathfrak m)$,

$$\frac{L_*(S, \nu; d+1)}{L_*(S, \nu; d)} = \Big(\prod_{w\in S} \mathrm{N}w\Big)^{(d+1)^2 - d^2} \big|L^S(d+1, \tilde\nu)\big|^2 = \big|L^S(d+1, \tilde\nu)\big|^2 \prod_{w\in S} (\mathrm{N}w)^{2(d+1)-1} = L_{\mathfrak c}^\sharp(d+1)^2,$$

so $r_Y(\nu, v') = C_1^2 L_{\mathfrak c}^\sharp(d+1)^2 |I_W(v)(1)|^2 / L_*(S, \nu; d+1) = C_1^2\, r_W(\nu, v)$, and $C = C_1^2 > 0$ does not depend on ν.

(2) Let ν and $\mathfrak{c}$ be as in Step 0. By (1) of Lemma 6.3.63 there are γ_0 and k with $x_{Y_1} = \gamma_0^{-1} x_Y k$; by Lemma 6.3.64, applied with $(W,V) = (Y_1, Y_1)$, $(W_1, V_1) = (Y, Y)$ and the pair (γ_0, k) on both sides, the integral defining $I_{Y_1}(v)(1)$ converges exactly when that defining $I_Y(v)(k)$ does, and then $I_{Y_1}(v)(1) = u\, I_Y(v)(k)$ with $|u| = 1$. By Proposition 6.3.17 (Y has even rank and the base-adapted splitting $Y = W \oplus \mathbb{H}$, Step 0), $I_Y(v)(k) = I_Y(v)(1)$. So $|I_{Y_1}(v)(1)| = |I_Y(v)(1)|$ and $r_{Y_1}(\nu, v) = r_Y(\nu, v)$.

(3) This is (2) of Lemma 6.3.63 for a one-element index set p: a splitting (k, l, i) of Y over W_1 along p is a decomposition $Y = iW_1 \oplus \mathbb{H}$ with $\mathbb{H}$ spanned by the isotropic vectors l, k, $l^* J_Y k = 1$, and base-adapted means adapted. □

Proposition 6.3.67. *Let n, m, l, b, p, a be finite index sets with bijections $j\colon m \sqcup l \to n$, $f\colon p \sqcup l \to b$, $e\colon p \sqcup a \to m$, $\sigma\colon b \sqcup a \to n$. Let W be a space with index set n and signs sgn_j, V' a space with index set b and signs sgn_f, and I_a the standard definite space. Let $d \geq 0$ with $|a| = |b| + 2d$, assume $2|l| + 2 \leq |n|$, and let $\iota = (\iota_\tau)_{\tau \in \Phi}$ be finite sets. Then there is $C \in \mathbb{R}$ (possibly 0) with the following property. For every modulus $\mathfrak{m}$, every character χ of $R_{\mathfrak{m}}$ and every automorphic character α of $\mathrm{U}(1)$ tame of weight $\tau \mapsto |l| - |\iota_\tau|$ for $(\mathfrak{m}, \chi)$ there is $c \in \mathbb{C}$ with*

$$L_*(\mathfrak{m}, \alpha^{-1} \upsilon^{|b|+d}; d) \neq 0, \qquad L_*(\mathfrak{m}, \alpha^{-1} \upsilon^{|b|+d}; d)\, |c|^2 = C,$$

such that for every family $\eta = (\eta_{\tau k})_{\tau \in \Phi,\, k \in \iota_\tau}$ of complex $p \times m$ matrices, all Φ, Ψ matched for (σ, χ^{-1}) modulo $\mathfrak{m}$, every automorphic character β of $\mathrm{U}(1)$ and every $g \in \mathrm{U}(W)(\mathbb{A}_F)$,

$$c \cdot \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} \theta^{W, I_a}_{\alpha, \beta; \mathfrak{m}}[\Phi, \Delta^j(e; \eta)](g, h) = \int_{[\mathrm{U}(V')]} \theta^{V', W}_{\alpha/\beta,\, \alpha; \mathfrak{m}}[\Psi, Q_{f,j}(\eta)](x, g)\, dx.$$

Proof. The set a is nonempty: otherwise $|b| = |a| - 2d \leq 0$, so $b = \emptyset$, $d = 0$ and $|n| = |a| + |b| = 0 < 2|l| + 2$. Let $c_a > 0$ be the total mass of the measure of $G_\infty(s_a^+)$.

Step 1: the archimedean matching. Write $\gamma_0(\tau) = |l| - |\iota_\tau|$, $\mathcal{H}_1 = \mathcal{F}_{W, I_a}$ for the Fock model of the pair (W, I_a), $\omega^\infty = \Omega_{\gamma_0, 0}$ for its real Weil representation of $G_\infty(\mathrm{sgn}_j) \times G_\infty(s_a^+)$, and v_P for the Fock vector of a polynomial P in either pair. By Lemma 6.3.68, for the index sets, the bijections j, f, e, the spaces W, V' and the sets ι of the statement, there is $Q_0 \in \mathbb{C}[x]_{n \times b}$ such that every $v \in \mathcal{H}_1$ has a number $\varkappa(v)$ with: for every family $(\lambda_{g'})_{g' \in G_\infty(\mathrm{sgn}_j)}$ of continuous linear forms on $\mathcal{H}_1$ and every linear form λ' on $\mathbb{C}[x]_{n \times b}$ such that (H1) $\lambda_{g'}(\omega^\infty(x_1, x_2) w) = \lambda_{g' x_1}(w)$ for all $g', x_1 \in G_\infty(\mathrm{sgn}_j)$, $x_2 \in G_\infty(s_a^+)$ and $w \in \mathcal{H}_1$, and (H2) $\lambda_x(v) = \lambda'(Q)$ whenever $\Omega_{\gamma_0, 0}(1, x) v_{Q_0} = v_Q$ in the Fock model $\mathcal{F}_{V', W}$ of the pair (V', W), one has $\varkappa(v)\, \lambda_1(v_{\Delta^j(e;\eta)}) = \lambda'(Q_{f,j}(\eta))$ for every η.

Step 2: the exchange identity and the constant. Apply Theorem 6.3.2 to W, $V = I_a$, V', σ, $e = d$, the weight $\mu(\tau) = |\iota_\tau| - |l| + |b| + d$ and the Schwartz vector v_{Q_0} ((XD3): Fock vectors of polynomials are Schwartz vectors). Its hypotheses hold:

It gives $C_0 > 0$ and a Schwartz vector x_0 for (W, I_a). Put $C = c_a^2 |\varkappa(x_0)|^2 / C_0$.

Let $\mathfrak{m}, \chi, \alpha$ be as in the statement and $\nu = \alpha^{-1} \upsilon^{|b|+d}$; it is tame of weight μ for $(\mathfrak{m}, \chi^{-1})$, and $\nu^{-1} \upsilon^{|n|/2} = \alpha$ because $|n| = |a| + |b| = 2(|b| + d)$. Indeed, by (WD3) of Definition 3.2.12, υ restricted to $\mathrm{U}(1)(\mathbb{A})$ has weight 1 and trivial tame part; if α has the tame part ψ ($\psi_w \neq 1$ exactly for $w \in \Sigma(\mathfrak{m})$, and $\chi(u) = \prod_w \psi_w(u \bmod w)$ on units), then ν has weight $-\gamma_0 + |b| + d = \mu$ and tame part ψ^{-1}, which gives χ^{-1} on units. Moreover the pair of characters $(1, \alpha)$ on (I_a, V') satisfies the compatibility $1[|a|]\, \alpha[|b|] = \tilde{\nu}^{-1}$ of Theorem 6.3.2: the base change of υ on $\mathrm{U}(1)(\mathbb{A})$ is $x \mapsto \upsilon(x/\bar{x}) = \upsilon(x)^2$, as $\upsilon(\bar{x}) = \upsilon(x)^{-1}$ (WD3), so $\tilde{\nu}^{-1} = \tilde{\alpha}\, \upsilon^{-2(|b|+d)}$, while

$1[|a|]\,\alpha[|b|] = \upsilon^{-|a|}\tilde{\alpha}\,\upsilon^{-|b|} = \tilde{\alpha}\,\upsilon^{-2(|b|+d)}$ since $|a|+|b| = 2(|b|+d)$. Theorem 6.3.2 gives c_0 with $|c_0|^2 = C_0 L_*(\mathfrak{m},\nu;d) \neq 0$ and, for all Φ,Ψ matched for (σ,χ^{-1}) and all $g' \in \mathrm{U}(W)(\mathbb{A}_F)$,

$$I_{\alpha,1}^{W,I_a}\big(\mathrm{mod}_{\mathfrak{m}}(\Phi,x_0)\big)(g') = c_0 \int_{[\mathrm{U}(V')]} \theta_{\alpha,\alpha;\mathfrak{m}}^{V',W}[\Psi,Q_0](x,g')\,dx. \tag{6.52}$$

Put $c = c_a\varkappa(x_0)/c_0$. As $C_0 > 0$ and $|c_0|^2 \neq 0$, $L_*(\mathfrak{m},\nu;d) \neq 0$, and $L_*(\mathfrak{m},\nu;d)\,|c|^2 = c_a^2|\varkappa(x_0)|^2 L_*(\mathfrak{m},\nu;d)/(C_0 L_*(\mathfrak{m},\nu;d)) = C$, with $\nu = \alpha^{-1}\upsilon^{|b|+d}$.

Step 3: the identity for $\beta = 1$. Fix η, matched Φ,Ψ and g. For $g' \in G_\infty(\mathrm{sgn}_j)$ write $(g',1)$ for the adelic point with infinite component g' and finite component 1, and for $w \in \mathcal{H}_1$ and $Q \in \mathbb{C}[x]_{n\times b}$ let

$$\lambda_{g'}(w) = I_{\alpha,1}^{W,I_a}\big(\mathrm{mod}_{\mathfrak{m}}(\Phi,w)\big)\big(g(g',1)\big), \qquad \lambda'(Q) = c_0\int_{[\mathrm{U}(V')]} \theta_{\alpha,\alpha;\mathfrak{m}}^{V',W}[\Psi,Q](x,g)\,dx.$$

(a) *The forms.* By (3) of Lemma 6.3.71 for the pair (W,I_a) ($a \neq \emptyset$) and the characters α, 1 of weights γ_0, 0, each $\lambda_{g'}$ is a continuous linear form on $\mathcal{H}_1$, and $\lambda_{g'}(\omega^\infty(x_1,x_2)w) = \lambda_{g'x_1}(w)$, because $g(g',1)(x_1,1) = g(g'x_1,1)$; this is (H1). The function Ψ vanishes off the matrices k_b formed by the columns b of some $k \in \mathrm{GL}_n(R_{\mathfrak{m}})$, and k_b has the left inverse formed by the rows b of k^{-1}; so by (2) of Lemma 6.3.71 for the pair (V',W) the integral defining $\lambda'(Q)$ converges absolutely and λ' is a linear form on $\mathbb{C}[x]_{n\times b}$.

(b) *(H2) for $v = x_0$.* Let $g' \in G_\infty(\mathrm{sgn}_j)$ and Q with $\Omega_{\gamma_0,0}(1,g')v_{Q_0} = v_Q$. The characters α,α of the pair (V',W) have weights γ_0,γ_0, and $\Omega_{\gamma_0,\gamma_0}(1,g') = \Omega_{\gamma_0,0}(1,g')$, the factor $\prod_v \det(x_v)^{-\gamma'(v)}$ of (WR5) being 1 at $x = 1$. So (1) of Lemma 6.3.71 for (V',W) gives $\theta_{\alpha,\alpha;\mathfrak{m}}^{V',W}[\Psi,Q_0](x,g(g',1)) = \theta_{\alpha,\alpha;\mathfrak{m}}^{V',W}[\Psi,Q](x,g)$ for every x, and (6.52) at the point $g(g',1)$ gives $\lambda_{g'}(x_0) = \lambda'(Q)$.

(c) *The class sum.* By (5) of Lemma 6.3.71 (W has the signs sgn_j and $\gamma_0(\tau) = |l| - |\iota_\tau|$), $\Omega_{\gamma_0,0}(1,y)v_{\Delta^j(e;\eta)} = v_{\Delta^j(e;\eta)}$ for all $y \in G_\infty(s_a^+)$. For $u \in \mathrm{GL}_a(R_{\mathfrak{m}})$ let $D_u \in \mathrm{GL}_n(R_{\mathfrak{m}})$ act as the identity on the basis vectors $\sigma(b)$ and as u on $\sigma(a)$. For $k \in \mathrm{GL}_n(R_{\mathfrak{m}})$, the columns b of kD_u are those of k, the rows a of $(kD_u)^{-1} = D_u^{-1}k^{-1}$ form $u^{-1}(k^{-1})_a$, and $\det(kD_u) = \det k\det u$; so, Φ and Ψ being matched for (σ,χ^{-1}), $\Phi(u^{-1}(k^{-1})_a) = \chi(\det k\det u)^{-1}\Psi(k_b) = \chi(\det u)^{-1}\Phi((k^{-1})_a)$, while for X not of the form $(k^{-1})_a$ neither is $u^{-1}X$ (as $X = u\,(k'^{-1})_a = ((k'D_u^{-1})^{-1})_a$ otherwise), and both values are 0. Hence $\Phi(u^{-1}X) = \chi(\det u)^{-1}\Phi(X)$ for all X. For $k \in \mathbf{K}_a$ the determinant $\det k \in \mathrm{U}(1)(\mathbb{A})$ has integral finite components and infinite components 1, so $\alpha(\det k) = \prod_w \psi_w(\det k \bmod w) = \chi(\det \bar{k})$ (Definition 3.1.1 and (XD4)), $\bar{k}$ the reduction modulo $\mathfrak{m}$; taking $u = \bar{k}$, $\alpha(\det k)\Phi(\bar{k}^{-1}X) = \Phi(X)$. So (4) of Lemma 6.3.71 applies to $P = \Delta^j(e;\eta)$ and gives

$$\lambda_1(v_{\Delta^j(e;\eta)}) = I_{\alpha,1}^{W,I_a}\big(\mathrm{mod}_{\mathfrak{m}}(\Phi,v_{\Delta^j(e;\eta)})\big)(g) = c_a \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} \theta_{\alpha,1;\mathfrak{m}}^{W,I_a}\big[\Phi,\Delta^j(e;\eta)\big](g,h).$$

(d) *Conclusion.* By (a) and (b), Step 1 applies to $v = x_0$ and gives $\varkappa(x_0)\lambda_1(v_{\Delta^j(e;\eta)}) = \lambda'(Q_{f,j}(\eta))$. Inserting (c) and dividing by $c_0 \neq 0$,

$$c \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} \theta_{\alpha,1;\mathfrak{m}}^{W,I_a}\big[\Phi,\Delta^j(e;\eta)\big](g,h) = \int_{[\mathrm{U}(V')]} \theta_{\alpha,\alpha;\mathfrak{m}}^{V',W}\big[\Psi,Q_{f,j}(\eta)\big](x,g)\,dx.$$

Step 4: the character β. By (XD2) of Definition 3.2.22, (g,h) acts on the datum by $\alpha(\det h)\beta(\det g)^{-1}$ times the Weil operator, and the theta functional is linear; hence

$$\theta_{\alpha\varrho,\beta\varrho'}^{S,T}(\varphi)(g,h) = \varrho(\det h)\varrho'(\det g)^{-1}\theta_{\alpha,\beta}^{S,T}(\varphi)(g,h)$$

for automorphic characters ϱ, ϱ' of U(1) ((WR4) of Definition 3.2.18). So replacing the second character 1 on the left (it twists U(W)) by β, and the first character α on the right (it twists U(W) there) by α/β, multiplies both sides by $\beta(\det g)^{-1}$. This gives the statement. □

Lemma 6.3.68. *Let n, m, l, b, p, a be finite index sets with bijections $j\colon m \sqcup l \to n$, $f\colon p \sqcup l \to b$, $e\colon p \sqcup a \to m$; let W be a space with signs sgn_j on n and V' a space with signs sgn_f on b; let $\iota = (\iota_\tau)_{\tau\in\Phi}$ be finite sets and $\gamma_0(\tau) = \#l - \#\iota_\tau$. Then there is $Q_0 \in \mathbb{C}[x]_{n\times b}$ such that every $v \in \mathcal{F}_{W,I_a}$ has a number $\varkappa(v) \in \mathbb{C}$ with the following property. Let $(\lambda_g)_{g\in G_\infty(\mathrm{sgn}_j)}$ be continuous linear forms on $\mathcal{F}_{W,I_a}$ and λ' a linear form on $\mathbb{C}[x]_{n\times b}$ such that*

$$\lambda_g(\Omega_{\gamma_0,0}(x_1,x_2)w) = \lambda_{gx_1}(w) \qquad (g, x_1 \in G_\infty(\mathrm{sgn}_j),\ x_2 \in G_\infty(s_a^+),\ w \in \mathcal{F}_{W,I_a}),$$

and $\lambda_x(v) = \lambda'(Q)$ whenever $x \in G_\infty(\mathrm{sgn}_j)$ and $Q \in \mathbb{C}[x]_{n\times b}$ satisfy $\Omega_{\gamma_0,0}(1,x)v_{Q_0} = v_Q$ in $\mathcal{F}_{V',W}$. Then for every family $\eta = (\eta_{\tau k})_{\tau\in\Phi,\, k\in\iota_\tau}$ of complex $p\times m$ matrices

$$\varkappa(v)\,\lambda_1(v_{\Delta^j(e;\eta)}) = \lambda'(Q_{f,j}(\eta)).$$

Proof. Notation. For $k \in G_\infty(s_m^+)$ let $k^\sharp \in G_\infty(\mathrm{sgn}_j)$ act as k on $j(m)$ and as the identity on $j(l)$, so $(kk')^\sharp = k^\sharp k'^\sharp$; put $\chi_m(k) = \prod_\tau \det(k_\tau)^{\#\iota_\tau}$. For a family η and k write ηk^{T} for the family $(\eta_{\tau i}k_\tau^{\mathsf{T}})$, similarly $\eta(k^{-1})^{\mathsf{T}}$. Let η^0, $t(z)$, $\Omega^\circ(z)$ be as in Lemma 6.3.69 for $n, m, l, p, a, j, e, W, \iota$. Put $Q_0 = Q_{f,j}(\eta^0)$, fix v and let $\varkappa(v) = \kappa(v)$ be the number of Lemma 6.3.69. Let (λ_g), λ' satisfy the two hypotheses; call them the equivariance and the matching hypothesis.

Step 1: two laws of the real Weil representation. All elements below are block diagonal for the signs, so (5) of Lemma 4.1.1 applies. For $k \in G_\infty(s_m^+)$, $u \in G_\infty(s_a^+)$ and every family η,

$$\Omega_{\gamma_0,0}(k^\sharp, u)\, v_{\Delta^j(e;\eta(k^{-1})^{\mathsf{T}})} = \chi_m(k)^{-1}\, v_{\Delta^j(e;\eta)} \quad \text{in } \mathcal{F}_{W,I_a}, \tag{6.53}$$

$$\Omega_{\gamma_0,0}(1, k^\sharp)\, v_{Q_{f,j}(\eta)} = \chi_m(k)^{-1}\, v_{Q_{f,j}(\eta k^{\mathsf{T}})} \quad \text{in } \mathcal{F}_{V',W}. \tag{6.54}$$

Step 2: the identity for unitary translates of η^0. Let $k \in G_\infty(s_m^+)$ and $\xi = \eta^0 k^{\mathsf{T}}$. By (6.53) for η^0, k^{-1}, $u = 1$, and since $\Omega_{\gamma_0,0}$ is a representation ((2) of Lemma 4.1.1), $v_{\Delta^j(e;\xi)} = \chi_m(k)\,\Omega_{\gamma_0,0}(k^\sharp, 1)v_{\Delta^j(e;\eta^0)}$, so by equivariance

$$\lambda_1(v_{\Delta^j(e;\xi)}) = \ell(v_{\Delta^j(e;\eta^0)}), \qquad \ell = \chi_m(k)\,\lambda_{k^\sharp}. \tag{6.55}$$

By equivariance with $x_1 = 1$, ℓ is a continuous linear form invariant under $\Omega_{\gamma_0,0}(1,u)$, $u \in G_\infty(s_a^+)$, so Lemma 6.3.69 gives $\varkappa(v)\,\ell(v_{\Delta^j(e;\eta^0)}) = \frac{1}{2\pi}\int_0^{2\pi} \ell(\Omega^\circ(e^{i\theta})v)\,d\theta$. Let $|z| = 1$. By equivariance, $\ell(\Omega^\circ(z)v) = z^{-\#a\sum_\tau \#\iota_\tau}\chi_m(k)\,\lambda_{(kt(z))^\sharp}(v)$. Since $t(z)$ is diagonal with entry z^{-2} at the places $e(p)$ where the rows of η^0 have their 1, $\eta^0(kt(z))^{\mathsf{T}} = \eta^0 t(z)k^{\mathsf{T}} = z^{-2}\xi$, and each factor $\det(\xi_{\tau i}y_\tau^{++})$ of $Q_{f,j}$ is a $p\times p$ determinant, so $Q_{f,j}(z^{-2}\xi) = z^{-2\#p\sum_\tau \#\iota_\tau}Q_{f,j}(\xi)$. By (6.54) for $kt(z)$, $\Omega_{\gamma_0,0}(1,(kt(z))^\sharp)v_{Q_0} = v_{Q'}$ with $Q' = \chi_m(kt(z))^{-1}z^{-2\#p\sum \#\iota_\tau}Q_{f,j}(\xi)$, and the matching hypothesis gives $\lambda_{(kt(z))^\sharp}(v) = \lambda'(Q')$. As $\chi_m(t(z)) = z^{-(2\#p+\#a)\sum_\tau \#\iota_\tau}$,

$$\ell(\Omega^\circ(z)v) = z^{-\#a\sum \#\iota_\tau}\, z^{(2\#p+\#a)\sum \#\iota_\tau}\, z^{-2\#p\sum \#\iota_\tau}\,\lambda'(Q_{f,j}(\xi)) = \lambda'(Q_{f,j}(\xi))$$

for all z, so the circle mean is $\lambda'(Q_{f,j}(\xi))$, and with (6.55)

$$\varkappa(v)\,\lambda_1(v_{\Delta^j(e;\eta^0k^{\mathsf{T}})}) = \lambda'(Q_{f,j}(\eta^0k^{\mathsf{T}})) \qquad (k \in G_\infty(s_m^+)). \tag{6.56}$$

Step 3: polarisation. Let η be any family. Lemma 6.3.70, for $r = e|_p$ (row i of $\eta^0_{\tau k}$ is the basis vector at $e(i)$) and $\xi = \eta$, gives a finitely supported c on $G_\infty(s^+_m)$ with $\prod_{\tau,i} \det(\eta_{\tau i} Y_\tau) = \sum_k c(k) \prod_\tau \det(\eta^0 k_\tau^{\mathsf T} Y_\tau)^{\#\iota_\tau}$ over every commutative $\mathbb{C}$-algebra. Taking $Y_\tau = y_\tau^{++}$ in $\mathbb{C}[x]_{n\times b}$ and multiplying by the factor $\prod_\tau \det(y_\tau^{--})^{\max(0,\#\iota_\tau+\#n-2\#l)}$, which does not depend on the family, gives $Q_{f,j}(\eta) = \sum_k c(k) Q_{f,j}(\eta^0 k^{\mathsf T})$. For the stacked determinants fix complex values of the variables of $\mathbb{C}[x]_{a\times n}$ and τ, and let Z_τ be the complex $a \times m$ matrix $(x_{\tau,i,j(k')})$. There are an $m\times p$ matrix Y_τ and $d_\tau \in \mathbb{C}$ with $\Delta_\tau(\zeta) = d_\tau \det(\zeta Y_\tau)$ at this point for all $p\times m$ matrices ζ: if the rows of Z_τ are dependent, both sides vanish for $d_\tau = 0$; otherwise choose $g \in \mathrm{GL}_m(\mathbb{C})$ whose row $e(i)$ is row i of Z_τ for $i \in a$; multiplying the matrix of $\Delta_\tau(\zeta)$ on the right by g^{-1} turns the rows $e(a)$ into the basis vectors at $e(a)$, and expanding along them gives $\Delta_\tau(\zeta) = \det g \cdot \det(\zeta g^{-1} J)$, J the $m \times p$ matrix whose column i is the basis vector at $e(i)$; take $Y_\tau = g^{-1}J$, $d_\tau = \det g$. Hence at this point $\Delta^j(e;\eta) = \prod_\tau d_\tau^{\#\iota_\tau} \prod_{\tau,i} \det(\eta_{\tau i} Y_\tau) = \sum_k c(k) \Delta^j(e;\eta^0 k^{\mathsf T})$; as the point is arbitrary, $\Delta^j(e;\eta) = \sum_k c(k) \Delta^j(e;\eta^0 k^{\mathsf T})$ as polynomials. Since $P \mapsto \lambda_1(v_P)$ and λ' are linear, (6.56) gives

$$\varkappa(v)\lambda_1\big(v_{\Delta^j(e;\eta)}\big) = \sum_k c(k)\, \varkappa(v)\lambda_1\big(v_{\Delta^j(e;\eta^0 k^{\mathsf T})}\big) = \sum_k c(k)\, \lambda'\big(Q_{f,j}(\eta^0 k^{\mathsf T})\big) = \lambda'\big(Q_{f,j}(\eta)\big).$$

□

Lemma 6.3.69. *Let n, m, l, p, a be finite index sets with bijections $j\colon m \sqcup l \to n$ and $e\colon p \sqcup a \to m$, W a space with signs sgn_j on n, $\iota = (\iota_\tau)_{\tau\in\Phi}$ finite sets and $\gamma_0(\tau) = \#l - \#\iota_\tau$. For $y \in G_\infty(s^+_m)$ let $y^\sharp \in G_\infty(\mathrm{sgn}_j)$ act as y on $j(m)$ (through j) and as the identity on $j(l)$. For $z \in \mathbb{C}$ with $|z| = 1$ let $t(z) \in G_\infty(s^+_m)$ be diagonal at every place, with entry z^{-2} at $e(k)$, $k \in p$, and z^{-1} at $e(i)$, $i \in a$, and put*

$$\Omega^\circ(z) = z^{-\#a \sum_\tau \#\iota_\tau}\, \Omega_{\gamma_0,0}\big(t(z)^\sharp,\, z^{-1} 1_a\big) \quad \text{on } \mathcal{F}_{W,I_a}.$$

Let η^0 be the family with $\eta^0_{\tau k}$ equal, for all τ and $k \in \iota_\tau$, to the $p \times m$ matrix whose row i is the standard basis vector at $e(i)$. Then for every $w \in \mathcal{F}_{W,I_a}$ there is $\kappa(w) \in \mathbb{C}$ such that every continuous linear form ℓ on $\mathcal{F}_{W,I_a}$ with $\ell(\Omega_{\gamma_0,0}(1,u)w') = \ell(w')$ for all $u \in G_\infty(s^+_a)$ and $w' \in \mathcal{F}_{W,I_a}$ satisfies

$$\kappa(w)\, \ell\big(v_{\Delta^j(e;\eta^0)}\big) = \frac{1}{2\pi} \int_0^{2\pi} \ell\big(\Omega^\circ(e^{i\theta}) w\big)\, d\theta.$$

Proof. Write $\mathcal{F} = \mathcal{F}_{W,I_a}$; its variables are $x_{\tau,i,k}$ ($\tau \in \Phi$, $i \in a$, $k \in n$). Call a continuous linear form ℓ as in the statement *invariant*, and put $\mathrm{Mn}(w,\ell) = \frac{1}{2\pi}\int_0^{2\pi} \ell(\Omega^\circ(e^{i\theta})w)\, d\theta$. By (2) of Lemma 4.1.1, $\Omega_{\gamma_0,0}$ is a continuous representation by bounded operators, so the integrand is continuous; the operators $\Omega^\circ(z)$, $|z| = 1$, are bounded uniformly, by M say (for the inner-product norm they are isometries; for the norm of $L^1(\nu)$, in which $\mathcal{F}$ is closed because the reproducing kernel is bounded, by the uniform boundedness principle, each orbit being bounded on the compact circle); hence $|\mathrm{Mn}(w,\ell) - \mathrm{Mn}(w',\ell)| \le M\|\ell\|\, \|w - w'\|$. Let $\mathrm{cols} = j(e(a)) \subseteq n$.

Step 1: the torus on Fock vectors of polynomials. Let $P \in \mathbb{C}[x]_{a\times n}$. The elements $t(z)^\sharp$ and $z^{-1}1_a$ are block diagonal for the signs, so (5) of Lemma 4.1.1 applies with $S = W$, $T = I_a$, $\gamma = \gamma_0$, $\gamma' = 0$:

Hence $\Omega^\circ(z) v_P = v_{P_z}$, where P_z is P with every variable $x_{\tau,i,k}$, $k \notin \mathrm{cols}$, multiplied by z. Writing $P = \sum_\alpha c_\alpha x^\alpha$ (finite sum) and $d(\alpha)$ for the total degree of x^α in the variables with $k \notin \mathrm{cols}$, $\ell(\Omega^\circ(z)v_P) = \sum_\alpha c_\alpha z^{d(\alpha)} \ell(v_{x^\alpha})$ is a polynomial in z, and its mean over the circle is its constant term:

$$\mathrm{Mn}(v_P, \ell) = \ell(v_{P_0}), \tag{6.57}$$

P_0 being P with the variables $x_{\tau,i,k}$, $k \notin \mathrm{cols}$, set to 0.

Step 2: averaging over the definite group. Let $z_{\tau,i,i'}$ $(i,i' \in a)$ be variables of square matrices Z_τ and ϱ the algebra map $z_{\tau,i,i'} \mapsto x_{\tau,i,j(e(i'))}$; then $P_0 = \varrho(q)$ for a unique polynomial q in the $z_{\tau,i,i'}$. For $u \in G_\infty(s_a^+)$ write q^u for q with Z_τ replaced by $u_\tau^{\mathsf T} Z_\tau$ and $\chi(u) = \prod_\tau \det(u_\tau)^{\#\iota_\tau}$. By (5) of Lemma 4.1.1 with $(x,y) = (1,u)$ the scalar is $\prod_\tau \det(u_\tau)^{\gamma_0(\tau)-\#l} = \chi(u)^{-1}$ and the substitution replaces the $a \times n$ matrix of variables at τ by $u_\tau^{\mathsf T}$ times it on the columns $j(m)$, so $\Omega_{\gamma_0,0}(1,u)v_{\varrho(q)} = \chi(u)^{-1} v_{\varrho(q^u)}$. For invariant ℓ the linear form $M(Q) = \ell(v_{\varrho(Q)})$ therefore satisfies

$$M(q^u) = \chi(u)\, M(q) \qquad (u \in G_\infty(s_a^+)). \tag{6.58}$$

The coefficients of q^u are polynomials in the entries of u; integrating them against $\chi(u)^{-1}$ for the Haar probability measure du of the compact group $G_\infty(s_a^+)$ (Theorem A.5.1) gives a polynomial $\bar q$ with $M'(\bar q) = \int \chi(u)^{-1} M'(q^u)\, du$ for every linear form M' (a finite sum of coefficients). By (6.58), $M(\bar q) = M(q)$. Evaluation at $Z_\tau = x_\tau^{\mathsf T}$, for $x \in G_\infty(s_a^+)$, is a linear form, and q^u evaluated there is q evaluated at $(x_\tau u_\tau)^{\mathsf T}$; by invariance of du under $u \mapsto x^{-1}u$ and multiplicativity of χ,

$$\bar q((x_\tau^{\mathsf T})_\tau) = \int \chi(u)^{-1} q(((x_\tau u_\tau)^{\mathsf T})_\tau) du = \chi(x) \int \chi(u)^{-1} q((u_\tau^{\mathsf T})_\tau) du = \kappa_q\, \chi(x),$$

with κ_q the last integral. So the polynomial $\bar q - \kappa_q \prod_\tau \det(Z_\tau)^{\#\iota_\tau}$ vanishes at the transposes of all families of unitary matrices; as the unitary group is Zariski dense in $\mathrm{GL}_{\#a}(\mathbb{C})$ (Weyl's unitarian trick: a polynomial vanishing on U vanishes on $\exp(\mathrm{M}_{\#a}(\mathbb{C}))$, the exponentials of complex combinations of hermitian matrices, which contain a neighbourhood of 1), it is 0. Hence $M(q) = \kappa_q\, M\big(\prod_\tau \det(Z_\tau)^{\#\iota_\tau}\big)$.

With (6.57): $\mathrm{Mn}(v_P, \ell) = \kappa_q\, \ell(v_{\Delta^j(e;\eta^0)})$ for every invariant ℓ, κ_q depending only on P and ι.

Step 3: all vectors. The Fock vectors of polynomials are dense in $\mathcal F$ by Lemma 6.3.29. Put $D = v_{\Delta^j(e;\eta^0)}$. If $\ell(D) = 0$ for every invariant ℓ, Step 2 gives $\mathrm{Mn}(v_P, \ell) = 0$ for all P and invariant ℓ, hence $\mathrm{Mn}(w, \ell) = 0$ for all w by density and continuity, and $\kappa(w) = 0$ works. Otherwise fix an invariant ℓ_0 with $\ell_0(D) = 1$ and put $\kappa(w) = \mathrm{Mn}(w, \ell_0)$, a continuous linear form in w. For invariant ℓ the continuous linear form $w \mapsto \mathrm{Mn}(w,\ell) - \kappa(w)\ell(D)$ vanishes at every v_P (Step 2 for ℓ and for ℓ_0 gives $\mathrm{Mn}(v_P,\ell) = \kappa_q \ell(D)$ and $\kappa(v_P) = \kappa_q$), hence on $\mathcal F$. □

Lemma 6.3.70. *Let p, m be finite index sets, $r\colon p \to m$ an injective map, and η^0 the complex $p \times m$ matrix whose row k is the standard basis vector at $r(k)$. Let $\iota = (\iota_\tau)_{\tau\in\Phi}$ be finite sets and $\xi = (\xi_{\tau k})_{\tau\in\Phi,\, k\in\iota_\tau}$ complex $p \times m$ matrices. Then there is a finitely supported function c on $G_\infty(s_m^+)$ such that for every commutative $\mathbb{C}$-algebra S and all $m \times p$ matrices Y_τ $(\tau \in \Phi)$ over S*

$$\prod_{\tau\in\Phi} \prod_{k\in\iota_\tau} \det(\xi_{\tau k} Y_\tau) = \sum_{u \in G_\infty(s_m^+)} c(u) \prod_{\tau\in\Phi} \det(\eta^0 u_\tau^{\mathsf T} Y_\tau)^{\#\iota_\tau}.$$

Proof. If $m = \emptyset$ then $p = \emptyset$, both sides are 1 for c the indicator of the identity. Let $m \neq \emptyset$ and write $d_\tau = \#\iota_\tau$.

Reduction to generic matrices. Let R be the polynomial ring over $\mathbb{C}$ in variables $y_{\tau,i,k}$ $(\tau \in \Phi,\ i \in m,\ k \in p)$ and $Y_\tau^{\mathrm g} = (y_{\tau,i,k})_{i,k}$. If the identity holds in R for the matrices $Y_\tau^{\mathrm g}$, the $\mathbb{C}$-algebra map $R \to S$ sending $y_{\tau,i,k}$ to the (i,k) entry of Y_τ gives it for (Y_τ), since both sides are polynomials in the entries with complex coefficients and c does not depend on S or Y. So it suffices to find c with the identity in R.

A module containing the products. Number m as $1,\dots,M$ $(M = \#m \geq 1)$ so that p goes to $1,\dots,P$ $(P = \#p \leq M)$ through a bijection, fixed once. For each τ let X_τ be an $M \times M$ matrix

of indeterminates and read Y^{g}_τ as its first P columns. Let $\nu_\tau \in \mathbb{Z}^M$ have entries d_τ in the first P places and 0 in the others; it is nonincreasing with last entry ≥ 0. By Theorem A.5.19 (with $K = \mathbb{C}$, $k = M$) the space $\nabla(\nu_\tau)$ of polynomials in X_τ homogeneous of degree d_τ in each of the first P columns and of degree 0 in the others (hence independent of them), and unchanged when a multiple of an earlier column is added to a later one, is an irreducible representation of $\mathrm{GL}_M(\mathbb{C})$ under $(g \cdot Q)(X_\tau) = Q(g^{\mathsf{T}} X_\tau)$. For a complex $p \times m$ matrix ζ put $f_\zeta(X_\tau) = \det(\zeta Y^{\mathrm{g}}_\tau)$. Column b of $\zeta Y^{\mathrm{g}}_\tau$ is ζ times column b of Y^{g}_τ, so f_ζ is linear in each of the first P columns of X_τ and independent of the others, and adding a multiple of column a to column $b > a$ of X_τ adds a multiple of column a to column b of $\zeta Y^{\mathrm{g}}_\tau$ (or changes nothing, if $b > P$), which leaves the determinant unchanged. Hence $\prod_{k \in \iota_\tau} f_{\zeta_k} \in \nabla(\nu_\tau)$ for any ζ_k. Moreover the first P columns of $g^{\mathsf{T}} X_\tau$ are $g^{\mathsf{T}} Y^{\mathrm{g}}_\tau$, so

$$g \cdot f_\zeta = f_{\zeta g^{\mathsf{T}}} \qquad (g \in \mathrm{GL}_M(\mathbb{C})). \tag{6.59}$$

Irreducibility of the product. Let $V \subseteq \mathbb{C}[X_\tau : \tau \in \Phi]$ be the span of the products $\prod_\tau Q_\tau$ with $Q_\tau \in \nabla(\nu_\tau)$; as the variables of different τ are disjoint, multiplication identifies $\bigotimes_\tau \nabla(\nu_\tau)$ with V, compatibly with the action of $\mathrm{GL}_M(\mathbb{C})^\Phi$, $g = (g_\tau)$ acting on the factor τ through g_τ. Each $\nabla(\nu_\tau)$ is irreducible and finite-dimensional over the algebraically closed field $\mathbb{C}$, so by Burnside's theorem the span of the operators of $\mathrm{GL}_M(\mathbb{C})$ on it is its full endomorphism algebra; hence the span of the operators of $\mathrm{GL}_M(\mathbb{C})^\Phi$ on V is $\bigotimes_\tau \operatorname{End} \nabla(\nu_\tau) = \operatorname{End} V$, and V is irreducible.

Unitary translates span V. Let $F_0 = \prod_\tau f_{\eta^0}^{d_\tau} \in V$. It is nonzero: at $Y^{\mathrm{g}}_\tau = (\eta^0)^{\mathsf{T}}$ for all τ its value is 1, because $\eta^0 (\eta^0)^{\mathsf{T}} = 1_p$ (r is injective). Let λ be a linear form on V vanishing on every $u \cdot F_0$, $u \in G_\infty(s^+_m)$ (read in $\mathrm{GL}_M(\mathbb{C})^\Phi$ through the numbering). Extend λ to a linear form $\tilde\lambda$ on the finite-dimensional space of polynomials in the X_τ of degree at most $\sum_\tau P d_\tau$, which contains $F_0(g^{\mathsf{T}} X)$ for every family g of complex $M \times M$ matrices. Then $h(g) = \tilde\lambda(F_0((g_\tau^{\mathsf{T}} X_\tau)_\tau))$ is a polynomial in the entries of $g \in \mathrm{M}_M(\mathbb{C})^\Phi$ that vanishes on $G_\infty(s^+_m)$. It vanishes identically: for a basis $H_1, \dots, H_{M^2}$ of the real space of hermitian $M \times M$ matrices, $z \mapsto h\big((\exp(i \sum_k z_{\tau k} H_k))_\tau\big)$ is an entire function on $\mathbb{C}^{\Phi \times M^2}$ vanishing on the real points, hence zero; since $\{i \sum_k z_k H_k : z \in \mathbb{C}^{M^2}\} = \mathrm{M}_M(\mathbb{C})$, h vanishes on $\exp(\mathrm{M}_M(\mathbb{C}))^\Phi$, which contains a neighbourhood of 1, so $h = 0$. Hence λ vanishes on $g \cdot F_0$ for all $g \in \mathrm{GL}_M(\mathbb{C})^\Phi$, whose span is a nonzero invariant subspace of V, equal to V by irreducibility. So $\lambda = 0$, and the $u \cdot F_0$ ($u \in G_\infty(s^+_m)$) span V.

Conclusion. $F_\xi = \prod_\tau \prod_{k \in \iota_\tau} f_{\xi_{\tau k}}$ lies in V, so $F_\xi = \sum_u c(u)\, u \cdot F_0$ for a finitely supported c. By (6.59), $u \cdot F_0 = \prod_\tau f_{\eta^0 u_\tau^{\mathsf{T}}}^{d_\tau}$. Both sides of this identity involve only the first P columns of the X_τ, so it is the asserted identity in R. □

Lemma 6.3.71. *Let S, T be spaces with signs s on n_S and s' on n_T, let α, β be automorphic characters of $\mathrm{U}(1)$ of weights γ, γ', and let $\mathfrak{m}$ be a modulus. For $x \in G_\infty(s)$ write $(x, 1)$ for the point of $\mathrm{G}(s)$ with infinite component x and finite component 1, and likewise for T.*

(1) For every function Ψ on $\mathrm{M}_{n_T \times n_S}(R_\mathfrak{m})$, $v \in \mathcal{F}_{S,T}$, $x \in G_\infty(s)$, $y \in G_\infty(s')$, $g \in \mathrm{G}(s)$ and $h \in \mathrm{G}(s')$,

$$\theta^{S,T}_{\alpha,\beta}\big(\mathrm{mod}_\mathfrak{m}(\Psi, v)\big)\big(g(x,1), h(y,1)\big) = \theta^{S,T}_{\alpha,\beta}\big(\mathrm{mod}_\mathfrak{m}(\Psi, \Omega_{\gamma,\gamma'}(x,y)v)\big)(g,h).$$

(2) Let Ψ vanish at every matrix without a left inverse over $R_\mathfrak{m}$, $P \in \mathbb{C}[x]_{n_T \times n_S}$ and $h \in \mathrm{G}(s')$. Then $\kappa(g) = \theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Psi, P](g,h)$ is continuous and left Γ_S-invariant on $\mathrm{G}(s)$, and $\sup_g |\kappa(g)| \operatorname{ht}_S(g)^B < \infty$ for every $B \in \mathbb{N}$. In particular κ is bounded and integrable on $[\mathrm{U}(S)]$, and $P \mapsto \int_{[\mathrm{U}(S)]} \theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Psi, P](x,h)\, dx$ is a linear form on $\mathbb{C}[x]_{n_T \times n_S}$.

(3) Let $T = \mathrm{I}_a$ with a nonempty and let Φ be a function on $\mathrm{M}_{a \times n_S}(R_\mathfrak{m})$. For $g \in \mathrm{G}(s)$ the integral $\lambda_g(w) = I^{S,\mathrm{I}_a}_{\alpha,\beta}\big(\mathrm{mod}_\mathfrak{m}(\Phi, w)\big)(g)$ converges absolutely for every $w \in \mathcal{F}_{S,\mathrm{I}_a}$, λ_g is a

continuous linear form on $\mathcal{F}_{S,\mathrm{I}_a}$, and

$$\lambda_g(\Omega_{\gamma,\gamma'}(x_1,x_2)w) = \lambda_{g(x_1,1)}(w) \qquad (x_1 \in G_\infty(s),\ x_2 \in G_\infty(s_a^+),\ w \in \mathcal{F}_{S,\mathrm{I}_a}).$$

(4) In (3), let $P \in \mathbb{C}[x]_{a\times n_S}$ satisfy $\Omega_{\gamma,\gamma'}(1,y)v_P = v_P$ for all $y \in G_\infty(s_a^+)$, and let

$$\alpha(\det k)\,\Phi(\bar{k}^{-1}X) = \Phi(X)$$

for all $k \in \mathbf{K}_a$ and X, $\bar{k}$ the reduction of k modulo $\mathfrak{m}$. Then for every $g \in \mathrm{G}(s)$ the function

$$h \mapsto \theta^{S,\mathrm{I}_a}_{\alpha,\beta;\mathfrak{m}}[\Phi,P](g,h)$$

of the finite points h is left $\mathrm{U}(\mathrm{I}_a)(F)$-invariant and right $\mathbf{K}_a$-invariant, and

$$I^{S,\mathrm{I}_a}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}}(\Phi,v_P))(g) = c_a \sum^{\mathrm{cl}}_{h \bmod \mathbf{K}_a} \theta^{S,\mathrm{I}_a}_{\alpha,\beta;\mathfrak{m}}[\Phi,P](g,h),$$

where $c_a > 0$ is the total mass of the measure of $G_\infty(s_a^+)$.

(5) Let n,m,l,p,a be finite index sets with bijections $j\colon m\sqcup l \to n$, $e\colon p\sqcup a \to m$, let $\iota = (\iota_\tau)_{\tau\in\Phi}$ be finite sets and $\eta = (\eta_{\tau k})$ complex $p\times m$ matrices, and let S have the signs sgn_j on $n_S = n$ and $\gamma(\tau) = \#l - \#\iota_\tau$. Then for the pair (S,I_a) and every γ', $\Omega_{\gamma,\gamma'}(1,y)v_{\Delta^j(e;\eta)} = v_{\Delta^j(e;\eta)}$ for all $y \in G_\infty(s_a^+)$.

Proof. Write $\theta = \theta^{S,T}_{\alpha,\beta}$, $\omega = \omega_{\alpha,\beta}$ and $A = \Sigma(\mathfrak{m})$. For a function Ψ on $\mathrm{M}_{n_T\times n_S}(R_{\mathfrak{m}})$ put $f_\Psi = \Psi^\natural \otimes_A v^0 \in \mathcal{M}_{S,T}$ ($\Psi^\natural \in \mathcal{T}_A$ by (6) of Lemma 4.1.1), so that $\mathrm{mod}_{\mathfrak{m}}(\Psi,v) = v \otimes f_\Psi$ with f_Ψ independent of v.

Step 1: (1). By (5) of Lemma 4.1.1 with $k = k' = 1$, $\omega((x,1),(y,1))(v\otimes f_\Psi) = (\Omega_{\gamma,\gamma'}(x,y)v)\otimes f_\Psi$, since $\omega((1,1),(1,1))$ is the identity. As ω is a representation,

$$\theta(v\otimes f_\Psi)(g(x,1),h(y,1)) = \theta_{\mathrm{Hom}(S,T)}(\omega(g,h)\,\omega((x,1),(y,1))(v\otimes f_\Psi)) = \theta((\Omega_{\gamma,\gamma'}(x,y)v)\otimes f_\Psi)(g,h).$$

Step 2: (2). The map $(g,h) \mapsto \omega(g,h)\varphi$ is continuous and $\theta_{\mathrm{Hom}(S,T)}$ is a bounded linear functional, so $\theta(\varphi)$ is continuous on $\mathrm{G}(s)\times\mathrm{G}(s')$ for every datum φ; it is left invariant under $\Gamma_S\times\Gamma_T$ by Lemma 6.2.5. The Fock vector v_P is a Schwartz vector ((XD3)), so $\mathrm{mom}_N(v_P) < \infty$ for every N. Given B, (1) of Lemma 6.3.74 with $M = B$ gives B', N, C with $|\kappa(g)|\,\mathrm{ht}_S(g)^B \le C\,\mathrm{mom}_N(v_P)\,\mathrm{ht}_T(h)^{B'}$ for all g. For $B = 0$ this bounds κ; as κ is continuous, left Γ_S-invariant and bounded and $[\mathrm{U}(S)]$ has finite volume (Theorem 4.2.18; for $n_S = \emptyset$ the group is trivial), κ is integrable on $[\mathrm{U}(S)]$. The datum $v_P \otimes f_\Psi = \int v_P(y)\rho(\mathrm{rv}(y))f_\Psi\,d\nu(y)$ is linear in v_P, $P \mapsto v_P$ is linear, and $\theta_{\mathrm{Hom}(S,T)}\circ\omega(x,h)$ is linear; so the integral is linear in P.

Step 3: (3). Put $f = f_\Phi$ and $\varphi_w = w\otimes f$. The operators $\rho(z)$ are isometries of $\mathcal{M}_{S,\mathrm{I}_a}$ (Lemma 4.1.10, (1)), so the Bochner integral $\varphi_w = \int w(y)\rho(\mathrm{rv}(y))f\,d\nu(y)$ satisfies $\|\varphi_w\| \le \|w\|\,\|f\|$, $\|w\|$ the L^1 norm of the Fock model; and $w \mapsto \varphi_w$ is linear. The space I_a is definite at every infinite place, so $\Gamma_{\mathrm{I}_a}\backslash\mathrm{G}(s_a^+)$ is compact (Theorem A.4.5); as the quotient map is open, finitely many images of relatively compact open sets cover it, and there is a compact $C \subseteq \mathrm{G}(s_a^+)$ with $\Gamma_{\mathrm{I}_a}C = \mathrm{G}(s_a^+)$. Fix g. For each $\varphi \in \mathcal{M}_{S,\mathrm{I}_a}$ the continuous map $h \mapsto \omega(g,h)\varphi$ is bounded on C; $\mathcal{M}_{S,\mathrm{I}_a}$ is a Banach space (a closed subspace of L^1, Lemma 4.1.10 (1)), so by the uniform boundedness principle $M_g = \sup_{h\in C}\|\omega(g,h)\| < \infty$. Hence $|\theta(\varphi_w)(g,h)| \le \|\theta_{\mathrm{Hom}(S,\mathrm{I}_a)}\|\,M_g\,\|f\|\,\|w\|$ for $h \in C$, and by the left Γ_{I_a}-invariance of Step 2 for all h. The function $h \mapsto \theta(\varphi_w)(g,h)$ is continuous, left Γ_{I_a}-invariant and bounded, and $[\mathrm{U}(\mathrm{I}_a)]$ has finite volume vol;

so $\lambda_g(w)$ converges absolutely, λ_g is linear, and $|\lambda_g(w)| \le \mathrm{vol}\cdot\|\theta_{\mathrm{Hom}(S,\mathrm{I}_a)}\|\,M_g\,\|f\|\,\|w\|$, so λ_g is continuous. By (1), $\theta(\varphi_{\Omega_{\gamma,\gamma'}(x_1,x_2)w})(g,h) = \theta(\varphi_w)(g(x_1,1),h(x_2,1))$. The group $\mathrm{G}(s_a^+)$ is unimodular (the adelic points of the reductive group $\mathrm{U}(\mathrm{I}_a)$), so the quotient measure of $[\mathrm{U}(\mathrm{I}_a)]$ is invariant under right translation by $(x_2,1)$, and integrating over h gives $\lambda_g(\Omega_{\gamma,\gamma'}(x_1,x_2)w) = \lambda_{g(x_1,1)}(w)$.

Step 4: (4). Fix g and put $F(h) = \theta(\varphi_{v_P})(g,h)$ on $\mathrm{G}(s_a^+) = G_\infty(s_a^+)\times G_f(a)$. By Step 2, F is continuous and left Γ_{I_a}-invariant. For $y \in G_\infty(s_a^+)$ and a finite point h_f, $(y,h_f) = (1,h_f)(y,1)$, and (1) with $x=1$ and the invariance of v_P give $F(y,h_f) = F(1,h_f)$. The point of I_a is 1, so $\mathbf{K}_a$ is the standard level $\mathbf{K}_0(a)$ of I_a, and for $k \in \mathbf{K}_a$, (6) of Lemma 4.1.1 (with the element 1 of $\mathbf{K}_0(n_S)$) gives $\omega((1,1),(1,k))\varphi_{v_P} = \alpha(\det k)\,v_P \otimes f_{\Phi'}$ with $\Phi'(X) = \Phi(\bar{k}^{-1}X)$; by hypothesis $\alpha(\det k)\Phi' = \Phi$, so $\omega((1,1),(1,k))\varphi_{v_P} = \varphi_{v_P}$ and $F(h(1,k)) = F(h)$. In particular $h_f \mapsto F(1,h_f)$ is left invariant under the finite components of Γ_{I_a}, which are the elements of $\mathrm{U}(\mathrm{I}_a)(F)$, and right $\mathbf{K}_a$-invariant. By (2) of Lemma 6.4.74 with $n=a$, $V=\mathbb{C}$, $f=F$ and $\mathrm{K} = \mathrm{K}' = \mathbf{K}_0(a)$, the function $H(h_f) = \int_{G_\infty(s_a^+)} F(y,h_f)\,dy = F(1,h_f)$ (dy the Haar probability measure) satisfies

$$I^{S,\mathrm{I}_a}_{\alpha,\beta}(\varphi_{v_P})(g) = \int_{[\mathrm{U}(\mathrm{I}_a)]} F = c_a\,\mathrm{CI}_{\mathbf{K}_0(a)}(H),$$

and by (1) of Lemma 6.4.74 with $\mathrm{K} = \mathrm{K}' = \mathbf{K}_0(a)$, $\mathrm{CI}_{\mathbf{K}_0(a)}(H) = \sum_{[h]} H(h)/\#(\Gamma_f \cap h\mathbf{K}_a h^{-1})$, the sum over $\Gamma_f\backslash G_f(a)/\mathbf{K}_a$; this is the class sum (6.22) of $h \mapsto F(1,h) = \theta^{S,\mathrm{I}_a}_{\alpha,\beta;\mathfrak{m}}[\Phi,P](g,h)$.

Step 5: (5). Apply the second formula of (5) of Lemma 4.1.1 to the pair (S,I_a), $x=1$ and $y \in G_\infty(s_a^+)$; both are block diagonal for the partitions by sign, the block of sign -1 of y_τ is empty and that of sign $+1$ is y_τ. The scalar factor is

$$\prod_{\tau\in\Phi} \det(y_\tau)^{\gamma(\tau)-\#\{i\in n:\mathrm{sgn}_j(i)=-1\}} = \prod_{\tau\in\Phi} \det(y_\tau)^{(\#l-\#\iota_\tau)-\#l} = \prod_{\tau\in\Phi} \det(y_\tau)^{-\#\iota_\tau},$$

the factors of $x=1$ being 1. For $i' \in a$ and $k \in n$ with $\mathrm{sgn}_j(k) = +1$ the substitution sends $X_{\tau,i',k}$ to $\sum_{i\in a}(y_\tau)_{ii'}X_{\tau,i,k}$. The polynomial $\Delta_\tau(\eta_{\tau k})$ contains only the variables $X_{\tau,i,j(k')}$, $i \in a$, $k' \in m$, and $\mathrm{sgn}_j(j(k')) = +1$; so the $a\times m$ matrix $X_\tau = (X_{\tau,i,j(k')})$ becomes $y_\tau^{\mathsf{T}}X_\tau$, and the $m\times m$ matrix whose determinant is $\Delta_\tau(\eta_{\tau k})$ is multiplied on the left by the matrix D_τ with $(D_\tau)_{e(i'),e(i)} = (y_\tau)_{ii'}$ for $i,i' \in a$, $(D_\tau)_{e(i'),e(i')} = 1$ for $i' \in p$ and all other entries 0, of determinant $\det y_\tau$. Hence $\Delta^j(e;\eta)$ becomes $\prod_\tau \det(y_\tau)^{\#\iota_\tau}\Delta^j(e;\eta)$, and $\Omega_{\gamma,\gamma'}(1,y)v_{\Delta^j(e;\eta)} = \prod_\tau \det(y_\tau)^{-\#\iota_\tau}\prod_\tau \det(y_\tau)^{\#\iota_\tau}\,v_{\Delta^j(e;\eta)} = v_{\Delta^j(e;\eta)}$. □

The last group turns the exchange identity into a law for squares of theta lifts (Proposition 6.3.72). For $W = U_1 \oplus U_2$ and spaces A, A' with $\mathrm{rk}\,A = \mathrm{rk}\,A' + 2t$, a form on U_1 can be lifted up to A and back to U_2, or down to A' and up to U_2. For matched data the second composite is κ/c_i times the first, with $|c_i|^2 = C\,L_*(\mathfrak{m}_i,\nu_i;t) \neq 0$ and $C>0$ and κ independent of i. The number κ may be 0, which is harmless where the law is used, since the scalar of the auxiliary forms is chosen afterwards (Proposition 6.4.6). In our reading this is a seesaw identity in the sense of Kudla [171], with the exchange identity supplying the constant and its size. It is used for the squares of the grids of Section 6.4, where the moduli of the constants are the turn ratios, and for the squares of the triangle of lifts, where they give the chain ratios. The proof applies the exchange identity at the Fock vector of the product of the polynomials of the four lifts (Lemma 6.3.73); the decay of the kernels, the factorisation of data and kernels over orthogonal sums, and the approximation of Schwartz vectors by Fock vectors of polynomials (Lemma 6.3.79) make this legitimate.

Proposition 6.3.72. *Let A', A, U_1, U_2 be spaces with index sets n, n', n_1, n_2, let $W = U_1 \oplus U_2$ and let $\sigma\colon n \sqcup n' \to n_1 \sqcup n_2$ be a bijection. Let $t \in \mathbb{N}$ and $\mu\colon \Phi \to \mathbb{Z}$. Let I be a set and, for*

$i \in I$, ν_i tame of weight μ for $(\mathfrak{m}_i, \chi_i)$. Let the pairs (U_1, A), (U_2, A), (A', U_1), (A', U_2) carry characters $(a_{1,i}, b_{1,i})$, $(a_{2,i}, b_{2,i})$, $(b'_{1,i}, a'_{1,i})$, $(b'_{2,i}, a'_{2,i})$ of $\mathrm{U}(1)$ and polynomials P_1, P_2, P'_1, P'_2 (real data: their Fock vectors). Assume:

(OS1) $\operatorname{rk} A = \operatorname{rk} A' + 2t$, $\operatorname{neg}(W) = \operatorname{neg}(A) + \operatorname{neg}(A')$, *and* $2\operatorname{neg}(W) + 2 \le \operatorname{rk} W \le 2\mu(v) + 2\operatorname{neg}(W)$ *for* $v \in \Phi$;

(OS2) *the characters of each pair have weights independent of i, and for types e, e', e_1, e_2 on A, A', U_1, U_2 the Fock vectors of P_1, P_2, P'_1, P'_2 are edges for the weights of the characters of their pairs (the weight of the first character first) from e_1 to e, from $\bar{e}_2$ to $\bar{e}$, from $\bar{e}'$ to $\bar{e}_1$ and from e' to e_2;*

(OS3) *each of $a_{1,i}[\operatorname{rk} U_1]a_{2,i}[\operatorname{rk} U_2]$, $a'_{1,i}[\operatorname{rk} U_1]a'_{2,i}[\operatorname{rk} U_2]$, $b_{1,i}[\operatorname{rk} A]b'_{1,i}[\operatorname{rk} A']$, $b_{2,i}[\operatorname{rk} A]b'_{2,i}[\operatorname{rk} A']$ equals $\tilde{\nu}_i^{-1}$.*

For $i \in I$ and a matrix x (indices $n' \times (n_1 \sqcup n_2)$) over $R_i = R_{\mathfrak{m}_i}$ let $\Theta_i(x)\colon \mathcal{A}_{e_1}(U_1) \to \mathcal{A}_{e_2}(U_2)$ be the theta lift from U_1 to A followed by the transposed lift from A to U_2, with the indicator functions of the two column blocks of x as data modulo $\mathfrak{m}_i$; for a matrix y (indices $(n_1 \sqcup n_2) \times n$) let $\Theta'_i(y)$ be the transposed lift from U_1 to A' followed by the lift from A' to U_2, with the indicator functions of the two row blocks of y. Then:

1. *$\Theta_i(kx) = \chi_i(\det k)\,\Theta_i(x)$ and $\Theta'_i(yk) = \chi_i(\det k)\,\Theta'_i(y)$ for invertible k over R_i;*
2. *there are $C > 0$ and $\kappa \in \mathbb{C}$, possibly 0, both independent of i, and for each i a number c_i with*
$$|c_i|^2 = C \cdot L_*(\mathfrak{m}_i, \nu_i; t) \neq 0, \qquad \sum_y \Psi'(y)\,\Theta'_i(y) = \frac{\kappa}{c_i} \sum_x \Psi(x)\,\Theta_i(x)$$
for all Ψ, Ψ' matched for (σ, χ_i) modulo $\mathfrak{m}_i$.

In particular, for every $f \in \mathcal{A}_{e_1}(U_1)$ and every linear functional l on $\mathcal{A}_{e_2}(U_2)$, the functions $L(x) = l(\Theta_i(x)f)$ and $L'(y) = l(\Theta'_i(y)f)$ satisfy the square law with constant κ/c_i: both transform by $\chi_i \circ \det$, and $\sum \Psi' L' = (\kappa/c_i) \sum \Psi L$ for matched Ψ, Ψ'.

Proof. **Step 1: the characters.** Base change is injective on automorphic characters of $\mathrm{U}(1)$: every $u \in \mathrm{U}(1)(\mathbb{A})$ is $x/\bar{x}$ for an idele x of E (Hilbert's Theorem 90 at each place of F, with x_v a unit wherever u_v is a unit and E/F is unramified at v, which holds at almost all v), so $\tilde{\alpha} = \tilde{\beta}$ forces $\alpha(u) = \tilde{\alpha}(x) = \tilde{\beta}(x) = \beta(u)$. By (OS1) and σ, $\operatorname{rk} W = \operatorname{rk} A + \operatorname{rk} A' = 2\operatorname{rk} A' + 2t$ is even; put $\gamma_i = \nu_i^{-1}\upsilon^{\operatorname{rk} W/2}$. As $\upsilon(\bar{x}) = \upsilon(x)^{-1}$, the base change of υ restricted to $\mathrm{U}(1)(\mathbb{A})$ is υ^2, so $\tilde{\gamma}_i = \tilde{\nu}_i^{-1}\upsilon^{\operatorname{rk} W}$. Since $\alpha[p] = \tilde{\alpha}\upsilon^{-p}$, (OS3) gives $(a_{1,i}a_{2,i})^{\sim} = \tilde{\nu}_i^{-1}\upsilon^{\operatorname{rk} W} = \tilde{\gamma}_i$ and likewise for $a'_{1,i}a'_{2,i}$, and $(b_{1,i}b'_{1,i})^{\sim} = \tilde{\nu}_i^{-1}\upsilon^{\operatorname{rk} A + \operatorname{rk} A'} = (b_{2,i}b'_{2,i})^{\sim}$. Hence $a_{1,i}a_{2,i} = a'_{1,i}a'_{2,i} = \gamma_i$ and $b_{1,i}b'_{1,i} = b_{2,i}b'_{2,i}$. Put $\nu_{0,i} = b_{1,i}/b_{2,i}$; then $b_{2,i}\nu_{0,i} = b_{1,i}$ and $b'_{1,i}\nu_{0,i} = b'_{2,i}$.

Step 2: the exchange identity for $W = U_1 \oplus U_2$. Apply Theorem 6.3.2 to $(W, V, V') = (U_1 \oplus U_2, A, A')$ with $e = t$ and v the Fock vector of the product $P'_1P'_2$ (in the variables of the row blocks), a Schwartz vector for (A', W); (OS1) gives its hypotheses. It yields $C > 0$, a Schwartz vector w for (W, A) and for each i a number c_i with $|c_i|^2 = C\,L_*(\mathfrak{m}_i, \nu_i; t) \neq 0$ such that, for the splitting characters $(b_{1,i}, b'_{1,i})$ (allowed by (OS3)) and matched Ψ, Ψ',

$$I^{W,A}_{\gamma_i, b_{1,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\Psi, w))(g) = c_i \int_{[\mathrm{U}(A')]} \theta^{A',W}_{b'_{1,i},\gamma_i}(\mathrm{mod}_{\mathfrak{m}_i}(\Psi', v))(h, g)\,dh \qquad (g \in \mathrm{U}(W)(\mathbb{A}_F)).$$

Let κ_w be the number of (2) of Lemma 6.3.73 for w (it does not depend on i), and put $\kappa = \kappa_w$.

Step 3: integration against $f_1 \otimes f_2$. Fix i, matched Ψ, Ψ', a form f_1 of type e_1 on U_1 and a form f_2 of type $\bar{e}_2$ on U_2. If $\Psi(x) \neq 0$, x is the block of rows n' of some k^{-1}, $k \in \mathrm{GL}_{n_1 \sqcup n_2}(R_i)$, and has the right inverse formed by the columns n' of k; if $\Psi'(y) \neq 0$, y is the block of columns n of some k and has a left inverse. The data are linear in the functions: $\mathrm{mod}_{\mathfrak{m}_i}(\Psi, w) = \sum_x \Psi(x)\mathrm{mod}_{\mathfrak{m}_i}(\delta_x, w)$, and likewise for Ψ'. Take $g = \mathrm{diag}(g_1, g_2)$ in Step 2, multiply by $f_1(g_1)f_2(g_2)\nu_{0,i}(\det g_2)$ and integrate over $[\mathrm{U}(U_1)] \times [\mathrm{U}(U_2)]$. On the left, the integrand is $\sum_x \Psi(x)\mathrm{Up}_{i,x}(w)$ in the notation of Lemma 6.3.73 (as $\gamma_i = a_{1,i}a_{2,i}$); each term with $\Psi(x) \neq 0$ is integrable on the triple quotient by (1) there, so by Fubini's theorem and (2) there the integral is $\kappa_w \sum_x \Psi(x) \int_{[\mathrm{U}(U_2)]} f_2 \cdot \Theta_i(x) f_1$. On the right, for y with $\Psi'(y) \neq 0$ and row blocks y_1, y_2, $\delta_y = \delta_{y_1} \otimes \delta_{y_2}$, so (a) of Lemma 6.3.80 gives $\mathrm{mod}_{\mathfrak{m}_i}(\delta_y, v) = \mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_1}, v_{P_1'}) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_2}, v_{P_2'})$, and the exact factorisation (d) of Lemma 6.3.52 (target sums, the character $b'_{1,i}$ on $\mathrm{U}(W)$ and $a'_{1,i}a'_{2,i} = \gamma_i$ on $\mathrm{U}(A')$), with the twist law for $b'_{2,i} = b'_{1,i}\nu_{0,i}$, gives

$$\nu_{0,i}(\det g_2)\, \theta^{A',W}_{b'_{1,i},\gamma_i}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_y, v))(h, \mathrm{diag}(g_1, g_2)) = K'_1(h, g_1)K'_2(h, g_2),$$

$K'_j = \theta^{A',U_j}_{b'_{j,i},a'_{j,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_j}, v_{P_j'}))$. By (1) of Lemma 6.3.73 the product with $f_1(g_1)f_2(g_2)$ is integrable on $[\mathrm{U}(U_1)] \times [\mathrm{U}(U_2)] \times [\mathrm{U}(A')]$; by Fubini's theorem its integral is $\int_{[\mathrm{U}(A')]} L'^{\mathsf{t}}_{1,i,y} f_1 \cdot L'^{\mathsf{t}}_{2,i,y} f_2$, with $L'^{\mathsf{t}}_{2,i,y}$ the transposed lift from U_2 to A' of the kernel K'_2; by (2) of Lemma 6.3.76 for the pair (A', U_2), the form $L'^{\mathsf{t}}_{1,i,y} f_1$ of type e' and the form f_2 of type $\bar{e}_2$, this is $\int_{[\mathrm{U}(U_2)]} f_2 \cdot \Theta'_i(y) f_1$. Hence

$$\kappa_w \sum_x \Psi(x) \int_{[\mathrm{U}(U_2)]} f_2 \cdot \Theta_i(x) f_1 = c_i \sum_y \Psi'(y) \int_{[\mathrm{U}(U_2)]} f_2 \cdot \Theta'_i(y) f_1.$$

By (3) of Lemma 6.3.73, $F = \sum_y \Psi'(y)\Theta'_i(y)f_1 - \frac{\kappa}{c_i}\sum_x \Psi(x)\Theta_i(x)f_1$ is a form of type e_2; as $c_i \neq 0$ the identity gives $\int f_2 F = 0$ for all forms f_2 of type $\bar{e}_2$, in particular for $f_2 = \bar{F}$. So $\int_{[\mathrm{U}(U_2)]} |F|^2 = 0$, and $F = 0$ since F is continuous and the quotient measure gives positive mass to the image of every nonempty open set. This is (2), with C and κ independent of i.

Step 4: equivariance. By Step 1, $(a_{1,i}a_{2,i})^{-1} = (a'_{1,i}a'_{2,i})^{-1} = \gamma_i^{-1} = \nu_i \upsilon^{-\mathrm{rk}\, W/2}$, which has the tame part of ν_i (υ has trivial tame part), so it is tame for $(\mathfrak{m}_i, \chi_i)$. (3) of Lemma 6.3.73 gives (1).

The square law. Apply (1) and (2) to f and follow by l. □

Lemma 6.3.73. *Let A, A', U_1, U_2 be spaces with signs s' on n', s on n, s_1 on n_1, s_2 on n_2, let $W = U_1 \oplus U_2$ (index set $n_1 \sqcup n_2$) and write $\mathrm{diag}(g_1, g_2)$ for the block diagonal point of $\mathrm{U}(W)(\mathbb{A}_F)$. Let e, e', e_1, e_2 be types on A, A', U_1, U_2 and I a set; for $i \in I$ let $\mathfrak{m}_i$ be a modulus, $R_i = R_{\mathfrak{m}_i}$, and let $a_{1,i}, b_{1,i}, a_{2,i}, b_{2,i}, a'_{1,i}, b'_{1,i}, a'_{2,i}, b'_{2,i}$ be automorphic characters of $\mathrm{U}(1)$ whose weights $\gamma_1, \delta_1, \gamma_2, \delta_2, \gamma'_1, \delta'_1, \gamma'_2, \delta'_2$ do not depend on i; put $\nu_{0,i} = b_{1,i}/b_{2,i}$. Let $P_1 \in \mathbb{C}[x]_{n' \times n_1}$, $P_2 \in \mathbb{C}[x]_{n' \times n_2}$, $P'_1 \in \mathbb{C}[x]_{n_1 \times n}$, $P'_2 \in \mathbb{C}[x]_{n_2 \times n}$ be such that v_{P_1} is an edge for (γ_1, δ_1) from e_1 to e (pair (U_1, A)), v_{P_2} one for (γ_2, δ_2) from $\bar{e}_2$ to $\bar{e}$ (pair (U_2, A)), $v_{P'_1}$ one for (δ'_1, γ'_1) from $\bar{e}'$ to $\bar{e}_1$ (pair (A', U_1)) and $v_{P'_2}$ one for (δ'_2, γ'_2) from e' to e_2 (pair (A', U_2)). For $x \in \mathrm{M}_{n' \times (n_1 \sqcup n_2)}(R_i)$ with column blocks x_1, x_2 let $L_{1,i,x}$ be the lift from U_1 to A with the kernel $\theta^{U_1,A}_{a_{1,i},b_{1,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_{x_1}, v_{P_1}))$, let $L_{2,i,x}$ and $L^{\mathsf{t}}_{2,i,x}$ be the lift from U_2 to A and the transposed lift from A to U_2 with the kernel $\theta^{U_2,A}_{a_{2,i},b_{2,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_{x_2}, v_{P_2}))$ (as in Lemma 6.3.76), and $\Theta_i(x) = L^{\mathsf{t}}_{2,i,x} \circ L_{1,i,x}$. For $y \in \mathrm{M}_{(n_1 \sqcup n_2) \times n}(R_i)$ with row blocks y_1, y_2 let $\Theta'_i(y) = L'_{2,i,y} \circ L'^{\mathsf{t}}_{1,i,y}$, where $L'^{\mathsf{t}}_{1,i,y}$ is the transposed lift from U_1 to A' with the kernel $\theta^{A',U_1}_{b'_{1,i},a'_{1,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_1}, v_{P'_1}))$ and $L'_{2,i,y}$ the lift from A' to U_2 with the kernel $\theta^{A',U_2}_{b'_{2,i},a'_{2,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_2}, v_{P'_2}))$. For $w \in \mathcal{F}_{W,A}$ and forms f_1 of type e_1 on U_1 and f_2 of type $\bar{e}_2$ on U_2 put*

$$\mathrm{Up}_{i,x}(w)(g_1, g_2, h) = f_1(g_1)f_2(g_2)\, \nu_{0,i}(\det g_2)\, \theta^{W,A}_{a_{1,i}a_{2,i},\, b_{1,i}}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_x, w))(\mathrm{diag}(g_1, g_2), h).$$

(1) (Integrability.) Let f_1, f_2 be forms of types e_1, $\bar{e}_2$, and α, β, ν' automorphic characters of $\mathrm{U}(1)$*. If x has a right inverse over R_i, there are $N \in \mathbb{N}$ and $D \geq 0$ such that for every $w \in \mathcal{F}_{W,A}$ with $\mathrm{mom}_N(w) < \infty$ the function*

$$f_1(g_1) f_2(g_2) \nu'(\det g_2) \theta^{W,A}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_x, w))(\mathrm{diag}(g_1, g_2), h)$$

is integrable on $[\mathrm{U}(U_1)] \times [\mathrm{U}(U_2)] \times [\mathrm{U}(A)]$ and bounded by $D\,\mathrm{mom}_N(w)$. If y has a left inverse over R_i, the same holds for

$$f_1(g_1) f_2(g_2) \nu'(\det g_2) \theta^{A',W}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_y, w'))(h, \mathrm{diag}(g_1, g_2))$$

on $[\mathrm{U}(U_1)] \times [\mathrm{U}(U_2)] \times [\mathrm{U}(A')]$, $w' \in \mathcal{F}_{A',W}$.

(2) (The factor κ.) For every Schwartz vector $w \in \mathcal{F}_{W,A}$ there is $\kappa \in \mathbb{C}$, possibly 0, such that for all $i \in I$, all x with a right inverse over R_i and all forms f_1 of type e_1 on U_1 and f_2 of type $\bar{e}_2$ on U_2

$$\int_{[\mathrm{U}(U_1)]\times[\mathrm{U}(U_2)]\times[\mathrm{U}(A)]} \mathrm{Up}_{i,x}(w) = \kappa \int_{[\mathrm{U}(A)]} L_{1,i,x} f_1 \cdot L_{2,i,x} f_2 = \kappa \int_{[\mathrm{U}(U_2)]} f_2 \cdot \Theta_i(x) f_1.$$

(3) (Equivariance.) $\Theta_i(x)$ maps forms of type e_1 on U_1 to forms of type e_2 on U_2, and so does $\Theta'_i(y)$. If $(a_{1,i} a_{2,i})^{-1}$ is tame of some weight for $(\mathfrak{m}_i, \chi)$, then $\Theta_i(kx) = \chi(\det k)\,\Theta_i(x)$ for every $k \in \mathrm{GL}_{n'}(R_i)$; if $(a'_{1,i} a'_{2,i})^{-1}$ is tame of some weight for $(\mathfrak{m}_i, \chi)$, then $\Theta'_i(yk) = \chi(\det k)\,\Theta'_i(y)$ for every $k \in \mathrm{GL}_n(R_i)$.

Proof. **Step 1: heights on W.** For $g_j \in \mathrm{U}(U_j)(\mathbb{A}_F)$, $\mathrm{ht}_W(\mathrm{diag}(g_1, g_2)) \leq \mathrm{ht}_{U_1}(g_1)\,\mathrm{ht}_{U_2}(g_2)$. Indeed the matrix and the point of W are block diagonal, so a vector $u = (u_1, u_2)$ lies in the lattice of the moved space $W_{\mathrm{diag}(g_1,g_2)}$ exactly when each u_j lies in that of $(U_j)_{g_j}$, and the euclidean norm of the infinite components of $(x_W \mathrm{diag}(g_1, g_2))^{-1} u$ is at least that for any nonzero u_j; so it is at least $\min(\lambda_{U_1}(g_1), \lambda_{U_2}(g_2)) \geq \lambda_{U_1}(g_1)\lambda_{U_2}(g_2)$, as $\lambda_{U_j} \leq 1$. Hence $\lambda_W(\mathrm{diag}(g_1, g_2)) \geq \lambda_{U_1}(g_1)\lambda_{U_2}(g_2)$.

Step 2: (1). By (ED4)(a) for the half edges v_{P_1} from e_1 and v_{P_2} from $\bar{e}_2$, the types e_1 and $\bar{e}_2$ are cusp kernels of order 0, so by Lemma 6.3.75 $\sup |f_j|\,\mathrm{ht}^B_{U_j} < \infty$ for every B. If x has a right inverse, δ_x vanishes at every matrix without a right inverse, and (2) of Lemma 6.3.74 for $(S, T) = (W, A)$ and $M = 0$ gives B, N, C with $|\theta^{W,A}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}_i}(\delta_x, w))(g, h)| \leq C\,\mathrm{mom}_N(w)\,\mathrm{ht}_W(g)^B$ for all w with $\mathrm{mom}_N(w) < \infty$. By Step 1 and $|\nu'| = 1$, the function of (1) is bounded by $D\,\mathrm{mom}_N(w)$ with $D = C \sup |f_1| \mathrm{ht}^B_{U_1} \sup |f_2| \mathrm{ht}^B_{U_2}$. It is continuous, and left invariant under $\Gamma_{U_1} \times \Gamma_{U_2} \times \Gamma_A$: $\mathrm{diag}(\gamma_1, \gamma_2) \in \Gamma_W$ for $\gamma_j \in \Gamma_{U_j}$, the kernel is invariant by Lemma 6.2.5, the forms are invariant, and $\nu'(\det \gamma_2) = 1$ as $\det \gamma_2 \in \mathrm{U}(1)(E)$. The three quotients have finite volume (Theorem 4.2.18), so the function is integrable on their product. For y with a left inverse the same argument applies with (1) of Lemma 6.3.74 for $(S, T) = (A', W)$ and $M = 0$.

Step 3: kernels of products of polynomials. Fix i and x with a right inverse, and drop i from the notation. Let $Q_1 \in \mathbb{C}[x]_{n' \times n_1}$, $Q_2 \in \mathbb{C}[x]_{n' \times n_2}$, and $Q_1 Q_2$ their product in the variables of the column blocks. As $\delta_x = \delta_{x_1} \otimes \delta_{x_2}$, (b) of Lemma 6.3.80 gives $\mathrm{mod}_{\mathfrak{m}}(\delta_x, v_{Q_1Q_2}) = \mathrm{mod}_{\mathfrak{m}}(\delta_{x_1}, v_{Q_1}) \boxtimes^{\mathrm{sc}} \mathrm{mod}_{\mathfrak{m}}(\delta_{x_2}, v_{Q_2})$, and the exact factorisation (d) of Lemma 6.3.52 (source sums, with the characters a_1, a_2 on $\mathrm{U}(A)$ and b_1 on $\mathrm{U}(W)$) gives

$$\theta^{W,A}_{a_1 a_2, b_1}(\mathrm{mod}_{\mathfrak{m}}(\delta_x, v_{Q_1Q_2}))(\mathrm{diag}(g_1, g_2), h) = K_1(g_1, h)\,\theta^{U_2,A}_{a_2,b_1}(\mathrm{mod}_{\mathfrak{m}}(\delta_{x_2}, v_{Q_2}))(g_2, h),$$

$K_1 = \theta^{U_1,A}_{a_1,b_1}(\mathrm{mod}_{\mathfrak{m}}(\delta_{x_1}, v_{Q_1}))$. By (WR4), $\theta^{U_2,A}_{a_2,b_1} = \nu_0(\det g_2)^{-1} \theta^{U_2,A}_{a_2,b_2}$; with

$$K_2 = \theta^{U_2,A}_{a_2,b_2}(\mathrm{mod}_{\mathfrak{m}}(\delta_{x_2}, v_{Q_2})),$$
$$\mathrm{Up}_x(v_{Q_1Q_2})(g_1, g_2, h) = \big(f_1(g_1) K_1(g_1, h)\big)\big(f_2(g_2) K_2(g_2, h)\big).$$

This is integrable by (1); by Fubini's theorem its integral is $\int_{[\mathrm{U}(A)]} L_1^{Q_1} f_1 \cdot L_2^{Q_2} f_2$, $L_j^{Q_j}$ the lift with the Fock vector v_{Q_j} in place of v_{P_j}. By (4) of Lemma 6.3.76 there are continuous compactly supported a_{Q_1}, a'_{Q_2} on $G_\infty(s')$, depending only on the weights, the types, P_j and Q_j (not on i, x, f_1, f_2), with $L_1^{Q_1} f_1 = R(a_{Q_1}) L_1 f_1$ and $L_2^{Q_2} f_2 = R(a'_{Q_2}) L_2 f_2$, where $L_1 f_1$ is a form of type e and $L_2 f_2$ one of type $\bar e$ on A ((1) of Lemma 6.3.76).

Step 4: pairing of real convolutions. By (ED4)(a) for the half edge v_{P_1} for $(y,x) \mapsto \Omega(x,y)$ from $\bar e$ to $\bar e_1$, $\bar e$ is a cusp kernel of order 0, in particular an integrable idempotent kernel with $\bar e(1) \neq 0$. For forms F_1 of type e and F_2 of type $\bar e$ on A, $\overline{F_1}$ is a form of type $\bar e$ ($R(\bar e)\overline{F_1} = \overline{R(e)F_1}$), so Lemma 6.3.78 for $\bar e$ gives $\int_{[\mathrm{U}(A)]} F_1(g) F_2(g(z,1))\, dg = \frac{e(z)}{\overline{e(1)}} \int F_1 F_2$ for $z \in G_\infty(s')$. For continuous compactly supported a, a', Fubini's theorem (the forms are bounded, the quotient has finite volume) and the right invariance of the quotient measure under $(x',1)^{-1}$ give

$$\int R(a)F_1 \cdot R(a')F_2 = \iint a(x')a'(y') \int F_1(g) F_2(g(x'^{-1}y',1))\, dg\, dx'\, dy' = r(a,a') \int F_1 F_2,$$
$$r(a,a') = \iint a(x')a'(y') \frac{e(x'^{-1}y')}{\overline{e(1)}}\, dx'\, dy'.$$

With Step 3, $\int \mathrm{Up}_{i,x}(v_{Q_1Q_2}) = \rho(Q_1,Q_2)\, \pi_{i,x}(f_1,f_2)$, where $\rho(Q_1,Q_2) = r(a_{Q_1}, a'_{Q_2})$ does not depend on (i,x,f_1,f_2) and $\pi_{i,x}(f_1,f_2) = \int_{[\mathrm{U}(A)]} L_{1,i,x} f_1 \cdot L_{2,i,x} f_2$.

Step 5: (2). Call a quadruple $j = (i,x,f_1,f_2)$ as in (2) a case, and write $J_j(w) = \int \mathrm{Up}_{i,x}(w)$ for w with finite moments; by (1) it is defined, linear in w, and $|J_j(w)| \leq \mathrm{vol}_j\, D_j \,\mathrm{mom}_{N_j}(w)$, vol_j the volume of the triple quotient. Every polynomial in $\mathbb{C}[x]_{n' \times (n_1 \sqcup n_2)}$ is a finite sum of products $Q_1 Q_2$ (monomials factor along the column blocks), so by Step 4 and linearity every polynomial Q has a number $\rho(Q)$ with $J_j(v_Q) = \rho(Q)\pi_j$ for all cases j. Let w be a Schwartz vector and (Q_k) the polynomials of Lemma 6.3.79; then $|J_j(w) - \rho(Q_k)\pi_j| = |J_j(w - v_{Q_k})| \leq \mathrm{vol}_j D_j \,\mathrm{mom}_{N_j}(w - v_{Q_k}) \to 0$ for every case j. If $\pi_j = 0$ for all cases, then $J_j(w) = 0$ for all j and $\kappa = 0$ serves. Otherwise fix j_0 with $\pi_{j_0} \neq 0$; then $\rho(Q_k) \to \kappa := J_{j_0}(w)/\pi_{j_0}$, and for every case $J_j(w) = \lim_k \rho(Q_k)\pi_j = \kappa \pi_j$. This is the first identity of (2). The second is (2) of Lemma 6.3.76 for the pair (U_2, A), the form f_2 of type $\bar e_2$ and the form $L_{1,i,x} f_1$ of type $e = \overline{\bar e}$: $\int_{[\mathrm{U}(A)]} L_{1,i,x} f_1 \cdot L_{2,i,x} f_2 = \int_{[\mathrm{U}(U_2)]} f_2 \cdot L^{\mathsf{t}}_{2,i,x}(L_{1,i,x} f_1)$.

Step 6: (3). By (1) of Lemma 6.3.76, $L_{1,i,x}$ maps forms of type e_1 to forms of type e, and $L^{\mathsf{t}}_{2,i,x}$ maps forms of type $\overline{\bar e} = e$ to forms of type $\overline{\bar e_2} = e_2$; likewise $L'^{\mathsf{t}}_{1,i,y}$ maps forms of type $\overline{\bar e_1} = e_1$ to forms of type $\overline{\bar e'} = e'$ and $L'_{2,i,y}$ forms of type e' to forms of type e_2. Let $k \in \mathrm{GL}_{n'}(R_i)$. Every $w \in \Sigma(\mathfrak{m}_i)$ lies over a place of F that splits as $w\bar w$ ($\bar w \notin \Sigma(\mathfrak{m}_i)$, so $\bar w \neq w$). Choose $\kappa_w \in \mathrm{GL}_{n'}(\mathcal{O}_{E,w})$ reducing to the w-component of k (lift the entries; the determinant is a unit because its reduction is), and let $\hat k \in \underline{G_f(n')}$ have the component κ_w at $w \in \Sigma(\mathfrak{m}_i)$, the component at $\bar w$ determined by $\hat k^* \hat k = 1$ (it is $\overline{(\kappa_w^{-1})^{\mathsf{T}}}$, read at $\bar w$), and the component 1 elsewhere. Then $\hat k$ is integral, $\hat k \in \mathbf{K}_0(n')$, and its reduction modulo $\mathfrak{m}_i$ is k. If μ has weight μ_∞ and tame part ψ with $\psi_{w'} \neq 1$ exactly for $w' \in \Sigma(\mathfrak{m}_i)$, and χ is the character of R_i it defines ((XD4)), then $u = \det \hat k$ has infinite components 1 and integral finite components, so by Definition 3.1.2 $\mu(u) = \prod_{w \in \Sigma(\mathfrak{m}_i)} \psi_w(\det \kappa_w \bmod w) = \chi(\det k)$ (the components at $\bar w$ contribute $\psi_{\bar w} = 1$). By (6) of Lemma 4.1.1 for the pair (U_j, A),

$$\omega_{a_j,b_j}((1,1),(1,\hat k^{-1}))\mathrm{mod}_{\mathfrak{m}_i}(\delta_{kx_j}, v_{P_j}) = a_j(\det \hat k)^{-1} \mathrm{mod}_{\mathfrak{m}_i}(\delta_{x_j}, v_{P_j}),$$

since $\delta_{kx_j}(kX) = \delta_{x_j}(X)$. By (3) of Lemma 6.3.76 (with the points 1 of $\mathrm{U}(U_j)$ and $\hat k^{-1}$ of $\mathrm{U}(A)$), $L_{1,kx} f_1(h(1,\hat k^{-1})) = a_1(\det \hat k)^{-1} L_{1,x} f_1(h)$, i.e. $L_{1,kx} f_1 = a_1(\det \hat k)^{-1}(L_{1,x} f_1)(\cdot(1,\hat k))$, and

$$L^{\mathsf{t}}_{2,kx} F = a_2(\det \hat k)^{-1} L^{\mathsf{t}}_{2,x}(F(\cdot(1,\hat k^{-1})))$$

for forms F of type e. Hence

$$\Theta_i(kx)f_1 = (a_1a_2)^{-1}(\det\hat{k})\,\Theta_i(x)f_1 = \chi(\det k)\Theta_i(x)f_1$$

by the preceding paragraph for $\mu = (a_1a_2)^{-1}$. For $k \in \mathrm{GL}_n(R_i)$ let $\hat{k} \in \mathbf{K}_0(n)$ be constructed in the same way. By (6) of Lemma 4.1.1 for the pair (A', U_j), whose second character a'_j twists $\mathrm{U}(A')$,

$$\omega_{b'_j,a'_j}((1,\hat{k}),(1,1))\mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_jk}, v_{P'_j}) = a'_j(\det\hat{k})^{-1}\mathrm{mod}_{\mathfrak{m}_i}(\delta_{y_j}, v_{P'_j}),$$

since $\delta_{y_jk}(Xk) = \delta_{y_j}(X)$. By (3) of Lemma 6.3.76, $L'^{\mathfrak{t}}_{1,yk}f_1 = a'_1(\det\hat{k})^{-1}(L'^{\mathfrak{t}}_{1,y}f_1)(\cdot(1,\hat{k})^{-1})$ and

$$L'_{2,yk}F = a'_2(\det\hat{k})^{-1}L'_{2,y}(F(\cdot(1,\hat{k})))$$

for forms F of type e'; hence

$$\Theta'_i(yk)f_1 = (a'_1a'_2)^{-1}(\det\hat{k})\,\Theta'_i(y)f_1 = \chi(\det k)\Theta'_i(y)f_1.$$

□

Lemma 6.3.74. *Let S, T be spaces with signs s on n_S and s' on n_T, let α, β be automorphic characters of $\mathrm{U}(1)$, $\mathfrak{m}$ a modulus, and Ψ a function on $\mathrm{M}_{n_T\times n_S}(R_\mathfrak{m})$. Write $K_v(g,h) = \theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_\mathfrak{m}(\Psi, v))(g,h)$ for $v \in \mathcal{F}_{S,T}$, $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$.*

(1) If Ψ vanishes at every matrix without a left inverse in $\mathrm{M}_{n_S\times n_T}(R_\mathfrak{m})$, then for every $M \in \mathbb{N}$ there are $B, N \in \mathbb{N}$ and $C \geq 0$ such that for every v with $\mathrm{mom}_N(v) < \infty$ and all g, h

$$|K_v(g,h)|\,\mathrm{ht}_S(g)^M \leq C\,\mathrm{mom}_N(v)\,\mathrm{ht}_T(h)^B.$$

(2) If Ψ vanishes at every matrix without a right inverse in $\mathrm{M}_{n_S\times n_T}(R_\mathfrak{m})$, then for every $M \in \mathbb{N}$ there are $B, N \in \mathbb{N}$ and $C \geq 0$ such that for every v with $\mathrm{mom}_N(v) < \infty$ and all g, h

$$|K_v(g,h)|\,\mathrm{ht}_T(h)^M \leq C\,\mathrm{mom}_N(v)\,\mathrm{ht}_S(g)^B.$$

(3) For every Ψ there are $B, N \in \mathbb{N}$ and $C \geq 0$ such that for every v with $\mathrm{mom}_N(v) < \infty$ and all g, h, $|K_v(g,h)| \leq C\,\mathrm{mom}_N(v)\,\big(\mathrm{ht}_S(g)\,\mathrm{ht}_T(h)\big)^B$.

Proof. Put $A = \Sigma(\mathfrak{m})$, a nonempty finite set of finite places containing the conjugate of none of its members (XD4), and $f_0 = \Psi^\natural \otimes_A v^0$, so that $\mathrm{mod}_\mathfrak{m}(\Psi, v) = v \otimes f_0$ and $\Psi^\natural \in \mathcal{T}_A$ by (4) of Lemma 4.1.3. Fix $w \in A$, and write $\#n_S$, $\#n_T$ for the numbers of columns and rows.

Step 1: the support of $\Psi^\natural$ at w. Let η be a finite adelic $n_T \times n_S$ matrix with $\Psi^\natural(\eta) \neq 0$. Then the components of η at A are integral and $x = \eta_A \bmod \mathfrak{m}$ has $\Psi(x) \neq 0$. The reduction $r\colon R_\mathfrak{m} = \mathcal{O}_E/\mathfrak{m} \to \mathcal{O}_E/w = k_w$ is a ring homomorphism, and $r(x)$ is the reduction modulo the maximal ideal of $\eta_w \in \mathrm{M}_{n_T\times n_S}(\mathcal{O}_{E,w})$ (the isomorphism $\mathcal{O}_E/\mathfrak{m} \cong \prod_{w'\in A}\mathcal{O}_{E,w'}/w'^{e_{w'}}$ is compatible with the reductions).

- If x has a left inverse $L \in \mathrm{M}_{n_S\times n_T}(R_\mathfrak{m})$, then $r(L)\,r(x) = 1$, so $r(x)$ has rank $\#n_S$ over k_w and some $\#n_S \times \#n_S$ minor of η_w is a unit of $\mathcal{O}_{E,w}$; hence η_w has rank $\#n_S$ over the field E_w and has a left inverse in $\mathrm{M}_{n_S\times n_T}(E_w)$.
- If x has a right inverse, the same argument with $r(x)\,r(R) = 1$ shows that η_w has rank $\#n_T$ and a right inverse in $\mathrm{M}_{n_S\times n_T}(E_w)$.

Step 2: (1) and (2). Under the hypothesis of (1), Step 1 shows that η_w has a left inverse over E_w whenever $\Psi^\natural(\eta) \neq 0$. Clause (2) of Lemma 6.2.27, for S, T, A, $\Psi^\natural$, w and the exponent M, gives $B, N \in \mathbb{N}$ and $C \geq 0$ with $|K_v(g,h)|\,\mathrm{ht}_S(g)^M \leq C\,\mathrm{mom}_N(v)\,\mathrm{ht}_T(h)^B$ for all v with $\mathrm{mom}_N(v) < \infty$ and all g, h (and all α, β); this is (1). Under the hypothesis of (2), Step 1 gives right inverses, and clause (1) of Lemma 6.2.27 gives (2) in the same way.

Step 3: (3). By Lemma 6.2.28 there are $Y \geq 0$ and $B \in \mathbb{N}$ with $|\theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)| \leq Y\|\varphi\|(\mathrm{ht}_S(g)\mathrm{ht}_T(h))^B$ for all $\varphi \in \mathcal{M}_{S,T}$. By (1) of Lemma 6.2.21, $\|v \otimes f_0\| \leq \|v\|_{L^1(\nu)}\|f_0\| = \mathrm{mom}_0(v)\|f_0\|$. Hence (3) holds with $N = 0$ and $C = Y\|f_0\|$. □

Lemma 6.3.75. *Let V be a space with a point with signs s on n, $B \in \mathbb{N}$, e a cusp kernel of order B on $G_\infty(s)$, and F a form of type e on V. Then*

$$\sup_{g \in \mathrm{G}(s)} |F(g)|\,\mathrm{ht}_V(g)^A < \infty \qquad \textit{for every } A \in \mathbb{N}.$$

Proof. Let $A \in \mathbb{N}$, let $K \subseteq G_f(n)$ be an open subgroup under which F is right invariant, and put $c = \sup|F| < \infty$ (F is bounded).

If $n = \emptyset$, the lattice of every moved space V_g is $\{0\}$, so $\lambda_V(g) = 1$ and $\mathrm{ht}_V(g) = 1$, and the supremum is c. Let $N = \#n \geq 1$ and number n as $\{1, \dots, N\}$.

The framed space of V. By (VP3) of Definition 3.2.2 V is a framed hermitian space U (E^n with the form h_V, the signs s, the columns of $x_{V,v}$ as frame at $v \in \Phi$ and the finite isometry $z \mapsto x_{V,f}z$; a framed space of rank N in the sense of (FT1) of Definition 3.2.4), with group $\mathrm{G}(s) = G_\infty(s) \times G_f(n)$, coordinate map $c_V(u) = x_V^{-1}u$ and rational points $\Gamma_U = \Gamma_V$, and $\lambda_V(g)$ is the first minimum of (VP4) for both readings:

$$\lambda_U(g) = \lambda_V(g) = \mathrm{ht}_V(g)^{-1} \qquad (g \in \mathrm{G}(s)).$$

The kernel and the form. Take for the Haar measures of (EK1) of Definition 5.6.2 the Cayley measures of the factors $\mathrm{U}(\mathrm{diag}\,s)$, the measure of $G_\infty(s)$ in (ED1). Since $(zx)^{-1} = x^{-1}z^{-1}$ and $\|x\| = \|x\|_\infty$, the conditions of (ED1) on e are those of (EK3) and (EK4)(a)–(c), so e is a cusp kernel of order B in the sense of (EK4); and $R(e)$ of (ED2) is the real convolution $R(e)$ of (EK2). Thus F is continuous, bounded by c, left Γ_U-invariant, right K-invariant and satisfies $R(e)F = F$ (e is integrable).

Conclusion. By Lemma 5.8.7 for E, N, s, U, B, e, K and A there is $R \geq 0$ with $|F(g)|\lambda_U(g)^{-A} \leq c\,R$ for all g, that is $|F(g)|\,\mathrm{ht}_V(g)^A \leq c\,R$ on $\mathrm{G}(s)$. □

Lemma 6.3.76. *Let S, T be spaces with signs s on n_S and s' on n_T, let α, β be automorphic characters of $\mathrm{U}(1)$ of weights γ, γ', $\mathfrak{m}$ a modulus, Ψ a function on $\mathrm{M}_{n_T \times n_S}(R_\mathfrak{m})$, and P a polynomial whose Fock vector $v_P \in \mathcal{F}_{S,T}$ is an edge for the weights (γ, γ') from e to e'. Put $\varphi = \mathrm{mod}_\mathfrak{m}(\Psi, v_P)$, $\kappa(g,h) = \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)$, and for functions F on $\mathrm{G}(s)$ and F' on $\mathrm{G}(s')$*

$$LF(h) = \int_{[\mathrm{U}(S)]} \kappa(g,h)F(g)\,dg, \qquad L^{\mathsf{t}}F'(g) = \int_{[\mathrm{U}(T)]} \kappa(g,h)F'(h)\,dh.$$

(1) For every form F of type e on S the integral $LF(h)$ converges absolutely for every h, and LF is a form of type e' on T. For every form F' of type $\bar{e}'$ on T the integral $L^{\mathsf{t}}F'(g)$ converges absolutely for every g, and $L^{\mathsf{t}}F'$ is a form of type $\bar{e}$ on S.

(2) For forms F of type e on S and F' of type $\bar{e}'$ on T, the function $(g,h) \mapsto \kappa(g,h)F(g)F'(h)$ is integrable on $[\mathrm{U}(S)] \times [\mathrm{U}(T)]$, and $\int_{[\mathrm{U}(T)]} F' \cdot LF = \int_{[\mathrm{U}(S)]} F \cdot L^{\mathsf{t}}F'$.

(3) *Let $k \in G_f(n_S)$, $k' \in G_f(n_T)$, $c \in \mathbb{C}$ and Ψ' a function on $\mathrm{M}_{n_T \times n_S}(R_\mathfrak{m})$ with*

$$\omega_{\alpha,\beta}((1,k),(1,k'))\varphi = c \bmod_\mathfrak{m}(\Psi', v_P),$$

and let L', $L'^{\mathfrak{t}}$ be formed with Ψ' in place of Ψ. Then for forms F of type e on S and F' of type $\bar{e}'$ on T the right translates $F(\cdot(1,k))$, $F'(\cdot(1,k'))$ are forms of the same types, and

$$LF(h(1,k')) = c\, L'(F(\cdot(1,k)))(h), \qquad L^{\mathfrak{t}}F'(g(1,k)) = c\, L'^{\mathfrak{t}}(F'(\cdot(1,k')))(g).$$

(4) *For every polynomial Q there is a continuous compactly supported function a_Q on $G_\infty(s')$, depending only on (γ,γ'), e, e', P and Q, such that for every form F of type e on S the integral $L_QF(h) = \int_{[\mathrm{U}(S)]} \theta^{S,T}_{\alpha,\beta}(\bmod_\mathfrak{m}(\Psi, v_Q))(g,h)F(g)\,dg$ converges absolutely and $L_QF = R(a_Q)\,LF$.*

Proof. Write $\omega = \omega_{\alpha,\beta}$, $\theta = \theta_{\mathrm{Hom}(S,T)}$ and $f = \Psi^\natural \otimes_{\Sigma(\mathfrak{m})} v^0$, so $\varphi = v_P \otimes f$.

Step 1: bounds. By (ED4)(a) for the half edge v_P from e to e', e is a cusp kernel of order 0, and by (ED4)(a) for the half edge from $\bar{e}'$ to $\bar{e}$, so is $\bar{e}'$. By Lemma 6.3.75, $\sup|F|\,\mathrm{ht}_S^A < \infty$ and $\sup|F'|\,\mathrm{ht}_T^A < \infty$ for forms F of type e on S, F' of type $\bar{e}'$ on T and every A. The Fock vector v_P is a Schwartz vector ((XD3)), so (3) of Lemma 6.3.74 gives B and C' with $|\kappa(g,h)| \le C'(\mathrm{ht}_S(g)\mathrm{ht}_T(h))^B$, and likewise for v_Q with some B_Q, C'_Q. Hence $|\kappa(g,h)F(g)| \le C''\mathrm{ht}_T(h)^B$, $|\kappa(g,h)F'(h)| \le C''\mathrm{ht}_S(g)^B$ and $|\kappa(g,h)F(g)F'(h)| \le C''$ for a constant C''. The function κ is continuous (as $(g,h) \mapsto \omega(g,h)\varphi$ is continuous and θ is bounded) and left invariant under $\Gamma_S \times \Gamma_T$ (Lemma 6.2.5); F, F' are continuous and left invariant. As $[\mathrm{U}(S)]$ and $[\mathrm{U}(T)]$ have finite volume (Theorem 4.2.18), the integrals $LF(h)$, $L^{\mathfrak{t}}F'(g)$, $L_QF(h)$ converge absolutely and the function of (2) is integrable on the product.

Step 2: a level of the datum. The characters α, β are continuous and the determinant is continuous, so there are open subgroups $U \subseteq \mathbf{K}_0(n_S)$ and $U' \subseteq \mathbf{K}_0(n_T)$ on which $\beta \circ \det = 1$, resp. $\alpha \circ \det = 1$, and whose elements reduce to 1 modulo $\mathfrak{m}$. For $k \in U$, $k' \in U'$, (6) of Lemma 4.1.1 gives $\omega((1,k),(1,k'))\varphi = \alpha(\det k')\beta(\det k)^{-1} v_P \otimes (\Psi^\natural \otimes v^0) = \varphi$, since $\Psi_{k,k'} = \Psi$ when $\bar{k} = 1$ and $\bar{k}' = 1$.

Step 3: (1). Let F be a form of type e. For $k' \in U'$, as ω is a representation, $LF(h(1,k')) = \int \theta(\omega(g,h)\,\omega((1,1),(1,k'))\varphi)F(g)\,dg = LF(h)$; so LF has the level U'. By Lemma 6.3.77, (ω,θ) is a theta kernel for (S,T) on $\mathrm{Hom}(S,T)$ with real part $\Omega_{\gamma,\gamma'}$, and $LF = L_{v_P \otimes f}F$ is its lift with the datum $v_P \otimes f$ ((ED3)). By (ED4)(c), LF is a form of type e' on T. The pair $(\omega^{\mathrm{sw}},\theta)$ with $\omega^{\mathrm{sw}}(h,g) = \omega(g,h)$ is a theta kernel for (T,S) on $\mathrm{Hom}(S,T)$ with real part $(y,x) \mapsto \Omega_{\gamma,\gamma'}(x,y)$: the homomorphism property, the continuity, the rational invariance and the identity $\omega^{\mathrm{sw}}((y,1),(x,1))(v \otimes f) = (\Omega_{\gamma,\gamma'}(x,y)v) \otimes f$ are those of (ω,θ). Its lift of F' with the datum $v_P \otimes f$ is $L^{\mathfrak{t}}F'$, which has the level U as above. By (ED4)(c) for the half edge v_P for $(y,x) \mapsto \Omega_{\gamma,\gamma'}(x,y)$ from $\bar{e}'$ to $\bar{e}$, $L^{\mathfrak{t}}F'$ is a form of type $\bar{e}$ on S.

Step 4: (2). By Step 1 and Fubini's theorem, both iterated integrals of $\kappa(g,h)F(g)F'(h)$ over $[\mathrm{U}(S)] \times [\mathrm{U}(T)]$ equal its integral, and they are $\int F' \cdot LF$ and $\int F \cdot L^{\mathfrak{t}}F'$.

Step 5: (3). Right translation by $(1,k)$ commutes with left translation by Γ_S and with right translation by the points $(x,1)$, $x \in G_\infty(s)$, and it carries a level U_0 of F to the open subgroup kU_0k^{-1}; so $F(\cdot(1,k))$ is continuous, bounded, left Γ_S-invariant, has a level and satisfies $R(e)F(\cdot(1,k)) = F(\cdot(1,k))$: it is a form of type e, and likewise for F'. The group $\mathrm{G}(s)$ is unimodular, so the quotient measure is invariant under the right translation $g \mapsto g(1,k)$, and

$$\begin{aligned} LF(h(1,k')) &= \int \theta(\omega(g(1,k),h(1,k'))\varphi)F(g(1,k))\,dg \\ &= c\int \theta(\omega(g,h)\bmod_\mathfrak{m}(\Psi',v_P))F(g(1,k))\,dg = c\,L'(F(\cdot(1,k)))(h). \end{aligned}$$

The second identity follows in the same way from the substitution $h \mapsto h(1, k')$ in $[\mathrm{U}(T)]$.

Step 6: (4). By (ED4)(d) for the half edge v_P for $\Omega_{\gamma,\gamma'}$ from e to e', there is a continuous compactly supported a_Q on $G_\infty(s')$ with $L_{v_Q \otimes f''} F'' = R(a_Q) L_{v_P \otimes f''} F''$ for all spaces with points of signs s, s', η, all theta kernels with real part $\Omega_{\gamma,\gamma'}$, all f'' and all forms F'' of type e; it depends only on $\Omega_{\gamma,\gamma'}$, e, e', v_P and Q. For the theta kernel (ω, θ) and $f'' = f$, $L_{v_Q \otimes f} F = L_Q F$ (convergent by Step 1) and $L_{v_P \otimes f} F = LF$. □

Lemma 6.3.77. *Let S, T be spaces with points, and α, β automorphic characters of* U(1) *of weights γ, γ'. Then $(\omega_{\alpha,\beta}, \theta_{\mathrm{Hom}(S,T)})$ is a theta kernel for (S, T) on* $\mathrm{Hom}(S, T)$*, and it has real part $\Omega_{\gamma,\gamma'}$.*

Proof. The space $\mathrm{Hom}(S, T)$ has signs $\eta(i, j) = s'(i)s(j)$ on $\iota = n' \times n$ ((VP5) of Definition 3.2.2), and $\mathcal{M}_{S,T} = \mathcal{M}_\eta$ (WR4). **Homomorphism and continuity.** By (2) of Lemma 4.1.1, $\omega_{\alpha,\beta}$ is a representation of $\mathrm{G}(s) \times \mathrm{G}(s')$ by bounded operators of $\mathcal{M}_\eta$: it is ω_η composed with the pair map, a continuous homomorphism, times the continuous character $(g, h) \mapsto \alpha(\det h)\beta(\det g)^{-1}$, and $(g, f) \mapsto \omega_\eta(g)f$ is jointly continuous; so $(p, \varphi) \mapsto \omega_{\alpha,\beta}(p)\varphi$ is continuous. **The theta functional.** $\theta_{\mathrm{Hom}(S,T)}$ is a bounded linear functional on $\mathcal{M}_\eta$ ((WC3) of Definition 4.1.15). For $\gamma \in \Gamma_S$, $\gamma' \in \Gamma_T$, $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$ and $\varphi \in \mathcal{M}_\eta$, apply Lemma 6.2.5 to the vector $\omega_{\alpha,\beta}(g, h)\varphi$: since $\omega_{\alpha,\beta}(\gamma g, \gamma' h) = \omega_{\alpha,\beta}(\gamma, \gamma')\omega_{\alpha,\beta}(g, h)$,

$$\theta_{\mathrm{Hom}(S,T)}\big(\omega_{\alpha,\beta}(\gamma g, \gamma' h)\varphi\big) = \theta_{\mathrm{Hom}(S,T)}\big(\omega_{\alpha,\beta}(g, h)\varphi\big).$$

So $(\omega_{\alpha,\beta}, \theta_{\mathrm{Hom}(S,T)})$ is a theta kernel for (S, T) on $\mathrm{Hom}(S, T)$ in the sense of (ED3). **Real part.** The Fock model of (ED3) for $V = \mathrm{Hom}(S, T)$ is $\mathcal{F}_\varepsilon$ with $\varepsilon(v, i, j) = s'(i)s(j)$, which is $\mathcal{F}_{S,T}$ of (WR5). By the first identity of (5) of Lemma 4.1.1 with $k = 1$, $k' = 1$, for $x \in G_\infty(s)$, $y \in G_\infty(s')$, $v \in \mathcal{F}_{S,T}$ and $f \in \mathcal{M}_\eta$, $\omega_{\alpha,\beta}((x, 1), (y, 1))(v \otimes f) = (\Omega_{\gamma,\gamma'}(x, y)v) \otimes f$, as $\omega_{\alpha,\beta}(1, 1)$ is the identity. Hence the theta kernel has real part $\Omega_{\gamma,\gamma'}$. □

Lemma 6.3.78. *Let V be a space with a point with signs s, e an idempotent kernel on $G_\infty(s)$, F and F' forms of type e on V, and $x \in G_\infty(s)$. Then*

$$\big\langle F,\ F'(\,\cdot\,(x, 1))\big\rangle_V = \frac{\overline{e(x)}}{e(1)}\,\langle F, F'\rangle_V.$$

Proof. **Preliminaries.** $G_\infty(s)$ is a finite product of real unitary groups $\mathrm{U}(p, q)$, which are reductive and hence unimodular; so dx is invariant under left and right translations and under $x \mapsto x^{-1}$. $\mathrm{G}(s)$ is unimodular and Γ_V is a discrete subgroup, so the quotient measure on $\Gamma_V \backslash \mathrm{G}(s)$ is invariant under right translation by $\mathrm{G}(s)$. It is finite: $\mathrm{U}(V)$ is reductive over F and has no nontrivial F-rational character, since its characters factor through $\det\colon \mathrm{U}(V) \to \mathrm{U}(1)$ and the torus $\mathrm{U}(1) = \ker \mathrm{N}_{E/F}$ is anisotropic over F; hence $[\mathrm{U}(V)]$ has finite volume by [37]. Consequently $\langle T, T'\rangle_V$ is defined and finite for bounded measurable left Γ_V-invariant T, T', with $|\langle T, T'\rangle_V| \le \mathrm{vol}([\mathrm{U}(V)]) \sup|T| \sup|T'|$, and $\langle T_y, T'\rangle_V = \langle T, T'_{y^{-1}}\rangle_V$ for $y \in G_\infty(s)$, by the substitution $g \mapsto g(y^{-1}, 1)$. The kernel e is integrable (ED1), so every form T of type e satisfies $R(e)T = T$ (ED2); forms are bounded and continuous, and a translate T_y of a form is again bounded, continuous and left invariant under Γ_V.

Step 1: $R(e)$ is self-adjoint. Let T, T' be bounded continuous functions on $\mathrm{G}(s)$, left invariant under Γ_V. The function $(g, y) \mapsto \overline{T(g)}\, e(y)\, T'(g(y, 1))$ on $[\mathrm{U}(V)] \times G_\infty(s)$ is bounded

by $\sup|T|\sup|T'|\,|e(y)|$, which is integrable for the product of the finite quotient measure and dx. By Fubini,

$$\langle T, R(e)T'\rangle_V = \int_{G_\infty(s)} e(y)\,\langle T, T'_y\rangle_V\,dy = \int_{G_\infty(s)} e(y)\,\langle T_{y^{-1}}, T'\rangle_V\,dy = \int_{G_\infty(s)} e(y^{-1})\,\langle T_y, T'\rangle_V\,dy,$$

by the translation rule of the preliminaries and the substitution $y \mapsto y^{-1}$. As $e(y^{-1}) = \overline{e(y)}$ (ED1), the last integral is $\int \overline{e(y)}\,\langle T_y, T'\rangle_V\,dy$, which by Fubini in the same way equals $\int_{[\mathrm{U}(V)]} \overline{\int e(y)T(g(y,1))\,dy}\;T'(g)\,dg = \langle R(e)T, T'\rangle_V$.

Step 2: the rank one formula. Let T be a form of type e and $x \in G_\infty(s)$. For $g \in \mathrm{G}(s)$, since $R(e)T = T$,

$$(R(e)T_x)(g) = \int e(z)\,T(g(zx,1))\,dz = \int e(z)\int e(y)\,T(g(zxy,1))\,dy\,dz.$$

The integrand is bounded by $\sup|T|\,|e(z)|\,|e(y)|$, integrable on $G_\infty(s)^2$. Substituting $y' = zxy$ in the inner integral (left invariance of dy) and applying Fubini,

$$\begin{aligned}(R(e)T_x)(g) &= \int\Big(\int e(z)\,e\big((zx)^{-1}y'\big)\,dz\Big)T(g(y',1))\,dy' \\ &= \frac{e(x^{-1})}{e(1)}\int e(y')\,T(g(y',1))\,dy' = \frac{\overline{e(x)}}{e(1)}\,T(g),\end{aligned}$$

by the idempotent law of (ED1), then $R(e)T = T$ and $e(x^{-1}) = \overline{e(x)}$.

Step 3: conclusion. $F = R(e)F$, Step 1 applied to $T = F$, $T' = F'_x$, and Step 2 applied to $T = F'$ give

$$\langle F, F'_x\rangle_V = \langle R(e)F, F'_x\rangle_V = \langle F, R(e)F'_x\rangle_V = \Big\langle F, \frac{\overline{e(x)}}{e(1)}F'\Big\rangle_V = \frac{\overline{e(x)}}{e(1)}\langle F, F'\rangle_V,$$

the product being linear in its second argument. □

Lemma 6.3.79. *Let S, T be spaces and $v \in \mathcal{F}_{S,T}$ a Schwartz vector. There is a sequence of polynomials P_k such that $\mathrm{mom}_N(v - v_{P_k}) \to 0$ as $k \to \infty$, for every $N \in \mathbb{N}$.*

Proof. Let $d = \#\iota$; if $d = 0$ then $\mathcal{F}_\varepsilon = \mathbb{C}$, every vector is v_P for a constant P, and there is nothing to prove. Let $d \geq 1$ and write $|\cdot|$ for the euclidean norm of $\mathbb{C}^\iota$; two norms on $\mathbb{C}^\iota$ are equivalent, so $(1+\|z\|)^N \leq C_N(1+|z|)^N$ and conversely, and it suffices to prove the claim for the moments formed with $|\cdot|$.

Step 1: the reproducing kernel. For $x, y \in \mathbb{C}^\iota$ put $\sigma(y,x) = \zeta(y)^*\zeta(x) = \sum_{i\in\iota}\overline{\zeta(y)_i}\,\zeta(x)_i$. Expanding $|x-y|^2 = |x|^2+|y|^2-x^*y-y^*x$ in the exponent of $\beta^\infty_\varepsilon(y,x)e^\infty(x-y)$, the contribution of a coordinate i is $\bar{x}_i y_i$ if $\varepsilon_i = 1$ and $\bar{y}_i x_i$ if $\varepsilon_i = -1$, so

$$\beta^\infty_\varepsilon(y,x)\,e^\infty(x-y) = e^\infty(x)\,e^\infty(y)\,\exp\big(\sigma(y,x)\big), \qquad |\sigma(y,x)| \leq |x|\,|y|.$$

Hence, by the reproducing identity of $v \in \mathcal{F}_\varepsilon$,

$$v(x) = e^\infty(x)\int v(y)\,e^\infty(y)\,\exp\big(\sigma(y,x)\big)\,d\nu(y) \qquad (x \in \mathbb{C}^\iota).$$

Step 2: the polynomials. For $k \geq 1$ let

$$P_k(X) = \int v(y)\,e^\infty(y)\sum_{j<k}\frac{1}{j!}\Big(\sum_{i\in\iota}\overline{\zeta(y)_i}\,X_i\Big)^j d\nu(y),$$

a polynomial of degree less than k: expanding the powers, its coefficients are integrals of $v(y)e^{\infty}(y)$ times monomials in the $\overline{\zeta(y)}_i$, which converge because $e^{\infty}(y)|y|^j$ is bounded and v is integrable. By (WR5), $v_{P_k}(x) = P_k(\zeta(x))e^{\infty}(x)$, so with $R_k(\sigma) = \sum_{j\geq k}\sigma^j/j!$, Step 1 gives

$$v(x) - v_{P_k}(x) = e^{\infty}(x)\int v(y)\,e^{\infty}(y)\,R_k\big(\sigma(y,x)\big)\,d\nu(y).$$

Step 3: domination. Let $N \in \mathbb{N}$. By Tonelli,

$$\begin{aligned}\mathrm{mom}_N(v - v_{P_k}) &\leq \iint g_k(x,y)\,d\nu(y)\,d\nu(x),\\ g_k(x,y) &= (1+|x|)^N e^{\infty}(x)e^{\infty}(y)\,|v(y)|\,\big|R_k(\sigma(y,x))\big|.\end{aligned}$$

For fixed (x,y), $R_k(\sigma(y,x)) \to 0$ as $k\to\infty$ (tail of a convergent series), and $|R_k(\sigma)| \leq e^{|\sigma|} \leq e^{|x||y|}$. Since $-\frac{1}{2}|x|^2 - \frac{1}{2}|y|^2 + |x||y| = -\frac{1}{2}(|x|-|y|)^2$,

$$g_k(x,y) \leq G(x,y) = (1+|x|)^N e^{-(|x|-|y|)^2/2}\,|v(y)|.$$

In polar coordinates on $\mathbb{C}^{\iota} = \mathbb{R}^{2d}$, with $r = |y|$ and $1+\varrho \leq (1+r)(1+|\varrho - r|)$,

$$\begin{aligned}\int (1+|x|)^N e^{-(|x|-r)^2/2}d\nu(x) &= c_d\int_0^{\infty}(1+\varrho)^N \varrho^{2d-1}e^{-(\varrho-r)^2/2}d\varrho\\ &\leq c_d(1+r)^{N+2d-1}\int_{\mathbb{R}}(1+|u|)^{N+2d-1}e^{-u^2/2}du,\end{aligned}$$

c_d the ν-measure factor of the unit sphere. Hence $\iint G \leq C\,\mathrm{mom}_{N+2d-1}(v) < \infty$, v being a Schwartz vector. By dominated convergence $\iint g_k \to 0$, so $\mathrm{mom}_N(v - v_{P_k}) \to 0$. The polynomials P_k do not depend on N, which proves the claim for every N. □

Lemma 6.3.80. *Let $\mathfrak{m}$ be a modulus.*

(a) Let S, T_1, T_2 be spaces with points with signs on n, n_1, n_2. For $i = 1,2$ let $P_i \in \mathbb{C}[x]_{n_i\times n}$ and let Φ_i be a function on $\mathrm{M}_{n_i\times n}(R_{\mathfrak{m}})$. Let $P_1P_2 \in \mathbb{C}[x]_{(n_1\sqcup n_2)\times n}$ be the product of P_1 and P_2 read in the variables of the rows n_1 and n_2, and $\Phi_1\otimes\Phi_2$ the function $y \mapsto \Phi_1(y_1)\Phi_2(y_2)$ on $\mathrm{M}_{(n_1\sqcup n_2)\times n}(R_{\mathfrak{m}})$, y_i the matrix of the rows n_i of y. Then, in $\mathcal{M}_{S,T_1\oplus T_2}$,

$$\mathrm{mod}_{\mathfrak{m}}(\Phi_1\otimes\Phi_2,\, v_{P_1P_2}) = \mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_{P_1}) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_{P_2}).$$

(b) Let S_1, S_2, T be spaces with points with signs on n_1, n_2, n'. For $i = 1,2$ let $P_i \in \mathbb{C}[x]_{n'\times n_i}$ and let Φ_i be a function on $\mathrm{M}_{n'\times n_i}(R_{\mathfrak{m}})$. Let $P_1P_2 \in \mathbb{C}[x]_{n'\times(n_1\sqcup n_2)}$ be the product of P_1 and P_2 read in the variables of the columns n_1 and n_2, and $\Phi_1\otimes\Phi_2$ the function $x \mapsto \Phi_1(x_1)\Phi_2(x_2)$ on $\mathrm{M}_{n'\times(n_1\sqcup n_2)}(R_{\mathfrak{m}})$, x_i the matrix of the columns n_i of x. Then, in $\mathcal{M}_{S_1\oplus S_2,T}$,

$$\mathrm{mod}_{\mathfrak{m}}(\Phi_1\otimes\Phi_2,\, v_{P_1P_2}) = \mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_{P_1}) \boxtimes^{\mathrm{sc}} \mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_{P_2}).$$

Proof. The two cases are proved together. Let $A = \Sigma(\mathfrak{m})$ and $N = n_1 \sqcup n_2$. In case (a) the space is $\mathrm{Hom}(S, T_1\oplus T_2)$, its coordinates are those of $N\times n$ matrices and the two blocks are the rows n_1, n_2; in case (b) the space is $\mathrm{Hom}(S_1\oplus S_2, T)$, its coordinates are those of $n'\times N$ matrices and the two blocks are the columns n_1, n_2. Read every function of such matrices (archimedean, finite or adelic, and on Φ times the coordinates for the Fock model) as a function of the pair of its two blocks, and write $f_1\boxtimes f_2$ for $(x_1,x_2)\mapsto f_1(x_1)f_2(x_2)$; thus $\boxtimes^{\mathrm{tg}}$ in case (a) and $\boxtimes^{\mathrm{sc}}$ in

case (b) are $\boxtimes$ for the identity bijection on each part. By (VP5) of Definition 3.2.2 the signs of the space, $(i,j)\mapsto t(i)s(j)$, restrict on the two blocks to those of $\mathrm{Hom}(S,T_1)$ and $\mathrm{Hom}(S,T_2)$ in case (a), and of $\mathrm{Hom}(S_1,T)$ and $\mathrm{Hom}(S_2,T)$ in case (b); and the theta models and Fock models depend only on the signs.

Step 1: factorisation of the ingredients. The bicharacters β of (WD6) and β^∞ of (WR5), the vacua e of (WD5) and e^∞, the phase of (WD8), the functions τ_y of (WR6), the holomorphic coordinates ζ of (WR5), the maps fv, rv and the measures μ, ν are sums, products or product measures over the coordinates, and the coordinates of the space are the disjoint union of those of the two blocks. Hence: (i) $\rho(z)(f_1\boxtimes f_2)=\rho(z_1)f_1\boxtimes\rho(z_2)f_2$ for $z=(z_1,z_2)$; (ii) $v^0=v^0\boxtimes v^0$; (iii) $v_{P_1P_2}=v_{P_1}\boxtimes v_{P_2}$; (iv) $\tau_{(y_1,y_2)}=\tau_{y_1}\boxtimes\tau_{y_2}$; (v) $(\Phi_1\otimes\Phi_2)^\natural=\Phi_1^\natural\boxtimes\Phi_2^\natural$, since the components at A of a matrix are integral exactly when those of both blocks are, and then the reduction modulo $\mathfrak{m}$ is taken blockwise.

Step 2: Schrödinger data. If $\Psi=\sum_y a_y\tau_y$ is any finite expansion, then $\Psi\otimes_A f=\sum_y a_y\rho(\mathrm{fv}(y))P^Af$: a linear section taking Ψ to (a_y) exists (extend from a basis containing Ψ), and the datum does not depend on the section. Expand $\Phi_i^\natural=\sum_y a_y^i\tau_y$ ($\mathcal{T}_A$ is spanned by the τ_y). By (iv), (v), $(\Phi_1\otimes\Phi_2)^\natural=\sum a^1_{y_1}a^2_{y_2}\tau_{(y_1,y_2)}$, so by $P^Av^0=v^0$, (i) and (ii),

$$(\Phi_1\otimes\Phi_2)^\natural\otimes_A v^0=\sum a^1_{y_1}a^2_{y_2}\,\rho(\mathrm{fv}(y_1))v^0\boxtimes\rho(\mathrm{fv}(y_2))v^0=(\Phi_1^\natural\otimes_A v^0)\boxtimes(\Phi_2^\natural\otimes_A v^0).$$

Step 3: data of products. Let v_i be Fock vectors and f_i vectors of the theta models of the two blocks. Evaluation at a point is a bounded functional ($|f(x)|=|\langle\rho(x)e,f\rangle|\le\|f\|$ as $|e|\le1$), so it commutes with the Bochner integral defining $v\otimes f$, and

$$\begin{aligned}((v_1\boxtimes v_2)\otimes(f_1\boxtimes f_2))(x)&=\int v_1(t_1)v_2(t_2)\,\beta(\mathrm{rv}(t),x)\,(f_1\boxtimes f_2)(x-\mathrm{rv}(t))\,d\nu(t)\\&=(v_1\otimes f_1)(x_1)\,(v_2\otimes f_2)(x_2)\end{aligned}$$

by Step 1 (factorisation of β, rv and ν) and Fubini (the integrand is bounded by

$$|v_1(t_1)||v_2(t_2)|\,\|f_1\|\|f_2\|,$$

which is integrable). So

$$(v_1\boxtimes v_2)\otimes(f_1\boxtimes f_2)=(v_1\otimes f_1)\boxtimes(v_2\otimes f_2).$$

Conclusion. By (iii), Step 2 and Step 3,

$$\mathrm{mod}_{\mathfrak{m}}(\Phi_1\otimes\Phi_2,v_{P_1P_2})=(v_{P_1}\boxtimes v_{P_2})\otimes((\Phi_1^\natural\otimes_A v^0)\boxtimes(\Phi_2^\natural\otimes_A v^0))=\mathrm{mod}_{\mathfrak{m}}(\Phi_1,v_{P_1})\boxtimes\mathrm{mod}_{\mathfrak{m}}(\Phi_2,v_{P_2}),$$

which is $\boxtimes^{\mathrm{tg}}$ in case (a) and $\boxtimes^{\mathrm{sc}}$ in case (b). □

6.4 Auxiliary forms span the target forms

This section proves that auxiliary forms span the target forms (Lemma 6.4.5), for a scaling γ of the twists with $\gamma(1)=1$ and $|\gamma(\vartheta)|=\mathrm{N}Q(\vartheta)^{e/2}\prod_{0\le i,j<m}\tau_{ij}(\vartheta)$. It follows from a statement about all forms of principal level on Y_0 (Proposition 6.4.6), which the good projection carries to the target forms.

The difficulty is that the chain Θ_ϑ runs through indefinite groups and integrality must hold for every twist at once, while integrality and size can be read off only on definite groups, where forms are algebraic modular forms [110]. The proof therefore moves the chain to definite spaces

through two grids of hermitian spaces (Definition 3.2.28), whose row m consists of definite spaces. A path through the grids pairs a form on Y_m with a form on the second grid, by moving both along its two halves and taking a period where they meet. On the first path the pairing is a period of a flat restriction, which is onto by deep-level vanishing (Lemma 6.4.9). Each turn of a path across a unit square is an instance of the one-square identity and costs one turn ratio, so the m^2 turns to the last path cost $\prod_{i,j}\tau_{ij}$ (Proposition 6.4.87). On the last path all spaces are definite, and the periods are finite sums with one denominator for all twists (Proposition 6.4.80). In our reading this is the device of the seesaw identity of Section 4, carried out in two directions on a grid rather than along one chain.

The section opens with the discrete series of $\mathrm{U}(p,q)$ and its parameters (Definition 6.4.1; see [119], and [163] for lowest K-types), followed by the objects of the first and the last path. The last path is defined for arbitrary weight parameters (Definition 6.4.4); right after it the weights are fixed, once and for all, as the numbers of Lemma 6.4.3. For Weyl modules realised by products of minors and their integral structure see [91, 3, 67, 151]. Deep level is measured with the sizes of Definition 5.6.3 (Section 5.6), and the type kernels are built from Flensted-Jensen's functions [81].

Definition 6.4.1. Let $n \geq 1$ and $j = (j_1, \dots, j_n) \in \{\pm 1\}^n$ a **signature vector**, with $p(j) = \#\{a : j_a = 1\}$, $q(j) = \#\{a : j_a = -1\}$ and $q_0(j) = \min(p(j), q(j))$. Put $J_j = \mathrm{diag}(j_1, \dots, j_n)$ and

$$\mathrm{U}(J_j) = \{g \in \mathrm{GL}_n(\mathbb{C}) : g^* J_j g = J_j\} \cong \mathrm{U}(p(j), q(j)),$$

with maximal compact subgroup $K_j = \mathrm{U}(J_j) \cap \{g : gJ_j = J_j g\} \cong \mathrm{U}(p(j)) \times \mathrm{U}(q(j))$ and diagonal maximal torus $T = \{\mathrm{diag}(e^{i\theta_1}, \dots, e^{i\theta_n})\} \subset K_j$. A weight $\mu \in \mathbb{R}^n$ is the character $\mathrm{diag}(e^{i\theta_a}) \mapsto e^{i\sum_a \mu_a \theta_a}$ of T. Put

$$\rho_c(j)_a = \tfrac{1}{2}\big(\#\{b > a : j_b = j_a\} - \#\{b < a : j_b = j_a\}\big),$$
$$\rho_n(j)_a = \tfrac{1}{2}\big(\#\{b > a : j_b \neq j_a\} - \#\{b < a : j_b \neq j_a\}\big).$$

(Hc1) A **Harish-Chandra parameter** is $\Xi \in \mathbb{R}^n$ with $\Xi_1 > \Xi_2 > \cdots > \Xi_n$ and $\Xi_a - \frac{n-1}{2} \in \mathbb{Z}$ for all a.

(Hc2) Ξ has **gap at least** h for j if $|\Xi_a - \Xi_b| \geq h$ whenever $j_a \neq j_b$.

(Hc3) Its **Blattner parameter** (lowest K-type) is $\beta_j(\Xi) = \Xi + \rho_n(j) - \rho_c(j)$, and the compact dominance order is: $\mu \preceq \mu'$ if $\mu' - \mu$ is a nonnegative integer combination of $e_a - e_b$ with $a < b$, $j_a = j_b$.

(Hc4) The **discrete-series gap threshold** is $h_{\mathrm{DS}}(j) = \max\big(n\,p(j)\,q(j) + 1,\ 16\,n\,q_0(j) + 8\sqrt{2q_0(j)}\big)$.

A unitary representation $(\pi, \mathcal{H})$ of $\mathrm{U}(J_j)$ on a nonzero Hilbert space is a **discrete series with parameter** Ξ if it is irreducible, its matrix coefficients are square-integrable, it contains an irreducible K_j-subrepresentation of highest weight $\beta_j(\Xi)$ (highest with respect to $\preceq$), and every K_j-type μ occurring in π satisfies $\|\mu + 2\rho_c(j)\| \geq \|\beta_j(\Xi) + 2\rho_c(j)\|$.

Definition 6.4.2. Let D be admissible data, ϑ an m-fold twist and $z \in \{\mathrm{I}, \mathrm{II}\}$; the first column of the grid z consists of the nodes $(z, 0, j)$, $0 \leq j \leq m$, with the spaces Y_j ($z = \mathrm{I}$) and $\tilde{Y}_0^j$ ($z = \mathrm{II}$), which are the spaces $V^0_{z,j}$ of (TV1). For $j \geq 0$ let $e^{\mathrm{col}}_{z,j}$ be the edge $((z,0,j),(z,0,j+1))$.

(FY1) Transposed point lifts and the transposed chain. For $j < m$, with $S = V^0_{z,j}$, $T = V^0_{z,j+1}$ and ν_1, ν_2, φ those of the triangle lift $\mathrm{Tl}^0_{\vartheta,z,j}$ ((TV3)), the **transposed point lift**

sends $F \in \mathcal{F}(z,0,j+1)$ to the function

$$\mathrm{Pt}_{\vartheta,z,j}F\,(g) = \#\mathrm{GL}_{n_{z,0,j}}(\mathcal{O}_E/\mathfrak{t}_\vartheta(z)) \int_{[\mathrm{U}(T)]} \theta^{S,T}_{\nu_1,\nu_2}(\varphi)(g,h)\,F(h)\,dh$$

on the adelic group of S. The **transposed chain** is $\Theta^\flat_{\vartheta,z,m} = \mathrm{id}$ and $\Theta^\flat_{\vartheta,z,j} = \mathrm{Pt}_{\vartheta,z,j} \circ \Theta^\flat_{\vartheta,z,j+1}$ $(j < m)$; write $\Theta^\flat = \Theta^\flat_{1,\mathrm{II},0}$.

(FY2) Forms of deep level. For $0 \le i \le m$, $\mathcal{F}_\mathfrak{b}(i)$ is the space of the grid forms $\varphi \in \mathcal{F}(\mathrm{II},0,i)$ on $\tilde{Y}^i_0$ with $\varphi(gk) = \varphi(g)$ for all g and all $k \in \mathbf{K}_0(n_{\mathrm{II},0,i})$ whose reduction modulo $\mathfrak{b}$ is 1.

(FY3) Flat restrictions. For an m-fold twist ϑ let $\mathrm{K}_\vartheta(Y_0) \subseteq \mathbf{K}_0(n_{\mathrm{I},0,0})$ be the group of the elements whose reduction modulo every chosen place and every place of Q is 1, and $\mathcal{F}^+_\vartheta(Y_0)$ the forms on Y_0 of type e_λ, $\lambda = \frac{1}{2}p_{\mathrm{I},0,0}$, fixed by $\mathrm{K}_\vartheta(Y_0)$. For a real point $g \in G_\infty(s)$ of $\tilde{Y}^0_0 = Y_0 \oplus \langle 1\rangle$, a linear map $r\colon \mathcal{F}_\mathfrak{b}(m) \to \mathcal{A}_M(Y_0)$ is a **flat restriction** at g if for all $\varphi \in \mathcal{F}_\mathfrak{b}(m)$, all m-fold twists ϑ and all $y \in \mathcal{F}^+_\vartheta(Y_0)$

$$\langle y, r\varphi\rangle_{Y_0} = \int_{[\mathrm{U}(Y_0)]} \overline{y(x)}\;(\Theta^\flat\varphi)\big(\mathrm{diag}(x,1)\,(g,1)\big)\,dx.$$

(FY4) The point data of the first path. For an edge tuple S for ϑ, the **point datum** of the first path is

$$\Psi^1(S) = \prod_z \prod_{0\le j<m} \Phi^{\mathrm{pt}}_j(S(e^{\mathrm{col}}_{z,j}) \bmod \mathfrak{t}_\vartheta(z)),$$

Φ^{pt}_j the point datum of (TV3) for the triangle z and the matrix reduced from $R_{\mathfrak{m}_\vartheta}$ to R_ϑ. A **level coset family** x is a choice, for each z and $0 \le j < m$, of a coset $x_{z,j}$ in $\mathrm{GL}_{n_{z,0,j}}(R_{\mathfrak{m}_\vartheta})$ of the trivial subgroup if $z = \mathrm{I}$ and of the kernel of the reduction modulo $\mathfrak{b}$ if $z = \mathrm{II}$. Fix a representative of each coset; the **family** g_x of x is the family of invertible matrices modulo $\mathfrak{m}_\vartheta$ at the nodes with the representative of $x_{z,j}$ at $(z,0,j)$, except $g_x(\mathrm{II},0,0) = g_x(\mathrm{I},0,0)\oplus 1$, and 1 at all other nodes. The **first-path datum** is

$$\Psi^0(S) = \sum_x \epsilon_w(g_x)\,\Psi^1(g_x \cdot S),$$

the sum over the level coset families, w the set of edges of the first path.

Lemma 6.4.3. *Let D be admissible data and $z \in \{\mathrm{I},\mathrm{II}\}$. For $0 \le i \le m$ let N_i be the rank of the space at the node (z,i,m), n_i the index set of its basis, and $\gamma_i = \gamma_{z,i}$, so that $\gamma_i(N)(v) = \lfloor (N+[\neg z])/2\rfloor - \kappa_{i+1}(v)$ is the weight of the character of the lift move along $((z,i,m),(z,i+1,m))$ at an end of rank N. There are natural numbers $\kappa(v,h)$ ($v \in \Phi$, $h \ge 1$; the number of columns of height h) and integers $e_i(v)$ ($0 \le i \le m$, $v \in \Phi$) such that:*

(1) for $0 \le i < m$: $N_i < N_{i+1}$, $\kappa(v,h) = 0$ for $N_i < h < N_{i+1}$, and $e_i(v) = \gamma_i(N_{i+1})(v) + \kappa(v,N_i)$, for every v;

(2) for $0 \le i < m$: $\gamma_i(N_i) = e_{i+1}$;

(3) for $0 \le i \le m$, the family $(a \mapsto -p_{z,i,m}(v)(a))_{v\in\Phi}$ of maps $n_i \to \mathbb{Z}$ is a doubled Harish-Chandra parameter of (κ, e_i) on n_i, κ read in the rank N_i;

(4) for $0 \le i \le m$, $\sum_{v\in\Phi}\sum_{1\le h<N_i} h\,\kappa(v,h) \le b\,r^4$;

(5) for $0 \le i \le m$, $|e_i(v)| \le 20b$ for every $v \in \Phi$.

Proof. Fix $v \in \Phi$ and z; write $c_j = \kappa_j(v)$, $R = r^8$, $[z] \in \{0,1\}$, and $d_i = 1$ if $z = \mathrm{I}$ and i is odd, $d_i = 0$ otherwise (the δ of (GP5) at the node (z,i,m), as m is even). Put $q_i = -p_{z,i,m}(v)\colon n_i \to \mathbb{Z}$. By (GP5) its entries are:

- at the down index (l,c), $1 \le l \le m$, $0 \le c < t - [z]$: $2c_l - t + [z] + 1 + 2c + d_i$;
- at the base index j' with $k-1 \le j' \le r - 1 + [z]$, $j = j' + 2 - k \in \{1, \dots, m + [z]\}$: $2c_j - 2R - [z] + d_i$;
- at the base index $j' < k - 1$: $2j' - k + 2 - [z] + d_i$;
- at the up index (l,c), $1 \le l \le i$, $0 \le c < t + [z]$: $-2c_l - t - [z] + 1 + 2c + d_i$.

The ranks are $N_i = r + (i+m)t$ for $z = \mathrm{I}$ and $N_i = r + 1 + i(t+1) + m(t-1)$ for $z = \mathrm{II}$, so $N_{i+1} = N_i + t + [z]$.

Step 1: the entries of q_i are distinct and $\equiv N_i - 1 \pmod 2$. All entries are $\equiv [z] + d_i \pmod 2$ (t odd); and $N_i - 1 \equiv i \equiv d_i$ for $z = \mathrm{I}$, $N_i - 1 \equiv r \equiv 1$ for $z = \mathrm{II}$ (r, t odd, m even). Within one group (a down block, the small base indices $j' < k-1$, an up block) consecutive entries differ by 2. Each group lies within distance $t+k+2$ of its centre: $2c_l = 2\kappa(v) + (4l+2)R$ for the down block l, $2\kappa(v) + 4jR$ for the base entry j, 0 for the small base entries, $-2\kappa(v) - (4l+2)R$ for the up block l; distinct centres differ by at least $2R > 2(t+k+2)$. So the entries are distinct, and in decreasing order the groups are: down block m (for $z = \mathrm{II}$ preceded by the base entry $m+1$), base entry m, down block $m-1$, …, down block 1, base entry 1, the small base entries, up block 1, …, up block i.

Step 2: definition of κ and e_i. Let $u_0^{(i)} > u_1^{(i)} > \cdots > u_{N_i-1}^{(i)}$ be the entries of q_i. The entries of q_i are those of q_{i+1} outside the up block $i+1$, shifted by $d_i - d_{i+1}$, and by Step 1 the up block $i+1$ consists of the $t + [z]$ smallest entries of q_{i+1}. Hence $u_p^{(i)} = u_p^{(m)} + d_i - d_m$ for $p < N_i$. Define, for $1 \le h < N_m$ and $h \ge N_m$ respectively,

$$\kappa(v,h) = \tfrac{1}{2}(u_{h-1}^{(m)} - u_h^{(m)}) - 1, \qquad \kappa(v,h) = 0, \qquad \text{and} \qquad e_i(v) = \tfrac{1}{2}(u_{N_i-1}^{(i)} + N_i - 1).$$

By Step 1 these are natural numbers and integers, and $\kappa(v,h) = \frac{1}{2}(u_{h-1}^{(i)} - u_h^{(i)}) - 1$ for $1 \le h < N_i$.

(3). With $\lambda(p) = \sum_{p<h<N_i} \kappa(v,h)$, the numbers $\mathrm{hc}(p) = 2(e_i(v) + \lambda(p)) + N_i - 1 - 2p$ satisfy $\mathrm{hc}(N_i - 1) = 2e_i(v) - N_i + 1 = u_{N_i-1}^{(i)}$ and $\mathrm{hc}(p) - \mathrm{hc}(p+1) = 2\kappa(v, p+1) + 2 = u_p^{(i)} - u_{p+1}^{(i)}$; so $\mathrm{hc}(p) = u_p^{(i)}$ for all p. Thus q_i is injective and each of its values is some $\mathrm{hc}(p)$, which is (3) at v.

(1), (2). $N_i < N_{i+1}$. For $N_i < h < N_{i+1}$, $u_{h-1}^{(i+1)}$ and $u_h^{(i+1)}$ are consecutive entries of the up block $i+1$, so $\kappa(v,h) = 0$. Let $s_i = u_{N_i-1}^{(i)}$ be the smallest entry of q_i; for $i \ge 1$ it is the entry $(i,0)$ of the up block i, $s_i = -2c_i - t - [z] + 1 + d_i$. The largest entry of the up block $i+1$ of q_{i+1} is $-2c_{i+1} + t + [z] - 1 + d_{i+1}$, and the entry of q_{i+1} just above it is $s_i + d_{i+1} - d_i$. Hence

$$\kappa(v,N_i) = \tfrac{1}{2}(s_i - d_i + 2c_{i+1} - t - [z] - 1), \qquad e_i(v) - \kappa(v,N_i) = \tfrac{1}{2}(N_i + t + [z] + d_i) - c_{i+1},$$

$$e_{i+1}(v) = \tfrac{1}{2}(s_{i+1} + N_{i+1} - 1) = \tfrac{1}{2}(N_i + d_{i+1}) - c_{i+1}.$$

It remains to check $\frac{1}{2}(N_i + t + [z] + d_i) = \lfloor \frac{1}{2}(N_{i+1} + [\neg z]) \rfloor$ and $\frac{1}{2}(N_i + d_{i+1}) = \lfloor \frac{1}{2}(N_i + [\neg z]) \rfloor$. For $z = \mathrm{II}$, $d = 0$ and N_i is even, $t+1$ even, so both sides agree. For $z = \mathrm{I}$, $N_i \equiv i + 1$: if i is even, $N_i + t$ is even, $d_i = 0$, $d_{i+1} = 1$, N_i odd; if i is odd, $N_i + t$ is odd, $d_i = 1$, $d_{i+1} = 0$, N_i even; in each case both identities hold. This is (1) and (2) at v.

(4), (5). By Lemma 4.2.67, $f \le x^{12}$, $r \le 3x^5$, $t \le 15x^5$, $m \le 2\sqrt{x}$, $R \le 3^8 x^{40}$, $x^{10^{12}} \le b$, and $r \ge x^5$ by (AD2); also $\kappa(v) \le b$ since $x \le x_1$. Every entry of every q_i ($i \le m$) has absolute value

at most $2c_{m+1}+t+k+2 \le 2b+2(2m+3)R+t+k+2 \le 3b$. Since $\kappa(v,h)=\frac{1}{2}(u_{h-1}-u_h)-1$, summation by parts gives

$$\sum_{1\le h<N_i} h\,\kappa(v,h) \le \tfrac{1}{2}\sum_{h=1}^{N_i-1} h\,(u^{(i)}_{h-1}-u^{(i)}_h) = \tfrac{1}{2}\sum_{p=0}^{N_i-1}(u^{(i)}_p - u^{(i)}_{N_i-1}) \le 3bN_i.$$

With $N_i \le r+1+2mt \le 64x^{11/2}$, the sum over $v\in\Phi$ is at most $3b\,x^{12}\cdot 64x^{11/2} = 192\,x^{35/2}b \le x^{20}b \le b\,r^4$, as $x^{5/2}\ge 192$. Finally $|e_i(v)| \le \frac{1}{2}(3b+N_i) \le 2b \le 20b$, as $N_i \le b$. □

Definition 6.4.4. Let D be admissible data. For $z\in\{\mathrm{I},\mathrm{II}\}$ and $i\ge 0$ let $n_{z,i}$ be the index set of the basis of the space at the node (z,i,m) and $N_{z,i}=\#n_{z,i}$; for $i\le m$ these spaces are positive definite ((GP4)), so their adelic unitary group is $G_\infty(1)\times G_f(n_{z,i})$. The edges of the half z of the last path are $e_{z,i}=((z,i,m),(z,i+1,m))$, $0\le i<m$.

(LQ1) Weights. For $0\le i\le m$ let $l_{z,i}=-p_{z,i,m}$ be the family of the maps $a\mapsto -p_{z,i,m}(v)(a)$ on $n_{z,i}$ ($v\in\Phi$). For each z let natural numbers $\kappa_z(v,h)$ ($v\in\Phi$, $h\ge 1$) and integers $e^{\det}_{z,i}(v)$ ($v\in\Phi$, $0\le i\le m$) be given, the **weight parameters** of the half z (the $e^{\det}_{z,i}$ are the determinant exponents; the letter $e_{z,i}$ alone denotes an edge), with the following two properties:

(i) $\kappa_z(v,h)=0$ for $N_{z,i}<h<N_{z,i+1}$, for every $v\in\Phi$ and $0\le i<m$;

(ii) for $0\le i\le m$, $l_{z,i}$ is a doubled Harish-Chandra parameter of $(\kappa_z, e^{\det}_{z,i})$ on $n_{z,i}$, κ_z read in the rank $N_{z,i}$.

This definition uses no other property of them. For $0\le i\le m$ the weight at (z,i,m) is $(\kappa_z,e^{\det}_{z,i})$, κ_z read in the rank $N_{z,i}$; its Weyl module is $\mathbb{V}_{z,i}=\mathbb{V}_{\kappa_z}$ in the rank $N_{z,i}$, with index set $I_{z,i}$, and its algebraic forms are $\mathcal{A}_{z,i}=\mathcal{A}_{n_{z,i}}(\kappa_z,e^{\det}_{z,i})$.

(LQ2) Levels. For an m-fold twist ϑ, the **level** $\mathrm{K}_\vartheta(z,i)\subseteq\mathbf{K}_0(n_{z,i})$ is the group of the elements whose reduction modulo $\mathfrak{m}_\vartheta$ is 1 if $(z,i)=(\mathrm{I},0)$, and of those whose reduction modulo $\mathfrak{b}$ is 1 otherwise; the reduction modulo an ideal $\mathfrak{a}$ is the map $\mathbf{K}_0(n)\subseteq\mathrm{GL}_n(\widehat{\mathcal{O}}_E)\to\mathrm{GL}_n(\mathcal{O}_E/\mathfrak{a})$.

(LQ3) Class integrals. Let n be an index set, $\mathrm{K}\subseteq\mathbf{K}_0(n)$ an open subgroup and F a function on $G_f(n)$ with values in a complex vector space, left invariant under the finite components of the rational points of I_n and right invariant under an open subgroup of $G_f(n)$. With $\mathrm{K}_F=\{k\in\mathrm{K}: F(gk)=F(g)\text{ for all }g\}$, the **class integral** of F at the level K is

$$\mathrm{CI}_\mathrm{K}(F)=[\mathrm{K}:\mathrm{K}_F]^{-1}\sum_{[h]}\frac{1}{\#\Gamma_h}F(h),$$

the class sum of Definition 3.2.23 for the level K_F.

(LQ4) Algebraic theta lifts. Let $0\le i<m$, $n=n_{z,i}$, $n'=n_{z,i+1}$, $N=N_{z,i}$, $N'=N_{z,i+1}$, and suppose $N\le N'$, so that by (i) of (LQ1) the Schur matrix of κ_z from the rank N to the rank N' is defined ((WM2)); let $\mathcal{M}_{n,n'}$ be the theta model of $\mathrm{Hom}(\mathrm{I}_n,\mathrm{I}_{n'})$, $\theta_{n,n'}$ its canonical theta functional. Let $X=(X_\tau)_{\tau\in\Phi}$ be the $n'\times n$ matrices of the variables $X_{\tau,b,a}$ ($b\in n'$, $a\in n$) of the Fock model of $\mathrm{Hom}(\mathrm{I}_n,\mathrm{I}_{n'})$, and $P_{i'i}$ the entry (i',i) of the Schur matrix $S_{\kappa_z}(X)$ from the rank N to the rank N' ($i'\in I_{z,i+1}$, $i\in I_{z,i}$). For $f\in\mathcal{M}_{n,n'}$ the **jet matrix** $\mathrm{jm}(f)\in\mathrm{M}_{I_{z,i+1}\times I_{z,i}}(\mathbb{C})$ has the entries

$$\mathrm{jm}(f)_{i'i}=\theta_{n,n'}(v_{P_{i'i}(\eta_P X)}\otimes f),$$

$P(\eta_P X)$ the polynomial obtained by substituting $\eta_P X_{\tau,b,a}$ for $X_{\tau,b,a}$. For an m-fold twist ϑ let α and β be the edge characters of the lift move along $e_{z,i}$ at the ends of ranks N and N' ((GP6) of Definition 3.2.28), and write $(1,g)$ for the adelic point with archimedean component 1. The **algebraic theta lift** along $e_{z,i}$ with datum f is the partial map sending a function $\eta\colon G_f(n) \to \mathbb{V}_{z,i}$ to the function on $G_f(n')$

$$\mathrm{Al}_{\vartheta,z,i}(f)\eta\,(h) = \mathrm{CI}_{\mathrm{K}_\vartheta(z,i)}\Big(g \mapsto \mathrm{jm}\big(\omega_{\alpha,\beta}((1,g),(1,h))f\big)\,\eta(g)\Big).$$

It is defined at η when, for every $h \in G_f(n')$, the integrand $g \mapsto \mathrm{jm}(\omega_{\alpha,\beta}((1,g),(1,h))f)\,\eta(g)$ satisfies the hypotheses of (LQ3) for the index set n. For an edge tuple S for ϑ, the **edge datum** is $\varphi^S_{z,i} = c_s^{NN'}\,\Phi^\natural \otimes_{\Sigma(\mathfrak{m}_\vartheta)} v^0 \in \mathcal{M}_{n,n'}$, where Φ is the indicator function of the matrix $S(e_{z,i})$ on the $n' \times n$ matrices over $R_{\mathfrak{m}_\vartheta}$.

(LQ5) Algebraic forms of grid forms and chains of lifts. The **algebraic form** of a grid form $y \in \mathcal{F}(z,0,m)$ is $y^\flat = y^\flat_{l_{z,0}}$, the algebraic form of the function y on $G_\infty(1) \times G_f(n_{z,0})$ for $l_{z,0}$ and the weight $(\kappa_z, e^{\det}_{z,0})$ ((WM7)). For an m-fold twist ϑ, an edge tuple S for ϑ and $y \in \mathcal{F}(z,0,m)$, the **chain of algebraic lifts** is

$$\mathrm{Lc}^S_{z,0}(y) = y^\flat, \qquad \mathrm{Lc}^S_{z,i+1}(y) = \mathrm{Al}_{\vartheta,z,i}(\varphi^S_{z,i})\,\mathrm{Lc}^S_{z,i}(y) \quad (0 \le i < m),$$

where $\mathrm{Lc}^S_{z,i+1}(y)$ is defined when $\mathrm{Lc}^S_{z,i}(y)$ is defined and $\mathrm{Al}_{\vartheta,z,i}(\varphi^S_{z,i})$ is defined at it ((LQ4)).

(LQ6) Branching pairings at (m,m). Let $n = n_{\mathrm{I},m}$ and $n' = n_{\mathrm{II},m}$, identified with $n \sqcup \{*\}$, $*$ the added line of (GP2); for g an $n \times n$ matrix and u a scalar, $\mathrm{diag}(g,u)$ is the $n' \times n'$ block matrix. Put $l = l_{\mathrm{I},m}$, $l' = l_{\mathrm{II},m}$ and let B_0 be the number of boxes $\sum_\tau \sum_{1 \le h < N'} h\,\kappa_{\mathrm{II}}(\tau,h)$, $N' = \#n'$. An integer matrix B with rows $I_{\mathrm{I},m}$ and columns $I_{\mathrm{II},m}$ is a **branching pairing at** (m,m) if:

(a) there are integers N_τ ($\tau \in \Phi$) with $|N_\tau| \le B_0 + |e^{\det}_{\mathrm{II},m}(\tau)|$ such that for every commutative ring S with an involution $x \mapsto \bar{x}$, every field R of characteristic 0, all ring homomorphisms $f_\tau\colon S \to R$ ($\tau \in \Phi$), every $g \in \mathrm{M}_n(S)$ with $\bar{g}^{\mathsf{T}} g = 1$, every $u \in S$ with $\bar{u}u = 1$ and all $v' \in R^{I_{\mathrm{I},m}}$, $v \in R^{I_{\mathrm{II},m}}$,

$$\big(P_{\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},m}}(f(g))\,v'\big)^{\mathsf{T}} B\, P_{\kappa_{\mathrm{II}}, e^{\det}_{\mathrm{II},m}}(f(\mathrm{diag}(g,u)))\,v = \prod_\tau f_\tau(u)^{N_\tau}\; v'^{\mathsf{T}} B v,$$

where $f(x)$ is the family $(f_\tau(x))_\tau$ of entrywise images;

(b) for every $M \in \mathbb{N}$ with $B_0 \le M$ and all $v' \in \mathbb{V}_{\mathrm{I},m}$, $v \in \mathbb{V}_{\mathrm{II},m}$, $|v'^{\mathsf{T}} B v| \le (M^M)^3\,\|v'\|_{\kappa_{\mathrm{I}}} \|v\|_{\kappa_{\mathrm{II}}}$;

(c) for every $g \in G_\infty(1)$ for n' there is $c \in \mathbb{C}$ such that for all $\eta \in \mathcal{A}_{\mathrm{I},m}$, $\varphi \in \mathcal{A}_{\mathrm{II},m}$, $u \in \mathrm{U}(1)(\mathbb{A}_f)$ and every open subgroup $\mathrm{K} \subseteq \mathbf{K}_0(n)$,

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} F^l_\eta(x)\,F^{l'}_\varphi\big(\mathrm{diag}(x,(1,u))\,(g,1)\big)\,dx = \frac{c}{[\mathbf{K}_0(n) : \mathrm{K}]}\,\mathrm{CI}_{\mathrm{K}}\Big(h \mapsto \eta(h)^{\mathsf{T}} B\,\varphi(\mathrm{diag}(h,u))\Big).$$

(LQ7) The last-path sum. For an m-fold twist ϑ and $h \in G_f(n_{\mathrm{I},m})$ the **block point** is $\mathrm{bp}_\vartheta(h) = \mathrm{diag}(h, \mathrm{flp}^m_\vartheta) \in G_f(n_{\mathrm{II},m})$. For a branching pairing B at (m,m), a function Ψ on the edge tuples for ϑ and a pair $y = (y_{\mathrm{I}}, y_{\mathrm{II}})$ with $y_z \in \mathcal{F}(z,0,m)$, the **last-path sum** is

$$\mathrm{Ls}_B(\Psi, y) = \sum_S \Psi(S)\;\mathrm{CI}_{\mathrm{K}_\vartheta(\mathrm{I},m)}\Big(h \mapsto \mathrm{Lc}^S_{\mathrm{I},m}(y_{\mathrm{I}})(h)^{\mathsf{T}} B\,\mathrm{Lc}^S_{\mathrm{II},m}(y_{\mathrm{II}})(\mathrm{bp}_\vartheta(h))\Big),$$

the sum over the edge tuples S for ϑ supported on the edges of the last path; it is defined when, for every such S, both chains $\mathrm{Lc}^S_{z,m}(y_z)$ are defined and the integrand of its class integral satisfies the hypotheses of (LQ3). The pair y is **fixed by the outer levels** if $y^\flat_z(gk) = y^\flat_z(g)$ for all g, all $k \in \mathrm{K}_\vartheta(z,0)$ and both z.

From now on, for all admissible data D and both $z \in \{\mathrm{I},\mathrm{II}\}$, the weight parameters of the half z in (LQ1) of Definition 6.4.4 are fixed as a choice of the numbers provided by Lemma 6.4.3 for D and z: $\kappa_z(v,h) = \kappa(v,h)$ ($v \in \Phi$, $h \geq 1$) and $e^{\det}_{z,i}(v) = e_i(v)$ ($v \in \Phi$, $0 \leq i \leq m$). In that lemma $N_i = N_{z,i}$ and $n_i = n_{z,i}$, and the family of its item (3) is $l_{z,i}$; so property (i) of (LQ1) is part of its item (1) and property (ii) is its item (3). Its item (1) also gives $N_{z,i} < N_{z,i+1}$ for $0 \leq i < m$, so the algebraic theta lifts of (LQ4) are defined along every edge of the last path; its items (2), (4) and (5) hold for the fixed weight parameters.

Lemma 6.4.5. *Let D be admissible data. There are $e \in \mathbb{Z}$ and a function γ from the m-fold twists to $\mathbb{C} \setminus \{0\}$ with $\gamma(1) = 1$ and*

$$|\gamma(\vartheta)| = \mathrm{N}Q(\vartheta)^{e/2} \prod_{0 \leq i,j < m} \tau_{ij}(\vartheta) \qquad \text{for every } m\text{-fold twist } \vartheta,$$

such that $\mathcal{T}$ is spanned by the target forms that are auxiliary for γ.

Proof. Let c be the function of Proposition 6.4.6 and $F = \prod_{0 \leq i,j < m} \tau_{ij}$.

The scalars. Put $\gamma(\vartheta) = c(\vartheta)/c(1)$; then $\gamma(\vartheta) \neq 0$ and $\gamma(1) = 1$. Each τ_{ij} is a product of ratios, so $F \geq 0$, and $F(1) = 1$, since $r_p(1) = 1$ for every critical pair p by Lemma 6.1.7(b) (so $\tau_{ij}(1) = 1$, Lemma 6.1.7(c)). By the choice of c there are $C \in \mathbb{R}$ and $e \in \mathbb{Z}$ with $|c(\vartheta)|^2 = C\,\mathrm{N}Q(\vartheta)^e F(\vartheta)^2$ for all ϑ; at $\vartheta = 1$, where $Q = \emptyset$, this gives $C = |c(1)|^2 > 0$. Hence $|\gamma(\vartheta)|^2 = \mathrm{N}Q(\vartheta)^e F(\vartheta)^2$, and taking nonnegative square roots, $|\gamma(\vartheta)| = \mathrm{N}Q(\vartheta)^{e/2} F(\vartheta)$.

Projection to the target. Let $P = |\bar{G}|\, e_0$, acting on $\mathcal{A}_M(Y_0)$. Since e_0 is an idempotent and $\mathcal{T} = e_0 \mathcal{A}_M(Y_0)$, the map P is onto $\mathcal{T}$. By Proposition 6.4.6 the forms y with (i) and (ii) span $\mathcal{A}_M(Y_0)$, so the forms Py for such y span $\mathcal{T}$. It remains to show that each such Py is auxiliary for γ.

(AF1). Let ϑ be an m-fold twist and $\iota \mid \ell$ with $\ell \nmid \mathrm{N}Q(\vartheta)$. By (i), $\gamma(\vartheta)\Theta_\vartheta y$ is integral at ι. By Lemma 4.5.1, applied with $c = \gamma(\vartheta)$, $z = y$ and the identity element $s = 1$ of $\bar{G}$, the form $\gamma(\vartheta)\Theta_\vartheta(|\bar{G}|e_0 y) = \gamma(\vartheta)\Theta_\vartheta(Py)$ is integral at ι.

(AF2). Let σ be an automorphism of $\mathbb{C}$. By (ii), every conjugated value $\sigma((\Theta_1 y)(g))$, $g \in \mathrm{U}(Y_m)(\mathbb{A}_f)$, has squared Weyl norm at most e^B with $B = x^{202}b^2$; so Lemma 4.5.2, applied with $z = y$ and $s = 1$, gives $\|Py\|^2_\sigma = \||\bar{G}|e_0 y\|^2_\sigma \leq \exp(x^{99} + x^{202}b^2)$. Finally $x^{99} + x^{202}b^2 \leq 2x_1^2 b^2$, because $x^{10^6} \leq x_1$ (Proposition 2.3.5) and $x, b \geq 1$ give $x^{99} \leq x_1^2 b^2$ and $x^{202} \leq x_1^2$. So $\|Py\|^2_\sigma \leq \exp(2x_1^2 b^2)$. □

The first group proves Proposition 6.4.6. A short form of deep level is restricted flatly and rescaled by a hook number times the denominator of the last path; the integrality of the rescaled chain and the bound for its conjugates then follow from those of the last-path sums, through an integral invariant pairing of dual Weyl modules that detects integrality up to the hook number (Lemma 6.4.73). The key statement is Lemma 6.4.7: the pairing of a vector with the value at a point of the rescaled chain of a restriction is one constant times a last-path sum at a delta form. It composes the first-path period (Lemma 6.4.8), the transfer of periods along the turns (Proposition 6.4.87) and the last-path periods (Proposition 6.4.80), with Schur's lemma for the Weyl module [91].

The surjective flat restriction rests on an abstract principle for triangles of arrows whose squares commute up to scalars: weighted chains are injective, and the Gram form of a full chain is the product of the Gram operators of the first arrows (Lemma 6.4.59). The lifts, descents and ascents of the triangle satisfy its conditions (Proposition 6.4.11), the squares commuting by the one-square identity, and the moduli of the square constants of the twisted triangle are the chain ratios. For the injectivity of theta lifts through the inner product formula see [237, 187]. All moves are theta lifts whose real data are joint harmonics, in our reading the harmonic polynomials of the archimedean theta correspondence [157, 135, 136], and on the last path they are multiples of chains of algebraic theta lifts (Lemma 6.4.68). Finally, forms of deep level on the outer definite space are spanned by short forms (Lemma 6.4.77), by the finiteness of class numbers [33, 37].

Proposition 6.4.6. *Let D be admissible data, and let Θ_ϑ also denote the same composite of the m lifts on all of $\mathcal{A}_M(Y_0)$. There is a function c from the m-fold twists to $\mathbb{C}^\times$, of absolute value $\prod_{0\le i,j<m}\tau_{ij}$ up to a norm power, such that $\mathcal{A}_M(Y_0)$ is spanned by the forms y with:*

(i) $(c(\vartheta)/c(1))\,\Theta_\vartheta y$ is integral at ι for every m-fold twist ϑ and every prime identification $\iota \mid \ell$ with $\ell \nmid \mathrm{N}Q(\vartheta)$;

(ii) for every automorphism σ of $\mathbb{C}$ and every $g \in \mathrm{U}(Y_m)(\mathbb{A}_f)$, the conjugate $\sigma((\Theta_1 y)(g))$ of the value at g, a vector of the Weyl module, has squared norm at most $\exp(x^{202}b^2)$ for the Gram matrix of the Weyl module.

Proof. Let $n = n_{\mathrm{I},0}$ be the index set of Y_m, $(\kappa', e') = (\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},0})$, and $P' = P_{\kappa',e'}$, $P_Y = P_{\kappa_Y,e_Y}$.

Step 1: the choices. By Lemma 6.4.78 fix a branching pairing B at (m,m). By (3) of Lemma 6.4.3 for $z = \mathrm{I}$, $i = 0$, $-p_{\mathrm{I},0,m}$ is a doubled Harish-Chandra parameter of (κ', e'); so Lemma 6.4.73 for n, (κ_Y, e_Y) with $l = p_{\mathrm{I},0,m}$ and (κ', e') gives an integer matrix A with rows $I_{\kappa'}$ and columns I_{κ_Y} and an integer matrix C with (1)–(4) there; let $h = h_{\kappa'} \ge 1$ be the hook number. Let c, (Ψ_ϑ), β, r be as in (3) of Lemma 6.4.7 for B and A, and N as in (b) of Proposition 6.4.80 for B. Put $s = 1$, $\varepsilon = 0$ if $\beta = 0$, and $s = hN/\beta$, $\varepsilon = 1$ otherwise; then $s \ne 0$ and $s\beta = h\varepsilon N$. By linearity of Θ_ϑ, for every m-fold twist ϑ, $\varphi \in \mathcal{F}_{\mathfrak{b}}(m)$, $x \in G_f(n)$ and $v \in \mathbb{V}_{\kappa'}$,

$$v^{\mathsf{T}} A \,\frac{c(\vartheta)}{c(1)}\,\big(\Theta_\vartheta(s\, r\varphi)\big)(x) = h\,\varepsilon\, N\,\mathrm{Ls}_B\big(\Psi_\vartheta, (\Delta^\vartheta_{x,v}, \varphi)\big). \tag{6.60}$$

Here every last-path sum is defined, by (ii) of Lemma 6.4.79. Call $\varphi \in \mathcal{F}_{\mathfrak{b}}(m)$ *short* if $\varphi^\flat$ is integral at every prime identification and $\|\sigma(\varphi^\flat(g))\|^2_{\kappa_{\mathrm{II}}} \le \exp(x^{99}b^2)$ for all σ, g. We show that $y = s\,r\varphi$ has (i) and (ii) for every short φ. This proves the proposition: the short forms span $\mathcal{F}_{\mathfrak{b}}(m)$ (Lemma 6.4.77), r is linear and onto $\mathcal{A}_M(Y_0)$, and $s \ne 0$, so the forms $s\,r\varphi$ with φ short span $\mathcal{A}_M(Y_0)$.

Step 2: (i). Let ϑ be an m-fold twist, $\iota \mid \ell$ with $\ell \nmid \mathrm{N}Q$, φ short and $g \in \mathrm{U}(Y_m)(\mathbb{A}_f) = G_f(n)$. Put $\Theta' = \frac{c(\vartheta)}{c(1)}(\Theta_\vartheta(s\,r\varphi))(g)$ and $\zeta = P_Y(f_\iota(g^{-1}))\,\iota(\Theta')$. For an integer vector $w \in \mathbb{Z}^{I_{\kappa'}}$ let $v_w = \iota^{-1}(P'(f_\iota(g))w)$, so that $P'(f_\iota(g^{-1}))\iota(v_w) = w$ has integral coordinates. By (2) of Lemma 6.4.7, $\delta^\vartheta_{g,v_w} = (\Delta^\vartheta_{g,v_w})^\flat$ is integral at ι; $\varphi^\flat$ is integral at ι; the pair $(\Delta^\vartheta_{g,v_w}, \varphi)$ is fixed by the outer levels by (1) there; and Ψ_ϑ is a path datum on the last path. So by (b) of Proposition 6.4.80, $N\,\mathrm{Ls}_B(\Psi_\vartheta, (\Delta^\vartheta_{g,v_w}, \varphi))$ is integral at ι, and by (6.60), $\iota(v_w^{\mathsf{T}} A\,\Theta') \in h\mathcal{O}$. By (1) of Lemma 6.4.73 over $R = \overline{\mathbb{Q}}_\ell$ for the family $f_\iota(g^{-1})$ of invertible matrices, and as A has integer entries,

$$w^{\mathsf{T}} A\,\zeta = \big(P'(f_\iota(g^{-1}))\iota(v_w)\big)^{\mathsf{T}} A\, P_Y(f_\iota(g^{-1}))\,\iota(\Theta') = \iota(v_w^{\mathsf{T}} A\,\Theta') \in h\mathcal{O}$$

for every w. In particular every coordinate of $A\zeta$ lies in $h\mathcal{O}$, so by (3) there, $h\zeta = CA\zeta$ has coordinates in $h\mathcal{O}$ (C is an integer matrix), and ζ has coordinates in $\mathcal{O}$. As g was arbitrary, $\frac{c(\vartheta)}{c(1)}\Theta_\vartheta y$ is integral at ι.

Step 3: (ii). Let $\vartheta = 1$, σ a field automorphism of $\mathbb{C}$, φ short, $g \in G_f(n)$ and $\Theta'' = (\Theta_1(s\, r\varphi))(g)$. Let $v \in \mathbb{V}_{\kappa'}$. By (2) of Lemma 6.4.7, $\|\sigma(\delta^1_{g,v}(g'))\|^2 \le \|\sigma(v)\|^2$ for all g'; φ is short; the pair is fixed by the outer levels; and Ψ_1 is a path datum of bound $V_1^{m^2}T_1$. By (c) of Proposition 6.4.80 and (6.60) (with $c(1)/c(1) = 1$, $|\sigma(\varepsilon)| \le 1$, and σ fixing the integers h, N),

$$|\sigma(v^{\mathsf{T}} A\, \Theta'')| \le hN \exp(x^{200}b^2) \exp(x^{99}b^2/2)\, \|\sigma(v)\|_{\kappa'} = K\, \|\sigma(v)\|_{\kappa'}.$$

By (4) of Lemma 6.4.73 for $\sigma(\Theta'')$ there is $w \in \mathbb{V}_{\kappa'}$ with $\|w\|_{\kappa'} = \|\sigma(\Theta'')\|_{\kappa_Y}$ and $u^{\mathsf{T}} A\, \sigma(\Theta'') = \langle w, u\rangle_{\kappa'}$ for all u. For $u = w$ and $v = \sigma^{-1}(w)$ (coordinatewise), as A has integer entries,

$$\|w\|^2_{\kappa'} = w^{\mathsf{T}} A\, \sigma(\Theta'') = \sigma\big(v^{\mathsf{T}} A\, \Theta''\big) \le K\, \|w\|_{\kappa'},$$

so $\|\sigma(\Theta'')\|^2_{\kappa_Y} = \|w\|^2_{\kappa'} \le K^2$.

Step 4: the constant. By (4) of Lemma 6.4.3 for $z = \mathrm{I}$, $i = 0$, the boxes of κ' in the rank of Y_m number at most $L = br^4$, so $h \le (L^L)^3$ by (5) of Lemma 6.4.73; and $N \le \exp(x^{99}b^2)$. With $\log L \le \log b + 4\log r \le b + 4r \le 5br$ and $r \le 3x^5$,

$$\log K^2 \le 6L \log L + 3x^{99}b^2 + 2x^{200}b^2 \le 30 \cdot 3^5 x^{25} b^2 + 3x^{99}b^2 + 2x^{200}b^2 \le x^{202}b^2,$$

the last step as $x \ge 3$ (Lemma 2.3.6). Hence $\|\sigma((\Theta_1 y)(g))\|^2 \le \exp(x^{202}b^2)$, which is (ii). □

Lemma 6.4.7. *Let D be admissible data, B a branching pairing at (m, m), $n = n_{\mathrm{I},0}$, and A an integer matrix with rows $I_{\mathrm{I},0}$ and columns I_{κ_Y} satisfying (1) and (2) of Lemma 6.4.73 for (κ_Y, e_Y) with $l = p_{\mathrm{I},0,m}$ and $(\kappa', e') = (\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},0})$. For an m-fold twist ϑ put $V_\vartheta = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{2n_m}$ and $T_\vartheta = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{8mn^2_m}$. For $x \in G_f(n)$ and $v \in \mathbb{V}_{\mathrm{I},0}$ let $\delta^\vartheta_{x,v}$ be the function on $G_f(n)$ with $\delta^\vartheta_{x,v}(\gamma_f x k) = \rho_{\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},0}}(\gamma_\infty)v$ for rational points γ of I_n and $k \in \mathrm{K}_\vartheta(\mathrm{I}, 0)$, and 0 off $\Gamma_f x \mathrm{K}_\vartheta(\mathrm{I}, 0)$. Then:*

(1) $\delta^\vartheta_{x,v}$ is a well-defined element of $\mathcal{A}_{\mathrm{I},0}$, there is a unique $\Delta^\vartheta_{x,v} \in \mathcal{F}(\mathrm{I}, 0, m)$ with $(\Delta^\vartheta_{x,v})^\flat = \delta^\vartheta_{x,v}$, and for every $\varphi \in \mathcal{F}_{\mathfrak{b}}(m)$ the pair $(\Delta^\vartheta_{x,v}, \varphi)$ is fixed by the outer levels;

(2) if $\iota \mid \ell$ is a prime identification with $\ell \nmid \mathrm{N}Q$ and $P_{\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},0}}(f_\iota(x^{-1}))\, \iota(v)$ has integral coordinates, then $\delta^\vartheta_{x,v}$ is integral at ι; and $\|\sigma(\delta^\vartheta_{x,v}(g))\|_{\kappa_{\mathrm{I}}} \le \|\sigma(v)\|_{\kappa_{\mathrm{I}}}$ for every field automorphism σ of $\mathbb{C}$ and every g;

(3) there are a function c from the m-fold twists to $\mathbb{C}^\times$ of absolute value $\prod_{0 \le i,j < m} \tau_{ij}$ up to a norm power, path data Ψ_ϑ of bound $V_\vartheta^{m^2}T_\vartheta$ on the edges of the last path, a number $\beta \in \mathbb{C}$ and a surjective linear map $r\colon \mathcal{F}_{\mathfrak{b}}(m) \to \mathcal{A}_M(Y_0)$ such that for every m-fold twist ϑ, $\varphi \in \mathcal{F}_{\mathfrak{b}}(m)$, $x \in G_f(n)$ and $v \in \mathbb{V}_{\mathrm{I},0}$,

$$v^{\mathsf{T}} A\, \frac{c(\vartheta)}{c(1)}\, (\Theta_\vartheta r\varphi)(x) = \beta\, \mathrm{Ls}_B\big(\Psi_\vartheta, (\Delta^\vartheta_{x,v}, \varphi)\big).$$

Proof. Write $n = n_{\mathrm{I},0}$, $\mathrm{K} = \mathrm{K}_\vartheta(\mathrm{I}, 0)$, $\mathrm{ix}_\vartheta = [\mathbf{K}_0(n) : \mathrm{K}]$, $p = p_{\mathrm{I},0,m}$, $l = l_{\mathrm{I},0} = -p$, $(\kappa', e') = (\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},0})$, $\rho' = \rho_{\kappa',e'}$, $\rho_Y = \rho_{\kappa_Y, e_Y}$, and Γ for the rational points of I_n. By (3) of Lemma 6.4.3, l is a doubled Harish-Chandra parameter of (κ', e').

Step 1: trivial stabilisers. Every element of K reduces to 1 modulo $\mathfrak{m}_\vartheta$, hence modulo every chosen place w (which divides $\mathfrak{m}_\vartheta$), so it acts trivially on L_w/wL_w for the lattice $L=\mathcal{O}_E^n$ of I_n, whose stabiliser is $\mathbf{K}_0(n)$. By (c) of Lemma 4.6.2, $\Gamma_f\cap h\mathrm{K}h^{-1}=\{1\}$ for every $h\in G_f(n)$.

Step 2: (1). If $\gamma_f x k=\gamma'_f x k'$ with $\gamma,\gamma'\in\Gamma$, $k,k'\in\mathrm{K}$, then $(\gamma'^{-1}\gamma)_f=xk'k^{-1}x^{-1}$, so $\gamma=\gamma'$ by Step 1; hence $\delta^\vartheta_{x,v}$ is well defined. It is right invariant under the open subgroup K, and $\delta^\vartheta_{x,v}(\gamma'_f h)=\rho'(\gamma'_\infty)\delta^\vartheta_{x,v}(h)$ for every rational point γ' (both sides vanish off $\Gamma_f x\mathrm{K}$, and on it $\rho'((\gamma'\gamma)_\infty)=\rho'(\gamma'_\infty)\rho'(\gamma_\infty)$), so $\delta^\vartheta_{x,v}\in\mathcal{A}_{\mathrm{I},0}$. By (4) of Lemma 6.4.68 there is a unique $\Delta^\vartheta_{x,v}\in\mathcal{F}(\mathrm{I},0,m)$ with $(\Delta^\vartheta_{x,v})^\flat=\delta^\vartheta_{x,v}$, and $\Delta^\vartheta_{x,v}=F^l_{\delta^\vartheta_{x,v}}$. Its algebraic form is fixed by $\mathrm{K}=\mathrm{K}_\vartheta(\mathrm{I},0)$. For $\varphi\in\mathcal{F}_\mathfrak{b}(m)$ and $k\in\mathrm{K}_\vartheta(\mathrm{II},0)$, the kernel of the reduction modulo $\mathfrak{b}$, $\varphi(y,gk)=\varphi(y,g)$ by (FY2), so $\varphi^\flat(gk)=\varphi^\flat(g)$ by the formula of (WM7). So the pair is fixed by the outer levels.

Step 3: (2). Let $h=\gamma_f x k$. For $\gamma\in\mathrm{GL}_n(E)$, $f_{\iota,\tau}(\gamma_f)=\iota(\overline{\tau(\gamma)})$ entrywise, and $P_{\kappa',e'}$ has integer coefficients and integer powers of the determinant, so $\iota(\rho'(\gamma_\infty)v)=\iota(P_{\kappa',e'}(\bar\gamma_\infty)v)=P_{\kappa',e'}(f_\iota(\gamma_f))\iota(v)$ and

$$P_{\kappa',e'}(f_\iota(h^{-1}))\,\iota\big(\delta^\vartheta_{x,v}(h)\big)=P_{\kappa',e'}(f_\iota(k^{-1}))\,P_{\kappa',e'}(f_\iota(x^{-1}))\,\iota(v).$$

As $k\in\mathbf{K}_0(n)\subseteq\mathrm{GL}_n(\widehat{\mathcal{O}}_E)$, $f_\iota(k^{-1})$ is integral with unit determinant, so $P_{\kappa',e'}(f_\iota(k^{-1}))$ has integral entries, and the right side is integral under the hypothesis of (2). Off $\Gamma_f x\mathrm{K}$ the value is 0. So $\delta^\vartheta_{x,v}$ is integral at ι. For the norms: $\sigma(\rho'(\gamma_\infty)v)=P_{\kappa',e'}(u)\,\sigma(v)$ with $u_\tau=\sigma(\overline{\tau(\gamma)})$, the image of the unitary matrix γ under an embedding of the CM field E, which commutes with complex conjugation, so $u\in\prod_\tau\mathrm{U}(N)$. By (WM3), $\|\xi\|^2_{\kappa'}=\sum_T|\xi(\Delta_T)|^2$ over the increasing fillings, ξ read as the linear form $b_i\mapsto\xi_i$ on $\nabla_{\kappa'}$; $S_{\kappa'}(u)\xi$ is the form $f\mapsto\xi(f(u\,\cdot))$, and by the Cauchy–Binet formula $(\Delta_T(u\,\cdot))_T$ is the image of $(\Delta_T)_T$ under the tensor product of the exterior powers of the u_τ, a unitary matrix in the basis of increasing fillings. With $|\det u_\tau|=1$ this gives $\|P_{\kappa',e'}(u)\xi\|_{\kappa'}=\|\xi\|_{\kappa'}$, so $\|\sigma(\delta^\vartheta_{x,v}(g))\|_{\kappa'}\in\{0,\|\sigma(v)\|_{\kappa'}\}$.

Step 4: transfer to the last path. Let Ψ^0, g, α, r be as in Lemma 6.4.8, and c as in Proposition 6.4.87. The transfer of periods from the first to the last path with bound V^{m^2}, applied to $N(\vartheta)=T_\vartheta$ and Ψ^0, gives path data Ψ_ϑ of bound $V_\vartheta^{m^2}T_\vartheta$ on the edges of the last path such that $\Psi\propto_{\mathrm{last}}\Xi$ implies $\Psi^0\propto_{\mathrm{first}}\Xi/c$. The last-path sums used here are defined: for $y'\in\mathcal{F}(\mathrm{I},0,m)$ and $\varphi\in\mathcal{F}(\mathrm{II},0,m)$, $\mathrm{Ls}_B(\Psi_\vartheta,(y',\varphi))$ is defined by (ii) of Lemma 6.4.79. Let $\Xi(\vartheta,y',\varphi)=\mathrm{Ls}_B(\Psi_\vartheta,(y',\varphi))/\mathrm{ix}_\vartheta$. By (a) of Proposition 6.4.80, $\Psi\propto_{\mathrm{last}}\Xi$; so there is $\beta_1\in\mathbb{C}$ with $\mathrm{per}_{\mathrm{first}}(\Psi^0;g)(\vartheta,y',\varphi)=\beta_1\Xi(\vartheta,y',\varphi)/c(\vartheta)$ for every period triple, and by Lemma 6.4.8

$$\int_{[\mathrm{U}(Y_m)]}y'(x')\,F^p_{\Theta_\vartheta r\varphi}(x')\,dx'=\frac{\alpha\beta_1}{\mathrm{ix}_\vartheta\,c(\vartheta)}\,\mathrm{Ls}_B(\Psi_\vartheta,(y',\varphi)).\tag{6.61}$$

Step 5: the pairing with a delta form. Fix ϑ, φ, x, v and put $\Theta=\Theta_\vartheta r\varphi$, an algebraic form of weight (κ_Y,e_Y) on $\mathrm{U}(Y_m)=\mathrm{U}(\mathrm{I}_n)$ with $\Theta(hk)=\chi_\vartheta(k)\Theta(h)$ for $k\in\mathrm{K}_\vartheta$, χ_ϑ the character of K_ϑ, by (c) of Lemma 6.4.75; it is right invariant under K: every $k\in\mathrm{K}$ reduces to 1 at the chosen places and at the places of Q, so $k\in\mathrm{K}_\vartheta$, and $\chi_\vartheta(k)=1$ since every diagonal block of the reduction of k at a level place is 1. Let $f(y,h)=F^l_{\delta^\vartheta_{x,v}}(y,h)\,F^p_\Theta(y,h)$, continuous, left invariant under Γ (by the transformation laws of algebraic forms and the multiplicativity of ρ) and right K-invariant in h. By (2) of Lemma 6.4.73, $F^l_\delta(y,h)=\delta(h)^{\mathsf T}A\,\rho_Y(y)v_p^+$, and by (WM7) $F^p_\Theta(y,h)=\langle v_p^+,\rho_Y(y)^{-1}\Theta(h)\rangle_{\kappa_Y}$; so $\int_{G_\infty(1)}f(y,h)\,dy=\delta(h)^{\mathsf T}A\,T_0\,\Theta(h)$, dy the Haar probability measure, with

$$T_0\xi=\int_{G_\infty(1)}\rho_Y(y)v_p^+\,\langle v_p^+,\rho_Y(y)^{-1}\xi\rangle_{\kappa_Y}\,dy.$$

Substituting $y=y_0y'$ shows $T_0\rho_Y(y_0)=\rho_Y(y_0)T_0$. The module $\mathbb{V}_{\kappa_Y}$ is irreducible under $\rho_Y(G_\infty(1))$: it is irreducible under $\prod_\tau\mathrm{GL}_N(\mathbb{C})$ (the Weyl module of highest weight λ°, [91],

Ch. 8), and a subspace stable under $\prod_\tau \mathrm{U}(N)$ is stable under its Zariski closure $\prod_\tau \mathrm{GL}_N(\mathbb{C})$, the action being polynomial. By Schur's lemma $T_0 = t\cdot 1$, and taking traces, $t\,\dim \mathbb{V}_{\kappa_Y} = \langle v_p^+, v_p^+\rangle_{\kappa_Y}$. This is positive: $\xi \mapsto F_{\kappa_Y}\xi = (\xi(\Delta_T))_T$ is injective, as the Δ_T of increasing fillings span ∇_{κ_Y}, so $\langle\cdot,\cdot\rangle_{\kappa_Y}$ is positive definite; and $v_p^+ \neq 0$, as for the filling T whose sets $T(\tau,h,j)$ are the h indices with the h largest values of p_τ, the minors of y^p in $\Delta_T(y^p)$ are determinants of permutation matrices, so $\Delta_T(y^p) = \pm 1$, and Δ_T is an integer combination of the b_i. Hence $t \neq 0$ does not depend on ϑ, φ, x, v. By (2) of Lemma 6.4.74 at the level K,

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} f = \frac{c_n t}{\mathrm{ix}_\vartheta}\,\mathrm{CI}_\mathrm{K}(F), \qquad F(h) = \delta^\vartheta_{x,v}(h)^\mathsf{T} A\,\Theta(h).$$

F is right K-invariant, so by (LQ3) and Step 1, $\mathrm{CI}_\mathrm{K}(F) = \sum_{[h]} F(h)$ over $\Gamma_f\backslash G_f(n)/\mathrm{K}$, and as $\delta^\vartheta_{x,v}$ vanishes off $\Gamma_f x\mathrm{K}$ and $\delta^\vartheta_{x,v}(x) = v$, $\mathrm{CI}_\mathrm{K}(F) = v^\mathsf{T} A\,\Theta(x)$.

Step 6: (3). By Step 2, $y' = \Delta^\vartheta_{x,v} = F^l_{\delta^\vartheta_{x,v}}$ is a conjugate form on Y_m; comparing Step 5 with (6.61),

$$v^\mathsf{T} A\,\frac{c(\vartheta)}{c(1)}\,(\Theta_\vartheta r\varphi)(x) = \frac{\alpha\beta_1}{c_n\,t\,c(1)}\,\mathrm{Ls}_B\big(\Psi_\vartheta, (\Delta^\vartheta_{x,v}, \varphi)\big),$$

which is (3) with $\beta = \alpha\beta_1/(c_n t c(1))$; c has absolute value $\prod \tau_{ij}$ up to a norm power by Proposition 6.4.87, and r is linear and onto by Lemma 6.4.8. □

Lemma 6.4.8. *Let D be admissible data and, for an m-fold twist ϑ, $T_\vartheta = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{8mn^2_m}$. There are path data Ψ^0_ϑ of bound T_ϑ on the edges of the first path, a real point g of $\mathrm{U}(\tilde{Y}^0_0)$, a number $\alpha \in \mathbb{C}$ and a surjective linear map $r\colon \mathcal{F}_\mathfrak{b}(m) \to \mathcal{A}_M(Y_0)$ such that for every m-fold twist ϑ, every conjugate form y' on Y_m and every $\varphi \in \mathcal{F}_\mathfrak{b}(m)$,*

$$\int_{[\mathrm{U}(Y_m)]} y'(x)\,F^{p_{\mathrm{I},0,m}}_{\Theta_\vartheta r\varphi}(x)\,dx = \alpha\,\mathrm{per}_{\mathrm{first}}(\Psi^0; g)(\vartheta, y', \varphi).$$

Proof. **Step 1: the choices.** Let g and r be a real point of $\tilde{Y}^0_0$ and a surjective flat restriction $r\colon \mathcal{F}_\mathfrak{b}(m) \to \mathcal{A}_M(Y_0)$ at g, as given by Lemma 6.4.9; let C be the constant of Lemma 6.4.65, put $\alpha = C$, and let Ψ^0_ϑ be the first-path datum of (FY4), a path datum of bound T_ϑ on the edges of the first path by (1) of Lemma 6.4.65. It remains to prove the identity. Fix an m-fold twist ϑ, a conjugate form $y' \in \mathcal{F}(\mathrm{I},0,m)$ on Y_m and $\varphi \in \mathcal{F}_\mathfrak{b}(m)$, and put $y = r\varphi \in \mathcal{A}_M(Y_0)$.

Step 2: transposition down the column of Y. By (a) of Lemma 6.4.67, $y \in \mathcal{F}^0_\triangle(\mathrm{I},0)$, and by (b) of Lemma 6.4.67, $F^{p_{\mathrm{I},0,m}}_{\Theta_\vartheta y} = \mathrm{Wc}^0_{\vartheta,\mathrm{I},m} y$. By (3) of Lemma 6.4.63 for $z = \mathrm{I}$ and $b = m$, where $\Theta^\flat_{\vartheta,\mathrm{I},m} = \mathrm{id}$, $V^0_{\mathrm{I},m} = Y_m$ and $V^0_{\mathrm{I},0} = Y_0$,

$$\int_{[\mathrm{U}(Y_m)]} y'(x)\,F^{p_{\mathrm{I},0,m}}_{\Theta_\vartheta y}(x)\,dx = \int_{[\mathrm{U}(Y_m)]} y' \cdot \mathrm{Wc}^0_{\vartheta,\mathrm{I},m} y = \int_{[\mathrm{U}(Y_0)]} u\,y, \qquad u = \Theta^\flat_{\vartheta,\mathrm{I},0}\,y', \tag{6.62}$$

the integrals being absolutely convergent.

Step 3: $\bar{u}$ is a test form of the flat restriction. By (1) of Lemma 6.4.63 (with $b = 0 < m$), $u \in \mathcal{F}(\mathrm{I},0,0)$ and $u(h(1,k)) = u(h)$ for every $k \in \mathbf{K}_0(n_{\mathrm{I},0,0})$ whose reduction modulo $\mathfrak{t}_\vartheta(\mathrm{I}) = \pi_M \prod_{w\in Q} w$ is 1. The generator π_M of the product of the chosen places and the places of Q give pairwise distinct places (the chosen places lie above primes dividing M, and $\mathrm{N}Q$ is prime to M), each to the first power, so by the Chinese remainder theorem an element of $\mathbf{K}_0(n_{\mathrm{I},0,0})$ reduces to 1 modulo $\mathfrak{t}_\vartheta(\mathrm{I})$ if and only if it reduces to 1 modulo every chosen place and every place of Q; that is, the group of these k is $\mathrm{K}_\vartheta(Y_0)$. By (b) of Lemma 6.4.15 (offset 0, $p = (\mathrm{I},0,0)$, $\lambda = \frac{1}{2}p_{\mathrm{I},0,0}$), the grid forms at $(\mathrm{I},0,0)$ have the type $\bar{e}_\lambda$; as the conditions of (ED2) are invariant

under complex conjugation, $\bar{u}$ is a form of type e_λ on Y_0, and it is right invariant under $\mathrm{K}_\vartheta(Y_0)$; so $\bar{u} \in \mathcal{F}^+_\vartheta(Y_0)$.

Step 4: the flat restriction. By (FY3) for φ, ϑ and $\bar{u}$,

$$\int_{[\mathrm{U}(Y_0)]} u\,(r\varphi) = \langle \bar{u}, r\varphi\rangle_{Y_0} = \int_{[\mathrm{U}(Y_0)]} u(x)\,(\Theta^\flat\varphi)\big(\mathrm{diag}(x,1)\,(g,1)\big)\,dx = \big\langle u,\ \Theta^\flat_{1,\mathrm{II},0}\varphi\big\rangle_{0,g},$$

the last equality being the definition of the period $\langle\cdot,\cdot\rangle_{0,g}$ in (3.3) for $l=0$, where $Y_0^0 = Y_0$, the restriction is along $x \mapsto \mathrm{diag}(x,1)$ into $\mathrm{U}(\tilde{Y}_0^0)$ and the power $\mathrm{flp}_\vartheta^0 = 1$ of the flip idele acts trivially.

Step 5: the period of the first path. As $\varphi \in \mathcal{F}_\mathfrak{b}(m) \subseteq \mathcal{F}(\mathrm{II},0,m)$, (2) of Lemma 6.4.65 gives $\langle u, \Theta^\flat_{1,\mathrm{II},0}\varphi\rangle_{0,g} = C\,\mathrm{per}_{\mathrm{first}}(\Psi^0;g)(\vartheta,y',\varphi)$. With (6.62) and Step 4,

$$\int_{[\mathrm{U}(Y_m)]} y'(x)\,F^{p_{\mathrm{I},0,m}}_{\Theta_\vartheta r\varphi}(x)\,dx = \alpha\,\mathrm{per}_{\mathrm{first}}(\Psi^0;g)(\vartheta,y',\varphi),$$

which is the assertion; r is linear and surjective by Step 1. □

Lemma 6.4.9. *Let D be admissible data. There are a real point $g \in G_\infty(s)$ of $\tilde{Y}_0^0$ and a flat restriction $r\colon \mathcal{F}_\mathfrak{b}(m) \to \mathcal{A}_M(Y_0)$ at g that is surjective.*

Proof. Write $\mathcal{A} = \mathcal{A}_M(Y_0)$, $n_0 = n_{\mathrm{I},0,0}$, $e = e_\varsigma$, and for a real point g of $\tilde{Y}_0^0$, a bounded continuous left Γ_{Y_0}-invariant function y on the adelic group of Y_0 and $\psi \in \mathcal{F}_\mathfrak{b}(0)$

$$P_g(y,\psi) = \int_{[\mathrm{U}(Y_0)]} \overline{y(x)}\,\psi\big(\mathrm{diag}(x,1)\,(g,1)\big)\,dx.$$

Step 0: P_g is defined. As $\tilde{Y}_0^0 = Y_0 \oplus \langle 1\rangle$ is an orthogonal sum ((GP2); block diagonal matrix and point, (VP5)), $\mathrm{diag}(\gamma,1)$ is a rational point of $\tilde{Y}_0^0$ for every rational point γ of Y_0, so $x \mapsto \psi(\mathrm{diag}(x,1)(g,1))$ is left Γ_{Y_0}-invariant; the integrand is continuous and bounded, and $[\mathrm{U}(Y_0)]$ has finite volume (Theorem 4.2.18), so the integral converges absolutely. P_g is conjugate-linear in y and linear in ψ.

Step 1: the representing map. By (b) of Lemma 6.4.15 for the triangle I at $(0,0)$, the Fock vector of the joint harmonic is an edge from $e_{\frac{1}{2}p_{\mathrm{I},0,0}} = e$, so e is a cusp kernel of order 0 ((a) of (ED4)); with the open subgroup K_M, Lemma 6.4.64 shows that $\mathcal{A}$ is finite-dimensional. The Petersson product is positive definite on $\mathcal{A}$: if $\langle y,y\rangle = 0$ then $y = 0$ almost everywhere, hence everywhere by continuity. So for every $\psi \in \mathcal{F}_\mathfrak{b}(0)$ there is a unique $R_g\psi \in \mathcal{A}$ with $\langle y, R_g\psi\rangle = P_g(y,\psi)$ for all $y \in \mathcal{A}$, and $\psi \mapsto R_g\psi$ is linear by uniqueness.

Step 2: the representing identity for all test forms. Let ϑ be an m-fold twist, $y \in \mathcal{F}^+_\vartheta(Y_0)$ and $\psi \in \mathcal{F}_\mathfrak{b}(0)$; we show $\langle y, R_g\psi\rangle = P_g(y,\psi)$. For $k \in \mathbf{K}_0(n_0)$ put $y_k(x) = y(x(1,k))$.

(i) Let $k \in \mathrm{K}_M$. At each chosen place w (with $\bar{w} \neq w$, as $\mathfrak{b}$ is a modulus) an element of $\mathbf{K}_0(n_0)$ is determined at the pair $\{w,\bar{w}\}$ by its component at w, which may be any element of $\mathrm{GL}_{n_0}(\mathcal{O}_{E,w})$. As $\mathcal{O}_{E,w}$ is local, every lift of an invertible matrix modulo $\mathfrak{b}\mathcal{O}_{E,w}$ is invertible; so there is $u \in \mathbf{K}_0(n_0)$ with $u_w \equiv k_w^{-1} \pmod{\mathfrak{b}\mathcal{O}_{E,w}}$ at every chosen place w and component 1 at all places other than the chosen places and their conjugates. Then ku reduces to 1 modulo $\mathfrak{b}$; u reduces to 1 at every chosen place (as k does), and to 1 at every place of Q, since the places of Q lie above primes prime to M and so are none of the chosen places or their conjugates. Hence $u \in \mathrm{K}_\vartheta(Y_0)$, $y(x(1,u)) = y(x)$, and $y_{ku} = y_k$. Substituting $x \mapsto x(1,ku)^{-1}$ in $P_g(y_{ku},\psi)$ (the quotient measure is right invariant) and using that $(1,ku)$ commutes with $(g,1)$,

$$P_g(y_k,\psi) = P_g(y_{ku},\psi) = \int_{[\mathrm{U}(Y_0)]} \overline{y(x)}\,\psi\big(\mathrm{diag}(x,1)(g,1)\,(1,\mathrm{diag}((ku)^{-1},1))\big)\,dx = P_g(y,\psi),$$

because $\mathrm{diag}((ku)^{-1},1) \in \mathbf{K}_0(n_{\mathrm{II},0,0})$ reduces to 1 modulo $\mathfrak{b}$ and $\psi \in \mathcal{F}_{\mathfrak{b}}(0)$ ((FY2)). Likewise $\langle y_k, R_g\psi\rangle = \langle y, R_g\psi\rangle$, by the substitution $x \mapsto x(1,k)^{-1}$ and the right K_M-invariance of $R_g\psi$.

(ii) Let $\bar{y}(x) = \int_{\mathrm{K}_M} y_k(x)\,dk$, dk the Haar probability measure of the compact open group K_M. It is continuous, bounded, left Γ_{Y_0}-invariant and right K_M-invariant, and $R(e)\bar{y} = \bar{y}$ by Fubini's theorem, because $R(e)$ acts in the infinite component and $R(e)y_k = y_k$ for every k; so $\bar{y} \in \mathcal{A}$. By Fubini's theorem on $[\mathrm{U}(Y_0)] \times \mathrm{K}_M$ (bounded integrands, finite measures) and (i),

$$\langle y, R_g\psi\rangle = \int_{\mathrm{K}_M} \langle y_k, R_g\psi\rangle\,dk = \langle \bar{y}, R_g\psi\rangle = P_g(\bar{y},\psi) = \int_{\mathrm{K}_M} P_g(y_k,\psi)\,dk = P_g(y,\psi),$$

the middle equality by Step 1.

Step 3: a flat restriction at every point. By (1) of Lemma 6.4.63 for $z = \mathrm{II}$, the trivial twist and $b = 0 < m$, where $\mathfrak{t}_1(\mathrm{II}) = \mathfrak{b}$, $\Theta^\flat = \Theta^\flat_{1,\mathrm{II},0}$ maps $\mathcal{F}(\mathrm{II},0,m) \supseteq \mathcal{F}_{\mathfrak{b}}(m)$ linearly into the grid forms at $(\mathrm{II},0,0)$ fixed by the elements reducing to 1 modulo $\mathfrak{b}$, that is, into $\mathcal{F}_{\mathfrak{b}}(0)$. Put $r_g = R_g \circ \Theta^\flat\colon \mathcal{F}_{\mathfrak{b}}(m) \to \mathcal{A}$, a linear map. By Step 2 with $\psi = \Theta^\flat\varphi$, $\langle y, r_g\varphi\rangle_{Y_0} = \int_{[\mathrm{U}(Y_0)]} \overline{y(x)}\,(\Theta^\flat\varphi)(\mathrm{diag}(x,1)(g,1))\,dx$ for all φ, ϑ and $y \in \mathcal{F}^+_\vartheta(Y_0)$: r_g is a flat restriction at g ((FY3)).

Step 4: surjectivity at the point of deep-level vanishing. Let $g = \omega$ be the real point of $\tilde{Y}^0_0$ given by Lemma 6.4.98, and $r = r_g$. As $\mathcal{A}$ is finite-dimensional with a positive definite inner product, it suffices that a $y \in \mathcal{A}$ orthogonal to $r(\mathcal{F}_{\mathfrak{b}}(m))$ vanishes. For such y and every $\psi \in \mathcal{F}_{\mathfrak{b}}(0)$ choose, by (b) of Lemma 6.4.10, $\varphi \in \mathcal{F}_{\mathfrak{b}}(m)$ with $\Theta^\flat\varphi = \psi$; then $0 = \langle y, r\varphi\rangle = P_\omega(y,\psi)$ by Step 1. Taking complex conjugates,

$$\int_{[\mathrm{U}(Y_0)]} y(x)\,\overline{\psi\big((x\oplus 1)\,\omega\big)}\,dx = 0 \qquad \text{for every } \psi \in \mathcal{F}_{\mathfrak{b}}(0),$$

and $\mathcal{F}_{\mathfrak{b}}(0)$ is the space of the grid forms at $(\mathrm{II},0,0)$ of the deep level, the forms of Lemma 6.4.98. By Lemma 6.4.98, $y = 0$. So r is surjective, and (g,r) is as asserted. □

Lemma 6.4.10. *Let D be admissible data.*

(a) The weighted chain $\mathrm{Wc}^0_{1,\mathrm{II},m}$ of row 0 of the triangle II*, for the trivial twist, is injective on $\mathcal{F}^{\mathrm{bs}}_{\mathrm{II}}$.*

(b) $\Theta^\flat(\mathcal{F}_{\mathfrak{b}}(m)) = \mathcal{F}_{\mathfrak{b}}(0)$.

Proof. Write $z = \mathrm{II}$ throughout.

(a). By (c) of Lemma 6.4.15 choose a left pair $\Phi_{i,n}$ at every position (i,n) with $i+n<m$. By (a) of Proposition 6.4.11 for these left pairs, the data I (the m-fold twists), $\mathcal{H}_{i,n} = \mathcal{F}^i_\triangle(z,n)$, $a^\vartheta_{i,n} = \mathrm{Tl}^i_{\vartheta,z,n}$ for $i+n<m$, $w_\vartheta(n) = \#\mathrm{GL}_{n_n}(R_\vartheta)$, $V_0 = \mathcal{F}^{\mathrm{bs}}_z$ and u_i the inclusion satisfy the hypotheses and (Qu1)–(Qu3) of Lemma 6.4.59. Its weighted chain of row 0 for the trivial twist satisfies $X^1_{0,0} = \mathrm{id}$ and, for $n<m$, $X^1_{0,n+1} = \#\mathrm{GL}_{n_n}(\mathcal{O}_E/\mathfrak{t}_1(z))\,\mathrm{Tl}^0_{1,z,n} \circ X^1_{0,n}$, the recursion of $\mathrm{Wc}^0_{1,z,n}$ in (TV3); so $X^1_{0,n} = \mathrm{Wc}^0_{1,z,n}$ for $n \le m$. By (1) of Lemma 6.4.59 with $i=0$, $n=m$, the map $\mathrm{Wc}^0_{1,z,m} \circ u_0$ is injective, which is (a).

(b), the inclusion $\subseteq$. By (1) of Lemma 6.4.63 for the trivial twist and $b = 0 < m$, $\Theta^\flat$ maps $\mathcal{F}(z,0,m)$, hence $\mathcal{F}_{\mathfrak{b}}(m)$, linearly into the grid forms at $(z,0,0)$ fixed by the elements of $\mathbf{K}_0(n_{z,0,0})$ that reduce to 1 modulo $\mathfrak{b}$, that is into $\mathcal{F}_{\mathfrak{b}}(0)$ ((FY2)).

(b), finite dimension. Let $\lambda = \frac{1}{2}p_{z,0,0}$. By (b) of Lemma 6.4.15 at $(0,0)$, e_λ is a cusp kernel of order 0 ((a) of (ED4)); the conditions of (ED1) are invariant under complex conjugation (a replaced by $\bar{a}$), so $\bar{e}_\lambda$ is one too. By the same clause (offset 0) the grid forms at $(z,0,0)$ are the

forms of type $\bar{e}_\lambda$, so $\mathcal{F}_{\mathfrak{b}}(0)$ is finite-dimensional by Lemma 6.4.64, and the Petersson product is positive definite on it (a continuous F with $\int |F|^2 = 0$ vanishes).

(b), the inclusion $\supseteq$. Let $\mathcal{V} = \Theta^\flat(\mathcal{F}_{\mathfrak{b}}(m)) \subseteq \mathcal{F}_{\mathfrak{b}}(0)$; by finite dimension $\mathcal{F}_{\mathfrak{b}}(0) = \mathcal{V} \oplus (\mathcal{V}^\perp \cap \mathcal{F}_{\mathfrak{b}}(0))$, so it suffices that $\psi \in \mathcal{F}_{\mathfrak{b}}(0)$ with $\langle \psi, v\rangle = 0$ for all $v \in \mathcal{V}$ vanishes. Put $y = \bar{\psi}$. As ψ is a form of type $\bar{e}_\lambda$ and the conditions of (ED2) are invariant under complex conjugation, y is a form of type e_λ on $V^0_{z,0}$, that is $y \in \mathcal{F}^0_\triangle(z,0)$ ((TV2)), and it is right invariant under the elements reducing to 1 modulo $\mathfrak{b}$, so $y \in \mathcal{F}^{\mathrm{bs}}_z$ ((TV4)). Let $U = \mathrm{Wc}^0_{1,z,m} y$, a triangle form at $(0,m)$ right invariant under the elements of $\mathbf{K}_0(n_{z,0,m})$ reducing to 1 modulo $\mathfrak{b}$ ((2) of Lemma 6.4.63, $m \geq 1$), and $\varphi = \bar{U}$; U is a form of type e_{λ_m}, $\lambda_m = \frac{1}{2} p_{z,0,m}$ ((TV2)), and by (b) of Lemma 6.4.15 (offset 0) the grid forms at $(z,0,m)$ are the forms of type $\bar{e}_{\lambda_m}$, so φ is a grid form there, so $\varphi \in \mathcal{F}_{\mathfrak{b}}(m)$ ((FY2)). By (3) of Lemma 6.4.63 with $b = m$ ($\Theta^\flat_{1,z,m} = \mathrm{id}$),

$$\langle U, U\rangle = \int_{[\mathrm{U}(\tilde{Y}^m_0)]} \varphi\, U = \int_{[\mathrm{U}(\tilde{Y}^0_0)]} (\Theta^\flat \varphi)\, y = \langle \psi, \Theta^\flat \varphi\rangle = 0,$$

as $\Theta^\flat \varphi \in \mathcal{V}$. So $U = 0$ by continuity, $y = 0$ by (a), and $\psi = 0$. □

Proposition 6.4.11. *Let D be admissible data, $z \in \{\mathrm{I}, \mathrm{II}\}$, and for $i + n < m$ let $\Phi_{i,n}$ be a left pair at (i,n). For every m-fold twist ϑ there are functions $e_\vartheta(i,n)$ on $\mathrm{M}_{n_{n+1}\times n_n}(R_\vartheta)$ ($i+n<m$) with $e_\vartheta(i,n+1) = e_\vartheta(i,n)^\natural$ whenever $i+n+1<m$, such that the following holds for the data: I the set of m-fold twists; $\mathcal{H}_{i,n} = \mathcal{F}^i_\triangle(z,n)$ with the Petersson product of $V^i_{z,n}$; $a^\vartheta_{i,n} = \mathrm{Tl}^i_{\vartheta,z,n}$ and $b^\vartheta_{i,n} = \mathrm{Ds}^i_{\vartheta,z,n}(\Phi_{i,n}, e_\vartheta(i,n))$ if $i+n<m$, and $a^\vartheta_{i,n} = 0$, $b^\vartheta_{i,n} = 0$ otherwise; $w_\vartheta(n) = \#\mathrm{GL}_{n_n}(R_\vartheta)$; $V_0 = \mathcal{F}^{\mathrm{bs}}_z$ with the Petersson product of $V^0_{z,0}$; and $u_i \colon V_0 \to \mathcal{H}_{i,0}$ the inclusion, $\mathcal{F}^i_\triangle(z,0)$ being $\mathcal{F}^0_\triangle(z,0)$ (Lemma 6.4.15(a)).*

(a) The maps $a^\vartheta_{i,n}$, $b^\vartheta_{i,n}$ are linear maps $\mathcal{H}_{i,n} \to \mathcal{H}_{i,n+1}$, $\mathcal{H}_{i,n+1} \to \mathcal{H}_{i+1,n}$, the u_i are linear isometries, and (Qu1)–(Qu3) hold.

(b) Let $z = \mathrm{I}$ and $\mathcal{F}^{\mathrm{bs}}_z \neq 0$, let $\mathcal{M}(c,g)$ mean that c has absolute value g up to a norm power (a unital and multiplicative relation), and $f_{r,k} = q_{rk}$ for $1 \leq r < k \leq m$. Then (Qx1) and (Qx2) hold.

Proof. **Step 0: the data.** The left pairs exist by Lemma 6.4.15(c). For $i < m$ and each ϑ let $e_\vartheta(i,0) = \Psi_0$ be the function of Lemma 6.4.54 for $\Phi_{i,0}$, and define $e_\vartheta(i,n+1) = e_\vartheta(i,n)^\natural$ recursively for $i+n+1<m$. By Lemma 6.4.51(a), (b) the maps of the statement take $\mathcal{H}_{i,n}$ to $\mathcal{H}_{i,n+1}$ and $\mathcal{H}_{i,n+1}$ to $\mathcal{H}_{i+1,n}$ (the zero maps trivially), and they are linear; u_i is an isometry by Lemma 6.4.15(a). Write $w = w_\vartheta$, $a_{i,n} = a^\vartheta_{i,n}$, $b_{i,n} = b^\vartheta_{i,n}$ and $X_{i,n}$ for the weighted chains of Lemma 6.4.59.

Step 1: (Qu1). Let $i+n+2 \leq m$. By Lemma 6.4.12 for $\Phi_0 = \Phi_{i,n}$, $\Phi_1 = \Phi_{i,n+1}$ there are $\kappa_{i,n} \in \mathbb{C}$ and $C_{i,n} > 0$, independent of ϑ, and $c_{i,n}(\vartheta)$ with $|c_{i,n}(\vartheta)|^2 = C_{i,n} L_*(\Sigma(\mathfrak{t}_\vartheta(z)), \nu_\vartheta; t') \neq 0$ such that, with $p = e_\vartheta(i,n)$ and $p^\natural = e_\vartheta(i,n+1)$,

$$w(n)\, a_{i+1,n} \circ b_{i,n} = \frac{\kappa_{i,n}}{c_{i,n}(\vartheta)}\, w(n+2)\, b_{i,n+1} \circ a_{i,n+1} \qquad \text{on } \mathcal{H}_{i,n+1}, \tag{6.63}$$

which is (Qu1) with $\gamma = \kappa_{i,n} w(n+2)/c_{i,n}(\vartheta)$.

Step 2: (Qu2). For $i < m$, $y \in V_0$ and $x \in \mathcal{H}_{i,1}$, Lemma 6.4.54 gives $\langle x, a_{i,0} u_i y\rangle = \langle b_{i,0} x, u_{i+1} y\rangle$; it holds for every $y \in \mathcal{F}^0_\triangle(z,0)$.

Step 3: (Qu3). Let $i < m$, $y \in V_0$ and $v = b_{i,0} a_{i,0} y \in \mathcal{H}_{i+1,0} = \mathcal{F}^0_\triangle(z,0)$. For every $x \in \mathcal{F}^0_\triangle(z,0)$, Step 2 with $a_{i,0} y$ in place of x and x in place of y gives $\langle a_{i,0} y, a_{i,0} x\rangle = \langle v, x\rangle$, the

Petersson products of $V^{i+1}_{z,0}$ and $V^0_{z,0}$ agreeing (Lemma 6.4.15(a)). The first lift of row i is $a_{i,0}$ on the forms at $(0,0)$ (TV5); so Lemma 6.4.58(c) gives $v \in \mathcal{F}^{\mathrm{bs}}_z$, i.e. $b_{i,0}a_{i,0}u_i y = u_{i+1}v \in u_{i+1}(V_0)$. If $v = 0$, then $\langle a_{i,0}y, a_{i,0}y\rangle = \langle v, y\rangle = 0$, so $a_{i,0}y = 0$ (a continuous function of Petersson norm 0 vanishes, the quotient measure charging nonempty open sets), and $y = 0$ by Lemma 6.4.58(b).

Step 4: if $V_0 \neq 0$, every $\kappa_{i,k}$ is nonzero. Let $i+k+2 \le m$ with $\kappa_{i,k} = 0$; fix ϑ, and write $\gamma_n = \kappa_{i,n}w(n+2)/c_{i,n}(\vartheta)$ for $n \le k$. Put $c_0 = 1/w(0)$ and $c_{n+1} = c_n\gamma_n/w(n+1)$. For $n \le k$, $X_{i+1,n}\, b_{i,0}a_{i,0} = c_n\, b_{i,n}X_{i,n+1}$ on $\mathcal{H}_{i,0}$: for $n = 0$ both sides are $b_{i,0}a_{i,0}$, and if it holds for $n < k$, then by (6.63) and $X_{i,n+2} = w(n+1)a_{i,n+1}X_{i,n+1}$,

$$\begin{aligned} X_{i+1,n+1}b_{i,0}a_{i,0} &= w(n)\, a_{i+1,n}X_{i+1,n}b_{i,0}a_{i,0} = c_n\, w(n)\, a_{i+1,n}b_{i,n}X_{i,n+1} \\ &= c_n\gamma_n\, b_{i,n+1}a_{i,n+1}X_{i,n+1} = c_{n+1}\, b_{i,n+1}X_{i,n+2}. \end{aligned}$$

With $n = k$ and (6.63) at (i,k), where $\gamma_k = 0$: $X_{i+1,k+1}b_{i,0}a_{i,0} = c_k w(k)\, a_{i+1,k}b_{i,k}X_{i,k+1} = c_k\gamma_k\, b_{i,k+1}a_{i,k+1}X_{i,k+1} = 0$. Let $y \in V_0$; by Step 3 there is $x \in V_0$ with $u_{i+1}x = b_{i,0}a_{i,0}u_i y$, so $X_{i+1,k+1}u_{i+1}x = 0$, and as $(i+1)+(k+1) \le m$, Lemma 6.4.59(1) (whose hypotheses are Steps 1–3) gives $x = 0$; then $y = 0$ by Step 3. So $V_0 = 0$.

Step 5: (Qx1). Let $z = \mathrm{I}$ (so $t' = t$, $\Sigma(\mathfrak{t}_\vartheta(z)) = S_M \cup Q$ with S_M the chosen places), $V_0 \neq 0$ and $i+n+2 \le m$. By Step 4, $\kappa_{i,n} \neq 0$; put $\beta(\vartheta) = \overline{c_{i,n}(\vartheta)}/\overline{\kappa_{i,n}} \neq 0$. Multiplying (6.63) by $c_{i,n}(\vartheta)/\kappa_{i,n} = \overline{\beta(\vartheta)}$ gives $w(n)\,\overline{\beta(\vartheta)}\, a_{i+1,n}b_{i,n} = w(n+2)\, b_{i,n+1}a_{i,n+1}$, the identity of (Qx1). Its modulus: with $\nu_q = \mu^0_{i+n+2}(\mu^0_{i+1})^{-1}$, so that $\nu_\vartheta = (\nu_q\vartheta^{\,n+1})^{-1}$, and $\vartheta^{\,n+1}$ having the modulus Q of ϑ, the definitions of the ratios give

$$q_{i+1,i+n+2}(\vartheta)\prod_{z'=1}^{t}|L^{S_M}(z',\widetilde{\nu_q^{-1}})| = \prod_{z'=1}^{t}|L^{S_M\cup Q}(z',\tilde\nu_\vartheta)|,$$

provided the factors $L^{S_M}(z',\widetilde{\nu_q^{-1}})$ are nonzero. They are: $\widetilde{\nu_q^{-1}}$, $x \mapsto \nu_q^{-1}(x/\bar x)$, is a unitary Hecke character of E; at a chosen place w and an idele x with a unit a at w and 1 elsewhere, $x/\bar x$ is integral with component a at w and 1 at the infinite places, so $\widetilde{\nu_q^{-1}}(x) = \omega_w^{-(n+1)}(a \bmod w)$ (the tame part of ν_q^{-1} is $\omega^{-(n+1)}$, trivial at $\bar w$), which is not identically 1 by Lemma 6.7.3, as $1 \le n+1 < m$; so the character is ramified, not of the form $|\cdot|^{i\tau}_{\mathbb{A}}$, and by Theorem A.1.12(3) its L-function has no zeros on $\mathrm{Re}\, s \ge 1$, while the finitely many removed Euler factors are finite and nonzero there. Hence, by (XD7),

$$|\beta(\vartheta)|^2 = \frac{C_{i,n}}{|\kappa_{i,n}|^2}\,(\mathrm{N}S_M\cdot\mathrm{N}Q)^{t^2}\prod_{z'=1}^{t}\left|L^{S_M\cup Q}(z',\tilde\nu_\vartheta)\right|^2 = C'\,(\mathrm{N}Q)^{t^2}\,q_{i+1,i+n+2}(\vartheta)^2,$$

$\mathrm{N}S_M = \prod_{w\in S_M}\mathrm{N}w$, with $C' = C_{i,n}|\kappa_{i,n}|^{-2}(\mathrm{N}S_M)^{t^2}\prod_{z'}|L^{S_M}(z',\widetilde{\nu_q^{-1}})|^2$ independent of ϑ. So $\mathcal{M}(\beta, f_{i+1,i+n+2})$. The relation $\mathcal{M}$ is unital ($C = 1$, exponent 0) and multiplicative (multiply the constants, add the exponents).

Step 6: the central translations. Let $z = \mathrm{I}$, $i' + n' < m$, and $u \in G_f(n_{n'})$, $u' \in G_f(n_{n'+1})$ the scalar matrices of the norm-one idele $\zeta = \overline{\alpha_{\mathrm{W}}t}/(\alpha_{\mathrm{W}}t)$ of Lemma 6.4.60. By (XD2), $((1,u),(1,u'))$ acts on the datum φ of $\mathrm{Tl}^{i'}_{\vartheta,z,n'}$ by $\alpha(\zeta^{N_{n'+1}})\beta(\zeta^{N_{n'}})^{-1}$, (α,β) its characters, times the Weil operator of $X \mapsto u'Xu^{-1} = X$, which is the identity ((2) of Lemma 4.1.1); so $\omega((1,u),(1,u'))\varphi = \eta\varphi$ with $|\eta| = 1$, and $\omega((1,u),1)\varphi = \eta\,\omega(1,(1,u'^{-1}))\varphi$. For a triangle form y at (i',n'), the substitution $g \mapsto g(1,u)$ in $[\mathrm{U}(V^{i'}_{z,n'})]$ gives

$$\mathrm{Tl}^{i'}_{\vartheta,z,n'}(\rho(u^{-1})y)(h) = \int\theta(\omega(g,h)\,\omega((1,u),1)\varphi)y(g)\,dg = \eta\,\mathrm{Tl}^{i'}_{\vartheta,z,n'}y(h(1,u'^{-1})),$$

i.e. $\mathrm{Tl}^{i'}_{\vartheta,z,n'}\circ\rho(u^{-1}) = \eta\,\rho(u'^{-1})\circ\mathrm{Tl}^{i'}_{\vartheta,z,n'}$.

Step 7: (Qx2). Let $z = \mathrm{I}$, $i+n+2 \le m$, and let $\Phi'_{i,n}$, $\Phi'_{i,n+1}$ be reversed pairs (Lemma 6.4.15(c)). By Lemma 6.4.60 at (i,n) and at $(i,n+1)$ and Lemma 6.4.62 there are c_1, c_2, γ of absolute value 1 up to a norm power with, for every ϑ and $\Psi = e_\vartheta(i,n)$ (so $\Psi^\natural = e_\vartheta(i,n+1)$): $\langle b_{i,n}x, y'\rangle = c_1(\vartheta)\langle x, A_0\rho(u^{-1})y'\rangle$ for $x \in \mathcal{H}_{i,n+1}$, $y' \in \mathcal{H}_{i+1,n}$; $\langle x', A_1\rho(u'^{-1})y\rangle = c_2(\vartheta)\langle b_{i,n+1}x', y\rangle$ for $x' \in \mathcal{H}_{i,n+2}$, $y \in \mathcal{H}_{i+1,n+1}$; and $a_{i,n+1}A_0 = \gamma(\vartheta)A_1a_{i+1,n}$ on $\mathcal{H}_{i+1,n}$; here $A_0 = \mathrm{As}^i_{\vartheta,z,n}(\Phi'_{i,n}, \widehat{\Psi})$, $A_1 = \mathrm{As}^i_{\vartheta,z,n+1}(\Phi'_{i,n+1}, \widehat{\Psi^\natural})$, and u, u' are as in Step 6 for $n' = n$. Let $\kappa = c_1\gamma\eta c_2$, which satisfies $\mathcal{M}(\kappa, 1)$ ($\mathcal{M}(\eta,1)$ as $|\eta| = 1$). Let $z' \in \mathcal{H}_{i,n+2}$, and let $x \in \mathcal{H}_{i,n+1}$ be the vector of Lemma 6.4.51(d) for $a_{i,n+1}$, so that $\langle a_{i,n+1}y, z'\rangle = \langle y, x\rangle$ for all y, hence $\langle x, y\rangle = \langle z', a_{i,n+1}y\rangle$. For $y' \in \mathcal{H}_{i+1,n}$, using Step 6 for $(i',n') = (i+1,n)$,

$$\begin{aligned}\langle b_{i,n}x, y'\rangle &= c_1\langle z', a_{i,n+1}A_0\rho(u^{-1})y'\rangle = c_1\gamma\langle z', A_1a_{i+1,n}\rho(u^{-1})y'\rangle\\ &= c_1\gamma\eta\langle z', A_1\rho(u'^{-1})a_{i+1,n}y'\rangle = \kappa(\vartheta)\langle b_{i,n+1}z', a_{i+1,n}y'\rangle,\end{aligned}$$

which is (Qx2). □

Lemma 6.4.12. *Let D be admissible data, $z \in \{\mathrm{I},\mathrm{II}\}$, $i,n \ge 0$ with $i+n+2 \le m$, Φ_0 a left pair at (i,n) and Φ_1 a left pair at $(i,n+1)$. Write $n_{n+1} = n_n \sqcup B_{n+1}$ and $n_{n+2} = n_{n+1} \sqcup B_{n+2}$, B_l the down block l, and identify B_{n+2} with B_{n+1} by $(n+2,c) \mapsto (n+1,c)$. For a function p on $\mathrm{M}_{n_{n+1}\times n_n}(R_\vartheta)$ let $p^\natural$ be its next datum formed for $(I,J,K) = (n_{n+1}, n_n, B_{n+1})$, read through this identification as a function on $\mathrm{M}_{n_{n+2}\times n_{n+1}}(R_\vartheta)$. Then there are $\kappa \in \mathbb{C}$ and $C > 0$, independent of ϑ, and for every m-fold twist ϑ a number c_ϑ with*

$$|c_\vartheta|^2 = C\,L_*\big(\Sigma(\mathfrak{t}_\vartheta(z)), \nu_\vartheta; t'\big) \ne 0,$$

such that for every m-fold twist ϑ and every function p on $\mathrm{M}_{n_{n+1}\times n_n}(R_\vartheta)$, on $\mathcal{F}^i_\triangle(z, n+1)$,

$$\#\mathrm{GL}_{n_n}(R_\vartheta)\ \mathrm{Tl}^{i+1}_{\vartheta,z,n} \circ \mathrm{Ds}^i_{\vartheta,z,n}(\Phi_0, p) = \frac{\kappa}{c_\vartheta}\ \#\mathrm{GL}_{n_{n+2}}(R_\vartheta)\ \mathrm{Ds}^i_{\vartheta,z,n+1}(\Phi_1, p^\natural) \circ \mathrm{Tl}^i_{\vartheta,z,n+1}.$$

Proof. **Step 1: the one-square identity for the square at (i,n).** Let I_{tw} be the set of m-fold twists. We apply Proposition 6.3.72 to the spaces $A' = V^{i+1}_{z,n}$, $A = V^i_{z,n+2}$, $U_1 = V^i_{z,n+1}$, $U_2 = V^{i+1}_{z,n+1}$ with index sets n_n, n_{n+2}, n_{n+1}, n_{n+1}, the integer t', the weight $\mu = (n+1)\Delta$, the family $\vartheta \mapsto \nu_\vartheta$, tame of weight μ for $(\mathfrak{t}_\vartheta(z), \chi^{\mathrm{sq}}_\vartheta)$ by Lemma 6.4.14(c), the characters of Lemma 6.4.14(a) on the four pairs, the polynomials $P_1 = H_{i,n+1}$ and $P'_2 = H_{i+1,n}$, the joint harmonics of the triangle lifts at $(i,n+1)$ and $(i+1,n)$, $P_2 = \Phi_1$, $P'_1 = \Phi_0$, and the bijection $\sigma\colon n_n \sqcup n_{n+2} \to n_{n+1} \sqcup n_{n+1}$ that is the identity from $n_{n+2} \supseteq n_{n+1}$ onto the first copy, maps n_n identically into the second copy and maps B_{n+2} onto B_{n+1} in the second copy by the identification of the statement. Its hypotheses: (OS1) and (OS3) are Lemma 6.4.14(a). (OS2): the weights of the characters do not depend on ϑ (Lemma 6.4.14(c)); with the types $e_1 = e_{\lambda_1}$, $e = e_\lambda$, $e' = e_{\lambda'}$, $e_2 = e_{\lambda_2}$ of the triangle forms on U_1, A, A', U_2 ($\lambda_1 = \frac12 p^i_{z,0,n+1}$, $\lambda = \frac12 p^i_{z,0,n+2}$, $\lambda' = \frac12 p^{i+1}_{z,0,n}$, $\lambda_2 = \frac12 p^{i+1}_{z,0,n+1}$), v_{P_1} is an edge from e_1 to e and $v_{P'_2}$ one from e' to e_2 for the weights of the characters of their pairs by Lemma 6.4.15(b) (as $i+n+1 < m$); v_{Φ_1} is an edge from $e_{-\lambda_2} = \overline{e_2}$ to $e_{-\lambda} = \overline{e}$, and v_{Φ_0} one from $e_{-\lambda'} = \overline{e'}$ to $e_{-\lambda_1} = \overline{e_1}$, for the weights $(\delta_i(N_{n+1}), \delta_i(N_{n+2}))$ and $(\delta_i(N_n), \delta_i(N_{n+1}))$ of the left-pair characters, by (TV6). For a matrix x over R_ϑ with rows n_{n+2} and columns $n_{n+1} \sqcup n_{n+1}$, with column blocks x_1, x_2, the composite $\Theta_\vartheta(x)$ of Proposition 6.3.72 is $\mathrm{Ds}^i_{\vartheta,z,n+1}(\Phi_1, \mathbf{1}_{x_2}) \circ \mathrm{Tl}^i_{\vartheta,z,n+1}[\mathbf{1}_{x_1}]$, the transposed lift from A to U_2 being the descent (TV7), the integral over $[\mathrm{U}(A)]$ against the theta kernel of the pair (U_2, A); for y with rows $n_{n+1} \sqcup n_{n+1}$, columns n_n and row blocks y_1, y_2, $\Theta'_\vartheta(y) = \mathrm{Tl}^{i+1}_{\vartheta,z,n}[\mathbf{1}_{y_2}] \circ \mathrm{Ds}^i_{\vartheta,z,n}(\Phi_0, \mathbf{1}_{y_1})$. These maps take triangle forms to triangle forms by Lemma 6.4.51. So Proposition 6.3.72 gives $C > 0$ and

$\kappa \in \mathbb{C}$ independent of ϑ and numbers c_ϑ with $|c_\vartheta|^2 = C\, L_*(\Sigma(\mathfrak{t}_\vartheta(z)), \nu_\vartheta; t') \neq 0$, such that for every form $f \in \mathcal{F}^i_\triangle(z, n+1)$ and every linear functional l on $\mathcal{F}^{i+1}_\triangle(z, n+1)$ the functions $L(x) = l(\Theta_\vartheta(x)f)$ and $L'(y) = l(\Theta'_\vartheta(y)f)$ satisfy: $L(kx) = \chi^{\mathrm{sq}}_\vartheta(\det k)L(x)$ for $k \in \mathrm{GL}_{n_{n+2}}(R_\vartheta)$, $L'(yk) = \chi^{\mathrm{sq}}_\vartheta(\det k)L'(y)$ for $k \in \mathrm{GL}_{n_n}(R_\vartheta)$, and $\sum_y \Psi'(y)L'(y) = \frac{\kappa}{c_\vartheta}\sum_x \Psi(x)L(x)$ for all Ψ, Ψ' matched for $(\sigma, \chi^{\mathrm{sq}}_\vartheta)$.

Step 2: the square law at the inclusion. Put $R = R_\vartheta$, $I = n_{n+1}$, $J = n_n$, $K = B_{n+1}$, so that $J \sqcup K = n_{n+1}$, $I \sqcup K$ is n_{n+2} through the identification of the statement, and $W = I \sqcup J \sqcup K$ is $n_{n+1} \sqcup n_{n+1}$ (I the first copy, $J \sqcup K$ the second); under these identifications the canonical bijection $J \sqcup (I \sqcup K) \to W$ of Lemma 6.4.13 is σ. By Step 1, L and L' satisfy (i) and (ii) of Lemma 6.4.13 for the character $\chi^{\mathrm{sq}}_\vartheta$ and $c = \kappa/c_\vartheta$. Part (1) there gives, for every function p on $\mathrm{M}_{I\times J}(R)$,

$$\#\mathrm{GL}_{n_n}(R)\sum_y p(y)\, L'\begin{pmatrix} y \\ \iota_J \end{pmatrix} = \frac{\kappa}{c_\vartheta}\,\#\mathrm{GL}_{n_{n+2}}(R)\sum_x p^\natural(x)\, L(\iota_I \;\; x).$$

Here $\iota_J \in \mathrm{M}_{n_{n+1}\times n_n}(R)$ and $\iota_I \in \mathrm{M}_{n_{n+2}\times n_{n+1}}(R)$ are the matrices with entry 1 at (c, c) and 0 elsewhere, whose indicator functions are the point data Φ^{pt}_n and Φ^{pt}_{n+1} of (TV3). So $L'\binom{y}{\iota_J} = l(\mathrm{Tl}^{i+1}_{\vartheta,z,n}\,\mathrm{Ds}^i_{\vartheta,z,n}(\Phi_0, \mathbf{1}_y)f)$ and $L(\iota_I\; x) = l\big(\mathrm{Ds}^i_{\vartheta,z,n+1}(\Phi_1, \mathbf{1}_x)\,\mathrm{Tl}^i_{\vartheta,z,n+1}f\big)$.

Step 3: summing the data. By Lemma 6.4.51(c), $\sum_y p(y)\mathrm{Ds}^i_{\vartheta,z,n}(\Phi_0, \mathbf{1}_y) = \mathrm{Ds}^i_{\vartheta,z,n}(\Phi_0, p)$ and $\sum_x p^\natural(x)\mathrm{Ds}^i_{\vartheta,z,n+1}(\Phi_1, \mathbf{1}_x) = \mathrm{Ds}^i_{\vartheta,z,n+1}(\Phi_1, p^\natural)$; with the linearity of Tl and of l, Step 2 reads

$$l\Big(\#\mathrm{GL}_{n_n}(R)\,\mathrm{Tl}^{i+1}_{\vartheta,z,n}\mathrm{Ds}^i_{\vartheta,z,n}(\Phi_0, p)f - \frac{\kappa}{c_\vartheta}\#\mathrm{GL}_{n_{n+2}}(R)\,\mathrm{Ds}^i_{\vartheta,z,n+1}(\Phi_1, p^\natural)\mathrm{Tl}^i_{\vartheta,z,n+1}f\Big) = 0$$

for every linear functional l on $\mathcal{F}^{i+1}_\triangle(z, n+1)$. Linear functionals separate the points of a vector space (extend a basis containing a given nonzero vector), so the vector in brackets is 0 for every f, which is the claim. □

Lemma 6.4.13. *Let R be a finite commutative ring and χ a multiplicative character of R. For finite sets I', J', K' and a function p on $\mathrm{M}_{I'\times J'}(R)$, the **next datum** $p^\natural$ is the function on $\mathrm{M}_{(I'\sqcup K')\times(J'\sqcup K')}(R)$ given on block matrices by*

$$p^\natural\begin{pmatrix} \eta & s \\ \zeta & d \end{pmatrix} = \begin{cases} p(-\eta)/\#\mathrm{M}_{I'\times K'}(R) & \text{if } \zeta = 0 \text{ and } d = 1, \\ 0 & \text{otherwise,} \end{cases}$$

and $\iota_{J'} \in \mathrm{M}_{(J'\sqcup K')\times J'}(R)$ is the matrix $\binom{1}{0}$. For an additive character ψ_R and a function f on $\mathrm{M}_{X\times Y}(R)$ put $\hat{f}(\rho) = \sum_{v\in\mathrm{M}_{X\times Y}(R)} f(v)\,\psi_R(\mathrm{tr}(\rho v))$ for $\rho \in \mathrm{M}_{Y\times X}(R)$.

Let I, J, K be finite sets, $W = I \sqcup J \sqcup K$, and $\sigma\colon J \sqcup (I \sqcup K) \to W$ the canonical bijection. Let $c \in \mathbb{C}$ and let L on $\mathrm{M}_{(I\sqcup K)\times W}(R)$ and L' on $\mathrm{M}_{W\times J}(R)$ satisfy

(i) $L(gx) = \chi(\det g)\,L(x)$ for $g \in \mathrm{GL}_{I\sqcup K}(R)$, and $L'(yh) = \chi(\det h)\,L'(y)$ for $h \in \mathrm{GL}_J(R)$;

(ii) $\sum_y \Psi(y)\,L'(y) = c\sum_x \Phi(x)\,L(x)$ for all Φ on $\mathrm{M}_{(I\sqcup K)\times W}(R)$ and Ψ on $\mathrm{M}_{W\times J}(R)$ matched for (σ, χ).

Then:

1. *for every function p on $\mathrm{M}_{I\times J}(R)$, with $p^\natural$ formed for (I, J, K),*

$$\#\mathrm{GL}_J(R)\sum_{y\in\mathrm{M}_{I\times J}(R)} p(y)\,L'\begin{pmatrix} y \\ \iota_J \end{pmatrix} = c\,\#\mathrm{GL}_{I\sqcup K}(R)\sum_{x\in\mathrm{M}_{(I\sqcup K)\times(J\sqcup K)}(R)} p^\natural(x)\,L(\iota_I \;\; x),$$

where $\binom{y}{\iota_J}$ has the rows y (index I) above ι_J (index $J \sqcup K$), and $(\iota_I \;\; x)$ has the columns ι_I (index I) before x (index $J \sqcup K$);

2. *suppose moreover that χ is primitive, ψ_R is a primitive additive character and $J = I \sqcup K$. There is $\gamma \in \mathbb{C}$, depending only on R, χ, ψ_R, $|I|$ and $|K|$, with*

$$|\gamma|^2 \, (\#R)^{|K|(|K|+2|I|)} = 1,$$

such that for all c, L, L' as above and every function p on $\mathrm{M}_{(I\sqcup K)\times I}(R)$, with $p^\natural$ formed for $(I \sqcup K, I, K)$,

$$\sum_{y \in \mathrm{M}_{I\times(I\sqcup K)}(R)} \widehat{\overline{p}}(y) \, L'\begin{pmatrix} y \\ \iota_J \end{pmatrix} = \gamma \, c \sum_{x \in \mathrm{M}_{(I\sqcup K)\times((I\sqcup K)\sqcup K)}(R)} \widehat{p^\natural}(x) \, L(\iota_I \;\; x).$$

Proof. **Step 1: two block identities.** Let $k \in \mathrm{GL}_W(R)$, let $x = (x_1 \; x_2) \in \mathrm{M}_{a\times W}(R)$ be the rows a of k^{-1} (x_1 on the columns b, x_2 on a) and $y = \binom{y_1}{y_2} \in \mathrm{M}_{W\times b}(R)$ the columns b of k (y_1 on the rows b). Since $k^{-1}k = 1$, the rows a of $k^{-1}k$ are $(0 \;\; 1)$; hence $x_1y_1 + x_2y_2 = 0$, and

$$\begin{pmatrix} 1 & 0 \\ x_1 & x_2 \end{pmatrix} k = \begin{pmatrix} y_1 & * \\ 0 & 1 \end{pmatrix}, \qquad \text{so} \qquad \det x_2 \cdot \det k = \det y_1.$$

Step 2: block functions are matched. Let δ be a function on $\mathrm{M}_{a\times b}(R)$, and put $\Phi_\delta(x) = \chi^{-1}(\det x_2)\,\delta(x_2^{-1}x_1)$ if x_2 is invertible and 0 otherwise, and $\Psi_\delta(y) = \chi^{-1}(\det y_1)\,\delta(-y_2y_1^{-1})$ if y_1 is invertible and 0 otherwise. They are matched for (σ, χ). Support: if $\Phi_\delta(x) \neq 0$, then x_2 is invertible and x is the rows a of k^{-1} for $k = \left(\begin{smallmatrix} 1 & 0 \\ x_1 & x_2 \end{smallmatrix}\right)^{-1}$; if $\Psi_\delta(y) \neq 0$, then y_1 is invertible and y is the columns b of $k = \left(\begin{smallmatrix} y_1 & 0 \\ y_2 & 1 \end{smallmatrix}\right)$. Values: let k, x, y be as in Step 1. If x_2 is invertible, so is y_1 (Step 1, $\det k$ a unit), and $y_2 = -x_2^{-1}x_1y_1$, so $-y_2y_1^{-1} = x_2^{-1}x_1$; then $\chi(\det k)\Psi_\delta(y) = \chi(\det k)\chi^{-1}(\det x_2)\chi^{-1}(\det k)\,\delta(x_2^{-1}x_1) = \Phi_\delta(x)$. If x_2 is not invertible, then $\det y_1 = \det x_2 \det k$ is not a unit and both values are 0.

Step 3: the law at a point. Let $w \in \mathrm{M}_{a\times b}(R)$ and δ the indicator function of $\{w\}$. By (ii) for $(\Phi_\delta, \Psi_\delta)$,

$$\sum_{y_1} \chi^{-1}(\det y_1) \sum_{y_2} \delta(-y_2y_1^{-1}) L'\begin{pmatrix} y_1 \\ y_2 \end{pmatrix} = c \sum_{x_2} \chi^{-1}(\det x_2) \sum_{x_1} \delta(x_2^{-1}x_1) \, L(x_1 \; x_2),$$

the outer sums running over the invertible y_1, resp. x_2, since χ^{-1} vanishes at non-units. For $y_1 = h \in \mathrm{GL}_b(R)$ the inner sum on the left has the single term $y_2 = -wh$, and $L'\left(\begin{smallmatrix} h \\ -wh \end{smallmatrix}\right) = L'\left(\left(\begin{smallmatrix} 1 \\ -w \end{smallmatrix}\right)h\right) = \chi(\det h)L'\left(\begin{smallmatrix} 1 \\ -w \end{smallmatrix}\right)$ by (i); for $x_2 = g$ the inner sum on the right has the single term $x_1 = gw$, and $L(gw \; g) = \chi(\det g)L(w \; 1)$. Hence

$$\#\mathrm{GL}_b(R) \; L'\begin{pmatrix} 1 \\ -w \end{pmatrix} = c \, \#\mathrm{GL}_a(R) \; L(w \;\; 1). \tag{6.64}$$

Step 4: part (1). Return to the order $I \sqcup J \sqcup K$ of W. Let $\eta \in \mathrm{M}_{I\times J}(R)$, $s \in \mathrm{M}_{I\times K}(R)$, and take $w = \binom{\eta}{0} \in \mathrm{M}_{(I\sqcup K)\times J}(R)$ in (6.64). In the order $I \sqcup J \sqcup K$ of the rows, $\left(\begin{smallmatrix} 1 \\ -w \end{smallmatrix}\right)$ is $\binom{-\eta}{\iota_J}$; in that order of the columns, $(w \;\; 1)$ is $\left(\iota_I \;\; \left(\begin{smallmatrix} \eta & 0 \\ 0 & 1 \end{smallmatrix}\right)\right)$. The matrix $u = \left(\begin{smallmatrix} 1 & s \\ 0 & 1 \end{smallmatrix}\right) \in \mathrm{GL}_{I\sqcup K}(R)$ has determinant 1, fixes ι_I and maps $\left(\begin{smallmatrix} \eta & 0 \\ 0 & 1 \end{smallmatrix}\right)$ to $\left(\begin{smallmatrix} \eta & s \\ 0 & 1 \end{smallmatrix}\right)$; by (i),

$$\#\mathrm{GL}_J(R) \, L'\begin{pmatrix} -\eta \\ \iota_J \end{pmatrix} = c \, \#\mathrm{GL}_{I\sqcup K}(R) \, L\Big(\iota_I \;\; \begin{pmatrix} \eta & s \\ 0 & 1 \end{pmatrix}\Big) \qquad \text{for all } \eta, s.$$

By the definition of $p^\natural$,

$$\sum_x p^\natural(x)L(\iota_I\, x) = \sum_{\eta,s} \frac{p(-\eta)}{\#\mathrm{M}_{I\times K}(R)} L(\iota_I \left(\begin{smallmatrix}\eta & s\\ 0 & 1\end{smallmatrix}\right)).$$

Multiplying by $c\,\#\mathrm{GL}_{I\sqcup K}(R)$ and inserting the last display, the sum over s cancels the denominator, and the result is $\#\mathrm{GL}_J(R)\sum_\eta p(-\eta)L'\binom{-\eta}{\iota_J}$, which is the left side of (1) after $y=-\eta$.

Step 5: the transform of a next datum. Let ψ_R be primitive, I', J', K' finite sets and q a function on $\mathrm{M}_{I'\times J'}(R)$. For $\rho = \left(\begin{smallmatrix}A & B\\ C & D\end{smallmatrix}\right) \in \mathrm{M}_{(J'\sqcup K')\times(I'\sqcup K')}(R)$ and $v = \left(\begin{smallmatrix}\eta & s\\ 0 & 1\end{smallmatrix}\right)$, $\mathrm{tr}(\rho v) = \mathrm{tr}(A\eta)+\mathrm{tr}(Cs)+\mathrm{tr}\,D$. Summing first over s, by orthogonality of characters ($\sum_s \psi_R(\mathrm{tr}(Cs))$ is a product over the entries of sums $\sum_{t\in R}\psi_R(C_{ji}t)$, so it is $\#\mathrm{M}_{I'\times K'}(R)$ for $C=0$ and 0 otherwise, ψ_R being primitive), and then over η, substituting $\eta\mapsto -\eta$,

$$\widehat{q^\natural}(\rho) = \begin{cases} \hat q(-A)\,\psi_R(\mathrm{tr}\,D) & C=0,\\ 0 & C\neq 0.\end{cases}$$

Step 6: part (2). Here $J = I\sqcup K$, and $\overline{p^\natural} = (\overline{p})^\natural$. Let G be the Gauss sum of Lemma 6.2.39 for (R,χ,ψ_R) and the set K, so $|G|^2 = (\#R)^{|K|^2}$, and put $q = \widehat{\overline{p}}$, a function on $\mathrm{M}_{I\times(I\sqcup K)}(R)$. For $\eta\in\mathrm{M}_{I\times(I\sqcup K)}(R)$, $s\in\mathrm{M}_{I\times K}(R)$ and $d\in\mathrm{M}_K(R)$ put $F_{\eta,s}(d) = L(\iota_I \left(\begin{smallmatrix}\eta & s\\ 0 & d\end{smallmatrix}\right))$. For $g\in \mathrm{GL}_K(R)$ the block matrix $\mathrm{diag}(1,g)\in\mathrm{GL}_{I\sqcup K}(R)$ fixes ι_I and maps $\left(\begin{smallmatrix}\eta & s\\ 0 & d\end{smallmatrix}\right)$ to $\left(\begin{smallmatrix}\eta & s\\ 0 & gd\end{smallmatrix}\right)$, so $F_{\eta,s}(gd) = \chi(\det g)F_{\eta,s}(d)$ by (i), and Lemma 6.2.39 at $y=1$ gives $\sum_d F_{\eta,s}(d)\psi_R(\mathrm{tr}\,d) = G\,F_{\eta,s}(1)$. By Step 5 (for $(I',J',K') = (I\sqcup K, I, K)$; the block A is indexed by $I\times(I\sqcup K)$) and the definition of $q^\natural$ (formed for $(I, I\sqcup K, K)$),

$$\sum_x \widehat{\overline{p^\natural}}(x)L(\iota_I\, x) = \sum_{\eta,s} q(-\eta)\sum_d F_{\eta,s}(d)\psi_R(\mathrm{tr}\,d) = G\,\#\mathrm{M}_{I\times K}(R)\sum_x q^\natural(x)\,L(\iota_I\, x).$$

By part (1) applied to q, and $\#\mathrm{GL}_J(R) = \#\mathrm{GL}_{I\sqcup K}(R)\neq 0$, $\sum_y q(y)L'\binom{y}{\iota_J} = c\sum_x q^\natural(x)L(\iota_I\, x)$. So the assertion holds with $\gamma = \left(G\,\#\mathrm{M}_{I\times K}(R)\right)^{-1}$, and $|\gamma|^{-2} = (\#R)^{|K|^2}(\#R)^{2|I||K|}$. □

Lemma 6.4.14. *Let D be admissible data, $z\in\{\mathrm{I},\mathrm{II}\}$, $[z]\in\{0,1\}$ with $[\mathrm{II}]=1$, $t' = t-[z]$, and $i,n\geq 0$ with $i+n+2\leq m$. For an m-fold twist ϑ let $\vartheta' = \vartheta$ if $z=\mathrm{I}$ and $\vartheta' = 1$ if $z=\mathrm{II}$, let $\epsilon_\vartheta(N)$ be the edge character with $c=\neg z$ and $l = n+i+1$ at the rank N, $\chi_\vartheta(N) = \chi^{\mathrm{lp}}_{\vartheta,z,i}(N)$, and*

$$\nu_\vartheta = \left(\mu^0_{n+i+2}\left(\mu^0_{i+1}\right)^{-1}\vartheta'^{\,n+1}\right)^{-1}, \qquad \mu = (n+1)\Delta \text{ (constant on } \Phi).$$

(a) (Left squares.) Put $U_1 = V^i_{z,n+1}$, $A = V^i_{z,n+2}$, $A' = V^{i+1}_{z,n}$, $U_2 = V^{i+1}_{z,n+1}$, $W = U_1\oplus U_2$, and give the pairs (U_1,A), (U_2,A), (A',U_1), (A',U_2) the characters $(\epsilon_\vartheta(N_{n+1}),\epsilon_\vartheta(N_{n+2}))$, $(\chi_\vartheta(N_{n+1}),\chi_\vartheta(N_{n+2}))$, $(\chi_\vartheta(N_n),\chi_\vartheta(N_{n+1}))$, $(\epsilon_\vartheta(N_n),\epsilon_\vartheta(N_{n+1}))$. Then $\mathrm{rk}\,A = \mathrm{rk}\,A' + 2t'$, $\mathrm{neg}(W) = \mathrm{neg}(A)+\mathrm{neg}(A')$, $2\,\mathrm{neg}(W)+2\leq \mathrm{rk}\,W\leq 2\mu+2\,\mathrm{neg}(W)$, and, writing (a_k,b_k) for the characters of (U_k,A) and (b'_k,a'_k) for those of (A',U_k),

$$a_1[\mathrm{rk}\,U_1]\,a_2[\mathrm{rk}\,U_2] = a'_1[\mathrm{rk}\,U_1]\,a'_2[\mathrm{rk}\,U_2] = b_1[\mathrm{rk}\,A]\,b'_1[\mathrm{rk}\,A'] = b_2[\mathrm{rk}\,A]\,b'_2[\mathrm{rk}\,A'] = \tilde\nu_\vartheta^{-1}.$$

(b) (Reversed squares.) Let $z=\mathrm{I}$. Put $U_1 = V^{i+1}_{z,n}$, $A = V^{i+1}_{z,n+1}$, $A' = V^i_{z,n+1}$, $U_2 = V^i_{z,n+2}$, $W = U_1\oplus U_2$, and give (U_1,A), (U_2,A), (A',U_1), (A',U_2) the characters $(\epsilon_\vartheta(N_n),\epsilon_\vartheta(N_{n+1}))$, $(\chi_\vartheta(N_{n+2}),\chi_\vartheta(N_{n+1}))$, $(\chi_\vartheta(N_{n+1}),\chi_\vartheta(N_n))$, $(\epsilon_\vartheta(N_{n+1}),\epsilon_\vartheta(N_{n+2}))$. Then $\mathrm{rk}\,A = \mathrm{rk}\,A'$, $\mathrm{neg}(W) = \mathrm{neg}(A)+\mathrm{neg}(A')$, $2\,\mathrm{neg}(W)+2\leq\mathrm{rk}\,W\leq 2\mu+2\,\mathrm{neg}(W)$, and the four products of (a), formed with these characters, equal $\tilde\nu_\vartheta^{-1}$.

(c) ν_ϑ is tame of weight μ for $(\mathfrak{t}_\vartheta(z), \chi_\vartheta^{\mathrm{sq}})$, where $\chi_\vartheta^{\mathrm{sq}}(u) = \prod_{w\in\Sigma(\mathfrak{t}_\vartheta(z))} \psi_w^\nu(u \bmod w)$ for the tame part ψ^ν of ν_ϑ; its weight and the weights of all the characters in (a) and (b) do not depend on ϑ.

Proof. **Ranks.** $N_{n+2} = N_n + 2t'$, and $N_n + N_{n+2} = 2N_{n+1}$. In (a), $\operatorname{rk} W = 2N_{n+1}$ and $\operatorname{rk} A - \operatorname{rk} A' = N_{n+2} - N_n = 2t'$; in (b), $\operatorname{rk} W = N_n + N_{n+2} = 2N_{n+1}$ and $\operatorname{rk} A = \operatorname{rk} A' = N_{n+1}$.

Signs. By (TV1) the space $V^o_{z,c}$ has the signs with offset o of the node $(z,0,c)$: by (GP5) every block index has the sign $+1$, and the base index β has the sign $(-1)^{o+e+\min(e\dot{-}o,\,c)}$, $e = \max(\beta+1-k, 0)$. Fix β and write $\pi(o,c) \in \{0,1\}$ for the parity of $o+e+\min(e\dot{-}o, c)$, so that $\pi(o,c) = 1$ exactly when β has the sign -1 in $V^o_{z,c}$. We claim $\pi(i,n+1) + \pi(i+1,n+1) = \pi(i,n+2) + \pi(i+1,n)$. Put $a = i+e$ and $d = e\dot{-}i$, so that $e\dot{-}(i+1) = d\dot{-}1$. If $d \le n+1$, then $\min(d, n+1) = \min(d, n+2) = d$ and $d\dot{-}1 \le n$, so $\min(d\dot{-}1, n+1) = \min(d\dot{-}1, n)$, and the two sides agree term by term. If $d \ge n+2$, then $d\dot{-}1 = d-1 \ge n+1$, the left side is the sum of the parities of $a+n+1$ and $a+n+2$ and the right side that of $a+n+2$ and $a+n+1$. Summing over β gives $\operatorname{neg}(V^i_{z,n+1}) + \operatorname{neg}(V^{i+1}_{z,n+1}) = \operatorname{neg}(V^i_{z,n+2}) + \operatorname{neg}(V^{i+1}_{z,n})$, which is $\operatorname{neg}(W) = \operatorname{neg}(A) + \operatorname{neg}(A')$ in (a), and, read as $\operatorname{neg}(V^{i+1}_{z,n}) + \operatorname{neg}(V^i_{z,n+2}) = \operatorname{neg}(V^{i+1}_{z,n+1}) + \operatorname{neg}(V^i_{z,n+1})$, the same in (b).

The inequalities. Only base indices have negative signs, so $\operatorname{neg}(W) \le 2(r+[z]) \le 2r+2$, while $\operatorname{rk} W = 2N_{n+1} \ge 2(r+t') \ge 2(6r-1)$; as $r \ge 3$ ((AD2)), $2\operatorname{neg}(W) + 2 \le 4r+6 \le \operatorname{rk} W$. Also $N_{n+1} \le r+1+(n+1)\,5r \le (n+1)(6r+1) \le (n+1)\,2r^8 = \mu$, so $\operatorname{rk} W \le 2\mu \le 2\mu + 2\operatorname{neg}(W)$.

The characters. By (GP6) and (TV6), $\epsilon_\vartheta(N) = \lambda\, \upsilon^{f(N)}$ and $\chi_\vartheta(N) = \lambda_0^{-1} \upsilon^{N-f(N)}$ with $\lambda = \mu^0_{n+i+2} \vartheta'^{\,n+i+2}$ and $\lambda_0 = \mu^0_{i+1} \vartheta'^{\,i+1}$, so $\lambda\lambda_0^{-1} = \nu_\vartheta^{-1}$. By (WD3), $\upsilon(\bar{x}) = \upsilon(x)^{-1}$, so the base change of υ restricted to $\mathrm{U}(1)(\mathbb{A})$ is $x \mapsto \upsilon(x/\bar{x}) = \upsilon(x)^2$; with $\alpha[p] = \tilde{\alpha}\,\upsilon^{-p}$ and $(\alpha\beta)^\sim = \tilde{\alpha}\tilde{\beta}$,

$$\epsilon_\vartheta(N)[p]\ \chi_\vartheta(N')[p'] = \tilde{\nu}_\vartheta^{-1}\, \upsilon^{\,2f(N)+2N'-2f(N')-p-p'}.$$

As $f(N+2t') = f(N) + t'$, the exponent vanishes in each of the eight cases: in (a), (N, N', p, p') is $(N_{n+1}, N_{n+1}, N_{n+1}, N_{n+1})$ for the first two products, $(N_{n+2}, N_n, N_{n+2}, N_n)$ for the third and $(N_n, N_{n+2}, N_n, N_{n+2})$ for the fourth; in (b) it is $(N_n, N_{n+2}, N_n, N_{n+2})$, $(N_{n+2}, N_n, N_{n+2}, N_n)$, $(N_{n+1}, N_{n+1}, N_{n+1}, N_{n+1})$ and $(N_{n+1}, N_{n+1}, N_{n+1}, N_{n+1})$.

Tameness and weights. By Definition 3.2.26, μ_j^0 has weight $-\kappa_j$ and tame part ω^j; ϑ' has weight 0; weights add and tame parts multiply under products. So ν_ϑ has weight $\kappa_{n+i+2} - \kappa_{i+1} = (n+1)\Delta = \mu$ and tame part $\psi^\nu = \omega^{-(n+1)}\psi'^{-(n+1)}$, ψ' the tame part of ϑ' (trivial if $z = \mathrm{II}$). At a chosen place w, $\psi_w = 1$ (the places of Q are prime to M, Definition 3.1.2) and $\omega_w = \eta_w^{q_2}$ has order q_2; as $1 \le n+1 < m < q_2$ ($q_2 = (q_0 d)^{s+6} \ge q_0 \ge 18480$ and $m \le 2\sqrt{x}$ is a power of 2 with $2^s = m^{22}$, so $m < 2^{s+6} \le q_2$), $\psi_w^\nu \ne 1$. At $w \in Q$ (only if $z = \mathrm{I}$), $\omega_w = 1$ and $\psi_w^{-(n+1)} \ne 1$, ϑ being an m-fold twist and $1 \le n+1 \le m$. At all other places $\psi_w^\nu = 1$. So the tame part of ν_ϑ is nontrivial exactly at $\Sigma(\mathfrak{t}_\vartheta(z))$ ((TV2): the chosen places, and the places of Q if $z = \mathrm{I}$), which with (XD4) is the tameness claimed. The weights of $\epsilon_\vartheta(N)$ and $\chi_\vartheta(N)$ are $\gamma_{\neg z, n+i+1}(N)$ and $\delta_i(N)$ ((GP6), (TV6)), independent of ϑ. □

Lemma 6.4.15. *Let D be admissible data and $z \in \{\mathrm{I}, \mathrm{II}\}$. For a node p write N_p for its rank and, if p has offset 0, $e_p = e_{-\frac{1}{2}p_{z,i,j}}$ for the type of the grid forms $\mathcal{F}(p)$, $p = (z,i,j)$.*

(a) For every $i \ge 0$, the triangle forms at $(i,0)$ are the triangle forms at $(0,0)$: a function on the common adelic group of $V^0_{z,0}$ and $V^i_{z,0}$ lies in $\mathcal{F}^i_\triangle(z,0)$ if and only if it lies in $\mathcal{F}^0_\triangle(z,0)$, and the Petersson products of $V^i_{z,0}$ and of $V^0_{z,0}$ agree on these forms.

(b) Let $o, a, b \ge 0$ with $a \le m$, $b+1+o \le m$, and $o = 0$ or $a = 0$; let $p = (z,a,b)$, $q = (z,a,b+1)$, $\gamma = \gamma_{\neg z, b+o}(N_p)$, $\gamma' = \gamma_{\neg z, b+o}(N_q)$, $\lambda = \frac{1}{2}p^o_{z,a,b}$, $\lambda' = \frac{1}{2}p^o_{z,a,b+1}$, and let

H be the joint harmonic (GP7) for the signs with offset o of p and q, the weights (γ,γ') and the doubled parameters $(2\lambda,2\lambda')$, a polynomial in the entries of $q\times p$ matrices. Then v_H is an edge for the weights (γ,γ') from e_λ to $e_{\lambda'}$. For $o=0$, H is the joint harmonic of the transposed move between p and q, and $e_\lambda=\overline{e_p}$, $e_{\lambda'}=\overline{e_q}$. For $a=0$, $o=i$, $b=n$ with $i+n<m$, H is the joint harmonic of the triangle lift at (i,n): its Fock vector is an edge for the weights $(\gamma_{\neg z,n+i}(N_n),\gamma_{\neg z,n+i}(N_{n+1}))$ from e_λ to $e_{\lambda'}$, where $\lambda=\frac{1}{2}p^i_{z,0,n}$ and $\lambda'=\frac{1}{2}p^i_{z,0,n+1}$.

(c) For all $i,n\geq 0$ with $i+n<m$ there are a left pair and a reversed pair at (i,n) ((TV6) of Definition 3.2.30).

(d) Let $0\leq a<m$, $0\leq b\leq m$, $p=(z,a,b)$ and $q=(z,a+1,b)$. The Fock vector of the joint harmonic of the lift move from p to q is an edge for the weights $(\gamma_{z,a}(N_p),\gamma_{z,a}(N_q))$ from e_p to e_q.

(e) Let O be a descent pair with ranks $1\leq r<n$ that fits a parameter $l=(l_\tau)_{\tau\in\Phi}$, let $\xi_O=v^+_{l_O}$, and put $\gamma(\tau)=r_-(O)$ and $\gamma'(\tau)=\lfloor n/2\rfloor+\mathrm{wt}_O(\tau)$ for $\tau\in\Phi$. Then the Fock vector $v_{\mathrm{Har}_O(\xi_O)}$ of the pair $(W(O),\mathrm{I}_n)$ is an edge for the weights (γ,γ') from $e_{l/2}$ to $e_{l_O/2}$ (types on $G_\infty(\varepsilon_O)$ and $G_\infty(\mathbf{1}_n)$).

Proof. Every node has a nonempty index set: its base $\{0,\dots,r-1+[z]\}$ is nonempty (GP5).

(a): the opposite space carries the same forms. Let $V=(J_V,x_V)$ be a space with a point with signs s on n and $V^-=(-J_V,c\,x_V)$ its opposite space, with signs $-s$; here c is a scalar idele with infinite components 1. We show that $\mathrm{G}(-s)=\mathrm{G}(s)$, that the two measures agree, that $\Gamma_{V^-}=\Gamma_V$, and that the type kernel e_λ of any family of parameters λ is the same function for the signs $-s$ as for s.

- Groups. A matrix g satisfies $g^*\varepsilon_{-s}g=\varepsilon_{-s}$ if and only if $g^*\varepsilon_s g=\varepsilon_s$, as $\varepsilon_{-s}=-\varepsilon_s$ at the infinite places and $\varepsilon_{\pm s}=1$ at the finite places; so $\mathrm{U}(\mathrm{diag}(-s))=\mathrm{U}(\mathrm{diag}\,s)$, $G_\infty(-s)=G_\infty(s)$, and $G_f(n)$ does not depend on the signs.
- Measures. For the hermitian involution $J=\mathrm{diag}\,s$ write $D_J(y)=1-\frac{1}{2}JS(y)$ and $\kappa_J(y)=2D_J(y)^{-1}-1$. Since S is linear, $D_{-J}(y)=1+\frac{1}{2}JS(y)=D_J(-y)$ and $\kappa_{-J}(y)=\kappa_J(-y)$. Hence the Cayley measure of $\mathrm{U}(-J)$, the image under κ_{-J} of $|\det D_{-J}(y)|^{-2N}\mathrm{vol}\,\mathrm{U}(N)^{-1}dy$, is the image under κ_J of the image of $|\det D_J(y)|^{-2N}\mathrm{vol}\,\mathrm{U}(N)^{-1}dy$ under $y\mapsto -y$, which preserves Lebesgue measure; so the two Cayley measures agree, and so do the measures of G_∞, $G_f(n)$ and G.
- Rational points. $\mathrm{U}(V^-)(F)=\{g\in\mathrm{GL}_n(E):g^*(-J_V)g=-J_V\}=\mathrm{U}(V)(F)$, and as c is central in $\mathrm{GL}_n(\mathbb{A}_E)$, $\Gamma_{V^-}=(c\,x_V)^{-1}\mathrm{U}(V)(F)(c\,x_V)=x_V^{-1}\mathrm{U}(V)(F)x_V=\Gamma_V$. So the quotients $[\mathrm{U}(V^-)]$ and $[\mathrm{U}(V)]$ and their quotient measures agree.
- Type kernels. In Definition 3.2.3 the signs ε enter only through the group $\mathrm{U}(\mathrm{diag}\,\varepsilon)$, its subgroup K_ε of unitary matrices with its Haar probability measure, the block-diagonal part bd_ε and the counts $2\rho^c_l$, and these depend only on the relations $\varepsilon_i=\varepsilon_j$, which are the same for ε and $-\varepsilon$. So Flensted-Jensen's function c_λ for $-s$ is that for s, on the same group; by the previous items its formal degree for the Cayley measure is the same; hence e_λ of (FT3) is the same function on $G_\infty(s)=G_\infty(-s)$.

Every clause of (ED2) (continuity, boundedness, left invariance under the rational points, a level, $R(e)F=F$ with the measure of G_∞) and the Petersson product are thus the same for

V^- and V. Now the node $(z,0,0)$ has no block indices, its parameter has $\delta = 0$, and the offset changes, at a base index i, only the sign, from $(-1)^e$ to $(-1)^{o+e+\min(e-o,0)} = (-1)^o(-1)^e$; so $p^i_{z,0,0} = p^0_{z,0,0}$, and the triangle forms at $(i,0)$ are the forms of type e_λ, $\lambda = \frac{1}{2}p^0_{z,0,0}$, on $V^i_{z,0}$. As $V^{i+1}_{z,0} = (V^i_{z,0})^-$ ((TV1)), (a) follows by induction on i.

(b): transposed moves with offset. By Lemma 6.4.16(ii) the families $2\lambda = p^o_{z,a,b}$ and $2\lambda' = p^o_{z,a,b+1}$ correspond for the weights (γ,γ') and the signs with offset o of p and q. By Lemma 6.4.18(iii) for these data (index sets nonempty), v_H is an edge for the weights (γ,γ') from e_λ to $e_{\lambda'}$. For $o = 0$ the data of H are those that (GP7) assigns to the transposed move between p and q (the signs of p and q, $\gamma_{\neg z,b}$ at the two ranks, the doubled parameters $p_{z,a,b}$, $p_{z,a,b+1}$, $q \times p$ matrices); and Lemma 6.4.18(i) gives $e_{-\lambda} = \overline{e_\lambda}$, hence $e_\lambda = \overline{e_{-\lambda}} = \overline{e_p}$, and likewise $e_{\lambda'} = \overline{e_q}$. For $a = 0$, $o = i$, $b = n$, the hypothesis $b + 1 + o \le m$ is $i + n < m$, and the data of H are those of the triangle lift at (i,n) in (TV3): the spaces $V^i_{z,n}$, $V^i_{z,n+1}$ carry the signs with offset i of $(z,0,n)$, $(z,0,n+1)$ (TV1), the weights are $\gamma_{\neg z,n+i}(N_n)$, $\gamma_{\neg z,n+i}(N_{n+1})$, and the doubled parameters $p^i_{z,0,n}$, $p^i_{z,0,n+1}$.

(c): left and reversed pairs. Let $i + n < m$, $\mu = \frac{1}{2}p^{i+1}_{z,0,n}$, $\mu' = \frac{1}{2}p^i_{z,0,n+1}$, s_1, s_2 the signs with offset $i+1$ of $(z,0,n)$ and with offset i of $(z,0,n+1)$, and $\delta = \delta_i(N_n)$, $\delta' = \delta_i(N_{n+1})$. By Lemma 6.4.16(iii), $l = -2\mu$ and $l' = -2\mu'$ correspond for the weights (δ,δ') and the signs (s_1,s_2). By Lemma 6.4.18(i), $e_{-\mu} = e_{l/2}$ and $e_\mu = e_{-l/2}$ are cusp kernels of order 0 with $e_\mu = \overline{e_{-\mu}}$, so $e_{-\mu} = \overline{e_\mu}$; likewise for μ'. Let H_1 be the joint harmonic (GP7) for $(s_1,s_2,\delta,\delta',l,l')$, a polynomial in the entries of $n_{n+1} \times n_n$ matrices; by Lemma 6.4.18(iii), v_{H_1} is an edge for the weights (δ,δ') from $e_{-\mu}$ to $e_{-\mu'}$. So H_1 is a left pair at (i,n). The block rule of (WM8) is symmetric: exchanging (n,s,l,γ) with (n',t,l',γ') leaves the gap condition (a) unchanged, maps the shifted entries $\tilde{l}$, $\tilde{l}'$ to $\tilde{l}'$, $\tilde{l}$, and exchanges the two cases of (b) and the two sides of the equalities in (c). Hence l' and l correspond for the weights (δ',δ) and the signs (s_2,s_1), and by Lemma 6.4.18(iii) the joint harmonic H_2 for $(s_2,s_1,\delta',\delta,l',l)$, a polynomial in the entries of $n_n \times n_{n+1}$ matrices, has a Fock vector that is an edge for the weights (δ',δ) from $e_{-\mu'}$ to $e_{-\mu}$; with the kernel conditions shown above, H_2 is a reversed pair at (i,n).

(d): lift moves. By Lemma 6.4.16(i), $-p_{z,a,b}$ and $-p_{z,a+1,b}$ correspond for the weights $(\gamma_{z,a}(N_p),\gamma_{z,a}(N_q))$ and the signs of p and q; these, with the doubled parameters $-p_{z,a,b}$, $-p_{z,a+1,b}$, are the data that (GP7) assigns to the lift move from p to q. By Lemma 6.4.18(iii) its Fock vector is an edge for these weights from $e_{-\frac{1}{2}p_{z,a,b}} = e_p$ to $e_{-\frac{1}{2}p_{z,a+1,b}} = e_q$.

(e): fitted descent pairs. By (i) of the fitting condition (DP11), l and l_O correspond for the weights (γ,γ') and the signs $(\varepsilon_O, \mathbf{1}_n)$; the index sets $\{1,\dots,r\}$ and $\{1,\dots,n\}$ are nonempty. By Lemma 6.4.47, $\mathrm{Har}_O(\xi_O) = \prod_{\tau\in\Phi} P_\tau$ with P_τ in the variables of τ a joint harmonic for the signs $(\varepsilon_O,\mathbf{1}_n)$, the weights $(\gamma(\tau),\gamma'(\tau))$ and the parameters $(l_\tau, l_{O,\tau})$. By Lemma 6.4.18(iii), $v_{\mathrm{Har}_O(\xi_O)}$ is an edge for the weights (γ,γ') from $e_{l/2}$ to $e_{l_O/2}$. □

Lemma 6.4.16. *Let D be admissible data and $z \in \{\mathrm{I},\mathrm{II}\}$. For a node p and an offset $o \ge 0$ write s^o_p for its signs with offset o and N_p for its rank.*

(i) Let $0 \le a < m$, $0 \le b \le m$, $p = (z,a,b)$, $q = (z,a+1,b)$. Then $-p_{z,a,b}$ and $-p_{z,a+1,b}$ correspond for the weights $(\gamma_{z,a}(N_p),\gamma_{z,a}(N_q))$ and the signs (s^0_p, s^0_q).

(ii) Let $o,a,b \ge 0$ with $a \le m$, $b+1+o \le m$, and $o = 0$ or $a = 0$; let $p = (z,a,b)$, $q = (z,a,b+1)$. Then $p^o_{z,a,b}$ and $p^o_{z,a,b+1}$ correspond for the weights $(\gamma_{\neg z,b+o}(N_p),\gamma_{\neg z,b+o}(N_q))$ and the signs (s^o_p, s^o_q).

(iii) Let $i,n \ge 0$ with $i+n < m$, $p = (z,0,n)$, $q = (z,0,n+1)$. Then $-p^{i+1}_{z,0,n}$ and $-p^i_{z,0,n+1}$ correspond for the weights $(\delta_i(N_p),\delta_i(N_q))$ and the signs (s^{i+1}_p, s^i_q).

Proof. Fix $\tau \in \Phi$ and z; write $\kappa_l = \kappa_l(\tau)$, $\varsigma_i = \varsigma_i(\tau)$ and $[z] \in \{0,1\}$. A pair of families corresponds if the block rule holds at every τ, so it suffices to prove the three block rules at τ.

Sizes. By (AD1) and $C_P \geq 6$, $\log x \geq 100 \log\log b \geq 6 \cdot 10^{14}$, so $r \geq x^5 \geq 10^4$ and $m \leq 2\sqrt{x} \leq r$. Every node (z,i,j) with $i,j \leq m$ has rank $N \leq r+1+2m(t+1) \leq 14r^2$, so for two such nodes $500(N_p+N_q)^3 \leq 500 \cdot 28^3 r^6 < r^8 \leq \Delta - t - 2$. Further:

(F1) $\kappa_{l'} - \kappa_l = (l'-l)\Delta$, and $\kappa_l \geq \kappa_1 \geq \Delta$ for $l \geq 1$;

(F2) ς is strictly decreasing, $2\varsigma_i \leq k-2$, and for $0 \leq i \leq r$, $l \geq 1$: $\varsigma_i + \kappa_l \geq \frac{\Delta}{2}$ if $i < k+l-1$, and $\varsigma_i + \kappa_l \leq -\frac{\Delta}{2}$ if $i \geq k+l-1$.

The centre system of the grid z at τ. Let $\Sigma = \{2\varsigma_i + [z] : 0 \leq i < r + [z]\}$ (so $\#\Sigma = r + [z]$ by (F2)), and let C consist of the up centres U_l with $z_{U_l} = \kappa_l$, $d_{U_l} = t + [z]$ and the down centres D_l with $z_{D_l} = -\kappa_l$, $d_{D_l} = t - [z]$, for $1 \leq l \leq m$. It satisfies (a)–(d) of Lemma 6.4.17 with $h = \Delta - t - 2$: (a) $t \pm [z] \equiv 1 + [z] \equiv r + [z]$, as r and t are odd; (b) $2\varsigma_i + [z] + r + [z] \equiv r \equiv 1$; (c) for $y = 2\varsigma_i + [z] \in \Sigma$: $2\kappa_l - y \geq 2\Delta - k + 1 \geq h + t + 1$ by (F1), (F2), and $|y + 2\kappa_l| \geq 2|\varsigma_i + \kappa_l| - 1 \geq \Delta - 1 \geq h + t$ by (F2); (d) an entry y of a block $b_{c'}$ has $|y - 2z_{c'}| \leq t$, and $|2z_c - 2z_{c'}| \geq 2\Delta$ for $c \neq c'$ by (F1) (centres of one kind differ by multiples of Δ, of different kinds by $\kappa_l + \kappa_{l'} \geq 2\Delta$), so $|y - 2z_c| \geq 2\Delta - t \geq h + t + 1 \geq h + d_c$.

Claim. Let $o, a, b \geq 0$ with $a \leq m$, $o + b \leq m$, and $o = 0$ or $a = 0$, and put $B(o,a,b) = \{U_l : 1 \leq l \leq a\} \cup \{D_l : o+1 \leq l \leq o+b\} \subseteq C$. Then $p^o_{z,a,b}(\tau)$ on the index set of the node (z,a,b), with the signs $s^o_{(z,a,b)}$, is a parameter of $B(o,a,b)$ with common sign $(-1)^o$.

Proof of the claim. Write $B = B(o,a,b)$. The rank $r + [z] + a(t + [z]) + b(t - [z])$ of the node is n_B. As $\#\Sigma = r + [z]$ is odd exactly for $z = \mathrm{I}$ and $\#B = a + b$, λ_B is the number δ of (GP5). So by (GP5) the numbers $p^o_{z,a,b}(\tau)(x) + \lambda_B$ are: $2\varsigma_i + [z]$ at the base index i; $2\kappa_l + t + [z] - 1 - 2c$ $(0 \leq c < t + [z])$ at the up index (l,c), that is the block b_{U_l}; and $-2\kappa_{l+o} + t - [z] - 1 - 2c$ $(0 \leq c < t - [z])$ at the down index (l,c), that is the block $b_{D_{l+o}}$. Their set is E_B. For the signs, let y be the number at an index x and count the centres outside B that count for y (up and $y > 2z_c$, or down and $y < 2z_c$).

- Up index (l,c), $l \leq a$ (so $a \geq 1$ and $o = 0$): $0 < y \leq 2\kappa_l + t$; an up centre $U_{l'} \notin B$ has $l' > l$ and $2\kappa_{l'} \geq 2\kappa_l + 2\Delta > y$, and no down centre counts as $y > 0$. So $\mathrm{sg}_B(y) = 1 = s^o(x)/(-1)^o$.
- Down index (l,c), $1 \leq l \leq b$: $|y + 2\kappa_{o+l}| \leq t$ and $y < 0$, so no up centre counts; a down centre $D_{l'} \notin B$ has $l' \leq o$ or $l' > o + b$, and by (F1) $-2\kappa_{l'} \geq -2\kappa_{o+l} + 2\Delta > y$ in the first case and $-2\kappa_{l'} < y$ in the second. So exactly the o centres $D_1, \ldots, D_o$ count, and $(-1)^o \mathrm{sg}_B(y) = 1 = s^o(x)$.
- Base index i, $y = 2\varsigma_i + [z] \leq k-1$: no up centre counts, by (F1). By (F2), $D_{l'}$ counts, that is $2(\varsigma_i + \kappa_{l'}) + [z] < 0$, exactly when $i \geq k + l' - 1$, that is $l' \leq e$ with $e = \max(i + 1 - k, 0)$; here $e \leq r + 1 - k = m$. The $D_{l'}$ with $1 \leq l' \leq e$ and $o + 1 \leq l' \leq o + b$ are $\min(e \dot{-} o, b)$ in number, so $e - \min(e \dot{-} o, b)$ centres count and $(-1)^o \mathrm{sg}_B(y) = (-1)^{o+e+\min(e\dot{-}o,b)} = s^o(x)$.

This proves the claim. Note also that replacing the signs s by $-s$ and the common sign ϵ by $-\epsilon$ keeps the property of being a parameter of B.

Weights. For a node of rank N, $\gamma_{c,l}(N) = \lfloor (N + [\neg c])/2 \rfloor - \kappa_{l+1}$ (GP6). In the grid $\tilde{Y}$ ($z = \mathrm{II}$) every rank $r + 1 + a(t+1) + b(t-1)$ is even. Hence $\gamma_{z,a}(N) = -\kappa_{a+1} + \lceil N/2 \rceil$ (for $z = \mathrm{I}$ by definition, for $z = \mathrm{II}$ as N is even) and $\gamma_{\neg z,l}(N) = -\kappa_{l+1} + \lfloor N/2 \rfloor$ (likewise).

(i). Here $o = 0$, $a + 1 \leq m$, $b \leq m$; $B(0, a+1, b) = B(0,a,b) \cup \{U_{a+1}\}$ with $U_{a+1} \notin B(0,a,b)$, and by the claim $p_{z,a,b}(\tau)$ and $p_{z,a+1,b}(\tau)$ are parameters of these sets with common sign 1.

As $h \geq 500(N_p + N_q)^3$, (i) of Lemma 6.4.17 for the up centre U_{a+1} gives the block rule for $(-p_{z,a,b}(\tau), -p_{z,a+1,b}(\tau))$, the weights

$$(-\kappa_{a+1} + \lceil N_p/2 \rceil, -\kappa_{a+1} + \lceil N_q/2 \rceil) = (\gamma_{z,a}(N_p), \gamma_{z,a}(N_q))$$

and the signs (s_p^0, s_q^0).

(ii). Here $a \leq m$, $o + b + 1 \leq m$, and $o = 0$ or $a = 0$, so the claim applies to (o, a, b) and $(o, a, b+1)$, with common sign $(-1)^o$; $B(o, a, b+1) = B(o, a, b) \cup \{D_{o+b+1}\}$, and $D_{o+b+1} \notin B(o, a, b)$. (i) of Lemma 6.4.17 for the down centre D_{o+b+1} gives the block rule for $(p^o_{z,a,b}(\tau), p^o_{z,a,b+1}(\tau))$, the weights

$$(-\kappa_{b+o+1} + \lfloor N_p/2 \rfloor, -\kappa_{b+o+1} + \lfloor N_q/2 \rfloor) = (\gamma_{\neg z,b+o}(N_p), \gamma_{\neg z,b+o}(N_q))$$

and the signs (s_p^o, s_q^o).

(iii). Here $i + n < m$. By the claim, $p^{i+1}_{z,0,n}(\tau)$ with the signs s_p^{i+1} is a parameter of $B(i + 1, 0, n) = \{D_{i+2}, \dots, D_{i+n+1}\}$ with common sign $(-1)^{i+1}$, hence with the signs $-s_p^{i+1}$ a parameter of the same set with common sign $(-1)^i$; and $p^i_{z,0,n+1}(\tau)$ with the signs s_q^i is a parameter of $B(i, 0, n+1) = B(i+1, 0, n) \cup \{D_{i+1}\}$ with common sign $(-1)^i$. (i) of Lemma 6.4.17 for the down centre D_{i+1} gives the block rule for $(p^{i+1}_{z,0,n}(\tau), p^i_{z,0,n+1}(\tau))$, the weights $(\gamma_{\neg z,i}(N_p), \gamma_{\neg z,i}(N_q))$ and the signs $(-s_p^{i+1}, s_q^i)$. By (ii) of Lemma 6.4.17, $(-p^{i+1}_{z,0,n}(\tau), -p^i_{z,0,n+1}(\tau))$ satisfies the block rule for the weights $(N_p - \gamma_{\neg z,i}(N_p), N_q - \gamma_{\neg z,i}(N_q)) = (\delta_i(N_p), \delta_i(N_q))$ and the signs (s_p^{i+1}, s_q^i). □

Lemma 6.4.17. *Let $\Sigma \subset \mathbb{Z}$ be a finite set and C a finite set; for $c \in C$ let $z_c \in \mathbb{Z}$, $d_c \in \mathbb{N}$ and a kind,* up *or* down*, be given, and put $b_c = \{2z_c + d_c - 1 - 2\beta : 0 \leq \beta < d_c\} = 2z_c + [d_c]$. Let $h \geq 1$ be an integer with*

(a) $d_c \equiv \#\Sigma \pmod 2$ for every $c \in C$;

(b) $y + \#\Sigma$ is odd for every $y \in \Sigma$;

(c) $|y - 2z_c| \geq h + d_c$ for every $c \in C$ and $y \in \Sigma$;

(d) $|y - 2z_c| \geq h + d_c$ for all $c \neq c'$ in C and $y \in b_{c'}$.

For $B \subseteq C$ put $E_B = \Sigma \cup \bigcup_{c \in B} b_c$, $n_B = \#\Sigma + \sum_{c \in B} d_c$, $\lambda_B = 1$ if $\#\Sigma$ and $\#B$ are both odd and $\lambda_B = 0$ otherwise, and for $y \in \mathbb{Z}$

$$\mathrm{sg}_B(y) = (-1)^{\#\{c \in C \setminus B:\ c \text{ is up and } y > 2z_c, \text{ or } c \text{ is down and } y < 2z_c\}}.$$

A map $l\colon I \to \mathbb{Z}$ on a finite set I with signs $s\colon I \to \{\pm 1\}$ is a parameter of B with common sign $\epsilon \in \{\pm 1\}$ *if $\#I = n_B$, $\{l(x) + \lambda_B : x \in I\} = E_B$, and $s(x) = \epsilon\, \mathrm{sg}_B(l(x) + \lambda_B)$ for every $x \in I$.*

(i) Let $B \subseteq C$, $c \in C \setminus B$ and $B' = B \cup \{c\}$; let l on I with signs s be a parameter of B and l' on I' with signs s' a parameter of B', with the same common sign; let $N = \#I$, $N' = \#I'$ and $h \geq 500(N + N')^3$. If c is down, the pair (l, l') satisfies the block rule for the weights $(z_c + \lfloor N/2 \rfloor,\ z_c + \lfloor N'/2 \rfloor)$ and the signs (s, s'). If c is up, the pair $(-l, -l')$ satisfies the block rule for the weights $(-z_c + \lceil N/2 \rceil,\ -z_c + \lceil N'/2 \rceil)$ and the signs (s, s').

(ii) Let $l\colon I \to \mathbb{Z}$ with signs s and $l'\colon I' \to \mathbb{Z}$ with signs t, on finite sets with $N = \#I$, $N' = \#I'$, satisfy the block rule for the weights (γ, γ') and the signs (s, t). Then $(-l, -l')$ satisfies the block rule for the weights $(N - \gamma, N' - \gamma')$ and the signs $(-s, t)$.

Proof. Throughout, a centre $c \notin B$ *counts for* y if c is up and $y > 2z_c$, or c is down and $y < 2z_c$; so $\mathrm{sg}_B(y) = (-1)^{\#\{c \in C \setminus B:\ c \text{ counts for } y\}}$.

Step 1: the entries. Let $B \subseteq C$ and $c \in C \setminus B$. Every $y \in E_B$ satisfies $|y - 2z_c| \geq h + d_c$, by (c) if $y \in \Sigma$ and by (d) if $y \in b_{c'}$ with $c' \in B$, $c' \neq c$. Every element y' of b_c satisfies $|y' - 2z_c| \leq d_c - 1$. Hence $b_c \cap E_B = \emptyset$, and by induction on $\#B$ the sets Σ and b_c ($c \in B$) are pairwise disjoint; as $\#b_c = d_c$, $\#E_B = n_B$. If l on I is a parameter of B, then $x \mapsto l(x) + \lambda_B$ maps I, of size n_B, onto E_B, of size n_B; so it is bijective and l is injective.

Step 2: parities. Every $y \in E_B$ has $y + \#\Sigma$ odd: for $y \in \Sigma$ by (b), and for $y = 2z_c + d_c - 1 - 2\beta \in b_c$ because $y + \#\Sigma \equiv d_c - 1 + \#\Sigma \equiv 1$ by (a). By (a), $n_B \equiv \#\Sigma\,(1 + \#B) \pmod 2$, so $n_B \equiv \#\Sigma - \lambda_B \pmod 2$ (both sides are 0 for $\#\Sigma$ even; for $\#\Sigma$ odd, $\lambda_B \equiv \#B$). Hence for a parameter l of B, $l(x) = (l(x) + \lambda_B) - \lambda_B \equiv \#\Sigma - 1 - \lambda_B \equiv n_B - 1 \pmod 2$.

Step 3: the gap. Let l on I with signs s be a parameter of B with common sign ϵ, and $x, x' \in I$ with $s(x) \neq s(x')$. With $y = l(x) + \lambda_B$, $y' = l(x') + \lambda_B$ we get $\mathrm{sg}_B(y) \neq \mathrm{sg}_B(y')$, so some $c \in C \setminus B$ counts for exactly one of y, y'; then $2z_c$ lies weakly between y and y', and both are at distance at least $h + d_c \geq h > 0$ from $2z_c$ by Step 1. So y and y' lie strictly on opposite sides of $2z_c$ and $|l(x) - l(x')| = |y - y'| \geq 2h$. With Steps 1 and 2, l has gap h for s in the sense of (WM8), hence gap h' for every $h' \leq h$.

Step 4: the lowerings. In (i), $N = n_B$ and $N' = n_{B'} = N + d_c$. We claim $N' \bmod 2 = \lambda_B$ and $N \bmod 2 = \lambda_{B'}$. If $\#\Sigma$ is even, $\lambda_B = \lambda_{B'} = 0$ and $N \equiv N' \equiv 0$ by Step 2. If $\#\Sigma$ is odd, $\lambda_{B'} = 1 - \lambda_B$ since $\#B' = \#B + 1$; by Step 2, $N \equiv 1 - \lambda_B = \lambda_{B'}$, and $N' \equiv N + d_c \equiv N + 1 \equiv \lambda_B$ by (a).

Step 5: signs under insertion. As $C \setminus B$ is the disjoint union of $C \setminus B'$ and $\{c\}$, $\mathrm{sg}_B(y) = -\mathrm{sg}_{B'}(y)$ if c counts for y, and $\mathrm{sg}_B(y) = \mathrm{sg}_{B'}(y)$ otherwise.

Step 6: (i) for a down centre. Let $\gamma = z_c + \lfloor N/2 \rfloor$, $\gamma' = z_c + \lfloor N'/2 \rfloor$. Since $N' - 2\lfloor N'/2 \rfloor = N' \bmod 2 = \lambda_B$ and $N - 2\lfloor N/2 \rfloor = \lambda_{B'}$ (Step 4), the shifted entries of (WM8) are

$$\tilde{l}(x) = l(x) - 2\gamma' + N' = l(x) + \lambda_B - 2z_c, \qquad \tilde{l}'(x') = l'(x') - 2\gamma + N = l'(x') + \lambda_{B'} - 2z_c.$$

(a) of (WM8): by Step 3 (for B and for B'), l and l' have gap $h \geq 500(N + N')^3$ for s and s'. (b) of (WM8): $N \leq N'$, and $\tilde{l}'(I') = E_{B'} - 2z_c = (E_B - 2z_c) \cup (b_c - 2z_c) = \tilde{l}(I) \cup [d_c] = \tilde{l}(I) \cup [N' - N]$. (c) of (WM8): if $\tilde{l}(x) = \tilde{l}'(x')$, then $y = l(x) + \lambda_B = l'(x') + \lambda_{B'}$, $s(x) = \epsilon\,\mathrm{sg}_B(y)$ and $s'(x') = \epsilon\,\mathrm{sg}_{B'}(y)$; as c is down, it counts for y exactly when $y < 2z_c$, that is when $\tilde{l}(x) < 0$. By Step 5, $s(x) = s'(x')$ if $\tilde{l}(x) > 0$ and $s(x) = -s'(x')$ if $\tilde{l}(x) < 0$.

Step 7: (i) for an up centre. Let $\Gamma = -z_c + \lceil N/2 \rceil$, $\Gamma' = -z_c + \lceil N'/2 \rceil$. As $2\lceil N'/2 \rceil - N' = \lambda_B$ and $2\lceil N/2 \rceil - N = \lambda_{B'}$, the shifted entries of $(-l, -l')$ are

$$-l(x) - 2\Gamma' + N' = -(l(x) + \lambda_B - 2z_c), \qquad -l'(x') - 2\Gamma + N = -(l'(x') + \lambda_{B'} - 2z_c).$$

(a): $-l$ and $-l'$ are injective, have the parities of l and l' and the same absolute differences, so Step 3 gives the gaps. (b): the shifted entries of $-l'$ form $-(E_{B'} - 2z_c) = -(E_B - 2z_c) \cup (-[d_c])$, which is the set of shifted entries of $-l$ together with $[d_c] = [N' - N]$, as $[d] = -[d]$. (c): for a common shifted entry $u = -(y - 2z_c)$, with y as in Step 6, the up centre c counts for y exactly when $y > 2z_c$, that is when $u < 0$; by Step 5 the signs agree when $u > 0$ and are opposite when $u < 0$.

(ii). The shifted entries of $-l$ and $-l'$ for the weights $(N - \gamma, N' - \gamma')$ are $-l(a) - 2(N' - \gamma') + N' = -\tilde{l}(a)$ and $-l'(b) - 2(N - \gamma) + N = -\tilde{l}'(b)$, with $\tilde{l}, \tilde{l}'$ the shifted entries of (l, l') for (γ, γ'). (a): a gap condition depends only on $|l(a) - l(a')|$, the parity of $l(a)$ and whether $s(a) \neq s(a')$; all are unchanged by $l \mapsto -l$, $s \mapsto -s$. (b): negate both sides of (b) for (l, l') and use $[d] = -[d]$. (c): if $-\tilde{l}(a) = -\tilde{l}'(b) > 0$, then $\tilde{l}(a) < 0$, so $s(a) = -t(b)$, that is $(-s)(a) = t(b)$; if $-\tilde{l}(a) < 0$, then $s(a) = t(b)$, that is $(-s)(a) = -t(b)$. □

Lemma 6.4.18. *Let n, n' be nonempty finite index sets with signs s on n and t on n', let $\gamma, \gamma' \colon \Phi \to \mathbb{Z}$, and let $l = (l_v)_{v\in\Phi}$, $l' = (l'_v)_{v\in\Phi}$ be families of maps $l_v \colon n \to \mathbb{Z}$, $l'_v \colon n' \to \mathbb{Z}$ that correspond for the weights (γ, γ') and the signs (s, t).*

(i) $e_{l/2}$ and $e_{-l/2}$ are cusp kernels of order 0 on $G_\infty(s)$ with $e_{-l/2} = \overline{e_{l/2}}$, and $e_{l'/2}$, $e_{-l'/2}$ are cusp kernels of order 0 on $G_\infty(t)$ with $e_{-l'/2} = \overline{e_{l'/2}}$.

(ii) For every $v \in \Phi$ there is a joint harmonic for the signs (s, t), the weights $(\gamma(v), \gamma'(v))$ and the parameters (l_v, l'_v).

(iii) For every $v \in \Phi$ let H_v be a joint harmonic for the signs (s, t), the weights $(\gamma(v), \gamma'(v))$ and the parameters (l_v, l'_v), written in the variables $X_{v,a,c}$ ($a \in n'$, $c \in n$), and $H = \prod_{v\in\Phi} H_v$ (for instance the joint harmonic of (GP7) for $(s, t, \gamma, \gamma', l, l')$, by (ii)). Then the Fock vector v_H is an edge for the weights (γ, γ') from $e_{l/2}$ to $e_{l'/2}$.

Proof. Write $N = \#n$, $N' = \#n'$.

(i). By (a) of the block rule (WM8), every l_v has gap $h = 500(N + N')^3$ for s, and so has $-l_v$ (the conditions are invariant under $l \mapsto -l$). As $h \geq 500N^3$, Lemma 5.6.21 with $B = 0$ shows that $e_{l/2}$ and $e_{-l/2}$ are cusp kernels of order 0 on $G_\infty(s)$. By (ii) of Lemma 5.6.29, $c_{-l_v/2} = \overline{c_{l_v/2}}$ on $\mathrm{U}(\operatorname{diag} s)$; hence $|c_{-l_v/2}| = |c_{l_v/2}|$, so $d_{-l_v/2} = d_{l_v/2}$, a real number, and $e_{-l/2}(x) = \prod_v d_{l_v/2}\, c_{l_v/2}(x_v) = \overline{e_{l/2}(x)}$. The same argument applies to l' on $G_\infty(t)$ (gap $h \geq 500N'^3$ for t). By (ED1), moreover, $e(x^{-1}) = \overline{e(x)}$ for each of these kernels, so

$$e_{l/2}(x^{-1}) = e_{-l/2}(x), \qquad e_{-l'/2}(y^{-1}) = e_{l'/2}(y) \qquad (x \in G_\infty(s),\ y \in G_\infty(t)). \tag{6.65}$$

(ii). For every v the pair (l_v, l'_v) satisfies the block rule for the weights $(\gamma(v), \gamma'(v))$ and the signs (s, t), and Lemma 6.4.19 gives the joint harmonic.

(iii), Step 1: the local facts. Let $\iota = n' \times n$, $\varepsilon(v, a, c) = t(a)s(c)$ on $\Phi \times \iota$, $\Omega = \Omega_{\gamma,\gamma'}$ on $\mathcal{F}_\varepsilon$, and P, P' the operators of (o) of Proposition 6.4.21 for H, with the kernels $e_{-l/2}$ on $G_\infty(s)$ and $e_{l'/2}$ on $G_\infty(t)$; its hypotheses hold. Put $\Omega^{\mathrm{sw}}(y, x) = \Omega(x, y)$ on $G_\infty(t) \times G_\infty(s)$. By (2) of Lemma 4.1.1, Ω is a representation of $G_\infty(s) \times G_\infty(t)$ and $y \mapsto \Omega(1, y)u$, $x \mapsto \Omega(x, 1)u$ are continuous. Every $c \in \mathcal{F}_\varepsilon$ is bounded with $\sup|c| \leq \|c\|$, since $|\beta^\infty_\varepsilon| = 1$ and $0 < e^\infty \leq 1$ in the reproducing identity of (WR5); so $|\langle c, c'\rangle| \leq \|c\|\,\|c'\|$ and $u \mapsto \langle c, u\rangle$ is a bounded linear functional.

Step 2: lifts by kernels with a real part. Let (σ, σ') be (s, t) or (t, s), Ω_0 the map Ω or Ω^{sw} on $G_\infty(\sigma) \times G_\infty(\sigma')$ accordingly, and k_0 a cusp kernel of order 0 on $G_\infty(\sigma)$ such that $x \mapsto k_0(x^{-1})\Omega_0(x, 1)u$ is Bochner integrable for every $u \in \mathcal{F}_\varepsilon$; put $P_0 u = \int k_0(x^{-1})\Omega_0(x, 1)u\, dx$. Let S, T, V be spaces with points with signs σ, σ', and $\eta(a, c) = t(a)s(c)$ on ι (in both cases, so that the Fock model of (ED3) is $\mathcal{F}_\varepsilon$); let (ω, θ) be a theta kernel for (S, T) on V with real part Ω_0, $f \in \mathcal{M}_\eta$, and F a form of type k_0 on S.

(L1) By Lemma 6.4.45 there are C, A with $|\theta(\omega(g, h)\varphi)| \leq C\|\varphi\|(\mathrm{ht}_S(g)\mathrm{ht}_T(h))^A$, and by Lemma 6.3.75 $D = \sup_g |F(g)|\mathrm{ht}_S(g)^A < \infty$. Hence $|\theta(\omega(g, h)\varphi)F(g)| \leq CD\,\mathrm{ht}_T(h)^A\|\varphi\|$ for all g, h, φ. The integrand is continuous and $[\mathrm{U}(S)]$ has finite volume (Theorem 4.2.18); so for each h, $\Lambda_h(\varphi) = L_\varphi F(h)$ is a bounded linear functional on $\mathcal{M}_\eta$, of norm at most $CD\,\mathrm{vol}([\mathrm{U}(S)])\,\mathrm{ht}_T(h)^A$.

(L2) As ω is a homomorphism, $L_\varphi F(hh') = L_{\omega(1,h')\varphi}F(h)$; so $L_\varphi F(h) = \Lambda_1(\omega(1, h)\varphi)$ is continuous in h, and it is left invariant under Γ_T by the invariance of (ED3).

(L3) By the real part, $\omega(1,(y,1))(u\otimes f)=(\Omega_0(1,y)u)\otimes f$, hence

$$L_{(\Omega_0(1,y)u)\otimes f}F(h)=L_{u\otimes f}F(h(y,1));$$

likewise $\omega((x,1),1)(u\otimes f)=(\Omega_0(x,1)u)\otimes f$.

(L4) The map $u\mapsto u\otimes f$ is bounded linear from $\mathcal{F}_\varepsilon$ to $\mathcal{M}_\eta$, of norm at most $\|f\|$ ((1) of Lemma 6.2.21). So if k is a function on $G_\infty(\sigma')$ and $y\mapsto k(y)\Omega_0(1,y)u$ is Bochner integrable, then $y\mapsto k(y)L_{u\otimes f}F(h(y,1))$ is integrable and its integral is $\Lambda_h\big((\int k(y)\Omega_0(1,y)u\,dy)\otimes f\big)$, by (L3); the same holds in the first variable.

(L5) *Projection.* For every $u\in\mathcal{F}_\varepsilon$, $L_{u\otimes f}F=L_{(P_0u)\otimes f}F$. Fix h and put $\varphi=u\otimes f$. By (L4) in the first variable, (L3) and the right invariance of the quotient measure (substituting $g\mapsto g(x,1)^{-1}$),

$$\begin{aligned}\Lambda_h((P_0u)\otimes f)&=\int k_0(x^{-1})\,\Lambda_h(\omega((x,1),1)\varphi)\,dx\\&=\int k_0(x^{-1})\int_{[\mathrm{U}(S)]}\theta(\omega(g,h)\varphi)\,F(g(x^{-1},1))\,dg\,dx.\end{aligned}$$

Substitute $x\mapsto x^{-1}$; the double integrand becomes $k_0(x)\,\theta(\omega(g,h)\varphi)\,F(g(x,1))$. It is absolutely integrable on $G_\infty(\sigma)\times[\mathrm{U}(S)]$: writing $\theta(\omega(g,h)\varphi)=\theta(\omega(g(x,1),h)\,\omega((x^{-1},1),1)\varphi)$, (L1) bounds its modulus by $CD\,\mathrm{ht}_T(h)^A\|f\|\,|k_0(x)|\,\|\Omega_0(x^{-1},1)u\|$, whose integral over x is $\int|k_0(x^{-1})|\,\|\Omega_0(x,1)u\|\,dx<\infty$, and $[\mathrm{U}(S)]$ has finite volume. By Fubini and $R(k_0)F=F$ (k_0 is integrable and F is a form of type k_0), the integral is $\int_{[\mathrm{U}(S)]}\theta(\omega(g,h)\varphi)F(g)\,dg=L_\varphi F(h)$.

Step 3: the first half edge, for Ω from $e_{l/2}$ to $e_{l'/2}$. Take $(\sigma,\sigma')=(s,t)$, $\Omega_0=\Omega$, $k_0=e_{l/2}$: by (6.65), $k_0(x^{-1})=e_{-l/2}(x)$, so $P_0=P$, and (o) of Proposition 6.4.21 gives the integrability. (a): $e_{l/2}$ is a cusp kernel of order 0 by (i). (b): by (i), $\overline{e_{l/2}}=e_{-l/2}$, and the bounded functional $\langle v_H,\cdot\rangle$ commutes with the Bochner integral, so the zeta integral is $e_{l/2}(1)^{-1}\langle v_H,Pv_H\rangle$, nonzero by (a) of Proposition 6.4.21 ($e_{l/2}(1)\neq0$ by (ED1)). (c): let $S,T,V,(\omega,\theta),f,F$ be as in (ED4)(c) and $F_H=L_{v_H\otimes f}F$. By (L5), $F_H=L_{(Pv_H)\otimes f}F$. By (o) for $u=Pv_H$, (L4) with $k=e_{l'/2}$ and (b) of Proposition 6.4.21, for every h, $y\mapsto e_{l'/2}(y)F_H(h(y,1))$ is integrable and

$$R(e_{l'/2})F_H(h)=\Lambda_h((P'Pv_H)\otimes f)=\Lambda_h((Pv_H)\otimes f)=F_H(h).$$

If F_H is right invariant under an open subgroup K', it is moreover continuous and left invariant under Γ_T (L2), and Lemma 6.4.46 (with the cusp kernel $e_{l'/2}$ of order 0, by (i)) shows that $F_H=R(e_{l'/2})F_H$ is a form of type $e_{l'/2}$ on T. (d): for a polynomial Q let a be the function on $G_\infty(t)$ of (c) of Proposition 6.4.21; it depends on Q only. As a is continuous with compact support and $y\mapsto\Omega(1,y)Pv_H$ is continuous, $y\mapsto a(y)\Omega(1,y)Pv_H$ is Bochner integrable. By (L5), Proposition 6.4.21 (c), (L4) and (L5) again,

$$L_{v_Q\otimes f}F(h)=\Lambda_h((Pv_Q)\otimes f)=\int a(y)\,L_{(Pv_H)\otimes f}F(h(y,1))\,dy=R(a)F_H(h).$$

Step 4: the second half edge, for Ω^{sw} from $\overline{e_{l'/2}}=e_{-l'/2}$ to $\overline{e_{l/2}}=e_{-l/2}$. Take $(\sigma,\sigma')=(t,s)$, $\Omega_0=\Omega^{\mathrm{sw}}$, $k_0=e_{-l'/2}$: by (6.65), $k_0(y^{-1})=e_{l'/2}(y)$, so $P_0=P'$, integrable by (o). (a): $e_{-l'/2}$ is a cusp kernel of order 0 by (i). (b): the zeta integral $\int\langle v_H,\Omega(1,y)v_H\rangle\overline{e_{-l'/2}(y)}\,dy/e_{-l'/2}(1)$ equals $e_{-l'/2}(1)^{-1}\langle v_H,P'v_H\rangle\neq0$ by (i) and (a) of Proposition 6.4.21. (c): with $F_H=L_{v_H\otimes f}F$ for a form F of type $e_{-l'/2}$, (L5) gives $F_H=L_{(P'v_H)\otimes f}F$, and (o) for $u=P'v_H$, (L4) with

$k = e_{-l/2}$ and $PP'v_H = P'v_H$ ((b) of Proposition 6.4.21) give $R(e_{-l/2})F_H = F_H$ with integrable integrands; with a level, Lemma 6.4.46 for the cusp kernel $e_{-l/2}$ of order 0 shows that F_H is a form of type $e_{-l/2}$. (d): with the function b on $G_\infty(s)$ of (c) of Proposition 6.4.21, as in Step 3, $L_{v_Q\otimes f}F = R(b)F_H$.

So v_H is a half edge for Ω from $e_{l/2}$ to $e_{l'/2}$ and a half edge for Ω^{sw} from $\overline{e_{l'/2}}$ to $\overline{e_{l/2}}$: an edge for the weights (γ, γ'). □

Lemma 6.4.19. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma, \gamma' \in \mathbb{Z}$, and let $\lambda\colon I \to \mathbb{Z}$, $\lambda'\colon I' \to \mathbb{Z}$ be such that (λ, λ') satisfies the block rule for the weights (γ, γ') and the signs (s, t). Then there is a joint harmonic for the signs (s, t), the weights (γ, γ') and the parameters (λ, λ').*

Proof. We construct H as a product of determinants and check the conditions of (HV7). Condition (a) of (HV7) is the hypothesis, so it remains to find H satisfying (b): jointly highest of weights $(\mu_{\lambda'}, \mu_{-\lambda})$ for $(\lambda', -\lambda)$, for the row and column units of (s, t) with the shifts $(\gamma, -\gamma')$.

Step 1: the conditions in coordinates. For a row $a \in I'$, a column $c \in I$ and $\sigma \in \{\pm 1\}$ let $D^\sigma_a = \sum_{c'\colon t(a)s(c')=\sigma} X_{ac'}\partial_{ac'}$ and $D^\sigma_c = \sum_{a'\colon t(a')s(c)=\sigma} X_{a'c}\partial_{a'c}$ be the Euler operators of row a and of column c in the variables of sign σ. From (HV5) with the shifts $(\gamma, -\gamma')$,

$$\begin{aligned}
E^{\mathrm{row}}_{aa} &= D^+_a - D^-_a + \gamma - \#\{c : t(a)s(c) = -1\},\\
E^{\mathrm{row}}_{aa'} &= \sum_{c\colon t(a)s(c)=1} X_{ac}\partial_{a'c} - \sum_{c\colon t(a)s(c)=-1} X_{a'c}\partial_{ac} \qquad (a \neq a',\ t(a) = t(a')),\\
E^{\mathrm{col}}_{cc} &= D^-_c - D^+_c - \gamma' + \#\{a : t(a)s(c) = -1\},\\
E^{\mathrm{col}}_{cc'} &= -\sum_{a\colon t(a)s(c)=1} X_{ac'}\partial_{ac} + \sum_{a\colon t(a)s(c)=-1} X_{ac}\partial_{ac'} \qquad (c \neq c',\ s(c) = s(c')).
\end{aligned}$$

By the definitions of ν and ν' in Lemma 6.4.20, a polynomial H is K-highest of weight $\mu_{\lambda'}$ for λ' for the row units if and only if

$$(D^+_a - D^-_a)H = \nu(a)H \ (a \in I'), \qquad E^{\mathrm{row}}_{aa'}H = 0 \ \text{ when } t(a) = t(a'),\ \lambda'(a') < \lambda'(a), \tag{6.66}$$

and K-highest of weight $\mu_{-\lambda}$ for $-\lambda$ for the column units if and only if

$$(D^-_c - D^+_c)H = \nu'(c)H \ (c \in I), \qquad E^{\mathrm{col}}_{cc'}H = 0 \ \text{ when } s(c) = s(c'),\ \lambda(c) < \lambda(c'). \tag{6.67}$$

Step 2: layers. By (d) of Lemma 6.4.20 and the uniqueness of partners in (a) there, every row a with $\nu(a) \neq 0$ is matched with exactly one column c_a, and $t(a)s(c_a) = \operatorname{sgn}\nu(a)$. For $m \in \mathbb{N}$ and $\tau, \tau' \in \{\pm 1\}$ let the *layer* $L_{m,\tau,\tau'}$ be the set of matched pairs (a, c) with $|\nu(a)| > m$, $t(a) = \tau$ and $s(c) = \tau'$; let $R(L)$ and $C(L)$ be its sets of rows and of columns, so that $a \mapsto c_a$ is a bijection $R(L) \to C(L)$. Put $D_L = \det(X_{a\,c_b})_{a,b\in R(L)}$ (one ordering of $R(L)$ for rows and columns; a simultaneous reordering does not change it), $D_\emptyset = 1$, and

$$H = \prod_{m\geq 0} \prod_{\tau,\tau'\in\{\pm1\}} D_{L_{m,\tau,\tau'}},$$

a finite product, since $L_{m,\tau,\tau'} = \emptyset$ for $m \geq \max_a |\nu(a)|$. The following hold.

(L1) D_L is the generic determinant in the distinct variables X_{ac}, $a \in R(L)$, $c \in C(L)$, hence nonzero; it involves no other variable, is homogeneous of degree one in each row of $R(L)$ and in each column of $C(L)$, and all its variables have the sign $\tau\tau'$.

(L2) A row a lies in $R(L_{m,\tau,\tau'})$ if and only if $\nu(a) \neq 0$, $(\tau,\tau') = (t(a), s(c_a))$ and $m < |\nu(a)|$: it lies in exactly $|\nu(a)|$ layers, all with columns of sign $s(c_a)$ and variables of sign $\operatorname{sgn}\nu(a)$. A column lies in some $C(L)$ if and only if it is c_a for a row a with $\nu(a) \neq 0$, and then it lies exactly in the layers of a.

(L3) Let (a,c) be matched with $\nu(a) \neq 0$ and let $a' \in I'$ satisfy $t(a') = t(a)$ and $t(a)s(c)(\lambda'(a') - \lambda'(a)) > 0$. Then a' lies in every layer that contains a. Indeed, by (e) of Lemma 6.4.20, a' is matched with a column c' with $s(c') = s(c)$ and $|\nu(a')| \geq |\nu(a)| > 0$; so $c' = c_{a'}$, and by (L2) the layers of a' are the $L_{m,t(a),s(c)}$ with $m < |\nu(a')|$, which include those of a.

(L4) Let (a,c) be matched with $\nu(a) \neq 0$, $p = t(a)s(c)$, and let $c' \in I$ satisfy $s(c') = s(c)$ and $p(\lambda(c') - \lambda(c)) > 0$. Then c' lies in every layer that contains c. Indeed, by (a) of Lemma 6.4.20, $p = \operatorname{sgn}\tilde{\lambda}(c)$ and $p\tilde{\lambda}(c) > |N' - N|$; as $\tilde{\lambda} - \lambda$ is constant, $p\tilde{\lambda}(c') > p\tilde{\lambda}(c) > |N' - N|$. A column matched with no row has $|\tilde{\lambda}| < N - N' \leq |N' - N|$ by (a) there, so c' is matched with a row a', and $t(a')s(c') = \operatorname{sgn}\tilde{\lambda}(c') = p$; hence $t(a') = ps(c) = t(a)$. As $\tilde{\lambda}'(a') = \tilde{\lambda}(c')$, $\tilde{\lambda}'(a) = \tilde{\lambda}(c)$ and $\tilde{\lambda}' - \lambda'$ is constant, $p(\lambda'(a') - \lambda'(a)) = p(\tilde{\lambda}(c') - \tilde{\lambda}(c)) > 0$. By (L3), a' lies in every layer containing a; these layers contain c', the partner of a', and they are the layers containing c by (L2).

Step 3: $H \neq 0$, termwise harmonicity and the weights. H is a product of nonzero polynomials by (L1), so $H \neq 0$. By (L1) and (L2), the variables of row a occurring in H come from the layers of a, whose columns have the one sign $s(c_a)$, and the variables of a column $c = c_a$ come from the same layers, whose rows have the one sign $t(a)$. So no monomial of H contains two variables of one row from columns of opposite signs, or two variables of one column from rows of opposite signs: H is termwise harmonic. By (L1) and (L2), H is homogeneous of degree $|\nu(a)|$ in row a, in variables of the single sign $\operatorname{sgn}\nu(a)$ when $\nu(a) \neq 0$; hence $(D_a^+ - D_a^-)H = \nu(a)H$, also when $\nu(a) = 0$ (row a does not occur). For a column $c = c_a$ with $\nu(a) \neq 0$, H is homogeneous of degree $|\nu(a)|$ in column c, in variables of sign $\operatorname{sgn}\nu(a)$, so $(D_c^- - D_c^+)H = -\nu(a)H = \nu'(c)H$ by (b) of Lemma 6.4.20. Any other column c does not occur in H, and $\nu'(c) = 0$: if c is matched with no row, by (c) of Lemma 6.4.20; if c is matched with a row a, then $\nu(a) = 0$ and $\nu'(c) = -\nu(a) = 0$ by (b) there.

Step 4: a replacement rule. Let L be a layer and $b \neq b'$ rows with $b' \in R(L)$, and let $\delta = \sum_{c \in C(L)} X_{bc}\partial_{b'c}$. By the Laplace expansion along row b', δD_L is the determinant of the matrix of D_L with row b' replaced by $(X_{bc})_{c \in C(L)}$; it is 0 if $b \in R(L)$, the matrix then having two equal rows. In the same way, for columns $e \neq e'$ with $e' \in C(L)$, $\sum_{a \in R(L)} X_{ae}\partial_{ae'} D_L$ is D_L with column e' replaced by column e, and is 0 if $e \in C(L)$. Moreover $\partial_{ac} D_L = 0$ unless $a \in R(L)$ and $c \in C(L)$. Every operator T below is a sum of derivations $X_{bc}\partial_{b'c}$, so $TH = \sum_L (\prod_{L' \neq L} D_{L'}) T D_L$, the sum over the layers.

Step 5: the raising conditions. Let $a \neq a'$ with $t(a) = t(a')$ and $\lambda'(a') < \lambda'(a)$. Let $T_1 = \sum_{c:\, t(a)s(c) = 1} X_{ac}\partial_{a'c}$ and $T_2 = \sum_{c:\, t(a)s(c) = -1} X_{a'c}\partial_{ac}$, so $E^{\mathrm{row}}_{aa'} = T_1 - T_2$. If $T_1 D_L \neq 0$ for a layer L, then $a' \in R(L)$ and some column of L has $t(a')s(c) = 1$; all columns of L have the sign $s(c_{a'})$, so $t(a')s(c_{a'}) = 1$, T_1 contains $X_{ac}\partial_{a'c}$ for every $c \in C(L)$, and $T_1 D_L$ is D_L with row a' replaced by row a. But (L3) for the pair $(a', c_{a'})$ and the row a applies, since $t(a')s(c_{a'})(\lambda'(a) - \lambda'(a')) = \lambda'(a) - \lambda'(a') > 0$, so $a \in R(L)$ and $T_1 D_L = 0$ by Step 4, a contradiction. If $T_2 D_L \neq 0$, then $a \in R(L)$, $t(a)s(c_a) = -1$, and $T_2 D_L$ is D_L with row a replaced by row a'; (L3) for (a, c_a) and a' applies, since $t(a)s(c_a)(\lambda'(a') - \lambda'(a)) = \lambda'(a) - \lambda'(a') > 0$, so $a' \in R(L)$ and $T_2 D_L = 0$, a contradiction. Hence $T_1 H = T_2 H = 0$ and $E^{\mathrm{row}}_{aa'} H = 0$.

Let $c \neq c'$ with $s(c) = s(c')$ and $\lambda(c) < \lambda(c')$. Let $T_3 = \sum_{a:\, t(a)s(c) = 1} X_{ac'}\partial_{ac}$ and $T_4 = \sum_{a:\, t(a)s(c) = -1} X_{ac}\partial_{ac'}$, so $E^{\mathrm{col}}_{cc'} = -T_3 + T_4$. If $T_3 D_L \neq 0$, then $c \in C(L)$, say $c = c_b$ with $b \in R(L)$; all rows of L have the sign $t(b)$, so $t(b)s(c) = 1$ and $T_3 D_L$ is D_L with column c replaced

by column c'; (L4) for (b,c), $p=1$, and c' gives $c'\in C(L)$, so $T_3D_L=0$, a contradiction. If $T_4D_L\neq 0$, then $c'=c_b\in C(L)$ with $t(b)s(c')=-1$, and T_4D_L is D_L with column c' replaced by column c; (L4) for (b,c'), $p=-1$, and c applies, since $-(\lambda(c)-\lambda(c'))>0$, so $c\in C(L)$ and $T_4D_L=0$, a contradiction. Hence $E^{\mathrm{col}}_{cc'}H=0$.

Step 6: conclusion. By Steps 3 and 5, H satisfies (6.66) and (6.67), is nonzero and termwise harmonic; so it is jointly highest of weights $(\mu_{\lambda'},\mu_{-\lambda})$ for $(\lambda',-\lambda)$ for the row and column units of (s,t) with the shifts $(\gamma,-\gamma')$. With the block rule, it is a joint harmonic. □

Lemma 6.4.20. *Let I, I' be nonempty finite sets with signs s on I and t on I', $N=\#I$, $N'=\#I'$, $\gamma,\gamma'\in\mathbb{Z}$, and let $\lambda\colon I\to\mathbb{Z}$, $\lambda'\colon I'\to\mathbb{Z}$ be such that (λ,λ') satisfies the block rule for the weights (γ,γ') and the signs (s,t). Let $\tilde\lambda(c)=\lambda(c)-2\gamma'+N'$ and $\tilde\lambda'(a)=\lambda'(a)-2\gamma+N$ be the shifted entries. Call $(a,c)\in I'\times I$ **matched** if $\tilde\lambda'(a)=\tilde\lambda(c)$ and $t(a)s(c)\,\tilde\lambda'(a)>|N'-N|$, and put*

$$\nu(a)=\mu_{\lambda'}(a)-\gamma+\#\{c\in I: t(a)s(c)=-1\}\quad(a\in I'),$$
$$\nu'(c)=\mu_{-\lambda}(c)+\gamma'-\#\{a\in I': t(a)s(c)=-1\}\quad(c\in I),$$

with $\mu_{\lambda'}$ the lowest K-type of λ' for the signs t and $\mu_{-\lambda}$ that of $-\lambda$ for the signs s. Then:

(a) every row $a\in I'$ is matched with at most one column and every column with at most one row; a row a matched with no column has $|\tilde\lambda'(a)|<N'-N$, and a column c matched with no row has $|\tilde\lambda(c)|<N-N'$; for a matched pair (a,c), $\tilde\lambda'(a)\neq 0$ and $t(a)s(c)$ is the sign of $\tilde\lambda'(a)$;

(b) $\nu(a)=-\nu'(c)$ for every matched pair (a,c);

(c) for $u\in\{\pm1\}$: if $a\in I'$ and $u\tilde\lambda'(a)>N-N'$, then $u\,\nu(a)\geq 0$; if $c\in I$ and $-u\tilde\lambda(c)>N'-N$, then $u\,\nu'(c)\geq 0$. In particular $\nu(a)=0$ for every row matched with no column and $\nu'(c)=0$ for every column matched with no row;

(d) if $\nu(a)\neq 0$, then a is matched with a column c, and $t(a)s(c)$ is the sign of $\nu(a)$;

(e) if (a,c) is matched, $\nu(a)\neq 0$, and $a'\in I'$ satisfies $t(a')=t(a)$ and $t(a)s(c)(\lambda'(a')-\lambda'(a))>0$, then a' is matched with a column c' with $s(c')=s(c)$, and $|\nu(a)|\leq|\nu(a')|$.

Proof. **Step 0: parities and the lowest K-types.** Let $h=500(N+N')^3\geq N+N'$. By (a) of the block rule, λ is injective, $\lambda(c)\equiv N-1 \pmod 2$, and $|\lambda(c)-\lambda(d)|\geq 2h$ whenever $s(c)\neq s(d)$; likewise for λ' with N' and t. Hence $\tilde\lambda$ and $\tilde\lambda'$ are injective, $\tilde\lambda(c)\equiv N-N'-1$ and $\tilde\lambda'(a)\equiv N'-N-1 \pmod 2$. For an injective integer vector l on a set n with signs ε and $l_i\equiv\#n-1 \pmod 2$, Definition 3.2.3 gives $2\rho_l(i)=\sum_j\operatorname{sgn}(l_i-l_j)\equiv\#n-1\equiv l_i$, so the floor in l_i^ρ is exact and

$$2\mu_l(i)=l_i+\sum_j\operatorname{sgn}(l_i-l_j)-2\sum_{j:\varepsilon_j=\varepsilon_i}\operatorname{sgn}(l_i-l_j)=l_i+\sum_{j\in n}\varepsilon_i\varepsilon_j\operatorname{sgn}(l_j-l_i).\tag{6.68}$$

Applied to λ' and to $-\lambda$, with $2\#\{c: t(a)s(c)=-1\}=N-\sum_c t(a)s(c)$ and $2\#\{a: t(a)s(c)=-1\}=N'-\sum_a t(a)s(c)$,

$$2\nu(a)=\tilde\lambda'(a)+\sum_{j\in I'}t(a)t(j)\operatorname{sgn}\bigl(\lambda'(j)-\lambda'(a)\bigr)-\sum_{c\in I}t(a)s(c),\tag{6.69}$$

$$2\nu'(c)=-\tilde\lambda(c)+\sum_{e\in I}s(c)s(e)\operatorname{sgn}\bigl(\lambda(c)-\lambda(e)\bigr)+\sum_{a\in I'}t(a)s(c).\tag{6.70}$$

Step 1: (a). The partners are unique because $\tilde\lambda$ and $\tilde\lambda'$ are injective, and for a matched pair $t(a)s(c)\tilde\lambda'(a) > |N'-N| \ge 0$ gives the last assertion. Suppose $N \le N'$ and put $d = N'-N$. By (b) of the block rule, $\tilde\lambda'(I') = \tilde\lambda(I) \cup [d]$; as $\#\tilde\lambda'(I') = N' = \#\tilde\lambda(I) + \#[d]$, the union is disjoint. The set $[d]$ consists of the integers $x \equiv d-1 \pmod 2$ with $|x| < d$. Let $c \in I$; then $\tilde\lambda(c) = \tilde\lambda'(a)$ for some a, and $\tilde\lambda'(a) \notin [d]$ with $\tilde\lambda'(a) \equiv d-1$, so $|\tilde\lambda'(a)| > d = |N'-N|$ (the value d has the wrong parity). By (c) of the block rule $t(a) = s(c)$ if $\tilde\lambda'(a) > 0$ and $t(a) = -s(c)$ if $\tilde\lambda'(a) < 0$, so $t(a)s(c)\tilde\lambda'(a) = |\tilde\lambda'(a)| > |N'-N|$ and (a,c) is matched. A row a has $\tilde\lambda'(a) \in \tilde\lambda(I)$, and then it is matched as just shown, or $\tilde\lambda'(a) \in [d]$, i.e. $|\tilde\lambda'(a)| < N'-N$. If $N' \le N$, the same argument with $\tilde\lambda(I) = \tilde\lambda'(I') \cup [N-N']$ shows that every row is matched and that a column matched with no row has $|\tilde\lambda(c)| < N-N'$ ((c) of the block rule is symmetric in the two sides).

Step 2: a counting principle. Let (A,B) be (I',I) or (I,I'), so that by (a) the matched pairs form a bijection between subsets of A and B. If $f\colon A \to \mathbb{Z}$ and $g\colon B \to \mathbb{Z}$ satisfy $g(b) \le f(a)$ for matched a, b, $f(a) \ge 0$ for unmatched a and $g(b) \le 0$ for unmatched b, then

$$\sum_{b\in B} g(b) \le \sum_{b \text{ matched}} g(b) \le \sum_{b \text{ matched}} f(\text{partner of } b) = \sum_{a \text{ matched}} f(a) \le \sum_{a\in A} f(a). \tag{6.71}$$

Step 3: (b). Let (a,c) be matched, $x = \tilde\lambda'(a) = \tilde\lambda(c)$ and $p = t(a)s(c) = \operatorname{sgn} x$, so $|x| > |N'-N|$. As $\tilde\lambda' - \lambda'$ and $\tilde\lambda - \lambda$ are constant, $\operatorname{sgn}(\lambda'(j) - \lambda'(a)) = -\operatorname{sgn}(x - \tilde\lambda'(j))$ and $\operatorname{sgn}(\lambda(c) - \lambda(e)) = \operatorname{sgn}(x - \tilde\lambda(e))$. Put $f(j) = -s(c)t(j) + t(a)t(j)\operatorname{sgn}(x - \tilde\lambda'(j))$ on I' and $g(e) = s(c)s(e)\operatorname{sgn}(x - \tilde\lambda(e)) - t(a)s(e)$ on I. Adding (6.69) and (6.70),

$$2\nu(a) + 2\nu'(c) = \sum_{e\in I} g(e) - \sum_{j\in I'} f(j).$$

For a matched pair (j,e) let $y = \tilde\lambda'(j) = \tilde\lambda(e)$, $q = t(j)s(e) = \operatorname{sgn} y$ and $\sigma = \operatorname{sgn}(x-y)$; with $s(c) = pt(a)$ and $s(e) = qt(j)$, $g(e) = t(a)t(j)\,q(p\sigma - 1)$ and $f(j) = t(a)t(j)(\sigma - p)$. If $q = p$ these agree since $p^2 = 1$; if $q \ne p$, then x and y have opposite signs, so $\sigma = p$ and both vanish. For an unmatched row j, $|\tilde\lambda'(j)| < N'-N < |x|$, so $\operatorname{sgn}(x - \tilde\lambda'(j)) = p$ and $f(j) = 0$; for an unmatched column e, $|\tilde\lambda(e)| < N-N' < |x|$, so $g(e) = p^2 t(a)s(e) - t(a)s(e) = 0$. By (6.71) for (f,g) and for $(-f,-g)$, $\sum g = \sum f$, hence $\nu(a) = -\nu'(c)$.

Step 4: (c) for rows. Let $u\tilde\lambda'(a) > N-N'$. For $j \in I'$ the number $u\tilde\lambda'(j) + N' - N$ is odd (Step 0); write it $2v(j)+1$. Then v is injective, $v(a) \ge 0$, and with $S = \{0,\dots,v(a)\}$ at most $v(a)+1$ rows have $v(j) \in S$. Put $f(j) = ut(a)t(j)\operatorname{sgn}(\lambda'(j) - \lambda'(a)) + 2[v(j) \in S] - 1 \ge -2$ and $g(c) = ut(a)s(c) - 1 \le 0$. Let (j,c) be matched. If $ut(a)s(c) = -1$, then $g(c) = -2 \le f(j)$. Otherwise $s(c) = ut(a)$ and $g(c) = 0$. If $t(j) = t(a)$, then $u\tilde\lambda'(j) = t(j)s(c)\tilde\lambda'(j) > |N'-N|$, so $v(j) \ge 0$; either $v(j) \le v(a)$ and $f(j) \ge 0$, or $u(\lambda'(j) - \lambda'(a)) > 0$ and the first term of $f(j)$ is 1, so $f(j) \ge 0$. If $t(j) = -t(a)$, then $-u\tilde\lambda'(j) > |N'-N|$, so $u\tilde\lambda'(j) < N-N' < u\tilde\lambda'(a)$, and the first term is $u\cdot(-1)\cdot(-u) = 1$. Let j be unmatched: $|\tilde\lambda'(j)| < N'-N$ gives $v(j) \ge 0$; if $v(j) > v(a)$, then $N-N' < u\tilde\lambda'(a) < u\tilde\lambda'(j) < N'-N$, so $0 < |\lambda'(j) - \lambda'(a)| < 2N' < 2h$, hence $t(j) = t(a)$ and the first term is 1; in all cases $f(j) \ge 0$. By (6.71) with $(A,B) = (I',I)$,

$$u\sum_c t(a)s(c) - N \le u\sum_j t(a)t(j)\operatorname{sgn}(\lambda'(j) - \lambda'(a)) + 2(v(a)+1) - N',$$

and (6.69) gives $2u\nu(a) \ge u\tilde\lambda'(a) - 2v(a) - 2 + N' - N = -1$. As $\nu(a)$ is an integer, $u\nu(a) \ge 0$.

Step 5: (c) for columns. Let $-u\tilde\lambda(c) > N'-N$. For $e \in I$ the number $-u\tilde\lambda(e) + N - N'$ is odd; write it $2w(e)+1$, so w is injective, $w(c) \ge 0$, and at most $w(c)+1$ columns have $w(e) \in S' = \{0,\dots,w(c)\}$. Put $f'(e) = us(c)s(e)\operatorname{sgn}(\lambda(c) - \lambda(e)) + 2[w(e) \in S'] - 1 \ge -2$ on I and $g'(a) = -ut(a)s(c) - 1 \le 0$ on I'. Let (a,e) be matched. If $-ut(a)s(c) = -1$, $g'(a) = -2 \le$

$f'(e)$. Otherwise $t(a) = -us(c)$, $g'(a) = 0$, and matching reads $-us(c)s(e)\tilde{\lambda}(e) > |N' - N|$. If $s(e) = s(c)$, then $-u\tilde{\lambda}(e) > |N' - N|$, so $w(e) \geq 0$, and either $w(e) \leq w(c)$ or $u(\lambda(c) - \lambda(e)) > 0$ and the first term is 1; so $f'(e) \geq 0$. If $s(e) = -s(c)$, then $-u\tilde{\lambda}(e) < N' - N < -u\tilde{\lambda}(c)$, so $\operatorname{sgn}(\lambda(c) - \lambda(e)) = -u$ and the first term is 1. Let e be unmatched: $|\tilde{\lambda}(e)| < N - N'$ gives $w(e) \geq 0$; if $w(e) > w(c)$, then $N' - N < -u\tilde{\lambda}(c) < -u\tilde{\lambda}(e) < N - N'$, so $0 < |\lambda(c) - \lambda(e)| < 2N < 2h$, hence $s(e) = s(c)$ and the first term is 1; so $f'(e) \geq 0$. By (6.71) with $(A, B) = (I, I')$,

$$-u \sum_a t(a)s(c) - N' \leq u \sum_e s(c)s(e) \operatorname{sgn}(\lambda(c) - \lambda(e)) + 2(w(c) + 1) - N,$$

and (6.70) gives $2u\nu'(c) \geq -u\tilde{\lambda}(c) - 2w(c) - 2 + N - N' = -1$, so $u\nu'(c) \geq 0$. Finally, for an unmatched row $|\tilde{\lambda}'(a)| < N' - N$ gives $u\tilde{\lambda}'(a) > N - N'$ for both u, so $\nu(a) = 0$; for an unmatched column $|\tilde{\lambda}(c)| < N - N'$ gives $-u\tilde{\lambda}(c) > N' - N$ for both u, so $\nu'(c) = 0$.

Step 6: (d). If $\nu(a) \neq 0$, then a is matched with some c by (c), and $p = t(a)s(c) = \operatorname{sgn} \tilde{\lambda}'(a)$ satisfies $p\tilde{\lambda}'(a) = |\tilde{\lambda}'(a)| > |N' - N| \geq N - N'$; by (c), $p\nu(a) \geq 0$, so p is the sign of $\nu(a)$.

Step 7: (e). First, $\mu = \mu_{\lambda'}$ is dominant: if $t(b) = t(b')$ and $\lambda'(b') < \lambda'(b)$, then $\mu(b') \leq \mu(b)$. Indeed, by (6.68), $2\mu(b) - 2\mu(b') = \lambda'(b) - \lambda'(b') + \sum_j t(b)t(j)(\operatorname{sgn}(\lambda'(j) - \lambda'(b)) - \operatorname{sgn}(\lambda'(j) - \lambda'(b')))$; the bracket is -1 for $j \in \{b, b'\}$, -2 for $\lambda'(b') < \lambda'(j) < \lambda'(b)$ and 0 otherwise, so the sum is $-2 - 2m_= + 2m_\neq$, $m_=$, $m_\neq$ the numbers of rows strictly between of the sign of b and of the other sign; and $\lambda'(b) - \lambda'(b') \geq 2(m_= + m_\neq + 1)$, the entries being distinct of one parity. Hence $2\mu(b) - 2\mu(b') \geq 4m_\neq \geq 0$. Now let (a, c), a' be as in (e) and $p = t(a)s(c)$, the sign of $\nu(a)$ by (d) (the partner of a being unique). As $t(a') = t(a)$, $\nu(a') - \nu(a) = \mu(a') - \mu(a)$, and $p(\lambda'(a') - \lambda'(a)) > 0$ with dominance gives $p(\mu(a') - \mu(a)) \geq 0$. So $p\nu(a') \geq p\nu(a) = |\nu(a)| > 0$: $\nu(a') \neq 0$ has the sign p and $|\nu(a')| \geq |\nu(a)|$. By (d), a' is matched with a column c' with $t(a')s(c') = p = t(a)s(c)$, so $s(c') = s(c)$. □

This group supplies the local theta correspondence at the infinite places for a product of joint harmonics (Proposition 6.4.21), which Lemma 6.4.18 needs. For the operators P and P' obtained by integrating the real Weil representation against the type kernels of the two groups, the Fock vector v_H of a product of joint harmonics has positive projections, each projection is reproduced by the partner kernel, and the projections of v_H generate those of all Fock vectors of polynomials. In our reading this is an explicit form of the archimedean theta correspondence between discrete series of two unitary groups [136]: the joint harmonic is a common lowest vector, in the spirit of [157], and reproduction says that the discrete series of parameters l and l' correspond (see [186, 229]). It is proved in full, with Flensted-Jensen's functions [81] for the discrete series of Harish-Chandra [119].

The statement reduces to one place, since the Weil representation acts place by place on pure tensors (Lemma 6.4.23) and its derivative on the Fock vectors of polynomials is a quadratic oscillator operator [14, 135]. At one place (Proposition 6.4.26) each property has its own proof. Positivity comes from the positivity of oscillator coefficients on harmonic polynomial vectors (Proposition 6.4.29) and an average over the compact group. Reproduction is a rigidity statement (Theorem 6.4.36), made in the context printed before Proposition 6.4.26: a vector of the lowest K-type that is killed by the compact raising operators, with Casimir eigenvalue at least κ_l, has Flensted-Jensen's function as its matrix coefficient. The Casimir value is computed in two ways, the second by matching the Casimir operators of the two groups of the pair; in our reading this is the classical coincidence of the Casimir operators of a dual pair on the oscillator representation (see [136]). Generation is Howe's argument (Lemma 6.4.40), with the Fischer decomposition [135, 137]. The group ends with the remaining lemmas of the spanning proof.

Proposition 6.4.21. *Let n, n' be nonempty finite sets with signs s on n and t on n', let $\gamma, \gamma' \colon \Phi \to \mathbb{Z}$, and let $l = (l_v)_{v \in \Phi}$, $l' = (l'_v)_{v \in \Phi}$ be families of maps $l_v \colon n \to \mathbb{Z}$, $l'_v \colon n' \to \mathbb{Z}$.*

For every $v \in \Phi$ let H_v be a joint harmonic for the signs (s,t), the weights $(\gamma(v),\gamma'(v))$ and the parameters (l_v,l'_v), written in the variables $X_{v,a,c}$ ($a \in n'$, $c \in n$), and $H = \prod_{v\in\Phi} H_v$. Let $\varepsilon(v,a,c) = t(a)s(c)$ on $\iota = \Phi \times n' \times n$, $\Omega = \Omega_{\gamma,\gamma'}$, $e = e_{-l/2}$ on $G_\infty(s)$ and $e' = e_{l'/2}$ on $G_\infty(t)$. Then:

(o) for every $u \in \mathcal{F}_\varepsilon$ the functions $x \mapsto e(x)\,\Omega(x,1)u$ on $G_\infty(s)$ and $y \mapsto e'(y)\,\Omega(1,y)u$ on $G_\infty(t)$ are Bochner integrable in $\mathcal{F}_\varepsilon$; write

$$Pu = \int e(x)\Omega(x,1)u\,dx \quad \text{and} \quad P'u = \int e'(y)\Omega(1,y)u\,dy;$$

(a) $\mathrm{Re}\langle v_H, Pv_H\rangle > 0$ and $\mathrm{Re}\langle v_H, P'v_H\rangle > 0$;

(b) $P'Pv_H = Pv_H$ and $PP'v_H = P'v_H$;

(c) for every polynomial Q in the variables $X_{v,a,c}$ there are continuous compactly supported functions a on $G_\infty(t)$ and b on $G_\infty(s)$ with

$$Pv_Q = \int_{G_\infty(t)} a(y)\,\Omega(1,y)Pv_H\,dy, \qquad P'v_Q = \int_{G_\infty(s)} b(x)\,\Omega(x,1)P'v_H\,dx.$$

Proof. **Step 0: the places.** By (FT3) of Definition 3.2.4, $e(x) = \prod_v e_v(x_v)$ and $e'(y) = \prod_v e'_v(y_v)$, where $e_v = d_{-l_v/2}\overline{c_{-l_v/2}}$ on $\mathrm{U}(\mathrm{diag}\,s)$ and $e'_v = d_{l'_v/2}\overline{c_{l'_v/2}}$ on $\mathrm{U}(\mathrm{diag}\,t)$, the formal degrees being taken for the Cayley measures. For each v, the operators π_v, π'_v are those of Proposition 6.4.26 for the signs (s,t) and the weights $(\gamma(v),\gamma'(v))$, and H_v is a joint harmonic for the parameters (l_v,l'_v); write p_v, p'_v for the operators of Proposition 6.4.26 (o) at v. By (a) of Lemma 6.4.23, $v_H = \otimes(v_{H_v})_v$.

(o). Let $u \in \mathcal{F}_\varepsilon$. The functions e and $x \mapsto \Omega(x,1)u$ are continuous ((i) of Lemma 6.4.22), so $x \mapsto e(x)\Omega(x,1)u$ is strongly measurable on the σ-compact group $G_\infty(s)$, and by (ii) of Lemma 6.4.22 with $y = 1$,

$$\|e(x)\Omega(x,1)u\| \le 2^{\#\iota}\,\|u\| \prod_{v\in\Phi} |e_v(x_v)|\,\|x_v\|^A,$$

whose integral is $2^{\#\iota}\|u\|\prod_v \int |e_v(g)|\|g\|^A dg < \infty$ by Tonelli's theorem and (o) of Proposition 6.4.26. So the function is Bochner integrable; the same argument applies to $y \mapsto e'(y)\Omega(1,y)u$.

Step 1: projections of pure tensors. Let $w = (w_v)$ with $w_v \in \mathcal{F}_v$. By (o) of Proposition 6.4.26, $g \mapsto e_v(g)\pi_v(g)w_v$ and $h \mapsto e'_v(h)\pi'_v(h)w_v$ are Bochner integrable, so (d) of Lemma 6.4.23 with $k_v = e_v$, respectively $k_v = e'_v$, gives

$$P(\otimes w) = \otimes(p_v w_v)_v, \qquad P'(\otimes w) = \otimes(p'_v w_v)_v.$$

(a). By Step 1, $Pv_H = \otimes(p_v v_{H_v})_v$, and by (a) of Lemma 6.4.23, $\langle v_H, Pv_H\rangle = \prod_v \langle v_{H_v}, p_v v_{H_v}\rangle$, a product of positive real numbers by (a) of Proposition 6.4.26. So $\langle v_H, Pv_H\rangle > 0$, in particular its real part is positive; likewise for P'.

(b). By Step 1 twice and (b) of Proposition 6.4.26 at every place, $P'Pv_H = \otimes(p'_v p_v v_{H_v})_v = \otimes(p_v v_{H_v})_v = Pv_H$, and $PP'v_H = \otimes(p_v p'_v v_{H_v})_v = \otimes(p'_v v_{H_v})_v = P'v_H$.

(c). First let $Q = \prod_v Q_v$, where Q_v is a polynomial in the variables $X_{v,a,c}$ ($a \in n'$, $c \in n$) of the place v. By (a) of Lemma 6.4.23 and Step 1, $Pv_Q = \otimes(p_v v_{Q_v})_v$, and by (c) of Proposition 6.4.26 there are smooth compactly supported α_v on $\mathrm{U}(\mathrm{diag}\,t)$ with $p_v v_{Q_v} =$

$\int \alpha_v(h)\pi'_v(h)\,p_v v_{H_v}\,dh$. The functions $h \mapsto \alpha_v(h)\pi'_v(h)p_v v_{H_v}$ are continuous with compact support, hence Bochner integrable, so (d) of Lemma 6.4.23 for the second group with $k_v = \alpha_v$ and $w_v = p_v v_{H_v}$, together with Step 1 for Pv_H, gives

$$\int_{G_\infty(t)} a_Q(y)\,\Omega(1,y)\,Pv_H\,dy = \otimes\Big(\int \alpha_v(h)\pi'_v(h)p_v v_{H_v}\,dh\Big)_v = \otimes(p_v v_{Q_v})_v = Pv_Q,$$
$$a_Q(y) = \prod_v \alpha_v(y_v),$$

and a_Q is continuous with compact support. A general polynomial Q is a finite sum $\sum_i Q_i$ of monomials, each a product over the places of monomials in the variables of one place; as $Q \mapsto Pv_Q$ is linear, $a = \sum_i a_{Q_i}$ satisfies the first identity. The second identity follows in the same way from the second identity of (c) of Proposition 6.4.26, with smooth compactly supported β_v on $\mathrm{U}(\operatorname{diag} s)$, $b_Q(x) = \prod_v \beta_v(x_v)$, (d) of Lemma 6.4.23 for the first group and Step 1 for P'. □

Lemma 6.4.22. *Let n, n' be finite index sets with signs s on n and t on n', $\gamma, \gamma' \colon \Phi \to \mathbb{Z}$, $\iota = \Phi \times n' \times n$ with $\varepsilon(v,a,c) = t(a)s(c)$, and $\Omega = \Omega_{\gamma,\gamma'}$. Then:*

(i) $x \mapsto \Omega(x,1)$ and $y \mapsto \Omega(1,y)$ are representations of $G_\infty(s)$ and $G_\infty(t)$ by bounded operators of $\mathcal{F}_\varepsilon$ that commute with each other, preserve the inner product of $\mathcal{F}_\varepsilon$, and are strongly continuous: $x \mapsto \Omega(x,1)w$ and $y \mapsto \Omega(1,y)w$ are continuous for every $w \in \mathcal{F}_\varepsilon$;

(ii) for $x \in G_\infty(s)$, $y \in G_\infty(t)$, the operator norm on $\mathcal{F}_\varepsilon$ satisfies

$$\|\Omega(x,y)\| \le 2^{\#\iota} \prod_{v\in\Phi} \left(\|x_v\|\,\|y_v\|\right)^{\#n\cdot\#n'} \le 2^{\#\iota} \max_{v\in\Phi} \left(\|x_v\|\,\|y_v\|\right)^{\#\iota}.$$

Proof. By (WR5), $\Omega(x,y) = \delta(x,y)\,\omega_\varepsilon^\infty(u(x,y))$ with $\delta(x,y) = \prod_v \det(y_v)^{\gamma(v)} \det(x_v)^{-\gamma'(v)}$ and $u(x,y) = \bigoplus_v y_v \otimes (x_v^{-1})^{\mathsf{T}} \in \mathrm{U}(J_\varepsilon)$ ((VP5) of Definition 3.2.2). For $g \in \mathrm{U}(J_\sigma)$, $g^* J_\sigma g = J_\sigma$ gives $|\det g| = 1$ and $g^{-1} = J_\sigma g^* J_\sigma$, so $\|g^{-1}\| = \|g\|$ and $1 = \|gg^{-1}\| \le \|g\|^2$, i.e. $\|g\| \ge 1$; in particular $|\delta(x,y)| = 1$.

(i). By (2) of Lemma 4.1.1, Ω is a representation of $G_\infty(s) \times G_\infty(t)$; as $(x,1)$ and $(1,y)$ commute in this product, so do $\Omega(x,1)$ and $\Omega(1,y)$, and $x \mapsto \Omega(x,1)$, $y \mapsto \Omega(1,y)$ are representations. By the same clause each $\omega_\varepsilon^\infty(u)$ is bounded and preserves the inner product, and $(u,w) \mapsto \omega_\varepsilon^\infty(u)w$ is continuous; since $|\delta| = 1$, $\Omega(x,y)$ preserves the inner product, and since δ and u are continuous, $x \mapsto \Omega(x,1)w$ and $y \mapsto \Omega(1,y)w$ are continuous.

(ii). Let $u \in \mathrm{U}(J_\varepsilon)$, $c \in \mathcal{F}_\varepsilon$ and ι_- the indices of sign -1. The exponent of $\beta_\varepsilon^\infty(z,x)$ is $(x^* J_\varepsilon z - z^* J_\varepsilon x)/2$, which is purely imaginary, so $|\beta_\varepsilon^\infty| = 1$, and $e^\infty > 0$. By the integral formula of (WR5) and Tonelli's theorem,

$$\|\omega_\varepsilon^\infty(u)c\| \le |\det u_-| \iint |c(z)|\,e^\infty(x - uz)\,d\nu_\iota(z)\,d\nu_\iota(x) = |\det u_-| \int e^\infty\,d\nu_\iota\;\|c\|,$$

using the translation invariance of ν_ι. Here $\int e^\infty d\nu_\iota = \prod_{i\in\iota} \pi^{-1} \int_{\mathbb{C}} e^{-|w|^2/2}\,dw = 2^{\#\iota}$, and $|\det w_-| \le \|w_-\|^m \le \|w\|^m$ for a matrix w whose block w_- on the indices of sign -1 has size m, w_- being a compression of w. For $u = u(x,y)$ the matrix is block diagonal for $\iota = \bigsqcup_v \iota_v$, $\iota_v = \{v\} \times n' \times n$, with blocks $u_v = y_v \otimes (x_v^{-1})^{\mathsf{T}}$, so u_- is the direct sum of the $(u_v)_-$ and $|\det u_-| = \prod_v |\det(u_v)_-| \le \prod_v \|u_v\|^{\#n\cdot\#n'}$, using $\|u_v\| \ge 1$ (u_v is unitary for the signs ε on ι_v). The operator norm of a Kronecker product is the product of the operator norms, so $\|u_v\| = \|y_v\|\,\|x_v^{-1}\| = \|y_v\|\,\|x_v\|$. With $|\delta| = 1$ this gives the first inequality of (ii); the second follows since every factor $\|x_v\|\,\|y_v\|$ is at least 1 and $\#\iota = \#\Phi \cdot \#n \cdot \#n'$. □

Lemma 6.4.23. *Let n, n' be finite index sets with signs s on n and t on n', $\gamma,\gamma'\colon \Phi\to\mathbb{Z}$, $\iota=\Phi\times n'\times n$ with $\varepsilon(v,a,c)=t(a)s(c)$, $\Omega=\Omega_{\gamma,\gamma'}$ on $\mathcal{F}_\varepsilon$, and for $v\in\Phi$ let $\iota_v=n'\times n$ with $\varepsilon_v(a,c)=t(a)s(c)$, $\mathcal{F}_v=\mathcal{F}_{\varepsilon_v}$,*

$$\pi_v(g)=\det(g)^{-\gamma'(v)}\,\omega^\infty_{\varepsilon_v}(1_{n'}\otimes(g^{-1})^{\mathsf T})\quad(g\in\mathrm U(\operatorname{diag}s)),$$
$$\pi'_v(h)=\det(h)^{\gamma(v)}\,\omega^\infty_{\varepsilon_v}(h\otimes 1_n)\quad(h\in\mathrm U(\operatorname{diag}t)).$$

For a family $w=(w_v)_{v\in\Phi}$ with $w_v\in\mathcal{F}_v$ let $\otimes w$ be the function $z\mapsto\prod_v w_v(z_v)$ on $\mathbb{C}^\iota$, where $z_v=(z_{v,a,c})_{(a,c)\in\iota_v}$. Then:

(a) $\otimes w\in\mathcal{F}_\varepsilon$, $\|\otimes w\|=\prod_v\|w_v\|$ and $\langle\otimes w,\otimes w'\rangle=\prod_v\langle w_v,w'_v\rangle$; for polynomials P_v in the variables $X_{a,c}$, $\otimes(v_{P_v})_v=v_P$ with $P=\prod_v P_v(X_{v,\cdot,\cdot})$;

(b) $\Omega(x,y)(\otimes w)=\otimes\big(\pi_v(x_v)\pi'_v(y_v)w_v\big)_v$ for $x\in G_\infty(s)$, $y\in G_\infty(t)$;

(c) for every v, π_v and π'_v are commuting representations of $\mathrm U(\operatorname{diag}s)$ and $\mathrm U(\operatorname{diag}t)$ by bounded operators of $\mathcal{F}_v$ that preserve its inner product, are strongly continuous and satisfy $\|\pi_v(g)\|\le 2^{\#\iota}\|g\|^{\#n\cdot\#n'}$, $\|\pi'_v(h)\|\le 2^{\#\iota}\|h\|^{\#n\cdot\#n'}$; and for X, Y with $X^*\operatorname{diag}(s)+\operatorname{diag}(s)X=0$, $Y^*\operatorname{diag}(t)+\operatorname{diag}(t)Y=0$ and every polynomial P in the variables $X_{a,c}$, the maps $\tau\mapsto\pi_v(\exp\tau X)v_P$ and $\tau\mapsto\pi'_v(\exp\tau Y)v_P$ are differentiable at 0 in $\mathcal{F}_v$ with derivatives v_Q and $v_{Q'}$, $Q=\sum_{c,c'}X_{cc'}E^{\mathrm{col}}_{cc'}P$, $Q'=\sum_{a,a'}Y_{aa'}E^{\mathrm{row}}_{aa'}P$, the units being those of the signs (s,t) with the shifts $(\gamma(v),-\gamma'(v))$;

(d) if for every v a measurable k_v on $\mathrm U(\operatorname{diag}s)$ makes $g\mapsto k_v(g)\pi_v(g)w_v$ Bochner integrable, then $x\mapsto\prod_v k_v(x_v)\,\Omega(x,1)(\otimes w)$ is Bochner integrable on $G_\infty(s)$ and

$$\int_{G_\infty(s)}\prod_v k_v(x_v)\,\Omega(x,1)(\otimes w)\,dx=\otimes\Big(\int k_v(g)\pi_v(g)w_v\,dg\Big)_v;$$

the same holds for $G_\infty(t)$, π'_v and $\Omega(1,y)$.

Proof. **Factorisation of the ingredients.** Under $\mathbb{C}^\iota=\prod_v\mathbb{C}^{\iota_v}$, $\nu_\iota=\bigotimes_v\nu_{\iota_v}$, and, the exponents being sums over the coordinates, $\beta^\infty_\varepsilon(y,z)=\prod_v\beta^\infty_{\varepsilon_v}(y_v,z_v)$ and $e^\infty(z)=\prod_v e^\infty(z_v)$; also $|\beta^\infty|=1$.

(a). By Tonelli, $\int|\otimes w|\,d\nu_\iota=\prod_v\|w_v\|<\infty$. The reproducing identity of (WR5) for $\otimes w$ at z is the product over v of those of the w_v at z_v, by Fubini (the integrand is integrable, being bounded in modulus by $\prod_v|w_v(y_v)|$). So $\otimes w\in\mathcal{F}_\varepsilon$ with the stated norm; the inner product factors by Fubini in the same way. For polynomials, $v_P(z)=P(\zeta(z))e^\infty(z)=\prod_v P_v(\zeta(z_v))e^\infty(z_v)$, ζ being taken coordinatewise.

(b). By (WR5), $\Omega(x,y)=\delta\,\omega^\infty_\varepsilon(u)$ with $\delta=\prod_v\det(y_v)^{\gamma(v)}\det(x_v)^{-\gamma'(v)}$ and $u=\bigoplus_v u_v$, $u_v=y_v\otimes(x_v^{-1})^{\mathsf T}$, block diagonal for $\iota=\bigsqcup_v\iota_v$; so its block on the indices of sign -1 is the direct sum of those of the u_v, and $\overline{\det u_-}=\prod_v\overline{\det(u_v)_-}$. In the integral formula of (WR5) for $\omega^\infty_\varepsilon(u)(\otimes w)(z)$ the integrand is $\prod_v w_v(y_v)\beta^\infty_{\varepsilon_v}(u_vy_v,z_v)e^\infty(z_v-u_vy_v)$, integrable by Tonelli, so by Fubini $\omega^\infty_\varepsilon(u)(\otimes w)=\otimes(\omega^\infty_{\varepsilon_v}(u_v)w_v)_v$. By (2) of Lemma 4.1.1, $\omega^\infty_{\varepsilon_v}$ is a representation, so $\omega^\infty_{\varepsilon_v}(u_v)=\omega^\infty_{\varepsilon_v}(y_v\otimes 1)\,\omega^\infty_{\varepsilon_v}(1\otimes(x_v^{-1})^{\mathsf T})$; distributing δ over the places gives (b).

(c). Fix v. For $u\ne v$ let $e_u=e^\infty\in\mathcal{F}_u$ (the real vacuum v_1; $\|e_u\|=2^{\#\iota_u}>0$, $\langle e_u,e_u\rangle>0$), and let $j\colon\mathcal{F}_v\to\mathcal{F}_\varepsilon$ send w_0 to $\otimes w$ with $w_v=w_0$, $w_u=e_u$. By (a), j is linear, $\|j(w_0)\|=C\|w_0\|$ and $\langle j(w_0),j(w'_0)\rangle=C'\langle w_0,w'_0\rangle$ with constants $C,C'>0$, and $j(v_P)=v_{P(X_{v,\cdot,\cdot})}$. For $g\in\mathrm U(\operatorname{diag}s)$ let $\hat g\in G_\infty(s)$ have component g at v and 1 elsewhere, and similarly $\hat h$; as $\pi_u(1)=\pi'_u(1)=1$, (b) gives $j(\pi_v(g)w_0)=\Omega(\hat g,1)j(w_0)$ and $j(\pi'_v(h)w_0)=\Omega(1,\hat h)j(w_0)$. Since

j is injective and the properties of Lemma 6.4.22 (i) hold for Ω, π_v and π'_v are commuting representations preserving the inner product, and they are strongly continuous since $\|\pi_v(g)w_0 - \pi_v(g_0)w_0\| = C^{-1}\|\Omega(\hat{g},1)j(w_0) - \Omega(\hat{g}_0,1)j(w_0)\|$. By the first inequality of (ii) of Lemma 6.4.22, in which the factors at the places $u \neq v$ are $\|1\| = 1$, $\|\pi_v(g)w_0\| = C^{-1}\|\Omega(\hat{g},1)j(w_0)\| \leq 2^{\#\iota}\|g\|^{\#n\cdot\#n'}\|w_0\|$, and likewise for π'_v. For the derivatives let $\hat{X}$ have component X at v and 0 elsewhere; then $\exp\tau\hat{X} = \widehat{\exp\tau X}$, and by Lemma 6.4.24 the curve $\Omega(\exp\tau\hat{X},1)j(v_P) = j(\pi_v(\exp\tau X)v_P)$ is differentiable at 0 with derivative $v_{\rho_{\mathrm{col}}(\hat{X})P(X_{v,\cdot,\cdot})} = j(v_Q)$, the units at the place v acting on the variables at v only. As $\|j(w_0)\| = C\|w_0\|$, the difference quotients of $\tau \mapsto \pi_v(\exp\tau X)v_P$ converge to v_Q. The same argument with $\hat{Y}$ and the row units gives $v_{Q'}$.

(d). Put $f_v(g) = k_v(g)\pi_v(g)w_v$, Bochner integrable on $\mathrm{U}(\mathrm{diag}\, s)$. By (b),

$$\prod_v k_v(x_v)\Omega(x,1)(\otimes w) = \otimes(f_v(x_v))_v.$$

The map $(w_v)_v \mapsto \otimes w$ is multilinear with $\|\otimes w\| = \prod_v \|w_v\|$ by (a), hence a bounded multilinear map; so $x \mapsto \otimes(f_v(x_v))$ is strongly measurable and $\|\otimes(f_v(x_v))\| = \prod_v \|f_v(x_v)\|$ is integrable for the product measure by Tonelli. A bounded linear map commutes with Bochner integrals; applying this to $\otimes$ in one variable at a time, the others fixed, and using Fubini's theorem for Bochner integrals on the product of the groups (induction on $\#\Phi$), $\int \otimes(f_v(x_v))\,dx = \otimes(\int f_v)_v$. The second group is treated in the same way with π'_v. □

Lemma 6.4.24. *Let n, n' be finite index sets with signs s on n and t on n', $\gamma,\gamma' \colon \Phi \to \mathbb{Z}$, $\iota = \Phi \times n' \times n$ with $\varepsilon(v,a,c) = t(a)s(c)$, and $\Omega = \Omega_{\gamma,\gamma'}$ on $\mathcal{F}_\varepsilon$. For $v \in \Phi$ let $E^{\mathrm{row}}_{v,aa'}$ and $E^{\mathrm{col}}_{v,cc'}$ be the row and column units of the signs (s,t) with the shifts $(\gamma(v), -\gamma'(v))$, acting on the variables $X_{v,a,c}$ of $\mathbb{C}[X_\iota]$. Let $X = (X_v)_{v\in\Phi}$ and $Y = (Y_v)_{v\in\Phi}$ be families of matrices with $X_v^*\mathrm{diag}(s) + \mathrm{diag}(s)X_v = 0$ and $Y_v^*\mathrm{diag}(t) + \mathrm{diag}(t)Y_v = 0$. Then for every polynomial $P \in \mathbb{C}[X_\iota]$ the maps $\tau \mapsto \Omega(\exp\tau X,1)v_P$ and $\tau \mapsto \Omega(1,\exp\tau Y)v_P$ from $\mathbb{R}$ to $\mathcal{F}_\varepsilon$ are differentiable at $\tau = 0$, with derivatives*

$$v_{\rho_{\mathrm{col}}(X)P}, \quad \rho_{\mathrm{col}}(X) = \sum_{v\in\Phi}\sum_{c,c'\in n}(X_v)_{cc'}E^{\mathrm{col}}_{v,cc'}, \qquad v_{\rho_{\mathrm{row}}(Y)P}, \quad \rho_{\mathrm{row}}(Y) = \sum_{v\in\Phi}\sum_{a,a'\in n'}(Y_v)_{aa'}E^{\mathrm{row}}_{v,aa'}.$$

Proof. By (WR5), $\Omega(x,y) = \prod_v \det(y_v)^{\gamma(v)}\det(x_v)^{-\gamma'(v)}\,\omega_\varepsilon^\infty(\bigoplus_v y_v \otimes (x_v^{-1})^{\mathsf{T}})$, the matrix $y_v \otimes (x_v^{-1})^{\mathsf{T}}$ acting on $n' \times n$ matrices by $Z \mapsto y_v Z x_v^{-1}$, so $(y_v \otimes (x_v^{-1})^{\mathsf{T}})_{(a,c),(a',c')} = (y_v)_{aa'}(x_v^{-1})_{c'c}$.

The first group. Put $Z_X = \bigoplus_v 1_{n'} \otimes (-X_v^{\mathsf{T}})$, with entries $(Z_X)_{(v,a,c),(v',a',c')} = -\delta_{vv'}\delta_{aa'}(X_v)_{c'c}$. Then

$$\exp(\tau Z_X) = \bigoplus_v 1 \otimes (\exp(\tau X_v)^{-1})^{\mathsf{T}},$$

which lies in $\mathrm{U}(\mathrm{diag}\,\varepsilon)$ for every τ by (VP5) of Definition 3.2.2, as $\exp(\tau X_v) \in \mathrm{U}(\mathrm{diag}\, s)$; differentiating $\exp(\tau Z_X)^*\mathrm{diag}(\varepsilon)\exp(\tau Z_X) = \mathrm{diag}(\varepsilon)$ at $\tau = 0$ gives $Z_X^*\mathrm{diag}(\varepsilon) + \mathrm{diag}(\varepsilon)Z_X = 0$. As $\det\exp(\tau X_v) = e^{\tau\,\mathrm{tr}\,X_v}$,

$$\Omega(\exp\tau X,1) = e^{-\tau\sum_v \gamma'(v)\,\mathrm{tr}\,X_v}\,\omega_\varepsilon^\infty(\exp\tau Z_X).$$

By Lemma 6.4.25 and the product rule (a smooth scalar factor equal to 1 at 0 times a curve differentiable at 0), the derivative at 0 is v_{P_1} with

$$\begin{aligned} P_1 &= \sum_{i,j\in\iota}(Z_X)_{ij}\mathrm{ra}_i\mathrm{lo}_j P - \sum_v \gamma'(v)\,\mathrm{tr}(X_v)P \\ &= -\sum_v\sum_{c,c'}(X_v)_{cc'}\sum_{a\in n'}\mathrm{ra}_{v,a,c'}\mathrm{lo}_{v,a,c}P - \sum_v\gamma'(v)\,\mathrm{tr}(X_v)P, \end{aligned}$$

after exchanging the names c, c'. For one variable, $\mathrm{lo}\,\mathrm{ra} - \mathrm{ra}\,\mathrm{lo} = 1$ ($[\partial, X] = 1$ for sign 1, $[X, -\partial] = 1$ for sign -1), and operators in different variables commute, so $\mathrm{lo}_{v,a,c}\mathrm{ra}_{v,a,c'} = \mathrm{ra}_{v,a,c'}\mathrm{lo}_{v,a,c} + \delta_{cc'}$. By (HV5) with the shifts $(\gamma(v), -\gamma'(v))$,

$$E^{\mathrm{col}}_{v,cc'} = -\sum_{a\in n'} \mathrm{lo}_{v,a,c}\mathrm{ra}_{v,a,c'} + (-\gamma'(v) + \#n')\delta_{cc'} = -\sum_{a\in n'} \mathrm{ra}_{v,a,c'}\mathrm{lo}_{v,a,c} - \gamma'(v)\delta_{cc'}.$$

Multiplying by $(X_v)_{cc'}$ and summing gives $P_1 = \rho_{\mathrm{col}}(X)P$.

The second group. Put $Z_Y = \bigoplus_v Y_v \otimes 1_n$, with entries $(Z_Y)_{(v,a,c),(v',a',c')} = \delta_{vv'}(Y_v)_{aa'}\delta_{cc'}$. As above $\exp(\tau Z_Y) = \bigoplus_v \exp(\tau Y_v) \otimes 1 \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$, Z_Y satisfies $Z_Y^*\mathrm{diag}(\varepsilon) + \mathrm{diag}(\varepsilon)Z_Y = 0$, and $\Omega(1, \exp\tau Y) = e^{\tau\sum_v \gamma(v)\,\mathrm{tr}\,Y_v}\omega_\varepsilon^\infty(\exp\tau Z_Y)$. By Lemma 6.4.25 and the product rule the derivative at 0 is v_{P_2} with

$$P_2 = \sum_v \sum_{a,a'} (Y_v)_{aa'} \sum_{c\in n} \mathrm{ra}_{v,a,c}\mathrm{lo}_{v,a',c}P + \sum_v \gamma(v)\,\mathrm{tr}(Y_v)P = \sum_v \sum_{a,a'} (Y_v)_{aa'} E^{\mathrm{row}}_{v,aa'}P = \rho_{\mathrm{row}}(Y)P,$$

since by (HV5) $E^{\mathrm{row}}_{v,aa'} = \sum_c \mathrm{ra}_{v,a,c}\mathrm{lo}_{v,a',c} + \gamma(v)\delta_{aa'}$. □

Lemma 6.4.25. *Let ι be a finite index set with signs ε, and for $i \in \iota$ let A_i be the multiplication by X_i if $\varepsilon_i = 1$ and $-\partial/\partial X_i$ if $\varepsilon_i = -1$, and B_i be $\partial/\partial X_i$ if $\varepsilon_i = 1$ and the multiplication by X_i if $\varepsilon_i = -1$, operators on $\mathbb{C}[X_i : i \in \iota]$. Let $Y \in \mathrm{M}_\iota(\mathbb{C})$ satisfy $Y^*\mathrm{diag}(\varepsilon) + \mathrm{diag}(\varepsilon)Y = 0$. Then for every polynomial $P \in \mathbb{C}[X_i : i \in \iota]$ the map $t \mapsto \omega_\varepsilon^\infty(\exp(tY))\,v_P$ from $\mathbb{R}$ to $\mathcal{F}_\varepsilon$ is differentiable at $t = 0$ for the norm of $\mathcal{F}_\varepsilon$, with derivative $v_{P'}$, where*

$$P' = \sum_{i,j\in\iota} Y_{ij}\, A_iB_jP.$$

Proof. Put $J = \mathrm{diag}(\varepsilon)$ and $N = \#\iota$. If $N = 0$, the group and its Lie algebra are trivial, and both derivatives in the assertion are zero. Suppose $N > 0$. Write $u(t) = \exp(tY)$ and $\delta(t) = \overline{\det u(t)_-}$. Differentiation of $u(t)^*Ju(t)$ shows that $u(t) \in \mathrm{U}(J)$. In the following integrals the measure in each complex vector variable is $\nu_\iota = \pi^{-N}\,d\mathrm{Leb}$.

We first differentiate in the stated L^1 norm. By (WR5), the representative of $\omega_\varepsilon^\infty(u(t))v_P$ is the integral, in y, of

$$K_t(x,y) = \delta(t)P(\zeta(y))\exp\left(-\frac{|y|^2 + |x - u(t)y|^2}{2} + \frac{x^*Ju(t)y - (u(t)y)^*Jx}{2}\right).$$

This expression is continuously differentiable in the real variable t. Choose a closed interval about zero on which $\|u(t)\| \le 2$. On this interval u', δ and δ' are bounded. The last term in the exponent is purely imaginary. Moreover

$$|x|^2 + |y|^2 \le 9(|y|^2 + |x - u(t)y|^2),$$

since $|x|^2 \le 2|x-u(t)y|^2+8|y|^2$. If D is the degree of P (take $D = 0$ when $P = 0$), differentiation of the exponent and the polynomial growth bound for P therefore give a constant C such that

$$|\partial_t K_t(x,y)| \le C(1 + |x| + |y|)^{D+2}\exp(-(|x|^2 + |y|^2)/18). \tag{1}$$

Indeed the differentiated exponent has absolute value at most a constant times $|x||y| + |y|^2$. The right side of (1) is integrable on the product of the two complex vector spaces. The fundamental

theorem of calculus bounds every sufficiently small nonzero difference quotient $(K_t - K_0)/t$ by (1). Pointwise convergence and dominated convergence on the product space consequently imply

$$\left\| \frac{\int K_t(\,\cdot\,,y)\,d\nu_\iota(y) - \int K_0(\,\cdot\,,y)\,d\nu_\iota(y)}{t} - \int \partial_t K_0(\,\cdot\,,y)\,d\nu_\iota(y) \right\|_{L^1} \longrightarrow 0. \tag{2}$$

Here the norm is bounded by the product integral of the absolute difference of the integrands, which tends to zero by the same domination. Thus (2) proves norm differentiability, rather than merely differentiability of matrix coefficients.

We evaluate its derivative. Put $z = \zeta(x)$ and $\eta_i(y) = \overline{\zeta_i(y)}$. For a polynomial Q define

$$\mathcal{I}_z(Q) = \int Q(\zeta(y)) \exp\left(-|y|^2 + \sum_i z_i \eta_i(y) \right) d\nu_\iota(y).$$

The elementary complex Gaussian moments give

$$\mathcal{I}_z(Q) = Q(z), \qquad \int \eta_i(y) Q(\zeta(y)) e^{-|y|^2 + z\cdot\eta(y)} d\nu_\iota(y) = \partial_i Q(z), \tag{3}$$

and insertion of $\eta_i \eta_j$ gives $\partial_i \partial_j Q(z)$. To check normalization, in one variable

$$\pi^{-1} \int_{\mathbb{C}} \bar{w}^a w^b e^{-|w|^2}\, d\mathrm{Leb}(w) = \mathbf{1}_{a=b} a!$$

by polar coordinates. Expanding the exponential proves the first identity in (3), coordinate by coordinate; conjugating a coordinate preserves Lebesgue measure and covers both signs. Differentiating in z proves the other identities. These operations are justified uniformly on compact sets of z by a polynomial times $e^{-|y|^2 + M|y|}$, which is integrable.

At $t = 0$ the kernel is

$$K_0(x,y) = e^{-|x|^2/2} P(\zeta(y)) e^{-|y|^2 + z\cdot\eta(y)}.$$

In particular its integral is $v_P(x)$. The derivative of the scalar is

$$\delta'(0) = \overline{\mathrm{tr}(Y_{--})} = -\mathrm{tr}(Y_{--}), \tag{4}$$

because $Y^* J + JY = 0$ makes every diagonal entry of Y purely imaginary. The derivative of the remaining exponent at zero is

$$\begin{aligned} T(x,y) &= x^* \frac{1+J}{2} Y y + y^* J Y \frac{1-J}{2} x - \tfrac{1}{2} y^* (Y + Y^*) y \\ &= \sum_{i,j} Y_{ij} \left(\mathbf{1}_{\varepsilon_i = 1} \bar{x}_i y_j + \varepsilon_i \mathbf{1}_{\varepsilon_j = -1} \bar{y}_i x_j - \mathbf{1}_{\varepsilon_i \neq \varepsilon_j} \bar{y}_i y_j \right). \end{aligned} \tag{5}$$

For the first equality differentiate the Gaussian and phase in K_t and use $Y^* = -JYJ$; that identity also gives the second equality.

Apply (3) to each coefficient of Y_{ij} in (5), with the factor $P(\zeta(y))$. For $(\varepsilon_i, \varepsilon_j) = (+,+)$ its integral is $z_i \partial_j P(z)$. For $(+,-)$ its three terms give respectively $z_i z_j P(z)$, $z_i z_j P(z)$ and $-z_i z_j P(z)$, whose sum is $z_i z_j P(z)$. For $(-,+)$ it is $-\partial_i \partial_j P(z)$. For $(-,-)$ it is $-z_j \partial_i P(z)$. Adding (4), the polynomial multiplying $e^{-|x|^2/2}$ in the derivative is therefore

$$\sum_{++} Y_{ij} X_i \partial_j P + \sum_{+-} Y_{ij} X_i X_j P - \sum_{-+} Y_{ij} \partial_i \partial_j P - \sum_{--} Y_{ij} (X_j \partial_i P + \mathbf{1}_{i=j} P).$$

Here each sum ranges over the indicated signs of (i,j). This is exactly $\sum_{i,j} Y_{ij} A_i B_j P$, since in the last case $A_i B_j P = -\partial_i (X_j P)$. In particular the negative-block vacuum scalar has not been discarded. The derivative in (2) is thus $v_{P'}$. This is a Fock vector, and the Fock norm is the inherited L^1 norm, so (2) is precisely the differentiability asserted. □

Scope. This convention is in force in, and only in, the rigidity statements of the local theta correspondence at one real place that are placed under it; the text opening their part of the argument names them. Within those results the letters below have the meaning fixed here and no other; in particular G, K, X, M, A, B, π, ρ and ι are local to this context and do not denote the global objects written with the same letters elsewhere. Every further hypothesis (the parameter l and its gap, highest vectors and weights, Casimir eigenvalues, Haar measures) is stated in each result.

The rigidity context consists of the following data.

- **The group.** A nonempty finite index set n (an integer $n \geq 1$ is read as $\{1, \dots, n\}$), $N = \#n$, signs $\varepsilon \in \{\pm 1\}^n$, $J = \mathrm{diag}(\varepsilon)$, the group $G = \mathrm{U}(J) = \{g \in \mathrm{GL}_n(\mathbb{C}) : g^* J g = J\}$, its **block compact subgroup** $K = G \cap \mathrm{U}(N)$ (the elements of G preserving the blocks of indices of sign $+1$ and of sign -1), and its real Lie algebra $\mathfrak{u}(J) = \{Z \in \mathrm{M}_n(\mathbb{C}) : Z^* J + J Z = 0\}$. For $g \in G$, $\|g\|$ is the operator norm of g on $\mathbb{C}^n$ with the euclidean norm.
- **The representation.** A complex Banach space X, a real number $A \geq 0$, a constant $C_\pi \in (0, \infty)$, and a homomorphism $\pi \colon G \to \mathcal{L}(X)$ into the bounded complex-linear operators which is strongly continuous ($g \mapsto \pi(g)x$ is continuous for every $x \in X$) and satisfies
$$\|\pi(g)\| \leq C_\pi \|g\|^A \qquad (g \in G).$$
- **The invariant form.** A continuous Hermitian form B on X, conjugate-linear in its first and linear in its second argument, positive definite ($B(x,x) > 0$ for $x \neq 0$), with $B(\pi(g)x, \pi(g)x') = B(x,x')$ for all $g \in G$ and $x, x' \in X$.
- **The compatible module.** A complex vector space M with a Lie algebra representation $\rho \colon \mathfrak{gl}_n(\mathbb{C}) \to \mathrm{End}_{\mathbb{C}}(M)$, and a complex-linear map $\iota \colon M \to X$ such that for every $Z \in \mathfrak{u}(J)$ and $w \in M$
$$\left.\frac{d}{dt}\right|_{t=0} \pi\big(\exp(tZ)\big)\iota(w) = \iota\big(\rho(Z)w\big),$$
the derivative taken in the norm of X.

Proposition 6.4.26. *Let I, I' be nonempty finite sets with signs s on I and t on I', $N = \#I$, $N' = \#I'$, let $\gamma, \gamma' \in \mathbb{Z}$, $\lambda \colon I \to \mathbb{Z}$, $\lambda' \colon I' \to \mathbb{Z}$, and let H be a joint harmonic for the signs (s,t), the weights (γ, γ') and the parameters (λ, λ'). Let $\varepsilon(a,c) = t(a)s(c)$ on $I' \times I$, $\mathcal{F} = \mathcal{F}_\varepsilon$, and*

$$\pi(x) = \det(x)^{-\gamma'} \omega_\varepsilon^\infty\big(1 \otimes (x^{-1})^{\mathsf{T}}\big) \ \ (x \in \mathrm{U}(\mathrm{diag}\, s)), \qquad \pi'(y) = \det(y)^{\gamma} \omega_\varepsilon^\infty(y \otimes 1) \ \ (y \in \mathrm{U}(\mathrm{diag}\, t)).$$

With the Cayley measures dx, dy of the two groups, let $e(x) = d\,\overline{c_{-\lambda/2}(x)}$ with $d^{-1} = \int |c_{-\lambda/2}|^2 dx$, and $e'(y) = d'\,\overline{c_{\lambda'/2}(y)}$ with $d'^{-1} = \int |c_{\lambda'/2}|^2 dy$. Then:

(o) $\int |e(x)|\,\|x\|^{NN'} dx < \infty$ and $\int |e'(y)|\,\|y\|^{NN'} dy < \infty$; for every $u \in \mathcal{F}$ the functions $x \mapsto e(x)\pi(x)u$ and $y \mapsto e'(y)\pi'(y)u$ are Bochner integrable in $\mathcal{F}$, and $pu = \int e(x)\pi(x)u\,dx$, $p'u = \int e'(y)\pi'(y)u\,dy$ define bounded operators;

(a) $\langle v_H, p v_H \rangle$ and $\langle v_H, p' v_H \rangle$ are positive real numbers;

(b) $p' p v_H = p v_H$ and $p p' v_H = p' v_H$;

(c) for every polynomial Q in the variables X_{ac} ($a \in I'$, $c \in I$) there are smooth compactly supported functions α on $\mathrm{U}(\mathrm{diag}\, t)$ and β on $\mathrm{U}(\mathrm{diag}\, s)$ with

$$p v_Q = \int \alpha(y)\,\pi'(y)\,p v_H\,dy, \qquad p' v_Q = \int \beta(x)\,\pi(x)\,p' v_H\,dx.$$

Proof. **Step 0: the Fock space.** For $c \in \mathcal{F}$, the reproducing identity of (WR5) with $|\beta^\infty_\varepsilon| = 1$ and $0 < e^\infty \le 1$ gives $|c(x)| \le \|c\|$ for every x. Hence $|\langle c, c'\rangle| \le \int |c||c'|\,d\nu \le \|c\|\,\|c'\|$, so $\langle\,,\rangle$ is a continuous hermitian form, positive definite because $\langle c, c\rangle = 0$ forces $c = 0$ almost everywhere and then everywhere by the reproducing identity. $\mathcal{F}$ is complete: if $c_k \to c$ in $L^1(\nu)$ with $c_k \in \mathcal{F}$, then $\tilde c(x) = \int c(y)\beta^\infty_\varepsilon(y,x)e^\infty(x-y)\,d\nu(y)$ is the pointwise limit of the $c_k(x)$ (the kernel is bounded by 1), so $\tilde c = c$ almost everywhere, $\tilde c$ satisfies the reproducing identity, and $c_k \to \tilde c \in \mathcal{F}$.

Step 1: the two oscillator representations. Apply Lemma 6.4.23 with the constant weights γ, γ' on Φ, $n = I$, $n' = I'$, and any $v \in \Phi$: its π_v, π'_v, $\mathcal{F}_v$ are π, π', $\mathcal{F}$. By its (c), π and π' are commuting strongly continuous representations by bounded operators preserving $\langle\,,\rangle$, $\|\pi(x)\| \le C\|x\|^A$, $\|\pi'(y)\| \le C\|y\|^A$ with $C = 2^{\#\Phi\cdot A}$, and for $X \in \mathfrak{u}(\operatorname{diag} s)$, $Y \in \mathfrak{u}(\operatorname{diag} t)$ and every polynomial P, $\frac{d}{d\tau}\big|_0 \pi(e^{\tau X})v_P = v_{\rho_{\mathrm{col}}(X)P}$ and $\frac{d}{d\tau}\big|_0 \pi'(e^{\tau Y})v_P = v_{\rho_{\mathrm{row}}(Y)P}$. The maps ρ_{row}, ρ_{col} are representations of the Lie algebras $\mathfrak{gl}(I')$, $\mathfrak{gl}(I)$: with the identity $[AB, CD] = A[B,C]D + C[A,D]B$ (valid when $[A,C] = [B,D] = 0$) and the canonical commutation relations $[\mathrm{lo}_{ac}, \mathrm{ra}_{a'c'}] = \delta_{aa'}\delta_{cc'}$, raising operators commuting among themselves and lowering operators too,

$$[E^{\mathrm{row}}_{ab}, E^{\mathrm{row}}_{cd}] = \sum_{x,y}[\mathrm{ra}_{ax}\mathrm{lo}_{bx}, \mathrm{ra}_{cy}\mathrm{lo}_{dy}] = \delta_{bc}\sum_x \mathrm{ra}_{ax}\mathrm{lo}_{dx} - \delta_{ad}\sum_x \mathrm{ra}_{cx}\mathrm{lo}_{bx} = \delta_{bc}E^{\mathrm{row}}_{ad} - \delta_{ad}E^{\mathrm{row}}_{cb}$$

(the shift terms cancel), so $[\rho_{\mathrm{row}}(Z), \rho_{\mathrm{row}}(W)] = \rho_{\mathrm{row}}(ZW - WZ)$; for the columns, (a) of Lemma 6.4.27 writes $E^{\mathrm{col}}_{cd} = -\check E^{\mathrm{row}}_{dc}$ with row units $\check E^{\mathrm{row}}$ of the transposed setting, which satisfy the same relations, and $[E^{\mathrm{col}}_{ab}, E^{\mathrm{col}}_{cd}] = [\check E^{\mathrm{row}}_{ba}, \check E^{\mathrm{row}}_{dc}] = \delta_{bc}E^{\mathrm{col}}_{ad} - \delta_{ad}E^{\mathrm{col}}_{cb}$.

Step 2: the data of the one-group lemmas. For the column group $\mathrm{U}(\operatorname{diag} s)$ take $X = \mathcal{F}$, $B = \langle\,,\rangle$ (Step 0), π, the Haar measure dx (Lemma 5.2.41), $M = \mathbb{C}[X]$, $\rho = \rho_{\mathrm{col}}$, the map ι, the growth exponent A (Step 1) and the parameter $l = -\lambda$. By (a) of (WM8) for the block rule ((a) of (HV7)), λ has gap $500(N+N')^3 \ge 500N^3 + NN'$, hence $-\lambda$ has large gap A for s; the kernel $d_{l/2}\overline{c_{l/2}}$ of the lemmas is e; by (b) of (HV7), H is K-highest of weight $\mu_{-\lambda}$ for the order $-\lambda$ for ρ_{col}. For the row group $\mathrm{U}(\operatorname{diag} t)$ take π', dy, $\rho = \rho_{\mathrm{row}}$, ι and $l = \lambda'$, which has gap $500(N+N')^3 \ge 500N'^3 + NN'$, hence large gap A for t; the kernel is e', and H is K-highest of weight $\mu_{\lambda'}$ for λ' for ρ_{row}. We use Lemma 6.4.28, Lemma 6.4.30, Lemma 6.4.33, Lemma 6.4.34 and Theorem 6.4.36 for these data, possibly with ι replaced by $p\circ\iota$ or $p'\circ\iota$. By (i) of Lemma 6.4.28, p commutes with every $\pi'(y)$ and p' with every $\pi(x)$ (Step 1); so for $Y \in \mathfrak{u}(\operatorname{diag} t)$, $\pi'(e^{\tau Y})pv_P = p\,\pi'(e^{\tau Y})v_P$ has derivative $pv_{\rho_{\mathrm{row}}(Y)P}$ at 0, p being bounded: $p\circ\iota$ is a derived map for $(\pi', \rho_{\mathrm{row}})$, and likewise $p'\circ\iota$ for $(\pi, \rho_{\mathrm{col}})$.

(o). This is (i) of Lemma 6.4.28 for both groups.

(a). $H \ne 0$ is termwise harmonic, so by Proposition 6.4.29 $\langle v_H, \pi(z)v_H\rangle > 0$ for every positive definite $z \in \mathrm{U}(\operatorname{diag} s)$, and Lemma 6.4.30 gives $\mathrm{Re}\langle v_H, pv_H\rangle > 0$. By (i) of Lemma 6.4.28, $\langle v_H, pv_H\rangle = \langle pv_H, pv_H\rangle$ is real and ≥ 0; so it is a positive real number. The same argument applies to p'.

Step 3: Casimir values. Let $\Omega_{\mathrm{row}} = \sum_{a,a'} E^{\mathrm{row}}_{aa'}E^{\mathrm{row}}_{a'a}$, $\Omega_{\mathrm{col}} = \sum_{c,c'} E^{\mathrm{col}}_{cc'}E^{\mathrm{col}}_{c'c}$, and let c_{row}, c_{col}, b_{pair}, $\mathrm{Cas}_{\mathrm{row}}(w)$, $\mathrm{Cas}_{\mathrm{col}}(w)$, κ_l and $\kappa_l(w)$ be as in Lemma 6.4.35. Expanding, $\mathrm{Cas}_{\mathrm{row}}(w) = \Omega_{\mathrm{row}} - 2w\sum_a E^{\mathrm{row}}_{aa} + N'w^2$ and $\mathrm{Cas}_{\mathrm{col}}(w) = \Omega_{\mathrm{col}} - 2w\sum_c E^{\mathrm{col}}_{cc} + Nw^2$, and on H the diagonal units act by $\mu_{\lambda'}$, $\mu_{-\lambda}$. By Lemma 6.4.34 for the column group, $pv_{\Omega_{\mathrm{col}}P} = \kappa_{-\lambda}pv_P$ for every P, so $pv_{\mathrm{Cas}_{\mathrm{col}}(c_{\mathrm{col}})H} = \kappa_{-\lambda}(c_{\mathrm{col}})pv_H$. By (1) and (3) of Lemma 6.4.35, $pv_{\mathrm{Cas}_{\mathrm{row}}(c_{\mathrm{row}})H} = (\kappa_{-\lambda}(c_{\mathrm{col}}) - b_{\mathrm{pair}})pv_H = \kappa_{\lambda'}(c_{\mathrm{row}})pv_H$, and therefore

$$pv_{\Omega_{\mathrm{row}}H} = \Big(\kappa_{\lambda'}(c_{\mathrm{row}}) + 2c_{\mathrm{row}}\sum_a \mu_{\lambda'}(a) - N'c^2_{\mathrm{row}}\Big)pv_H = \kappa_{\lambda'}\,pv_H.$$

Symmetrically, Lemma 6.4.34 for the row group gives $p'v_{\Omega_{\mathrm{row}}P} = \kappa_{\lambda'}p'v_P$, hence $p'v_{\mathrm{Cas}_{\mathrm{row}}(c_{\mathrm{row}})H} = \kappa_{\lambda'}(c_{\mathrm{row}})p'v_H$, $p'v_{\mathrm{Cas}_{\mathrm{col}}(c_{\mathrm{col}})H} = (\kappa_{\lambda'}(c_{\mathrm{row}}) + b_{\mathrm{pair}})p'v_H = \kappa_{-\lambda}(c_{\mathrm{col}})p'v_H$, and $p'v_{\Omega_{\mathrm{col}}H} = \kappa_{-\lambda}\,p'v_H$.

Step 4: rigidity. By Steps 2 and 3, Theorem 6.4.36 applies to the row group with ι replaced by $p\circ\iota$, the vector H and $c = \kappa_{\lambda'}$: for every measurable f on $\mathrm{U}(\mathrm{diag}\,t)$ with $\int |f(y)|\|y\|^A dy < \infty$ and $\int f(y)e'(y^{-1}g)\,dy = e'(g)$ for all g,

$$\int f(y)\pi'(y)\,pv_H\,dy = pv_H;$$

and it applies to the column group with $p'\circ\iota$, H and $c = \kappa_{-\lambda}$: $\int f(x)\pi(x)\,p'v_H\,dx = p'v_H$ for every such f on $\mathrm{U}(\mathrm{diag}\,s)$ reproducing e.

(b). $f = e'$ is admissible: its moment is finite by (o), and $\int e'(y)e'(y^{-1}g)\,dy = e'(g)$ by (i) of Lemma 5.6.22 (with $x = 1$; λ' has gap $500N'^3$). So $p'pv_H = pv_H$; likewise $pp'v_H = p'v_H$ with $f = e$.

(c), first identity. Let $S(\varphi) = \int \varphi(y)\pi'(y)\,pv_H\,dy$ for smooth compactly supported φ on $\mathrm{U}(\mathrm{diag}\,t)$, and let G_1 be the set of polynomials Q with $pv_Q = S(\varphi)$ for some such φ, a linear subspace. We verify the hypotheses of (JC) of Lemma 6.4.40.

- G_1 is stable under the row units. Let $pv_Q = S(\varphi)$ and $Y \in \mathfrak{u}(\mathrm{diag}\,t)$. The curve $\pi'(e^{\tau Y})pv_Q$ has derivative $pv_{\rho_{\mathrm{row}}(Y)Q}$ at 0 (Step 2) and, being $\pi'(e^{\tau Y})S(\varphi)$, derivative $S(\varphi_Y)$ by (iii) of Lemma 6.4.28; so $pv_{\rho_{\mathrm{row}}(Y)Q} = S(\varphi_Y)$. Every $Z \in \mathrm{M}_{I'}(\mathbb{C})$ is $Y_1 + iY_2$ with $Y_1 = \frac{1}{2}(Z - JZ^*J)$ and $Y_2 = \frac{1}{2i}(Z + JZ^*J)$ in $\mathfrak{u}(J)$, $J = \mathrm{diag}\,t$; by linearity $pv_{\rho_{\mathrm{row}}(Z)Q} = S(\varphi_{Y_1} + i\varphi_{Y_2})$. Taking for Z the matrix units, $E^{\mathrm{row}}_{aa'}Q \in G_1$.

- $H \in G_1$: by (ii) of Lemma 6.4.28 there is a smooth compactly supported β' on $\mathrm{U}(\mathrm{diag}\,t)$ reproducing e', and its moment is finite; by Step 4, $S(\beta') = pv_H$.

- (JC1): let $s(c) \neq s(d)$, $-\lambda(c) < -\lambda(d)$, and P be K-highest of weight $\nu = \mu_{-\lambda} + e_c - e_d$ for $-\lambda$ for ρ_{col}. Apply Lemma 6.4.33 to the column group with $l = -\lambda$ and $o = \lambda$: $o_x < o_y$ whenever $l_x > l_y$, and $\sum_x o_x(\nu_x - \mu_l(x)) = \lambda(c) - \lambda(d) > 0$. It gives $pv_{E^{\mathrm{col}}_{dc}P} = p\,\iota(\rho_{\mathrm{col}}(E_{dc})P) = 0 = S(0)$.

- (JC2): let $s(c) = s(d)$ and $-\lambda(d) < -\lambda(c)$. By Lemma 6.4.34 for the column group ($l = -\lambda$) there is a linear map P from $\mathcal{H}_{c_{\lambda/2}}$ to bounded operators with $\mathsf{P}(c_{\lambda/2}) = p$ and $\mathsf{P}(f)v_{\rho_{\mathrm{col}}(Z)P} = -\mathsf{P}(Zf)v_P$. By (iii) of Lemma 5.6.24 for the parameter λ (which has gap 0), $E_{dc}c_{\lambda/2} = 0$, as $d \neq c$, $s(d) = s(c)$ and $\lambda(d) > \lambda(c)$. Hence $pv_{E^{\mathrm{col}}_{dc}P} = 0 = S(0)$ for every P.

- (JC3): by the same two results, $E_{cc}c_{\lambda/2} = \mu_\lambda(c)c_{\lambda/2}$ and $pv_{E^{\mathrm{col}}_{cc}P - \mu_{-\lambda}(c)P} = -(\mu_\lambda(c) + \mu_{-\lambda}(c))pv_P = 0$ by (e) of Lemma 6.4.27.

By (JC) of Lemma 6.4.40, G_1 consists of all polynomials; take $\alpha = \varphi$.

(c), second identity. Let $S'(\varphi) = \int \varphi(x)\pi(x)\,p'v_H\,dx$ for smooth compactly supported φ on $\mathrm{U}(\mathrm{diag}\,s)$ and G_2 the set of Q with $p'v_Q = S'(\varphi)$ for some φ. As above, with the groups exchanged: G_2 is stable under the column units (derivative of $\pi(e^{\tau X})p'v_Q$, Step 2, and (iii) of Lemma 6.4.28); $H \in G_2$ (a smooth bump reproducing e, (ii) of Lemma 6.4.28, and Step 4). (JR1): for $t(a) \neq t(b)$, $\lambda'(a) < \lambda'(b)$ and P K-highest of weight $\mu_{\lambda'} + e_a - e_b$ for λ' for ρ_{row}, Lemma 6.4.33 for the row group with $l = \lambda'$ and $o = -\lambda'$ ($\sum_x o_x(\nu_x - \mu_l(x)) = \lambda'(b) - \lambda'(a) > 0$) gives $p'v_{E^{\mathrm{row}}_{ba}P} = 0$. (JR2): for $t(a) = t(b)$ and $\lambda'(b) < \lambda'(a)$, Lemma 6.4.34 for the row group ($l = \lambda'$, $\mathsf{P}(c_{-\lambda'/2}) = p'$) and (iii) of Lemma 5.6.24 for $-\lambda'$ ($b \neq a$, $t(b) = t(a)$, $-\lambda'(b) > -\lambda'(a)$) give $E_{ba}c_{-\lambda'/2} = 0$ and $p'v_{E^{\mathrm{row}}_{ba}P} = 0$. (JR3): $E_{aa}c_{-\lambda'/2} = \mu_{-\lambda'}(a)c_{-\lambda'/2}$, so $p'v_{E^{\mathrm{row}}_{aa}P - \mu_{\lambda'}(a)P} =$

$-(\mu_{-\lambda'}(a)+\mu_{\lambda'}(a))p'v_P=0$ by (e) of Lemma 6.4.27. By (JR) of Lemma 6.4.40, G_2 consists of all polynomials; take $\beta=\varphi$. □

Lemma 6.4.27. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma,\gamma'\in\mathbb{Z}$, and identify the polynomial rings $\mathbb{C}[X_{ac}: a\in I',\, c\in I]$ and $\mathbb{C}[Y_{ca}: c\in I,\, a\in I']$ by $Y_{ca}=X_{ac}$. Let $E^{\mathrm{row}}_{aa'}$, $E^{\mathrm{col}}_{cc'}$ be the row and column units of the signs (s,t) with the shifts $(\gamma,-\gamma')$ and $\Delta^{\mathrm{row}}_{aa'}$, $\Delta^{\mathrm{col}}_{cc'}$ the row and column Laplacians of (s,t) (rows I', columns I, variables X_{ac}); let $\check{E}^{\mathrm{row}}_{cc'}$, $\check{E}^{\mathrm{col}}_{aa'}$ be the row and column units of the signs (t,s) with the shifts $(\gamma',-\gamma)$ and $\check{\Delta}^{\mathrm{row}}_{cc'}$, $\check{\Delta}^{\mathrm{col}}_{aa'}$ the row and column Laplacians of (t,s) (rows I, columns I', variables Y_{ca}). Then:*

(a) $\check{E}^{\mathrm{row}}_{cc'}=-E^{\mathrm{col}}_{c'c}$ for all $c,c'\in I$, and $\check{E}^{\mathrm{col}}_{aa'}=-E^{\mathrm{row}}_{a'a}$ for all $a,a'\in I'$;

(b) $\check{\Delta}^{\mathrm{row}}_{cc'}=\Delta^{\mathrm{col}}_{c'c}$ whenever $s(c)\neq s(c')$, and $\check{\Delta}^{\mathrm{col}}_{aa'}=\Delta^{\mathrm{row}}_{a'a}$ whenever $t(a)\neq t(a')$; a polynomial is termwise harmonic, respectively Laplace harmonic, for (t,s) if and only if it is so for (s,t);

(c) for maps $o,\nu\colon I\to\mathbb{Z}$, a polynomial is K-highest of weight ν for o for the column units $(E^{\mathrm{col}}_{cc'})$ if and only if it is K-highest of weight $-\nu$ for $-o$ for the row units $(\check{E}^{\mathrm{row}}_{cc'})$; for maps $o',\nu'\colon I'\to\mathbb{Z}$, a polynomial is K-highest of weight ν' for o' for the row units $(E^{\mathrm{row}}_{aa'})$ if and only if it is K-highest of weight $-\nu'$ for $-o'$ for the column units $(\check{E}^{\mathrm{col}}_{aa'})$;

(d) for $\lambda\colon I\to\mathbb{Z}$ and $\lambda'\colon I'\to\mathbb{Z}$, a polynomial H is a joint harmonic for the signs (s,t), the weights (γ,γ') and the parameters (λ,λ') if and only if it is a joint harmonic for the signs (t,s), the weights (γ',γ) and the parameters (λ',λ);

(e) if J is a nonempty finite set with signs and $l\colon J\to\mathbb{Z}$ is injective with $l(j)\equiv\#J-1 \pmod 2$ for all j (for instance λ or λ' when (λ,λ') satisfies the block rule), then $\mu_{-l}=-\mu_l$.

Proof. **Step 1: the elementary operators.** In the setting (t,s) the variable Y_{ca} lies in the row c of sign $s(c)$ and the column a of sign $t(a)$, so its sign is $s(c)t(a)$, the sign of X_{ac} in the setting (s,t). Hence the raising and lowering operators of Y_{ca} are ra_{ac} and lo_{ac}. Operators attached to different variables commute, and for each variable

$$\mathrm{lo}_{ac}\,\mathrm{ra}_{ac}=\mathrm{ra}_{ac}\,\mathrm{lo}_{ac}+1.$$

So $\mathrm{lo}_{ac'}\mathrm{ra}_{ac}=\mathrm{ra}_{ac}\mathrm{lo}_{ac'}+\delta_{cc'}$ and $\mathrm{lo}_{ac}\mathrm{ra}_{a'c}=\mathrm{ra}_{a'c}\mathrm{lo}_{ac}+\delta_{aa'}$.

Step 2: (a). In the setting (t,s) there are N rows, so (HV5) with the shifts $(\gamma',-\gamma)$ gives

$$\check{E}^{\mathrm{row}}_{cc'}=\sum_{a\in I'}\mathrm{ra}_{ac}\,\mathrm{lo}_{ac'}+\gamma'\delta_{cc'},\qquad \check{E}^{\mathrm{col}}_{aa'}=-\sum_{c\in I}\mathrm{lo}_{ac}\,\mathrm{ra}_{a'c}+(-\gamma+N)\delta_{aa'},$$

while in the setting (s,t) with the shifts $(\gamma,-\gamma')$

$$E^{\mathrm{col}}_{c'c}=-\sum_{a\in I'}\mathrm{lo}_{ac'}\,\mathrm{ra}_{ac}+(-\gamma'+N')\delta_{cc'},\qquad E^{\mathrm{row}}_{a'a}=\sum_{c\in I}\mathrm{ra}_{a'c}\,\mathrm{lo}_{ac}+\gamma\delta_{aa'}.$$

By Step 1, $E^{\mathrm{col}}_{c'c}=-\sum_a\mathrm{ra}_{ac}\mathrm{lo}_{ac'}-N'\delta_{cc'}+(-\gamma'+N')\delta_{cc'}=-\check{E}^{\mathrm{row}}_{cc'}$, and $\check{E}^{\mathrm{col}}_{aa'}=-\sum_c\mathrm{ra}_{a'c}\mathrm{lo}_{ac}-N\delta_{aa'}+(-\gamma+N)\delta_{aa'}=-E^{\mathrm{row}}_{a'a}$.

Step 3: (b). By (HV6) for (t,s), for $s(c)\neq s(c')$, $\check{\Delta}^{\mathrm{row}}_{cc'}=\sum_{a:\,s(c)t(a)=-1}\partial_{ac}\partial_{ac'}$, while $\Delta^{\mathrm{col}}_{c'c}=\sum_{a:\,t(a)s(c')=1}\partial_{ac'}\partial_{ac}$; the two index sets agree because $s(c')=-s(c)$. For $t(a)\neq t(a')$, $\check{\Delta}^{\mathrm{col}}_{aa'}=\sum_{c:\,s(c)t(a)=1}\partial_{ac}\partial_{a'c}$ and $\Delta^{\mathrm{row}}_{a'a}=\sum_{c:\,t(a')s(c)=-1}\partial_{a'c}\partial_{ac}$, with the same index sets as

$t(a') = -t(a)$. The two families of conditions defining termwise harmonic polynomials for (t,s) (two variables of one column of Y from rows of opposite signs, two variables of one row of Y from columns of opposite signs) are those for (s,t) in the other order, and the Laplacians of (t,s) are those of (s,t) by the identities just shown; so both notions agree.

Step 4: (c). Let x be a polynomial. By (a), $E^{\mathrm{col}}_{cc}x = \nu(c)x$ is $\check{E}^{\mathrm{row}}_{cc}x = -\nu(c)x$, and $E^{\mathrm{col}}_{cc'}x = 0$ is $\check{E}^{\mathrm{row}}_{c'c}x = 0$. The condition "$E^{\mathrm{col}}_{cc'}x = 0$ whenever $s(c) = s(c')$ and $o(c') < o(c)$" therefore reads "$\check{E}^{\mathrm{row}}_{jj'}x = 0$ whenever $s(j) = s(j')$ and $(-o)(j') < (-o)(j)$" (with $j = c'$, $j' = c$). This is the first equivalence; the second is the same computation with $\check{E}^{\mathrm{col}}_{aa'} = -E^{\mathrm{row}}_{a'a}$.

Step 5: (d). The block rule (WM8) for (λ,λ') with the weights (γ,γ') and the signs (s,t) has the shifted entries $\tilde{\lambda}(c) = \lambda(c) - 2\gamma' + N'$ and $\tilde{\lambda}'(a) = \lambda'(a) - 2\gamma + N$. For (λ',λ) with the weights (γ',γ) and the signs (t,s) (first index set I', second I) the shifted entries are $\lambda'(a) - 2\gamma + N = \tilde{\lambda}'(a)$ and $\lambda(c) - 2\gamma' + N' = \tilde{\lambda}(c)$. Conditions (a), (b), (c) of (WM8) for the second datum are those for the first with the two sides exchanged, and each of them is unchanged by this exchange (the gap $500(N+N')^3$ is symmetric, the two cases of (b) are exchanged, and $s(c) = \pm t(a)$ is symmetric). So (λ,λ') satisfies the block rule for (γ,γ'), (s,t) if and only if (λ',λ) does for (γ',γ), (t,s).

(e). Under the block rule, λ is injective with $\lambda(c) \equiv N-1 \pmod 2$ by (a) of (WM8), and likewise λ' with N'. For a vector l as in (e), Definition 3.2.3 gives $2\rho_{-l} = -2\rho_l$ and $2\rho^{\mathrm{c}}_{-l} = -2\rho^{\mathrm{c}}_l$; and $l(j) + 2\rho_l(j)$ is even, because $2\rho_l(j)$ is a sum of $\#J - 1$ terms ± 1 (l injective), hence $\equiv \#J - 1 \equiv l(j)$. So $(-l)^\rho = -l^\rho$ and

$$\mu_{-l} = -\mu_l.$$

End of (d). Now let the block rule hold. By (HV7), H is a joint harmonic for (s,t), (γ,γ'), (λ,λ') if and only if $H \neq 0$ is termwise harmonic, K-highest of weight $\mu_{\lambda'}$ for λ' for $(E^{\mathrm{row}}_{aa'})$ and K-highest of weight $\mu_{-\lambda}$ for $-\lambda$ for $(E^{\mathrm{col}}_{cc'})$; and H is a joint harmonic for (t,s), (γ',γ), (λ',λ) if and only if $H \neq 0$ is termwise harmonic for (t,s), K-highest of weight μ_λ for λ for $(\check{E}^{\mathrm{row}}_{cc'})$ and K-highest of weight $\mu_{-\lambda'}$ for $-\lambda'$ for $(\check{E}^{\mathrm{col}}_{aa'})$, both pairs of units having the shifts of the statement. By (b) and (c), with $-\mu_{-\lambda} = \mu_\lambda$ and $-\mu_{\lambda'} = \mu_{-\lambda'}$, the two lists of conditions coincide. □

Lemma 6.4.28. *Let $n \geq 1$, $\varepsilon \in \{\pm 1\}^n$, $J = \mathrm{diag}(\varepsilon)$, $G = \mathrm{U}(J)$ with a Haar measure dg, $\mathfrak{u}(J) = \{Y : Y^*J + JY = 0\}$, and $\|g\|$ the operator norm. Let X be a complex Banach space, B a continuous positive definite hermitian form on X, conjugate linear in its first variable, and $\pi\colon G \to \mathrm{GL}(X)$ a representation by bounded operators, strongly continuous, with $B(\pi(g)x, \pi(g)y) = B(x,y)$ and $\|\pi(g)\| \leq C\|g\|^A$ for some $C > 0$, $A \in \mathbb{N}$ and all g.*

(i) Let $l \in \mathbb{Z}^n$ have large gap A for ε, $\lambda = \frac{1}{2}l$, $d_\lambda = (\int_G |c_\lambda|^2 dg)^{-1}$ and $e_\lambda = d_\lambda \overline{c_\lambda}$. Then $\int_G |e_\lambda(g)|\,\|g\|^A dg < \infty$; for every $x \in X$ the function $g \mapsto e_\lambda(g)\pi(g)x$ is Bochner integrable, and $\pi(e_\lambda)x = \int_G e_\lambda(g)\pi(g)x\,dg$ defines a bounded operator with

$$B(y, \pi(e_\lambda)x) = B(\pi(e_\lambda)y, x), \qquad \pi(e_\lambda)\pi(e_\lambda) = \pi(e_\lambda),$$
$$B(x, \pi(e_\lambda)x) = B(\pi(e_\lambda)x, \pi(e_\lambda)x) \geq 0$$

for all $x, y \in X$; and $\pi(e_\lambda)$ commutes with every bounded operator on X that commutes with all $\pi(g)$.

(ii) In the situation of (i) there is a smooth compactly supported $\beta\colon G \to \mathbb{C}$ with

$$\int_G \beta(y)\, e_\lambda(y^{-1}g)\, dy = e_\lambda(g)$$

for every $g \in G$.

(iii) For $w \in X$ and a smooth compactly supported $\varphi\colon G \to \mathbb{C}$ put $S_w(\varphi) = \int_G \varphi(y)\pi(y)w\,dy$ and, for $Y \in \mathfrak{u}(J)$, $\varphi_Y(y) = \frac{d}{dt}\big|_{t=0}\varphi(e^{-tY}y)$. Then $\tau \mapsto \pi(\exp \tau Y)S_w(\varphi)$ is differentiable at $\tau = 0$ with derivative $S_w(\varphi_Y)$, and φ_Y is smooth and compactly supported.

Proof. **(i).** The vector l has gap $h = 500n^3 + A$; let $L = \max_i |l_i|$ and $c = A + 8n^2 + 1 \le h$. By (1) of Lemma 5.7.38, $|c_\lambda(g)| \le (2/\|g\|)^c$, so

$$|e_\lambda(g)|\,\|g\|^A \le d_\lambda 2^c \|g\|^{A-c} = 2^A\, d_\lambda \Big(\frac{2}{\|g\|}\Big)^{8n^2+1},$$

which is integrable with $d_\lambda > 0$ by (3) of Lemma 5.7.38. By (i) of Lemma 5.6.22 (l has gap $500n^3$), e_λ is continuous, $e_\lambda(g^{-1}) = \overline{e_\lambda(g)}$ and $\int_G e_\lambda(z)e_\lambda(z^{-1}y)\,dz = e_\lambda(y)$ (take $x = 1$ there). The function $g \mapsto e_\lambda(g)\pi(g)x$ is continuous on the σ-compact group G, hence strongly measurable, with norm at most $C|e_\lambda(g)|\|g\|^A\|x\|$; so it is Bochner integrable and $\|\pi(e_\lambda)\| \le C\int |e_\lambda|\|g\|^A dg$.

Self-adjointness. By invariance of B and of dg under inversion,

$$\begin{aligned} B(y, \pi(e_\lambda)x) &= \int e_\lambda(g)B(\pi(g^{-1})y, x)\,dg = \int e_\lambda(g^{-1})B(\pi(g)y, x)\,dg \\ &= \int \overline{e_\lambda(g)}B(\pi(g)y, x)\,dg = B(\pi(e_\lambda)y, x). \end{aligned}$$

Idempotence. $\pi(e_\lambda)\pi(e_\lambda)x = \iint e_\lambda(g)e_\lambda(h)\pi(gh)x\,dh\,dg$, where the integrand is bounded in norm by $C|e_\lambda(g)||e_\lambda(h)|\|g\|^A\|h\|^A\|x\|$ ($\|gh\| \le \|g\|\|h\|$), integrable for the product measure. The substitution $h = g^{-1}k$ preserves the product measure, and Fubini's theorem for Bochner integrals gives $\int(\int e_\lambda(g)e_\lambda(g^{-1}k)\,dg)\pi(k)x\,dk = \int e_\lambda(k)\pi(k)x\,dk = \pi(e_\lambda)x$. Hence $B(x, \pi(e_\lambda)x) = B(x, \pi(e_\lambda)\pi(e_\lambda)x) = B(\pi(e_\lambda)x, \pi(e_\lambda)x) \ge 0$. If T is bounded and commutes with every $\pi(g)$, then $T\pi(e_\lambda)x = \int e_\lambda(g)T\pi(g)x\,dg = \pi(e_\lambda)Tx$.

(ii). The gap h exceeds $8n^2$, so (ii) of Lemma 5.7.36 gives a smooth compactly supported β with $c_\lambda(g) = \int \beta(y)c_\lambda(gy)\,dy$ for all g. Multiplying by d_λ and conjugating, $e_\lambda(g) = \int \overline{\beta(y)}e_\lambda(gy)\,dy$. At g^{-1}, after conjugation and with $\overline{e_\lambda(z)} = e_\lambda(z^{-1})$,

$$e_\lambda(g) = \overline{e_\lambda(g^{-1})} = \int \beta(y)\,\overline{e_\lambda(g^{-1}y)}\,dy = \int \beta(y)\,e_\lambda(y^{-1}g)\,dy.$$

(iii). By (i) of Lemma 5.7.36 (whose definition of φ_Y is the present one), φ_Y is smooth with support in that of φ. The integrand of $S_w(\varphi)$ is continuous with compact support. By left invariance of dy,

$$\pi(e^{\tau Y})S_w(\varphi) = \int \varphi(y)\pi(e^{\tau Y}y)w\,dy = \int \varphi(e^{-\tau Y}y)\pi(y)w\,dy.$$

Since $\frac{d}{d\sigma}\varphi(e^{-\sigma Y}y) = \varphi_Y(e^{-\sigma Y}y)$, for $0 < |\tau| \le 1$

$$r_\tau(y) = \frac{\varphi(e^{-\tau Y}y) - \varphi(y)}{\tau} - \varphi_Y(y) = \frac{1}{\tau}\int_0^\tau \big(\varphi_Y(e^{-\sigma Y}y) - \varphi_Y(y)\big)\,d\sigma,$$

which vanishes outside the compact set $K = \{e^{\sigma Y} : |\sigma| \le 1\} \cdot \operatorname{supp}\varphi$. The function $(\sigma, y) \mapsto \varphi_Y(e^{-\sigma Y}y)$ is uniformly continuous on $[-1, 1] \times K$ and φ_Y vanishes off K, so $\sup_y |r_\tau(y)| \to 0$ as $\tau \to 0$. Therefore

$$\Big\|\frac{\pi(e^{\tau Y})S_w(\varphi) - S_w(\varphi)}{\tau} - S_w(\varphi_Y)\Big\| = \Big\|\int_K r_\tau(y)\pi(y)w\,dy\Big\| \le \sup_y |r_\tau(y)| \int_K \|\pi(y)w\|\,dy \to 0.$$

□

Proposition 6.4.29. *Let I, I' be nonempty finite index sets with signs s on I and t on I', and let $\gamma, \gamma' \in \mathbb{Z}$. Put $\iota = I' \times I$ and $\varepsilon(a,c) = t(a)s(c)$. On the SAME Fock model $\mathcal{F}_\varepsilon$ put*

$$\pi(x) = \det(x)^{-\gamma'}\,\omega_\varepsilon^\infty(1 \otimes (x^{-1})^{\mathsf{T}}), \qquad \pi'(y) = \det(y)^{\gamma}\,\omega_\varepsilon^\infty(y \otimes 1).$$

If $P \in \mathbb{C}[X_{ac} : a \in I', c \in I]$ is nonzero and termwise harmonic, then

$$\langle v_P, \pi(z) v_P\rangle \in \mathbb{R}_{>0} \quad \textit{for every positive-definite hermitian } z \in \mathrm{U}(\mathrm{diag}\, s),$$

and

$$\langle v_P, \pi'(w) v_P\rangle \in \mathbb{R}_{>0} \quad \textit{for every positive-definite hermitian } w \in \mathrm{U}(\mathrm{diag}\, t).$$

Proof. **Polynomial inner products in the given model.** All inner products below are the integrals in (WR5), conjugate-linear in their first argument. They are taken in the prescribed L^1 Fock model; no replacement by a Hilbert representation is made. For multi-indices $\mathbf{a}, \mathbf{b}$ the elementary one-variable Gaussian integrals give

$$\langle v_{X^{\mathbf{a}}}, v_{X^{\mathbf{b}}}\rangle = \begin{cases} \prod_i a_i! & \mathbf{a} = \mathbf{b}, \\ 0 & \mathbf{a} \neq \mathbf{b}. \end{cases}$$

Indeed angular integration gives orthogonality in each coordinate, and radial integration of $|z|^{2m} e^{-|z|^2}$ with measure $\pi^{-1} dz$ gives $m!$. Conjugating a coordinate when its sign is positive leaves this integral unchanged. Thus, writing $(Q,P)_{\mathrm{F}} = \langle v_Q, v_P\rangle$ locally in this proof,

$$(X_i Q, P)_{\mathrm{F}} = (Q, \partial_i P)_{\mathrm{F}}, \qquad (P,P)_{\mathrm{F}} > 0 \quad (P \neq 0).$$

For a matrix M let $L_M P$ mean the substitution $X_j \mapsto \sum_i M_{ij} X_i$. The chain rule in the displayed Gaussian pairing, or its expansion on symmetric tensors degree by degree, gives

$$L_M L_N = L_{MN}, \qquad (L_M Q, P)_{\mathrm{F}} = (Q, L_{M^*} P)_{\mathrm{F}}.$$

For completeness the degree-d monomials identify this pairing with $d!$ times the induced pairing on symmetric tensors: the tensor $M^{\otimes d}$ has adjoint $(M^*)^{\otimes d}$, and restriction to symmetric tensors proves the last equality. Distinct degrees are orthogonal. These are finite-dimensional polynomial identities.

The harmonic coefficient formula. We prove the needed formula on a finite coordinate set J with signs ϵ_i, allowing an arbitrary finite labeling d_i. Suppose that $U \in \mathrm{U}(\mathrm{diag}\,\epsilon)$ is block diagonal for these labels: $U_{ij} = 0$ if $d_i \neq d_j$. Put

$$C_{ij} = \begin{cases} U_{ij} & \epsilon_i = \epsilon_j = +1, \\ \bar{U}_{ij} & \epsilon_i = \epsilon_j = -1, \\ 0 & \epsilon_i \neq \epsilon_j, \end{cases} \qquad A = C^{-1}, \qquad \delta = \det(U_{--})^{-1}.$$

Both sign principal blocks are invertible: from $U^* \mathrm{diag}(\epsilon) U = \mathrm{diag}(\epsilon)$, $U_{--}^* U_{--} = 1 + U_{+-}^* U_{+-}$ and $U_{++}^* U_{++} = 1 + U_{-+}^* U_{-+}$. Thus C and A are defined and are block diagonal jointly for labels and signs.

Call a polynomial label-harmonic here if $\partial_i \partial_j P = 0$ whenever $d_i = d_j$ and $\epsilon_i \neq \epsilon_j$. We claim that for two such polynomials,

$$\langle v_Q, \omega_\epsilon^\infty(U) v_P\rangle = \delta\,(L_A Q, P)_{\mathrm{F}}. \tag{$*$}$$

We give the coefficient recurrences and induction proving this claim.

Use the raising and lowering operators R_i, B_i of (HV5), with coordinate signs ϵ_i. The derivative at zero of the Heisenberg operator in direction $z \in \mathbb{C}^J$ on a polynomial vector is the vector of

$$D_z P = \sum_i (z_i R_i P - \epsilon_i \bar{z}_i B_i P).$$

Indeed, for real τ, set $\zeta_i(x) = \bar{x}_i$ for $\epsilon_i = +1$ and $\zeta_i(x) = x_i$ for $\epsilon_i = -1$. The definitions give the exact identity

$$(\rho(\tau z) v_P)(x) = e^{-|x|^2/2} \exp\left(-\frac{\tau^2 |z|^2}{2} + \tau \sum_{\epsilon_i = +1} \bar{x}_i z_i + \tau \sum_{\epsilon_i = -1} x_i \bar{z}_i \right) P(\zeta(x) - \tau \zeta(z)).$$

Its derivative at $\tau = 0$ is $\sum_{\epsilon_i=+1}(z_i X_i P - \bar{z}_i \partial_i P) + \sum_{\epsilon_i=-1}(\bar{z}_i X_i P - z_i \partial_i P)$, which is precisely the displayed D_z. Thus neither a factor 2 nor a sign is suppressed. The polynomial operators obey $[\partial_i, X_j] = \delta_{ij}$; their Fischer adjoints are $R_i^* = \epsilon_i B_i$ and $B_i^* = \epsilon_i R_i$. These follow separately from $(X_i)^* = \partial_i$: for a negative coordinate $R_i = -\partial_i$, $B_i = X_i$, so both adjoints acquire the minus sign. The differentiation is valid in the L^1 norm: on a bounded interval of the translation parameter every differentiated expression is bounded by a fixed polynomial times $\exp(-|x|^2/4 + C)$, an integrable function. Unitarity and Heisenberg covariance of the actual real Weil action are Lemma 4.1.1(2). Differentiating covariance and moving the skew-adjoint Heisenberg derivative across the inner product, first for $z = e_j$ and then for $z = ie_j$, gives, with $B_U(Q, P) = \langle v_Q, \omega_\epsilon^\infty(U) v_P \rangle$,

$$B_U(Q, R_j P) = \sum_i U_{ij} \epsilon_i B_U(B_i Q, P),$$
$$\epsilon_j B_U(Q, B_j P) = \sum_i \bar{U}_{ij} B_U(R_i Q, P).$$

These two equalities also follow directly by comparing the coefficients of z_j and $\bar{z}_j$ in $B_U(Q, D_z P) = -B_U(D_{Uz} Q, P)$; conjugate-linearity is in the first entry.

We now solve these recurrences explicitly. Fix j and suppose

$$\partial_k Q = 0 \quad \text{if } d_k = d_j \text{ and } \epsilon_k \neq \epsilon_j. \tag{a}$$

The polynomial P in this calculation is arbitrary. Put $S_j = \{i : d_i = d_j,\ \epsilon_i = \epsilon_j\}$ and, for every index k,

$$w_k = B_U(X_k Q, P), \qquad b_i = B_U(Q, \partial_i P).$$

For every $i \in S_j$, condition (a) also holds with i in place of j.

If $\epsilon_i = +1$, the second recurrence, with $B_i = \partial_i$, gives

$$\begin{aligned} b_i &= \sum_{\epsilon_k = +1} \bar{U}_{ki} w_k - \sum_{\epsilon_k = -1} \bar{U}_{ki} B_U(\partial_k Q, P) \\ &= \sum_{k \in S_j} \bar{U}_{ki} w_k = \sum_{k \in S_j} \bar{C}_{ki} w_k. \end{aligned} \tag{b+}$$

In the first sum, a term outside S_j has $d_k \neq d_i$ and therefore $U_{ki} = 0$. In the second sum, if $d_k = d_i$ its derivative is zero by (a), and if $d_k \neq d_i$ its matrix entry is zero. This accounts for every opposite-sign summand, including its minus sign.

If $\epsilon_i = -1$, use instead $R_i = -\partial_i$ in the first recurrence:

$$\begin{aligned} b_i &= -B_U(Q, R_i P) \\ &= -\sum_{\epsilon_k=+1} U_{ki} B_U(\partial_k Q, P) + \sum_{\epsilon_k=-1} U_{ki} w_k \\ &= \sum_{k\in S_j} U_{ki} w_k = \sum_{k\in S_j} \bar{C}_{ki} w_k. \end{aligned} \tag{b-}$$

Again every first-sum term vanishes either by (a) or by the label condition, and the second sum has no other surviving label. Here $C_{ki} = \bar{U}_{ki}$ on the negative block, which explains the final conjugation. We have proved, in both cases and for every $i \in S_j$,

$$b_i = \sum_{k\in S_j} \bar{C}_{ki} w_k. \tag{b}$$

The matrix C is a direct sum over the joint label-and-sign classes. Each summand is invertible: C is invertible, and its determinant is the product of the determinants of these finite diagonal blocks. Its inverse A is the direct sum of their inverses, as is verified by multiplying those blocks with C. In particular $A_{ij} = 0$ for $i \notin S_j$. Multiply (b) by $\bar{A}_{ij}$ and sum over $i \in S_j$. The calculation is

$$\begin{aligned} \sum_{i\in S_j} \bar{A}_{ij} b_i &= \sum_{k\in S_j} \overline{\sum_{i\in S_j} C_{ki} A_{ij}}\, w_k \\ &= \sum_{k\in S_j} \overline{(CA)_{kj}}\, w_k = \sum_{k\in S_j} \delta_{kj} w_k = w_j. \end{aligned}$$

All sums are finite. The extension from S_j to all indices adds only zero entries of A. Thus the required solved recurrence is

$$B_U(X_j Q, P) = \sum_i \bar{A}_{ij} B_U(Q, \partial_i P). \tag{**}$$

This computation proves the inverse orientation directly: the system is $b_{S_j} = (C_{S_j})^* w_{S_j}$ and its inverse has entry $((C_{S_j})^*)^{-1}_{ji} = \bar{A}_{ij}$. No inverse mixes a discarded label or sign, and no harmonicity assumption on P has been used in (**).

The constant coefficient is $B_U(1,1) = \delta$. To calculate it, set $H = (1 + U^*U)/2$. Evaluation at zero is pairing with the vacuum by the reproducing formula. Hence the literal integral kernel gives

$$B_U(1,1) = \overline{\det U_{--}} \int e^{-y^* H y}\, \pi^{-\#J} dy = \frac{\overline{\det U_{--}}}{\det H} = \frac{1}{\det U_{--}}.$$

Here $\det H = |\det U_{--}|^2$. Explicitly, with $E = \mathrm{diag}(\epsilon)$, put $D_0 = \mathrm{diag}(U_{++}, U_{--}) = (U + EUE)/2$. Then

$$U^* D_0 = (U^*U + U^*EUE)/2 = (U^*U + 1)/2 = H.$$

Since $U^*EU = E$, one has $|\det U| = 1$, whence

$$\det H = \det U_{++} \det U_{--} / \det U.$$

The complementary-minor formula gives $\det U_{++}/\det U = \det(U^{-1})_{--}$, and $U^{-1} = EU^*E$ makes the latter $\overline{\det U_{--}}$. The Gaussian integral follows by a unitary diagonalization of the positive matrix H and one-dimensional integration.

A label-harmonic polynomial is a sum of monomials which contain no pair of variables with the same label and opposite signs. This is because each prohibited second derivative sends different monomials containing that pair to different monomials, with nonzero integer coefficients. For a nonconstant allowed monomial X_jQ, the remaining Q has no prohibited opposite-sign variable relative to j. The inverse retains the label condition, since $(U^{-1})_{ik} = \epsilon_i\epsilon_k\bar{U}_{ki}$. Apply (**) for U^{-1} and second polynomial 1; every $\partial_i 1$ is exactly zero. By unitarity $B_U(1, X_jQ) = \overline{B_{U^{-1}}(X_jQ, 1)} = 0$. Together with the constant calculation this proves $B_U(1, P) = \delta(1, P)_{\mathrm{F}}$ for every label-harmonic P.

Now induct on the degree of an allowed monomial Q, simultaneously for every label-harmonic P. Its derivatives remain label-harmonic. For X_jQ, (**) and the induction hypothesis give

$$\begin{aligned} B_U(X_jQ, P) &= \delta \sum_i \bar{A}_{ij}(L_AQ, \partial_i P)_{\mathrm{F}} \\ &= \delta \sum_i \bar{A}_{ij}(X_iL_AQ, P)_{\mathrm{F}} = \delta(L_A(X_jQ), P)_{\mathrm{F}}. \end{aligned}$$

Linearity in P and conjugate-linearity in Q extend this identity to their monomial sums. This proves (*), with every determinant and conjugation retained.

Positivity for a positive element. If U is additionally positive-definite hermitian, its two sign principal blocks are positive definite, as is the entrywise conjugate of the negative block. Consequently $C > 0$, $A = C^{-1} > 0$ and $\det U_{--} > 0$. Choose the positive square root $S = A^{1/2}$. It is invertible, $S^* = S$, and the polynomial adjoint identity gives

$$(L_AP, P)_{\mathrm{F}} = (L_SL_SP, P)_{\mathrm{F}} = (L_SP, L_SP)_{\mathrm{F}} > 0 \qquad (P \neq 0).$$

The last inequality holds because L_S is invertible, with inverse $L_{S^{-1}}$. Thus (*) gives

$$\langle v_P, \omega_\epsilon^\infty(U) v_P \rangle = \frac{(L_SP, L_SP)_{\mathrm{F}}}{\det U_{--}} > 0$$

for every nonzero label-harmonic polynomial. The empty sign block has determinant 1, so this also covers definite signatures.

The two actual oscillator factors. For the column action take $U = 1 \otimes (z^{-1})^{\mathsf{T}}$ and labels $d(a, c) = a$. The matrix is positive-definite hermitian: inverse, transpose and tensoring with the identity preserve this property. It is unitary for the signs $t(a)s(c)$ and is block diagonal in the row labels. Within one row, opposite coordinate signs mean $s(c) \neq s(c')$, so the second termwise-harmonic condition of (HV6) is exactly the required label-harmonicity. The preceding formula applies to this U, not to $z \otimes 1$.

For the row action take $U = w \otimes 1$ and labels $d(a, c) = c$. It is likewise positive-definite hermitian and unitary for the same coordinate signs. Within a column, opposite signs mean $t(a) \neq t(a')$, so the first termwise-harmonic condition gives the needed hypothesis. Thus the same formula applies to the row factor.

Finally $\det z$ and $\det w$ are positive real numbers, while their unitary defining equations give $|\det z| = |\det w| = 1$. Therefore both determinants equal 1. The twists $\det(z)^{-\gamma'}$ and $\det(w)^{\gamma}$ are exactly 1, irrespective of the integer exponents. There is no omitted phase. The two asserted strict inequalities follow in the original Fock inner product. □

Lemma 6.4.30. *Let $n \geq 1$ be read as $\{1, \ldots, n\}$ in that context, assume $A \in \mathbb{N}$, and let $l \in \mathbb{Z}^n$ have large gap A for s, with $\lambda = l/2$. Suppose that $v \in M$ is K-highest of weight μ_l for the order l, that is,*

$$\rho(E_{aa})v = \mu_l(a)v, \qquad \rho(E_{ab})v = 0 \quad \text{if } s_a = s_b \text{ and } l_b < l_a.$$

If $B(\iota v, \pi(z)\iota v)$ is a strictly positive real number for every positive-definite matrix $z \in G$, then $g \mapsto e_\lambda(g)\pi(g)x$ is Bochner integrable for every $x \in X$, its integral defines a bounded operator $\pi(e_\lambda)$, and

$$\operatorname{Re} B\big(\iota v, \pi(e_\lambda)\iota v\big) > 0.$$

Proof. Put $K = K_s$, $\mu = \mu_l$, $x = \iota v$, $m = m_\mu$ and

$$D = \int_K |m(k)|^2 \, dk > 0, \qquad a(u, z) = m_{-l^\rho}(u^* z u).$$

The measure dk has mass one; the measure dg of G is the Cayley measure used to define d_λ and e_λ. By Lemma 5.2.41 it is invariant on both sides.

The kernel has the moment required for the integrated representation. Let $c = 8n^2 + 1$ and choose an integer $L \geq \max_a |l_a|$. Since $c \leq 500n^3$, the gap $500n^3 + A$ and Lemma 5.7.38(1),(3) give $d_\lambda > 0$ and

$$|e_\lambda(g)| \, \|g\|^A \leq 2^A d_\lambda (2/\|g\|)^c, \qquad Q_A := \int_G |e_\lambda(g)| \, \|g\|^A \, dg < \infty.$$

Indeed use the coefficient bound with exponent $A + c$; its product with $\|g\|^A$ is the displayed bound. More explicitly the cited integral estimate gives

$$Q_A \leq 8 \, 2^{A+c} \big(2000(n + L + 1)^6\big)^{2n^2}.$$

Apply Lemma 6.4.28(i) to the same Banach representation, invariant form, integer exponent A, Cayley Haar measure and gap $500n^3 + A$. Its vector integrals define the bounded operator

$$Ty := \int_G e_\lambda(g)\pi(g)y \, dg = \pi(e_\lambda)y, \qquad \|T\| \leq C_\pi Q_A.$$

The norm bound follows by integrating the growth bound. Bounded linear functionals commute with this Bochner integral, so $f(Ty) = \int_G e_\lambda(g) f(\pi(g)y) \, dg$.

A compact highest-weight average reproduces x. Apply Lemma 6.4.31 with $I = \{1, \dots, n\}$, $\nu = \mu_l$ and the representation, form, module and map of the statement. Large gap implies that the entries of l are distinct. The norm-derived action and the two highest-vector equations are precisely its hypotheses; no compact-finiteness assumption is needed. Since its a_ν is the number D above, it gives

$$\int_K \overline{m(k)} \, \pi(k)x \, dk = Dx. \tag{6.72}$$

In particular, for $w \in X$ and $g \in G$,

$$\int_K \overline{m(k)} \, B(w, \pi(gk)x) \, dk = DB(w, \pi(g)x), \tag{6.73}$$

$$\int_K m(k) \, B(x, \pi(k^{-1})w) \, dk = DB(x, w). \tag{6.74}$$

The first identity follows by applying the bounded functional $B(w, \pi(g)\,\cdot\,)$ to (6.72); the second follows from invariance of B, conjugate linearity in its first argument, and the same identity.

The double compact average is strictly positive. Define the integrable scalar function

$$F(g) = e_\lambda(g) B(x, \pi(g)x), \qquad \mathcal{A}(g) = \int_{K \times K} F(k_1^{-1} g k_2) \, dk_1 \, dk_2.$$

The moment bound and continuity of B prove integrability of F. Bi-invariance of dg and Tonelli give $\int_{K\times K}\int_G |F(k_1^{-1}gk_2)|\,dg\,dk_1dk_2 = \int_G |F|$. Consequently $\mathcal{A}$ is integrable, Fubini applies, and

$$B(x,Tx) = \int_G F(g)\,dg = \int_G \mathcal{A}(g)\,dg. \tag{6.75}$$

Fix $g \in G$. By Lemma 5.6.30(ii), write $g = k_0 z$ with $k_0 \in K$ and $z \in G$ positive definite. For $u \in K$ the matrix u^*zu is positive definite, so all its principal minors and its determinant are positive. Thus $a(u,z) > 0$, even when some powers in m_{-l^ρ} are negative. The function $u \mapsto a(u,z)^{-1}$ is continuous on K.

Apply Lemma 5.6.26(i),(ii) with the block-diagonal factors $k_1^{-1}k_0$ and k_2^{-1} and the accretive matrix z; positive definiteness implies accretivity. It gives the exact polar identity

$$\overline{c_\lambda(k_1^{-1}k_0zk_2)} = \frac{1}{D}\int_K \frac{m(u^*k_0^*k_1)\,m(k_2^*u)}{a(u,z)}\,du.$$

Here conjugation of the numerator uses $m(y^*) = \overline{m(y)}$ from Lemma 5.6.27(i), and the denominator is real. For this fixed z every function in the resulting triple integral over K^3 is continuous, with nonvanishing denominator. Hence it is absolutely integrable and the order of integration may be exchanged.

For each fixed u, replace k_1 by k_0ua and k_2 by ub in the inner integral; Haar probability is unchanged. The two minor factors become $m(a)$ and $\overline{m(b)}$, and the matrix coefficient becomes $B(x,\pi(a^{-1}u^{-1}zub)x)$. Integrating first in a by (6.74), and then in b by (6.73), gives

$$\mathcal{A}(g) = d_\lambda D\int_K \frac{B(x,\pi(u^{-1}zu)x)}{m_{-l^\rho}(u^*zu)}\,du.$$

The numerator is a strictly positive real number by hypothesis, since $u^{-1} = u^*$ and $u^*zu \in G$ is positive definite. The denominator, d_λ and D are strictly positive. The integrand is continuous and strictly positive on the nonempty compact group K, whose measure is one. Therefore $\mathcal{A}(g)$ is a strictly positive real number for every $g \in G$.

Finally $\operatorname{Re}\mathcal{A}$ is integrable and strictly positive everywhere, and dg is a nonzero Haar measure. Its integral is strictly positive. Taking real parts in (6.75) yields $\operatorname{Re} B(x,\pi(e_\lambda)x) > 0$, as required. □

Lemma 6.4.31. *Let I be a nonempty finite set, $s \in \{\pm1\}^I$, $J = \operatorname{diag}(s)$, $G = \mathrm{U}(J)$ and $K = K_s$. Let $l \in \mathbb{Z}^I$ have distinct entries and let $\nu \in \mathbb{Z}^I$. Let X be a complex Banach space, B a continuous positive-definite hermitian form on X, conjugate-linear in its first argument, and $\pi\colon G \to \mathrm{GL}(X)$ a strongly continuous representation by bounded complex-linear operators preserving B. Let M be a complex vector space, $\rho\colon \mathfrak{gl}(I,\mathbb{C}) \to \mathrm{End}_{\mathbb{C}}(M)$ a Lie algebra representation and $\iota\colon M \to X$ linear. Suppose that*

$$\left.\frac{d}{dt}\right|_{t=0} \pi(\exp(tY))\iota(w) = \iota(\rho(Y)w) \qquad (Y^*J + JY = 0,\ w \in M)$$

in the norm of X. Let $v \in M$ satisfy

$$\rho(E_{aa})v = \nu_a v, \qquad \rho(E_{ab})v = 0 \quad (s_a = s_b,\ l_a > l_b).$$

Then:

1. *If $\iota v \neq 0$, then $\nu_a \geq \nu_b$ whenever $s_a = s_b$ and $l_a > l_b$.*

2. *The number $a_\nu = \int_K |m_\nu(k)|^2\,dk$ is strictly positive, the following Bochner integral exists, and*

$$\int_K \overline{m_\nu(k)}\,\pi(k)\iota v\,dk = a_\nu\,\iota v.$$

Proof. Put $x = \iota v$, $m = m_\nu$, $D = \int_K |m(k)|^2\,dk$, and $I_\pm = \{a \in I : s_a = \pm 1\}$. The function m is continuous on K: its defining principal-minor factors are polynomials and its only negative powers are powers of the nonzero determinant. Since $m(1) = 1$, positivity of Haar measure on nonempty open sets gives $D > 0$. The map $k \mapsto \overline{m(k)}\pi(k)x$ is continuous on the compact group K, hence Bochner integrable. If $x = 0$, the averaging assertion is immediate. Assume from now on that $x \neq 0$.

Positivity of the form forces compact dominance. Differentiate

$$B(\pi(\exp(tY))\iota(w), \pi(\exp(tY))\iota(w')) = B(\iota(w), \iota(w'))$$

at zero for $Y^*J + JY = 0$. This yields

$$B(\iota(\rho(Y)w), \iota(w')) + B(\iota(w), \iota(\rho(Y)w')) = 0.$$

For $s_a = s_b$, the matrices $E_{ab} - E_{ba}$ and $i(E_{ab} + E_{ba})$ are in this real Lie algebra. Taking their two identities and using conjugate linearity in the first variable gives

$$B(\iota(\rho(E_{ab})w), \iota(w')) = B(\iota(w), \iota(\rho(E_{ba})w')).$$

Fix $l_a > l_b$ in a sign block. The highest-vector equation and $[E_{ab}, E_{ba}] = E_{aa} - E_{bb}$ therefore give

$$0 \le B(\iota(\rho(E_{ba})v), \iota(\rho(E_{ba})v)) = B(x, \iota(\rho(E_{ab})\rho(E_{ba})v)) = (\nu_a - \nu_b)B(x, x).$$

As $B(x, x) > 0$, this proves (i).

The highest vector lies in one compact irreducible module. This argument does not require the norm of X to come from B. Complete X for the norm $B(y, y)^{1/2}$, and denote this Hilbert space by $\mathcal{H}$. The natural map $X \to \mathcal{H}$ is continuous and injective, since B is continuous and positive definite. The operators $\pi(k)$ extend to unitary operators $U(k)$ on $\mathcal{H}$. Strong continuity first holds on the image of X and then on $\mathcal{H}$, by density and $\|U(k)\| = 1$. The derivative hypothesis passes to $\mathcal{H}$.

For completeness, the compact-type decomposition needed here follows from the quoted Peter–Weyl statement for class functions, without assuming completeness for the norm defined by B. Choose one representative of each irreducible unitary isomorphism class of K. For such a finite-dimensional representation σ, of dimension d_σ, set

$$P^\sigma_{ij} = d_\sigma \int_K \overline{\sigma_{ij}(k)}\,U(k)\,dk, \qquad P_\sigma = \sum_i P^\sigma_{ii}.$$

These are strong operator integrals. Schur orthogonality gives

$$P^\sigma_{ij}P^\tau_{ab} = \begin{cases} \delta_{ja}P^\sigma_{ib}, & \sigma \simeq \tau, \\ 0, & \sigma \not\simeq \tau, \end{cases} \qquad U(h)P^\sigma_{ij} = \sum_a \sigma_{ai}(h)P^\sigma_{aj}.$$

These identities can be obtained directly by substituting $k = h^{-1}g$ in the double integrals: the average of a linear map between irreducible unitary spaces is an intertwiner, hence is zero between inequivalent representations and is its trace divided by d_σ times the identity on one

irreducible space. Also $(P^\sigma_{ij})^* = P^\sigma_{ji}$. Thus P_σ is an orthogonal projection, commutes with $U(K)$, and the orbit of $P_\sigma y$ lies in the finite span of the vectors $P^\sigma_{ij} y$.

The highest-weight classification for $K \cong \mathrm{U}(\#I_+) \times \mathrm{U}(\#I_-)$ ([163], compact-group highest-weight theory) now applies to that finite-dimensional orbit. Since P_σ commutes with $U(K)$, it commutes with the infinitesimal action on every vector where the latter is defined, and hence with its complex-linear extension. Therefore $P_\sigma x$ has weight ν and is killed by the compact raising operators. In an irreducible compact module a nonzero vector with these properties has its highest weight; consequently $P_\sigma x = 0$ unless σ has highest weight ν. Such an irreducible representation exists by the tensor construction below and is unique by highest-weight classification; denote it by σ_ν.

Here is the completeness step. Put $y = x - P_{\sigma_\nu} x$ in $\mathcal{H}$, so $P_\sigma y = 0$ for every σ. The continuous class function

$$H(k) = \int_K \langle y, U(hkh^{-1}) y \rangle_{\mathcal{H}} \, dh$$

has zero inner product with every irreducible character: invariance of the character and Fubini reduce that inner product to $d_\sigma^{-1} \langle y, P_\sigma y \rangle_{\mathcal{H}} = 0$. By Peter–Weyl for class functions ([163], Chapter I, §5), $H = 0$ almost everywhere. A continuous function zero almost everywhere for Haar measure on a compact group is identically zero, since every nonempty open set has positive measure. Hence $0 = H(1) = \|y\|^2_{\mathcal{H}}$ and $x = P_{\sigma_\nu} x$.

The integrals defining $P^\sigma_{ij} x$ also exist in X, because their integrands are continuous on K. Injectivity of $X \to \mathcal{H}$ transfers the preceding equality to X. Thus the cyclic K-module generated by x is finite-dimensional, is of highest weight ν, and is irreducible: in an isotypic sum its highest vectors are $h_\nu \otimes b$, and the orbit of any such vector spans $\sigma_\nu \otimes \mathbb{C} b$.

We identify its normalized highest coefficient explicitly. In a sign block with indices $i_1, \dots, i_p$ in decreasing l order and dominant entries $\nu_1 \geq \cdots \geq \nu_p$, take the tensor product of $\det^{\nu_p}$ with

$$\bigotimes_{j=1}^{p-1} \left(\bigwedge^j \mathbb{C}^p \right)^{\otimes(\nu_j - \nu_{j+1})} .$$

The tensor of the vectors $e_{i_1} \wedge \cdots \wedge e_{i_j}$ and the determinant vector is a unit highest vector. Its weight is ν, and its matrix coefficient is $\det(k)^{\nu_p} \prod_{j<p} \Delta_{\{i_1,\dots,i_j\}}(k)^{\nu_j - \nu_{j+1}}$. Take the tensor product over the two sign blocks, omitting an empty block. The displayed coefficient is precisely $m_\nu(k)$: principal minors of a block-diagonal matrix split over the two blocks, so the defining level-set product for m_ν gives these two products. The highest-weight space of this tensor product at weight ν is one-dimensional; its cyclic submodule is therefore the irreducible highest-weight module of weight ν, by finite-dimensional complete reducibility and highest-weight classification.

It follows that in a unitary realization of σ_ν, with unit highest vector h_ν, one has $m(k) = \langle h_\nu, \sigma_\nu(k) h_\nu \rangle$. Schur orthogonality, or the matrix-unit calculation above with h_ν as the first basis vector, gives $D = 1/d_{\sigma_\nu}$ and $\int_K \overline{m(k)} \sigma_\nu(k) h_\nu \, dk = D h_\nu$. Apply this on the cyclic module of x to obtain the asserted identity. □

Theorem 6.4.32. *Let $j \in \{\pm 1\}^n$, $K = K_j \cong \mathrm{U}(p(j)) \times \mathrm{U}(q(j))$, $\mathfrak{k}_{\mathbb{C}} = \{Y \in M_n(\mathbb{C}) : Y J_j = J_j Y\}$ (the complexified Lie algebra of K, spanned by the matrix units E_{ab} with $j_a = j_b$) and $K_{\mathbb{C}} = \{y \in \mathrm{GL}_n(\mathbb{C}) : y J_j = J_j y\} \cong \mathrm{GL}_{p(j)}(\mathbb{C}) \times \mathrm{GL}_{q(j)}(\mathbb{C})$. For a finite-dimensional continuous representation (τ, W) of K let $d\tau$ be its differential, extended complex-linearly to $\mathfrak{k}_{\mathbb{C}}$, and for $\eta \in \mathbb{Z}^n$ put $W(\eta) = \{x \in W : d\tau(E_{aa}) x = \eta_a x \text{ for all } a\}$. Let Q^+ be the set of nonnegative integer combinations of the vectors $e_a - e_b$ with $a < b$, $j_a = j_b$.*

1. *(Weights.) $W = \bigoplus_\eta W(\eta)$, and $d\tau(E_{ab}) W(\eta) \subseteq W(\eta + e_a - e_b)$ for $j_a = j_b$. W is a direct sum of irreducible subrepresentations. If W is irreducible, there is a unique $\mu \in \mathbb{Z}^n$, its*

highest weight, such that $W(\mu) \neq 0$ and $d\tau(E_{ab})W(\mu) = 0$ for all $a < b$ with $j_a = j_b$; then $\dim W(\mu) = 1$, W is spanned by $\tau(K)W(\mu)$, and $\mu - \eta \in Q^+$ for every η with $W(\eta) \neq 0$. Two irreducible representations are isomorphic if and only if their highest weights agree.

2. *(Brauer–Klimyk.) If W is irreducible with highest weight μ and U is a finite-dimensional continuous representation of K, every irreducible subrepresentation of $W \otimes U$ has highest weight $\mu + \omega$ for some ω with $U(\omega) \neq 0$.*

3. *(Holomorphic extension.) τ extends uniquely to a holomorphic representation $\tilde{\tau}$ of $K_{\mathbb{C}}$, with $\tilde{\tau}(e^Y) = e^{d\tau(Y)}$ for $Y \in \mathfrak{k}_{\mathbb{C}}$. If τ is unitary for an inner product on W, then $\tilde{\tau}(y^*) = \tilde{\tau}(y)^*$ for all $y \in K_{\mathbb{C}}$.*

Proof. The highest-weight theorem for a compact connected Lie group is [164], Theorem 5.110 and the properties in Theorem 5.5; complete reducibility is Corollary 4.7. Apply them to $K = \mathrm{U}(p) \times \mathrm{U}(q)$. Its torus characters are exactly $\mathrm{diag}(e^{i\theta_a}) \mapsto e^{i\sum_a \eta_a \theta_a}$ with $\eta \in \mathbb{Z}^n$. Their differentials give $d\tau(E_{aa}) = \eta_a$ on the corresponding spaces. The bracket $[E_{cc}, E_{ab}] = (\delta_{ca} - \delta_{cb})E_{ab}$ gives the weight shift. The positive roots in the two factors are exactly the stated $e_a - e_b$; the highest-weight theorem therefore gives all of item 1, including the cone Q^+ and the one-dimensional highest-weight space. Its orbit spans by irreducibility. An empty block contributes the trivial group and no roots.

For two irreducible factors the tensor-constituent assertion is precisely [164], Proposition 9.72, printed p.598. Decompose U into irreducibles by Corollary 4.7 and apply that proposition to each direct summand of $W \otimes U$. Every constituent lies in such a summand: its projections to the summands are intertwining maps, and a nonzero projection is injective on an irreducible constituent. This proves item 2.

We supply the extension and adjoint deductions explicitly. Complexify $d\tau$ and integrate it on the simply connected covering group of $K_{\mathbb{C}}$, using Lie-algebra integration. The resulting homomorphism is holomorphic because its differential is complex-linear. Polar decomposition gives a deformation retraction $K_{\mathbb{C}} \to K$; hence the inclusion induces an isomorphism on fundamental groups. The inverse image of K in the simply connected covering group is its connected simply connected cover. On it the integrated homomorphism equals the pullback of τ, since both have the same differential on its real Lie algebra and the group is connected. In particular it is trivial on the covering kernel, which is contained in this inverse image. It descends to a holomorphic representation $\widetilde{\tau}$ on $K_{\mathbb{C}}$. Uniqueness follows since its differential is forced to be the complexification of $d\tau$, and a homomorphism on a connected Lie group is determined by its differential. The exponential identity follows from integration on one-parameter subgroups. These are the usual complexification construction; see [164], Chapter I, Sections 11–12, and Chapter VII, Section 1.

If τ is unitary and $H = H^*$ lies in $\mathfrak{k}_{\mathbb{C}}$, then iH lies in the compact Lie algebra, so $d\tau(iH)$ is skew-adjoint. Complex linearity gives $d\tau(H) = d\tau(iH)/i$, which is self-adjoint. Write $y = k \exp H$ by blockwise polar decomposition. Then

$$\widetilde{\tau}(y^*) = e^{d\tau(H)}\tau(k)^{-1} = \big(\tau(k)e^{d\tau(H)}\big)^* = \widetilde{\tau}(y)^*.$$

This proves item 3 without an unstated analytic continuation principle. □

Lemma 6.4.33. *Give K Haar probability measure dk, and fix a Haar measure dg on G. Assume $A \in \mathbb{N}$, and let $l \in \mathbb{Z}^n$ have gap $500N^3 + A$ for ε. Put $\lambda = l/2$ and*

$$e_\lambda(g) = d_\lambda \overline{c_\lambda(g)}, \qquad d_\lambda = \left(\int_G |c_\lambda(g)|^2 \, dg \right)^{-1}.$$

Then the Bochner integral

$$T_\lambda x = \int_G e_\lambda(g)\pi(g)x\,dg$$

exists for every $x \in X$ and defines a bounded linear operator. Let $\nu \in \mathbb{Z}^n$ and let $v \in M$ be K-highest of weight ν for l, meaning

$$\rho(E_{aa})v = \nu_a v, \qquad \rho(E_{ab})v = 0 \quad (\varepsilon_a = \varepsilon_b,\ l_a > l_b).$$

If there is $o \in \mathbb{Z}^n$ such that $o_a < o_b$ whenever $l_a > l_b$ and

$$\sum_{a\in n} o_a(\nu_a - \mu_l(a)) > 0,$$

then

$$T_\lambda \pi(y)\iota(v) = 0 \quad (y \in G), \qquad T_\lambda \iota(\rho(Y)v) = 0 \quad (Y \in \mathfrak{gl}_n(\mathbb{C})).$$

Proof. **The weighted moment defines a bounded operator.** Apply Lemma 6.4.28(i): the same Banach representation, invariant form, integer growth exponent A, Haar measure and gap $500N^3 + A$ supply all its hypotheses. Enumerating the finite index set preserves these data and the operator norm. It gives

$$Q_A := \int_G |e_\lambda(g)|\|g\|^A\,dg < \infty, \qquad T_\lambda x = \int_G e_\lambda(g)\pi(g)x\,dg, \qquad \|T_\lambda\| \le C_\pi Q_A.$$

The last inequality follows by integrating the given growth bound.

Compact averaging reproduces the highest vector. Put $u = \iota(v)$. If $u = 0$, the orbit assertion is immediate, and the derivative argument below also applies. Suppose $u \neq 0$. Apply Lemma 6.4.31 with the signs ε, the order given by l, and the representation, Hermitian form, module and map (π, B, M, ρ, ι) of the statement. The entries of l are distinct by its gap hypothesis. The strong continuity, continuity and positivity of B, invariance of B and norm-derived action required there are exactly the hypotheses stated here. No compact-finiteness hypothesis is imposed. The lemma proves

$$\nu_a \ge \nu_b \quad (\varepsilon_a = \varepsilon_b,\ l_a > l_b)$$

and the Banach-valued averaging identity

$$\int_K \overline{m_\nu(k)}\,\pi(k)u\,dk = a_\nu u, \qquad a_\nu = \int_K |m_\nu(k)|^2\,dk > 0. \tag{1}$$

For later use, $m_\nu(k^{-1}) = \overline{m_\nu(k)}$: since $k^{-1} = k^*$, each principal minor and the determinant in the defining product for m_ν is conjugated.

The same average annihilates the shifted kernel. The dominance just proved and the assumed vector o are exactly the hypotheses of Lemma 5.6.31(ii). Thus, for every $h, y \in G$,

$$\int_K \overline{m_\nu(k)}\,c_\lambda(hky^{-1})\,dk = 0.$$

Invert k in the Haar probability measure and use the preceding identity for $m_\nu(k^{-1})$ and the definition of e_λ. Since d_λ is real, this gives

$$\int_K \overline{m_\nu(k)}\,e_\lambda(hk^{-1}y^{-1})\,dk = d_\lambda \overline{\int_K \overline{m_\nu(k)}c_\lambda(hky^{-1})\,dk} = 0. \tag{2}$$

Fix $y \in G$. Equation (1), boundedness of T_λ and the representation law imply

$$a_\nu T_\lambda \pi(y)u = \int_K \int_G \overline{m_\nu(k)} e_\lambda(g)\pi(gyk)u \, dg \, dk.$$

This is an absolutely integrable Banach-valued double integral. Indeed, $\|k\| = 1$ and submultiplicativity give the upper bound

$$C_\pi \|u\| \|y\|^A \left(\int_K |m_\nu(k)| \, dk \right) \left(\int_G |e_\lambda(g)| \|g\|^A \, dg \right) < \infty$$

for its integral of norms. The group $G = \mathrm{U}(J)$ is unimodular, so for fixed k the substitution $h = gyk$ preserves dg. The resulting double integral is still absolutely integrable. Fubini and (2) give

$$a_\nu T_\lambda \pi(y)u = \int_G \left(\int_K \overline{m_\nu(k)} e_\lambda(hk^{-1}y^{-1}) \, dk \right) \pi(h)u \, dh = 0.$$

As $a_\nu > 0$, this proves the orbit assertion. The sign of the separating inequality has not changed: it is $o \cdot (\nu - \mu_l) > 0$, with o reversing the order of l.

Differentiate the zero orbit and complexify. For $Z^*J + JZ = 0$, the function $t \mapsto T_\lambda \pi(\exp(tZ))u$ is identically zero by the orbit assertion. The assumed derivative formula and boundedness of T_λ therefore give $T_\lambda \iota(\rho(Z)v) = 0$. For an arbitrary complex matrix Y put

$$Z_1 = (Y - JY^*J)/2, \qquad Z_2 = (Y + JY^*J)/(2\mathrm{i}).$$

Both satisfy $Z_r^* J + JZ_r = 0$, and $Y = Z_1 + \mathrm{i}Z_2$. Complex linearity of ρ, ι and T_λ proves the asserted vanishing for every Y. □

Lemma 6.4.34. *Let dg be a Haar measure on G. Assume $A \in \mathbb{N}$, and let $l \in \mathbb{Z}^n$ have large gap A; put $\lambda = l/2$, $d_\lambda = (\int_G |c_\lambda(g)|^2 \, dg)^{-1}$, $e_\lambda = d_\lambda \overline{c_\lambda}$, and*

$$\kappa_l = \frac{1}{4} \sum_{a=1}^{n} (l_a^2 - (2\rho_l(a))^2).$$

There is a complex linear map

$$P : \mathcal{H}_{c_{-\lambda}} \longrightarrow \mathcal{L}(X), \qquad P(f)w = d_\lambda \int_G f(g)\pi(g)w \, dg,$$

where each displayed integral is a Bochner integral and each $P(f)$ is bounded. It satisfies

$$P(c_{-\lambda}) = \pi(e_\lambda), \qquad P(f)\iota(\rho(Z)v) = -P(Zf)\iota(v) \quad (Z \in \mathfrak{gl}_n(\mathbb{C}),\ f \in \mathcal{H}_{c_{-\lambda}},\ v \in M),$$

where

$$\pi(e_\lambda)w = \int_G e_\lambda(g)\pi(g)w \, dg.$$

Consequently, with E_{ab} the matrix units and $\Omega_\rho = \sum_{a,b} \rho(E_{ab})\rho(E_{ba})$,

$$\pi(e_\lambda)\iota(\Omega_\rho v) = \kappa_l \, \pi(e_\lambda)\iota(v) \qquad (v \in M).$$

Proof. Write $c_0 = c_{-\lambda}$, $\mathcal{H} = \mathcal{H}_{c_0}$, and $h = 500n^3 + A$. The parameter $-l$ has the same gap h, and $h > 8n^2$. The group G is unimodular, so dg is invariant under right as well as left translations. Also $g^{-1} = Jg^*J$, whence $\|g^{-1}\| = \|g\| \geq 1$.

Every function in the cyclic module has the required moments. Set $r = A + 8n^2 + 1$. Since $n \geq 1$, $r \leq h$. By Lemma 5.7.38(1), applied to $-l$,

$$|c_0(g)| \leq (2/\|g\|)^r.$$

Part (3) of that lemma, with exponent $r - A = 8n^2 + 1$ and $L = \max_a |l_a|$, shows that $(2/\|g\|)^{r-A}$ is integrable; the positive formal degree can be divided out. By Lemma 5.7.36(ii), for every $f \in \mathcal{H}$ there is a smooth compactly supported φ_f with

$$f(g) = \int_G \varphi_f(y) c_0(gy)\, dy.$$

The inequality $\|g\| \leq \|gy\|\|y^{-1}\|$ gives

$$|f(g)| \leq K_f (2/\|g\|)^r, \qquad K_f = \int_G |\varphi_f(y)|\, \|y^{-1}\|^r\, dy < \infty. \tag{1}$$

Consequently

$$I_f := \int_G |f(g)| \|g\|^A\, dg \leq K_f 2^A \int_G (2/\|g\|)^{r-A}\, dg < \infty. \tag{2}$$

The same conclusions hold for Zf, for every complex matrix Z, since $\mathcal{H}$ is stable under complexified right derivatives by Lemma 5.7.36(ii). These functions are smooth by Lemma 5.6.24(i),(ii).

Vector integration defines the bounded operators. For fixed $f \in \mathcal{H}$ and $w \in X$, the vector-valued function $g \mapsto f(g)\pi(g)w$ is continuous and has norm at most $C_\pi |f(g)| \|g\|^A \|w\|$. It is strongly measurable: G is second countable, and a continuous image of G has separable range. Thus (2) makes its Bochner integral well defined. Define $P(f)$ by the formula in the statement. Linearity of the integral gives linearity in w, and

$$\|P(f)w\| \leq d_\lambda C_\pi I_f \|w\|.$$

Here $d_\lambda > 0$ by Lemma 5.7.38(3). Thus $P(f)$ is a bounded operator. Linearity of the integral also gives complex linearity of $f \mapsto P(f)$. This construction integrates vectors; it does not require the map $g \mapsto \pi(g)$ to be measurable for the operator norm. By Lemma 5.6.29(ii), $c_0 = \overline{c_\lambda}$, so $d_\lambda c_0 = e_\lambda$ and $P(c_0) = \pi(e_\lambda)$.

Right translation proves integration by parts without a boundary term. First let $Z \in \mathfrak{u}(J)$, $f \in \mathcal{H}$, and $v \in M$. Define continuous X-valued functions

$$F(g) = f(g)\pi(g)\iota(v), \qquad Q(g) = (Zf)(g)\pi(g)\iota(v) + f(g)\pi(g)\iota(\rho(Z)v).$$

Both are Bochner integrable by (2). The derivative hypothesis at 0, the representation law, and $e^{(t+s)Z} = e^{tZ}e^{sZ}$ give, for every $g \in G$ and $t \in \mathbb{R}$,

$$\frac{d}{dt}\pi(ge^{tZ})\iota(v) = \pi(ge^{tZ})\iota(\rho(Z)v).$$

By the right-derivative identity in Lemma 5.6.24(i) and the product rule,

$$\frac{d}{dt}F(ge^{tZ}) = Q(ge^{tZ}). \tag{3}$$

The derivative is continuous in t.

For completeness, (3) has a common integrable bound for $0 \le t \le 1$. Put

$$D_Z = \max_{0\le t\le 1} \max(\|e^{tZ}\|, \|e^{-tZ}\|),$$

which is finite and at least 1. For $u = f$ or $u = Zf$, (1) and $\|g\| \le \|ge^{tZ}\| D_Z$ imply

$$|u(ge^{tZ})| \le K_u D_Z^r (2/\|g\|)^r, \qquad \|\pi(ge^{tZ})\| \le C_\pi D_Z^A \|g\|^A.$$

Hence $\|Q(ge^{tZ})\|$ is bounded by

$$C_\pi D_Z^{r+A} 2^A \big(K_{Zf}\|\iota(v)\| + K_f \|\iota(\rho(Z)v)\|\big)(2/\|g\|)^{r-A},$$

an integrable function of g. Thus the Banach-valued fundamental theorem of calculus applies pointwise to (3), and Bochner Fubini applies to its integral over $G \times [0,1]$. Right invariance gives

$$\begin{aligned}\int_G Q(g)\,dg &= \int_0^1 \int_G Q(ge^{tZ})\,dg\,dt \\ &= \int_G \int_0^1 Q(ge^{tZ})\,dt\,dg \\ &= \int_G (F(ge^Z) - F(g))\,dg = 0.\end{aligned}$$

The last two integrals exist by the integrability of F and right invariance. Multiplication by d_λ now gives

$$P(f)\iota(\rho(Z)v) = -P(Zf)\iota(v). \tag{4}$$

No differentiation of an improper integral or unproved vanishing at infinity has been used.

Every $Z \in \mathfrak{gl}_n(\mathbb{C})$ has the decomposition

$$Z = Z_1 + iZ_2, \quad Z_1 = \tfrac{1}{2}(Z - JZ^*J), \quad Z_2 = \tfrac{1}{2i}(Z + JZ^*J), \qquad Z_1, Z_2 \in \mathfrak{u}(J).$$

The action ρ, ι, P, and the complexified right derivative are complex linear. Applying (4) to Z_1, Z_2 therefore proves it for every complex matrix Z.

Two integrations by parts give the Casimir eigenvalue. For every a, b, apply (4) first with $f = c_0$, $Z = E_{ab}$, and v replaced by $\rho(E_{ba})v$, and then with $f = E_{ab}c_0$, $Z = E_{ba}$:

$$P(c_0)\iota(\rho(E_{ab})\rho(E_{ba})v) = P\big(E_{ba}(E_{ab}c_0)\big)\iota(v).$$

Summing and interchanging the finite indices a, b on the right yields

$$\pi(e_\lambda)\iota(\Omega_\rho v) = P\left(\sum_{a,b} E_{ab}(E_{ba}c_0)\right)\iota(v).$$

By Lemma 5.7.36(v), applied to $-l$, the function in parentheses is $\kappa_{-l}c_0$. Since $2\rho_{-l} = -2\rho_l$, the displayed formula for the Casimir value gives $\kappa_{-l} = \kappa_l$. Complex linearity of P and $P(c_0) = \pi(e_\lambda)$ prove the final identity. □

Lemma 6.4.35. *Let I, I' be nonempty finite sets with signs s on I and t on I', put $N = \#I$, $N' = \#I'$, and let $\gamma, \gamma' \in \mathbb{Z}$. On $\mathbb{C}[X_{ac} : a \in I', c \in I]$ use the row and column units with shifts $(\gamma, -\gamma')$. Put*

$$c_{\mathrm{row}} = \gamma - \frac{N}{2}, \qquad c_{\mathrm{col}} = -\gamma' + \frac{N'}{2}, \qquad b_{\mathrm{pair}} = \frac{NN'(N'-N)}{4}.$$

For $w \in \mathbb{C}$ define

$$\mathrm{Cas}_{\mathrm{row}}(w) = \sum_{a,a' \in I'} (E^{\mathrm{row}}_{aa'} - w\delta_{aa'}\mathrm{id})(E^{\mathrm{row}}_{a'a} - w\delta_{a'a}\mathrm{id}),$$
$$\mathrm{Cas}_{\mathrm{col}}(w) = \sum_{c,c' \in I} (E^{\mathrm{col}}_{cc'} - w\delta_{cc'}\mathrm{id})(E^{\mathrm{col}}_{c'c} - w\delta_{c'c}\mathrm{id}),$$

where multiplication means composition of operators. For either $J = I$ or $J = I'$, with its given signs, and an integer parameter l on J, put

$$\kappa_l = \frac{1}{4}\sum_{j \in J}(l(j)^2 - (2\rho_l(j))^2), \qquad \kappa_l(w) = \kappa_l - 2w\sum_{j \in J}\mu_l(j) + \#J\, w^2.$$

Then:

1. *The following identity holds on every polynomial:*

$$\mathrm{Cas}_{\mathrm{col}}(c_{\mathrm{col}}) = \mathrm{Cas}_{\mathrm{row}}(c_{\mathrm{row}}) + b_{\mathrm{pair}}\mathrm{id}.$$

2. *If l has gap 0, then for every $w \in \mathbb{C}$,*

$$\kappa_l(w) = \sum_{j \in J}\left(\frac{l(j)}{2} - w\right)^2 - \frac{\#J((\#J)^2 - 1)}{12}.$$

3. *If $\lambda : I \to \mathbb{Z}$ and $\lambda' : I' \to \mathbb{Z}$ satisfy the block rule for (γ, γ') and (s, t), then*

$$\kappa_{-\lambda}(c_{\mathrm{col}}) = \kappa_{\lambda'}(c_{\mathrm{row}}) + b_{\mathrm{pair}}.$$

Proof. **The two operator sums have the same nonconstant terms.** Composition of polynomial operators satisfies

$$\mathrm{lo}_{ac}\mathrm{ra}_{bd} = \mathrm{ra}_{bd}\mathrm{lo}_{ac} + \delta_{ab}\delta_{cd}\mathrm{id}.$$

For a positive variable this is the product rule $\partial(XP) = X\partial P + P$; for a negative variable it is $X(-\partial P) = -\partial(XP) + P$. Operators belonging to different variables commute. In particular all the raising operators commute with one another, as do all the lowering operators.

Put, only within this proof,

$$D_2 = \sum_{a,c}\mathrm{ra}_{ac}\mathrm{lo}_{ac}, \qquad D_4 = \sum_{a,b,c,d}\mathrm{ra}_{ac}\mathrm{ra}_{bd}\mathrm{lo}_{bc}\mathrm{lo}_{ad}.$$

The defining row units give

$$E^{\mathrm{row}}_{ab} - c_{\mathrm{row}}\delta_{ab}\mathrm{id} = \sum_{c}\mathrm{ra}_{ac}\mathrm{lo}_{bc} + \frac{N}{2}\delta_{ab}\mathrm{id}.$$

For the column units, commuting the lowering operator past the raising operator gives

$$E^{\mathrm{col}}_{cd} = -\sum_{a}\mathrm{ra}_{ad}\mathrm{lo}_{ac} - \gamma'\delta_{cd}\mathrm{id}, \qquad E^{\mathrm{col}}_{cd} - c_{\mathrm{col}}\delta_{cd}\mathrm{id} = -\left(\sum_{a}\mathrm{ra}_{ad}\mathrm{lo}_{ac} + \frac{N'}{2}\delta_{cd}\mathrm{id}\right).$$

Indeed each diagonal term in the commutation contributes 1, so the N' such terms cancel the $+N'$ in the defining column shift.

For the row sum, the only interchange required to put each product in normal order is

$$\mathrm{ra}_{ac}\mathrm{lo}_{bc}\mathrm{ra}_{bd}\mathrm{lo}_{ad} = \mathrm{ra}_{ac}\mathrm{ra}_{bd}\mathrm{lo}_{bc}\mathrm{lo}_{ad} + \delta_{cd}\mathrm{ra}_{ac}\mathrm{lo}_{ad}.$$

Summing the second term over a, b, c, d gives $N'D_2$: setting $d = c$ leaves the free row index b, with N' choices. The two cross terms from the added scalar $N/2$ give ND_2, and the product of the two scalars gives $N'N^2/4$ copies of the identity. Consequently

$$\mathrm{Cas}_{\mathrm{row}}(c_{\mathrm{row}}) = D_4 + (N + N')D_2 + \frac{N'N^2}{4}\mathrm{id}. \tag{1}$$

For the column sum the two minus signs cancel. Its product without the diagonal scalars expands into

$$\sum_{c,d,a,b} \mathrm{ra}_{ad}\mathrm{lo}_{ac}\mathrm{ra}_{bc}\mathrm{lo}_{bd} = \sum_{c,d,a,b} \mathrm{ra}_{ad}\mathrm{ra}_{bc}\mathrm{lo}_{ac}\mathrm{lo}_{bd} + \sum_{c,d,a} \mathrm{ra}_{ad}\mathrm{lo}_{ad}.$$

The last sum is ND_2, because c is free. In the first sum exchange c, d and then commute the two lowering operators. It becomes exactly D_4. The scalar cross terms now give $N'D_2$, and the scalar product gives $N(N')^2/4$ copies of the identity. Thus

$$\mathrm{Cas}_{\mathrm{col}}(c_{\mathrm{col}}) = D_4 + (N + N')D_2 + \frac{N(N')^2}{4}\mathrm{id}. \tag{2}$$

Subtracting (1) from (2) proves (i). All sums here are finite and all equalities are identities of operators on the full polynomial ring; no harmonicity assumption is used.

The centering of a parameter gives the stated quadratic value. First note the elementary operator identity, valid for any square family of operators indexed by a finite set J:

$$\sum_{i,j}(E_{ij} - w\delta_{ij}\mathrm{id})(E_{ji} - w\delta_{ji}\mathrm{id}) = \sum_{i,j} E_{ij}E_{ji} - 2w\sum_i E_{ii} + \#J\, w^2\mathrm{id}.$$

Both mixed sums are $-w\sum_i E_{ii}$, since their Kronecker symbols force $i = j$. On a vector of diagonal weight μ_l and full Casimir value κ_l, this identity gives precisely $\kappa_l(w)$.

Write $r = \#J$ and order the distinct entries of l increasingly as $l(j_0) < \cdots < l(j_{r-1})$. By the definition of the two counts,

$$2\rho_l(j_b) = 2b - r + 1 \quad (0 \le b < r).$$

The identities $\sum_{b=0}^{r-1} b = r(r-1)/2$ and $\sum_{b=0}^{r-1} b^2 = r(r-1)(2r-1)/6$ therefore give

$$\sum_{j\in J}(2\rho_l(j))^2 = 4\frac{r(r-1)(2r-1)}{6} - 4(r-1)\frac{r(r-1)}{2} + r(r-1)^2 = \frac{r(r^2-1)}{3}. \tag{3}$$

The gap-zero parity condition makes $l(j) + 2\rho_l(j)$ even, because both summands are congruent to $r - 1$ modulo 2. Thus the integer part in l^ρ is exact, and $\mu_l(j) = l(j)/2 + \rho_l(j) - 2\rho_l^{\mathrm{c}}(j)$. The sums of the entries of $2\rho_l$ and of $2\rho_l^{\mathrm{c}}$ are both zero: in their double sums the contribution of the ordered pair (i, j) is the negative of that of (j, i), and equality of signs is a symmetric condition. Hence

$$2\sum_j \mu_l(j) = \sum_j l(j). \tag{4}$$

Substituting (3)–(4) into the definition of $\kappa_l(w)$, and expanding each square, gives

$$\kappa_l(w) = \frac{1}{4}\sum_j l(j)^2 - \frac{r(r^2-1)}{12} - w\sum_j l(j) + rw^2 = \sum_j (l(j)/2 - w)^2 - \frac{r(r^2-1)}{12}.$$

This proves (ii) for every complex w.

The unmatched entries account for the entire scalar difference. Assume the block rule. Use its shifted entries

$$\widetilde{\lambda}'(a) = \lambda'(a) - 2\gamma + N, \qquad \widetilde{\lambda}(c) = \lambda(c) - 2\gamma' + N'.$$

They are injective on their respective index sets. The matching of Lemma 6.4.20(a) is a partial bijection, with equal shifted entries at each matched pair.

Suppose first that $N' \geq N$, and put $d = N' - N$. Every column is matched: an unmatched column would have $|\widetilde{\lambda}(c)| < N - N' = -d$, which is impossible. There are therefore exactly d unmatched rows. Each has $|\widetilde{\lambda}'(a)| < d$ by the same lemma. Its shifted entry is congruent to $d-1$ modulo 2, since

$$\lambda'(a) - 2\gamma + N \equiv N' - 1 + N \equiv N' - N - 1 \pmod 2.$$

If $d = 0$ there are no unmatched rows. If $d > 0$, the integers of that parity and modulus below d are exactly $d-1, d-3, \ldots, 1-d$, a set of cardinality d. The d unmatched entries are distinct, so they fill this set. Cancelling the equal squares at matched pairs gives

$$\sum_a \widetilde{\lambda}'(a)^2 - \sum_c \widetilde{\lambda}(c)^2 = \sum_{b=0}^{d-1} (d - 1 - 2b)^2 = \frac{d(d^2-1)}{3}. \tag{5}$$

The last equality follows by the two finite-sum formulas used in (3); it also holds for $d = 0$.

If $N' < N$, the same argument with the index sets exchanged gives $\sum_c \widetilde{\lambda}(c)^2 - \sum_a \widetilde{\lambda}'(a)^2 = (N - N')((N-N')^2 - 1)/3$. Negating it gives (5) with the signed integer $d = N' - N$. Thus (5) holds in both rank orders.

Finally,

$$\lambda'(a)/2 - c_{\mathrm{row}} = \widetilde{\lambda}'(a)/2, \qquad -\lambda(c)/2 - c_{\mathrm{col}} = -\widetilde{\lambda}(c)/2.$$

The block rule supplies gap zero for λ' and $-\lambda$, so (ii) applies to both. Using (5) gives

$$\begin{aligned} \kappa_{\lambda'}(c_{\mathrm{row}}) - \kappa_{-\lambda}(c_{\mathrm{col}}) &= \frac{d(d^2-1) - N'((N')^2-1) + N(N^2-1)}{12} \\ &= \frac{d^3 - (N')^3 + N^3}{12} = -\frac{NN'd}{4}. \end{aligned}$$

Here the last equality is the expansion of $d = N' - N$. Rearranging proves (iii), with exactly the scalar in (i). □

Theorem 6.4.36. *Assume $A \in \mathbb{N}$, and let $l \in \mathbb{Z}^n$ have large gap A for $\varepsilon \in \{\pm 1\}^n$. Put*

$$\kappa_l = \frac{1}{4}\sum_a (l_a^2 - (2\rho_l(a))^2), \quad d_l = \left(\int_G |c_{l/2}(g)|^2\, dg\right)^{-1}, \quad e_l(g) = d_l\, \overline{c_{l/2}(g)}.$$

Write $\Omega = \sum_{a,b} \rho(E_{ab})\rho(E_{ba})$. Suppose $v \in M$ satisfies

$$\rho(E_{aa})v = \mu_l(a)v, \qquad \rho(E_{ab})v = 0 \quad (\varepsilon_a = \varepsilon_b,\ l_a > l_b), \qquad \iota(\Omega v) = c\,\iota(v)$$

for a real number $c \geq \kappa_l$. Then

$$B(\iota(v), \pi(g)\iota(v)) = B(\iota(v), \iota(v))c_{l/2}(g) \qquad (g \in G).$$

Moreover, for every measurable $f : G \to \mathbb{C}$ with $\int_G |f(g)|\|g\|^A\,dg < \infty$ and

$$\int_G f(y)e_l(y^{-1}g)\,dy = e_l(g) \qquad (g \in G),$$

the Bochner integral satisfies

$$\int_G f(g)\pi(g)\iota(v)\,dg = \iota(v).$$

Proof. **The derived action descends to a positive inner product space.** Write $x = \iota(v)$ and $q = B(x, x) \geq 0$. If $x = 0$, both conclusions are immediate, so assume $x \neq 0$. Equip X, for the moment, with the possibly incomplete inner product B; this changes neither its vectors nor its linear maps. Differentiate invariance along $\exp(tY)$, using boundedness of B and the assumed derivative identity. For $Y^*J + JY = 0$ this gives

$$B(\iota(\rho(Y)u), \iota(w)) = -B(\iota(u), \iota(\rho(Y)w)).$$

Complexifying, since every matrix Z decomposes as $Z = (Z - JZ^*J)/2 + i(Z + JZ^*J)/(2i)$ with both summands in the real Lie algebra, yields

$$B(\iota(\rho(Z)u), \iota(w)) = B(\iota(u), \iota(\rho(JZ^*J)w)). \tag{1}$$

If $\iota(u) = 0$, apply (1) with $w = \rho(Z)u$. Positive definiteness implies $\iota(\rho(Z)u) = 0$. Thus the action descends to $\iota(M)$, and restricts to its submodule H_x generated by x. On this pre-Hilbert space its elementary operators have adjoints $E_{ab}^* = \varepsilon_a\varepsilon_b E_{ba}$. The full Casimir is central: expanding $[E_{cd}, \sum_{a,b} E_{ab}E_{ba}]$ gives two sums that cancel term by term. Hence it acts as c on H_x, since it acts as c on its generator. In particular its quadratic form is bounded below by κ_l.

The comparison module has a normalized generator. Let $\mathcal{H}_c$ be the derivative module of $c_{l/2}$ in Lemma 5.7.36, with inner product

$$\langle u, w\rangle_D = d_l \int_G \overline{u(g)}w(g)\,dg.$$

The large gap is greater than $8n^2$, so Lemma 5.6.23 gives $d_l > 0$. Write $b = c_{l/2}$ as an element of this module. By Lemma 5.7.36, $\|b\|_D = 1$, $|u(g)| \leq \|u\|_D$, the adjoints have the same signs, b is highest of weight μ_l, and the full Casimir is κ_l. For every $u \in \mathcal{H}_c$,

$$\langle b, u\rangle_D = u(1). \tag{2}$$

Indeed $u = f_\varphi$ for a compactly supported smooth φ, by that lemma; substitute its integral formula, use Fubini with the bound $|\varphi(y)||b(z)|$, and apply Schur orthogonality in Lemma 5.6.23 with $x = 1$. This gives (2) exactly.

On $H = H_x \oplus \mathcal{H}_c$ take the orthogonal direct sum inner product and the componentwise Lie algebra action. It has the signed adjoints and full Casimir lower bound κ_l. The two vectors

$$z = (x, b), \qquad a = (x, -qb)$$

are highest of weight μ_l, and $\langle a, z\rangle = q - q = 0$.

Compact orthogonality propagates through every filtration level. Let $F_0 = U(\mathfrak{k}_{\mathbb{C}})z$ and $F_{s+1} = F_s + \sum_{i,j} E_{ij}F_s$. Apply Lemma 6.4.37 to the direct-sum module and its highest

vectors z, a. Their common weight is μ_l, the signed adjoints and full Casimir lower bound were checked above, and $\langle a, z\rangle = 0$. Thus

$$a \perp F_s \qquad (s \geq 0). \tag{3}$$

The scalar coefficient difference vanishes. For $g \in G$ define the linear functional on H

$$L_g(u, w) = B(x, \pi(g)u) - q\, w(g).$$

It satisfies the coefficient derivative identity at every real time along every $Y \in \mathfrak{u}(J)$. On the first summand this follows from the representation law and the derivative hypothesis, by shifting the time origin; on the second it is the right derivative of the locally holomorphic functions of Lemma 5.7.36. Moreover, invariance of B, Cauchy–Schwarz and the evaluation bound give

$$|L_g(u, w)| \leq (\sqrt{q} + q)\|(u, w)\|_H$$

uniformly in g. Equations (2) and (3) give $L_1(u, w) = \langle a, (u, w)\rangle = 0$ on every F_s. The coefficient uniqueness assertion of Lemma 6.4.39, applied to z, therefore gives $L_g(z) = 0$ for every g. This is the claimed coefficient identity.

The convolution identity fixes the vector. Strong measurability follows from the continuous orbit map and the measurable scalar f. The growth bound and the moment assumption make $g \mapsto f(g)\pi(g)x$ Bochner integrable. By inversion in Lemma 5.7.40, the assumed convolution identity at g^{-1}, divided by $d_l > 0$, is

$$\int_G f(y) c_{l/2}(gy)\, dy = c_{l/2}(g). \tag{4}$$

All these scalar integrals are absolutely convergent, since $\|y\| \geq 1$ and $|c_{l/2}| \leq 1$. Put $r = \int f(y)\pi(y)x\, dy - x$. For each g, invariance, the coefficient identity and (4) give

$$B(\pi(g)x, r) = q\left(\int_G f(y) c_{l/2}(g^{-1}y)\, dy - c_{l/2}(g^{-1})\right) = 0.$$

Hermitian symmetry gives $B(r, \pi(g)x) = 0$. Boundedness of B permits it to pass through the Bochner integral in its second variable, so

$$B(r, r) = \int_G f(y) B(r, \pi(y)x)\, dy - B(r, x) = 0.$$

Positive definiteness forces $r = 0$, proving the second conclusion. □

Lemma 6.4.37. *Let $n \geq 1$, let $\varepsilon \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have large gap A for an integer $A \geq 0$. Put*

$$\kappa_l = \frac{1}{4}\sum_{i=1}^{n} (l_i^2 - (2\rho_l(i))^2).$$

Let H be a complex pre-Hilbert space, with inner product conjugate-linear in the first variable, and let $\rho : \mathfrak{gl}_n(\mathbb{C}) \to \mathrm{End}_{\mathbb{C}}(H)$ be a Lie algebra representation. Write $D_{ij} = \rho(E_{ij})$ and $\Omega = \sum_{i,j} D_{ij} D_{ji}$. Suppose

$$\langle D_{ij} u, w\rangle = \varepsilon_i \varepsilon_j \langle u, D_{ji} w\rangle, \qquad \mathrm{Re}\langle u, \Omega u\rangle \geq \kappa_l \|u\|^2$$

for all $u, w \in H$ and all i, j. Let $z, a \in H$ satisfy, for $v = z, a$,

$$D_{ii} v = \mu_l(i) v, \qquad D_{ij} v = 0 \quad (\varepsilon_i = \varepsilon_j,\ l_i > l_j).$$

Let $F_0(z)$ be the span of all compact words $D_{i_1j_1}\cdots D_{i_rj_r}z$, where $\varepsilon_{i_\nu}=\varepsilon_{j_\nu}$, including the empty word, and recursively set

$$F_{r+1}(z)=F_r(z)+\sum_{i,j}D_{ij}F_r(z).$$

If $\langle a,z\rangle=0$, then $a\perp F_r(z)$ for every integer $r\ge 0$.

Proof. Write $\mu=\mu_l$, $r_i=2\rho_l^{\mathrm{c}}(i)$, $R_i=2\rho_l(i)$ and

$$C_K=\sum_{\varepsilon_i=\varepsilon_j}D_{ij}D_{ji},\qquad q(\nu)=\sum_i\nu_i(\nu_i+r_i),\qquad q_0=q(\mu).$$

All compact sums below run over ordered pairs (i,j) with $\varepsilon_i=\varepsilon_j$. The matrix-unit commutator is

$$[D_{ij},D_{pq}]=\delta_{jp}D_{iq}-\delta_{qi}D_{pj}. \tag{1}$$

Here and below the adjoint of a matrix unit means the algebraic adjoint $D_{ij}^*=\varepsilon_i\varepsilon_jD_{ji}$, defined on all of H; no completeness or boundedness of these units is required. For a fixed compact unit $X=D_{ij}$, expansion of its commutator with C_K gives four sums:

$$\begin{aligned}[X,C_K]=&\sum_{\varepsilon_q=\varepsilon_j}D_{iq}D_{qj}-\sum_{\varepsilon_p=\varepsilon_i}D_{pj}D_{ip}\\&+\sum_{\varepsilon_p=\varepsilon_j}D_{pj}D_{ip}-\sum_{\varepsilon_q=\varepsilon_i}D_{iq}D_{qj}=0.\end{aligned}$$

The cancellation uses $\varepsilon_i=\varepsilon_j$, so the first and fourth indexing sets agree, as do the second and third. Thus C_K commutes with every compact unit.

Suppose u is compact highest of real weight ν. For each compact pair with $l_i>l_j$, $D_{ij}u=0$ and

$$(D_{ij}D_{ji}+D_{ji}D_{ij})u=[D_{ij},D_{ji}]u=(\nu_i-\nu_j)u.$$

The diagonal terms are $D_{ii}^2u=\nu_i^2u$. Every unordered off-diagonal compact pair occurs once in this calculation, and $\sum_{\varepsilon_i=\varepsilon_j,\ l_i>l_j}(\nu_i-\nu_j)=\sum_i r_i\nu_i$. Consequently $C_Ku=q(\nu)u$. For arbitrary u, compact adjointness gives the separate norm identity

$$\langle u,C_Ku\rangle=\sum_{\varepsilon_i=\varepsilon_j}\langle u,D_{ij}D_{ji}u\rangle=\sum_{\varepsilon_i=\varepsilon_j}\|D_{ji}u\|^2. \tag{2}$$

In particular $C_K=q_0$ on $F_0(z)$. By Lemma 6.4.38, every $F_j(z)$ is finite-dimensional; its hypotheses hold since large gap includes distinctness and the required parity of l, and the integer vector μ has a finite coordinate bound. The commutators (1) show that every $F_j(z)$ is compact-invariant. Thus its orthogonal complement is also compact-invariant. Let P be the orthogonal projection onto $F_0(z)$. It exists in the pre-Hilbert space since this subspace is finite-dimensional, and commutes with every compact unit.

The first new compact types have a uniform Casimir gap. We first prove that any nonzero compact highest vector of weight $\mu+\eta$ satisfies

$$0\le n^3+\sum_i\eta_i(\eta_i+l_i). \tag{3}$$

Let $u\neq 0$ be compact highest of weight $\nu=\mu+\eta$; we use (3) only for integer η. The diagonal weights are real. For each noncompact pair with $l_i>l_j$, (1) gives

$$D_{ij}D_{ji}+D_{ji}D_{ij}=2D_{ij}D_{ji}-D_{ii}+D_{jj},\qquad \langle u,D_{ij}D_{ji}u\rangle=-\|D_{ji}u\|^2.$$

Let $\mathcal{P} = \{(i,j) : \varepsilon_i \neq \varepsilon_j,\ l_i > l_j\}$; it selects exactly one ordering of every noncompact unordered pair. Since

$$\sum_{(i,j)\in\mathcal{P}} (\nu_i - \nu_j) = \sum_i (R_i - r_i)\nu_i,$$

adding the compact and noncompact contributions to the full Casimir gives the exact equality

$$\begin{aligned}\mathrm{Re}\langle u, \Omega u\rangle &= \left(q(\nu) - \sum_i (R_i - r_i)\nu_i\right)\|u\|^2 - 2\sum_{(i,j)\in\mathcal{P}} \|D_{ji}u\|^2 \\ &= \left(\sum_i \nu_i(\nu_i + 2r_i - R_i)\right)\|u\|^2 - 2\sum_{(i,j)\in\mathcal{P}} \|D_{ji}u\|^2.\end{aligned}$$

The lower bound on Ω, nonnegativity of all squared norms, and $\|u\|^2 > 0$ therefore imply

$$\kappa_l \leq \sum_i \nu_i(\nu_i + 2r_i - R_i).$$

Parity in the parameter gives $2\mu_i = l_i + R_i - 2r_i$ without a rounding term. Thus

$$\nu_i(\nu_i + 2r_i - R_i) = (\mu_i + \eta_i)(l_i - \mu_i + \eta_i) = \eta_i(\eta_i + l_i) + \mu_i(l_i - \mu_i).$$

Writing $S = \sum_i \eta_i(\eta_i + l_i)$, subtracting $\kappa_l = \sum_i (l_i^2 - R_i^2)/4$ gives

$$0 \leq S - \frac{1}{4}\sum_i (l_i - 2\mu_i)^2 + \frac{1}{4}\sum_i R_i^2 \leq S + \frac{1}{4}n^3.$$

Here $|R_i| \leq n$ was used. It follows in particular that $0 \leq S + n^3$, which is (3).

Put $U = F_1(z) \cap F_0(z)^\perp$. A nonzero compact highest vector $u \in U$ pairs nontrivially with some $D_{ij}z$. To see this, interchange compact units using (1), putting compact lowering factors on the left. This expresses $F_1(z)$ as the span of compact lowering words applied to z or to a vector $D_{ij}z$. If all those short words were orthogonal to u, move the leftmost lowering factor across the inner product: its compact raising adjoint kills u. Thus u would be orthogonal to $F_1(z)$, a contradiction. The diagonal units are self-adjoint, so a nonzero pairing forces the weight of u to be $\mu + e_i - e_j$. The pair must be noncompact, since $D_{ij}z \in F_0(z)$ for a compact pair. In particular $i \neq j$. By (3),

$$l_i - l_j \geq -n^3 - 2.$$

Large gap gives $|l_i - l_j| \geq 1000n^3$; hence $l_i - l_j \geq 1000n^3$. Direct subtraction gives

$$q(\mu + e_i - e_j) - q_0 = l_i - l_j + R_i - R_j - r_i + r_j + 2 \geq 1000n^3 - 4(n-1) + 2 \geq 4n + 2. \quad (4)$$

Here a noncompact pair entails $n \geq 2$.

Consequently $C_K \geq q_0 + 4n + 2$ on U. For completeness, diagonalize the self-adjoint C_K on the finite-dimensional compact-invariant U. Every nonzero eigenspace is compact-invariant and contains a highest vector: simultaneously diagonalize the commuting self-adjoint diagonal units, and choose a weight maximizing its pairing with l. A nonzero raising image would increase that pairing. Formula (4) bounds the eigenvalue of this eigenspace. This proves the stated operator inequality.

A projection inequality controls the first commutator. For $v \perp F_0(z)$ define

$$\begin{aligned}B(v) &= \sum_{p,q} \|PD_{qp}v\|^2, \\ T(v) &= \sum_{p,q}\sum_{\varepsilon_i=\varepsilon_j} \mathrm{Re}\langle D_{ji}PD_{qp}v,\ P[D_{qp}, D_{ji}]v\rangle, \\ W(v) &= \sum_{p,q}\sum_{\varepsilon_i=\varepsilon_j} \|P[D_{ji}, D_{qp}]v\|^2.\end{aligned}$$

We claim $B(v) \le T(v)$. Only the orthogonal projection of v onto $F_1(z)$ contributes to these three quantities: if $v \perp F_1(z)$ then $D_{pq}v \perp F_0(z)$ by the adjoint identity, and the same holds for any commutator in (1). We may therefore assume $v \in U$.

The positive form $\sum_{p,q}\langle PD_{qp}u, PD_{qp}v\rangle$ has operator

$$D^{(1)} = \sum_{p,q} \varepsilon_p\varepsilon_q D_{pq}PD_{qp}.$$

We verify the invariant contraction that will also be needed at later levels. If D is any operator commuting with every compact unit, put

$$\mathcal{A}(D) = \sum_{p,q} \varepsilon_p\varepsilon_q D_{pq}DD_{qp}.$$

For a compact $X = D_{ij}$ the term $D_{pq}[X, D]D_{qp}$ vanishes. Expanding the other two terms by (1) gives

$$\begin{aligned}[X, \mathcal{A}(D)] = &\sum_q \varepsilon_j\varepsilon_q D_{iq}DD_{qj} - \sum_p \varepsilon_p\varepsilon_i D_{pj}DD_{ip} \\ &+ \sum_p \varepsilon_p\varepsilon_j D_{pj}DD_{ip} - \sum_q \varepsilon_i\varepsilon_q D_{iq}DD_{qj} = 0.\end{aligned} \tag{5a}$$

The first and fourth sums cancel term by term because $\varepsilon_i = \varepsilon_j$, and so do the second and third. Hence $\mathcal{A}(D)$ commutes with all compact units and therefore with C_K. Taking $D = P$ proves this assertion for $D^{(1)}$.

More generally, suppose an indexed family $\mathcal{J}$ has form operator D: $\sum_{J\in\mathcal{J}}\langle Ju, Jv\rangle = \langle u, Dv\rangle$, and D commutes with compact units. Then

$$\begin{aligned}\sum_J \sum_{\varepsilon_i=\varepsilon_j} \langle JD_{ji}u, JD_{ji}v\rangle &= \sum_{\varepsilon_i=\varepsilon_j} \langle D_{ji}u, DD_{ji}v\rangle \\ &= \sum_{\varepsilon_i=\varepsilon_j} \langle u, D_{ij}DD_{ji}v\rangle \\ &= \langle u, DC_Kv\rangle = \sum_J \langle Ju, JC_Kv\rangle.\end{aligned} \tag{5b}$$

The second equality uses the positive compact sign; the third uses $[D, D_{ij}] = 0$. This does not require the individual J to commute with the compact units.

Here $\mathcal{J}$ consists of all PD_{qp} and its form operator is $D^{(1)}$: indeed $\langle PD_{qp}u, PD_{qp}v\rangle = \varepsilon_p\varepsilon_q\langle u, D_{pq}PD_{qp}v\rangle$. Let Q_U be the orthogonal projection onto the finite-dimensional space U. The compact stability of U and its orthogonal complement shows that Q_U commutes with each compact unit and with C_K. The operators

$$D_U = Q_U D^{(1)}|_U, \qquad C_U = C_K|_U$$

are self-adjoint on U, and D_U is positive. They commute: for $u \in U$,

$$D_UC_Uu = Q_UD^{(1)}C_Ku = Q_UC_KD^{(1)}u = C_KQ_UD^{(1)}u = C_UD_Uu.$$

Thus each eigenspace of C_U is preserved by D_U; diagonalizing the positive D_U on each such space gives an orthonormal basis e_α with $C_Ue_\alpha = \theta_\alpha e_\alpha$, $D_Ue_\alpha = d_\alpha e_\alpha$, $\theta_\alpha \ge q_0 + 4n + 2$ and $d_\alpha \ge 0$. For $v = \sum_\alpha v_\alpha e_\alpha$ one consequently has

$$\langle v, D_UC_Uv\rangle = \sum_\alpha d_\alpha\theta_\alpha|v_\alpha|^2 \ge (q_0 + 4n + 2)\sum_\alpha d_\alpha|v_\alpha|^2 = (q_0 + 4n + 2)B(v).$$

Apply (5b) to the family PD_{qp} and put $u = v$. Since $v \in U$, its left side is the right side below, while its right side is $\langle v, D_U C_U v\rangle$. We obtain

$$(q_0 + 4n + 2)B(v) \le \sum_{p,q} \sum_{\varepsilon_i = \varepsilon_j} \|PD_{qp}D_{ji}v\|^2. \tag{5}$$

Expand $PD_{qp}D_{ji}v = D_{ji}PD_{qp}v + P[D_{qp}, D_{ji}]v$. By (2) on the range of P, the right side of (5) is $q_0 B(v) + 2T(v) + W(v)$. On the other hand (1), the inequality $\|u - w\|^2 \le 2\|u\|^2 + 2\|w\|^2$, and extension of the compact sum to all (i, j) give

$$W(v) \le 2 \sum_{p,q,i,j} \left(\delta_{iq}\|PD_{jp}v\|^2 + \delta_{pj}\|PD_{qi}v\|^2\right) = 4nB(v).$$

The two sums each equal $nB(v)$. Subtracting these bounds from (5) gives $2B(v) \le 2T(v)$, proving the claim.

Finite detecting families propagate this inequality. Use the family consisting of P at level zero, and at level $k+1$ use all operators JD_{qp}, where J belongs to the level-k family. Write $\mathcal{J}_k$ for this finite indexed family and

$$b_k(v) = \sum_{J \in \mathcal{J}_k} \|Jv\|^2.$$

We prove the following four properties by induction:

(a) Every $J \in \mathcal{J}_k$ kills $F_k(z)^\perp$; if $v \perp F_j(z)$ for every $j < k$ and every $Jv = 0$, then $v \perp F_k(z)$.

(b) The form $\sum_J \langle Ju, Jv\rangle = \langle u, D^{(k)}v\rangle$ has a positive operator $D^{(k)}$ commuting with the compact units.

(c) For $v \perp F_k(z)$ and each $J \in \mathcal{J}_k$,

$$2\sum_{p,q} \|JD_{qp}v\|^2 \le 2\sum_{p,q} \sum_{\varepsilon_i = \varepsilon_j} \mathrm{Re}\langle D_{ji}JD_{qp}v,\ J[D_{qp}, D_{ji}]v\rangle.$$

(d) If $v \perp F_j(z)$ for every $j < k$, then

$$(q_0 + 2k)b_k(v) \le \sum_{J \in \mathcal{J}_k} \sum_{\varepsilon_i = \varepsilon_j} \left(\|JD_{ji}v\|^2 - \|[D_{ji}, J]v\|^2\right). \tag{6}$$

At level zero, (a) is the projection identity and (b) follows from $P^* = P$. Property (c) is the projection inequality just proved. For (d), P commutes with compact units and $C_K = q_0$ on its range, so (6) is equality.

Here are the induction details. The adjoint relation gives

$$v \perp F_{k+1}(z) \quad \Longrightarrow \quad D_{pq}v \perp F_k(z). \tag{7}$$

This proves the killing assertion of (a) at the next level. For detection, suppose v is orthogonal to the earlier levels and $JD_{qp}v = 0$ for all J, p, q. Apply the preceding detection assertion to $D_{qp}v$, using (7) for its earlier levels. Thus every $D_{qp}v$ is orthogonal to $F_k(z)$. Taking adjoints shows $v \perp D_{pq}F_k(z)$; together with $v \perp F_k(z)$ this proves detection at level $k + 1$. The next form operator is

$$D^{(k+1)} = \sum_{p,q} \varepsilon_p \varepsilon_q D_{pq} D^{(k)} D_{qp}.$$

To check that this is its form operator, expand

$$\sum_{J\in\mathcal{J}_k}\sum_{p,q}\langle JD_{qp}u, JD_{qp}v\rangle = \sum_{p,q}\langle D_{qp}u, D^{(k)}D_{qp}v\rangle$$
$$= \sum_{p,q}\varepsilon_p\varepsilon_q\langle u, D_{pq}D^{(k)}D_{qp}v\rangle.$$

It is positive because at $u = v$ the left side is a sum of squared norms, and is self-adjoint by polarization of this Hermitian form. Formula (5a), applied to $D = D^{(k)}$, proves its commutation with each compact unit. This proves (b) at the next level with no additional invariance hypothesis.

For (c) at the next level take $v \perp F_{k+1}(z)$ and fix $J \in \mathcal{J}_k$, D_{qp}. For every matrix unit, and hence every matrix Y, $J\rho(Y)v = 0$ by (7) and (a). Consequently

$$J\rho(Y)D_{qp}v = JD_{qp}\rho(Y)v, \tag{8}$$

because their difference is $J\rho([Y, E_{qp}])v$. For clarity fix the prepended unit $E_0 = D_{qp}$, and use $E = D_{ba}$ for the units summed in (c) and $C = D_{ji}$ for its compact units. Applying the preceding (c) to $E_0v \perp F_k(z)$ gives

$$2\sum_{a,b}\|JEE_0v\|^2 \le 2\sum_{a,b}\sum_{\varepsilon_i=\varepsilon_j}\mathrm{Re}\langle CJEE_0v, J[E,C]E_0v\rangle.$$

Equation (8) holds for every Lie algebra element, so it applies both to E and to $[E, C]$ (a linear combination of matrix units by (1)). It changes this inequality into

$$2\sum_{a,b}\|JE_0Ev\|^2 \le 2\sum_{a,b}\sum_{\varepsilon_i=\varepsilon_j}\mathrm{Re}\langle CJE_0Ev, JE_0[E,C]v\rangle.$$

This is exactly (c) for the member JE_0 of $\mathcal{J}_{k+1}$.

It remains to prove (d) at level $k+1$. Let $v \perp F_j(z)$ for every $j < k+1$. For $j < k$ one has $j+1 < k+1$, so (7) applied at index j gives $D_{qp}v \perp F_j(z)$. Thus (d) at level k applies to every $D_{qp}v$. Sum its inequalities over all p, q. In the following displays $\sum_{J,E,C}$ means $J \in \mathcal{J}_k$, all $E = D_{qp}$, and all compact $C = D_{ji}$, with each family indexed including repetitions. The result is

$$(q_0 + 2k)b_{k+1}(v) \le \sum_{J,E,C}(\|JCEv\|^2 - \|[C,J]Ev\|^2). \tag{9a}$$

Moreover $v \perp F_k(z)$, so (c) at level k applies to v. Summing it over J gives

$$2b_{k+1}(v) \le 2\sum_{J,E,C}\mathrm{Re}\langle CJEv, J[E,C]v\rangle. \tag{9b}$$

For each fixed J, E, C put $u_1 = JCEv$, $u_2 = CJEv$, $u_3 = J[E,C]v$. Then $JECv = u_1 + u_3$, $[C,J]Ev = u_2 - u_1$, and $[C,JE]v = u_2 - u_1 - u_3$. Expanding squared norms therefore gives

$$\begin{aligned}\|JECv\|^2 - \|[C,JE]v\|^2 &= \|u_1+u_3\|^2 - \|u_2-u_1-u_3\|^2\\ &= \|u_1\|^2 - \|u_2-u_1\|^2 + 2\,\mathrm{Re}\langle u_2, u_3\rangle\\ &= \|JCEv\|^2 - \|[C,J]Ev\|^2 + 2\,\mathrm{Re}\langle CJEv, J[E,C]v\rangle.\end{aligned} \tag{9}$$

In the second equality, the terms $\|u_3\|^2$ cancel and the two mixed terms combine to $2\,\mathrm{Re}\langle u_1 + (u_2 - u_1), u_3\rangle$. Add (9a) and (9b), and apply (9) in every summand. This yields

$$\begin{aligned}(q_0 + 2(k+1))b_{k+1}(v) &\le \sum_{J,E,C}(\|(JE)Cv\|^2 - \|[C,JE]v\|^2)\\ &= \sum_{J'\in\mathcal{J}_{k+1}}\sum_{\varepsilon_i=\varepsilon_j}(\|J'D_{ji}v\|^2 - \|[D_{ji},J']v\|^2).\end{aligned}$$

The last equality is exactly the indexed definition $J' = JD_{qp}$, not an assertion that these operators are distinct. This proves (d), completing the induction.

The compact eigenvalue forces orthogonality at every level. Compact word interchange, with lowering factors first and raising factors last, shows $F_0(z)$ is spanned by compact lowering words applied to z. In the pairing with a, a nonempty lowering word has a raising adjoint killing a; the empty word pairs to zero by hypothesis. Hence $a \perp F_0(z)$. The same highest-vector calculation used above gives $C_K a = q_0 a$.

Proceed by induction on k. Suppose $a \perp F_j(z)$ for all $j < k$. Property (b) and compact adjointness give the exact identity

$$\sum_{J\in\mathcal{J}_k}\sum_{\varepsilon_i=\varepsilon_j}\|JD_{ji}a\|^2 = \operatorname{Re}\sum_J\langle Ja, JC_K a\rangle = q_0 b_k(a). \tag{10}$$

The first equality is (5b) for $\mathcal{J} = \mathcal{J}_k$, $D = D^{(k)}$ and $u = v = a$; property (b) supplies its exact commutation hypothesis. The last equality uses $C_K a = q_0 a$ and the reality of q_0. Combining (6) with (10), and discarding the subtracted nonnegative squares in (6), gives

$$(q_0 + 2k)b_k(a) \le q_0 b_k(a).$$

For $k > 0$ this implies $b_k(a) = 0$, so every $Ja = 0$. Property (a) now gives $a \perp F_k(z)$. The case $k = 0$ was already established. This proves the assertion for all k. □

Lemma 6.4.38. *Let $n \ge 1$, let $\varepsilon_a \in \{1, -1\}$, and let $l \in \mathbb{Z}^n$ have pairwise distinct entries with $l_a \equiv n - 1 \pmod 2$. Let H be a complex pre-Hilbert space and let $\rho : \mathfrak{gl}_n(\mathbb{C}) \to \operatorname{End}_{\mathbb{C}}(H)$ be a Lie algebra representation. Write $T_{ab} = \rho(E_{ab})$, and suppose*

$$\langle T_{ab}u, v\rangle = \varepsilon_a\varepsilon_b\langle u, T_{ba}v\rangle, \qquad \operatorname{Re}\langle u, \Omega u\rangle \ge \kappa_l\|u\|^2, \quad \Omega = \sum_{a,b} T_{ab}T_{ba}, \quad \kappa_l = \frac{1}{4}\sum_a\bigl(l_a^2 - (2\rho_l(a))^2\bigr)$$

for all $u, v \in H$. Let $x \in H$ satisfy

$$T_{aa}x = \nu_a x, \qquad T_{ab}x = 0 \quad (\varepsilon_a = \varepsilon_b,\ l_a > l_b), \qquad \nu \in \mathbb{Z}^n.$$

Let F_0 be the smallest subspace containing x and invariant under all T_{ab} with $\varepsilon_a = \varepsilon_b$, and define

$$F_{s+1} = F_s + \sum_{a,b} T_{ab}F_s \qquad (s \ge 0).$$

For every integer $R \ge 0$ with $|\nu_a| \le R$, every $s \ge 0$, every $u \in F_s$, and every complex $n \times n$ matrix Z, the space F_s is finite-dimensional, $\rho(Z)u \in F_{s+1}$, and

$$\|\rho(Z)u\| \le (n+1)^4(R + 1 + s)\|Z\|_{\mathrm{op}}\|u\|.$$

Proof. **Compact words give finite-dimensional filtration spaces.** Put $\mathfrak{k}_{\mathbb{C}} = \operatorname{span}\{E_{ab} : \varepsilon_a = \varepsilon_b\}$ and

$$\Omega_K = \sum_{\varepsilon_a=\varepsilon_b} T_{ab}T_{ba}, \qquad c_K(\mu) = \sum_a \mu_a^2 + \sum_{\substack{\varepsilon_a=\varepsilon_b\\ l_a>l_b}}(\mu_a - \mu_b).$$

The commutator relations $[T_{ab}, T_{cd}] = \delta_{bc}T_{ad} - \delta_{da}T_{cb}$ show that Ω_K commutes with $\mathfrak{k}_{\mathbb{C}}$. Pairing the two orders of each off-diagonal compact pair, and using the highest-vector equations, gives $\Omega_K x = c_K(\nu)x$. Thus $\Omega_K = c_K(\nu)$ on F_0. Its quadratic form is

$$\langle v, \Omega_K v\rangle = \sum_{\varepsilon_a=\varepsilon_b}\|T_{ba}v\|^2. \tag{1}$$

If $x = 0$, all assertions are immediate; assume otherwise. In particular $c_K(\nu) \geq 0$.

Order the compact matrix units with the lowering units $l_a < l_b$ first, diagonal units next, and raising units last. Repeatedly use the displayed commutator relation to interchange adjacent units in a word. The interchange term has the same length and the commutator term has smaller length. Induction on length and then on the number of inversions therefore expresses F_0 as the span of compact lowering words applied to x: the raising factors kill x and diagonal factors act by scalars. Every word vector is a simultaneous diagonal eigenvector, of weight $\mu = \nu + \sum(e_a - e_b)$, by commuting each T_{cc} through the word. A compact lowering word of length q has

$$l \cdot \mu \leq l \cdot \nu - q.$$

For a nonzero such word vector v, (1) and its diagonal terms give $\sum_a \mu_a^2 \leq c_K(\nu)$. Consequently

$$q \leq l \cdot \nu + \|l\|_2 \sqrt{c_K(\nu)}.$$

There are only finitely many words of bounded length in the finitely many compact lowering units. This proves that F_0 is finite-dimensional. The recursion then proves the same for every F_s. The commutator relation also proves inductively that every F_s is $\mathfrak{k}_{\mathbb{C}}$-invariant.

The compact Casimir is bounded above on F_s. We first record how a highest vector in F_s detects a short word. The same word interchanges as above, now commuting compact units past arbitrary units, show that F_s is spanned by vectors

$$T_{a_1 b_1} \cdots T_{a_q b_q}\, \rho(w)x, \tag{2}$$

where all the displayed units are compact lowering units and w is a word of length at most s in arbitrary matrix units. Indeed a commutator of a compact unit with a matrix unit is a sum of matrix units, so it never increases the number of arbitrary factors; compact raising and diagonal factors can be moved to the right until they act on x. If a nonzero compact highest vector $z \in F_s$ were orthogonal to every $\rho(w)x$ with $\text{length}(w) \leq s$, it would be orthogonal to every vector (2): moving its leftmost lowering factor across the inner product produces a raising factor that kills z. This would give $z \perp F_s$, a contradiction. Hence some such word has $\langle \rho(w)x, z\rangle \neq 0$.

The diagonal operators are self-adjoint, so vectors of different diagonal weights are orthogonal. The weight μ of this highest vector therefore equals the weight of a detecting word. Each factor changes each weight coordinate by at most one, whence

$$|\mu_a| \leq R + s. \tag{3}$$

This conclusion applies to every compact highest vector in F_s.

The self-adjoint operator Ω_K preserves the finite-dimensional space F_s, and each of its eigenspaces is compact-invariant. Each nonzero eigenspace contains a compact highest vector: the commuting self-adjoint diagonal units admit a simultaneous orthogonal eigenspace decomposition; among its finitely many weights choose one maximizing $l \cdot \mu$. A nonzero raising image would have strictly larger pairing, which is impossible. On that highest vector the calculation preceding (1) gives the eigenvalue $c_K(\mu)$. Put $T = R + s$. By (3), and because each coordinate occurs with coefficient of absolute value at most n in the linear part of c_K,

$$c_K(\mu) \leq nT(T + n).$$

The spectral theorem on F_s now yields

$$\langle u, \Omega_K u\rangle \leq nT(T + n)\|u\|^2 \qquad (u \in F_s). \tag{4}$$

The full Casimir controls all matrix units. The adjoint identities give

$$\sum_{a,b} \|T_{ab}u\|^2 = 2\langle u, \Omega_K u\rangle - \mathrm{Re}\langle u, \Omega u\rangle.$$

Since $|2\rho_l(a)| \le n$, one has $\kappa_l \ge -n^3/4$. Therefore (4) gives

$$\sum_{a,b} \|T_{ab}u\|^2 \le \left(2nT(T+n) + \frac{n^3}{4}\right)\|u\|^2. \tag{5}$$

Each entry satisfies $|Z_{ab}| \le \|Z\|_{\mathrm{op}}$. The triangle inequality and Cauchy–Schwarz over the n^2 pairs imply

$$\|\rho(Z)u\|^2 \le n^2\|Z\|_{\mathrm{op}}^2 \sum_{a,b} \|T_{ab}u\|^2.$$

For $T \ge 0$ and $n \ge 1$,

$$n^2\left(2nT(T+n) + \frac{n^3}{4}\right) \le \left(2n^4 + \frac{n^5}{4}\right)(T+1)^2 \le 3n^5(T+1)^2 \le (n+1)^8(T+1)^2.$$

Combining this with (5) and taking square roots proves the claimed norm bound. Finally $\rho(Z) = \sum_{a,b} Z_{ab}T_{ab}$, so its image of F_s lies in F_{s+1} by the defining recursion. □

Lemma 6.4.39. *Let $n \ge 1$, let $\varepsilon \in \{\pm 1\}^n$, and let $l \in \mathbb{Z}^n$ have large gap A for some integer $A \ge 0$. Put $J = \mathrm{diag}(\varepsilon)$, $G = \{g \in \mathrm{GL}_n(\mathbb{C}) : g^*Jg = J\}$ and*

$$\kappa_l = \frac{1}{4}\sum_a (l_a^2 - (2\rho_l(a))^2).$$

Let H be a complex pre-Hilbert space, with inner product conjugate-linear in the first variable, and let $\rho : \mathfrak{gl}_n(\mathbb{C}) \to \mathrm{End}_{\mathbb{C}}(H)$ be a Lie algebra representation. Write $T_{ab} = \rho(E_{ab})$ and $\Omega = \sum_{a,b} T_{ab}T_{ba}$. Assume that for all $u, w \in H$,

$$\langle T_{ab}u, w\rangle = \varepsilon_a\varepsilon_b\langle u, T_{ba}w\rangle, \qquad \mathrm{Re}\langle u, \Omega u\rangle \ge \kappa_l\|u\|^2.$$

Let $x \in H$ and $\nu \in \mathbb{Z}^n$ satisfy

$$T_{aa}x = \nu_a x, \qquad T_{ab}x = 0 \quad (\varepsilon_a = \varepsilon_b,\ l_a > l_b).$$

Let $\mathfrak{k}_{\mathbb{C}}$ be spanned by the E_{ab} with $\varepsilon_a = \varepsilon_b$, set $F_0 = U(\mathfrak{k}_{\mathbb{C}})x$, and recursively set

$$F_{s+1} = F_s + \sum_{a,b} T_{ab}F_s \qquad (s \ge 0).$$

Suppose that $C_g : H \to \mathbb{C}$ is complex linear for every $g \in G$, and that there is one $D \ge 0$ such that

$$|C_g(u)| \le D\|u\| \qquad (g \in G,\ u \in H).$$

Assume the derivative identity

$$\frac{d}{dt}C_{g\exp(tY)}(u) = C_{g\exp(tY)}(\rho(Y)u)$$

for every $g \in G$, $u \in H$, $Y \in \mathfrak{u}(J) = \{Y : Y^*J + JY = 0\}$ and every real t. If $C_1(u) = 0$ for every $s \ge 0$ and $u \in F_s$, then $C_g(x) = 0$ for every $g \in G$.

Proof. **Repeated derivatives have a common radius of control.** Choose an integer $R \geq 0$ with $|\nu_a| \leq R$ for every a. The large-gap hypotheses in particular imply that the entries of l are distinct and have parity $n-1$. Thus Lemma 6.4.38 applies to the given module and filtration. For a fixed $Y \in \mathfrak{u}(J)$ put

$$a = (n+1)^4 \|Y\|_{\mathrm{op}}, \qquad b = \max\{a, 1\}.$$

It follows by induction that, for $u \in F_s$ and $k \geq 0$,

$$\rho(Y)^k u \in F_{s+k}, \qquad \|\rho(Y)^k u\| \leq a^k \prod_{j=0}^{k-1} (R+1+s+j)\, \|u\|. \tag{1}$$

For $k = 0$ the product and a^0 mean 1; the induction step applies the growth estimate on F_{s+k}.

Fix $g \in G$ and $u \in H$, and write $f_u(t) = C_{g\exp(tY)}(u)$. The derivative assumption gives

$$f_u^{(k)}(t) = C_{g\exp(tY)}(\rho(Y)^k u) \qquad (k \geq 0). \tag{2}$$

Indeed each right-hand side is differentiable, by applying the same assumption to the vector $\rho(Y)^k u$. It is therefore continuous, and induction proves both that f_u is smooth and that (2) holds. This argument uses only derivatives of scalar functions; it requires no completion of H.

Suppose that C_g vanishes on every F_s. For $u \in F_s$, all the derivatives (2) at zero vanish, by (1). Taylor's integral remainder on the real interval from zero to t, applied to the real and imaginary parts, gives for every integer $k \geq 1$

$$\begin{aligned} |C_{g\exp(tY)}(u)| &\leq \frac{|t|^k}{k!} \sup_{r \text{ between } 0 \text{ and } t} |C_{g\exp(rY)}(\rho(Y)^k u)| \\ &\leq D\|u\|\, (a|t|)^k \frac{\prod_{j=0}^{k-1}(R+1+s+j)}{k!}. \end{aligned} \tag{3}$$

The first inequality also follows directly by taking the absolute value in the complex-valued integral remainder; thus no extra factor is needed. If $a = 0$, (1) makes the right-hand side zero. The assertion at $t = 0$ is immediate. If $a > 0$ and $0 < |t| \leq 1/(2b)$, the ratio of successive nonnegative factors on the last line of (3) is

$$a|t|\, \frac{R+1+s+k}{k+1} \;\longrightarrow\; a|t| \leq \frac{1}{2}.$$

Consequently that line tends to zero as $k \to \infty$. We have proved

$$C_g|_{F_s} = 0 \text{ for all } s \quad \Longrightarrow \quad C_{g\exp(tY)}|_{F_s} = 0 \text{ for all } s \quad \left(|t| \leq \frac{1}{2b}\right). \tag{4}$$

Although the bound in (3) depends on s, the permitted radius in (4) does not.

Vanishing propagates along a full one-parameter subgroup. Choose an integer $N \geq 2b$. Apply (4) successively with base points $g\exp(jY/N)$, for $j = 0, \ldots, N-1$, and $t = 1/N$. The uniform bound by D is valid at all these base points, and the derivative identity is assumed there as well. The one-parameter subgroup law gives

$$C_g|_{F_s} = 0 \text{ for all } s \quad \Longrightarrow \quad C_{g\exp Y}|_{F_s} = 0 \text{ for all } s. \tag{5}$$

Every group element is a product of two such exponentials. Let $g \in G$, put $Q = g^* g$, and let $h = Q^{1/2}$ be its positive Hermitian square root. The relation $g^* J g = J$ gives $JQJ = Q^{-1}$. By diagonalizing the positive Hermitian matrix Q, functional calculus gives

$$JhJ = h^{-1}, \qquad J(\log h)J = -\log h.$$

Hence $Y_2 = \log h$ satisfies $Y_2^* J + J Y_2 = 0$. Put $k = g h^{-1}$. Direct calculation shows $k^* k = 1$ and $k^* J k = J$, so k commutes with J. Thus k is block unitary for the positive and negative eigenspaces of J. Diagonalize its two unitary blocks, choose real arguments of their eigenvalues, and obtain a block skew-Hermitian matrix Y_1 with $\exp Y_1 = k$. It commutes with J, so $Y_1 \in \mathfrak{u}(J)$ as well. Therefore

$$g = \exp Y_1 \exp Y_2.$$

Starting with the assumed vanishing of C_1 on every F_s, apply (5) first with Y_1 and then with Y_2. It follows that C_g vanishes on every F_s. Finally $x \in F_0$, and hence $C_g(x) = 0$, as required. □

Lemma 6.4.40. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma, \gamma' \in \mathbb{Z}$, $\lambda\colon I \to \mathbb{Z}$, $\lambda'\colon I' \to \mathbb{Z}$, and let H be a joint harmonic for the signs (s,t), the weights (γ, γ') and the parameters (λ, λ'). Let $E^{\mathrm{row}}_{aa'}$ and $E^{\mathrm{col}}_{cc'}$ be the row and column units of (s,t) with the shifts $(\gamma, -\gamma')$, acting on $\mathbb{C}[X] = \mathbb{C}[X_{ac} : a \in I', c \in I]$, and let e_j denote the indicator function of an index j. Let $G \subseteq \mathbb{C}[X]$ be a linear subspace containing H.*

(JR) Suppose that $E^{\mathrm{col}}_{cc'} G \subseteq G$ for all $c, c' \in I$, and that

- *(JR1) $E^{\mathrm{row}}_{ba} P \in G$ whenever $t(a) \neq t(b)$, $\lambda'(a) < \lambda'(b)$ and P is K-highest of weight $\mu_{\lambda'} + e_a - e_b$ for λ' for the row units;*
- *(JR2) $E^{\mathrm{row}}_{ba} P \in G$ for every polynomial P whenever $t(a) = t(b)$ and $\lambda'(b) < \lambda'(a)$;*
- *(JR3) $E^{\mathrm{row}}_{aa} P - \mu_{\lambda'}(a) P \in G$ for every polynomial P and every $a \in I'$.*

Then $G = \mathbb{C}[X]$.

(JC) Suppose that $E^{\mathrm{row}}_{aa'} G \subseteq G$ for all $a, a' \in I'$, and that

- *(JC1) $E^{\mathrm{col}}_{dc} P \in G$ whenever $s(c) \neq s(d)$, $-\lambda(c) < -\lambda(d)$ and P is K-highest of weight $\mu_{-\lambda} + e_c - e_d$ for $-\lambda$ for the column units;*
- *(JC2) $E^{\mathrm{col}}_{dc} P \in G$ for every polynomial P whenever $s(c) = s(d)$ and $-\lambda(d) < -\lambda(c)$;*
- *(JC3) $E^{\mathrm{col}}_{cc} P - \mu_{-\lambda}(c) P \in G$ for every polynomial P and every $c \in I$.*

Then $G = \mathbb{C}[X]$.

Here $\mu_{\lambda'}$ is the lowest K-type of λ' for the signs t and $\mu_{-\lambda}$ that of $-\lambda$ for the signs s.

Proof. **Proof of (JR).** Every polynomial has a total degree, so it suffices to show $\mathrm{Pol}_{\le j} \subseteq G$ for every $j \in \mathbb{Z}$, by induction on j; for $j < 0$, $\mathrm{Pol}_{\le j} = 0$. Let $j \ge 0$, assume $\mathrm{Pol}_{\le j-1} \subseteq G$, and suppose $\mathrm{Pol}_{\le j} \not\subseteq G$. Put $W = G^{\perp_j}$; by (i) of Lemma 6.4.41, $W \neq 0$, W is finite-dimensional, and $G \cap W = 0$.

Step 1: W contains a nonzero Q with $E^{\mathrm{col}}_{cc'} Q = 0$ whenever $s(c) = s(c')$ and $-\lambda(c') < -\lambda(c)$. Let $s(c) = s(d)$. By (a) of Lemma 6.4.27, $\check{E}^{\mathrm{row}}_{cd} G = E^{\mathrm{col}}_{dc} G \subseteq G$, so by (ii) of Lemma 6.4.41 for the transposed setting (with $N = G$) $\check{E}^{\mathrm{row}}_{dc} W \subseteq W$, i.e. $E^{\mathrm{col}}_{cd} W \subseteq W$. By (iv) of Lemma 6.4.41 for the transposed setting and the order λ on its rows I, there are $Q \in W \setminus \{0\}$ and ν with Q K-highest of weight ν for λ for $(\check{E}^{\mathrm{row}}_{cc'})$; by (c) of Lemma 6.4.27, Q is K-highest of weight $-\nu$ for $-\lambda$ for $(E^{\mathrm{col}}_{cc'})$, which contains the claim.

Step 2: Q is K-highest of weight $\mu_{\lambda'}$ for λ' for the row units. Let $a \in I'$. By (JR3), $E^{\mathrm{row}}_{aa} P = (E^{\mathrm{row}}_{aa} P - \mu_{\lambda'}(a) P) + \mu_{\lambda'}(a) P \in G$ for $P \in G$, so $E^{\mathrm{row}}_{aa} G \subseteq G$ and, by (ii) of Lemma 6.4.41 with $N = G$, $E^{\mathrm{row}}_{aa} W \subseteq W$. Hence $E^{\mathrm{row}}_{aa} Q - \mu_{\lambda'}(a) Q$ lies in W, and in G by (JR3), so it is 0. Let $t(a) = t(b)$ and $\lambda'(b) < \lambda'(a)$. By (JR2), E^{row}_{ba} maps $\mathbb{C}[X]$ into G, so by (ii) of Lemma 6.4.41 with

$N = \mathbb{C}[X]$, $E^{\mathrm{row}}_{ab}Q$ lies in $\mathbb{C}[X]^{\perp j}$, which is 0 (an element of it lies in $\mathrm{Pol}_{\leq j}$ and is orthogonal to itself). So $E^{\mathrm{row}}_{ab}Q = 0$.

Step 3: the column Laplacians kill Q. Let $s(c) \neq s(d)$. By (b) of Lemma 6.4.27, $\Delta^{\mathrm{col}}_{cd}Q = \check{\Delta}^{\mathrm{row}}_{dc}Q$. By (iii) of Lemma 6.4.41 for the transposed setting (rows d, c of opposite signs, $P = Q \in G^{\perp j}$), $R = \check{\Delta}^{\mathrm{row}}_{dc}Q$ lies in G, and $\check{E}^{\mathrm{row}}_{cd}R = -E^{\mathrm{col}}_{dc}R \in G$ by stability; hence $R = 0$.

Step 4: the row Laplacians kill Q. By (a) of (HV7) the pair (λ, λ') satisfies the block rule, so the shifted entries $\tilde{\lambda}'$, the matched pairs and the integers $\nu(a)$ of Lemma 6.4.20 are defined, and λ' is injective. By Step 2 and Lemma 6.4.42 (order λ', weight $\mu_{\lambda'}$) it suffices to show: if $t(a) \neq t(b)$ and $R = \Delta^{\mathrm{row}}_{ab}Q$ is K-highest of weight $\mu_{\lambda'} + e_a - e_b$ for λ', then $R = 0$. As $a \neq b$, either $\lambda'(a) < \lambda'(b)$ or $\lambda'(b) < \lambda'(a)$.

If $\lambda'(a) < \lambda'(b)$: $R \in G$ by (iii) of Lemma 6.4.41, and $E^{\mathrm{row}}_{ba}R \in G$ by (JR1); so $R = 0$ by (iii) of Lemma 6.4.41.

If $\lambda'(b) < \lambda'(a)$: first, $\tilde{\lambda}'(a) > N - N'$ or $-\tilde{\lambda}'(b) > N - N'$. Indeed, by (a) of Lemma 6.4.20, either a is matched with no column, and then $|\tilde{\lambda}'(a)| < N' - N$ gives $\tilde{\lambda}'(a) > N - N'$; or a is matched with a column c and $\sigma(a,c)\tilde{\lambda}'(a) > |N' - N|$: if $\sigma(a,c) = 1$, $\tilde{\lambda}'(a) > N - N'$; if $\sigma(a,c) = -1$, then $-\tilde{\lambda}'(b) > -\tilde{\lambda}'(a) > |N' - N| \geq N - N'$, because $\tilde{\lambda}' - \lambda'$ is constant. Next apply Lemma 6.4.43 with $(R, C, \tau, \kappa, l) = (I', I, t, s, \lambda')$ and $Y = X$, so $\theta = \sigma$ and $\mathrm{Pl}^q_{x \leftarrow x'} = \sum_{c:\, \sigma(x',c)=q} X_{xc}\partial_{x'c}$. Its hypothesis (i) is $\Delta^{\mathrm{col}}_{cc'}Q = 0$ ($s(c) \neq s(c')$), which is Step 3. For $x \neq x'$ with $t(x) = t(x')$ one has $E^{\mathrm{row}}_{xx'} = \mathrm{Pl}^+_{x \leftarrow x'} - \mathrm{Pl}^-_{x' \leftarrow x}$ (formula of (ii) of Lemma 6.4.41, the variables X_{xc}, $X_{x'c}$ being distinct), so its hypothesis (ii) follows from Step 2. Moreover $E^{\mathrm{row}}_{xx} = \mathrm{Pl}^+_{x \leftarrow x} - \mathrm{Pl}^-_{x \leftarrow x} + \gamma - \#\{c : \sigma(x,c) = -1\}$, so $E^{\mathrm{row}}_{xx}Q = \mu_{\lambda'}(x)Q$ gives $(\mathrm{Pl}^+_{x \leftarrow x} - \mathrm{Pl}^-_{x \leftarrow x})Q = \nu(x)Q$ with $\nu(x) = \mu_{\lambda'}(x) - \gamma + \#\{c : \sigma(x,c) = -1\}$ as in Lemma 6.4.20. For $u \in \{\pm 1\}$ and $x \in I'$ with $u\tilde{\lambda}'(x) > N - N'$, (c) of Lemma 6.4.20 gives $u\nu(x) \geq 0$, and (b) of Lemma 6.4.43 gives $\partial_{xc}Q = 0$ for every c with $\sigma(x,c) = -u$. If $\tilde{\lambda}'(a) > N - N'$, take $(x,u) = (a,1)$: $\partial_{ac}Q = 0$ whenever $\sigma(a,c) = -1$, so every term $\partial_{bc}\partial_{ac}Q$ of $R = \sum_{c:\, \sigma(a,c)=-1} \partial_{ac}\partial_{bc}Q$ vanishes. If $-\tilde{\lambda}'(b) > N - N'$, take $(x,u) = (b,-1)$: $\partial_{bc}Q = 0$ whenever $\sigma(b,c) = 1$, which holds for every c in the sum, as $\sigma(b,c) = -\sigma(a,c)$. In both cases $R = 0$.

Step 5: contradiction. By Steps 3 and 4, Q is Laplace harmonic for (s,t); by Step 2 it is K-highest of weight $\mu_{\lambda'}$ for λ' for the row units; by Step 1, $E^{\mathrm{col}}_{cc'}Q = 0$ whenever $s(c) = s(c')$ and $-\lambda(c') < -\lambda(c)$. By Lemma 6.4.44, $Q = aH$ for some $a \in \mathbb{C}$, so $Q \in G$. As $Q \in W$ and $G \cap W = 0$, $Q = 0$, contradicting Step 1. Hence $\mathrm{Pol}_{\leq j} \subseteq G$, and (JR) follows.

Proof of (JC). By (d) of Lemma 6.4.27, H is a joint harmonic for the signs (t,s), the weights (γ', γ) and the parameters (λ', λ), written in the variables Y_{ca}; its row units are the $\check{E}^{\mathrm{row}}_{cc'}$, its column units the $\check{E}^{\mathrm{col}}_{aa'}$, its row parameter is λ on I with the signs s, and its lowest K-type there is μ_λ, the lowest K-type of λ for the signs s. Moreover $\mu_\lambda = -\mu_{-\lambda}$: the polynomial $H \neq 0$ is K-highest of weight $\mu_{-\lambda}$ for $(E^{\mathrm{col}}_{cc'})$, hence of weight $-\mu_{-\lambda}$ for $(\check{E}^{\mathrm{row}}_{cc'})$ by (c) of Lemma 6.4.27, and of weight μ_λ for $(\check{E}^{\mathrm{row}}_{cc'})$ as a joint harmonic of the transposed data; compare the eigenvalues of $\check{E}^{\mathrm{row}}_{cc}$ on H. We check the hypotheses of (JR) for these data and G, using (a) and (c) of Lemma 6.4.27. Stability: $\check{E}^{\mathrm{col}}_{aa'}G = E^{\mathrm{row}}_{a'a}G \subseteq G$. (JR1): let $s(c) \neq s(d)$, $\lambda(c) < \lambda(d)$, and P be K-highest of weight $\mu_\lambda + e_c - e_d$ for λ for $(\check{E}^{\mathrm{row}})$; then P is K-highest of weight $\mu_{-\lambda} + e_d - e_c$ for $-\lambda$ for (E^{col}), and $-\lambda(d) < -\lambda(c)$, so (JC1) with (c,d) exchanged gives $E^{\mathrm{col}}_{cd}P \in G$, i.e. $\check{E}^{\mathrm{row}}_{dc}P \in G$. (JR2): let $s(c) = s(d)$ and $\lambda(d) < \lambda(c)$; then $-\lambda(c) < -\lambda(d)$, and (JC2) with (c,d) exchanged gives $E^{\mathrm{col}}_{cd}P \in G$, i.e. $\check{E}^{\mathrm{row}}_{dc}P \in G$, for every P. (JR3): $\check{E}^{\mathrm{row}}_{cc}P - \mu_\lambda(c)P = -(E^{\mathrm{col}}_{cc}P - \mu_{-\lambda}(c)P) \in G$ by (JC3). So (JR) for the transposed data gives $G = \mathbb{C}[Y] = \mathbb{C}[X]$. □

Lemma 6.4.41. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma, \gamma'' \in \mathbb{Z}$, and let $E^{\mathrm{row}}_{aa'}$ $(a, a' \in I')$ be the row units of (s,t) with the shifts (γ, γ'') and $\Delta^{\mathrm{row}}_{ab}$ $(t(a) \neq t(b))$ the row Laplacians, operators on $\mathbb{C}[X] = \mathbb{C}[X_{ac} : a \in I', c \in I]$. For $p = \sum_m p_m X^m$ and $q = \sum_m q_m X^m$*

(multi-indices $m \in \mathbb{N}^{I' \times I}$, $m! = \prod_{a,c} m_{ac}!$) let $\langle p, q\rangle_{\mathrm{Fi}} = \sum_m m! \overline{p_m}\, q_m$ be the Fischer inner product. For $j \in \mathbb{Z}$ let $\mathrm{Pol}_{\le j}$ be the space of polynomials of total degree at most j ($\mathrm{Pol}_{\le j} = 0$ for $j < 0$), and for a subspace $G \subseteq \mathbb{C}[X]$ let $G^{\perp j} = \{p \in \mathrm{Pol}_{\le j} : \langle q, p\rangle_{\mathrm{Fi}} = 0$ for all $q \in G \cap \mathrm{Pol}_{\le j}\}$. Then:

(i) $\mathrm{Pol}_{\le j} = (G \cap \mathrm{Pol}_{\le j}) \oplus G^{\perp j}$ *for every subspace G and every j; in particular $G \cap G^{\perp j} = 0$, and $G^{\perp j} \neq 0$ if $\mathrm{Pol}_{\le j} \not\subseteq G$;*

(ii) if $t(a) = t(a')$, then $E^{\mathrm{row}}_{aa'}$ maps $\mathrm{Pol}_{\le j}$ into itself and $\langle q, E^{\mathrm{row}}_{aa'} p\rangle_{\mathrm{Fi}} = \langle E^{\mathrm{row}}_{a'a} q, p\rangle_{\mathrm{Fi}}$ for all p, q; consequently, for subspaces G, N with $E^{\mathrm{row}}_{a'a} N \subseteq G$, the operator $E^{\mathrm{row}}_{aa'}$ maps $G^{\perp j}$ into $N^{\perp j}$;

(iii) let $j \in \mathbb{Z}$, let G be a subspace containing $\mathrm{Pol}_{\le j-1}$, $P \in G^{\perp j}$, $a, b \in I'$ with $t(a) \neq t(b)$, and $Q = \Delta^{\mathrm{row}}_{ab} P$; then $Q \in G$, and if $E^{\mathrm{row}}_{ba} Q \in G$, then $Q = 0$;

(iv) if $W \neq 0$ is a finite-dimensional subspace of $\mathbb{C}[X]$ with $E^{\mathrm{row}}_{aa'} W \subseteq W$ whenever $t(a) = t(a')$, then for every map $o\colon I' \to \mathbb{Z}$ there are $x \in W \setminus \{0\}$ and $\nu\colon I' \to \mathbb{Z}$ such that x is K-highest of weight ν for o for the row units $(E^{\mathrm{row}}_{aa'})$.

Proof. **Step 0: the Fischer product.** $\langle\,,\rangle_{\mathrm{Fi}}$ is conjugate linear in the first and linear in the second variable, hermitian and positive definite, and distinct monomials are orthogonal. For every variable X_i,

$$\langle X_i p, q\rangle_{\mathrm{Fi}} = \langle p, \partial_i q\rangle_{\mathrm{Fi}}, \qquad \langle p, X_i q\rangle_{\mathrm{Fi}} = \langle \partial_i p, q\rangle_{\mathrm{Fi}}.$$

(i). $\mathrm{Pol}_{\le j}$ is finite-dimensional and the restriction of $\langle\,,\rangle_{\mathrm{Fi}}$ to it is positive definite, so $\mathrm{Pol}_{\le j}$ is the orthogonal direct sum of its subspace $G \cap \mathrm{Pol}_{\le j}$ and the orthogonal complement of that subspace in $\mathrm{Pol}_{\le j}$, which is $G^{\perp j}$. An element of $G \cap G^{\perp j}$ is orthogonal to itself, hence 0; and if $G^{\perp j} = 0$, then $\mathrm{Pol}_{\le j} = G \cap \mathrm{Pol}_{\le j} \subseteq G$.

(ii). Let $t(a) = t(a')$, so $\sigma(a, c) = \sigma(a', c)$ for every c. By (HV5),

$$E^{\mathrm{row}}_{aa'} = \sum_{c\colon \sigma(a,c)=1} X_{ac}\partial_{a'c} - \sum_{c\colon \sigma(a,c)=-1} \partial_{ac} X_{a'c} + \gamma\delta_{aa'}.$$

Each term maps a homogeneous polynomial to a homogeneous polynomial of the same degree, so $\mathrm{Pol}_{\le j}$ is preserved. By Step 0, $\langle q, X_{ac}\partial_{a'c} p\rangle_{\mathrm{Fi}} = \langle \partial_{ac} q, \partial_{a'c} p\rangle_{\mathrm{Fi}} = \langle X_{a'c}\partial_{ac} q, p\rangle_{\mathrm{Fi}}$ and $\langle q, \partial_{ac} X_{a'c} p\rangle_{\mathrm{Fi}} = \langle X_{ac} q, X_{a'c} p\rangle_{\mathrm{Fi}} = \langle \partial_{a'c} X_{ac} q, p\rangle_{\mathrm{Fi}}$; as γ is real and the formula for $E^{\mathrm{row}}_{a'a}$ is the displayed one with a, a' exchanged, $\langle q, E^{\mathrm{row}}_{aa'} p\rangle_{\mathrm{Fi}} = \langle E^{\mathrm{row}}_{a'a} q, p\rangle_{\mathrm{Fi}}$. Now let $E^{\mathrm{row}}_{a'a} N \subseteq G$ and $y \in G^{\perp j}$. Then $E^{\mathrm{row}}_{aa'} y \in \mathrm{Pol}_{\le j}$, and for $z \in N \cap \mathrm{Pol}_{\le j}$ the vector $E^{\mathrm{row}}_{a'a} z$ lies in $G \cap \mathrm{Pol}_{\le j}$, so $\langle z, E^{\mathrm{row}}_{aa'} y\rangle_{\mathrm{Fi}} = \langle E^{\mathrm{row}}_{a'a} z, y\rangle_{\mathrm{Fi}} = 0$. Hence $E^{\mathrm{row}}_{aa'} y \in N^{\perp j}$.

(iii). Let $t(a) \neq t(b)$, so $\sigma(b, c) = -\sigma(a, c)$. By (HV5) and (HV6),

$$E^{\mathrm{row}}_{ba} = \sum_{c\colon \sigma(a,c)=-1} X_{ac}X_{bc} - \sum_{c\colon \sigma(a,c)=1} \partial_{ac}\partial_{bc}, \qquad Q = \Delta^{\mathrm{row}}_{ab} P = \sum_{c\colon \sigma(a,c)=-1} \partial_{ac}\partial_{bc} P.$$

As $P \in \mathrm{Pol}_{\le j}$, $Q \in \mathrm{Pol}_{\le j-2} \subseteq G$, and $\sum_{c\colon \sigma(a,c)=1} \partial_{ac}\partial_{bc} Q \in \mathrm{Pol}_{\le j-4} \subseteq G$. Suppose $E^{\mathrm{row}}_{ba} Q \in G$. Then

$$A = \sum_{c\colon \sigma(a,c)=-1} X_{ac}X_{bc} Q = E^{\mathrm{row}}_{ba} Q + \sum_{c\colon \sigma(a,c)=1} \partial_{ac}\partial_{bc} Q$$

lies in $G \cap \mathrm{Pol}_{\le j}$, so $\langle A, P\rangle_{\mathrm{Fi}} = 0$ because $P \in G^{\perp j}$. By Step 0,

$$\langle A, P\rangle_{\mathrm{Fi}} = \sum_{c\colon \sigma(a,c)=-1} \langle Q, \partial_{bc}\partial_{ac} P\rangle_{\mathrm{Fi}} = \langle Q, Q\rangle_{\mathrm{Fi}}.$$

Hence $Q = 0$.

(iv). For a multi-index m define $w_m\colon I' \to \mathbb{Z}$ by

$$w_m(a) = \sum_{c\colon \sigma(a,c)=1} m_{ac} - \sum_{c\colon \sigma(a,c)=-1} (m_{ac}+1) + \gamma,$$

and let M_w be the span of the monomials X^m with $w_m = w$; then $\mathbb{C}[X] = \bigoplus_w M_w$. By the formula of (ii) with $a' = a$, using $\partial_{ac}X_{ac} = X_{ac}\partial_{ac} + 1$, E^{row}_{aa} acts on M_w as the scalar $w(a)$. Let $t(a) = t(a')$ and $a \neq a'$. Each term $X_{ac}\partial_{a'c}$ ($\sigma(a,c) = 1$) and $-\partial_{ac}X_{a'c} = -X_{a'c}\partial_{ac}$ ($\sigma(a,c) = -1$) of $E^{\mathrm{row}}_{aa'}$ sends X^m to a multiple of $X^{m+e_{(a,c)}-e_{(a',c)}}$, respectively $X^{m+e_{(a',c)}-e_{(a,c)}}$, whose weight is $w_m + e_a - e_{a'}$ in both cases (a variable of sign 1 moves from row a' to row a, or one of sign -1 from row a to row a'). So $E^{\mathrm{row}}_{aa'}M_w \subseteq M_{w+e_a-e_{a'}}$.

Let W be as in (iv). Then $W = \bigoplus_w (W \cap M_w)$: if $x \in W$ has the nonzero components x_w for w in a finite set S, and $w_0 \in S$, choose for every $w \in S \smallsetminus \{w_0\}$ some a_w with $w(a_w) \neq w_0(a_w)$; the operator $\prod_{w\neq w_0}(E^{\mathrm{row}}_{a_wa_w} - w(a_w))/(w_0(a_w) - w(a_w))$ maps W into W, kills x_w for $w \neq w_0$ and fixes x_{w_0}, so $x_{w_0} \in W$. Since $W \neq 0$ is finite-dimensional, the set S_W of weights w with $W \cap M_w \neq 0$ is finite and nonempty. Choose $\nu \in S_W$ with $\phi(\nu) = \sum_a o(a)\nu(a)$ maximal and $x \in W \cap M_\nu$, $x \neq 0$. Then $E^{\mathrm{row}}_{aa}x = \nu(a)x$ for every a. If $t(a) = t(a')$ and $o(a') < o(a)$, then $E^{\mathrm{row}}_{aa'}x \in W \cap M_{\nu+e_a-e_{a'}}$ and $\phi(\nu + e_a - e_{a'}) = \phi(\nu) + o(a) - o(a') > \phi(\nu)$, so $\nu + e_a - e_{a'} \notin S_W$ and $E^{\mathrm{row}}_{aa'}x = 0$. So x is K-highest of weight ν for o. □

Lemma 6.4.42. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma, \gamma'' \in \mathbb{Z}$, and let $E^{\mathrm{row}}_{aa'}$ be the row units of (s,t) with the shifts (γ,γ'') and $\Delta^{\mathrm{row}}_{ab}$ ($t(a) \neq t(b)$) the row Laplacians. Let $o, \nu\colon I' \to \mathbb{Z}$, for $a \in I'$ let $e_a\colon I' \to \mathbb{Z}$ be its indicator function, and let $P \in \mathbb{C}[X_{ac} : a \in I',\, c \in I]$ be K-highest of weight ν for o for the row units. Suppose that for all $a, b \in I'$ with $t(a) \neq t(b)$, if $\Delta^{\mathrm{row}}_{ab}P$ is K-highest of weight $\nu + e_a - e_b$ for o for the row units, then $\Delta^{\mathrm{row}}_{ab}P = 0$. Then $\Delta^{\mathrm{row}}_{ab}P = 0$ for all $a, b \in I'$ with $t(a) \neq t(b)$.*

Proof. **Step 1: commutators.** The raising operators commute with each other, the lowering operators commute with each other, and $[\mathrm{lo}_{ac}, \mathrm{ra}_{a'c'}] = \delta_{aa'}\delta_{cc'}$. For $t(a) \neq t(b)$ and c with $\sigma(a,c) = -1$ one has $\sigma(b,c) = 1$, $\partial_{ac} = -\mathrm{ra}_{ac}$ and $\partial_{bc} = \mathrm{lo}_{bc}$, so

$$\Delta^{\mathrm{row}}_{ab} = -\sum_{c\colon \sigma(a,c)=-1} \mathrm{ra}_{ac}\,\mathrm{lo}_{bc}.$$

For operators with $[A,C] = [B,D] = 0$ one has $[AB,CD] = A[B,C]D + C[A,D]B$. Applied to $A = \mathrm{ra}_{xc}$, $B = \mathrm{lo}_{zc}$, $C = \mathrm{ra}_{ac'}$, $D = \mathrm{lo}_{bc'}$ it gives $[\mathrm{ra}_{xc}\mathrm{lo}_{zc}, \mathrm{ra}_{ac'}\mathrm{lo}_{bc'}] = \delta_{za}\delta_{cc'}\,\mathrm{ra}_{xc}\mathrm{lo}_{bc'} - \delta_{xb}\delta_{cc'}\,\mathrm{ra}_{ac'}\mathrm{lo}_{zc}$. Let $t(x) = t(z)$ and $t(a) \neq t(b)$. Summing over c and over c' with $\sigma(a,c') = -1$ (the scalar term of E^{row}_{xz} is central),

$$[E^{\mathrm{row}}_{xz}, \Delta^{\mathrm{row}}_{ab}] = -\delta_{za}\sum_{c\colon \sigma(a,c)=-1} \mathrm{ra}_{xc}\mathrm{lo}_{bc} + \delta_{xb}\sum_{c\colon \sigma(a,c)=-1} \mathrm{ra}_{ac}\mathrm{lo}_{zc}.$$

If $z = a$, then $t(x) = t(a)$, so for these c, $\mathrm{ra}_{xc} = -\partial_{xc}$ and $\mathrm{lo}_{bc} = \partial_{bc}$, and the first sum is $-\Delta^{\mathrm{row}}_{xb}$. If $x = b$, then $t(z) = t(b)$, so $\mathrm{lo}_{zc} = \partial_{zc}$, $\mathrm{ra}_{ac} = -\partial_{ac}$, and the second sum is $-\Delta^{\mathrm{row}}_{az}$. Hence

$$E^{\mathrm{row}}_{xz}\Delta^{\mathrm{row}}_{ab} = \Delta^{\mathrm{row}}_{ab}E^{\mathrm{row}}_{xz} + \delta_{za}\Delta^{\mathrm{row}}_{xb} - \delta_{xb}\Delta^{\mathrm{row}}_{az} \qquad (t(x) = t(z),\ t(a) \neq t(b)), \tag{6.76}$$

where $\Delta^{\mathrm{row}}_{xb}$ and $\Delta^{\mathrm{row}}_{az}$ occur only when $t(x) = t(a) \neq t(b)$, respectively $t(a) \neq t(b) = t(z)$, so they are defined.

Step 2: a minimal nonvanishing Laplacian is K-highest. Suppose some $\Delta^{\mathrm{row}}_{ab}P$ with $t(a) \neq t(b)$ is nonzero. Among the finitely many such pairs choose one with $o(b) - o(a)$ minimal;

then $\Delta^{\mathrm{row}}_{a'b'}P = 0$ whenever $t(a') \neq t(b')$ and $o(b') - o(a') < o(b) - o(a)$. Put $Q = \Delta^{\mathrm{row}}_{ab}P$. For $x \in I'$, (6.76) with $z = x$ and $E^{\mathrm{row}}_{xx}P = \nu(x)P$ gives $E^{\mathrm{row}}_{xx}Q = \nu(x)Q + \delta_{xa}\Delta^{\mathrm{row}}_{ab}P - \delta_{xb}\Delta^{\mathrm{row}}_{ab}P = (\nu + e_a - e_b)(x)\,Q$. Let $t(x) = t(z)$ and $o(z) < o(x)$. Then $E^{\mathrm{row}}_{xz}P = 0$, and (6.76) gives $E^{\mathrm{row}}_{xz}Q = \delta_{za}\Delta^{\mathrm{row}}_{xb}P - \delta_{xb}\Delta^{\mathrm{row}}_{az}P$. If $z = a$, then $o(b) - o(x) < o(b) - o(a)$, so $\Delta^{\mathrm{row}}_{xb}P = 0$; if $x = b$, then $o(z) - o(a) < o(b) - o(a)$, so $\Delta^{\mathrm{row}}_{az}P = 0$. Hence $E^{\mathrm{row}}_{xz}Q = 0$, and Q is K-highest of weight $\nu + e_a - e_b$ for o. By hypothesis $Q = 0$, a contradiction. So all $\Delta^{\mathrm{row}}_{ab}P$ vanish. □

Lemma 6.4.43. *Let R, C be finite sets with signs $\tau\colon R \to \{\pm1\}$, $\kappa\colon C \to \{\pm1\}$, let Y_{xy} ($x \in R$, $y \in C$) be variables, $\theta(x,y) = \tau(x)\kappa(y)$, $\partial_{xy} = \partial/\partial Y_{xy}$, and $l\colon R \to \mathbb{Z}$ injective. For $x, x' \in R$ with $\tau(x) = \tau(x')$ and $q \in \{\pm1\}$ put $\mathrm{Pl}^q_{x\leftarrow x'} = \sum_{y\in C:\ \theta(x',y)=q} Y_{xy}\partial_{x'y}$, an operator on $\mathbb{C}[Y]$. Let $F \in \mathbb{C}[Y]$ satisfy*

(i) $\sum_{x''\in R:\ \theta(x'',y)=1} \partial_{x''y}\partial_{x''y'}F = 0$ *whenever* $\kappa(y) \neq \kappa(y')$;

(ii) $\mathrm{Pl}^+_{x\leftarrow x'}F = \mathrm{Pl}^-_{x'\leftarrow x}F$ *whenever* $\tau(x) = \tau(x')$ *and* $l(x') < l(x)$.

Then:

(a) $\mathrm{Pl}^q_{x\leftarrow x'}F = 0$ *whenever* $\tau(x) = \tau(x')$ *and* $q\,(l(x) - l(x')) > 0$;

(b) if $x \in R$, $k \in \mathbb{Z}$ and $u \in \{\pm1\}$ satisfy $(\mathrm{Pl}^+_{x\leftarrow x} - \mathrm{Pl}^-_{x\leftarrow x})F = kF$ and $uk \geq 0$, then $\partial_{xy}F = 0$ for every y with $\theta(x,y) = -u$, and $\mathrm{Pl}^u_{x\leftarrow x}F = uk\,F$.

Proof. **The Fischer product.** For $p = \sum_m p_m Y^m$, $p' = \sum_m p'_m Y^m$ (multi-indices m, $m! = \prod m_i!$) put $\langle p, p'\rangle = \sum_m m!\,\overline{p_m}\,p'_m$, a positive definite hermitian form with $\langle Y_i p, p'\rangle = \langle p, \partial_i p'\rangle$ and $\langle p, Y_i p'\rangle = \langle \partial_i p, p'\rangle$.

Orthogonality. Let $\tau(x) = \tau(x')$, so $\theta(x,\cdot) = \theta(x',\cdot)$. Put $u_x(y,y') = \partial_{xy}\partial_{xy'}F$ and $M(q,x,x') = \sum_{y'\colon \theta(x,y')=-q}\sum_{y\colon \theta(x,y)=q}\langle u_x(y,y'), u_{x'}(y,y')\rangle$. In each term $y \neq y'$, so $\partial_{x'y'}(Y_{xy}\,\cdot) = Y_{xy}\partial_{x'y'}$, and the adjointness gives

$$\langle \mathrm{Pl}^{-q}_{x'\leftarrow x}F, \mathrm{Pl}^q_{x\leftarrow x'}F\rangle = \sum_{y',y}\langle \partial_{xy'}F,\ Y_{xy}\partial_{x'y'}\partial_{x'y}F\rangle = M(q,x,x').$$

As $u_x(y,y') = u_x(y',y)$, $M(-q,x,x') = M(q,x,x')$. Each $M(1,x,x')$ is real and ≥ 0: if $l(x') < l(x)$ it is $\|\mathrm{Pl}^+_{x\leftarrow x'}F\|^2$ by (ii); if $x' = x$ it is a sum of squared norms; if $l(x) < l(x')$ it is $M(-1,x,x') = \langle \mathrm{Pl}^+_{x'\leftarrow x}F, \mathrm{Pl}^-_{x\leftarrow x'}F\rangle = \|\mathrm{Pl}^-_{x\leftarrow x'}F\|^2$ by (ii) for (x',x). The x' with $\tau(x') = \tau(x)$ are those with $\theta(x',y) = 1$ for the y with $\theta(x,y) = 1$, so

$$\sum_{x'\colon \tau(x')=\tau(x)} M(1,x,x') = \sum_{y'\colon \theta(x,y')=-1}\ \sum_{y\colon \theta(x,y)=1}\Big\langle u_x(y,y'),\ \sum_{x''\colon \theta(x'',y)=1}\partial_{x''y}\partial_{x''y'}F\Big\rangle = 0$$

by (i), as $\kappa(y) \neq \kappa(y')$. Hence all $M(1,x,x')$ vanish, and

$$\langle \mathrm{Pl}^{-q}_{x'\leftarrow x}F, \mathrm{Pl}^q_{x\leftarrow x'}F\rangle = 0 \qquad (\tau(x) = \tau(x'),\ q = \pm1). \tag{6.77}$$

(a). By (ii), for (x,x') if $q = 1$ and for (x',x) if $q = -1$, $\mathrm{Pl}^q_{x\leftarrow x'}F = \mathrm{Pl}^{-q}_{x'\leftarrow x}F$; so $\|\mathrm{Pl}^q_{x\leftarrow x'}F\|^2 = 0$ by (6.77).

(b). Put $D^q = \mathrm{Pl}^q_{x\leftarrow x} = \sum_{y\colon \theta(x,y)=q} Y_{xy}\partial_{xy}$. The hypothesis gives $D^uF = D^{-u}F + ukF$, and (6.77) with $x' = x$, $q = u$ gives

$$0 = \langle D^{-u}F, D^uF\rangle = \|D^{-u}F\|^2 + uk\,\langle D^{-u}F, F\rangle, \qquad \langle D^{-u}F, F\rangle = \sum_{y\colon \theta(x,y)=-u}\|\partial_{xy}F\|^2 \geq 0.$$

Both terms are ≥ 0, so $D^{-u}F = 0$; then $\sum_{y\colon \theta(x,y)=-u}\|\partial_{xy}F\|^2 = \langle D^{-u}F, F\rangle = 0$, and $D^uF = ukF$. □

Lemma 6.4.44. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma, \gamma' \in \mathbb{Z}$, $\lambda\colon I \to \mathbb{Z}$, $\lambda'\colon I' \to \mathbb{Z}$, and let Q be a joint harmonic for the signs (s,t), the weights (γ,γ') and the parameters (λ,λ'). Let P be a polynomial in the variables X_{ac} ($a \in I'$, $c \in I$) such that P is Laplace harmonic for (s,t) ((HV6)), P is K-highest of weight $\mu_{\lambda'}$ for λ' for the row units of (s,t) with the shifts $(\gamma,-\gamma')$, and $C_{cc'}P = 0$ whenever $s(c) = s(c')$ and $-\lambda(c') < -\lambda(c)$, ($C_{cc'}$) the column units with these shifts. Then $P = aQ$ for some $a \in \mathbb{C}$.*

Proof. **Step 1: a linear class containing P and Q.** For a row a and $q \in \{\pm 1\}$ let $D_a^q = \sum_{c\colon \sigma(a,c)=q} X_{ac}\partial_{ac}$. By (HV5), $E_{aa}^{\mathrm{row}} = D_a^+ - D_a^- + \gamma - \#\{c : \sigma(a,c) = -1\}$, and for $a \neq b$ with $t(a) = t(b)$ and $c \neq d$ with $s(c) = s(d)$,

$$E_{ab}^{\mathrm{row}} = \sum_{c\colon \sigma(a,c)=1} X_{ac}\partial_{bc} - \sum_{c\colon \sigma(a,c)=-1} X_{bc}\partial_{ac}, \qquad E_{cd}^{\mathrm{col}} = -\sum_{a\colon \sigma(a,c)=1} X_{ad}\partial_{ac} + \sum_{a\colon \sigma(a,c)=-1} X_{ac}\partial_{ad}.$$

With ν as in Lemma 6.4.20, let $\mathcal{K}$ be the set of polynomials F with

(K1) $\Delta_{ab}^{\mathrm{row}}F = 0$ ($t(a) \neq t(b)$) and $\Delta_{cd}^{\mathrm{col}}F = 0$ ($s(c) \neq s(d)$);

(K2) $(D_a^+ - D_a^-)F = \nu(a)F$ for every row a;

(K3) $E_{ab}^{\mathrm{row}}F = 0$ whenever $t(a) = t(b)$ and $\lambda'(b) < \lambda'(a)$;

(K4) $E_{cd}^{\mathrm{col}}F = 0$ whenever $s(c) = s(d)$ and $\lambda(c) < \lambda(d)$.

$\mathcal{K}$ is a vector space; (K2) is $E_{aa}^{\mathrm{row}}F = \mu_{\lambda'}(a)F$ by the formula above, so $P \in \mathcal{K}$. Also $Q \in \mathcal{K}$: it is jointly highest of weights $(\mu_{\lambda'}, \mu_{-\lambda})$ for $(\lambda', -\lambda)$ ((b) of (HV7)), and since it is termwise harmonic every term $\partial_{ac}\partial_{bc}Q$ ($t(a) \neq t(b)$) and $\partial_{ac}\partial_{ad}Q$ ($s(c) \neq s(d)$) of the Laplacians vanishes. By (a) of the block rule, λ and λ' are injective.

Step 2: the rows. Let $F \in \mathcal{K}$. Apply Lemma 6.4.43 with $(R, C, \tau, \kappa, l) = (I', I, t, s, \lambda')$ and $Y = X$, so $\theta = \sigma$ and $\mathrm{Pl}_{a\leftarrow b}^q = \sum_{c\colon \sigma(b,c)=q} X_{ac}\partial_{bc}$: its (i) is $\Delta_{cc'}^{\mathrm{col}}F = 0$ (K1), and its (ii) is (K3), as $E_{ab}^{\mathrm{row}} = \mathrm{Pl}_{a\leftarrow b}^+ - \mathrm{Pl}_{b\leftarrow a}^-$ by Step 1. With (K2) ($D_a^q = \mathrm{Pl}_{a\leftarrow a}^q$, $k = \nu(a)$) it gives:

(R1) if $t(a) = t(b)$ and $q(\lambda'(a) - \lambda'(b)) > 0$, then $\mathrm{Pl}_{a\leftarrow b}^q F = 0$;

(R2) if $u \in \{\pm 1\}$ and $u\nu(a) \geq 0$, then $\partial_{ac}F = 0$ whenever $\sigma(a,c) = -u$, and $D_a^u F = u\nu(a)F$.

Step 3: the columns. Apply Lemma 6.4.43 with $(R, C, \tau, \kappa, l) = (I, I', s, t, \lambda)$ and $Y_{cb} = X_{bc}$, so $\theta(c,b) = \sigma(b,c)$ and $\mathrm{Pl}_{c\leftarrow c'}^q = \sum_{b\colon \sigma(b,c')=q} X_{bc}\partial_{bc'}$: its (i) reads $\sum_{c\colon \sigma(b,c)=1} \partial_{bc}\partial_{b'c}F = 0$ for $t(b) \neq t(b')$, which is $\Delta_{b'b}^{\mathrm{row}}F = 0$ (K1), since $\sigma(b', c) = -1$ for these c; its (ii) is (K4), as $E_{c'c}^{\mathrm{col}} = -\mathrm{Pl}_{c\leftarrow c'}^+ + \mathrm{Pl}_{c'\leftarrow c}^-$ by Step 1. By (a) there:

(C1) if $s(c) = s(c')$ and $q(\lambda(c) - \lambda(c')) > 0$, then $\sum_{b\colon \sigma(b,c')=q} X_{bc}\partial_{bc'}F = 0$.

Step 4: a nonzero element of $\mathcal{K}$ does not vanish at the matching matrix. Let x be the matrix with $x_{ac} = 1$ if (a,c) is matched and 0 otherwise; each row and each column of x has at most one entry 1 ((a) of Lemma 6.4.20). Let $F \in \mathcal{K}$, $F \neq 0$, and suppose $F(x) = 0$. Let $G(Y) = F(x + Y)$, G_d its nonzero homogeneous component of least degree ($d \geq 1$), and Y_{rc} a variable occurring in a monomial of G_d with nonzero coefficient, so $\partial G_d/\partial Y_{rc} \neq 0$; let $\varsigma = \sigma(r,c)$. A contradiction follows if (A) $\partial_{rc}F = 0$, or (B) there are an operator $T = \sum_j X_{\alpha_j}\partial_{\beta_j}$ and a constant k with $(T-k)F = 0$ and $\sum_j x_{\alpha_j}\partial_{\beta_j} = \partial_{rc}$: in the variables Y, $T - k = \partial/\partial Y_{rc} + \sum_j Y_{\alpha_j}\partial/\partial Y_{\beta_j} - k$, and the component of degree $d-1$ of $(T-k)G = 0$ is $\partial G_d/\partial Y_{rc} = 0$. By (a) of Lemma 6.4.20, either r is matched with no column and $|\tilde{\lambda}'(r)| < N' - N$, or r is matched with a column d_r, $p = \sigma(r, d_r) = \operatorname{sgn}\tilde{\lambda}'(r)$ and $|\tilde{\lambda}'(r)| > |N' - N|$.

Case 1: r unmatched, or $\varsigma = -p$. Then $-\varsigma\tilde\lambda'(r) > N - N'$, so $-\varsigma\nu(r) \geq 0$ by (c) of Lemma 6.4.20, and (R2) with $u = -\varsigma$ gives $\partial_{rc}F = 0$: (A).

Case 2: $\varsigma = p$ and $d_r = c$. Then $\varsigma\tilde\lambda'(r) > N - N'$, so $\varsigma\nu(r) \geq 0$, and (R2) with $u = \varsigma$ gives $(D_r^\varsigma - \varsigma\nu(r))F = 0$; row r of x has its only 1 in column c, which occurs in D_r^ς: (B).

Case 3: $\varsigma = p$, $d_r \neq c$, $\varsigma(\lambda(d_r) - \lambda(c)) > 0$. Here $s(d_r) = s(c)$. By (C1) with $(c, c') = (d_r, c)$ and $q = \varsigma$, $T = \sum_{b:\,\sigma(b,c)=\varsigma} X_{bd_r}\partial_{bc}$ kills F; column d_r of x has its only 1 in row r, which occurs in T: (B).

Case 4: $\varsigma = p$, $d_r \neq c$, $\varsigma(\lambda(c) - \lambda(d_r)) > 0$. Then $\varsigma\tilde\lambda(c) > \varsigma\tilde\lambda(d_r) = \varsigma\tilde\lambda'(r) > |N' - N|$; a column matched with no row has $|\tilde\lambda| < N - N' \leq |N' - N|$, so c is matched with a row $a \neq r$, with $\sigma(a, c) = \operatorname{sgn}\tilde\lambda(c) = \varsigma$, hence $t(a) = t(r)$, and $\varsigma(\lambda'(a) - \lambda'(r)) = \varsigma(\tilde\lambda(c) - \tilde\lambda(d_r)) > 0$. By (R1) with $(a, b) = (a, r)$ and $q = \varsigma$, $T = \mathrm{Pl}^\varsigma_{a\leftarrow r} = \sum_{c':\,\sigma(r,c')=\varsigma} X_{ac'}\partial_{rc'}$ kills F; row a of x has its only 1 in column c, which occurs in T: (B).

So $F(x) \neq 0$.

Step 5: conclusion. $Q \neq 0$ lies in $\mathcal{K}$, so $Q(x) \neq 0$; with $a = P(x)/Q(x)$, $P - aQ \in \mathcal{K}$ vanishes at x, hence $P = aQ$ by Step 4. □

Lemma 6.4.45. *Let S, T, V be spaces with points with signs s on n, s' on n', η on ι, and let (ω, θ) be a theta kernel for (S, T) on V. There are $C \geq 0$ and $A \in \mathbb{N}$ such that*

$$|\theta(\omega(g, h)\varphi)| \leq C\,\|\varphi\|\,(\mathrm{ht}_S(g)\,\mathrm{ht}_T(h))^A \qquad (g \in \mathrm{G}(s),\ h \in \mathrm{G}(s'),\ \varphi \in \mathcal{M}_\eta).$$

Proof. **Operators on a compact set.** Let $\Omega_S \subseteq \mathrm{G}(s)$ and $\Omega_T \subseteq \mathrm{G}(s')$ be the compact sets of Lemma 6.2.29 for S and T. The set $B_S = \{(x, 1) : x \in G_\infty(s),\ \|x_v\| \leq 2\ (v \in \Phi)\}$ is compact: $\mathrm{U}(\operatorname{diag} s)$ is closed in $\mathrm{M}_n(\mathbb{C})$, and on it $\|x^{-1}\| = \|\operatorname{diag}(s)x^*\operatorname{diag}(s)\| = \|x\|$, so $\{x \in \mathrm{U}(\operatorname{diag} s) : \|x\| \leq 2\}$ is a compact subset of $\mathrm{GL}_n(\mathbb{C})$; likewise $B_T \subseteq \mathrm{G}(s')$. Let $\mathcal{K} = (\Omega_S \cup B_S \cup \{1\}) \times (\Omega_T \cup B_T \cup \{1\})$, a compact subset of $\mathrm{G}(s) \times \mathrm{G}(s')$. For each $\varphi \in \mathcal{M}_\eta$ the map $k \mapsto \omega(k)\varphi$ is continuous ((ED3)), hence bounded on $\mathcal{K}$. The space $\mathcal{M}_\eta$ is a Banach space, a closed subspace of $L^1(\mu)$ by (1) of Lemma 4.1.10, and every $\omega(k)$ is a bounded operator; so the uniform boundedness principle gives $C_0 = \max(1, \sup_{k\in\mathcal{K}}\|\omega(k)\|) < \infty$. Choose $A \in \mathbb{N}$ with $2^A \geq C_0$.

The bound. Let $g \in \mathrm{G}(s)$ and $h \in \mathrm{G}(s')$. By Lemma 6.2.29, $g = \gamma z(x_1 \cdots x_k, 1)$ and $h = \delta z'(y_1 \cdots y_l, 1)$ with $\gamma \in \Gamma_S$, $\delta \in \Gamma_T$, $z \in \Omega_S$, $z' \in \Omega_T$, all $(x_i, 1) \in B_S$ and $(y_j, 1) \in B_T$, $2^k \leq \mathrm{ht}_S(g)$ and $2^l \leq \mathrm{ht}_T(h)$. The invariance of (ED3), applied to $\gamma^{-1}g$ and $\delta^{-1}h$, gives $\theta(\omega(g, h)\varphi) = \theta(\omega(\gamma^{-1}g, \delta^{-1}h)\varphi)$. As ω is a homomorphism on the product group,

$$\omega(\gamma^{-1}g, \delta^{-1}h) = \omega(z, 1)\prod_{i=1}^{k}\omega((x_i, 1), 1)\cdot\omega(1, z')\prod_{j=1}^{l}\omega(1, (y_j, 1)),$$

a product of $k + l + 2$ operators $\omega(\kappa)$ with $\kappa \in \mathcal{K}$. Hence

$$|\theta(\omega(g, h)\varphi)| \leq \|\theta\|\,2^{A(k+l+2)}\|\varphi\| \leq 4^A\|\theta\|\,(\mathrm{ht}_S(g)\,\mathrm{ht}_T(h))^A\|\varphi\|,$$

and $C = 4^A\|\theta\|$ works. □

Lemma 6.4.46. *Let V be a space with a point with signs s on n, e a cusp kernel of order 0 on $G_\infty(s)$, $K \subseteq G_f(n)$ an open subgroup, and F a continuous function on $\mathrm{G}(s)$, left invariant under Γ_V and right invariant under K, such that $x \mapsto e(x)F(g(x,1))$ is integrable on $G_\infty(s)$ for every $g \in \mathrm{G}(s)$. Then $R(e)F$ is a form of type e on V, right invariant under K.*

Proof. By (VP3) of Definition 3.2.2 V is a framed hermitian space U (with E^n as underlying space, the columns of $(x_V)_v$ as frames at $v \in \Phi$ and the finite isometry $z \mapsto x_{V,f}z$; a framed space of rank $\#n$ in the sense of (FT1) of Definition 3.2.4), with the signs s at every infinite place, $G^U = \mathrm{G}(s) = G_\infty(s) \times G_f(n)$ and $\Gamma_U = \Gamma_V$; so Lemma 5.8.29 applies to V. For $t > 0$ let $F_t = F \cdot \mathbf{1}_{\{|F| \le t\}}$. It is measurable ($F$ is continuous), bounded by t, left invariant under Γ_V and right invariant under K, as $|F|$ is. By Lemma 5.8.29, $R(e)F_t$ is defined everywhere, continuous, bounded, left invariant under Γ_V, right invariant under K, and $R(e)R(e)F_t = R(e)F_t$; since e is integrable, $R(e)F_t$ is a form of type e on V, right invariant under K ((ED2)). Let $\mathcal{W}$ be the space of these forms; it is finite-dimensional by Lemma 6.4.64.

Fix $g \in \mathrm{G}(s)$. For every x, $|e(x)F_t(g(x,1))| \le |e(x)F(g(x,1))|$, an integrable function of x by hypothesis, and $F_t(g(x,1)) \to F(g(x,1))$ as $t \to \infty$. By dominated convergence $R(e)F_t(g) \to R(e)F(g)$. So $R(e)F$ is the pointwise limit of elements of $\mathcal{W}$. In the space of all complex functions on $\mathrm{G}(s)$ with the topology of pointwise convergence, a Hausdorff topological vector space, the finite-dimensional subspace $\mathcal{W}$ is closed. Hence $R(e)F \in \mathcal{W}$. □

Lemma 6.4.47. *Let O be a descent pair with ranks $1 \le r < n$ that fits a parameter $l = (l_\tau)_{\tau\in\Phi}$, and let $\xi_O = v^+_{l_O}$. Then $\mathrm{Har}_O(\xi_O) = \prod_{\tau\in\Phi} P_\tau$, where each P_τ is a polynomial in the variables $X_{\tau,i,c}$ ($1 \le i \le n$, $1 \le c \le r$) that is a joint harmonic for the signs $(\varepsilon_O, \mathbf{1}_n)$, the weights $(r_-(O), \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau))$ and the parameters $(l_\tau, l_{O,\tau})$.*

Proof. Fix τ where it is not displayed; write $\kappa^\pm = \kappa^\pm_O$, $r_\pm = r_\pm(O)$, $\gamma = r_-$, $\gamma' = \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau)$.

Step 1: the highest vector. $l_{O,\tau}$ is strictly decreasing (DP11), so $\#\{a' : l_{O,\tau}(a') > l_{O,\tau}(a)\} = a - 1$ and, by (WM6), $\xi_O = \mathrm{ev}_{\kappa_O}(y_{\mathrm{id}})$, y_{id} the array with entry 1 at row a, column $a-1$. As $\kappa_O(\tau,i) = \kappa^+(\tau,i) + \kappa^-(\tau,n-i)$ (DP3), (c) of Lemma 3.2.20 gives $C_O\xi_O = \mathrm{ev}_{\kappa^+}(y_{\mathrm{id}}) \otimes \mathrm{ev}_{\kappa^-}(y_{w_0})$, y_{w_0} with entry 1 at row a, column $n-a$. By (DP8),

$$\mathrm{Har}_O(\xi_O) = \mathrm{Let}_1\big(\mathrm{Pol}_{\kappa^+}(\mathrm{ev}_{\kappa^+}(y_{\mathrm{id}}))\big) \cdot \mathrm{Let}_{-1}\big(\mathrm{Pol}_{\kappa^-}(\mathrm{ev}_{\kappa^-}(y_{w_0}))\big).$$

Step 2: the polynomial of an evaluation vector at a permutation array. Let κ be a weight of rank n and, for every τ, π_τ a bijection of $\{1,\dots,n\}$ onto $\{0,\dots,n-1\}$; let y^π have entry 1 at $(\tau, a, \pi_\tau(a))$ and 0 elsewhere. By Lemma 6.4.50 for the rows $R = \{1,\dots,n\}$ in their natural order,

$$\mathrm{Pol}_\kappa(\mathrm{ev}_\kappa(y^\pi)) = \prod_\tau \prod_{1\le h<n} M_{\tau,h}^{\kappa(\tau,h)}, \qquad M_{\tau,h} = \det\big(y_{\tau,\pi_\tau^{-1}(i),j}\big)_{0\le i,j<h}.$$

Step 3: the staircase. By (ii) of (DP11) and the injectivity of l_τ ((a) of the block rule, (i) of (DP11)), ord_O restricted to the columns of sign σ is a bijection onto $\{0,\dots,r_\sigma - 1\}$; let $c_\sigma(j)$ be the column of sign σ with $\mathrm{ord}_O = j$. So $\mathrm{Let}_\sigma(y_{\tau,i,j}) = X_{\tau,i,c_\sigma(j)}$ for $j < r_\sigma$ and $= 0$ for $j \ge r_\sigma$. For y_{id}, $\pi_\tau(a) = a - 1$; for y_{w_0}, $\pi_\tau(a) = n - a$. By Steps 1 and 2 and since Let_σ is a homomorphism of algebras, $\mathrm{Har}_O(\xi_O) = \prod_\tau P_\tau$ with

$$P_\tau = \prod_{\eta=\pm1} \prod_{1\le p<n} D_{\tau,\eta,p}^{\kappa^\eta(\tau,p)}, \qquad D_{\tau,1,p} = \det(X_{\tau,i+1,c_1(j)})_{i,j<p}, \quad D_{\tau,-1,p} = \det(X_{\tau,n-i,c_{-1}(j)})_{i,j<p},$$

where for $p > r_\eta$ the factor is 1: then a column $j \ge r_\eta$ of the minor is mapped to 0, but $\kappa^\eta(\tau,p) = 0$ by (iii) of (DP11). This is the polynomial P of Lemma 6.4.48 for $R = \{1,\dots,n\}$,

$C = \{1, \dots, r\}$, $\sigma = \varepsilon_O$, $l' = l_{O,\tau}$, $l = l_\tau$, $k(\eta, p) = \kappa^\eta(\tau, p)$ and the shifts $(\gamma_1, \gamma_2) = (\gamma, -\gamma')$: as $l_{O,\tau}$ is strictly decreasing, $x_1(a) = a - 1$ and $x_{-1}(a) = n - a$, so the rows of $D_{\tau,\eta,p}$ are the a_i of that lemma; its o is ord_O by (ii) of (DP11); $k(\eta, p) = 0$ for $p > r_\eta$ by (iii); and if $i + j > n$ then, as $r_+ + r_- = r < n$, $i > r_+$ or $j > r_-$, so $k(1, i) = 0$ or $k(-1, j) = 0$. By Lemma 6.4.48, P_τ is jointly highest of weights (ν, w) for $(l_{O,\tau}, -l_\tau)$ for the row and column units of $(\varepsilon_O, \mathbf{1}_n)$ with the shifts $(\gamma, -\gamma')$, with ν, w as there.

Step 4: the row weight is the lowest K-type of $l_{O,\tau}$. With $\gamma = r_-$,

$$\nu(a) = \sum_{a-1<p<n} \kappa^+(\tau, p) - \sum_{n-a<p<n} \kappa^-(\tau, p).$$

For the signs $\mathbf{1}_n$, $2\rho^{\mathrm{c}} = 2\rho$ in Definition 3.2.3, and as $l_{O,\tau}$ is strictly decreasing, $2\rho_{l_{O,\tau}}(a) = (n - a) - (a - 1)$. With $l_{O,\tau}(a) = 2(e_O(\tau) + \lambda_{O,\tau}(a - 1)) + n + 1 - 2a$ this gives $l^\rho_a = e_O(\tau) + \lambda_{O,\tau}(a - 1) + n + 1 - 2a$ and $\mu_{l_{O,\tau}}(a) = e_O(\tau) + \lambda_{O,\tau}(a - 1)$. By (DP3) and the head of Definition 3.2.19,

$$\begin{aligned} e_O(\tau) + \lambda_{O,\tau}(a - 1) &= -\sum_{1\le i<n} \kappa^-(\tau, i) + \sum_{a-1<h<n} \big(\kappa^+(\tau, h) + \kappa^-(\tau, n - h)\big) \\ &= \sum_{a-1<h<n} \kappa^+(\tau, h) - \sum_{n-a<i<n} \kappa^-(\tau, i), \end{aligned}$$

as $\sum_{a-1<h<n} \kappa^-(\tau, n - h) = \sum_{1\le i\le n-a} \kappa^-(\tau, i)$. So $\nu = \mu_{l_{O,\tau}}$.

Step 5: the column weight, and conclusion. By (i) of (DP11), $(l_\tau, l_{O,\tau})$ satisfies the block rule for the weights (γ, γ') and the signs $(\varepsilon_O, \mathbf{1}_n)$, so by Lemma 6.4.19 there is a joint harmonic Q for these signs, weights and parameters. By Steps 3 and 4, P_τ is termwise harmonic, K-highest of weight $\mu_{l_{O,\tau}}$ for $l_{O,\tau}$ for the row units, and killed by the column raising operators for $-l_\tau$; by Lemma 6.4.49, $P_\tau = aQ$ with $a \in \mathbb{C}$, and $a \ne 0$ as $P_\tau \ne 0$. For each column c the column unit C_{cc} multiplies P_τ by $w(c)$ and Q by $\mu_{-l_\tau}(c)$ ((b) of (HV7) for Q), so $w = \mu_{-l_\tau}$. Hence P_τ is jointly highest of weights $(\mu_{l_{O,\tau}}, \mu_{-l_\tau})$ for $(l_{O,\tau}, -l_\tau)$ with the shifts $(\gamma, -\gamma')$, and with the block rule it is a joint harmonic for $(\varepsilon_O, \mathbf{1}_n)$, (γ, γ'), $(l_\tau, l_{O,\tau})$. □

Lemma 6.4.48. *Let R and C be nonempty finite sets, $N = \#R$, σ signs on C, $\mathbf{1}_R$ the constant sign $+1$ on R, and $\gamma_1, \gamma_2 \in \mathbb{Z}$; consider the polynomials in the variables X_{ac} ($a \in R$, $c \in C$) with the row and column units of the signs $(\sigma, \mathbf{1}_R)$ with the shifts (γ_1, γ_2). Let $l' \colon R \to \mathbb{Z}$ and $l \colon C \to \mathbb{Z}$ be injective; for $\eta = \pm 1$ and $a \in R$ put $x_\eta(a) = \#\{a' \in R : \eta l'(a') > \eta l'(a)\}$, and for $c \in C$ put $o(c) = \#\{d \in C : \sigma(d) = \sigma(c),\ \sigma(c)l(c) < \sigma(c)l(d)\}$. Let $k(\eta, p) \in \mathbb{N}$ ($\eta = \pm 1$, $1 \le p < N$) satisfy $k(\eta, p) = 0$ whenever $p > \#\{c : \sigma(c) = \eta\}$, and $k(1, i) = 0$ or $k(-1, j) = 0$ whenever $i + j > N$. For $p \le \#\{c : \sigma(c) = \eta\}$ let $D_{\eta,p} = \det(X_{a_i,c_j})_{0\le i,j<p}$, where $a_i \in R$ is the row with $x_\eta(a_i) = i$ and $c_j \in C$ the column with $\sigma(c_j) = \eta$ and $o(c_j) = j$, and let*

$$P = \prod_{\eta=\pm1} \prod_{1\le p<N} D_{\eta,p}^{k(\eta,p)}.$$

Then P is jointly highest of weights (ν, w) for $(l', -l)$, where

$$\begin{aligned} \nu(a) &= \gamma_1 - \#\{c : \sigma(c) = -1\} + \sum_{\eta=\pm1} \eta \sum_{x_\eta(a)<p<N} k(\eta, p), \\ w(c) &= \gamma_2 + N\,[\sigma(c) = -1] - \sigma(c) \sum_{o(c)<p<N} k(\sigma(c), p), \end{aligned}$$

$[\sigma(c) = -1]$ being 1 if $\sigma(c) = -1$ and 0 otherwise.

Proof. Write $C_\pm = \{c \in C : \sigma(c) = \pm 1\}$ and $\partial_{ac} = \partial/\partial X_{ac}$. A factor $D_{\eta,p}$ with $k(\eta,p) > 0$ is defined, as then $p \le \#C_\eta$; factors with $k(\eta,p) = 0$ are 1. For $D = D_{\eta,p}$ let $\mathrm{rows}(D) = \{a \in R : x_\eta(a) < p\}$ and $\mathrm{cols}(D) = \{c \in C_\eta : o(c) < p\}$, the rows and columns of the $p \times p$ matrix whose determinant is D. The maps x_η and $o|_{C_\eta}$ are bijections onto $\{0,\dots,N-1\}$ and $\{0,\dots,\#C_\eta - 1\}$, l' and l being injective.

Step 1: the units as differential operators. From (HV5), using $\partial_{ac} X_{a'c'} = X_{a'c'}\partial_{ac} + \delta_{aa'}\delta_{cc'}$: for $a, a' \in R$,

$$E^{\mathrm{row}}_{aa'} = \sum_{c\in C_+} X_{ac}\partial_{a'c} - \sum_{c\in C_-} X_{a'c}\partial_{ac} + (\gamma_1 - \#C_-)\,\delta_{aa'}, \tag{6.78}$$

and for $c, c' \in C$ of the same sign,

$$E^{\mathrm{col}}_{cc'} = -\sum_{a\in R} X_{ac'}\partial_{ac} + \gamma_2\,\delta_{cc'} \quad (c,c' \in C_+), \qquad E^{\mathrm{col}}_{cc'} = \sum_{a\in R} X_{ac}\partial_{ac'} + (\gamma_2 + N)\,\delta_{cc'} \quad (c,c' \in C_-). \tag{6.79}$$

In each case the operator minus its scalar part is a derivation δ of $\mathbb{C}[X]$, so

$$\delta(P) = P\sum_{\eta,p} k(\eta,p)\,\delta(D_{\eta,p})/D_{\eta,p}$$

in the field of fractions; it suffices to compute δ on the factors. Two facts on a determinant D of a matrix of distinct variables are used: $\sum_{c\in\mathrm{cols}(D)} X_{bc}\partial_{b'c} D$ for $b' \in \mathrm{rows}(D)$ is the determinant with row b' replaced by row b (in the columns of D), which is 0 if $b \in \mathrm{rows}(D)$, $b \ne b'$, and D if $b = b'$; it is 0 if $b' \notin \mathrm{rows}(D)$; and the same holds for columns. Variables outside the rows or columns of D do not occur in D.

Step 2: the weights. Let $a \in R$. By (6.78) with $a' = a$ and Step 1, $\sum_{c\in C_+} X_{ac}\partial_{ac} D_{+,p} = [x_+(a) < p]\,D_{+,p}$ and $\sum_{c\in C_-} X_{ac}\partial_{ac} D_{-,p} = [x_-(a) < p]\,D_{-,p}$, while the sum over the columns of the other sign kills the factor. Hence

$$E^{\mathrm{row}}_{aa} P = \Big(\gamma_1 - \#C_- + \sum_{x_+(a)<p<N} k(1,p) - \sum_{x_-(a)<p<N} k(-1,p)\Big)P = \nu(a)\,P.$$

Let $c \in C_+$. Only the factors $D_{+,p}$ involve column c, each of degree $[o(c) < p]$ in it, so $E^{\mathrm{col}}_{cc} P = (\gamma_2 - \sum_{o(c)<p<N} k(1,p))P = w(c)P$. For $c \in C_-$ likewise $E^{\mathrm{col}}_{cc} P = (\gamma_2 + N + \sum_{o(c)<p<N} k(-1,p))P = w(c)P$.

Step 3: the raising conditions. Let $a \ne a'$ in R with $l'(a') < l'(a)$; then $x_+(a) < x_+(a')$ and $x_-(a') < x_-(a)$. On $D_{+,p}$ the operator (6.78) acts as $\sum_{c\in C_+} X_{ac}\partial_{a'c}$, which is 0 unless $a' \in \mathrm{rows}(D_{+,p})$; but then $x_+(a) < x_+(a') < p$, so $a \in \mathrm{rows}(D_{+,p})$ and the result is 0 by Step 1. On $D_{-,p}$ it acts as $-\sum_{c\in C_-} X_{a'c}\partial_{ac}$, which is 0 unless $a \in \mathrm{rows}(D_{-,p})$, and then $x_-(a') < x_-(a) < p$ gives $a' \in \mathrm{rows}(D_{-,p})$ and 0 again. So $E^{\mathrm{row}}_{aa'} P = 0$, and P is K-highest of weight ν for l' for the row units (all rows have the sign $+1$). Let $c \ne c'$ in C with $\sigma(c) = \sigma(c')$ and $-l(c') < -l(c)$, i.e. $l(c) < l(c')$. If both lie in C_+, then $o(c') < o(c)$, and $-\sum_a X_{ac'}\partial_{ac}$ is 0 on every factor unless $c \in \mathrm{cols}(D_{+,p})$, in which case $o(c') < o(c) < p$ puts c' among the columns and the result is 0. If both lie in C_-, then $o(c) < o(c')$, and $\sum_a X_{ac}\partial_{ac'}$ is 0 unless $c' \in \mathrm{cols}(D_{-,p})$, in which case c is a column too and the result is 0. So P is K-highest of weight w for $-l$ for the column units.

Step 4: $P \ne 0$ and termwise harmonicity. Each factor is a nonzero polynomial, so $P \ne 0$. All rows have the sign $+1$, so the first condition of termwise harmonicity is empty. Let $a \in R$. If a is a row of a factor $D_{1,p}$ and of a factor $D_{-1,q}$ with $k(1,p) > 0$ and $k(-1,q) > 0$, then $p \ge x_+(a) + 1$ and $q \ge x_-(a) + 1$, and $x_+(a) + x_-(a) = N - 1$, so $p + q \ge N + 1 > N$, which

the hypothesis on k excludes. So the variables of row a occurring in P all have columns of one sign, every monomial of P has this property, and $\partial^2 P/\partial X_{ac}\partial X_{ac'} = 0$ whenever $\sigma(c) \neq \sigma(c')$.

By Steps 2 to 4, P is jointly highest of weights (ν, w) for $(l', -l)$ (HV7). □

Lemma 6.4.49. *Let I, I' be nonempty finite sets with signs s on I and t on I', let $\gamma, \gamma' \in \mathbb{Z}$, $\lambda\colon I \to \mathbb{Z}$, $\lambda'\colon I' \to \mathbb{Z}$, and let Q be a joint harmonic for the signs (s,t), the weights (γ, γ') and the parameters (λ, λ'). Let P be a polynomial in the variables X_{ac} ($a \in I'$, $c \in I$) that is termwise harmonic, K-highest of weight $\mu_{\lambda'}$ for λ' for the row units of (s,t) with the shifts $(\gamma, -\gamma')$, and that satisfies $C_{cc'}P = 0$ whenever $s(c) = s(c')$ and $-\lambda(c') < -\lambda(c)$, $(C_{cc'})$ the column units with these shifts. Then $P = aQ$ for some $a \in \mathbb{C}$.*

Proof. As P is termwise harmonic, $\partial^2 P/\partial X_{ac}\partial X_{bc} = 0$ whenever $t(a) \neq t(b)$ and $\partial^2 P/\partial X_{ac}\partial X_{ad} = 0$ whenever $s(c) \neq s(d)$; every term of $\Delta^{\mathrm{row}}_{ab}P$ ($t(a) \neq t(b)$) and of $\Delta^{\mathrm{col}}_{cd}P$ ($s(c) \neq s(d)$) is of this form, so these Laplacians kill P. The remaining hypotheses of Lemma 6.4.44 (row weight $\mu_{\lambda'}$, compact row and column raising operators) are those of the statement, so $P = aQ$ for some $a \in \mathbb{C}$ by that lemma. □

Lemma 6.4.50. *Let Φ be a finite set, R a totally ordered finite set of $N \geq 1$ rows (the order used for the minors of (WM1)), and κ a weight in rank N at every $\tau \in \Phi$ with rows R. For every $\tau \in \Phi$ let $\pi_\tau\colon R \to \{0, \dots, N-1\}$ be a bijection, and let y^π be the array with $y^\pi_{\tau,a,c} = 1$ if $c = \pi_\tau(a)$ and $y^\pi_{\tau,a,c} = 0$ otherwise. Then*

$$\mathrm{Pol}_\kappa(\mathrm{ev}_\kappa(y^\pi)) = \prod_{\tau\in\Phi}\prod_{1\leq h<N} M_{\tau,h}^{\kappa(\tau,h)}, \qquad M_{\tau,h} = \det\bigl(y_{\tau,\pi_\tau^{-1}(i),j}\bigr)_{0\leq i,j<h}.$$

Proof. By (WM4) and (WM3), and since $\Delta_T = \sum_i (F_\kappa)_{Ti} b_i$ as polynomials and hence also at y,

$$\mathrm{Pol}_\kappa(\mathrm{ev}_\kappa(y)) = \sum_{i,j} (F_\kappa^{\mathsf{T}} F_\kappa)_{ij}\, b_j(y)\, b_i = \sum_{T\in\mathcal{C}_\kappa} \Delta_T(y)\, \Delta_T$$

for every array y. Let $T \in \mathcal{C}_\kappa$ and let $T(\tau,h,j) = \{a_0 < \dots < a_{h-1}\}$ be one of its sets. The matrix $(y^\pi_{\tau,a_k,c})_{0\leq k,c<h}$ has in row k a single nonzero entry 1, in the column $\pi_\tau(a_k)$, if $\pi_\tau(a_k) < h$, and no nonzero entry otherwise. So it is a permutation matrix if $\pi_\tau(T(\tau,h,j)) = \{0,\dots,h-1\}$, and it has a zero row otherwise. Hence $\Delta_T(y^\pi) \neq 0$ only for the one filling with $T(\tau,h,j) = A_{\tau,h} = \pi_\tau^{-1}\{0,\dots,h-1\}$ for all (τ,h,j), and then $\Delta_{\tau,A_{\tau,h}}(y^\pi) = \epsilon_{\tau,h}$ is the sign of the permutation $k \mapsto \pi_\tau(a_k)$ of $\{0,\dots,h-1\}$. Therefore

$$\mathrm{Pol}_\kappa(\mathrm{ev}_\kappa(y^\pi)) = \prod_{\tau,h} \bigl(\epsilon_{\tau,h}\, \Delta_{\tau,A_{\tau,h}}\bigr)^{\kappa(\tau,h)},$$

and $\epsilon_{\tau,h}\Delta_{\tau,A_{\tau,h}} = M_{\tau,h}$: permuting the rows of the minor $\Delta_{\tau,A_{\tau,h}}$ from the increasing order $a_0 < \dots < a_{h-1}$ to the order $\pi_\tau^{-1}(0), \dots, \pi_\tau^{-1}(h-1)$ multiplies it by $\epsilon_{\tau,h}$. □

Lemma 6.4.51. *Let D be admissible data, $z \in \{\mathrm{I}, \mathrm{II}\}$, $i, n \geq 0$ with $i + n < m$, and ϑ an m-fold twist.*

*(a) For every function Ψ on $\mathrm{M}_{n_{n+1}\times n_n}(R_\vartheta)$, the **datum lift** $\mathrm{Tl}^i_{\vartheta,z,n}[\Psi] = L_\varphi$, for the theta kernel and the characters of the triangle lift at (i,n) and $\varphi = \mathrm{mod}_{\mathfrak{t}_\vartheta(z)}(\Psi, v_H)$, maps $\mathcal{F}^i_\triangle(z,n)$ to $\mathcal{F}^i_\triangle(z,n+1)$; $\mathrm{Tl}^i_{\vartheta,z,n}$ is the case of the point datum.*

(b) *For a left pair* Φ *at* (i,n) *and every function* Ψ *on* $\mathrm{M}_{n_{n+1}\times n_n}(R_\vartheta)$, $\mathrm{Ds}^i_{\vartheta,z,n}(\Phi,\Psi)$ *maps* $\mathcal{F}^i_\triangle(z,n+1)$ *to* $\mathcal{F}^{i+1}_\triangle(z,n)$*; for a reversed pair* Φ' *at* (i,n) *and every function* Ψ' *on* $\mathrm{M}_{n_n\times n_{n+1}}(R_\vartheta)$, $\mathrm{As}^i_{\vartheta,z,n}(\Phi',\Psi')$ *maps* $\mathcal{F}^{i+1}_\triangle(z,n)$ *to* $\mathcal{F}^i_\triangle(z,n+1)$.

(c) *All these maps are linear in the form and in the finite datum: for instance* $\mathrm{Ds}^i_{\vartheta,z,n}(\Phi,\Psi)=\sum_\eta \Psi(\eta)\,\mathrm{Ds}^i_{\vartheta,z,n}(\Phi,\mathbf{1}_\eta)$, $\mathbf{1}_\eta$ *the indicator function of* η.

(d) *For every function* Ψ *as in (a) and every* $x\in\mathcal{F}^i_\triangle(z,n+1)$ *there is* $x^\dagger\in\mathcal{F}^i_\triangle(z,n)$ *with* $\langle \mathrm{Tl}^i_{\vartheta,z,n}[\Psi]\,y,\ x\rangle=\langle y,\ x^\dagger\rangle$ *for every* $y\in\mathcal{F}^i_\triangle(z,n)$*, the Petersson products of* $V^i_{z,n+1}$ *and* $V^i_{z,n}$.

Proof. Write $\mathfrak{t}=\mathfrak{t}_\vartheta(z)$ and $P=\Sigma(\mathfrak{t})$, a nonempty set of places containing the conjugate of none of its members (the chosen places and, if $z=\mathrm{I}$, the places of Q: (DP1) of Definition 3.2.23 through (LF4) of Definition 3.2.26).

Step 1: the characters are trivial at integral points that are 1 modulo $\mathfrak{t}$. The characters involved are edge characters (GP6) with $c=\neg z$ and left-pair characters $\chi^{-1}\upsilon^N$ with χ an edge character (TV6). By Definition 3.2.26, μ^0_{l+1} has a tame part trivial off the chosen places, υ has trivial tame part, and ϑ^{l+1} (present only if $\neg z=\mathrm{II}$, i.e. $z=\mathrm{I}$) has a tame part trivial off Q; tame parts multiply under products and inverses. So each character α involved has a tame part ψ with $\psi_w=1$ for $w\notin P$. For an index set n' and $k\in\mathbf{K}_0(n')$ with $k\equiv\mathbf{1}\pmod{\mathfrak{t}}$, $u=\det k$ has infinite components 1, unit finite components and $u\bmod w=1$ for $w\in P$, so $\alpha(u)=1$ by the definition of weight and tame part. The group $K_\mathfrak{t}(n')$ of such k is open in $G_f(n')$ (it contains the product of the principal congruence subgroups at the places below P with the integral points elsewhere).

Step 2: the data are fixed by these groups. Let (S,T) be the pair of spaces of one of the maps, with index sets a, b and characters (α,β), and $\varphi=\mathrm{mod}_\mathfrak{t}(\Psi,\upsilon)$ its datum, υ the Fock vector of the polynomial. For $k\in K_\mathfrak{t}(a)$ and $k'\in K_\mathfrak{t}(b)$, (6) of Lemma 4.1.1 gives $\omega_{\alpha,\beta}((1,k),(1,k'))\varphi=\alpha(\det k')\beta(\det k)^{-1}\,\mathrm{mod}_\mathfrak{t}(\Psi_{k,k'},\upsilon)$ with $\Psi_{k,k'}(X)=\Psi(\bar{k}'^{-1}X\bar{k})=\Psi(X)$, the reductions modulo $\mathfrak{t}$ being $\mathbf{1}$; by Step 1, $\omega_{\alpha,\beta}((1,k),(1,k'))\varphi=\varphi$.

Step 3: the images have a level. For a lift L_φ and a form F on S, $h\in\mathrm{G}$ (the adelic group of T) and $k'\in K_\mathfrak{t}(b)$,

$$L_\varphi F(h(1,k'))=\int_{[\mathrm{U}(S)]}\theta\big(\omega_{\alpha,\beta}(g,h)\,\omega_{\alpha,\beta}(1,(1,k'))\varphi\big)F(g)\,dg=L_\varphi F(h)$$

by Step 2 with $k=\mathbf{1}$. For a descent or an ascent, F is a function on the adelic group of T and the map is $g\mapsto\int_{[\mathrm{U}(T)]}\theta(\omega_{\alpha,\beta}(g,h)\varphi)F(h)\,dh$; the same computation with $k\in K_\mathfrak{t}(a)$, $k'=\mathbf{1}$ shows that its value is right invariant under $K_\mathfrak{t}(a)$.

Step 4: the images are triangle forms. By Lemma 6.3.77, $(\omega_{\alpha,\beta},\theta_{\mathrm{Hom}(S,T)})$ is a theta kernel for (S,T) on $\mathrm{Hom}(S,T)$ with real part $\Omega_{\gamma,\gamma'}$, (γ,γ') the weights of (α,β); by Lemma 6.4.53 (exchanging the two factors), $((h,g)\mapsto\omega_{\alpha,\beta}(g,h),\theta_{\mathrm{Hom}(S,T)})$ is a theta kernel for (T,S) on the same space with real part $(y,x)\mapsto\Omega_{\gamma,\gamma'}(x,y)$, whose lift is the map

$$F\mapsto\big(g\mapsto\int_{[\mathrm{U}(T)]}\theta(\omega_{\alpha,\beta}(g,h)\varphi)F(h)\,dh\big).$$

(a): by Lemma 6.4.15(b), v_H is an edge for the weights of the characters of the triangle lift from e_λ to $e_{\lambda'}$, $\lambda=\frac12 p^i_{z,0,n}$, $\lambda'=\frac12 p^i_{z,0,n+1}$; by (ED4)(c) for its first half edge and Step 3, the image of a form of type e_λ is a form of type $e_{\lambda'}$. (b): for a left pair Φ, v_Φ is an edge for the weights

of $(\chi^{\mathrm{lp}}_{\vartheta,z,i}(N_n), \chi^{\mathrm{lp}}_{\vartheta,z,i}(N_{n+1}))$ from $e_{-\mu}$ to $e_{-\mu'}$, $\mu = \frac{1}{2}p^{i+1}_{z,0,n}$, $\mu' = \frac{1}{2}p^{i}_{z,0,n+1}$, with $e_{-\mu} = \overline{e_\mu}$ and $e_{-\mu'} = \overline{e_{\mu'}}$ (TV6); its second half edge is for $(y,x) \mapsto \Omega(x,y)$ from $\overline{e_{-\mu'}} = e_{\mu'}$ to $\overline{e_{-\mu}} = e_\mu$, so by (ED4)(c) for the exchanged kernel and Step 3 the descent maps forms of type $e_{\mu'}$ on $V^i_{z,n+1}$ to forms of type e_μ on $V^{i+1}_{z,n}$. For a reversed pair the same argument, with $v_{\Phi'}$ an edge from $e_{-\mu'}$ to $e_{-\mu}$ for the weights $(\delta_i(N_{n+1}), \delta_i(N_n))$, shows that the ascent maps forms of type e_μ on $V^{i+1}_{z,n}$ to forms of type $e_{\mu'}$ on $V^i_{z,n+1}$.

Step 5: (c). The map $\Psi \mapsto \Psi^\natural$ is linear, so $\Psi \mapsto \mathrm{mod}_{\mathfrak{t}}(\Psi, v) = v \otimes (\Psi^\natural \otimes_P v^0)$ is linear ((WR6) of Definition 3.2.18); θ and $\omega_{\alpha,\beta}(g,h)$ are linear, so the kernel of Ψ is $\sum_\eta \Psi(\eta)$ times the kernel of $\mathbf{1}_\eta$, pointwise; each summand, multiplied by a triangle form, is integrable by Lemma 6.4.52 (the types e_λ, $e_{\mu'}$, e_μ are cusp kernels of order 0 by (ED4)(a) of the edges of Step 4), so the integral of the sum is the sum of the integrals. Writing $\Psi = \sum_\eta \Psi(\eta)\mathbf{1}_\eta$ gives (c); linearity in the form is linearity of the integral.

Step 6: (d). Let $(S,T) = (V^i_{z,n}, V^i_{z,n+1})$, $\theta(g,h) = \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)$ the kernel of $\mathrm{Tl}^i_{\vartheta,z,n}[\Psi]$, and put $x^\dagger(g) = \int_{[\mathrm{U}(T)]} \overline{\theta(g,h)}\, x(h)\, dh$. By Lemma 6.4.52 the function $(g,h) \mapsto \theta(g,h)y(g)\overline{x(h)}$ is integrable, and Fubini gives $\langle \mathrm{Tl}^i_{\vartheta,z,n}[\Psi]y, x\rangle = \int_{[\mathrm{U}(S)]} \overline{y(g)}\, x^\dagger(g)\, dg = \langle y, x^\dagger\rangle$. Now $x^\dagger = \overline{G}$ with $G(g) = \int_{[\mathrm{U}(T)]} \theta(g,h)\overline{x(h)}\, dh$, the lift of $\overline{x}$ for the exchanged kernel of Step 4. The function $\overline{x}$ is a form of type $\overline{e_{\lambda'}}$ (complex conjugation preserves continuity, boundedness, left invariance and levels, and $R(\overline{e})\overline{F} = \overline{R(e)F}$); G has a level by Step 3; and the second half edge of v_H is a half edge for the exchanged real part from $\overline{e_{\lambda'}}$ to $\overline{e_\lambda}$, so G is a form of type $\overline{e_\lambda}$ by (ED4)(c), and $x^\dagger = \overline{G}$ is a form of type e_λ, i.e. $x^\dagger \in \mathcal{F}^i_\triangle(z,n)$. □

Lemma 6.4.52. *Let S, T be spaces with signs s on n and s' on n', α, β automorphic characters of $\mathrm{U}(1)$, $\mathfrak{m}$ a modulus, Ψ a function on $\mathrm{M}_{n'\times n}(R_\mathfrak{m})$, P a polynomial and $\varphi = \mathrm{mod}_\mathfrak{m}(\Psi, v_P)$. Let e, e' be cusp kernels of order 0 on $G_\infty(s)$, $G_\infty(s')$, and F, F' forms of type e on S and of type e' on T. Then for every $h \in \mathrm{G}(s')$ the function $g \mapsto \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)\, F(g)$ is integrable on $[\mathrm{U}(S)]$, and for every $g \in \mathrm{G}(s)$ the function $h \mapsto \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)\, F'(h)$ is integrable on $[\mathrm{U}(T)]$; moreover $(g,h) \mapsto \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)\, F(g)\, F'(h)$ is integrable on $[\mathrm{U}(S)] \times [\mathrm{U}(T)]$.*

Proof. Write $\kappa(g,h) = \theta^{S,T}_{\alpha,\beta}(\varphi)(g,h) = \theta_{\mathrm{Hom}(S,T)}(\omega_{\alpha,\beta}(g,h)\varphi)$. The datum $\varphi = \mathrm{mod}_\mathfrak{m}(\Psi, v_P)$ is an element of $\mathcal{M}_{S,T}$ ((XD5), (WR6)), so $\|\varphi\| < \infty$.

Continuity and invariance. By (2) of Lemma 4.1.1, $(x,f) \mapsto \omega_{s'\otimes s}(x)f$ is continuous; the pair map $(g,h) \mapsto h \otimes (g^{-1})^{\mathsf{T}}$ and the characters $\alpha(\det h)$, $\beta(\det g)^{-1}$ are continuous, and $\theta_{\mathrm{Hom}(S,T)}$ is bounded. Hence κ is continuous on $\mathrm{G}(s) \times \mathrm{G}(s')$. By Lemma 6.2.5, $\kappa(\gamma g, \gamma' h) = \kappa(g,h)$ for $\gamma \in \Gamma_S$, $\gamma' \in \Gamma_T$; forms are left invariant under the rational points (ED2). So the three functions of the statement are continuous and invariant under Γ_S, Γ_T, $\Gamma_S \times \Gamma_T$ respectively, and define continuous, hence measurable, functions on $[\mathrm{U}(S)]$, $[\mathrm{U}(T)]$ and $[\mathrm{U}(S)] \times [\mathrm{U}(T)]$.

Bounds. By Lemma 6.2.28 there are $Y \geq 0$ and $A \in \mathbb{N}$ with $|\kappa(g,h)| \leq Y\|\varphi\|\, (\mathrm{ht}_S(g)\, \mathrm{ht}_T(h))^A$ for all g, h. By Lemma 6.3.75, applied with $B = 0$ to the cusp kernels e, e' of order 0 and the forms F, F', the numbers $C_F = \sup_g |F(g)|\, \mathrm{ht}_S(g)^A$ and $C_{F'} = \sup_h |F'(h)|\, \mathrm{ht}_T(h)^A$ are finite. Hence, as forms are bounded (ED2),

$$\begin{aligned} |\kappa(g,h)F(g)| &\leq Y\|\varphi\|\, C_F\, \mathrm{ht}_T(h)^A, \\ |\kappa(g,h)F'(h)| &\leq Y\|\varphi\|\, C_{F'}\, \mathrm{ht}_S(g)^A, \\ |\kappa(g,h)F(g)F'(h)| &\leq Y\|\varphi\|\, C_F C_{F'} \end{aligned}$$

for all $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$.

Integrability. By Theorem 4.2.18 (for $\mathrm{U}(S)$ and $\mathrm{U}(T)$ with the Haar measures of (VP1) of Definition 3.2.2; a space of rank 0 has the trivial group and nothing to prove), $[\mathrm{U}(S)]$ and $[\mathrm{U}(T)]$

have finite volume, and so has their product. A measurable function bounded by a constant is integrable on a space of finite measure. For fixed h the first bound is a constant in g, for fixed g the second is a constant in h, and the third is a constant; so the three functions are integrable on $[\mathrm{U}(S)]$, on $[\mathrm{U}(T)]$ and on $[\mathrm{U}(S)] \times [\mathrm{U}(T)]$. □

Lemma 6.4.53. *Let S, T, V be spaces with points with signs s on n, s' on n', η on ι, let $\varepsilon(v,i) = \eta_i$, and let (ω, θ) be a theta kernel for (S,T) on V with real part Ω. Put $\omega^{\mathrm{ex}}(h,g) = \omega(g,h)$ for $h \in \mathrm{G}(s')$, $g \in \mathrm{G}(s)$, and $\Omega^{\mathrm{ex}}(y,x) = \Omega(x,y)$ for $y \in G_\infty(s')$, $x \in G_\infty(s)$. Then $(\omega^{\mathrm{ex}}, \theta)$ is a theta kernel for (T,S) on V with real part Ω^{ex}, and the lift with datum $\varphi \in \mathcal{M}_\eta$ of a function F on $\mathrm{G}(s')$ is*

$$g \longmapsto \int_{[\mathrm{U}(T)]} \theta(\omega(g,h)\varphi) F(h)\, dh \qquad (g \in \mathrm{G}(s)).$$

Proof. Let $\sigma\colon \mathrm{G}(s') \times \mathrm{G}(s) \to \mathrm{G}(s) \times \mathrm{G}(s')$, $\sigma(h,g) = (g,h)$; it is an isomorphism of topological groups, and $\omega^{\mathrm{ex}} = \omega \circ \sigma$.

Homomorphism and continuity. As a composite of homomorphisms, ω^{ex} is a homomorphism from $\mathrm{G}(s') \times \mathrm{G}(s)$ to the bounded operators of $\mathcal{M}_\eta$. The map $(p,\varphi) \mapsto \omega^{\mathrm{ex}}(p)\varphi$ is the composite of the homeomorphism $\sigma \times \mathrm{id}$ with the continuous map $(q,\varphi) \mapsto \omega(q)\varphi$ of (ED3), hence continuous.

Invariance of the functional. The functional θ is bounded and linear on $\mathcal{M}_\eta$. For $\gamma' \in \Gamma_T$, $\gamma \in \Gamma_S$, $h \in \mathrm{G}(s')$, $g \in \mathrm{G}(s)$ and $\varphi \in \mathcal{M}_\eta$, the invariance of (ω, θ) gives

$$\theta(\omega^{\mathrm{ex}}(\gamma' h, \gamma g)\varphi) = \theta(\omega(\gamma g, \gamma' h)\varphi) = \theta(\omega(g,h)\varphi) = \theta(\omega^{\mathrm{ex}}(h,g)\varphi).$$

So $(\omega^{\mathrm{ex}}, \theta)$ is a theta kernel for (T,S) on V; the signs of T, S, V are s', s, η, and ε is unchanged.

Real part. Ω^{ex} maps $G_\infty(s') \times G_\infty(s)$ to bounded operators of $\mathcal{F}_\varepsilon$, and for $y \in G_\infty(s')$, $x \in G_\infty(s)$, $v \in \mathcal{F}_\varepsilon$, $f \in \mathcal{M}_\eta$,

$$\omega^{\mathrm{ex}}\big((y,1),(x,1)\big)(v \otimes f) = \omega\big((x,1),(y,1)\big)(v \otimes f) = \big(\Omega(x,y)v\big) \otimes f = \big(\Omega^{\mathrm{ex}}(y,x)v\big) \otimes f.$$

The lift. By (ED3) for the pair (T,S), the lift of F with datum φ is

$$g \mapsto \int_{[\mathrm{U}(T)]} \theta(\omega^{\mathrm{ex}}(h,g)\varphi) F(h)\, dh,$$

and $\omega^{\mathrm{ex}}(h,g) = \omega(g,h)$. □

Lemma 6.4.54. *Let D be admissible data, $z \in \{\mathrm{I}, \mathrm{II}\}$, $0 \le i < m$, Φ a left pair at $(i,0)$ and ϑ an m-fold twist. There is a function Ψ_0 on $\mathrm{M}_{n_1 \times n_0}(R_\vartheta)$ such that for all $y \in \mathcal{F}^i_\triangle(z,0)$ and $x \in \mathcal{F}^i_\triangle(z,1)$*

$$\big\langle x,\ \mathrm{Tl}^i_{\vartheta,z,0}\, y \big\rangle_{V^i_{z,1}} = \big\langle \mathrm{Ds}^i_{\vartheta,z,0}(\Phi, \Psi_0)\, x,\ y \big\rangle_{V^{i+1}_{z,0}},$$

where on the right y is read as a triangle form at $(i+1,0)$ (Lemma 6.4.15(a)).

Proof. Write $S = V^i_{z,0}$, $S^- = V^{i+1}_{z,0}$ (its opposite space, with the same adelic group, (TV1)), $T = V^i_{z,1}$, $\mathfrak{t} = \mathfrak{t}_\vartheta(z)$, ν_1, ν_2 the edge characters with $c = \neg z$, $l = i$ at the ranks N_0, N_1, H the joint harmonic and $\varphi = \mathrm{mod}_{\mathfrak{t}}(\Phi_0^{\mathrm{pt}}, v_H)$ the datum of $\mathrm{Tl}^i_{\vartheta,z,0}$, $\theta = \theta^{S,T}_{\nu_1,\nu_2}(\varphi)$, and $\lambda = \frac{1}{2}p^i_{z,0,0}$, $\lambda' = \frac{1}{2}p^i_{z,0,1}$, so that the triangle forms at $(i,0)$, $(i+1,0)$ and $(i,1)$ are the forms of type e_λ, e_λ and $e_{\lambda'}$ (Lemma 6.4.15(a)).

Step 1: Fubini. By Lemma 6.4.15(b), v_H is an edge from e_λ to $e_{\lambda'}$, so e_λ and $\overline{e_{\lambda'}}$ are cusp kernels of order 0 ((ED4)(a) of its two half edges), and so is $e_{\lambda'}$ (every clause of (ED1) is preserved by complex conjugation). By Lemma 6.4.52, $(g,h)\mapsto \theta(g,h)\,y(g)\,\overline{x(h)}$ is integrable on $[\mathrm{U}(S)]\times[\mathrm{U}(T)]$, and Fubini gives

$$\langle x, \mathrm{Tl}^i_{\vartheta,z,0} y\rangle_T = \int_{[\mathrm{U}(T)]} \overline{x(h)} \int_{[\mathrm{U}(S)]} \theta(g,h)\,y(g)\,dg\,dh = \int_{[\mathrm{U}(S)]} \overline{D(g)}\,y(g)\,dg,$$
$$D(g) = \int_{[\mathrm{U}(T)]} \overline{\theta(g,h)}\,x(h)\,dh.$$

Step 2: the conjugate kernel. By Lemma 6.4.55 there are c with $|c|=1$ and $\Psi'(X) = \overline{\Phi_0^{\mathrm{pt}}(u^{-1}X)}$ with $\overline{\theta(g,h)} = c\,\theta^{S^-,T}_{\nu_1^{-1}\upsilon^{N_0},\,\nu_2^{-1}\upsilon^{N_1}}(\mathrm{mod}_{\mathfrak{t}}(\Psi', v_{\bar H}))(g,h)$. By (TV6), $\nu_1^{-1}\upsilon^{N_0} = \chi^{\mathrm{lp}}_{\vartheta,z,i}(N_0)$ and $\nu_2^{-1}\upsilon^{N_1} = \chi^{\mathrm{lp}}_{\vartheta,z,i}(N_1)$, the characters of the descents at $(i,0)$. For a polynomial Q write D_Q for the map $x\mapsto (g\mapsto \int_{[\mathrm{U}(T)]}\theta^{S^-,T}_{\chi^{\mathrm{lp}}(N_0),\chi^{\mathrm{lp}}(N_1)}(\mathrm{mod}_{\mathfrak{t}}(\Psi', v_Q))(g,h)\,x(h)\,dh)$; so $D = c\,D_{\bar H}x$, and $D_\Phi = \mathrm{Ds}^i_{\vartheta,z,0}(\Phi,\Psi')$ (TV7).

Step 3: trading $\bar H$ for the left pair. By Lemma 6.3.77 and Lemma 6.4.53 (exchanging the two factors), the theta kernel of the pair (S^-,T) with these characters gives a theta kernel for (T,S^-) whose real part is $(y',x')\mapsto \Omega_{\delta,\delta'}(x',y')$, $(\delta,\delta') = (\delta_i(N_0),\delta_i(N_1))$, and D_Q is its lift with datum $\mathrm{mod}_{\mathfrak{t}}(\Psi', v_Q)$. By (TV6), v_Φ is an edge for (δ,δ') from $e_{-\mu}$ to $e_{-\mu'}$, $\mu = \frac12 p^{i+1}_{z,0,0} = \lambda$ ((GP5): no block indices at column 0), $\mu' = \frac12 p^i_{z,0,1} = \lambda'$, with $e_{-\mu} = \overline{e_\mu}$; its second half edge is a half edge for the exchanged real part from $\overline{e_{-\mu'}} = e_{\lambda'}$ to $\overline{e_{-\mu}} = e_\lambda$, and e_λ is an idempotent kernel (Step 1). The lift $D_\Phi x$ has a level (Lemma 6.4.51(b)). So Lemma 6.4.57, with $P=\bar H$, the form x of type $e_{\lambda'}$ on T and the form y of type e_λ on S^-, gives $\kappa\in\mathbb{C}$, depending only on $\bar H$, Φ and e_λ, with $\langle y, D_{\bar H}x\rangle_{S^-} = \kappa\,\langle y, D_\Phi x\rangle_{S^-}$.

Step 4: conclusion. The Petersson products of S and S^- agree (Lemma 6.4.15(a)). By Steps 1–3,

$$\langle x, \mathrm{Tl}^i_{\vartheta,z,0} y\rangle_T = \langle D, y\rangle_{S^-} = \bar c\,\overline{\langle y, D_{\bar H}x\rangle} = \bar c\,\bar\kappa\,\overline{\langle y, D_\Phi x\rangle}$$
$$= \big\langle c\kappa\,\mathrm{Ds}^i_{\vartheta,z,0}(\Phi,\Psi')x,\ y\big\rangle_{S^-},$$

and $c\kappa\,\mathrm{Ds}^i_{\vartheta,z,0}(\Phi,\Psi') = \mathrm{Ds}^i_{\vartheta,z,0}(\Phi, c\kappa\Psi')$ by Lemma 6.4.51(c). So $\Psi_0 = c\kappa\Psi'$. □

Lemma 6.4.55. *Let S, T be spaces with signs s on n and s' on n', and S^- the opposite space of S, whose adelic group $\mathrm{G}(-s)$ is $\mathrm{G}(s)$. There is $c_{S,T}\in\mathbb{C}$ with $|c_{S,T}|=1$ such that for all automorphic characters α, β of $\mathrm{U}(1)$, every modulus $\mathfrak{m}$, every function Ψ on $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$, every polynomial P and all $g\in\mathrm{G}(s)$, $h\in\mathrm{G}(s')$,*

$$\overline{\theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}}(\Psi, v_P))(g,h)} = c_{S,T}\,\theta^{S^-,T}_{\alpha^{-1}\upsilon^{\#n},\,\beta^{-1}\upsilon^{\#n'}}(\mathrm{mod}_{\mathfrak{m}}(\Psi', v_{\bar P}))(g,h),$$

where $\Psi'(X) = \overline{\Psi(u^{-1}X)}$, $u\in R_{\mathfrak{m}}^\times$ is the reduction of c modulo $\mathfrak{m}$, and $\bar P$ is P with conjugated coefficients (its Fock vector taken for the signs of $\mathrm{Hom}(S^-,T)$).

Proof. Write $\iota = n'\times n$ and $\varepsilon = s'\otimes s$ (the signs of $\mathrm{Hom}(S,T)$), so that $\mathrm{Hom}(S^-,T)$ has the signs $-\varepsilon$. Let σ_c and cj be those of (WR7) of Definition 3.2.18, $\sigma_c(x) = (x_\infty, c^{-1}x_f)$ on $\mathbb{A}_E^\iota$ and $(\mathrm{cj}\,f)(x) = \overline{f(\sigma_c x)}$, and $c_{S,T}$ that of Lemma 6.4.56; by (1) of Lemma 6.4.56, cj is an antilinear isometry of $\mathcal{M}_\varepsilon$ onto $\mathcal{M}_{-\varepsilon}$ with $\mathrm{cj}\,v^0 = v^0$ and $\mathrm{cj}\,\rho(z) = \rho(\sigma_c^{-1}z)\,\mathrm{cj}$, and $|c_{S,T}|=1$.

Step 1: the datum. Let $A = \Sigma(\mathfrak{m})$ and $\varphi = v_P\otimes(\Psi^\natural\otimes_A v^0)$ (XD5). *Real part.* $v\otimes f = \int v(t)\rho(\mathrm{rv}(t))f\,d\nu(t)$ is a Bochner integral (Lemma 6.2.21); cj is real-linear and bounded and $\sigma_c^{-1}\mathrm{rv}(t) = \mathrm{rv}(t)$, so $\mathrm{cj}(v\otimes f) = \bar v\otimes \mathrm{cj}\,f$, $\bar v$ the pointwise conjugate, read in the Fock model of

$-\varepsilon$. For $v = v_P$, $\overline{v_P(x)} = \bar{P}(\overline{\zeta_\varepsilon(x)})e^\infty(x)$ and $\overline{\zeta_\varepsilon(x)} = \zeta_{-\varepsilon}(x)$ (WR5), so $\overline{v_P} = v_{\bar{P}}$ for the signs of $\mathrm{Hom}(S^-, T)$. *Finite part.* Write $\Psi^\natural = \sum_y c_y\tau_y$ (WR6); as $P^A v^0 = v^0$ ((2) of Lemma 6.2.33), $\Psi^\natural \otimes_A v^0 = \sum_y c_y\rho(\mathrm{fv}(y))v^0$, and as $\sigma_c^{-1}\mathrm{fv}(y) = \mathrm{fv}(cy)$,

$$\mathrm{cj}(\Psi^\natural \otimes_A v^0) = \sum_y \bar{c}_y\,\rho(\mathrm{fv}(cy))v^0.$$

For $x \in \mathbb{A}_{E,f}^\iota$, $c^{-1}x+y$ is integral at A exactly when $x+cy$ is, and $-\bar{y}^\mathsf{T}(2c^{-1}x+y) = \overline{cy}^\mathsf{T}(2x+cy)$ (as $-c^{-1} = \bar{c}$, $\bar{c}c = -1$); hence $\overline{\tau_y(c^{-1}x)} = \tau_{cy}(x)$, and $\sum_y \bar{c}_y\tau_{cy}(x) = \overline{\Psi^\natural(c^{-1}x)} = \Psi'^\natural(x)$ with $\Psi'(X) = \overline{\Psi(u^{-1}X)}$, u the reduction of c. By (1) of Lemma 4.1.3 the Schrödinger datum does not depend on the representation of $\Psi'^\natural$ by the τ_y (every finite representation of a nonzero function is the value of some linear section; a representation of 0 is the difference of two representations of one nonzero function), so $\mathrm{cj}(\Psi^\natural \otimes_A v^0) = \Psi'^\natural \otimes_A v^0$ and

$$\mathrm{cj}\,\mathrm{mod}_\mathfrak{m}(\Psi, v_P) = \mathrm{mod}_\mathfrak{m}(\Psi', v_{\bar{P}}),$$

the right side formed for $\mathrm{Hom}(S^-, T)$.

Step 2: conclusion. By (4) of Lemma 6.4.56 for $f = \mathrm{mod}_\mathfrak{m}(\Psi, v_P)$ and Step 1,

$$\overline{\theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_\mathfrak{m}(\Psi, v_P))(g,h)} = c_{S,T}\,\theta^{S^-,T}_{\alpha^{-1}\upsilon^{\#n},\,\beta^{-1}\upsilon^{\#n'}}(\mathrm{mod}_\mathfrak{m}(\Psi', v_{\bar{P}}))(g,h).$$

□

Lemma 6.4.56. *Let S, T be spaces with points with signs s on n and s' on n', $\iota = n' \times n$, and $\varepsilon = s' \otimes s$ the signs of $\mathrm{Hom}(S,T)$, so that $\mathrm{Hom}(S^-,T)$ has the signs $-\varepsilon$. Let σ_c and the conjugate $\mathrm{cj}\,f$ of a function f on $\mathbb{A}_E^\iota$, $(\mathrm{cj}\,f)(x) = \overline{f(\sigma_c x)}$, be those of (WR7). Then:*

1. *cj is an antilinear bijection of $\mathcal{M}_{S,T} = \mathcal{M}_\varepsilon$ onto $\mathcal{M}_{S^-,T} = \mathcal{M}_{-\varepsilon}$ with $\|\mathrm{cj}\,f\| = \|f\|$, $\langle \mathrm{cj}\,f, \mathrm{cj}\,f'\rangle = \overline{\langle f, f'\rangle}$ and $\mathrm{cj}\,v^0 = v^0$, and $\mathrm{cj}\,\rho(z) = \rho(\sigma_c^{-1}z)\,\mathrm{cj}$ for $z \in \mathbb{A}_E^\iota$;*
2. *for automorphic characters α, β of $\mathrm{U}(1)$, $g \in \mathrm{G}(s)$ and $h \in \mathrm{G}(s')$,*

$$\mathrm{cj}\,\omega_{\alpha,\beta}(g,h) = \omega_{\alpha^{-1}\upsilon^{\#n},\,\beta^{-1}\upsilon^{\#n'}}(g,h)\,\mathrm{cj},$$

   the right side the Weil representation of the pair (S^-, T);
3. *there is $c_{S,T} \in \mathbb{C}$ with $|c_{S,T}| = 1$, depending only on S and T, such that*

$$\overline{\theta_{\mathrm{Hom}(S,T)}(f)} = c_{S,T}\,\theta_{\mathrm{Hom}(S^-,T)}(\mathrm{cj}\,f) \qquad (f \in \mathcal{M}_{S,T});$$

4. *consequently, for all α, β, g, h as in (2) and $f \in \mathcal{M}_{S,T}$,*

$$\overline{\theta^{S,T}_{\alpha,\beta}(f)(g,h)} = c_{S,T}\,\theta^{S^-,T}_{\alpha^{-1}\upsilon^{\#n},\,\beta^{-1}\upsilon^{\#n'}}(\mathrm{cj}\,f)(g,h).$$

Proof. Write $N = \#\iota$ and $\mathcal{X} = \mathbb{A}_E^\iota$; $\bar{c}c = -1$ and $c^{-1} = -\bar{c}$.

Step 1: three identities. For $a, b, z \in \mathcal{X}$:

$$\text{(I1) } \overline{\beta_\varepsilon(\sigma_c a, \sigma_c b)} = \beta_{-\varepsilon}(a,b), \qquad \text{(I2) } \overline{e_N(\sigma_c z)} = e_N(z), \qquad \text{(I3) } (\sigma_c)_*\mu_N = \mu_N.$$

(I1): $\overline{\beta_\varepsilon(\sigma_c a, \sigma_c b)} = \psi_E(-\frac{1}{2}\,\overline{\sigma_c b}^\mathsf{T} S\,\sigma_c a)$ by (WD6), S the diagonal matrix of (WD6) for the signs ε. At the infinite places σ_c is the identity and $S = \varepsilon$, which gives the infinite part $-\frac{1}{2}\bar{b}^\mathsf{T}\varepsilon a =$

$\frac{\jmath}{2}\bar{b}^{\mathsf{T}}(-\varepsilon)a$ of the argument of $\beta_{-\varepsilon}$; at the finite places $S=1$ and $\overline{c^{-1}}c^{-1}=(\bar{c}c)^{-1}=-1$, which gives $\frac{\jmath}{2}\bar{b}^{\mathsf{T}}a$, the finite part of that argument. (I2): the archimedean factor of e_N is real and does not see σ_c; at the finite places $c^{-1}z\in\alpha\widehat{\mathcal{O}}_E^{\iota}$ if and only if $z\in\alpha\widehat{\mathcal{O}}_E^{\iota}$ (c is a unit), and then $\overline{\psi_{E,f}(\frac{c_0\jmath}{2}\overline{c^{-1}z}^{\mathsf{T}}c^{-1}z)}=\overline{\psi_{E,f}(-\frac{c_0\jmath}{2}\bar{z}^{\mathsf{T}}z)}=\psi_{E,f}(\frac{c_0\jmath}{2}\bar{z}^{\mathsf{T}}z)$ (WD5). (I3): σ_c is the identity on the archimedean factor and multiplication by a unit idele on the finite one, which preserves its Haar measure (WD6).

Step 2: the antilinear map; proof of (1). If $f\in\mathcal{M}_\varepsilon$, then $\mathrm{cj}\,f$ is μ_N-integrable with $\|\mathrm{cj}\,f\|=\|f\|$ by (I3), and by (WD7), the substitution $y=\sigma_c y'$ (I3), (I1) and (I2),

$$\begin{aligned}(\mathrm{cj}\,f)(x)&=\int\overline{f(\sigma_c y')}\,\overline{\beta_\varepsilon(\sigma_c y',\sigma_c x)}\,\overline{e_N(\sigma_c(x-y'))}\,d\mu_N(y')\\&=\int(\mathrm{cj}\,f)(y')\,\beta_{-\varepsilon}(y',x)\,e_N(x-y')\,d\mu_N(y'),\end{aligned}$$

so $\mathrm{cj}\,f\in\mathcal{M}_{-\varepsilon}$. The same argument with σ_c^{-1} (again $\bar{c}c=-1$) shows that $g\mapsto\overline{g(\sigma_c^{-1}\cdot)}$ maps $\mathcal{M}_{-\varepsilon}$ to $\mathcal{M}_\varepsilon$; it is inverse to cj, so cj is an antilinear bijection. By (I3), $\langle\mathrm{cj}\,f,\mathrm{cj}\,f'\rangle=\int f(\sigma_c x)\overline{f'(\sigma_c x)}\,d\mu_N(x)=\int f\,\overline{f'}\,d\mu_N=\overline{\langle f,f'\rangle}$. By (I2), $\mathrm{cj}\,v^0=v^0$. By (I1), $(\mathrm{cj}\,\rho(z)f)(x)=\overline{\beta_\varepsilon(\sigma_c\sigma_c^{-1}z,\sigma_c x)}\,\overline{f(\sigma_c(x-\sigma_c^{-1}z))}=\beta_{-\varepsilon}(\sigma_c^{-1}z,x)\,(\mathrm{cj}\,f)(x-\sigma_c^{-1}z)=(\rho(\sigma_c^{-1}z)\mathrm{cj}\,f)(x)$.

Step 3: the Weil operators; proof of (2). Let $k\in\mathrm{G}(\varepsilon)$; it lies in $\mathrm{G}(-\varepsilon)$ too (the same matrices: $\varepsilon_{-\varepsilon}=-\varepsilon_\varepsilon$ at the infinite places and 1 at the finite places), and k commutes with σ_c (k acts by an adelic matrix, σ_c by a scalar idele). By (WR3), the substitution $y=\sigma_c y'$, (I1)–(I3),

$$\mathrm{cj}\,\omega_\varepsilon(k)f=\frac{\overline{\Delta_\varepsilon(k)}}{\Delta_{-\varepsilon}(k)}\,\omega_{-\varepsilon}(k)\,\mathrm{cj}\,f\qquad(f\in\mathcal{M}_\varepsilon),$$

where $\Delta_{-\varepsilon}(k)\neq0$ by (2) of Lemma 6.2.13. We show $\overline{\Delta_\varepsilon(k)}=\upsilon(\det k)\,\Delta_{-\varepsilon}(k)$. *Infinite places.* For $k_v\in\mathrm{U}(\mathrm{diag}\,\varepsilon)$, $k_v^{-1}=\mathrm{diag}(\varepsilon)k_v^*\mathrm{diag}(\varepsilon)$, whose block on the indices of sign -1 is $((k_v)_-)^*$; by Jacobi's identity for complementary minors of an inverse, $\overline{\det(k_v)_-}=\det((k_v^{-1})_-)=\det(k_v)_+/\det k_v$, $(k_v)_+$ the block of sign $+1$. As $|\det k_v|=1$, $\det(k_v)_-=\det k_v\cdot\overline{\det(k_v)_+}$. The archimedean factor of $\overline{\Delta_\varepsilon(k)}$ is $\prod_v\det(k_v)_-$, that of $\Delta_{-\varepsilon}(k)$ is $\prod_v\overline{\det(k_v)_+}$ (the block of sign -1 for $-\varepsilon$), and their ratio is $\prod_v\det k_v$. *Finite places.* The finite factor $\upsilon(\det u)|\det u|^{-1/2}$ of $\Delta_{\pm\varepsilon}(k)$ does not depend on the signs; it is the multiplier $\Delta(k_f)$ of Lemma 4.1.13 for υ_f the restriction of υ to the finite ideles (which has modulus 1, is trivial on the unit ideles by (WD3), and satisfies $\upsilon_f(\bar{t})=\upsilon_f(t)^{-1}$), whose hypotheses on $\jmath$, α, c_0 hold by (WD1) and Lemma 4.1.3; as $k_f^*k_f=1$, Lemma 4.1.13 gives $\overline{\Delta(k_f)}=\upsilon_f(\det k_f)\Delta(k_f)$. Since $\upsilon(\det k)=\prod_v\det k_v/|\det k_v|\cdot\upsilon_f(\det k_f)$ (WD3), the claim follows, and

$$\mathrm{cj}\,\omega_\varepsilon(k)=\upsilon(\det k)\,\omega_{-\varepsilon}(k)\,\mathrm{cj}\qquad(k\in\mathrm{G}(\varepsilon)).\tag{6.80}$$

Now let $k=h\otimes(g^{-1})^{\mathsf{T}}$, the image of (g,h) under the pair map of (S,T), which is also that of (S^-,T); $\det k=\det(h)^{\#n}\det(g)^{-\#n'}$ ((VP5) of Definition 3.2.2). By (WR4), the antilinearity of cj and (6.80),

$$\begin{aligned}\mathrm{cj}\,\omega_{\alpha,\beta}(g,h)&=\overline{\alpha(\det h)}\,\beta(\det g)\,\upsilon(\det h)^{\#n}\upsilon(\det g)^{-\#n'}\,\omega_{-\varepsilon}(k)\,\mathrm{cj}\\&=(\alpha^{-1}\upsilon^{\#n})(\det h)\,\big((\beta^{-1}\upsilon^{\#n'})(\det g)\big)^{-1}\omega_{-\varepsilon}(k)\,\mathrm{cj},\end{aligned}$$

which is $\omega_{\alpha^{-1}\upsilon^{\#n},\beta^{-1}\upsilon^{\#n'}}(g,h)\,\mathrm{cj}$ for the pair (S^-,T) by (WR4).

Step 4: the theta functionals; proof of (3). Let X be the point of $\mathrm{Hom}(S,T)$; that of $\mathrm{Hom}(S^-,T)$ is $x_T\otimes((cx_S)^{-1})^{\mathsf{T}}=c^{-1}X$ ((VP5) of Definition 3.2.2), so its rational vectors are

$cX^{-1}u = \sigma_c^{-1}(X^{-1}u)$ ($u \in E^\iota$): σ_c^{-1} maps the rational vectors $V(E)$ of $\mathrm{Hom}(S,T)$ onto those $V^-(E)$ of $\mathrm{Hom}(S^-,T)$. Put $\theta'(g) = \overline{\theta_{\mathrm{Hom}(S,T)}(\mathrm{cj}^{-1}g)}$ for $g \in \mathcal{M}_{-\varepsilon}$. It is linear (a composite of two antilinear maps and a linear one) and bounded (cj^{-1} is an isometry by (1)). By (1), $\mathrm{cj}^{-1}\rho(\sigma_c^{-1}\gamma) = \rho(\gamma)\mathrm{cj}^{-1}$, so $\theta'(\rho(\sigma_c^{-1}\gamma)g) = \theta'(g)$ for $\gamma \in V(E)$: θ' is invariant under $V^-(E)$. As $\mathrm{cj}^{-1}v^0 = v^0$, and σ_c induces an isomorphism of the compact groups $\mathcal{X}/V^-(E) \to \mathcal{X}/V(E)$ carrying invariant probability measure to invariant probability measure,

$$\begin{aligned}\int_{\mathcal{X}/V^-(E)} |\theta'(\rho(x)v^0)|^2\,dx &= \int_{\mathcal{X}/V^-(E)} |\theta_{\mathrm{Hom}(S,T)}(\rho(\sigma_c x)v^0)|^2\,dx\\ &= \int_{\mathcal{X}/V(E)} |\theta_{\mathrm{Hom}(S,T)}(\rho(y)v^0)|^2\,dy = 1,\end{aligned}$$

the first equality by $\mathrm{cj}^{-1}\rho(x) = \rho(\sigma_c x)\mathrm{cj}^{-1}$ (from (1)), the last by Lemma 4.1.17. So θ' and $\theta_{\mathrm{Hom}(S^-,T)}$ are normalised theta functionals of $\mathrm{Hom}(S^-,T)$ (Lemma 4.1.17), and by Lemma 4.1.7 there is $c_{S,T} \in \mathbb{C}$, $|c_{S,T}| = 1$, with $\theta' = c_{S,T}\,\theta_{\mathrm{Hom}(S^-,T)}$. Applied to $g = \mathrm{cj}\,f$ this is (3); $c_{S,T}$ depends only on S, T and the fixed theta functionals.

Step 5: proof of (4). By the definition of theta kernels (WC4), (3) and (2),

$$\begin{aligned}\overline{\theta^{S,T}_{\alpha,\beta}(f)(g,h)} &= \overline{\theta_{\mathrm{Hom}(S,T)}(\omega_{\alpha,\beta}(g,h)f)}\\ &= c_{S,T}\,\theta_{\mathrm{Hom}(S^-,T)}(\mathrm{cj}\,\omega_{\alpha,\beta}(g,h)f)\\ &= c_{S,T}\,\theta_{\mathrm{Hom}(S^-,T)}(\omega_{\alpha^{-1}\upsilon^{\#n},\beta^{-1}\upsilon^{\#n'}}(g,h)\mathrm{cj}\,f),\end{aligned}$$

which is the right side of (4). □

Lemma 6.4.57. *Let s, s', η, ε and Ω be as in (ED3), e a type for the signs s, e' an idempotent kernel on $G_\infty(s')$, and $\Phi \in \mathcal{F}_\varepsilon$ a half edge for Ω from e to e'. For every polynomial P there is $\kappa_P \in \mathbb{C}$ such that, for all spaces with points S, T, V with signs s, s', η, every theta kernel for (S,T) on V with real part Ω, every $f \in \mathcal{M}_\eta$, every form F of type e on S for which $L_{\Phi\otimes f}F$ has a level, and every form G of type e' on T,*

$$\langle G,\ L_{v_P\otimes f}F\rangle_T = \kappa_P\,\langle G,\ L_{\Phi\otimes f}F\rangle_T.$$

Proof. By (ED4)(d) there is a continuous compactly supported a on $G_\infty(s')$, depending only on P (and on Φ), with $L_{v_P\otimes f}F = R(a)L_{\Phi\otimes f}F$ for all data as in the statement. Put

$$\kappa_P = \mu = \frac{1}{e'(1)}\int_{G_\infty(s')} a(v)\,e'(v^{-1})\,dv,$$

a convergent integral (a is bounded with compact support and e' is integrable, hence so is $v \mapsto e'(v^{-1})$). Fix the data and write $L = L_{\Phi\otimes f}F$; by (ED4)(c) it is a form of type e', so $R(e')L = L$, and $R(e')G = G$; both are bounded and continuous.

Step 1: adjoints of the operators $R(k)$. For an integrable k on $G_\infty(s')$ and bounded measurable functions X, Y on $\Gamma_T\backslash\mathrm{G}(s')$, $\langle R(k)X,Y\rangle_T = \langle X,R(k^*)Y\rangle_T$ with $k^*(x) = \overline{k(x^{-1})}$. Indeed $(x,g) \mapsto \overline{k(x)X(g(x,1))}\,Y(g)$ is integrable on $G_\infty(s')\times[\mathrm{U}(T)]$ ($[\mathrm{U}(T)]$ has finite volume), so by Fubini, the invariance of the quotient measure under right translation by $(x,1)$ and then the inversion $x \mapsto x^{-1}$,

$$\begin{aligned}\langle R(k)X,Y\rangle_T &= \int \overline{k(x)}\int_{[\mathrm{U}(T)]} \overline{X(g)}\,Y(g(x^{-1},1))\,dg\,dx\\ &= \int_{[\mathrm{U}(T)]} \overline{X(g)}\int \overline{k(x^{-1})}\,Y(g(x,1))\,dx\,dg = \langle X,R(k^*)Y\rangle_T.\end{aligned}$$

As e' is an idempotent kernel, $e'(x^{-1}) = \overline{e'(x)}$, so $e'^{*} = e'$.

Step 2: $R(e')R(a)R(e')X = \mu\, R(e')X$ for bounded measurable X. For $g \in \mathrm{G}(s')$,

$$R(e')R(a)R(e')X(g) = \iiint e'(u)\, a(v)\, e'(w)\, X\big(g(uvw,1)\big)\, dw\, dv\, du,$$

the integrand being absolutely integrable on $G_\infty(s')^3$ (X bounded, e' and a integrable). Substituting $y = uvw$ in the innermost integral (left invariance of dw) and applying Fubini, the value is $\int\!\int a(v)\big(\int e'(u)\, e'((uv)^{-1}y)\, du\big)X(g(y,1))\, dy\, dv$, and by the defining identity of an idempotent kernel ((ED1), with $x = v$) the inner integral is $e'(v^{-1})e'(y)/e'(1)$. So the value is $\mu \int e'(y)X(g(y,1))\, dy = \mu\, R(e')X(g)$.

Step 3: the constant. By Steps 1 and 2,

$$\langle G, R(a)L\rangle_T = \langle R(e')G, R(a)R(e')L\rangle_T = \langle G, R(e')R(a)R(e')L\rangle_T = \mu\,\langle G, R(e')L\rangle_T = \mu\,\langle G, L\rangle_T,$$

and $\mu = \kappa_P$ depends only on a and e', that is on P, Φ and e'. □

Lemma 6.4.58. *Let D be admissible data, $z \in \{\mathrm{I}, \mathrm{II}\}$ and $0 \le i < m$. For an m-fold twist ϑ let $a_\vartheta \colon \mathcal{F}^0_\triangle(z,0) \to \mathcal{F}^i_\triangle(z,1)$ be the first lift of row i, Σ_ϑ the set of finite places of F below no place of $\Sigma(\mathfrak{t}_\vartheta(z))$, b_ϑ the edge character with $c = \neg z$ and $l = i$ at the rank N_1, and R_{Σ_ϑ} the Rallis series of $(V^i_{z,0}, V^i_{z,1}, b_\vartheta, \Sigma_\vartheta)$, acting on functions on the common adelic group of $V^0_{z,0}$ and $V^i_{z,0}$. Then there is $A_{z,i} \in \mathbb{C} \setminus \{0\}$, independent of ϑ, such that for every m-fold twist ϑ:*

(a) for every base form $y \in \mathcal{F}^{\mathrm{bs}}_z$ and every $x \in \mathcal{F}^0_\triangle(z,0)$,

$$\begin{aligned}\#\mathrm{GL}_{n_0}(R_\vartheta)\,\langle a_\vartheta x, a_\vartheta y\rangle_{V^i_{z,1}} &= \frac{A_{z,i}}{\#\mathrm{M}_{n_1\times n_0}(R_\vartheta)}\,\langle x, R_{\Sigma_\vartheta} y\rangle_{V^0_{z,0}} \\ &= \sum_q \frac{A_{z,i}}{\#\mathrm{M}_{n_1\times n_0}(R_\vartheta)}\,\mathrm{mc}_{b_\vartheta,\Sigma_\vartheta}(u_q)\,\langle x, y(\,\cdot\, u_q)\rangle_{V^0_{z,0}},\end{aligned}$$

the series absolutely convergent, q running over the cosets of K_{Σ_ϑ};

(b) a_ϑ is injective on $\mathcal{F}^{\mathrm{bs}}_z$;

(c) if $y \in \mathcal{F}^{\mathrm{bs}}_z$ and $v \in \mathcal{F}^0_\triangle(z,0)$ satisfy $\langle v, x\rangle_{V^0_{z,0}} = \langle a_\vartheta y, a_\vartheta x\rangle_{V^i_{z,1}}$ for every $x \in \mathcal{F}^0_\triangle(z,0)$, then $v \in \mathcal{F}^{\mathrm{bs}}_z$.

Proof. Fix D, z, $i < m$ and an m-fold twist ϑ. Write $\mathfrak{t} = \mathfrak{t}_\vartheta(z)$, $P = \Sigma(\mathfrak{t})$, $R = R_\vartheta$, $N = \#\mathrm{M}_{n_1\times n_0}(R)$, $S = V^i_{z,0}$, $T = V^i_{z,1}$, a and $b = b_\vartheta$ the edge characters with $c = \neg z$, $l = i$ at the ranks N_0 and N_1, H the joint harmonic of the triangle lift at $(i,0)$, $x_0 \in \mathrm{M}_{n_1\times n_0}(R)$ the matrix with entry 1 at (c,c) ($c \in n_0$) and 0 elsewhere, $\Phi = \Phi_0^{\mathrm{pt}}$ its indicator function, $f = \Phi^\natural \otimes_P v^0$ and $\varphi = \mathrm{mod}_{\mathfrak{t}}(\Phi, v_H) = v_H \otimes f$. By (TV3) and (TV5), $a_\vartheta x = L_\varphi x$ for the theta kernel $\theta^{S,T}_{a,b}$, the copy of x at $(i,0)$ being x itself on the common group (TV5). Let $\mathbf{1}$ also denote identity matrices, and put $J = \{k \in \mathbf{K}_0(N_0) : k \equiv \mathbf{1} \pmod{\mathfrak{t}}\}$.

Step 0: the places of $\mathfrak{t}$, reduction, and the level J. By (TV2), P consists of the chosen places and, if $z = \mathrm{I}$, the places of Q; these are the chosen and twist places of the level system of the descent pair $O_{1,\vartheta}$ ((LF4) of Definition 3.2.26), so by (DP1) of Definition 3.2.23 they are distinct and none is the conjugate of itself or of another; $P \neq \emptyset$, as $\pi_M\bar\pi_M = p_0p_1$ ((AD5)) makes π_M a nonunit. Hence each $w \in P$ lies over a place of F split in E, distinct w lie over distinct places, and for every index set n the component of $G_f(n)$ at the place below w is identified by projection to w with $\mathrm{GL}_n(E_w)$ (the condition $\bar g^{\mathsf{T}} g = \mathbf{1}$ determines the component

at $\bar{w}$), that of $\mathbf{K}_0(n)$ with $\mathrm{GL}_n(\mathcal{O}_{E,w})$. By the Chinese remainder theorem $R = \prod_{w\in P} \mathcal{O}_{E,w}/w^{e_w}$ (e_w the exponent of w in $\mathfrak{t}$), and a matrix over $\mathcal{O}_{E,w}$ whose determinant is a unit modulo w^{e_w} is invertible over $\mathcal{O}_{E,w}$. So reduction modulo $\mathfrak{t}$ maps $\mathbf{K}_0(n)$ onto $\mathrm{GL}_n(R)$, with kernel the elements $\equiv \mathbf{1} \pmod{\mathfrak{t}}$; in particular $[\mathbf{K}_0(N_0) : J] = \#\mathrm{GL}_{n_0}(R)$, and J is open. Every chosen place divides $\mathfrak{t}$ ((TV2): $\pi_M \mid \mathfrak{t}$ if $z = \mathrm{I}$, $\mathfrak{t} = \mathfrak{b} = \pi_M^b$ if $z = \mathrm{II}$), so an element of J reduces to $\mathbf{1}$ modulo every chosen place and, if $z = \mathrm{II}$, modulo $\mathfrak{b}$: $J \subseteq \mathrm{K}_z^{\mathrm{bs}}$ (TV4).

Step 1: inner products of data modulo $\mathfrak{t}$. For functions Ψ_1, Ψ_2 on $\mathrm{M}_{n_1\times n_0}(R)$,

$$\langle \Psi_1^\natural \otimes_P v^0, \Psi_2^\natural \otimes_P v^0\rangle = \frac{1}{N}\sum_X \overline{\Psi_1(X)}\,\Psi_2(X).$$

Indeed, by (1) and (2) of Lemma 6.2.33 and $\langle v^0, v^0\rangle = 1$ (Lemma 6.2.13) the left side is $\int_{X_P} \overline{\Psi_1^\natural}\Psi_2^\natural$; the integrand vanishes off the matrices integral at every finite place, a set of mass 1, and is there a function of the reduction modulo $\mathfrak{t}$; reduction is a continuous surjective homomorphism of compact groups onto $\mathrm{M}_{n_1\times n_0}(R)$, so it carries the Haar probability measure to the uniform measure. In particular $\langle f, f\rangle = 1/N$.

Step 2: the characters at integral points. Tame parts multiply under products of characters (their defining formula in Definition 3.1.2 is multiplicative). By (GP6) and Definition 3.2.26, a and b are $\mu_{i+1}^0 \vartheta^{i+1}$ (if $z = \mathrm{I}$) or μ_{i+1}^0 (if $z = \mathrm{II}$) times a power of υ; μ_{i+1}^0 has tame part ω^{i+1}, trivial off the chosen places, υ has trivial tame part (LF2), and ϑ^{i+1} has a tame part trivial off Q. So a and b have tame parts ψ with $\psi_w = 1$ for $w \notin P$. Let $k \in \mathbf{K}_0(n)$ ($n = n_0$ or n_1) with $k \equiv \mathbf{1} \pmod{\mathfrak{t}}$. Then $u = \det k \in \mathrm{U}(1)(\mathbb{A})$ has infinite components 1, unit finite components and $u \bmod w = 1$ for $w \in P$, so $a(u) = b(u) = 1$ by the definition of weight and tame part.

Step 3: f is sharp for J off the places below P, with mass $c = 1/(N\,\#\mathrm{GL}_{n_0}(R))$. Let S_0 be the set of places of F below P; Σ_ϑ is the set of the other finite places. We check (SH1)–(SH4) of Lemma 6.5.12 for f, J and the characters a, b. (SH1): $\langle f, f\rangle = 1/N \neq 0$ (Step 1) and $c = \langle f, f\rangle/[\mathbf{K}_0(N_0) : J]$ (Step 0); $v_1 \otimes f = f$ by (4) of Lemma 6.2.33; and f is a vacuum above Σ_ϑ: a vector $y \in \mathcal{O}_E^{n_1\times n_0}$ has components 0 at the places not above Σ_ϑ exactly when its components at $P\cup\bar{P}$ are 0, and then $\rho_f(y)f = f$ by (5) of Lemma 6.2.33. (SH2): let $k \in G_f(n_0)$ with $k_v \in K_v$ for $v \in \Sigma_\vartheta$. If $k \in \mathbf{K}_0(N_0)$, then by $f = v_1 \otimes f$ and (6) of Lemma 4.1.1 (with $\alpha = 1$, $\beta = b$, $k' = \mathbf{1}$),

$$\omega_{1,b}((1,k),1)f = b(\det k)^{-1}\,\Phi_k^\natural \otimes_P v^0, \qquad \Phi_k(X) = \Phi(X\bar{k}),$$

$\bar{k}$ the reduction of k modulo $\mathfrak{t}$; by Step 1 the coefficient $\langle f, \omega_{1,b}((1,k),1)f\rangle$ is

$$b(\det k)^{-1}N^{-1}\sum_X \overline{\Phi(X)}\Phi(X\bar{k}).$$

A term is nonzero only for $X = x_0 = x_0\bar{k}$, and then $\bar{k} = x_0^{\mathsf{T}}x_0\bar{k} = x_0^{\mathsf{T}}x_0 = \mathbf{1}$. So the coefficient is 0 if $k \notin J$, and $b(\det k)^{-1}N^{-1} = \langle f, f\rangle$ if $k \in J$ (Step 2). If $k \notin \mathbf{K}_0(N_0)$, write $k = k_1k_2$ with k_1 having the components of k at the places of S_0 and $\mathbf{1}$ elsewhere, k_2 the components of k elsewhere and $\mathbf{1}$ at S_0; then $k_2 \in J$, so $\omega_{1,b}((1,k_2),1)f = f$ by the case just treated (where $\Phi_{k_2} = \Phi$ and $b(\det k_2) = 1$), and $\omega_{1,b}((1,k),1)f = \omega_{1,b}((1,k_1),1)f$ by (2) of Lemma 4.1.1. By (4) of Lemma 4.1.1 (with $A = P$, $h = \mathbf{1}$) this is a scalar times $\Phi'\otimes_P v^0$ with $\Phi'(x) = \Phi^\natural(xk_1)$, and by (1), (2) of Lemma 6.2.33 the coefficient is that scalar times $\int_{X_P} \overline{\Phi^\natural(x)}\Phi^\natural(xk_1)\,dx$. The integrand vanishes everywhere: otherwise, for each $w \in P$, both x_w and x_wk_w are integral and reduce to x_0 modulo w^{e_w}, so $B = x_0^{\mathsf{T}}x_w$ and $B' = x_0^{\mathsf{T}}x_wk_w$ lie in $\mathrm{GL}_{n_0}(\mathcal{O}_{E,w})$ (they reduce to $\mathbf{1}$), $L = B^{-1}x_0^{\mathsf{T}}$ and $L' = B'^{-1}x_0^{\mathsf{T}}$ are integral left inverses of x_w and x_wk_w, and $k_w = L\,x_wk_w$, $k_w^{-1} = L'x_w$ are

integral; with Step 0 the components of k at S_0 are integral, and with the hypothesis at Σ_ϑ, $k \in \mathbf{K}_0(N_0)$, a contradiction. So the coefficient is 0. (SH3): $f = \Phi^\natural \otimes_P v^0$ with $\Phi^\natural \in \mathcal{T}_P$ ((6) of Lemma 4.1.1), P finite, nonempty and without conjugates (Step 0), and for $w \in P$, $\Phi^\natural(x) \neq 0$ forces x_w integral with $x_w \equiv x_0$, so x_w has the left inverse $(x_0^\intercal x_w)^{-1} x_0^\intercal$ as above. (SH4): for $k \in J$ and $k' \in \mathbf{K}_0(N_1)$ with $k' \equiv \mathbf{1} \pmod{\mathfrak{t}}$ (open subgroups, Step 0), (6) of Lemma 4.1.1 gives $\omega_{a,b}((1,k),(1,k'))f = a(\det k')\, b(\det k)^{-1}\, \Phi^\natural_{k,k'} \otimes_P v^0$ with $\Phi_{k,k'}(X) = \Phi(\bar{k}'^{-1} X \bar{k}) = \Phi(X)$, and $a(\det k') = b(\det k) = 1$ by Step 2; so f is fixed.

Step 4: (a) and (b). We apply Lemma 6.5.12 to S, T (signs on n_0 and n_1, with $2N_0 = 2(r + [z]) < r + t = N_1$, $[z] \in \{0,1\}$, $t = 5r$), the weights $\gamma = \gamma_{\neg z,i}(N_0)$, $\gamma' = \gamma_{\neg z,i}(N_1)$, the types $e = e_\lambda$, $e' = e_{\lambda'}$ with $\lambda = \frac{1}{2} p^i_{z,0,0}$, $\lambda' = \frac{1}{2} p^i_{z,0,1}$, the vector $v = v_H$ (a Schwartz vector, (XD3) of Definition 3.2.22, and an edge for (γ, γ') from e to e' by Lemma 6.4.15(b) with $n = 0$, as $i < m$), the characters a, b (of weights γ, γ' by (GP6)), S_0, J, the mass c and $F = f$, which is sharp by Step 3. It gives a constant $A \neq 0$ built from S, T, v_H, γ, γ' and e alone; none of these depends on ϑ ((TV1)–(TV3); the weights of the edge characters do not involve the twist), so $A_{z,i} = A$ is independent of ϑ. By Lemma 6.4.15(a) a form $x \in \mathcal{F}^0_\triangle(z,0)$ is a form of type e on S, and a base form y is moreover right invariant under $J \subseteq \mathrm{K}^{\mathrm{bs}}_z$ (Step 0). Hence $\langle a_\vartheta x, a_\vartheta y\rangle_T = A\, c\, \langle x, R_{\Sigma_\vartheta} y\rangle_S = \sum_q A\, c\, \mathrm{mc}_{b,\Sigma_\vartheta}(u_q) \langle x, y(\,\cdot\, u_q)\rangle_S$, absolutely convergent; multiplying by $\#\mathrm{GL}_{n_0}(R) = 1/(Nc)$ and replacing $\langle\cdot,\cdot\rangle_S$ by $\langle\cdot,\cdot\rangle_{V^0_{z,0}}$ (Lemma 6.4.15(a)) gives (a). The lift L_φ is injective on the forms of type e right invariant under J, which gives (b).

Step 5: (c). Let $u \in \mathrm{K}^{\mathrm{bs}}_z \subseteq \mathbf{K}_0(N_0)$ and write ρ for right translation by finite adelic points. By Step 0 choose $g \in \mathbf{K}_0(N_1)$ whose reduction modulo $\mathfrak{t}$ is $\bar{u} \oplus \mathbf{1}$, block diagonal for $n_1 = n_0 \sqcup (n_1 \setminus n_0)$. Then $\bar{g}^{-1} X \bar{u} = x_0$ holds exactly for $X = \bar{g} x_0 \bar{u}^{-1} = x_0$, so $\Phi_{u,g} = \Phi$ in (6) of Lemma 4.1.1, which gives $\omega_{a,b}((1,u),(1,g))\varphi = \lambda\varphi$ with $\lambda = a(\det g)\, b(\det u)^{-1}$, $|\lambda| = 1$. As $\omega_{a,b}$ is a representation of the product group, $\omega_{a,b}((1,u^{-1}),1)\varphi = \lambda^{-1}\omega_{a,b}(1,(1,g))\varphi$. For a form x of type e on S and $h \in \mathrm{G}(s')$, the substitution $g' \mapsto g'(1,u)^{-1}$, which preserves the quotient measure of $[\mathrm{U}(S)]$ ($\mathrm{G}(s)$ is unimodular), gives

$$L_\varphi(\rho(u)x)(h) = \int_{[\mathrm{U}(S)]} \theta\big(\omega_{a,b}(g',h)\, \omega_{a,b}((1,u^{-1}),1)\varphi\big)\, x(g')\, dg' = \lambda^{-1}\, L_\varphi x\big(h(1,g)\big),$$

that is $\rho(g)\, a_\vartheta x = \lambda\, a_\vartheta(\rho(u)x)$. Right translation by $(1,u)$ maps $\mathcal{F}^0_\triangle(z,0)$ bijectively onto itself (it preserves continuity, boundedness, left invariance under the rational points and the existence of a level, and commutes with $R(e)$, which acts by translation at the infinite places), and right translations preserve Petersson products. Now let y, v be as in (c); $\rho(u)y = y$. For every x,

$$\begin{aligned}\langle \rho(u)v, \rho(u)x\rangle &= \langle v, x\rangle = \langle a_\vartheta y, a_\vartheta x\rangle = \langle \rho(g) a_\vartheta y, \rho(g) a_\vartheta x\rangle \\ &= |\lambda|^2 \langle a_\vartheta(\rho(u)y), a_\vartheta(\rho(u)x)\rangle = \langle a_\vartheta y, a_\vartheta(\rho(u)x)\rangle = \langle v, \rho(u)x\rangle.\end{aligned}$$

As $\rho(u)$ is onto, $\rho(u)v - v$ is orthogonal to every triangle form at $(0,0)$, in particular to itself; it is continuous and the quotient measure charges every nonempty open set, so $\rho(u)v = v$. Hence $v \in \mathcal{F}^{\mathrm{bs}}_z$. □

Lemma 6.4.59. *Let $m \geq 0$ be an integer and I a set. Let V_0 and $\mathcal{H}_{i,n}$ ($i, n \in \mathbb{Z}_{\geq 0}$) be complex inner product spaces, and for $\vartheta \in I$ and $i, n \geq 0$ let*

$$a^\vartheta_{i,n} \colon \mathcal{H}_{i,n} \to \mathcal{H}_{i,n+1}, \qquad b^\vartheta_{i,n} \colon \mathcal{H}_{i,n+1} \to \mathcal{H}_{i+1,n}$$

*be linear maps, $w_\vartheta(n)$ positive integers, and $u_i \colon V_0 \to \mathcal{H}_{i,0}$ linear isometries. The **weighted chain** of row i is $X^\vartheta_{i,0} = \mathrm{id}$ and $X^\vartheta_{i,n+1} = w_\vartheta(n)\, a^\vartheta_{i,n} \circ X^\vartheta_{i,n} \colon \mathcal{H}_{i,0} \to \mathcal{H}_{i,n+1}$. Assume, for every $\vartheta \in I$:*

(Qu1) *for $i+n+2 \le m$ there is $\gamma \in \mathbb{C}$ with $w_\vartheta(n)\, a^\vartheta_{i+1,n} \circ b^\vartheta_{i,n} = \gamma\, b^\vartheta_{i,n+1} \circ a^\vartheta_{i,n+1}$ on $\mathcal{H}_{i,n+1}$;*

(Qu2) *for $i < m$, $y \in V_0$ and $z \in \mathcal{H}_{i,1}$: $\langle z, a^\vartheta_{i,0} u_i y\rangle = \langle b^\vartheta_{i,0} z, u_{i+1} y\rangle$;*

(Qu3) *for $i < m$, $b^\vartheta_{i,0} a^\vartheta_{i,0} u_i(V_0) \subseteq u_{i+1}(V_0)$, and $b^\vartheta_{i,0} a^\vartheta_{i,0} u_i y = 0$ only for $y = 0$.*

Then:

1. *for $i+n \le m$ and $\vartheta \in I$ the map $X^\vartheta_{i,n} \circ u_i$ is injective.*
2. *Let $\mathcal{M}$ be a relation between functions $c\colon I \to \mathbb{C}$ and $f\colon I \to \mathbb{R}$ (read "c has modulus f") such that $\mathcal{M}(1,1)$ holds and $\mathcal{M}(c,f)$, $\mathcal{M}(c',f')$ imply $\mathcal{M}(cc', ff')$. Let $f_{r,k}\colon I \to \mathbb{R}$ be given for $1 \le r < k \le m$, and assume:*

   (Qx1) *for $i+n+2 \le m$ there is $\beta\colon I \to \mathbb{C}\setminus\{0\}$ with $\mathcal{M}(\beta, f_{i+1,i+n+2})$ and, for every ϑ, $w_\vartheta(n)\,\overline{\beta(\vartheta)}\, a^\vartheta_{i+1,n} \circ b^\vartheta_{i,n} = w_\vartheta(n+2)\, b^\vartheta_{i,n+1} \circ a^\vartheta_{i,n+1}$ on $\mathcal{H}_{i,n+1}$;*

   (Qx2) *for $i+n+2 \le m$ there is $\kappa\colon I \to \mathbb{C}$ with $\mathcal{M}(\kappa, 1)$ such that for every ϑ and every $z \in \mathcal{H}_{i,n+2}$ some $x \in \mathcal{H}_{i,n+1}$ satisfies $\langle a^\vartheta_{i,n+1} y, z\rangle = \langle y, x\rangle$ for all $y \in \mathcal{H}_{i,n+1}$ and $\langle b^\vartheta_{i,n} x, y'\rangle = \kappa(\vartheta)\,\langle b^\vartheta_{i,n+1} z, a^\vartheta_{i+1,n} y'\rangle$ for all $y' \in \mathcal{H}_{i+1,n}$;*

   (Qx3) *U_0 is a complex vector space, $s\colon U_0 \to V_0$ a map, $S_\vartheta(i)$ ($i < m$) endomorphisms of U_0, and $C_i\colon I \to \mathbb{C}$ functions with $\mathcal{M}(C_i, 1)$, such that for $i < m$, $x \in V_0$, $y \in U_0$:*

$$w_\vartheta(0)\,\langle a^\vartheta_{i,0} u_i x,\ a^\vartheta_{i,0} u_i\, s(y)\rangle = C_i(\vartheta)\,\langle x,\ s(S_\vartheta(i) y)\rangle.$$

   Then for every $0 \le i \le m$ there is $\kappa_i\colon I \to \mathbb{C}$ with $\mathcal{M}\big(\kappa_i, \prod_{i<r<k\le m} f_{r,k}\big)$ such that, with $n = m - i$, for all ϑ, $x \in V_0$, $y \in U_0$,

$$\langle X^\vartheta_{i,n} u_i x,\ X^\vartheta_{i,n} u_i\, s(y)\rangle = \kappa_i(\vartheta)\,\frac{w_\vartheta(0)\, w_\vartheta(1)^n}{w_\vartheta(n)}\,\Big\langle x,\ s(S_\vartheta(i) S_\vartheta(i+1)\cdots S_\vartheta(m-1)\, y)\Big\rangle.$$

Products of functions on I are pointwise; an empty product is 1, an empty composite of endomorphisms is the identity.

Proof. **Step 1: moving $b \circ a$ past a chain.** Let $i \ge 0$ and $n \ge 0$ with $i+n < m$. For $k < n$ let γ_k be a scalar given by (Qu1) for the square (i,k) (admissible, since $i+k+2 \le i+n+1 \le m$). Put $c_0 = 1/w(0)$ and $c_{k+1} = c_k \gamma_k / w(k+1)$. We claim

$$X_{i+1,n} \circ b_{i,0} \circ a_{i,0} = c_n\, b_{i,n} \circ X_{i,n+1} \qquad \text{on } \mathcal{H}_{i,0}. \tag{6.81}$$

For $n = 0$ the right side is $\frac{1}{w(0)} b_{i,0}(w(0) a_{i,0}) = b_{i,0} a_{i,0}$. If (6.81) holds for n and $i+n+1 < m$, then for $y \in \mathcal{H}_{i,0}$, with $Y = X_{i,n+1} y$,

$$\begin{aligned} X_{i+1,n+1} b_{i,0} a_{i,0} y &= w(n)\, a_{i+1,n} X_{i+1,n} b_{i,0} a_{i,0} y = c_n\, w(n)\, a_{i+1,n} b_{i,n} Y \\ &= c_n \gamma_n\, b_{i,n+1} a_{i,n+1} Y = \frac{c_n \gamma_n}{w(n+1)}\, b_{i,n+1} X_{i,n+2} y, \end{aligned}$$

by (Qu1) and $X_{i,n+2} = w(n+1) a_{i,n+1} X_{i,n+1}$; this is (6.81) for $n+1$.

Step 2: part (1). Induction on n, for all i at once. For $n = 0$, $X_{i,0} u_i = u_i$ is an isometry. Let $i+n+1 \le m$ and $X_{i,n+1} u_i y = 0$. By (Qu3) (as $i < m$) there is $x \in V_0$ with $u_{i+1} x = b_{i,0} a_{i,0} u_i y$. By (6.81) (as $i+n < m$), $X_{i+1,n} u_{i+1} x = c_n\, b_{i,n} X_{i,n+1} u_i y = 0$; since $(i+1)+n \le m$, the induction hypothesis gives $x = 0$. Hence $b_{i,0} a_{i,0} u_i y = 0$, and $y = 0$ by (Qu3).

Step 3: the constants of part (2). Assume (Qx1)–(Qx3); (Qx1) implies (Qu1) with $\gamma = w(n+2)/\overline{\beta(\vartheta)}$. For a square (i,k) with $i+k+2 \le m$ fix $\beta_{i,k}$ as in (Qx1) and $\kappa'_{i,k}$ as in (Qx2). For $i+n<m$ put $\beta^{(i,n)} = \prod_{k<n} \beta_{i,k}$ and $\kappa^{(i,n)} = \prod_{k<n} \kappa'_{i,k}$. By the multiplicativity of $\mathcal{M}$ and since the square (i,k) has modulus $f_{i+1,i+k+2}$,

$$\mathcal{M}\Big(\beta^{(i,n)}, \prod_{i+1<k\le i+1+n} f_{i+1,k}\Big), \qquad \mathcal{M}\big(\kappa^{(i,n)}, 1\big).$$

With $\gamma_k = w(k+2)/\overline{\beta_{i,k}}$ in Step 1 the recursion telescopes: $c_n = \frac{1}{w(0)} \prod_{k<n} \frac{w(k+2)}{w(k+1)\,\overline{\beta_{i,k}}} = \frac{w(n+1)}{w(0)\,w(1)\,\overline{\beta^{(i,n)}}}$, a nonzero number.

Step 4: adjointness along a chain. For $i+n<m$, $y \in V_0$ and $z \in \mathcal{H}_{i,n+1}$,

$$\big\langle z,\, a_{i,n} X_{i,n} u_i y \big\rangle = \kappa^{(i,n)} \big\langle b_{i,n} z,\, X_{i+1,n} u_{i+1} y \big\rangle. \tag{6.82}$$

For $n=0$ this is (Qu2). Let it hold for n, with $i+n+1<m$, and let $z \in \mathcal{H}_{i,n+2}$. Take $x \in \mathcal{H}_{i,n+1}$ as in (Qx2) for the square (i,n). Then $\langle z, a_{i,n+1} v\rangle = \overline{\langle a_{i,n+1} v, z\rangle} = \overline{\langle v, x\rangle} = \langle x, v\rangle$ for $v \in \mathcal{H}_{i,n+1}$, so, writing $Y = X_{i+1,n} u_{i+1} y$,

$$\begin{aligned} \big\langle z, a_{i,n+1} X_{i,n+1} u_i y \big\rangle &= w(n) \big\langle x, a_{i,n} X_{i,n} u_i y \big\rangle = w(n)\, \kappa^{(i,n)} \langle b_{i,n} x, Y\rangle \\ &= w(n)\, \kappa^{(i,n)} \kappa'_{i,n} \big\langle b_{i,n+1} z, a_{i+1,n} Y \big\rangle, \end{aligned}$$

which is $\kappa^{(i,n+1)} \langle b_{i,n+1} z, X_{i+1,n+1} u_{i+1} y\rangle$.

Step 5: one row down. Let $i+n<m$, $x, z \in V_0$, and $x' \in V_0$ with $u_{i+1} x' = b_{i,0} a_{i,0} u_i x$ ((Qu3)). Put $X = X_{i,n+1} u_i x$, $Y = X_{i+1,n} u_{i+1} z$. By (6.82) with z replaced by X,

$$\langle X, X_{i,n+1} u_i z\rangle = w(n) \langle X, a_{i,n} X_{i,n} u_i z\rangle = w(n)\, \kappa^{(i,n)} \langle b_{i,n} X, Y\rangle.$$

By (6.81) and Step 3, $X_{i+1,n} u_{i+1} x' = c_n\, b_{i,n} X$, so $\langle X_{i+1,n} u_{i+1} x', Y\rangle = \overline{c_n} \langle b_{i,n} X, Y\rangle$ with $\overline{c_n} = w(n+1)/(w(0)w(1)\beta^{(i,n)}) \neq 0$. Hence

$$\big\langle X_{i,n+1} u_i x,\, X_{i,n+1} u_i z \big\rangle = \kappa^{(i,n)} \beta^{(i,n)}\, \frac{w(0)\, w(1)\, w(n)}{w(n+1)}\, \big\langle X_{i+1,n} u_{i+1} x',\, X_{i+1,n} u_{i+1} z \big\rangle. \tag{6.83}$$

Step 6: part (2). Descending induction on i from $i=m$, with $n = m-i$. For $i=m$ take $\kappa_m = 1$; both sides are $\langle x, s(y)\rangle$ (the factor is $w(0)/w(0) = 1$). Let $i<m$, $n+1 = m-i$, and let κ_{i+1} be given. For $x \in V_0$ take x' as in Step 5 and put $T = S(i+1)\cdots S(m-1)$. Applying (6.83) (with $z = s(y)$; here $i+n<m$) and then the statement for $i+1$,

$$\big\langle X_{i,n+1} u_i x, X_{i,n+1} u_i s(y)\big\rangle = \kappa^{(i,n)} \beta^{(i,n)} \kappa_{i+1}\, \frac{w(0)\, w(1)^{n+1}}{w(n+1)} \cdot w(0)\, \langle x', s(Ty)\rangle.$$

Since u_{i+1} is an isometry and by (Qu2) with $z = a_{i,0} u_i x$,

$$\langle x', s(Ty)\rangle = \big\langle b_{i,0} a_{i,0} u_i x,\, u_{i+1} s(Ty)\big\rangle = \big\langle a_{i,0} u_i x,\, a_{i,0} u_i s(Ty)\big\rangle,$$

and by (Qx3) $w(0)\langle x', s(Ty)\rangle = C_i\, \langle x, s(S(i)Ty)\rangle$. So the statement holds for i with $\kappa_i = \kappa^{(i,n)} \beta^{(i,n)} \kappa_{i+1} C_i$. Its modulus: $\mathcal{M}(\kappa^{(i,n)}, 1)$, $\mathcal{M}(C_i, 1)$, $\mathcal{M}(\beta^{(i,n)}, \prod_{i+1<k\le m} f_{i+1,k})$ (Step 3, $i+1+n = m$) and $\mathcal{M}(\kappa_{i+1}, \prod_{i+1<r<k\le m} f_{r,k})$ give, by multiplicativity, $\mathcal{M}(\kappa_i, \prod_{i<r<k\le m} f_{r,k})$, the factors with $r = i+1$ being those of $\beta^{(i,n)}$. $\square$

Lemma 6.4.60. *Let D be admissible data, $z = \mathrm{I}$, $i, n \geq 0$ with $i + n < m$, Φ a left pair and Φ' a reversed pair at (i, n). For an m-fold twist ϑ let $u_\vartheta \in G_f(n_n)$ be the scalar matrix of the finite idele $\overline{\alpha_{\mathrm{W}} t}/(\alpha_{\mathrm{W}} t)$, t the idele of (TV7) for ϑ, and ρ right translation. There are functions c_1, c_2 from the m-fold twists to $\mathbb{C}$, each of absolute value 1 up to a norm power, such that for every m-fold twist ϑ, every function Ψ on $\mathrm{M}_{n_{n+1} \times n_n}(R_\vartheta)$, every $x \in \mathcal{F}^i_\triangle(z, n+1)$ and every $y \in \mathcal{F}^{i+1}_\triangle(z, n)$,*

$$\langle \mathrm{Ds}^i_{\vartheta,z,n}(\Phi, \Psi)x,\ y\rangle = c_1(\vartheta)\,\langle x,\ \mathrm{As}^i_{\vartheta,z,n}(\Phi', \widehat{\Psi})\,\rho(u_\vartheta^{-1})y\rangle,$$
$$\langle x,\ \mathrm{As}^i_{\vartheta,z,n}(\Phi', \widehat{\Psi})\,\rho(u_\vartheta^{-1})y\rangle = c_2(\vartheta)\,\langle \mathrm{Ds}^i_{\vartheta,z,n}(\Phi, \Psi)x,\ y\rangle,$$

the Petersson products being those of $V^{i+1}_{z,n}$ and of $V^i_{z,n+1}$.

Proof. Write $V = V^{i+1}_{z,n}$, $W = V^i_{z,n+1}$, $\mathfrak{t} = \mathfrak{t}_\vartheta(z)$, $u = u_\vartheta$, $k = N_n N_{n+1}$, $\mu = \frac{1}{2}p^{i+1}_{z,0,n}$, $\mu' = \frac{1}{2}p^i_{z,0,n+1}$; the triangle forms on V and W are the forms of type e_μ and $e_{\mu'}$, which are cusp kernels of order 0 together with $e_{-\mu} = \overline{e_\mu}$, $e_{-\mu'} = \overline{e_{\mu'}}$ ((ED4)(a) of the edges of (TV6)). For a polynomial P write

$$K_P(g, h) = \theta^{V,W}_{\chi(N_n),\chi(N_{n+1})}(\mathrm{mod}_{\mathfrak{t}}(\Psi, v_P))(g, h),$$
$$K'_P(h, g) = \theta^{W,V}_{\chi(N_{n+1}),\chi(N_n)}(\mathrm{mod}_{\mathfrak{t}}(\widehat{\Psi}, v_P))(h, g)$$

(g on V, h on W), and D_P, A_P for the maps

$$x \mapsto \int_{[\mathrm{U}(W)]} K_P(\cdot, h)x(h)\,dh \quad \text{and} \quad y \mapsto \int_{[\mathrm{U}(V)]} K'_P(\cdot, g)y(g)\,dg;$$

by (TV7), $D_\Phi = \mathrm{Ds}^i_{\vartheta,z,n}(\Phi, \Psi)$ and $A_{\Phi'} = \mathrm{As}^i_{\vartheta,z,n}(\Phi', \widehat{\Psi})$, the idele t and the character ψ_ϑ of (TV7) being those of Lemma 6.4.61 for $\mathfrak{m} = \mathfrak{t}$.

Step 0: reversal and the norm of $\#R_\vartheta$. By Lemma 6.4.61 (with $(\alpha, \beta) = (\chi(N_n), \chi(N_{n+1}))$, $D = \Psi$) there is $\tau = \tau(\vartheta)$ with $|\tau|^2(\#R_\vartheta)^k = 1$ (so $\tau \neq 0$) and $\overline{K_P(g, h)} = \tau\, K'_{P^\flat}(h, g(1, u))$ for every polynomial P. Moreover $\#R_\vartheta = \#(\mathcal{O}_E/\pi_M\mathcal{O}_E)\cdot \mathrm{N}Q$ (Chinese remainder theorem, (TV2), the places of Q prime to π_M), so $|\tau|^2 = C_0\,(\mathrm{N}Q)^{-k}$ with $C_0 = \#(\mathcal{O}_E/\pi_M\mathcal{O}_E)^{-k}$, independent of ϑ. Right translation by the central element $(1, u^{\pm 1})$ maps triangle forms on V to triangle forms (it preserves continuity, boundedness, left invariance under the rational points and the existence of a level, and commutes with $R(e_\mu)$, which acts by right translation at the infinite places) and preserves Petersson products (the quotient measure of $[\mathrm{U}(V)]$ is right invariant, the adelic group being unimodular). The map $P \mapsto P^\flat$ for the pair (V, W) followed by the same map for (W, V) is the identity (the coefficients are conjugated twice and $X_{v,a,b} \mapsto (-s_b s'_a)(-s'_a s_b)X_{v,a,b}$), so $\Phi' = Q^\flat$ for $Q = \Phi'^\flat$ (formed for (W, V)).

Step 1: the first identity. By Lemma 6.4.52 the kernels are jointly integrable against products of triangle forms, so Fubini applies below. With $y' = \rho(u^{-1})y$ and the substitution $g \mapsto g(1, u)^{-1}$ (invariance of the quotient measure),

$$\begin{aligned}\langle D_\Phi x, y\rangle_V &= \int_{[\mathrm{U}(V)]} y(g) \int_{[\mathrm{U}(W)]} \overline{K_\Phi(g, h)}\,\overline{x(h)}\,dh\,dg \\ &= \tau \int_{[\mathrm{U}(W)]} \overline{x(h)} \int_{[\mathrm{U}(V)]} K'_{\Phi^\flat}(h, g)\,y'(g)\,dg\,dh = \tau\,\langle x, A_{\Phi^\flat}y'\rangle_W.\end{aligned}$$

By Lemma 6.3.77 and Lemma 6.4.53 (exchanging the two factors), A_P is the lift for a theta kernel for (V, W) whose real part is the exchanged $\Omega_{\delta,\delta'}$, $(\delta, \delta') = (\delta_i(N_{n+1}), \delta_i(N_n))$. The reversed pair $v_{\Phi'}$ is an edge for (δ, δ') from $e_{-\mu'}$ to $e_{-\mu}$ (TV6); its second half edge is a half edge for the exchanged real part from $\overline{e_{-\mu}} = e_\mu$ to $\overline{e_{-\mu'}} = e_{\mu'}$, an idempotent kernel, and $A_{\Phi'}y'$ has a level

(Lemma 6.4.51(b)). So Lemma 6.4.57 (with $P = \Phi^\flat$, the form y' of type e_μ on V and $G = x$ of type $e_{\mu'}$ on W) gives κ_1, independent of ϑ and Ψ, with $\langle x, A_{\Phi^\flat} y'\rangle_W = \kappa_1 \langle x, A_{\Phi'} y'\rangle_W$. Hence the first identity holds with $c_1(\vartheta) = \tau\kappa_1$, and $|c_1|^2 = |\kappa_1|^2 C_0(\mathrm{N}Q)^{-k}$: absolute value 1 up to a norm power.

Step 2: the second identity. By Step 0 applied to Q, $K'_{\Phi'}(h, g(1,u)) = \tau^{-1}\overline{K_Q(g,h)}$. With the substitution $g \mapsto g(1,u)$,

$$A_{\Phi'} y'(h) = \int_{[\mathrm{U}(V)]} K'_{\Phi'}(h, g(1,u))\, y(g)\, dg = \tau^{-1} \int_{[\mathrm{U}(V)]} \overline{K_Q(g,h)}\, y(g)\, dg,$$

so by Fubini $\langle x, A_{\Phi'} y'\rangle_W = \tau^{-1} \int_{[\mathrm{U}(V)]} y(g)\overline{D_Q x(g)}\, dg = \tau^{-1}\langle D_Q x, y\rangle_V$. The left pair v_Φ is an edge for $(\delta_i(N_n), \delta_i(N_{n+1}))$ from $e_{-\mu}$ to $e_{-\mu'}$; its second half edge is for the exchanged real part from $e_{\mu'}$ to e_μ, an idempotent kernel, and $D_\Phi x$ has a level (Lemma 6.4.51(b)); D_P is the lift for the exchanged kernel of the pair (V, W) (Lemma 6.3.77, Lemma 6.4.53). So Lemma 6.4.57 (with $P = Q$, the form x and $G = y$) gives κ_2, independent of ϑ and Ψ, with $\langle y, D_Q x\rangle_V = \kappa_2 \langle y, D_\Phi x\rangle_V$, i.e. $\langle D_Q x, y\rangle_V = \overline{\kappa_2}\langle D_\Phi x, y\rangle_V$. Hence the second identity holds with $c_2(\vartheta) = \tau^{-1}\overline{\kappa_2}$, and $|c_2|^2 = |\kappa_2|^2 C_0^{-1}(\mathrm{N}Q)^k$. □

Lemma 6.4.61. *Let S, T be spaces with signs s on n and s' on n', α, β automorphic characters of $\mathrm{U}(1)$, $\mathfrak{m}$ a modulus and t a finite idele, integral, with components 1 at the finite places outside $\Sigma(\mathfrak{m})$, generating $\mathfrak{m}\widehat{\mathcal{O}}_E$. Let $\psi_\mathfrak{m}$ be the additive character of $R_\mathfrak{m}$ with $\psi_\mathfrak{m}(x \bmod \mathfrak{m}) = \psi_{E,f}(\jmath\, \alpha_\mathrm{W}\bar\alpha_\mathrm{W}\, t^{-1} x)$ for $x \in \widehat{\mathcal{O}}_E$; for a function D on $\mathrm{M}_{n'\times n}(R_\mathfrak{m})$ let $\widehat{D}(\rho) = \sum_x \overline{D(x)}\, \psi_\mathfrak{m}(\mathrm{tr}(\rho x))$ on $\mathrm{M}_{n\times n'}(R_\mathfrak{m})$; for a polynomial P in the variables $X_{v,a,b}$ ($v \in \Phi$, $a \in n'$, $b \in n$) let $P^\flat$ be the polynomial obtained from P by conjugating its coefficients and substituting $X_{v,a,b} \mapsto -s'_a\, s_b\, X_{v,b,a}$; and let $u_\mathfrak{m} \in G_f(n)$ be the scalar matrix of the finite idele $\overline{\alpha_\mathrm{W} t}/(\alpha_\mathrm{W} t)$, of norm one. There is $c \in \mathbb{C}$ with $|c|^2\, (\#R_\mathfrak{m})^{\#n\cdot\#n'} = 1$ such that for all D, P, $g \in \mathrm{G}(s)$ and $h \in \mathrm{G}(s')$*

$$\overline{\theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_\mathfrak{m}(D, v_P))(g,h)} = c\, \theta^{T,S}_{\beta,\alpha}(\mathrm{mod}_\mathfrak{m}(\widehat{D}, v_{P^\flat}))(h,\, g\,(1, u_\mathfrak{m})).$$

Proof. Write $\varepsilon = s' \otimes s$, $\varepsilon(a,b) = s'_a s_b$ on $n' \times n$. Then $\mathrm{Hom}(S^-, T)$ has the signs $-\varepsilon$ on $n' \times n$ and $\mathrm{Hom}(T, S)$ the signs $\varepsilon'(b,a) = s_b s'_a$ on $n \times n'$ (VP5); their vectors are read as $n' \times n$ and $n \times n'$ adelic matrices. Put $N = \#n \cdot \#n'$ and $A = \Sigma(\mathfrak{m})$; as A contains the conjugate of none of its members, $A \cap \bar A = \emptyset$. The letter c also denotes the idele with infinite components 1 and finite component c; $c^{-1} = -\bar c$. Let $u_\mathrm{W}, u_t \in \mathrm{G}(s)$ be the scalar matrices with infinite components 1 and finite components $\bar\alpha_\mathrm{W}/\alpha_\mathrm{W}$ and $\bar t/t$ (both of norm one), so that $u_t u_\mathrm{W} = (1, u_\mathfrak{m})$, and let $S' = S_{u_\mathrm{W}} = (J_S, x_S u_\mathrm{W})$ be the moved space (VP4), with signs s.

Step 1: the flip. For an adelic $n' \times n$ matrix X let $X^\dagger$ be the $n \times n'$ matrix with components

$$(X^\dagger)_v = -\,\mathrm{diag}(s)\, X_v^*\, \mathrm{diag}(s') \quad (v \in \Phi), \qquad (X^\dagger)_f = c\,\alpha_\mathrm{W}\bar\alpha_\mathrm{W}^{-1}\, X_f^*,$$

that is $X^\dagger = \mu\, \varepsilon_s X^* \varepsilon_{s'}$ for the scalar idele μ with infinite components -1 and finite component $c\alpha_\mathrm{W}\bar\alpha_\mathrm{W}^{-1}$; entrywise $(X^\dagger)_{v,b,a} = -s_b s'_a \overline{X_{v,a,b}}$. It is additive and a homeomorphism, with inverse $Y \mapsto Y^\ddagger$, $(Y^\ddagger)_v = -\,\mathrm{diag}(s') Y_v^*\, \mathrm{diag}(s)$, $(Y^\ddagger)_f = -c\,\alpha_\mathrm{W}\bar\alpha_\mathrm{W}^{-1} Y_f^*$. It has five properties.

(F1) $\beta_{\varepsilon'}(x^\dagger, y^\dagger) = \beta_{-\varepsilon}(x, y)$ for $x, y \in \mathbb{A}_E^{n'\times n}$. Put $Q_v = \sum_{a,b} \varepsilon(a,b)\overline{y_{v,a,b}} x_{v,a,b}$ for $v \in \Phi$ and $Q_f = \sum_{a,b} \overline{y_{a,b}} x_{a,b}$ (finite components). By (WD4), (WD6),

$$\beta_{-\varepsilon}(x,y) = \exp(-2\pi i \sum_v 2\,\mathrm{Re}(-\jmath_v Q_v/2))\psi_{E,f}(\jmath Q_f/2).$$

For the flipped vectors, at $v \in \Phi$ the term of index (b,a) is

$$\varepsilon'(b,a)\overline{(y^\dagger)_{v,b,a}}(x^\dagger)_{v,b,a} = \varepsilon(a,b)y_{v,a,b}\overline{x_{v,a,b}},$$

with sum $\overline{Q_v}$, and at the finite places the factor is $\overline{c\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}^{-1}}\, c\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}^{-1} = \bar c c = -1$, with sum $-\overline{Q_f}$. Since $\bar\jmath = -\jmath$, $\mathrm{Re}(\jmath_v\overline{Q_v}) = \mathrm{Re}(\overline{\jmath_v}Q_v) = \mathrm{Re}(-\jmath_v Q_v)$ and $-\jmath\overline{Q_f}/2 = \overline{\jmath Q_f/2}$; and $\psi_{E,f}(\bar y_0) = \psi_{E,f}(y_0)$, because $y_0 - a \in \widehat{\mathcal{O}}_E$ with $a \in E$ gives $\bar y_0 - \bar a \in \widehat{\mathcal{O}}_E$ and $\mathrm{Tr}_{E/\mathbb{Q}}\,\bar a = \mathrm{Tr}_{E/\mathbb{Q}}\,a$. This gives (F1).

(F2) $e_N(x^\dagger) = e_N(x)$. The archimedean factor of e_N sees only $|x_{v,a,b}| = |(x^\dagger)_{v,b,a}|$. At the finite places write $x_f = \alpha_{\mathrm{W}} z$; then $(x^\dagger)_f = c\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}^{-1}\bar\alpha_{\mathrm{W}} z^* = \alpha_{\mathrm{W}}\, cz^*$, so $(x^\dagger)_f \in \alpha_{\mathrm{W}}\widehat{\mathcal{O}}_E^N$ if and only if $x_f \in \alpha_{\mathrm{W}}\widehat{\mathcal{O}}_E^N$. In that case $\sum\overline{(x^\dagger)_f}(x^\dagger)_f = \bar c c\sum x_f\overline{x_f} = -M$ with $M = \sum\overline{x_f}x_f = \alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}\sum\bar z z \in \alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}\widehat{\mathcal{O}}_E$. By Lemma 4.1.3, $c_0\jmath M \in \jmath\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}\widehat{\mathcal{O}}_E = \mathfrak{D}_{E/\mathbb{Q}}^{-1}\widehat{\mathcal{O}}_E = \mathfrak{D}_{E/\mathbb{Q}}^{-1} + \widehat{\mathcal{O}}_E$, on which $\psi_{E,f}$ is trivial ($\mathrm{Tr}_{E/\mathbb{Q}}\,\mathfrak{D}_{E/\mathbb{Q}}^{-1} \subseteq \mathbb{Z}$). Hence $\psi_{E,f}(-c_0\jmath M/2) = \psi_{E,f}(c_0\jmath M/2)\,\psi_{E,f}(-c_0\jmath M) = \psi_{E,f}(c_0\jmath M/2)$, and the finite factors of (WD5) agree.

(F3) The image of μ_N under $x \mapsto x^\dagger$ is μ_N. In the coordinates of (WD6) (archimedean coordinates divided by κ_v, which is real, and finite coordinates divided by α_{W}) the map is $u \mapsto (-s_b s'_a\overline{u_{v,a,b}})_{v,b,a}$ on $\mathbb{C}^{\Phi\times n'\times n}$, a real-linear isometry (a permutation of coordinates, conjugations and signs) that preserves Lebesgue measure, and $z \mapsto cz^*$ on the finite coordinates, a permutation of coordinates composed with the adelic conjugation (a ring automorphism of $\mathbb{A}_{E,f}$ mapping $\widehat{\mathcal{O}}_E$ onto itself) and multiplication by the unit c, each of which preserves the Haar measure giving $\widehat{\mathcal{O}}_E^N$ mass 1.

(F4) $X \mapsto X^\dagger$ maps the rational vectors of $\mathrm{Hom}(S^-,T)$ onto those of $\mathrm{Hom}(T,S')$. The point of $\mathrm{Hom}(S^-,T)$ is the map $X \mapsto x_T X(cx_S)^{-1}$ (VP5), so its rational vectors are the $X = c\,x_T^{-1}\xi_0 x_S$ with $\xi_0 \in \mathrm{M}_{n'\times n}(E)$; those of $\mathrm{Hom}(T,S')$, whose point is $Y \mapsto x_S u_{\mathrm{W}} Y x_T^{-1}$, are the $u_{\mathrm{W}}^{-1}x_S^{-1}\eta_0 x_T$ with $\eta_0 \in \mathrm{M}_{n\times n'}(E)$. From $x_S^* J_S x_S = \varepsilon_s$ and $x_T^* J_T x_T = \varepsilon_{s'}$ (VP2), $x_S^* = \varepsilon_s x_S^{-1} J_S^{-1}$ and $(x_T^*)^{-1} = J_T x_T \varepsilon_{s'}$, so for $X = c\,x_T^{-1}\xi_0 x_S$

$$\varepsilon_s X^* \varepsilon_{s'} = \bar c\,\varepsilon_s\,\varepsilon_s x_S^{-1} J_S^{-1}\xi_0^* J_T x_T \varepsilon_{s'}\,\varepsilon_{s'} = \bar c\, x_S^{-1}(J_S^{-1}\xi_0^* J_T)x_T.$$

The scalar idele $\mu\bar c$ has infinite components -1 and finite component $\bar c c\,\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}^{-1} = -\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}^{-1}$, i.e. $\mu\bar c = -u_{\mathrm{W}}^{-1}$. Hence $X^\dagger = u_{\mathrm{W}}^{-1}x_S^{-1}(-J_S^{-1}\xi_0^* J_T)x_T$, and $\xi_0 \mapsto -J_S^{-1}\xi_0^* J_T$ is a bijection of $\mathrm{M}_{n'\times n}(E)$ onto $\mathrm{M}_{n\times n'}(E)$.

(F5) For $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$: $(hXg^{-1})^\dagger = g\,X^\dagger h^{-1}$. Indeed $g^*\varepsilon_s g = \varepsilon_s$ gives $\varepsilon_s(g^{-1})^* = g\varepsilon_s$, $h^*\varepsilon_{s'}h = \varepsilon_{s'}$ gives $h^*\varepsilon_{s'} = \varepsilon_{s'}h^{-1}$, and μ is a scalar, so $(hXg^{-1})^\dagger = \mu\varepsilon_s(g^{-1})^* X^* h^*\varepsilon_{s'} = g\,\mu\varepsilon_s X^*\varepsilon_{s'}\,h^{-1}$.

Step 2: the transport. For a function f on $\mathbb{A}_E^{n'\times n}$ put $(\Pi f)(Y) = f(Y^\ddagger)$, the composite of f with the inverse of the flip $X \mapsto X^\dagger$. By (F1), (F2) and (F3) the flip, an additive homeomorphism, satisfies the hypotheses of (1) of Lemma 6.3.65 for the signs $-\varepsilon$ and ε'; so Π is a linear bijection of $\mathcal{M}_{-\varepsilon}$ onto $\mathcal{M}_{\varepsilon'}$ preserving norm and inner product, $\Pi v^0 = v^0$, and

$$\Pi\rho(y_0) = \rho(y_0^\dagger)\,\Pi \qquad (y_0 \in \mathbb{A}_E^{n'\times n}). \tag{6.84}$$

Let $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$, k the pair map of (g,h) for (S^-,T), $X \mapsto hXg^{-1}$, and k' the pair map of (h,g) for (T,S), $Y \mapsto gYh^{-1}$. By (F5), $(kX)^\dagger = k'X^\dagger$ for every X, so (2) of Lemma 6.3.65 gives

$$\Pi\,\omega_{-\varepsilon}(k) = \frac{\Delta_{-\varepsilon}(k)}{\Delta_{\varepsilon'}(k')}\,\omega_{\varepsilon'}(k')\,\Pi.$$

We show $\Delta_{\varepsilon'}(k') = \upsilon(\det k)\,\Delta_{-\varepsilon}(k)$. As matrices, $k_{(a,b),(a_1,b_1)} = h_{aa_1}(g^{-1})_{b_1 b}$ and $k'_{(b,a),(b_1,a_1)} = g_{bb_1}(h^{-1})_{a_1 a}$; since k^{-1} is $X \mapsto h^{-1}Xg$, $(k^{-1})_{(a_1,b_1),(a,b)} = k'_{(b,a),(b_1,a_1)}$: after the identification

$(b,a) \leftrightarrow (a,b)$, k' is the transpose of k^{-1}. The identification is a relabelling of the index set by a bijection; it carries the signs ε' to ε, the block of sign -1 at an infinite place to the corresponding block, and $\widehat{\mathcal{O}}_E^{n\times n'}$ to $\widehat{\mathcal{O}}_E^{n'\times n}$ (so an element u of (WR3) to its relabelling, of the same determinant); hence it does not change the multiplier, and $\Delta_{\varepsilon'}(k') = \Delta_\varepsilon((k^{-1})^{\mathsf{T}})$ with $k \in \mathrm{G}(-\varepsilon)$. By (4) of Lemma 6.3.65 for $\delta = -\varepsilon$, this is $\upsilon(\det k)\,\Delta_{-\varepsilon}(k)$, which is the claim, and $\Pi\omega_{-\varepsilon}(k) = \upsilon(\det k)^{-1}\omega_{\varepsilon'}(k')\Pi$. With $\det k = \det(h)^{\#n}\det(g)^{-\#n'}$ (VP5) and (WR4), for all automorphic characters α_1, β_1 of $\mathrm{U}(1)$,

$$\begin{aligned}\Pi\,\omega^{S^-,T}_{\alpha_1,\beta_1}(g,h) &= \alpha_1(\det h)\beta_1(\det g)^{-1}\upsilon(\det h)^{-\#n}\upsilon(\det g)^{\#n'}\omega_{\varepsilon'}(k')\,\Pi \\ &= \omega^{T,S}_{\alpha_2,\beta_2}(h,g)\,\Pi, \qquad \alpha_2 = \beta_1^{-1}\upsilon^{\#n'},\ \beta_2 = \alpha_1^{-1}\upsilon^{\#n}.\end{aligned} \tag{6.85}$$

Step 3: theta functionals and kernels. By (F4) the flip maps the rational vectors of $\mathrm{Hom}(S^-,T)$ onto those of $\mathrm{Hom}(T,S')$, a space with a point with the signs ε'; Π is bounded, $\langle \Pi v^0, \Pi v^0\rangle = \langle v^0, v^0\rangle = 1$ ((1) of Lemma 6.2.13), and (6.84) holds. So (3) of Lemma 6.3.65, for $V = \mathrm{Hom}(S^-,T)$, $V' = \mathrm{Hom}(T,S')$ and τ the flip, gives $z_0 \in \mathbb{C}$, $|z_0| = 1$, with $\theta_{\mathrm{Hom}(T,S')}(\Pi F) = z_0\,\theta_{\mathrm{Hom}(S^-,T)}(F)$ for all F. Next, the point of $\mathrm{Hom}(T,S')$ is that of $\mathrm{Hom}(T,S)$ composed with the pair map $k_{\mathrm{W}}\colon Y \mapsto u_{\mathrm{W}}Y$ of $(1,u_{\mathrm{W}})$ for (T,S), so $\mathrm{Hom}(T,S')$ is the moved space $\mathrm{Hom}(T,S)_{k_{\mathrm{W}}}$ (VP4). If k_0 is a transporting element of $\mathrm{Hom}(T,S)$ with point X_0, then $k_0k_{\mathrm{W}}(X_0k_{\mathrm{W}})^{-1}u = k_0X_0^{-1}u$, so k_0k_{W} is one of the moved space, and by Lemma 4.1.17 (independence of the transporting element) and (2) of Lemma 4.1.1, $\theta_{\mathrm{Hom}(T,S')}(G) = \theta_{\mathrm{Hom}(T,S)}(\omega_{\varepsilon'}(k_{\mathrm{W}})G)$. As $\omega^{T,S}_{\alpha_2,\beta_2}(1,u_{\mathrm{W}}) = \alpha_2(\det u_{\mathrm{W}})\,\omega_{\varepsilon'}(k_{\mathrm{W}})$ (WR4) and u_{W} is central, (WC4), (6.85) and (2) of Lemma 4.1.1 give, for $F \in \mathcal{M}_{-\varepsilon}$, $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$,

$$\theta^{S^-,T}_{\alpha_1,\beta_1}(F)(g,h) = z_0^{-1}\,\theta_{\mathrm{Hom}(T,S')}(\omega^{T,S}_{\alpha_2,\beta_2}(h,g)\Pi F) = z_0^{-1}\alpha_2(\det u_{\mathrm{W}})^{-1}\,\theta^{T,S}_{\alpha_2,\beta_2}(\Pi F)(h, g\,u_{\mathrm{W}}). \tag{6.86}$$

Step 4: the data. *Real part.* For $\tau \in \mathbb{C}^{\Phi\times n'\times n}$ let $\tau^\sharp \in \mathbb{C}^{\Phi\times n\times n'}$, $\tau^\sharp_{v,b,a} = -s_bs'_a\overline{\tau_{v,a,b}}$; then $\mathrm{rv}(\tau)^\dagger = \mathrm{rv}(\tau^\sharp)$ (κ_v is real and the finite components are 0), $\tau \mapsto \tau^\sharp$ preserves ν, and its inverse is φ_∞, $(\varphi_\infty\tau')_{v,a,b} = -s'_as_b\overline{\tau'_{v,b,a}}$. For an integrable w_0 on $\mathbb{C}^{\Phi\times n'\times n}$ and $f \in \mathcal{M}_{-\varepsilon}$, the Bochner integral of (1) of Lemma 6.2.21, the boundedness of Π and (6.84) give

$$\Pi(w_0\otimes f) = \int w_0(\tau)\,\rho(\mathrm{rv}(\tau^\sharp))\Pi f\,d\nu(\tau) = \int w_0(\varphi_\infty\tau')\,\rho(\mathrm{rv}(\tau'))\Pi f\,d\nu(\tau') = (w_0\circ\varphi_\infty)\otimes\Pi f.$$

For the Fock vector $v_{\bar P}$ of the signs $-\varepsilon$: $\zeta_{v,a,b}(x)$ is $\overline{x_{v,a,b}}$ if $s'_as_b = -1$ and $x_{v,a,b}$ if $s'_as_b = 1$, while for ε', $\zeta'_{v,b,a}(y)$ is $\overline{y_{v,b,a}}$ if $s_bs'_a = 1$ and $y_{v,b,a}$ otherwise (WR5). In both cases $\zeta_{v,a,b}(\varphi_\infty y) = -s'_as_b\,\zeta'_{v,b,a}(y)$, and $e^\infty(\varphi_\infty y) = e^\infty(y)$; hence $v_{\bar P}\circ\varphi_\infty = v_{P^\flat}$.

Class data as translates. For $r \in \mathrm{M}_{n'\times n}(\widehat{\mathcal{O}}_E)$ let δ_r be the indicator function of the class of r on $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$, and y_r the finite adelic $n'\times n$ matrix with components $-t^{-1}r$ at the places of A and 0 elsewhere. As $\bar y_r$ vanishes at A, (2) of Lemma 4.1.3 gives $R_A(y_r)\mathbf{1}_A = B_r$, $B_r(x) = \mathbf{1}_A(x+y_r)$, the indicator of the x whose components at A lie in $t^{-1}r$ plus integral matrices; by (1) of Lemma 4.1.3 and (2) of Lemma 6.2.33, $\mathbf{1}_A\otimes_A v^0 = P^Av^0 = v^0$, so $\rho(\mathrm{fv}(y_r))v^0 = B_r\otimes_A v^0$. The finite component of u_t is t^{-1} at the places of A and 1 outside $A\cup\bar A$, so $B_r(xu_t) = 1$ exactly when the components of x at A lie in $r + t\cdot$(integral matrices), i.e. when x is integral at A and congruent to r modulo $\mathfrak{m}$: $B_r(xu_t) = \delta_r^\natural(x)$. Let $\alpha' = \alpha^{-1}\upsilon^{\#n}$, $\beta' = \beta^{-1}\upsilon^{\#n'}$. By (4) and (5) of Lemma 4.1.1 (the latter with real components 1), for every Fock vector v of $\mathrm{Hom}(S^-,T)$,

$$\omega^{S^-,T}_{\alpha',\beta'}(u_t,1)(v\otimes\rho(\mathrm{fv}(y_r))v^0) = C_1\,\mathrm{mod}_{\mathfrak{m}}(\delta_r,v), \qquad C_1 = \beta'[\#n'](\det_A u_t)^{-1}\,|\det_A u_t|^{\#n'/2},$$

where $\det_A u_t$ has components $t^{-\#n}$ at A and 1 elsewhere; as t generates $\mathfrak{m}$ at A, $|\det_A u_t| = (\#R_{\mathfrak{m}})^{\#n}$, so $|C_1|^2 = (\#R_{\mathfrak{m}})^N$, and C_1 depends neither on r nor on v. By (WC4) and (2) of

Lemma 4.1.1,

$$\theta^{S^-,T}_{\alpha',\beta'}(\mathrm{mod}_{\mathfrak{m}}(\delta_r,v))(g,h)=C_1^{-1}\,\theta^{S^-,T}_{\alpha',\beta'}(v\otimes\rho(\mathrm{fv}(y_r))v^0)(g\,u_t,h).$$

The flipped translate. $\mathrm{fv}(y)^\dagger=(0,c\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}^{-1}(\alpha_{\mathrm{W}}y)^*)=\mathrm{fv}(cy^*)$. So by (6.84) and $\Pi v^0=v^0$, $\Pi\rho(\mathrm{fv}(y_r))v^0=\rho(\mathrm{fv}(y_r'))v^0$ with $y_r'=cy_r^*$, which vanishes at A. By (2) of Lemma 4.1.3 and $\mathbf{1}_A\otimes_A v^0=v^0$, $\rho(\mathrm{fv}(y_r'))v^0=(R_A(y_r')\mathbf{1}_A)\otimes_A v^0$ with

$$\begin{aligned}(R_A(y_r')\mathbf{1}_A)(x)&=\psi_0\big(\textstyle\sum_{b,a}\overline{(y_r')_{b,a}}\,(x_{b,a})_A\big)\mathbf{1}_A(x)=\psi_0\big(\bar c\,\mathrm{tr}(y_rx_A)\big)\mathbf{1}_A(x)\\&=\psi_0\big(-t^{-1}\bar c\,\mathrm{tr}(r\,x_A)\big)\mathbf{1}_A(x),\end{aligned}$$

$\psi_0(\cdot)=\psi_{E,f}(\jmath\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}\cdot)$. For x integral at A, $-\bar c\,\mathrm{tr}(rx_A)$ is an integral finite adele, so by the definition of $\psi_{\mathfrak{m}}$ this is $\psi_{\mathfrak{m}}(-\bar c\,\mathrm{tr}(rx_A)\bmod\mathfrak{m})$: $R_A(y_r')\mathbf{1}_A=\Psi_r^\natural$ for the function $\Psi_r(Z)=\psi_{\mathfrak{m}}(-\bar c\,\mathrm{tr}(Zr))$ on $\mathrm{M}_{n\times n'}(R_{\mathfrak{m}})$. With the real part, $\Pi(v_{\bar P}\otimes\rho(\mathrm{fv}(y_r))v^0)=\mathrm{mod}_{\mathfrak{m}}(\Psi_r,v_{P^\flat})$, formed for $\mathrm{Hom}(T,S)$.

Step 5: conclusion. (6.86) for $\alpha_1=\alpha'$, $\beta_1=\beta'$ has $\alpha_2=\beta$, $\beta_2=\alpha$. With Step 4 and $u_tu_{\mathrm{W}}=(1,u_{\mathfrak{m}})$, for every r, P, g, h,

$$\theta^{S^-,T}_{\alpha',\beta'}(\mathrm{mod}_{\mathfrak{m}}(\delta_r,v_{\bar P}))(g,h)=C_1^{-1}z_0^{-1}\beta(\det u_{\mathrm{W}})^{-1}\,\theta^{T,S}_{\beta,\alpha}(\mathrm{mod}_{\mathfrak{m}}(\Psi_r,v_{P^\flat}))(h,g\,(1,u_{\mathfrak{m}})).$$

Let D be a function on $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$ and $D'(X)=\overline{D(c^{-1}X)}$. Then $D'=\sum_{[r]}D'([r])\,\delta_r$ over the classes $[r]$, and $\Phi_0\mapsto\mathrm{mod}_{\mathfrak{m}}(\Phi_0,v)$ is linear ($\Phi_0\mapsto\Phi_0^\natural$ is linear, $\Psi\otimes_A f$ does not depend on the section by (1) of Lemma 4.1.3 and is therefore linear in Ψ, and $v\otimes\cdot$ is linear), as are the theta kernels. Hence the last identity holds with δ_r replaced by D' and Ψ_r by $\sum_{[r]}D'([r])\Psi_r$, and, substituting $r=cr_1$ (a bijection of the classes) and using $-\bar cc=1$,

$$\sum_{[r]}\overline{D([c^{-1}r])}\,\psi_{\mathfrak{m}}\big(-\bar c\,\mathrm{tr}(Zr)\big)=\sum_{[r_1]}\overline{D([r_1])}\,\psi_{\mathfrak{m}}\big(\mathrm{tr}(Zr_1)\big)=\widehat{D}(Z).$$

Finally, by Lemma 6.4.55 (with $\Psi'=D'$, the reduction of c being the unit there),

$$\overline{\theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}}(D,v_P))(g,h)}=c_{S,T}\,\theta^{S^-,T}_{\alpha',\beta'}(\mathrm{mod}_{\mathfrak{m}}(D',v_{\bar P}))(g,h)$$

with $|c_{S,T}|=1$. So the identity of the statement holds for all D, P, g, h with the constant $c_{S,T}\,C_1^{-1}z_0^{-1}\beta(\det u_{\mathrm{W}})^{-1}$, whose modulus squared is $(\#R_{\mathfrak{m}})^{-\#n\cdot\#n'}$. □

Lemma 6.4.62. *Let D be admissible data, $z=\mathrm{I}$, $i,n\geq0$ with $i+n+2\leq m$, Φ_0' a reversed pair at (i,n) and Φ_1' a reversed pair at $(i,n+1)$. There is a function γ from the m-fold twists to $\mathbb{C}$, of absolute value 1 up to a norm power, such that for every m-fold twist ϑ and every function Ψ on $\mathrm{M}_{n_{n+1}\times n_n}(R_\vartheta)$, on $\mathcal{F}^{i+1}_{\triangle}(z,n)$,*

$$\mathrm{Tl}^i_{\vartheta,z,n+1}\circ\mathrm{As}^i_{\vartheta,z,n}(\Phi_0',\widehat{\Psi})=\gamma(\vartheta)\,\mathrm{As}^i_{\vartheta,z,n+1}(\Phi_1',\widehat{\Psi^\natural})\circ\mathrm{Tl}^{i+1}_{\vartheta,z,n},$$

$\Psi^\natural$ the next datum of Ψ as in Lemma 6.4.12, a function on $\mathrm{M}_{n_{n+2}\times n_{n+1}}(R_\vartheta)$.

Proof. Fix ϑ where it is not quantified, and write $R=R_\vartheta$, $P=\Sigma(\mathfrak{t}_\vartheta(\mathrm{I}))$.

Step 0: R is a product of residue fields and $\chi_\vartheta^{\mathrm{sq}}$ is primitive. The primes p_0,p_1 are $\equiv1$ modulo q_2^2 ((AD5)), hence prime to d and to every prime factor of $q_1=q_0T(s)$ (these are the prime factors of q_0, as $2,3\mid q_0$; Definition 2.3.1), all of which divide $q_2=(q_0d)^{s+6}$; so p_0,p_1 are unramified in $E=K(\zeta_{q_1})$. As $\pi_M\bar\pi_M=p_0p_1$ in $\mathcal{O}_K$ with $p_0\neq p_1$, neither p_ϵ

is inert in K (p_ϵ^2 would divide p_0p_1), so $\pi_M\mathcal{O}_K$ is a product of two distinct primes of degree one, and $\pi_M\mathcal{O}_E$ is the product of the chosen places, each with exponent 1. With (TV2) and $\mathrm{N}Q$ prime to M (Definition 3.1.2), $\mathfrak{t}_\vartheta(\mathrm{I}) = \prod_{w\in P} w$ and $R = \prod_{w\in P} k_w$. By Lemma 6.4.14(c), $\chi^{\mathrm{sq}}_\vartheta(u) = \prod_{w\in P}\psi^\nu_w(u_w)$ with every ψ^ν_w nontrivial. Let $a \in R$, $a \neq 0$, with $a_w \neq 0$; take $v \in k_w^\times$ with $\psi^\nu_w(v) \neq 1$ and $c \in R$ with $c_w = (v-1)/a_w$ and $c_{w'} = 0$ for $w' \neq w$; then $\chi^{\mathrm{sq}}_\vartheta(1+ca) = \psi^\nu_w(v) \notin \{0,1\}$. So $\chi^{\mathrm{sq}}_\vartheta$ is primitive; ψ_ϑ is primitive by the context of (TV7) (self-duality of $\widehat{\mathcal{O}}_E$ for $z \mapsto \psi_{E,f}(\jmath\alpha_{\mathrm{W}}\bar\alpha_{\mathrm{W}}z)$). Moreover $\#R = \#(\mathcal{O}_E/\pi_M\mathcal{O}_E)\cdot \mathrm{N}Q$.

Step 1: the one-square identity for the reversed square. Apply Proposition 6.3.72 to $U_1 = V^{i+1}_{z,n}$, $A = V^{i+1}_{z,n+1}$, $A' = V^i_{z,n+1}$, $U_2 = V^i_{z,n+2}$ (index sets n_n, n_{n+1}, n_{n+1}, n_{n+2}), the integer 0, the weight $\mu = (n+1)\Delta$, the family ν_ϑ (tame for $(\mathfrak{t}_\vartheta(\mathrm{I}), \chi^{\mathrm{sq}}_\vartheta)$ by Lemma 6.4.14(c)), the characters of Lemma 6.4.14(b), the polynomials $P_1 = H_{i+1,n}$, $P_2' = H_{i,n+1}$ (joint harmonics of the triangle lifts at $(i+1,n)$ and $(i,n+1)$), $P_2 = \Phi_1'$, $P_1' = \Phi_0'$, and the bijection $\sigma\colon n_{n+1}\sqcup n_{n+1} \to n_n \sqcup n_{n+2}$ that maps the first copy identically into $n_{n+2} \supseteq n_{n+1}$, and the second copy $n_{n+1} = n_n \sqcup B_{n+1}$ by the identity on n_n (onto the first summand) and $B_{n+1} \to B_{n+2}$, $(n+1,c) \mapsto (n+2,c)$. (OS1), (OS3): Lemma 6.4.14(b). (OS2): the weights do not depend on ϑ; with the types e_1, e, e', e_2 of the triangle forms on U_1, A, A', U_2, $v_{H_{i+1,n}}$ is an edge from e_1 to e and $v_{H_{i,n+1}}$ one from e' to e_2 (Lemma 6.4.15(b), as $i+n+1 < m$); the reversed pair Φ_1' at $(i,n+1)$ is an edge for $(\delta_i(N_{n+2}), \delta_i(N_{n+1}))$, the weights of the characters of (U_2, A), from $e_{-\mu'} = \overline{e_2}$ to $e_{-\mu} = \overline{e}$ ($\mu = \frac12 p^{i+1}_{z,0,n+1}$, $\mu' = \frac12 p^i_{z,0,n+2}$), and Φ_0' at (i,n) is an edge from $\overline{e'}$ to $\overline{e_1}$ for the weights of (A', U_1) (TV6). The composites are $\Theta_\vartheta(x) = \mathrm{As}^i_{\vartheta,z,n+1}(\Phi_1', \mathbf{1}_{x_2}) \circ \mathrm{Tl}^{i+1}_{\vartheta,z,n}[\mathbf{1}_{x_1}]$ for x with rows n_{n+1} and column blocks x_1 (columns n_n), x_2 (columns n_{n+2}), and $\Theta'_\vartheta(y) = \mathrm{Tl}^i_{\vartheta,z,n+1}[\mathbf{1}_{y_2}] \circ \mathrm{As}^i_{\vartheta,z,n}(\Phi_0', \mathbf{1}_{y_1})$ for y with columns n_{n+1} and row blocks y_1 (rows n_n), y_2 (rows n_{n+2}), the transposed lifts being the ascents of (TV7); they map triangle forms to triangle forms (Lemma 6.4.51). As $L_*(\cdot,\cdot;0) = 1$ ((XD7)), Proposition 6.3.72 gives $\kappa \in \mathbb{C}$ and $C > 0$, independent of ϑ, and c_ϑ with $|c_\vartheta|^2 = C$, such that for every $f \in \mathcal{F}^{i+1}_\triangle(z,n)$ and every linear functional l on $\mathcal{F}^i_\triangle(z, n+2)$, $L(x) = l(\Theta_\vartheta(x)f)$ and $L'(y) = l(\Theta'_\vartheta(y)f)$ satisfy (i) and (ii) of Lemma 6.4.13 with $c = \kappa/c_\vartheta$, for the sets $I = n_n$, $K = B_{n+1}$, $J = I \sqcup K = n_{n+1}$, $W = I \sqcup J \sqcup K$ identified with $n_n \sqcup n_{n+2}$ through $J \sqcup K \cong n_{n+2}$ as above (so that the canonical bijection of Lemma 6.4.13 is σ).

Step 2: the Fourier form of the square law. By Step 0, part (2) of Lemma 6.4.13 applies with $\psi_R = \psi_\vartheta$: there is $\gamma_0 = \gamma_0(\vartheta)$ with $|\gamma_0|^2(\#R)^{|K|(|K|+2|I|)} = 1$ such that for every $p = \Psi$ on $\mathrm{M}_{(I\sqcup K)\times I}(R) = \mathrm{M}_{n_{n+1}\times n_n}(R)$, with $p^\natural$ formed for $(I\sqcup K, I, K) = (n_{n+1}, n_n, B_{n+1})$, i.e. $\Psi^\natural$ of the statement,

$$\sum_y \widehat{\Psi}(y)\, L'\begin{pmatrix} y \\ \iota_J \end{pmatrix} = \gamma_0 \frac{\kappa}{c_\vartheta} \sum_x \widehat{\Psi^\natural}(x)\, L(\iota_I \;\; x),$$

since $\widehat{\overline{p}}$ in the notation of Lemma 6.4.13 is the Fourier datum of (TV7). Here $\iota_J \in \mathrm{M}_{n_{n+2}\times n_{n+1}}(R)$ and $\iota_I \in \mathrm{M}_{n_{n+1}\times n_n}(R)$ are the inclusion matrices, whose indicators are the point data of the triangle lifts at $(i,n+1)$ and $(i+1,n)$; so $L'\binom{y}{\iota_J} = l(\mathrm{Tl}^i_{\vartheta,z,n+1}\mathrm{As}^i_{\vartheta,z,n}(\Phi_0', \mathbf{1}_y)f)$ and $L(\iota_I\; x) = l(\mathrm{As}^i_{\vartheta,z,n+1}(\Phi_1', \mathbf{1}_x)\mathrm{Tl}^{i+1}_{\vartheta,z,n}f)$.

Step 3: conclusion. By the linearity of Lemma 6.4.51(c) and of l, l annihilates

$$\mathrm{Tl}^i_{\vartheta,z,n+1}\mathrm{As}^i_{\vartheta,z,n}(\Phi_0', \widehat{\Psi})f - \gamma(\vartheta)\mathrm{As}^i_{\vartheta,z,n+1}(\Phi_1', \widehat{\Psi^\natural})\mathrm{Tl}^{i+1}_{\vartheta,z,n}f$$

with $\gamma = \gamma_0\kappa/c_\vartheta$; as linear functionals separate points, the identity holds. Finally $|\gamma(\vartheta)|^2 = |\kappa|^2C^{-1}(\#R)^{-e}$ with $e = |K|(|K|+2|I|)$ independent of ϑ and $\#R = \#(\mathcal{O}_E/\pi_M\mathcal{O}_E)\,\mathrm{N}Q$ (Step 0), so γ has absolute value 1 up to a norm power (the constant $|\kappa|^2C^{-1}\#(\mathcal{O}_E/\pi_M\mathcal{O}_E)^{-e}$ and the exponent $-e$). □

Lemma 6.4.63. *Let D be admissible data, $z \in \{\mathrm{I},\mathrm{II}\}$ and ϑ an m-fold twist. For $0 \le b \le m$ let K_b be the group of the $k \in \mathbf{K}_0(n_b)$ whose reduction modulo $\mathfrak{t}_\vartheta(z)$ is 1.*

(1) For $0 \le b \le m$, $\Theta^\flat_{\vartheta,z,b}$ is a linear map from $\mathcal{F}(z,0,m)$ to $\mathcal{F}(z,0,b)$, and if $b < m$ every $\Theta^\flat_{\vartheta,z,b}F$ is right invariant under K_b.

(2) For $0 \le b \le m$, $\mathrm{Wc}^0_{\vartheta,z,b}$ is a linear map from $\mathcal{F}^0_\triangle(z,0)$ to $\mathcal{F}^0_\triangle(z,b)$, and if $b \ge 1$ every $\mathrm{Wc}^0_{\vartheta,z,b}y$ is right invariant under K_b.

(3) For $0 \le b \le m$, $F \in \mathcal{F}(z,0,m)$ and $y \in \mathcal{F}^0_\triangle(z,0)$ the function $(\Theta^\flat_{\vartheta,z,b}F)\,(\mathrm{Wc}^0_{\vartheta,z,b}y)$ is integrable on $[\mathrm{U}(V^0_{z,b})]$, and

$$\int_{[\mathrm{U}(V^0_{z,b})]} (\Theta^\flat_{\vartheta,z,b}F)\,(\mathrm{Wc}^0_{\vartheta,z,b}y) = \int_{[\mathrm{U}(V^0_{z,0})]} (\Theta^\flat_{\vartheta,z,0}F)\,y.$$

Proof. Write $\mathfrak{t} = \mathfrak{t}_\vartheta(z)$ and $c_b = \#\mathrm{GL}_{n_b}(\mathcal{O}_E/\mathfrak{t})$.

Step 1: one edge. Fix $b < m$ and put $S = V^0_{z,b}$, $T = V^0_{z,b+1}$; let ν_1,ν_2, H and $\varphi = \mathrm{mod}_\mathfrak{t}(\Phi^{\mathrm{pt}}_b, v_H)$ be the characters, the joint harmonic and the datum of $\mathrm{Tl}^0_{\vartheta,z,b}$ ((TV3)), $\lambda = \frac12 p_{z,0,b}$, $\lambda' = \frac12 p_{z,0,b+1}$, $\kappa(g,h) = \theta^{S,T}_{\nu_1,\nu_2}(\varphi)(g,h)$, and L, $L^{\mathfrak{t}}$ the two integral operators of Lemma 6.3.76 for these data. By (GP6), ν_1 and ν_2 have the weights $\gamma = \gamma_{\neg z,b}(N_b)$ and $\gamma' = \gamma_{\neg z,b}(N_{b+1})$, and by (b) of Lemma 6.4.15 (with $i = 0$, $n = b$) the Fock vector v_H is an edge for the weights (γ,γ') from e_λ to $e_{\lambda'}$; so Lemma 6.3.76 applies with $e = e_\lambda$, $e' = e_{\lambda'}$, $P = H$, $\mathfrak{m} = \mathfrak{t}$, $\Psi = \Phi^{\mathrm{pt}}_b$. The triangle forms at $(0,b)$ and $(0,b+1)$ are the forms of type e_λ on S and of type $e_{\lambda'}$ on T ((TV2), offset 0). By the same clause read with offset 0, the type of the grid forms at $(z,0,b)$ is $\bar e_\lambda$ and that of the grid forms at $(z,0,b+1)$ is $\bar e_{\lambda'}$: the grid forms there are the forms of type $\bar e_\lambda$ on S and of type $\bar e_{\lambda'}$ on T. Since $\theta^{S,T}_{\nu_1,\nu_2}(\varphi)(g,h) = \theta_{\mathrm{Hom}(S,T)}(\omega_{\nu_1,\nu_2}(g,h)\varphi)$ ((XD2)), the lift L_φ of (ED3) is L, so $\mathrm{Tl}^0_{\vartheta,z,b} = L$, and $\mathrm{Pt}_{\vartheta,z,b} = c_b\,L^{\mathfrak{t}}$ by (FY1). By (1) and (2) of Lemma 6.3.76: $\mathrm{Tl}^0_{\vartheta,z,b}$ maps $\mathcal{F}^0_\triangle(z,b)$ to $\mathcal{F}^0_\triangle(z,b+1)$ and $\mathrm{Pt}_{\vartheta,z,b}$ maps $\mathcal{F}(z,0,b+1)$ to $\mathcal{F}(z,0,b)$, both linearly (the integrals are linear in the form); and for $w \in \mathcal{F}^0_\triangle(z,b)$, $G \in \mathcal{F}(z,0,b+1)$ the function $(g,h) \mapsto \kappa(g,h)w(g)G(h)$ is integrable on $[\mathrm{U}(S)] \times [\mathrm{U}(T)]$ and

$$\int_{[\mathrm{U}(T)]} G \cdot \mathrm{Tl}^0_{\vartheta,z,b}w = \int_{[\mathrm{U}(S)]} w \cdot L^{\mathfrak{t}}G. \tag{6.87}$$

By Fubini's theorem the integrability on the product gives the integrability of

$$h \mapsto G(h)\int \kappa(g,h)w(g)\,dg = G(h)\,(\mathrm{Tl}^0_{\vartheta,z,b}w)(h)$$

on $[\mathrm{U}(T)]$.

Step 2: levels. Keep $b < m$. Let $k \in \mathrm{K}_b$ and $k' \in \mathrm{K}_{b+1}$. The finite components of $\det k$ and $\det k'$ are integral and their infinite components are 1, so by the definition of weight and tame part, $\nu_i(\det k) = \prod_w \psi^{(i)}_w(\det k \bmod w)$ with $\psi^{(i)}$ the tame part of ν_i, and likewise for k'. By (GP6), ν_i is $\mu^0_{b+1}\vartheta^{\,b+1}\upsilon^e$ if $\neg z = \mathrm{II}$ and $\mu^0_{b+1}\upsilon^e$ if $\neg z = \mathrm{I}$, for an integer e; as the tame part of a product is the product of the tame parts, μ^0_{b+1} has tame part ω^{b+1}, trivial off the chosen places, υ has trivial tame part, and the tame part of ϑ is trivial off Q, the components $\psi^{(i)}_w \ne 1$ occur only at chosen places, and at places of Q only for $z = \mathrm{I}$. All these places divide $\mathfrak{t}$ ($\mathfrak{t} = \pi_M \prod_{w\in Q} w$ for $z = \mathrm{I}$, $\mathfrak{t} = \mathfrak{b}$, the deep level, for $z = \mathrm{II}$), and $k \equiv 1$, $k' \equiv 1$ modulo $\mathfrak{t}$, so $\det k \equiv \det k' \equiv 1$

modulo every such place and $\nu_i(\det k) = \nu_i(\det k') = 1$. By (6) of Lemma 4.1.1 for $A = \Sigma(\mathfrak{t})$, and since the reductions of k, k' modulo $\mathfrak{t}$ are 1,

$$\omega_{\nu_1,\nu_2}\big((1,k),(1,1)\big)\varphi = \nu_2(\det k)^{-1}\varphi = \varphi, \qquad \omega_{\nu_1,\nu_2}\big((1,1),(1,k')\big)\varphi = \nu_1(\det k')\varphi = \varphi.$$

By (3) of Lemma 6.3.76 with $c = 1$ and $\Psi' = \Psi$: $(\mathrm{Tl}^0_{\vartheta,z,b}w)(h(1,k')) = (\mathrm{Tl}^0_{\vartheta,z,b}w)(h)$ and $(L^{\mathsf{t}}G)(g(1,k)) = (L^{\mathsf{t}}G)(g)$. So every $\mathrm{Tl}^0_{\vartheta,z,b}w$ is right invariant under K_{b+1} and every $\mathrm{Pt}_{\vartheta,z,b}G$ under K_b.

Step 3: (1) and (2). By (FY1), $\Theta^\flat_{\vartheta,z,m} = \mathrm{id}$ and $\Theta^\flat_{\vartheta,z,b} = \mathrm{Pt}_{\vartheta,z,b} \circ \Theta^\flat_{\vartheta,z,b+1}$; by decreasing induction on b, Steps 1 and 2 give (1). By (TV3), $\mathrm{Wc}^0_{\vartheta,z,0} = \mathrm{id}$ and $\mathrm{Wc}^0_{\vartheta,z,b+1} = c_b\,\mathrm{Tl}^0_{\vartheta,z,b} \circ \mathrm{Wc}^0_{\vartheta,z,b}$; by induction on b, Steps 1 and 2 give (2).

Step 4: (3). Induction on b. For $b = 0$ the two sides agree, and the integrand is integrable: as $m \geq 1$, $\Theta^\flat_{\vartheta,z,0}F = c_0\,L^{\mathsf{t}}G$ with $G = \Theta^\flat_{\vartheta,z,1}F$ for the operator L^{t} of the edge $b = 0$, and $y \cdot L^{\mathsf{t}}G$ is integrable on $[\mathrm{U}(V^0_{z,0})]$ by Fubini's theorem, as in Step 1. Let $b < m$ and put $G = \Theta^\flat_{\vartheta,z,b+1}F \in \mathcal{F}(z,0,b+1)$ and $w = \mathrm{Wc}^0_{\vartheta,z,b}y \in \mathcal{F}^0_\triangle(z,b)$. By Step 1 the function $G \cdot \mathrm{Wc}^0_{\vartheta,z,b+1}y = c_b\,G \cdot \mathrm{Tl}^0_{\vartheta,z,b}w$ is integrable on $[\mathrm{U}(T)]$, and by (6.87)

$$\int_{[\mathrm{U}(T)]} G \cdot \mathrm{Wc}^0_{\vartheta,z,b+1}y = c_b \int_{[\mathrm{U}(S)]} w \cdot L^{\mathsf{t}}G = \int_{[\mathrm{U}(S)]} (\mathrm{Pt}_{\vartheta,z,b}G)\,w = \int_{[\mathrm{U}(S)]} (\Theta^\flat_{\vartheta,z,b}F)\,(\mathrm{Wc}^0_{\vartheta,z,b}y),$$

the function $w \cdot L^{\mathsf{t}}G$ being integrable by Fubini's theorem as in Step 1. The induction hypothesis turns the right side into $\int_{[\mathrm{U}(V^0_{z,0})]} (\Theta^\flat_{\vartheta,z,0}F)\,y$. □

Lemma 6.4.64. *Let V be a space with a point with signs s on n, e a cusp kernel of order 0 on $G_\infty(s)$ and $K \subseteq G_f(n)$ an open subgroup. Then the space of the forms of type e on V that are right invariant under K is finite-dimensional.*

Proof. Let $N = \#n$, $G_\infty = G_\infty(s)$ with its measure (the product of the Cayley measures, a Haar measure), $\Gamma = \Gamma_V$, and $\mathcal{A}$ the space of the forms of type e on V right invariant under K. By (VP3) of Definition 3.2.2 V is a framed hermitian space U (with E^n as underlying space, the columns of $(x_V)_v$ as frames at $v \in \Phi$ and the finite isometry $z \mapsto x_{V,f}z$; a framed space of rank N in the sense of (FT1)), with group $\mathrm{G}(s)$ and $\Gamma_U = \Gamma$, and $\lambda_V(g)$ is the first minimum of (VP4) for both readings: $\lambda_U(g) = \lambda_V(g)$. The conditions (ED1) on e coincide with (EK3), (EK4) of Definition 5.6.2 for the signs s, the Haar measures being the Cayley measures and $\|x\| = \prod_v \|x_v\|$ the archimedean size; and the convolution $R(e)$ of (ED2) is that of (EK2). So every $F \in \mathcal{A}$ is a continuous bounded function on $\mathrm{G}(s) = G^U$, left Γ_U-invariant, right K-invariant, with $R(e)F = F$.

By Lemma 5.8.7, applied to U (whose signs are s at every infinite place), e (order $B = 0$), K and $A = 1$, there is $R_1 \geq 0$ with $|F(g)|\lambda_U(g)^{-1} \leq R_1 \sup|F|$ for all $F \in \mathcal{A}$ and g; put $R_0 = \max(R_1, 1)$. By Lemma 5.8.20 with $T = 2R_0$ there is a compact $C \subseteq \mathrm{G}(s)$ such that every g with $\lambda_U(g)^{-1} \leq 2R_0$ has $\gamma g \in C$ for some $\gamma \in \Gamma$. As e is integrable, left translation is continuous in $L^1(G_\infty)$, so there is a neighbourhood W_∞ of 1 in G_∞ with $\int_{G_\infty} |e(u^{-1}h) - e(h)|\,dh \leq \frac{1}{2}$ for $u \in W_\infty$; put $W = W_\infty \times K$, a neighbourhood of 1 in $\mathrm{G}(s)$. For $F \in \mathcal{A}$ with $M = \sup|F|$, $g \in \mathrm{G}(s)$ and $w = (u,k) \in W$, by right K-invariance, $F = R(e)F$ and the substitution $h \mapsto u^{-1}h$ (left invariance of the Haar measure),

$$|F(gw) - F(g)| = \Big|\int_{G_\infty} (e(u^{-1}h) - e(h))F(g(h,1))\,dh\Big| \leq \tfrac{1}{2}M.$$

Cover C by finitely many $a_1W, \ldots, a_rW$ with $a_j \in C$. We show that $F \mapsto (F(a_1), \ldots, F(a_r))$ is injective on $\mathcal{A}$; then $\dim \mathcal{A} \leq r$. Let $F \in \mathcal{A}$ vanish at every a_j and suppose $M = \sup|F| > 0$.

Choose g with $|F(g)| > M/2$. Then $\lambda_U(g)^{-1} \le R_1 M/|F(g)| < 2R_0$, so $\gamma g \in C$ for some $\gamma \in \Gamma$, say $\gamma g = a_j w$ with $w \in W$. By Γ-invariance and the display, $|F(g)| = |F(a_j w) - F(a_j)| \le M/2$, a contradiction. Hence $F = 0$. □

Lemma 6.4.65. *Let D be admissible data and, for an m-fold twist ϑ, $T_\vartheta = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{8mn_m^2}$. There is $C \in \mathbb{C}$ such that for every m-fold twist ϑ:*

(1) the first-path datum Ψ^0_ϑ is a path datum of bound T_ϑ on the edges of the first path;

(2) for every real point g of $\tilde{Y}^0_0$, every $y' \in \mathcal{F}(\mathrm{I}, 0, m)$ and every $\varphi \in \mathcal{F}(\mathrm{II}, 0, m)$,

$$\langle \Theta^\flat_{\vartheta,\mathrm{I},0}\, y',\ \Theta^\flat_{1,\mathrm{II},0}\, \varphi \rangle_{0,g} = C \operatorname{per}_{\mathrm{first}}(\Psi^0; g)(\vartheta, y', \varphi).$$

Proof. Fix an m-fold twist ϑ; write $\mathfrak{m} = \mathfrak{m}_\vartheta = \mathfrak{b} \prod_{w \in Q} w$ ($\mathfrak{b}$ the deep level, a positive power of π_M), $\mathfrak{t}_z = \mathfrak{t}_\vartheta(z)$ ($\mathfrak{t}_\mathrm{I} = \pi_M \prod_{w \in Q} w$, $\mathfrak{t}_\mathrm{II} = \mathfrak{b}$, independent of ϑ), $n_{z,b} = n_{z,0,b}$, $e_{z,b}$ for the edge $((z,0,b),(z,0,b+1))$, w for the edges of the first path, $c_b(z) = \#\mathrm{GL}_{n_{z,b}}(\mathcal{O}_E/\mathfrak{t}_z)$, and $\mathcal{X}$ for the set of level coset families. All tuples below are supported on w. The ranks of the nodes $(z,0,b)$, $b \le m$, are at most $r + 1 + mt = n_m$.

Step 1: the moves. Let $b < m$, $S = V^0_{z,b}$, $T = V^0_{z,b+1}$, ν_1, ν_2, H those of $\mathrm{Tl}^0_{\vartheta,z,b}$, and for a function Ψ on $\mathrm{M}_{n_{z,b+1} \times n_{z,b}}(R_\mathfrak{m})$ let $L^\mathfrak{t}_\Psi G(g) = \int_{[\mathrm{U}(T)]} \theta^{S,T}_{\nu_1,\nu_2}(\mathrm{mod}_\mathfrak{m}(\Psi, v_H))(g,h) G(h)\, dh$. By (GP6), (GP7) the transposed move along $e_{z,b}$ with matrix y is $L^\mathfrak{t}_{\mathbf{1}_y}$ (same characters, harmonic and spaces as the triangle lift, (TV3)). As in (GP6) ν_1, ν_2 have the weights of the edge, and by (b) of Lemma 6.4.15 (v_H is an edge from e_λ to $e_{\lambda'}$, $\lambda = \frac{1}{2} p_{z,0,b}$, $\lambda' = \frac{1}{2} p_{z,0,b+1}$, and the grid forms at $(z,0,b)$, $(z,0,b+1)$ have the types $\bar{e}_\lambda$, $\bar{e}_{\lambda'}$), (1) of Lemma 6.3.76 shows that every $L^\mathfrak{t}_\Psi$ maps grid forms at $(z,0,b+1)$ to grid forms at $(z,0,b)$, the integrals converging absolutely. Since $\mathfrak{m} \subseteq \mathfrak{t}_z$, Lemma 6.4.66 gives $\mathrm{mod}_{\mathfrak{t}_z}(\Phi^{\mathrm{pt}}_b, v_H) = \mathrm{mod}_\mathfrak{m}(\Phi^{\mathrm{pt}}_b \circ \mathrm{red}, v_H)$, red the reduction from $R_\mathfrak{m}$ to $R_{\mathfrak{t}_z}$; the datum $\mathrm{mod}_\mathfrak{m}(\Psi, v_H)$ is linear in Ψ ((XD5), (WR6)) and the theta kernel is linear in the datum, so by (FY1)

$$\mathrm{Pt}_{\vartheta,z,b} = c_b(z) \sum_y \Phi^{\mathrm{pt}}_b(y \bmod \mathfrak{t}_z)\, L^\mathfrak{t}_{\mathbf{1}_y}, \tag{6.88}$$

y over $\mathrm{M}_{n_{z,b+1} \times n_{z,b}}(R_\mathfrak{m})$; the same holds for $\mathrm{Pt}_{1,\mathrm{II},b}$ with these moves for ϑ, because $\mathfrak{t}_1(\mathrm{II}) = \mathfrak{t}_\vartheta(\mathrm{II}) = \mathfrak{b}$ and the characters of the column of $\tilde{Y}$ ($c = \mathrm{I}$ in (GP6)) do not involve the twist.

Step 2: expansion of the left side. Composing (6.88) down the column, by induction on $m - b$, $\Theta^\flat_{\vartheta,\mathrm{I},0} = \prod_{b<m} c_b(\mathrm{I}) \sum_S \prod_{b<m} \Phi^{\mathrm{pt}}_b(S(e_{\mathrm{I},b}) \bmod \mathfrak{t}_\mathrm{I})\, \mathrm{fm}_\mathrm{I}(S)$, the sum over the tuples supported on the column, and likewise for $\Theta^\flat_{1,\mathrm{II},0}$. A tuple supported on w is the same as a pair of tuples supported on the two columns, and the period is bilinear, so with $\Pi = \prod_{b<m} c_b(\mathrm{I}) c_b(\mathrm{II})$ and $\mathrm{pd}(S) = \langle \mathrm{fm}_\mathrm{I}(S) y', \mathrm{fm}_\mathrm{II}(S) \varphi \rangle_{0,g}$,

$$\langle \Theta^\flat_{\vartheta,\mathrm{I},0} y', \Theta^\flat_{1,\mathrm{II},0} \varphi \rangle_{0,g} = \Pi \sum_S \Psi^1(S)\, \mathrm{pd}(S). \tag{6.89}$$

Step 3: translation of a tuple. Each $\Sigma(\mathfrak{m})$ is the set of places of a modulus, so its places w' satisfy $\bar{w}' \ne w'$, and the component of an element of $\mathbf{K}_0(n)$ at the pair $\{w', \bar{w}'\}$ is determined by any element of $\mathrm{GL}_n(\mathcal{O}_{E,w'})$ at w'; as $\mathcal{O}_{E,w'}$ is local, every element of $\mathrm{GL}_n(R_\mathfrak{m})$ is the reduction of some $k \in \mathbf{K}_0(n)$ (a **lift**). For k integral with infinite components 1, the definition of weight and tame part gives $\nu_i(\det k) = \prod_{w'} \psi_{w'}(\det k \bmod w')$, ψ the common tame part of ν_1, ν_2 (they differ by a power of υ, of trivial tame part), which is nontrivial only at places dividing $\mathfrak{m}$; so $\nu_i(\det k) = \chi_e(\det \bar{k})$ for the edge e, $\bar{k}$ the reduction modulo $\mathfrak{m}$. Let h be a family of invertible matrices modulo $\mathfrak{m}$ at the nodes, equal to 1 at $(z,0,m)$ for both z and with

$h(\mathrm{II},0,0) = h(\mathrm{I},0,0) \oplus 1$. Choose lifts $k_{z,b}$ of $h(z,0,b)$ with $k_{z,m} = 1$ and $k_{\mathrm{II},0} = \mathrm{diag}(k_{\mathrm{I},0}, 1)$. For a tuple S let $u_b(S) =$ fm of y' (resp. φ) down to $(z,0,b)$. We claim

$$u_b(h\cdot S)(g'(1,k_{z,b})) = \epsilon_b\, u_b(S)(g') \qquad \text{with} \qquad \epsilon_b = \prod_{b\le i<m} \chi_{e_{z,i}}(\det h(z,0,i+1)/\det h(z,0,i)).$$

For $b = m$ both sides are the form itself. If it holds at $b+1$: by (6) of Lemma 4.1.1,

$$\omega_{\nu_1,\nu_2}((1,k_{z,b}),(1,k_{z,b+1}))\,\mathrm{mod}_{\mathfrak{m}}(\mathbf{1}_y, v_H) = \nu_1(\det k_{z,b+1})\nu_2(\det k_{z,b})^{-1}\mathrm{mod}_{\mathfrak{m}}(\mathbf{1}_{\bar{k}_{z,b+1}y\bar{k}_{z,b}^{-1}}, v_H),$$

and for $y = (h\cdot S)(e_{z,b}) = h(z,0,b+1)^{-1}S(e_{z,b})h(z,0,b)$ the new matrix is $S(e_{z,b})$ and the factor is $\chi_{e_{z,b}}(\det h(z,0,b+1)/\det h(z,0,b))$; so (3) of Lemma 6.3.76 and the induction hypothesis give the claim at b. At $b = 0$, substituting $x \mapsto x(1,k_{\mathrm{I},0})^{-1}$ in the period (right invariance of the quotient measure; $(1,\mathrm{diag}(k,1))$ commutes with $(g,1)$ and $\mathrm{diag}(x(1,k)^{-1},1) = \mathrm{diag}(x,1)(1,\mathrm{diag}(k,1))^{-1}$; $\mathrm{flp}^0_\vartheta = 1$),

$$\mathrm{pd}(h\cdot S) = \epsilon_w(h)\,\mathrm{pd}(S). \tag{6.90}$$

Step 4: the sum over the translates. Every family g_x ($x \in \mathcal{X}$) is as in Step 3, and so is g_x^{-1}. As $S \mapsto g_x\cdot S$ is a bijection of the tuples supported on w with inverse $S \mapsto g_x^{-1}\cdot S$, and ϵ_w is multiplicative, (6.90) gives $\sum_S \epsilon_w(g_x)\Psi^1(g_x\cdot S)\,\mathrm{pd}(S) = \sum_S \Psi^1(S)\,\mathrm{pd}(S)$ for every x, hence

$$\mathrm{per}_{\mathrm{first}}(\Psi^0; g)(\vartheta, y', \varphi) = \sum_S \Psi^0(S)\,\mathrm{pd}(S) = \#\mathcal{X}\sum_S \Psi^1(S)\,\mathrm{pd}(S).$$

Step 5: the constant. $\#\mathcal{X} = \prod_{b<m}\#\mathrm{GL}_{n_{\mathrm{I},b}}(R_{\mathfrak{m}})\cdot\#(\mathrm{GL}_{n_{\mathrm{II},b}}(R_{\mathfrak{m}})/\ker)$, ker the kernel of the surjective reduction modulo $\mathfrak{b}$, so the second factor is $c_b(\mathrm{II})$. For a modulus $\mathfrak{a}$ and $n \ge 1$, $\#\mathrm{GL}_n(\mathcal{O}_E/\mathfrak{a}) = \#(\mathcal{O}_E/\mathfrak{a})^{n^2}\prod_{w'\in\Sigma(\mathfrak{a})}\prod_{i=1}^n(1-\mathrm{N}w'^{-i})$ (the reduction $\mathrm{GL}_n(\mathcal{O}/w'^e) \to \mathrm{GL}_n(k_{w'})$ is onto with kernel of order $\mathrm{N}w'^{(e-1)n^2}$). As $\mathfrak{t}_{\mathrm{I}}$ and $\mathfrak{m}$ have the same places, $c_b(\mathrm{I}) = \kappa_b\,\#\mathrm{GL}_{n_{\mathrm{I},b}}(R_{\mathfrak{m}})$ with $\kappa_b = (\#(\mathcal{O}_E/\pi_M)/\#(\mathcal{O}_E/\mathfrak{b}))^{n_{\mathrm{I},b}^2}$, the factors of the places of Q cancelling ; κ_b does not depend on ϑ. So $\Pi = C\,\#\mathcal{X}$ with $C = \prod_{b<m}\kappa_b$, and (6.89) with Step 4 gives (2).

Step 6: (1). (PD1): $\Psi^1(g_x\cdot S)$ depends only on the matrices of S on w. (PD2): let g be admissible. Define σ on $\mathcal{X}$ by $(\sigma x)_{z,b} = g(z,0,b)\,x_{z,b}$ (left multiplication permutes the cosets). Then $h = g_{\sigma x}^{-1} g\, g_x$ is, at the nodes of the first path, in the level of the node: 1 at $(\mathrm{I},0,b)$, $b < m$, by the choice of representatives; at $(\mathrm{I},0,m)$ and $(\mathrm{II},0,m)$ it is g there, in the level of these nodes by admissibility (trivial, resp. reducing to 1 modulo $\mathfrak{b}$); at $(\mathrm{II},0,b)$, $1 \le b < m$, it reduces to 1 modulo $\mathfrak{b}$; at $(\mathrm{II},0,0)$ it is $h(\mathrm{I},0,0)\oplus 1 = 1$, by (FY4) and admissibility. For such h, $\Psi^1(h\cdot S) = \Psi^1(S)$ (the reductions modulo $\mathfrak{t}_z$ of the matrices do not change) and $\epsilon_w(h) = 1$ (on the column of Y, $h = 1$ at both ends of each edge; on the column of $\tilde{Y}$, χ_e is built from the tame part of μ^0_{b+1}, nontrivial only at chosen places, where $\det h \equiv 1$). With $h'\cdot(h\cdot S) = (hh')\cdot S$,

$$\epsilon_w(g)\Psi^0(g\cdot S) = \sum_x \epsilon_w(gg_x)\Psi^1((gg_x)\cdot S) = \sum_x \epsilon_w(g_{\sigma x})\epsilon_w(h)\Psi^1(h\cdot(g_{\sigma x}\cdot S)) = \Psi^0(S).$$

(PD3): if $\Psi^0(S) \ne 0$, some $\Psi^1(g_x\cdot S) \ne 0$; the vertical edges of w are those of the column of Y, and there $M = (g_x\cdot S)(e)$ reduces modulo $\mathfrak{t}_{\mathrm{I}}$ to the inclusion J, so $\det(J^{\mathsf{T}}M)$ is a unit modulo every place of $\mathfrak{t}_{\mathrm{I}}$, which are the places of $\mathfrak{m}$, hence a unit of $R_{\mathfrak{m}}$; so M has a left inverse L, and $S(e) = g_x(q)\,M\,g_x(p)^{-1}$ has the left inverse $g_x(p)Lg_x(q)^{-1}$. (PD4): Ψ^1 takes the values $0,1$ and $\epsilon_w(g_x)$ is a root of unity (a value of characters of the finite group $R_{\mathfrak{m}}^\times$), so $\Psi^0(S)$ is a sum of at most $\#\mathcal{X}$ roots of unity, and $\#\mathcal{X} \le \prod_{z,b<m}\#\mathrm{M}_{n_{z,b}}(R_{\mathfrak{m}}) \le (\#R_{\mathfrak{m}}^{(2n_m)^2})^{2m} = T_\vartheta$. □

Lemma 6.4.66. *Let S, T be spaces with points with index sets n, n', let $\mathfrak{m}$, $\mathfrak{m}'$ be moduli with $\mathfrak{m}' \subseteq \mathfrak{m}$, and let Φ be a function on $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$. Let Φ' be the function $X \mapsto \Phi(X \bmod \mathfrak{m})$ on $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}'})$. Then $\mathrm{mod}_{\mathfrak{m}'}(\Phi', v) = \mathrm{mod}_{\mathfrak{m}}(\Phi, v)$ for every $v \in \mathcal{F}_{S,T}$.*

Proof. Let $A = \Sigma(\mathfrak{m})$ and $A' = \Sigma(\mathfrak{m}')$. Since $\mathfrak{m}' \subseteq \mathfrak{m}$, $A \subseteq A'$; let $R = A' \setminus A$ and $\mathbf{1}_R$ the indicator of the finite adelic matrices integral at R. Since A' contains the conjugate of none of its members, $\bar{R}$ meets neither A nor $\bar{A}$.

Step 1: $\Phi'^{\natural} = \Phi^{\natural}\mathbf{1}_R$. A finite adelic matrix x is integral at A' exactly when it is integral at A and at R, and then $\Phi'(x_{A'} \bmod \mathfrak{m}') = \Phi(x_A \bmod \mathfrak{m})$, as the reduction $R_{\mathfrak{m}'} \to R_{\mathfrak{m}}$ only reads the components at A.

Step 2: $\tau_y^{A'} = \tau_y^A \mathbf{1}_R$ for y supported on $A \cup \bar{A}$, where τ_y^A, $\tau_y^{A'}$ are the functions τ_y of (WR6) for A and for A'. Indeed $y_R = 0$ and $\bar{y}_R = \overline{y_{\bar{R}}} = 0$, so $\bar{y}^{\mathsf{T}}(2x+y)_{A'} = \bar{y}^{\mathsf{T}}(2x+y)_A$, and $\mathbf{1}_{A'}(x+y) = \mathbf{1}_A(x+y)\mathbf{1}_R(x)$.

Step 3. Expand $\Phi^{\natural} = \sum_y a_y \tau_y^A$ with y supported on $A \cup \bar{A}$. By Steps 1 and 2, $\Phi'^{\natural} = \sum_y a_y \tau_y^{A'}$. For any finite expansion $\Psi = \sum a_y \tau_y$ one has $\Psi \otimes_A f = \sum a_y \rho(\mathrm{fv}(y)) P^A f$ (a linear section taking Ψ to (a_y) exists, and the datum does not depend on the section). Hence, using $P^{A'}v^0 = v^0 = P^A v^0$,

$$\Phi'^{\natural} \otimes_{A'} v^0 = \sum_y a_y \, \rho(\mathrm{fv}(y)) v^0 = \Phi^{\natural} \otimes_A v^0,$$

and applying $v \otimes (\cdot)$ gives $\mathrm{mod}_{\mathfrak{m}'}(\Phi', v) = \mathrm{mod}_{\mathfrak{m}}(\Phi, v)$. □

Lemma 6.4.67. *Let D be admissible data.*

(a) $\mathcal{A}_M(Y_0) \subseteq \mathcal{F}^0_{\triangle}(\mathrm{I}, 0)$.

(b) For every m-fold twist ϑ and every $y \in \mathcal{A}_M(Y_0)$, lift 1, …, lift m applied in turn to y are defined (each defining integral converges absolutely at every point), so $\Theta_\vartheta y$ is defined, and $F^{p_{\mathrm{I},0,m}}_{\Theta_\vartheta y} = \mathrm{Wc}^0_{\vartheta,\mathrm{I},m}\, y$ as functions on $G_\infty(1) \times G_f(n)$.

Proof. **(a).** By (TV2) of Definition 3.2.30, $\mathcal{F}^0_{\triangle}(\mathrm{I}, 0)$ is the space of forms of type e_λ ((ED2) of Definition 3.2.29) on $V^0_{\mathrm{I},0} = Y_0$ with $\lambda = \frac{1}{2} p_{\mathrm{I},0,0}$. At the node $(\mathrm{I}, 0, 0)$ there are no blocks and $\delta = 0$, so $p_{\mathrm{I},0,0}(v)(i) = 2\varsigma_i(v)$ and $\lambda = \varsigma$ (GP5); the signs of the node, $(-1)^e$ at the base index i with $e = \max(i+1-k, 0)$, are the signs of the fixed frame of Y_0 in the numbering of Definition 3.2.31 ($(-1)^c$ at the vector of number $k-1+c$, $0 < c \leq m-1$, and $+1$ elsewhere). By Definition 3.2.16, $\mathcal{A}_M(Y_0) = \mathcal{A}_{\mathrm{K}_M}(Y_0, \varsigma)$, the forms of type e_ς in the sense of (FT2) on the framed space Y_0 that are right invariant under K_M. Through the frame, which is the point of Y_0, the group $G_\infty \times G_f$ and the rational points Γ_{Y_0} of (VP3) of Definition 3.2.2 (those of (FT1)) are $\mathrm{G}(s) = G_\infty(s) \times G_f(r)$ and Γ_{Y_0} of (VP1), (VP2) of Definition 3.2.2, the measure dx of (FT2) is the measure of $G_\infty(s)$ of (ED2) (products of Cayley measures), and the conditions of (FT2) (continuous, bounded, left invariant under the rational points, right invariant under an open subgroup of G_f, and $\int e(x) F(g(x,1)) dx = F(g)$ when e is integrable) are those of (ED2) for the same kernel e_ς. Hence $\mathcal{A}_M(Y_0) \subseteq \mathcal{F}^0_{\triangle}(\mathrm{I}, 0)$.

(b). Fix ϑ and $y \in \mathcal{A}_M(Y_0)$, write $\mathfrak{t} = \mathfrak{t}_\vartheta(\mathrm{I})$, $N_j = \mathrm{rk}\, Y_j$, $p = p_{\mathrm{I},0,m}$, and let $F_0 = y$ and F_j be lift j applied to F_{j-1}. We show by induction that $F_j = \mathrm{Wc}^0_{\vartheta,\mathrm{I},j}\, y \in \mathcal{F}^0_{\triangle}(\mathrm{I}, j)$ for $0 \leq j \leq m$; for $j = 0$ this is (a). Let $1 \leq j \leq m$ and assume it for $j-1$.

- *The data of lift j are those of the triangle lift at $(0, j-1)$.* The triangle lift $\mathrm{Tl}^0_{\vartheta,\mathrm{I},j-1}$ has $S = V^0_{\mathrm{I},j-1} = Y_{j-1}$ and $T = V^0_{\mathrm{I},j} = Y_j$ (TV1); its characters are the edge characters (GP6) with $c = \mathrm{II}$ and $l = j-1$ at the ranks N_{j-1} and N_j, namely $\mu_j^0 \vartheta^j \upsilon^{\lfloor N_{j-1}/2 \rfloor} = \nu_j \upsilon^{\lfloor N_{j-1}/2 \rfloor}$ and $\nu_j \upsilon^{\lfloor N_j/2 \rfloor}$, in the order of lift j; its joint harmonic is the fixed (GP7) harmonic for the signs of Y_{j-1} and Y_j, the weights $\gamma_{\mathrm{II},j-1}(N_{j-1})$, $\gamma_{\mathrm{II},j-1}(N_j)$ and the doubled parameters $p^0_{\mathrm{I},0,j-1} = p_{\mathrm{I},0,j-1}$, $p_{\mathrm{I},0,j}$, which is H_j; and its point datum Φ^{pt}_{j-1}, the indicator of the matrix

with entry 1 at (a,a) for the indices a of Y_{j-1}, which are the first indices of Y_j (GP5), is $\mathbf{1}_j^{\mathrm{inc}}$; the modulus is $\mathfrak{t}$ in both. So the theta kernels and data agree, and lift j of a function F for which the integral converges absolutely is $c_j\, L_\varphi F$, L_φ the lift of (ED3) used by $\mathrm{Tl}^0_{\vartheta,\mathrm{I},j-1}$ and c_j the index in $\mathbf{K}_0(n_{j-1})$ of its elements reducing to 1 at the level places.

- *Convergence.* By Lemma 6.4.15(b) (offset 0, $a=0$, $b=j-1$, $j-1<m$) the Fock vector of H_j is an edge from e_λ, $\lambda=\frac{1}{2}p_{\mathrm{I},0,j-1}$, so e_λ is a cusp kernel of order 0 ((ED4)(a)). As F_{j-1} is a form of type e_λ on Y_{j-1}, Lemma 6.4.52 shows that the integral defining lift j of F_{j-1} converges absolutely for every h.

- *The index.* The level places are the chosen places and the places of Q, whose prime ideals are distinct with product $\mathfrak{t}$ and which contain the conjugate of none of their members ($\mathfrak{t}$ is a modulus, (TV2), (XD4)). By Lemma 6.4.76, $c_j=\#\mathrm{GL}_{n_{j-1}}(\mathcal{O}_E/\mathfrak{t})$.

Hence $F_j=\#\mathrm{GL}_{n_{j-1}}(\mathcal{O}_E/\mathfrak{t})\,\mathrm{Tl}^0_{\vartheta,\mathrm{I},j-1}F_{j-1}=\mathrm{Wc}^0_{\vartheta,\mathrm{I},j}\,y$ by (TV3), and $F_j\in\mathcal{F}^0_\triangle(\mathrm{I},j)$ by (a) of Lemma 6.4.51 (with $i=0$, $n=j-1<m$) and linearity. This completes the induction.

So $F=F_m=\mathrm{Wc}^0_{\vartheta,\mathrm{I},m}\,y$ is a form of type $e_{p/2}$ on $V^0_{\mathrm{I},m}=Y_m=\mathrm{I}_n$ (TV1), (TV2). The doubled parameter $l=2\lambda(Y_m)$ of the chain is p , and p is a doubled Harish-Chandra parameter of (κ_Y,e_Y) . By Lemma 6.4.70, $F=F^p_\eta$ for an algebraic form η of weight (κ_Y,e_Y), and by (b) of Lemma 6.4.72, $\Theta_\vartheta y=F^\flat_p=(F^p_\eta)^\flat_p=\eta$. Hence $F^p_{\Theta_\vartheta y}=F^p_\eta=F=\mathrm{Wc}^0_{\vartheta,\mathrm{I},m}\,y$. □

Lemma 6.4.68. *Let D be admissible data and $z\in\{\mathrm{I},\mathrm{II}\}$.*

(1) For $0\le j\le m$ the space at the node (z,j,m) is the standard definite space $\mathrm{I}_{n_{z,j}}$, so that its grid forms are functions on $G_\infty(1)\times G_f(n_{z,j})$; and for every m-fold twist ϑ, $u\in\mathcal{F}(\mathrm{I},m,m)$, $v\in\mathcal{F}(\mathrm{II},m,m)$ and every real point g of $\mathrm{U}(\tilde{Y}^m_m)$, with $n=n_{\mathrm{I},m}$,

$$\langle u,v\rangle_{m,g}=\int_{[\mathrm{U}(\mathrm{I}_n)]}u(x)\,v\big(\mathrm{diag}(x,(1,\mathrm{flp}^m_\vartheta))\,(g,1)\big)\,dx.$$

(2) For every m-fold twist ϑ, edge tuple S for ϑ, $y\in\mathcal{F}(z,0,m)$ and $0\le j\le m$, the chain $\mathrm{Lc}^S_{z,j}(y)$ is defined (for $j<m$ and every h, the integrand of the class integral of (LQ4) that gives $\mathrm{Lc}^S_{z,j+1}(y)(h)$ satisfies the hypothesis of (LQ3)) and $\mathrm{Lc}^S_{z,j}(y)\in\mathcal{A}_{z,j}$.

(3) For $1\le j\le m$ there is $c_{z,j}\in\mathbb{C}$ such that for every m-fold twist ϑ, edge tuple S for ϑ and $y\in\mathcal{F}(z,0,m)$, the image of y under the composite of the lift moves along $e_{z,0},\dots,e_{z,j-1}$ with the matrices $S(e_{z,0}),\dots,S(e_{z,j-1})$ is the function $F^{l_{z,j}}_\eta$ with

$$\eta=\frac{c_{z,j}}{[\mathbf{K}_0(n_{z,0}):\mathrm{K}_\vartheta(z,0)]}\,\mathrm{Lc}^S_{z,j}(y).$$

(4) The map $y\mapsto y^\flat$ is a linear bijection from $\mathcal{F}(z,0,m)$ onto $\mathcal{A}_{z,0}$, and $y=F^{l_{z,0}}_{y^\flat}$ for every $y\in\mathcal{F}(z,0,m)$.

Proof. **(1).** By (GP4) the node (z,j,m) has $\lfloor[z]/2\rfloor=0$ negative signs, so all its signs are $+1$, and by (GP8) its space is the standard definite space $\mathrm{I}_{n_{z,j}}$; its adelic unitary group is $G_\infty(1)\times G_f(n_{z,j})$. Let $n=n_{\mathrm{I},m}$. By (GP2), $\tilde{Y}^m_m=Y^m_m\oplus\langle(-1)^m\rangle$, and $m=2^{e+1}$ is even by (AD2), so the added line has sign $+1$; by (GP8) and the numbering of (GP5), $\tilde{Y}^m_m$ is the standard definite space on $n\sqcup\{*\}$, $*$ the added line, and $\mathrm{U}(Y^m_m)\to\mathrm{U}(\tilde{Y}^m_m)$ is $x\mapsto\mathrm{diag}(x,1)$. By (3.3) with $l=m$, $\langle u,v\rangle_{m,g}$ is the integral over $[\mathrm{U}(\mathrm{I}_n)]$ of u against the restriction of the right translate

of v by $t=(g,1)\cdot\mathrm{diag}(1,(1,\mathrm{flp}_\vartheta^m))$, the real point g together with the finite element flp_ϑ^m on the added line. As $(g,1)$ has finite component 1 and $\mathrm{diag}(1,(1,\mathrm{flp}_\vartheta^m))$ has archimedean component 1, $\mathrm{diag}(x,1)\,t$ has archimedean component $\mathrm{diag}(x_\infty,1)g$ and finite component $\mathrm{diag}(x_f,\mathrm{flp}_\vartheta^m)$, that is $\mathrm{diag}(x,1)t=\mathrm{diag}(x,(1,\mathrm{flp}_\vartheta^m))(g,1)$. This is the formula of (1).

(4). By (1) the space at $(z,0,m)$ is $\mathrm{I}_{n_{z,0}}$, and by definition $\mathcal{F}(z,0,m)$ is the space of forms on it of the type of the negated grid parameter, $e_{l_{z,0}/2}$, with $l_{z,0}=-p_{z,0,m}$ (LQ1). By (3) of Lemma 6.4.3, $l_{z,0}$ is a doubled Harish-Chandra parameter of $(\kappa_z,e_{z,0}^{\det})$. Hence, by Lemma 6.4.70, $\eta\mapsto F_\eta^{l_{z,0}}$ maps $\mathcal{A}_{z,0}$ into $\mathcal{F}(z,0,m)$ and onto it; it is linear, since $F_\eta^l(x,g)=\langle v_l^+,\rho_{\kappa,e}(x^{-1})\eta(g)\rangle_\kappa$ is linear in η. By (b) of Lemma 6.4.72, $(F_\eta^{l_{z,0}})^\flat=\eta$ for every $\eta\in\mathcal{A}_{z,0}$, so the map is injective, hence a linear bijection whose inverse is $y\mapsto y^\flat$ (LQ5). In particular $y^\flat\in\mathcal{A}_{z,0}$ and $y=F_{y^\flat}^{l_{z,0}}$ for every $y\in\mathcal{F}(z,0,m)$.

The lift moves of the last path. Fix ϑ, an edge tuple S and $0\le i<m$; put $N_i=\#n_{z,i}$. By the definition of the lift move and (XD5), the lift move along $e_{z,i}$ with the matrix $S(e_{z,i})$ is L_φ for the theta kernel $(\omega_{\alpha,\beta},\theta)$ with α,β the edge characters at its ends and the datum $\varphi=\mathrm{mod}_{\mathfrak{m}_\vartheta}(\mathbf{1}_{S(e_{z,i})},v_H)=v_H\otimes(\Phi^\natural\otimes_{\Sigma(\mathfrak{m}_\vartheta)}v^0)$, H the joint harmonic of the move and Φ the indicator of $S(e_{z,i})$. By (LQ4), $\varphi=v_H\otimes f$ with $f=c_s^{-N_iN_{i+1}}\varphi_{z,i}^S$ ($c_s\ne0$). As jm, $\omega_{\alpha,\beta}$ and the class integral are linear, $\mathrm{Al}_{\vartheta,z,i}(f)=c_s^{-N_iN_{i+1}}\mathrm{Al}_{\vartheta,z,i}(\varphi_{z,i}^S)$, and both are linear in η. So Lemma 6.4.69 gives, for every $\eta\in\mathcal{A}_{z,i}$, that the integrands defining $\mathrm{Al}_{\vartheta,z,i}(\varphi_{z,i}^S)\eta$ satisfy the hypotheses of (LQ3), that $\mathrm{Al}_{\vartheta,z,i}(\varphi_{z,i}^S)\eta\in\mathcal{A}_{z,i+1}$, and

$$(\text{lift move along } e_{z,i} \text{ with } S(e_{z,i}))(F_\eta^{l_{z,i}})=\frac{c_s^{-N_iN_{i+1}}\beta_{z,i}^{\mathrm{h}}}{[\mathbf{K}_0(n_{z,i}):\mathrm{K}_\vartheta(z,i)]}\,F^{l_{z,i+1}}_{\mathrm{Al}_{\vartheta,z,i}(\varphi_{z,i}^S)\eta}.\qquad(*)$$

(2). For $0\le j<m$, $N_{z,j}<N_{z,j+1}$ by (1) of Lemma 6.4.3, so the algebraic theta lift along $e_{z,j}$ is the partial map of (LQ4). By induction on j: $\mathrm{Lc}_{z,0}^S(y)=y^\flat$ is defined and lies in $\mathcal{A}_{z,0}$ by (4); if $\mathrm{Lc}_{z,j}^S(y)$ is defined and lies in $\mathcal{A}_{z,j}$ and $j<m$, the preceding paragraph with $i=j$ and $\eta=\mathrm{Lc}_{z,j}^S(y)$ shows that the integrand of the class integral giving $\mathrm{Lc}_{z,j+1}^S(y)(h)$ satisfies the hypotheses of (LQ3) for every h, so that $\mathrm{Al}_{\vartheta,z,j}(\varphi_{z,j}^S)$ is defined at $\mathrm{Lc}_{z,j}^S(y)$ and $\mathrm{Lc}_{z,j+1}^S(y)$ is defined (LQ5), and that $\mathrm{Lc}_{z,j+1}^S(y)\in\mathcal{A}_{z,j+1}$.

(3). For $(z,i)\ne(\mathrm{I},0)$ the level $\mathrm{K}_\vartheta(z,i)$ is the kernel of the reduction modulo $\mathfrak{b}$ on $\mathbf{K}_0(n_{z,i})$ (LQ2), which does not depend on ϑ; it is open in the compact group $\mathbf{K}_0(n_{z,i})$, so $k_{z,i}=[\mathbf{K}_0(n_{z,i}):\mathrm{K}_\vartheta(z,i)]$ is a positive integer independent of ϑ for $i\ge1$. Put

$$c_{z,j}=\prod_{0\le i<j}c_s^{-N_iN_{i+1}}\beta_{z,i}^{\mathrm{h}}\cdot\prod_{1\le i<j}k_{z,i}^{-1}\qquad(1\le j\le m),$$

which depends on neither ϑ, S nor y. Let $M_j(y)$ be the image of y under the composite of the lift moves along $e_{z,0},\dots,e_{z,j-1}$ with the matrices $S(e_{z,0}),\dots,S(e_{z,j-1})$. We show by induction on $j\ge1$ that $M_j(y)$ is defined and equals $F_{\eta_j}^{l_{z,j}}$ with $\eta_j=c_{z,j}[\mathbf{K}_0(n_{z,0}):\mathrm{K}_\vartheta(z,0)]^{-1}\mathrm{Lc}_{z,j}^S(y)$. For $j=1$: $y=F^{l_{z,0}}_{\mathrm{Lc}_{z,0}^S(y)}$ by (4), and $(*)$ with $i=0$ gives $M_1(y)=F_{\eta_1}^{l_{z,1}}$. If the claim holds for $j<m$, then $\eta_j\in\mathcal{A}_{z,j}$ by (2), and $(*)$ with $i=j$, $\eta=\eta_j$ and the linearity of $\mathrm{Al}_{\vartheta,z,j}(\varphi_{z,j}^S)$ give

$$M_{j+1}(y)=\frac{c_s^{-N_jN_{j+1}}\beta_{z,j}^{\mathrm{h}}}{k_{z,j}}\,F^{l_{z,j+1}}_{\mathrm{Al}_{\vartheta,z,j}(\varphi_{z,j}^S)\eta_j}=F_{\eta_{j+1}}^{l_{z,j+1}},$$

since $\mathrm{Al}_{\vartheta,z,j}(\varphi_{z,j}^S)\mathrm{Lc}_{z,j}^S(y)=\mathrm{Lc}_{z,j+1}^S(y)$ by (LQ5). This is (3). □

Lemma 6.4.69. *Let D be admissible data, $z \in \{\mathrm{I},\mathrm{II}\}$, $0 \le i < m$, $n = n_{z,i}$, $n' = n_{z,i+1}$, and let H be the joint harmonic of the lift move along $e_{z,i}$. There is $\beta^{\mathrm{h}}_{z,i} \in \mathbb{C}$ such that for every m-fold twist ϑ, with α and β the edge characters of the lift move along $e_{z,i}$ at its ends of ranks $\#n$ and $\#n'$, every modulus $\mathfrak{m}$, every function Ψ on the $n' \times n$ matrices over $R_{\mathfrak{m}}$ with $f = \Psi^\natural \otimes_{\Sigma(\mathfrak{m})} v^0 \in \mathcal{M}_{n,n'}$, and every $\eta \in \mathcal{A}_{z,i}$:*

(a) for every $h \in G_f(n')$ the function $g \mapsto \mathrm{jm}(\omega_{\alpha,\beta}((1,g),(1,h))f)\,\eta(g)$ on $G_f(n)$ satisfies the hypotheses of (LQ3), so that the partial map $\mathrm{Al}_{\vartheta,z,i}(f)$ of (LQ4) is defined at η, and $\mathrm{Al}_{\vartheta,z,i}(f)\eta \in \mathcal{A}_{z,i+1}$;

(b) for the theta kernel $(\omega_{\alpha,\beta},\theta_{n,n'})$ of $\mathrm{Hom}(\mathrm{I}_n,\mathrm{I}_{n'})$, the integral defining $L_{v_H\otimes f}F_\eta^{l_{z,i}}$ converges absolutely at every point, and

$$L_{v_H\otimes f}\,F_\eta^{l_{z,i}} = \frac{\beta^{\mathrm{h}}_{z,i}}{[\mathbf{K}_0(n) : \mathrm{K}_\vartheta(z,i)]}\,F^{l_{z,i+1}}_{\mathrm{Al}_{\vartheta,z,i}(f)\eta}.$$

Proof. Fix z, i and put $N = \#n$, $N' = \#n'$, $\kappa = \kappa_z$, $e = e^{\det}_{z,i}$, $e' = e^{\det}_{z,i+1}$, $l = l_{z,i}$, $l' = l_{z,i+1}$, $\gamma' = \gamma_{z,i}(N')$, $\rho_{\mathrm{s}} = \rho_{\kappa,e}$ (rank N), $\rho_{\mathrm{t}} = \rho_{\kappa,e'}$ (rank N'), $v^+ = v^+_l$, $v'^+ = v^+_{l'}$, $G = G_\kappa$ in the rank N', $I = I_{z,i}$, $I' = I_{z,i+1}$, $B_\kappa = \sum_\tau \sum_{1\le h<N'} h\,\kappa(\tau,h)$, and for a rank M and $0 \le p < M$ let $\lambda^{(M)}_\tau(p) = \sum_{p<h<M}\kappa(\tau,h)$; τ runs over the infinite places.

Step 0: weights and positions. By (1), (2) of Lemma 6.4.3: $N < N'$, $\kappa(\tau,h) = 0$ for $N < h < N'$, $e = \gamma' + \kappa(\cdot,N)$, and by (GP6) the edge characters α, β at the ends of ranks N, N' have the weights $\gamma_{z,i}(N) = e'$ and γ'. By (3) of Lemma 6.4.3, l and l' are doubled Harish-Chandra parameters of (κ,e) and (κ,e'). By (WM6), l_τ is injective with values in the set of the N numbers $2(e_\tau + \lambda^{(N)}_\tau(p)) + N - 1 - 2p$, $0 \le p < N$, which strictly decrease in p; so with $\pi_\tau(a) = \#\{a' \in n : l_\tau(a') > l_\tau(a)\}$, a bijection $n \to \{0,\dots,N-1\}$,

$$l_\tau(a) = 2\big(e_\tau + \lambda^{(N)}_\tau(\pi_\tau(a))\big) + N - 1 - 2\pi_\tau(a), \qquad l'_\tau(b) = 2\big(e'_\tau + \lambda^{(N')}_\tau(\pi'_\tau(b))\big) + N' - 1 - 2\pi'_\tau(b),$$

with π'_τ defined likewise for l'_τ. As $\kappa(\tau,h) = 0$ for $N < h < N'$: $\kappa(\tau,N) + \lambda^{(N)}_\tau(p) = \lambda^{(N')}_\tau(p)$ for $p < N$, and $\lambda^{(N')}_\tau(p) = 0$ for $N \le p < N'$.

Step 1: the block rule. All signs are $+1$ ((GP4)). For every τ the pair (l_τ, l'_τ) satisfies the block rule (WM8) for the weights (e'_τ,γ'_τ) and the signs $(\mathbf{1}_n,\mathbf{1}_{n'})$: (a) holds since the signs agree, l_τ, l'_τ are injective, and $l_\tau(a) \equiv N-1$, $l'_\tau(b) \equiv N'-1 \pmod 2$; for (b) and (c), the shifted entries are

so $\tilde{l}'_\tau(n') = \tilde{l}_\tau(n) \cup [N'-N]$, which is (b), and $\tilde{l}_\tau(a) \ge N+N'-1-2(N-1) = N'-N+1 > 0$ for every a, so (c) only requires $s(a) = t(b)$, which holds.

Step 2: the joint harmonic is a Schur coefficient. For $A \in \mathbb{C}^{I'}$ and $\xi \in \mathbb{C}^I$ let $\mathrm{Sc}(A,\xi) = A^{\mathsf{T}} S_\kappa(X)\,\xi$, a polynomial in the variables $X_{\tau,b,a}$ ($b \in n'$, $a \in n$), $S_\kappa(X)$ the rectangular Schur matrix from the rank N to the rank N'. We show $H = c_H\,\mathrm{Sc}(Gv'^+, v^+)$ with $c_H \in \mathbb{C}^\times$.

(i) *The polynomial of v'^+.* By (WM3), (WM4), $\mathrm{Pol}_\kappa(\mathrm{ev}_\kappa(y)) = \sum_{i,j}(F_\kappa^{\mathsf{T}}F_\kappa)_{ij}b_j(y)\,b_i = \sum_{T\in\mathcal{C}_\kappa}\Delta_T(y)\,\Delta_T$ in the rank N', because $\Delta_T = \sum_i (F_\kappa)_{Ti}b_i$. Let $y' = y^{l'}$ be the array of (WM6), with entry 1 at $(\tau,b,\pi'_\tau(b))$ and 0 elsewhere. For $T \in \mathcal{C}_\kappa$ and a set $T(\tau,h,j) = \{b_0,\dots,b_{h-1}\}$ listed increasingly, the matrix $(y'_{\tau,b_k,c})_{k,c<h}$ has in row k a single nonzero entry, in column $\pi'_\tau(b_k)$ if $\pi'_\tau(b_k) < h$; it is a permutation matrix if $T(\tau,h,j) = A'_{\tau,h} = \pi'^{-1}_\tau\{0,\dots,h-1\}$ and has a zero row otherwise. So $\Delta_T(y') \ne 0$ only for the filling with $T(\tau,h,j) = A'_{\tau,h}$ for all (τ,h,j),

and for it $\Delta_{\tau,A'_{\tau,h}}(y') = \epsilon_{\tau,h}$ is the sign of $k \mapsto \pi'_\tau(b_k)$. As $\epsilon_{\tau,h}\Delta_{\tau,A'_{\tau,h}} = M_{\tau,h}$, the minor $\det(y_{\tau,\pi'^{-1}_\tau(k),c})_{0\le k,c<h}$,

$$\mathrm{Pol}_\kappa(v'^+) = \prod_\tau \prod_{1\le h<N'} M_{\tau,h}^{\kappa(\tau,h)}.$$

(ii) *Evaluation at Xy^l.* Let y^l be the array of (WM6) for l (rows n). The rectangular Schur matrix of (WM2) satisfies $b'_{i'}(Xy) = \sum_i S_\kappa(X)_{i'i}\, b_i(y) \prod_\tau \Delta_\tau(y)^{\kappa(\tau,N)}$ as polynomials (the identity holds over the ring of polynomials in X). At $y = y^l$, $b_i(y^l) = v_i^+$, and $\Delta_\tau(y^l) = \pm 1$ is the determinant of a permutation matrix; so

$$\varepsilon\,(Gv'^+)^{\mathsf T} S_\kappa(X)\, v^+ = \sum_{i'} (Gv'^+)_{i'}\, b'_{i'}(Xy^l) = \mathrm{Pol}_\kappa(v'^+)(Xy^l), \qquad \varepsilon = \prod_\tau \Delta_\tau(y^l)^{\kappa(\tau,N)} = \pm 1.$$

Here $(Xy^l)_{\tau,b,c} = X_{\tau,b,\pi_\tau^{-1}(c)}$ for $c < N$ and $= 0$ for $c \ge N$. So $M_{\tau,h}(Xy^l) = \Delta^{\mathrm{st}}_{\tau,h} = \det\big(X_{\tau,\pi'^{-1}_\tau(k),\pi_\tau^{-1}(c)}\big)_{0\le k,c<h}$ for $h \le N$, while $\kappa(\tau,h) = 0$ for $N < h < N'$. With (i), $\mathrm{Sc}(Gv'^+, v^+) = \varepsilon \prod_\tau \Pi_\tau$, $\Pi_\tau = \prod_{1\le h\le N} (\Delta^{\mathrm{st}}_{\tau,h})^{\kappa(\tau,h)}$.

(iii) *Staircase and uniqueness.* Fix τ. Apply Lemma 6.4.48 with $R = n'$, $C = n$, $\sigma = \mathbf{1}_n$, the shifts $(\gamma_1,\gamma_2) = (e'_\tau, -\gamma'_\tau)$, l'_τ, l_τ, $k(1,p) = \kappa(\tau,p)$ and $k(-1,p) = 0$ ($1 \le p < N'$): $k(1,p) = 0$ for $p > N = \#\{c : \sigma(c) = 1\}$ by Step 0, $k(-1,\cdot) = 0$, and with these signs $x_1 = \pi'_\tau$, $o = \pi_\tau$, so its $D_{1,p}$ is $\Delta^{\mathrm{st}}_{\tau,p}$ and its P is Π_τ. Hence Π_τ is termwise harmonic, K-highest of weight ν for l'_τ for the row units of $(\mathbf{1}_n, \mathbf{1}_{n'})$ with the shifts $(e'_\tau, -\gamma'_\tau)$, with $\nu(b) = e'_\tau + \sum_{\pi'_\tau(b)<p<N'} \kappa(\tau,p) = e'_\tau + \lambda^{(N')}_\tau(\pi'_\tau(b))$, and killed by the column units $E^{\mathrm{col}}_{cc'}$ whenever $-l_\tau(c') < -l_\tau(c)$. For the signs $\mathbf{1}_{n'}$, $2\rho_{l'_\tau}(b) = 2\rho^{\mathrm c}_{l'_\tau}(b) = N' - 1 - 2\pi'_\tau(b)$, so by Step 0 $l'^{\rho}_b = e'_\tau + \lambda^{(N')}_\tau(\pi'_\tau(b)) + N' - 1 - 2\pi'_\tau(b)$ and $\mu_{l'_\tau} = \nu$ (Definition 3.2.3). By Step 1 and Lemma 6.4.19 a joint harmonic for the signs $(\mathbf{1}_n, \mathbf{1}_{n'})$, the weights (e'_τ, γ'_τ) and the parameters (l_τ, l'_τ) exists; these are the data of (GP7) for the lift move along $e_{z,i}$ ($\gamma = \gamma_{z,i}(N) = e'$, $\lambda = -p_{z,i,m} = l$, $\lambda' = l'$), so the factor H_τ of H is such a joint harmonic. By Lemma 6.4.49, $\Pi_\tau = u_\tau H_\tau$ with $u_\tau \in \mathbb{C}$, and $u_\tau \ne 0$ since Π_τ is a product of determinants of matrices of distinct variables. Hence $H = \prod_\tau H_\tau = c_H\, \mathrm{Sc}(Gv'^+, v^+)$ with $c_H = \varepsilon \prod_\tau u_\tau^{-1}$.

Step 3: real points on Schur coefficients. Let $x \in G_\infty(1)$ for n and $y \in G_\infty(1)$ for n'. By the second formula of (5) of Lemma 4.1.1 (all signs $+1$, so no block of sign -1), $\Omega_{e',\gamma'}(x,y)v_P = \prod_\tau \det(y_\tau)^{e'_\tau} \det(x_\tau)^{-\gamma'_\tau}\, v_{P'}$ with $P'(X) = P(y^{\mathsf T} X x^{-\mathsf T})$, the substitution acting on each $n' \times n$ matrix X_τ. For unitary matrices $y^{\mathsf T} = \overline{y^{-1}}$, $x^{-\mathsf T} = \bar x$, $\det y = \det \overline{y^{-1}}$ and $\det x^{-1} = \det \bar x$. By (WM2), for square z of size N' and w of size N, $S_\kappa(zXw) = S_\kappa(z)S_\kappa(X)S_\kappa(w)\prod_\tau \det(w_\tau)^{\kappa(\tau,N)}$: expand $b'_{i'}(zXwy)$ by the square case at z, the rectangular case at X, and the square case $b_j(wy) = \sum_k S_\kappa(w)_{jk} b_k(y)$ with $\Delta_\tau(wy) = \det(w_\tau)\Delta_\tau(y)$, and compare coefficients (they are unique by (WM2)). With $e = \gamma' + \kappa(\cdot, N)$ this gives

$$\Omega_{e',\gamma'}(x,y)\, v_{\mathrm{Sc}(A,\xi)} = v_{\mathrm{Sc}(\rho_{\mathrm t}(y^{-1})^{\mathsf T} A,\ \rho_{\mathrm s}(x)\xi)}. \tag{6.91}$$

Step 4: theta values are coefficients of jet matrices. For $g \in G_f(n)$, $h \in G_f(n')$ put $\mathcal J(g,h) = \mathrm{jm}(\omega_{\alpha,\beta}((1,g),(1,h))f)$. Each entry $P_{i'i}$ of $S_\kappa(X)$ is homogeneous of degree B_κ: in the identity of Step 2 (ii) the left side $b'_{i'}(Xy)$ is homogeneous of degree B_κ in X (a minor on h rows of Xy is homogeneous of degree h in X), and the coefficients are unique. So $\mathrm{jm}(F)_{i'i} = \eta_P^{B_\kappa}\theta_{n,n'}(v_{P_{i'i}} \otimes F)$, and $\eta_P \ne 0$ ((OL4): a quotient of nonzero numbers). By the first formula of (5) of Lemma 4.1.1 (α, β of weights e', γ'), (6.91), and the linearity of $P \mapsto v_P$, of $v \mapsto v \otimes F$ and of $\theta_{n,n'}$: for x, y as in Step 3,

$$\theta_{n,n'}\Big(\omega_{\alpha,\beta}((x,g),(y,h))\big(v_{\mathrm{Sc}(A,\xi)} \otimes f\big)\Big) = \eta_P^{-B_\kappa}\, A^{\mathsf T}\rho_{\mathrm t}(y^{-1})\, \mathcal J(g,h)\, \rho_{\mathrm s}(x)\, \xi. \tag{6.92}$$

(1) *Rational points.* By Lemma 6.3.77, $(\omega_{\alpha,\beta}, \theta_{n,n'})$ is a theta kernel for $(\mathrm{I}_n, \mathrm{I}_{n'})$: $\theta_{n,n'}(\omega(\gamma p, \delta q)\varphi) = \theta_{n,n'}(\omega(p,q)\varphi)$ for rational points γ of I_n, δ of $\mathrm{I}_{n'}$, and $(p,\varphi) \mapsto \omega(p)\varphi$ is continuous with $\theta_{n,n'}$ bounded. As $(1, \gamma_f g) = \gamma\,(\gamma_\infty^{-1}, g)$ and $(1, \delta_f h) = \delta\,(\delta_\infty^{-1}, h)$, (6.92) at $(1,1)$ and at $(\gamma_\infty^{-1}, \delta_\infty^{-1})$ gives $A^{\mathsf{T}} \mathcal{J}(\gamma_f g, \delta_f h)\xi = A^{\mathsf{T}} \rho_{\mathrm{t}}(\delta_\infty) \mathcal{J}(g,h) \rho_{\mathrm{s}}(\gamma_\infty^{-1})\xi$ for all A, ξ; by (c) of Lemma 4.6.10,

$$\mathcal{J}(\gamma_f g, \delta_f h) = \rho_{\mathrm{t}}(\delta_\infty)\, \mathcal{J}(g,h)\, \rho_{\mathrm{s}}(\gamma_\infty)^{-1}.$$

(2) *Open stabilisers.* Let U be the set of $k \in \mathbf{K}_0(n)$ with $\bar{k} = 1$ modulo $\mathfrak{m}$ and $\beta(\det k) = 1$, and U' the set of $k' \in \mathbf{K}_0(n')$ with $\bar{k}' = 1$ and $\alpha(\det k') = 1$. These are open subgroups: the kernels of the reductions are open, and a continuous homomorphism from the profinite group $\mathbf{K}_0(n)$ to the circle is trivial on an open subgroup (the preimage of a neighbourhood of 1 containing no nontrivial subgroup contains an open subgroup, whose image is then trivial). For $(k,k') \in U \times U'$ and every polynomial Q, (6) of Lemma 4.1.1 gives $\omega_{\alpha,\beta}((1,k),(1,k'))(v_Q \otimes f) = v_Q \otimes f$, the function $\Psi(\bar{k}'^{-1} X \bar{k}) = \Psi(X)$ being unchanged; with the first formula of (5) at real components 1 and the homomorphism property, $\mathcal{J}(gk, hk') = \mathcal{J}(g,h)$, and likewise $\omega_{\alpha,\beta}((x,gk),(y,hk'))(v_Q \otimes f) = \omega_{\alpha,\beta}((x,g),(y,h))(v_Q \otimes f)$.

Step 5: (a). Fix h and put $F_h(g) = \mathcal{J}(g,h)\eta(g)$. For a rational point γ of I_n, Step 4 (1) and (WM7) give $F_h(\gamma_f g) = \mathcal{J}(g,h)\rho_{\mathrm{s}}(\gamma_\infty)^{-1}\rho_{\mathrm{s}}(\gamma_\infty)\eta(g) = F_h(g)$; and $F_h(gk) = F_h(g)$ for k in U intersected with an open subgroup fixing η (Step 4 (2), (WM7)). So F_h satisfies the hypotheses of (LQ3) for every h. As $N < N'$ (Step 0), the algebraic theta lift along $e_{z,i}$ is the partial map of (LQ4), and by its definition it is defined at η exactly when every F_h satisfies the hypotheses of (LQ3); this uses only $\eta \in \mathcal{A}_{z,i}$ and the datum f, not the chains of (LQ5). Hence $\mathrm{Al}_{\vartheta,z,i}(f)$ is defined at η, and $\mathrm{Al}_{\vartheta,z,i}(f)\eta(h) = \mathrm{CI}_{\mathrm{K}}(F_h) \in \mathbb{V}_\kappa$ (rank N'), $\mathrm{K} = \mathrm{K}_\vartheta(z,i)$. By (1) of Lemma 6.4.74, $\mathrm{CI}_{\mathrm{K}}(F)$ is, for any open subgroup $\mathrm{K}'' \subseteq \mathrm{K}$ fixing F, an explicit finite linear combination of values of F; hence $\mathrm{CI}_{\mathrm{K}}(L \circ F) = L(\mathrm{CI}_{\mathrm{K}}(F))$ for every linear map L. For $k' \in U'$, $F_{hk'} = F_h$; for a rational point δ of $\mathrm{I}_{n'}$, $F_{\delta_f h} = \rho_{\mathrm{t}}(\delta_\infty)F_h$ by Step 4 (1). So $\mathrm{Al}_{\vartheta,z,i}(f)\eta$ is right invariant under U' and satisfies $\mathrm{Al}_{\vartheta,z,i}(f)\eta(\delta_f h) = \rho_{\mathrm{t}}(\delta_\infty)\,\mathrm{Al}_{\vartheta,z,i}(f)\eta(h)$: it is an algebraic form of weight (κ, e') on n', that is, it lies in $\mathcal{A}_{z,i+1}$.

Step 6: (b). Fix (y,h) with $y \in G_\infty(1)$ for n' and $h \in G_f(n')$, put $\varphi = v_H \otimes f$ and $\Theta(x,g) = \theta_{n,n'}(\omega_{\alpha,\beta}((x,g),(y,h))\varphi)$ on $\mathrm{G}(1_n) = G_\infty(1) \times G_f(n)$. By Step 4 (1), Θ is continuous and left invariant under the rational points of I_n; the form of I_n is definite, so by Theorem A.4.5 Θ is bounded and $[\mathrm{U}(\mathrm{I}_n)]$ has finite volume. By (b) of Lemma 6.4.72, F_η^l is continuous, bounded, left invariant under the rational points and right invariant under an open subgroup. So the integral $L_\varphi F_\eta^l(y,h) = \int_{[\mathrm{U}(\mathrm{I}_n)]} \Theta\, F_\eta^l$ converges absolutely. By Step 2 and (6.92) with $A = Gv'^+$, $\xi = v^+$, $\Theta(x,g) = c_H \eta_P^{-B_\kappa} A_y^{\mathsf{T}} \mathcal{J}(g,h)\rho_{\mathrm{s}}(x)v^+$ with $A_y = \rho_{\mathrm{t}}(y^{-1})^{\mathsf{T}} G v'^+$. The function ΘF_η^l is right invariant under an open subgroup $\mathrm{K}' \subseteq \mathbf{K}_0(n)$ in the finite variable (Step 4 (2)). By (2) of Lemma 6.4.74 (with $V = \mathbb{C}$ and $c_N > 0$ the total mass of the measure of $G_\infty(1)$ for n),

$$L_\varphi F_\eta^l(y,h) = \frac{c_N}{[\mathbf{K}_0(n) : \mathrm{K}]}\,\mathrm{CI}_{\mathrm{K}}(H_0), \qquad H_0(g) = \int_{G_\infty(1)} \Theta(x,g) F_\eta^l(x,g)\,dx,$$

dx the Haar probability measure. A linear map commutes with the integral of a continuous vector-valued function on the compact group $G_\infty(1)$, so by (WM7) and (b) of Lemma 6.4.72,

$$\begin{aligned} H_0(g) &= c_H \eta_P^{-B_\kappa} A_y^{\mathsf{T}} \mathcal{J}(g,h) \int_{G_\infty(1)} F_\eta^l(x,g)\rho_{\mathrm{s}}(x)v^+\,dx \\ &= \frac{c_H \eta_P^{-B_\kappa}}{\#I}\, A_y^{\mathsf{T}} \mathcal{J}(g,h)\,(F_\eta^l)_l^\flat(g) = \frac{c_H \eta_P^{-B_\kappa}}{\#I}\, A_y^{\mathsf{T}} F_h(g). \end{aligned}$$

By Step 5, $\mathrm{CI}_{\mathrm{K}}(H_0) = c_H \eta_P^{-B_\kappa} (\#I)^{-1} A_y^{\mathsf{T}}\,\mathrm{Al}_{\vartheta,z,i}(f)\eta(h)$. The entries of $v'^+ = \mathrm{ev}_\kappa(y^{l'})$ are values of integral polynomials at a 0/1 array, hence real, and G is symmetric; so $A_y^{\mathsf{T}} w =$

$\overline{v'^+}^{\mathsf{T}} G\rho_{\mathrm{t}}(y^{-1})w = \langle v'^+, \rho_{\mathrm{t}}(y^{-1})w\rangle_\kappa$, and with $w = \mathrm{Al}_{\vartheta,z,i}(f)\eta(h)$ this is $F^{l'}_{\mathrm{Al}_{\vartheta,z,i}(f)\eta}(y,h)$ (WM7). Hence (b) holds with

$$\beta^{\mathrm{h}}_{z,i} = \frac{c_N\, c_H\, \eta_P^{-B_\kappa}}{\#I_{z,i}},$$

which depends only on z and i (through H, N, κ and η_P), not on ϑ, $\mathfrak{m}$, Ψ or η. □

Lemma 6.4.70. *Let n be a nonempty finite index set and (κ, e) a weight for the ranks $\#n$ with a doubled Harish-Chandra parameter l. A function F on $\mathrm{G}(1_n)$ is a form of type $e_{l/2}$ on I_n if and only if $F = F^l_\eta$ for an algebraic form η of weight (κ, e) on n.*

Proof. Write $\rho = \rho_{\kappa,e}$, $\langle\,,\rangle = \langle\,,\rangle_\kappa$, $v = v_l^+$, $d = \#I_\kappa$ and $k_l = e_{l/2}$. By Lemma 6.4.71(b), $k_l(y) = d\langle v, \rho(y)v\rangle$ for $y \in G_\infty(1)$; so k_l is continuous on the compact group $G_\infty(1)$, hence integrable, and a form of type k_l is a continuous bounded function F, left invariant under Γ, with a level, such that

$$F(x,g) = \int_{G_\infty(1)} k_l(y)\, F(xy,g)\, dy = d\int_{G_\infty(1)} \langle v, \rho(y)v\rangle\, F(xy,g)\, dy \qquad (x \in G_\infty(1),\ g \in G_f(n)). \tag{6.93}$$

By Lemma 4.6.10(c), ρ is unitary, so $F^l_\eta(x,g) = \langle v, \rho(x^{-1})\eta(g)\rangle = \langle \rho(x)v, \eta(g)\rangle$.

The functions of algebraic forms are forms of type k_l. Let η be an algebraic form of weight (κ, e) on n. By Lemma 6.4.72(b), F^l_η is continuous, bounded, left invariant under Γ and has a level. For $x, y \in G_\infty(1)$ and $g \in G_f(n)$, $F^l_\eta(xy,g) = \langle \rho(y)v, \rho(x^{-1})\eta(g)\rangle = \overline{\langle \rho(x^{-1})\eta(g), \rho(y)v\rangle}$, and (6.94) of Lemma 6.4.71(a) with $a = b = b' = v$, $c = \rho(x^{-1})\eta(g)$, together with $\langle v, v\rangle = 1$ (Lemma 6.4.72(a)), gives

$$d\int \langle v, \rho(y)v\rangle\, \overline{\langle \rho(x^{-1})\eta(g), \rho(y)v\rangle}\, dy = \langle v, \rho(x^{-1})\eta(g)\rangle = F^l_\eta(x,g),$$

which is (6.93) for F^l_η.

Every form of type k_l is the function of an algebraic form. Let F be a form of type k_l, right invariant under an open subgroup K of $G_f(n)$, and $\eta = F^\flat_l$, $\eta(g) = d\int F(x,g)\rho(x)v\, dx$ (an integral of a continuous function on a compact group with values in a finite-dimensional space). Then $\eta(gk) = \eta(g)$ for $k \in K$. For $\gamma \in \Gamma$ and $x \in G_\infty(1)$, $F(x, \gamma_f g) = F(\gamma\,(\gamma_\infty^{-1}x, g)) = F(\gamma_\infty^{-1}x, g)$, and the substitution $x = \gamma_\infty x'$ (left invariance of the Haar measure) gives

$$\eta(\gamma_f g) = d\int F(x', g)\, \rho(\gamma_\infty x')v\, dx' = \rho(\gamma_\infty)\, \eta(g);$$

so η is an algebraic form of weight (κ, e) on n. Moving the linear form $\langle v, \rho(x^{-1})\cdot\rangle$ inside the integral and substituting $x' = xy$,

$$F^l_\eta(x,g) = d\int F(x', g)\, \langle v, \rho(x^{-1}x')v\rangle\, dx' = d\int F(xy, g)\, \langle v, \rho(y)v\rangle\, dy = F(x,g)$$

by (6.93). Hence $F = F^l_\eta$. □

Lemma 6.4.71. *Let n be a nonempty finite index set, $N = \#n$, and (κ, e) a weight for the ranks N.*

(a) For all $a, b, c, b' \in \mathbb{V}_\kappa$,

$$\int_{G_\infty(1)} \langle a, \rho_{\kappa,e}(y)b\rangle_\kappa\, \overline{\langle c, \rho_{\kappa,e}(y)b'\rangle_\kappa}\, dy = \frac{1}{\#I_\kappa}\, \langle a, c\rangle_\kappa\, \overline{\langle b, b'\rangle_\kappa}. \tag{6.94}$$

(b) If l is a doubled Harish-Chandra parameter of (κ, e), then for every $z \in G_\infty(1)$

$$e_{l/2}(z) = \#I_\kappa \cdot \langle v_l^+, \rho_{\kappa,e}(z)\, v_l^+ \rangle_\kappa.$$

Proof. For (b) write $v = v_l^+$, $\rho = \rho_{\kappa,e}$, $\langle\,,\rangle = \langle\,,\rangle_\kappa$ (conjugate-linear in the first argument), $d = \#I_\kappa$, and for $\tau \in \Phi$ let $\sigma_\tau(a) = \#\{a' \in n : l_\tau(a') > l_\tau(a)\}$, a bijection $n \to \{0, \dots, N-1\}$ as l_τ is injective, and $A_{\tau,h} = \sigma_\tau^{-1}(\{0, \dots, h-1\})$. For a set $P \subseteq n$ and a matrix g, $\Delta_P(g)$ is the principal minor on P.

Step 0: the representation. For any finite set Φ' of places and any weight on it, ρ is a continuous unitary representation of the compact group $\prod_{\tau\in\Phi'} \mathrm{U}(N)$ on $\mathbb{V}_\kappa$ for the positive definite form $\langle\,,\rangle$ (Lemma 4.6.10(b),(c); its matrix entries are polynomials in the entries of $\bar{h}$), and it is irreducible: over $\mathbb{C}$ the Weyl module spanned by the products of minors is the irreducible polynomial representation of $\prod \mathrm{GL}_N(\mathbb{C})$ of highest weight $(\lambda_\tau)_\tau$ [3], the matrices $S_\kappa(z)$ give its action in the dual coordinates, $\prod \mathrm{U}(N)$ is Zariski dense in $\prod \mathrm{GL}_N(\mathbb{C})$, $h \mapsto \bar{h}$ is an automorphism of $\prod \mathrm{U}(N)$, and the scalar factor $\prod \det(\bar{h}_\tau)^{e_\tau}$ does not change invariant subspaces. Hence the Schur orthogonality relations for an irreducible unitary representation of a compact group with its Haar probability measure, of dimension $\#I_\kappa$, give (6.94) for every such Φ', in particular (a) (the product of the Cayley measures is the Haar probability measure of $G_\infty(1)$).

Step 1: the coefficient of the highest vector is a product of principal minors. We show, for every family $z = (z_\tau)$ of complex $N \times N$ matrices,

$$\langle v, S_\kappa(z)\, v\rangle = \prod_{\tau\in\Phi} \prod_{1\le h<N} \Delta_{A_{\tau,h}}(z_\tau)^{\kappa(\tau,h)}. \tag{6.95}$$

By (WM2), $b_i(zy) = \sum_j S_\kappa(z)_{ij} b_j(y)$, so $S_\kappa(z)\,\mathrm{ev}_\kappa(y) = \mathrm{ev}_\kappa(zy)$ for every array y, and $S_\kappa(z)v = \mathrm{ev}_\kappa(zy^l)$. By (WM3), $\Delta_T = \sum_i (F_\kappa)_{Ti} b_i$ for $T \in \mathcal{C}_\kappa$, so $(F_\kappa\,\mathrm{ev}_\kappa(y))_T = \Delta_T(y)$; as F_κ and v are real, $\langle v, w\rangle = (F_\kappa v)^{\mathsf{T}} F_\kappa w$, hence

$$\langle v, S_\kappa(z)v\rangle = \sum_{T\in\mathcal{C}_\kappa} \Delta_T(y^l)\,\Delta_T(zy^l).$$

The entry (a,c) of y_τ^l is 1 if $c = \sigma_\tau(a)$ and 0 otherwise (WM6), so $(z_\tau y_\tau^l)_{a,c} = (z_\tau)_{a,\sigma_\tau^{-1}(c)}$ for $c < N$. For a set A of h rows, the matrix of the minor $\Delta_{\tau,A}(zy^l)$ is therefore the submatrix of z_τ on the rows A and the columns $\sigma_\tau^{-1}(0), \dots, \sigma_\tau^{-1}(h-1)$, in this order. For $z = 1$ it is 0 unless $A = A_{\tau,h}$, when it is a permutation matrix with determinant $\epsilon_{\tau,h} = \pm 1$; and for $A = A_{\tau,h}$, reordering the columns increasingly multiplies the determinant by the same sign, so $\Delta_{\tau,A_{\tau,h}}(zy^l) = \epsilon_{\tau,h}\Delta_{A_{\tau,h}}(z_\tau)$. Thus $\Delta_T(y^l)$ vanishes except for the filling T_0 with $T_0(\tau,h,j) = A_{\tau,h}$ for all (τ,h,j), for which $\Delta_{T_0}(y^l) = \epsilon := \prod_{\tau,h} \epsilon_{\tau,h}^{\kappa(\tau,h)}$ and $\Delta_{T_0}(zy^l) = \epsilon \prod_{\tau,h} \Delta_{A_{\tau,h}}(z_\tau)^{\kappa(\tau,h)}$. As $\epsilon^2 = 1$, (6.95) follows.

Step 2: the lowest K-type. Fix τ, write $\lambda(p) = \sum_{p<h<N} \kappa(\tau,h)$ (non-increasing in p, $\lambda(N-1) = 0$) and $\sigma = \sigma_\tau$. The values $2(e_\tau + \lambda(p)) + N - 1 - 2p$, $0 \le p < N$, are strictly decreasing in p; l_τ is injective with each value among them (WM6), so $l_\tau(a)$ is the value at $p = \sigma(a)$. All signs being $+1$, $2\rho_l^{\mathrm{c}} = 2\rho_l$ and $2\rho_l(a) = (N-1-\sigma(a)) - \sigma(a)$; so $l^\rho(a) = e_\tau + \lambda(\sigma(a)) + N - 1 - 2\sigma(a)$ and $\mu_l(a) = e_\tau + \lambda(\sigma(a))$. Hence $\min \mu_l = e_\tau$, and for an integer $s \ge 1$, $\{a : \mu_l(a) \ge e_\tau + s\} = \sigma^{-1}\{p : \lambda(p) \ge s\} = A_{\tau,h}$ with $h = \#\{p : \lambda(p) \ge s\}$; the value h $(1 \le h < N)$ occurs for exactly $\lambda(h-1) - \lambda(h) = \kappa(\tau,h)$ values of s. By (3.1),

$$m_{\mu_l}(g) = \det(g)^{e_\tau} \prod_{1\le h<N} \Delta_{A_{\tau,h}}(g)^{\kappa(\tau,h)}.$$

By (6.95) and $\rho(z) = \prod_\tau \det(\bar{z}_\tau)^{e_\tau} S_\kappa(\bar{z})$, for $z \in G_\infty(1)$ (minors and determinants being integral polynomials),

$$\langle v, \rho(z)v\rangle = \prod_{\tau\in\Phi} m_{\mu_{l_\tau}}(\bar{z}_\tau) = \prod_{\tau\in\Phi} \overline{m_{\mu_{l_\tau}}(z_\tau)}. \tag{6.96}$$

Step 3: Flensted-Jensen's function on $\mathrm{U}(N)$**.** Fix τ and apply Steps 0–2 to the one-point set $\{\tau\}$ with the weight $(\kappa(\tau,\cdot), e_\tau)$ and the parameter l_τ: with the module $\mathbb{V}_\tau$ of dimension d_τ, its representation ρ_τ and highest vector v_τ (a unit vector by Lemma 6.4.72(a)), (6.96) gives $m(k) = \overline{\langle v_\tau, \rho_\tau(k)v_\tau\rangle} = \langle v_\tau, \rho_\tau(k^{-1})v_\tau\rangle$ for $k \in \mathrm{U}(N)$, $m = m_{\mu_{l_\tau}}$, by unitarity. Substituting $y = k'^{-1}$ (Haar measure is inversion invariant) and using (6.94) for ρ_τ,

$$\int_{\mathrm{U}(N)} m(kk')\,\overline{m(k')}\,dk' = \int \langle v_\tau, \rho_\tau(y)\rho_\tau(k^{-1})v_\tau\rangle\,\overline{\langle v_\tau, \rho_\tau(y)v_\tau\rangle}\,dy = \frac{1}{d_\tau}\,\overline{\langle \rho_\tau(k^{-1})v_\tau, v_\tau\rangle} = \frac{m(k)}{d_\tau},$$

and in the same way $\|m\|^2 = \int |m|^2 = d_\tau^{-1}$. For $k \in \mathrm{U}(N)$ all signs agree, so $\mathrm{bd}(k) = k$ is invertible and $\mathrm{bd}(k)^{-1}k = 1$ is accretive; as $m_{-l^\rho}(k'^* k') = m_{-l^\rho}(1) = 1$, (3.2) gives $c_{l_\tau/2}(k) = \|m\|^{-2} \int m(kk')\overline{m(k')}\,dk' = m(k)$. Its formal degree for the Cayley measure, the Haar probability measure, is $(\int |m|^2)^{-1} = d_\tau$.

Step 4: conclusion. By (FT3), Step 3 and (6.96),

$$e_{l/2}(z) = \prod_\tau d_\tau\,\overline{m_{\mu_{l_\tau}}(z_\tau)} = (\prod_\tau d_\tau)\langle v, \rho(z)v\rangle.$$

Finally, by (6.94) with $a = b = c = b' = v$, Lemma 6.4.72(a), (6.96) and Fubini's theorem for the product of the Haar probability measures,

$$\frac{1}{d} = \int_{G_\infty(1)} |\langle v, \rho(z)v\rangle|^2\,dz = \prod_\tau \int_{\mathrm{U}(N)} |m_{\mu_{l_\tau}}|^2 = \prod_\tau \frac{1}{d_\tau},$$

so $\prod_\tau d_\tau = d$. □

Lemma 6.4.72. *Let n be a nonempty finite index set, (κ, e) a weight for the ranks $N = \#n$ with a doubled Harish-Chandra parameter l, $v^+ = v_l^+$ and $d = \#I_\kappa$. Then:*

(a) $\langle v^+, v^+\rangle_\kappa = 1$*;*

(b) for every algebraic form η of weight (κ, e) on n, the function F_η^l is continuous, bounded, left invariant under the rational points of I_n and right invariant under an open subgroup of $G_f(n)$, and its algebraic form for l is η: $(F_\eta^l)_l^\flat = \eta$;

(c) let $K \subseteq \mathbf{K}_0(n)$ be an open subgroup and χ a character of K with values of modulus 1, and let η, η' be algebraic forms of weight (κ, e) on n with $\eta(gk) = \chi(k)\eta(g)$ and $\eta'(gk) = \chi(k)\eta'(g)$ for $g \in G_f(n)$, $k \in K$. Then $g \mapsto \langle \eta(g), \eta'(g)\rangle_\kappa$ is constant on the double cosets of the rational points and K, and its class sum for K is

$$\sum_{[h]} \frac{1}{\#\Gamma_h} \langle \eta(h), \eta'(h)\rangle_\kappa = [\mathbf{K}_0(n) : K] \cdot d \cdot \langle F_\eta^l, F_{\eta'}^l\rangle_{\mathrm{I}_n}.$$

Proof. **Step 0: ρ is a continuous irreducible unitary representation.** By Lemma 4.6.10(c), ρ is a homomorphism on $G_\infty(1)$, unitary for $\langle\,,\rangle$, which is positive definite by Lemma 4.6.10(b); its matrix entries are polynomials in the entries of $\bar{h}$, so it is continuous. The $\mathbb{C}$-span of the products of minors $\nabla_\kappa \otimes \mathbb{C}$, with $\prod_\tau \mathrm{GL}_N(\mathbb{C})$ acting by $P \mapsto P(z\,\cdot)$, is the irreducible polynomial representation of highest weight $(\lambda_\tau)_\tau$ (the Weyl module, [3]); by (WM2) the matrices

$S_\kappa(z)$ describe this action in the basis (b_i), so $z \mapsto S_\kappa(z)$ on $\mathbb{V}_\kappa$ (the coordinates in the dual basis) is irreducible, an invariant subspace of $\mathbb{V}_\kappa$ having an invariant annihilator in $\nabla_\kappa \otimes \mathbb{C}$. The group $\prod_\tau \mathrm{U}(N)$ is Zariski dense in $\prod_\tau \mathrm{GL}_N(\mathbb{C})$, $h \mapsto \bar{h}$ is an automorphism of it, and the scalar $\prod_\tau \det(\bar{h}_\tau)^{e_\tau}$ does not change invariant subspaces; so ρ is irreducible.

Step 1: Schur orthogonality. For $a, b, c \in \mathbb{V}_\kappa$,

$$\int_{G_\infty(1)} \langle \rho(y)a, b\rangle \, \rho(y)c \, dy = d^{-1}\langle a, c\rangle \, b. \tag{6.97}$$

Indeed the operator $T\colon b \mapsto \int \langle \rho(y)a, b\rangle \rho(y)c \, dy$ satisfies $T\rho(z) = \rho(z)T$ (substitute $y \mapsto zy$, the measure being left invariant, and use unitarity), so it is a scalar λ by Schur's lemma (Step 0), and its trace is $d\lambda = \int \langle \rho(y)a, \rho(y)c\rangle \, dy = \langle a, c\rangle$, the trace of $b \mapsto \langle u, b\rangle w$ being $\langle u, w\rangle$ and the measure having mass 1.

Step 2: (a). For each τ, l_τ is injective, so $\sigma_\tau(a) = \#\{a' : l_\tau(a') > l_\tau(a)\}$ is a bijection $n \to \{0, \dots, N-1\}$, and $y^l_{\tau,a,c} = 1$ exactly when $c = \sigma_\tau(a)$ (WM6). For a set A of h rows, the columns $0, \dots, h-1$ of y^l_τ restricted to the rows A form a matrix with at most one entry 1 in each column, all others 0; its determinant $\Delta_{\tau,A}(y^l)$ is ± 1 if $A = A_{\tau,h} := \sigma_\tau^{-1}(\{0, \dots, h-1\})$ and 0 otherwise. By (WM3), $(F_\kappa v^+)_T = \sum_i (F_\kappa)_{Ti} b_i(y^l) = \Delta_T(y^l)$ for $T \in \mathcal{C}_\kappa$; so it is ± 1 for the one filling with $T(\tau, h, j) = A_{\tau,h}$ (as an increasing tuple) for all (τ, h, j), and 0 for the others. As v^+ is real, $\langle v^+, v^+\rangle = (v^+)^{\mathsf{T}} F_\kappa^{\mathsf{T}} F_\kappa v^+ = |F_\kappa v^+|^2 = 1$.

Step 3: (b). By unitarity $F^l_\eta(x, g) = \langle \rho(x)v^+, \eta(g)\rangle$. It is continuous ($\rho$ is continuous and η is locally constant, being right invariant under an open subgroup), bounded by $\sup_g \|\eta(g)\|$, which is finite because η takes finitely many values: $\Gamma\backslash G_f(n)/K'$ is finite for an open K' fixing η ([33]) and $\|\rho(\gamma_\infty)w\| = \|w\|$; right invariant under any open subgroup fixing η; and for $\gamma \in \Gamma$, $F^l_\eta(\gamma_\infty x, \gamma_f g) = \langle \rho(\gamma_\infty)\rho(x)v^+, \rho(\gamma_\infty)\eta(g)\rangle = F^l_\eta(x, g)$. By (WM7) and (6.97) with $a = c = v^+$, $b = \eta(g)$, and (a),

$$(F^l_\eta)^\flat_l(g) = d \int_{G_\infty(1)} \langle \rho(x)v^+, \eta(g)\rangle \, \rho(x)v^+ \, dx = \langle v^+, v^+\rangle \, \eta(g) = \eta(g).$$

Step 4: unfolding. The space I_n is definite, so $\mathrm{U}(\mathrm{I}_n)$ is anisotropic and $[\mathrm{U}(\mathrm{I}_n)]$ is compact [37]; as $G_\infty(1) \times K$ is open, $\Gamma\backslash \mathrm{G}(1_n)/(G_\infty(1) \times K)$ is finite, i.e. there are finitely many double cosets $\Gamma_f h K$ in $G_f(n)$, Γ_f the finite components of Γ. For a representative h, $\Gamma_h = \{\gamma \in \Gamma : \gamma_f \in hKh^{-1}\}$ is finite (discrete and contained in the compact $G_\infty(1) \times hKh^{-1}$), acts on $G_\infty(1) \times hK$ by left multiplication, freely, and its orbits are the intersections of $G_\infty(1) \times hK$ with the Γ-orbits; the sets $\Gamma(G_\infty(1) \times hK)$ partition $\mathrm{G}(1_n)$. As hK has measure $[\mathbf{K}_0(n) : K]^{-1}$, for Ψ bounded, measurable, left Γ-invariant and right K-invariant,

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} \Psi = [\mathbf{K}_0(n) : K]^{-1} \sum_{[h]} \frac{1}{\#\Gamma_h} \int_{G_\infty(1)} \Psi(y, h) \, dy. \tag{6.98}$$

Step 5: (c). For $\gamma \in \Gamma$ and $k \in K$, $\langle \eta(\gamma_f hk), \eta'(\gamma_f hk)\rangle = |\chi(k)|^2 \langle \rho(\gamma_\infty)\eta(h), \rho(\gamma_\infty)\eta'(h)\rangle = \langle \eta(h), \eta'(h)\rangle$, so the class sum is defined. The function $\Psi = \overline{F^l_\eta} F^l_{\eta'}$ is bounded, continuous, left Γ-invariant (Step 3) and right K-invariant ($F^l_\eta(x, gk) = \chi(k)F^l_\eta(x, g)$ and $|\chi(k)| = 1$). By (6.97) with $a = c = v^+$, $b = \eta'(h)$, paired with $\eta(h)$, and (a),

$$\int_{G_\infty(1)} \overline{\langle \rho(y)v^+, \eta(h)\rangle} \, \langle \rho(y)v^+, \eta'(h)\rangle \, dy = \Big\langle \eta(h), \int \langle \rho(y)v^+, \eta'(h)\rangle \rho(y)v^+ \, dy \Big\rangle = d^{-1}\langle \eta(h), \eta'(h)\rangle,$$

and (6.98) gives $\langle F^l_\eta, F^l_{\eta'}\rangle_{\mathrm{I}_n} = [\mathbf{K}_0(n) : K]^{-1} d^{-1} \sum_{[h]} (\#\Gamma_h)^{-1} \langle \eta(h), \eta'(h)\rangle$, which is (c). □

Lemma 6.4.73. *Let $E = E_s$ with its set Φ of infinite places and n a nonempty finite index set with $N = \#n$, the ranks being $N_\tau = N$ ($\tau \in \Phi$) as in (WM6). Let (κ, e) and (κ', e') be weights with doubled Harish-Chandra parameters l and $-l$ respectively. There is an integer matrix A with rows $I_{\kappa'}$ and columns I_κ such that:*

(1) for every field R of characteristic 0, every $g \in \prod_\tau \mathrm{GL}_n(R)$ and all $v' \in R^{I_{\kappa'}}$, $v \in R^{I_\kappa}$,

$$(P_{\kappa',e'}(g)v')^{\mathsf{T}} A\, P_{\kappa,e}(g)v = v'^{\mathsf{T}} A v, \qquad P_{\kappa,e}(g) = \prod_\tau \det(g_\tau)^{e_\tau}\, S_\kappa(g);$$

(2) for all signs s on n, every algebraic form η of weight (κ', e'), $x \in G_\infty(s)$ and $g \in G_f(n)$,

$$F_\eta^{-l}(x, g) = \eta(g)^{\mathsf{T}} A\, \rho_{\kappa,e}(x)\, v_l^+;$$

(3) there is an integer matrix C with $CA = h_{\kappa'} \cdot 1$, $h_{\kappa'}$ the hook number of κ' in the ranks N;

(4) for every $v \in \mathbb{V}_\kappa$ there is $v' \in \mathbb{V}_{\kappa'}$ with $\|v'\|_{\kappa'} = \|v\|_\kappa$ and $u^{\mathsf{T}} A v = \langle v', u\rangle_{\kappa'}$ for all $u \in \mathbb{V}_{\kappa'}$;

(5) if $L \in \mathbb{N}$ and $\sum_\tau \sum_{1 \le h < N} h\, \kappa'(\tau, h) \le L$, then $h_{\kappa'} \le (L^L)^3$.

Proof. Write $\mathrm{hc}_\tau(p) = 2(e_\tau + \lambda_\tau(p)) + N - 1 - 2p$ and $\mathrm{hc}'_\tau(p)$ for the same with (κ', e') ($0 \le p < N$), and $\beta'_\tau = \sum_{1 \le h < N} \kappa'(\tau, h)$.

Step 1: the parameters determine κ' and e'. Since $\lambda_\tau(p) - \lambda_\tau(p+1) = \kappa(\tau, p+1) \ge 0$, $\mathrm{hc}_\tau(p) - \mathrm{hc}_\tau(p+1) = 2\kappa(\tau, p+1) + 2 \ge 2$, so the N values $\mathrm{hc}_\tau(p)$ are distinct and decreasing; l_τ is injective with values among them, hence a bijection of n onto them, and $l_\tau(a) = \mathrm{hc}_\tau(p_\tau(a))$ with $p_\tau(a) = \#\{a' : l_\tau(a') > l_\tau(a)\}$. Likewise $-l_\tau$ is a bijection onto the decreasing values $\mathrm{hc}'_\tau(p)$; as the values of $-l_\tau$ in decreasing order are $-\mathrm{hc}_\tau(N-1) > \cdots > -\mathrm{hc}_\tau(0)$, we get $\mathrm{hc}'_\tau(p) = -\mathrm{hc}_\tau(N-1-p)$. Comparing consecutive differences gives $\kappa'(\tau, h) = \kappa(\tau, N-h)$ for $1 \le h < N$, and $p = 0$ gives (with $\lambda_\tau(N-1) = 0$, $\lambda'_\tau(0) = \beta'_\tau$)

$$e_\tau + e'_\tau = -\beta'_\tau.$$

Step 2: the duality matrix. Apply Lemma 3.2.20 with $\kappa^+ = 0$ and $\kappa^- = \kappa'$: the mixed weight is $\kappa'(\tau, N-i) = \kappa(\tau, i)$, $e^- = \beta'$, and the Weyl module of the zero weight is $\mathbb{C}$ with basis the empty product, Gram matrix 1, evaluation vector 1 and Schur matrices 1. We obtain $C_0 \in \mathrm{M}_{I_{\kappa'} \times I_\kappa}(\mathbb{Z})$ with an integral left inverse L ($LC_0 = 1$), with $C_0^{\mathsf{T}} G_{\kappa'} C_0 = G_\kappa$, $C_0 \,\mathrm{ev}_\kappa(y_{\mathrm{id}}) = \mathrm{ev}_{\kappa'}(y_{w_0})$, and, over every field R of characteristic 0 and for invertible g,

$$C_0 \prod_\tau \det(g_\tau)^{-\beta'_\tau} S_\kappa(g) = S_{\kappa'}((g^{-1})^{\mathsf{T}}) C_0. \tag{6.99}$$

Let π_τ be the permutation matrix with $(\pi_\tau)_{aa'} = 1$ if and only if $a' = p_\tau(a) + 1$. Then $\pi y_{\mathrm{id}} = y^l$ and $\pi y_{w_0} = y^{-l}$ (the frame of $-l$ has its 1 in the column $\#\{a' : -l_\tau(a') > -l_\tau(a)\} = N - 1 - p_\tau(a)$), so $v_l^+ = S_\kappa(\pi)\mathrm{ev}_\kappa(y_{\mathrm{id}})$ and $v_{-l}^+ = S_{\kappa'}(\pi)\mathrm{ev}_{\kappa'}(y_{w_0})$ by (WM2). With $g = \pi$ in (6.99), as $(\pi^{-1})^{\mathsf{T}} = \pi$,

$$C_0 v_l^+ = \epsilon\, v_{-l}^+, \qquad \epsilon = \prod_\tau \det(\pi_\tau)^{\beta'_\tau} \in \{\pm 1\}.$$

Put $A = \epsilon\, G_{\kappa'} C_0$, an integer matrix with rows $I_{\kappa'}$ and columns I_κ.

(1). By (a) of Lemma 4.6.10 (a polynomial identity, valid over R), $S_{\kappa'}(g)^{\mathsf{T}} G_{\kappa'} = G_{\kappa'} S_{\kappa'}(g^{\mathsf{T}})$. Hence, by (6.99) and Step 1,

$$P_{\kappa',e'}(g)^{\mathsf{T}} A\, P_{\kappa,e}(g) = \epsilon \prod_\tau \det(g_\tau)^{e_\tau + e'_\tau + \beta'_\tau}\, G_{\kappa'} S_{\kappa'}(g^{\mathsf{T}}) S_{\kappa'}((g^{-1})^{\mathsf{T}}) C_0 = A,$$

using the multiplicativity of $S_{\kappa'}$. This is (1).

(2). Since v_{-l}^{+} has integer coordinates and $G_{\kappa'}$ is symmetric, $\langle v_{-l}^{+}, w\rangle_{\kappa'} = w^{\mathsf{T}} G_{\kappa'} v_{-l}^{+} = w^{\mathsf{T}} A\, v_l^{+}$ for $w \in \mathbb{V}_{\kappa'}$. With $w = \rho_{\kappa',e'}(x^{-1})\eta(g)$ this is $F_\eta^{-l}(x,g)$. Applying (1) over $\mathbb{C}$ to $\bar{x}$ (invertible) and the vectors w, $\rho_{\kappa,e}(x)v_l^{+}$, and using $\rho_{\kappa',e'}(x)w = \eta(g)$ (multiplicativity of $P_{\kappa',e'}$ and of complex conjugation),

$$F_\eta^{-l}(x,g) = w^{\mathsf{T}} A\, v_l^{+} = \big(\rho_{\kappa',e'}(x)w\big)^{\mathsf{T}} A\, \rho_{\kappa,e}(x) v_l^{+} = \eta(g)^{\mathsf{T}} A\, \rho_{\kappa,e}(x)\, v_l^{+}.$$

(3). Let $H_{\kappa'}$ be the matrix of Fock pairings of Lemma 4.6.9, so $H_{\kappa'} G_{\kappa'} = h_{\kappa'} \cdot 1$. Put $C = \epsilon L H_{\kappa'}$, an integer matrix; then $CA = \epsilon^2 L\, H_{\kappa'} G_{\kappa'}\, C_0 = h_{\kappa'} L C_0 = h_{\kappa'} \cdot 1$.

(4). For $v \in \mathbb{V}_\kappa$ put $v' = \epsilon\, \overline{C_0 v}$. For $u \in \mathbb{V}_{\kappa'}$, $\langle v', u\rangle_{\kappa'} = \epsilon (C_0 v)^{\mathsf{T}} G_{\kappa'} u = u^{\mathsf{T}} A v$, as $G_{\kappa'}$ is symmetric. And $\|v'\|_{\kappa'}^2 = (C_0 v)^{\mathsf{T}} G_{\kappa'} \overline{C_0 v} = v^{\mathsf{T}} C_0^{\mathsf{T}} G_{\kappa'} C_0 \bar{v} = v^{\mathsf{T}} G_\kappa \bar{v} = \|v\|_\kappa^2$, the last since G_κ is real symmetric and $\|v\|_\kappa^2$ is real.

(5). The highest polynomial $f = f_{\kappa'}$ is the product of $\sum_{\tau,h} \kappa'(\tau,h)$ minors, one of size h for each column of height h; it is homogeneous of degree $\beta = \sum_\tau \sum_{1\le h<N} h\, \kappa'(\tau,h) \le L$. A minor of size h is a sum of $h! \le h^h$ monomials with coefficients ± 1, so expanding the product, $f = \sum_\alpha f_\alpha y^\alpha$ with $\sum_\alpha |f_\alpha| \le \prod_{\text{columns}} h^h \le L^\beta \le L^L$ (for $L \ge 1$; if $L = 0$ then $f = 1$ and $h_{\kappa'} = 1$). Every α occurring has $|\alpha| = \beta$, so $\alpha! \le \beta! \le L^L$, and

$$h_{\kappa'} = \langle f, f\rangle_{\mathrm{F}} = \sum_\alpha f_\alpha^2\, \alpha! \le L^L \Big(\sum_\alpha |f_\alpha|\Big)^2 \le (L^L)^3.$$

□

Lemma 6.4.74. *Let n be a nonempty finite index set, Γ the group of rational points of I_n, embedded in $\mathrm{G}(1)$ by $\gamma \mapsto (\gamma_\infty, \gamma_f)$, Γ_f the group of the γ_f, V a finite-dimensional complex vector space and $\mathrm{K} \subseteq \mathbf{K}_0(n)$ an open subgroup.*

(1) Let $F\colon G_f(n) \to V$ satisfy $F(\gamma_f g k) = F(g)$ for all $\gamma \in \Gamma$, $g \in G_f(n)$ and k in an open subgroup $\mathrm{K}' \subseteq \mathrm{K}$. Then $\Gamma_f \backslash G_f(n) / \mathrm{K}'$ is finite, the groups $\Gamma'_h = \Gamma_f \cap h\mathrm{K}'h^{-1}$ are finite, and

$$\mathrm{CI}_{\mathrm{K}}(F) = \frac{1}{[\mathrm{K} : \mathrm{K}']} \sum_{[h] \in \Gamma_f \backslash G_f(n)/\mathrm{K}'} \frac{F(h)}{\#\Gamma'_h}.$$

(2) Let $f\colon \mathrm{G}(1) \to V$ be continuous, with $f(\gamma x) = f(x)$ for $\gamma \in \Gamma$, $x \in \mathrm{G}(1)$, and $f(y, gk) = f(y,g)$ for $(y,g) \in \mathrm{G}(1)$ and k in an open subgroup $\mathrm{K}' \subseteq \mathbf{K}_0(n)$. Then

$$H(g) = \int_{G_\infty(1)} f(y,g)\, dy,$$

dy the Haar probability measure, satisfies the hypothesis of (1) with the open subgroup $\mathrm{K}' \cap \mathrm{K}$, and

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} f = \frac{c_n}{[\mathbf{K}_0(n) : \mathrm{K}]}\, \mathrm{CI}_{\mathrm{K}}(H),$$

where $c_n > 0$ is the total mass of the measure of $G_\infty(1)$.

Proof. **Finiteness.** $\mathrm{U}(\mathrm{I}_n)$ is a linear algebraic group over E^+ with group of finite adelic points $G_f(n)$ and group of rational points Γ_f, so $\Gamma_f \backslash G_f(n)/\mathrm{K}'$ is finite by the finiteness of class numbers [33]. An element $\gamma \in \Gamma$ with $\gamma_f \in \Gamma'_h$ lies in $G_\infty(1) \times h\mathrm{K}'h^{-1}$, a compact subset of $\mathrm{G}(1)$; as Γ is discrete in $\mathrm{G}(1)$ ((VP2) of Definition 3.2.2) and $\gamma \mapsto \gamma_f$ is injective (a matrix over E is

determined by its image in $\mathrm{GL}_n(\mathbb{A}_{E,f})$), Γ'_h is finite. Conjugate subgroups give $\#\Gamma'_{\delta hk} = \#\Gamma'_h$ for $\delta \in \Gamma_f$, $k \in \mathrm{K}'$, so the summand of (1) is constant on double cosets; the same holds for every open subgroup in place of K'.

Proof of (1). Let $\mathrm{K}_F = \{k \in \mathrm{K} : F(gk) = F(g) \text{ for all } g\}$, a subgroup of K containing K', hence open, and of finite index $[\mathrm{K} : \mathrm{K}_F]$ in the compact group K; by (LQ3), $\mathrm{CI}_{\mathrm{K}}(F) = [\mathrm{K} : \mathrm{K}_F]^{-1} \sum_{[h]} F(h)/\#\Gamma_h$, the sum over $\Gamma_f \backslash G_f(n)/\mathrm{K}_F$ with $\Gamma_h = \Gamma_f \cap h\mathrm{K}_F h^{-1}$. As $[\mathrm{K} : \mathrm{K}'] = [\mathrm{K} : \mathrm{K}_F][\mathrm{K}_F : \mathrm{K}']$, it suffices to show, for each $h \in G_f(n)$,

$$\sum_{[h']} \frac{1}{\#\Gamma'_{h'}} = \frac{[\mathrm{K}_F : \mathrm{K}']}{\#\Gamma_h}, \tag{6.100}$$

the sum over the double cosets $\Gamma_f h'\mathrm{K}'$ contained in $\Gamma_f h\mathrm{K}_F$; indeed F takes the value $F(h)$ on all of them, and summing (6.100) times $F(h)$ over $\Gamma_f \backslash G_f(n)/\mathrm{K}_F$ gives the sum of (1) with $[\mathrm{K}_F : \mathrm{K}']$ in front. The group Γ_h acts on the finite set $X = \mathrm{K}_F/\mathrm{K}'$ by $\delta \cdot k\mathrm{K}' = h^{-1}\delta hk\mathrm{K}'$. The map $X \to \Gamma_f \backslash \Gamma_f h\mathrm{K}_F/\mathrm{K}'$, $k\mathrm{K}' \mapsto \Gamma_f hk\mathrm{K}'$, is surjective, and $\Gamma_f hk\mathrm{K}' = \Gamma_f hk'\mathrm{K}'$ if and only if $hk' = \delta hkk''$ with $\delta \in \Gamma_f$, $k'' \in \mathrm{K}'$; then $\delta = hk'k''^{-1}k^{-1}h^{-1} \in \Gamma_h$ and $k'\mathrm{K}' = \delta \cdot k\mathrm{K}'$, and conversely. So the double cosets in question are the Γ_h-orbits on X. The stabiliser of $k\mathrm{K}'$ is $\{\delta \in \Gamma_h : h^{-1}\delta h \in k\mathrm{K}'k^{-1}\} = \Gamma_f \cap hk\mathrm{K}'(hk)^{-1} = \Gamma'_{hk}$ (an element of this intersection lies in $h\mathrm{K}_F h^{-1}$ as $k \in \mathrm{K}_F$). By the orbit-stabiliser theorem the orbit of $k\mathrm{K}'$ has $\#\Gamma_h/\#\Gamma'_{hk}$ elements, and summing over the orbits, $\#X = \#\Gamma_h \sum_{[h']} 1/\#\Gamma'_{h'}$, which is (6.100).

The function H. f is bounded on the compact sets $G_\infty(1) \times g\mathrm{K}'$, so H is defined. For $k \in \mathrm{K}'$, $H(gk) = H(g)$. For $\gamma \in \Gamma$, $f(y, \gamma_f g) = f(\gamma(\gamma_\infty^{-1} y, g)) = f(\gamma_\infty^{-1} y, g)$, and left invariance of dy gives $H(\gamma_f g) = H(g)$. So H satisfies the hypothesis of (1) with $\mathrm{K}'' = \mathrm{K}' \cap \mathrm{K}$, an open subgroup of K.

Proof of (2). The measure of $G_\infty(1)$ is a Haar measure (the Cayley measure, Definition 3.2.1) of total mass c_n, hence equal to $c_n\, dy$; the measure μ_f of $G_f(n)$ gives $\mathbf{K}_0(n)$ the mass 1, so $\mu_f(\mathrm{K}'') = [\mathbf{K}_0(n) : \mathrm{K}'']^{-1}$. Let $h_1, \ldots, h_s$ represent $\Gamma_f \backslash G_f(n)/\mathrm{K}''$ (finite by (1)) and put $\Gamma''_i = \Gamma_f \cap h_i \mathrm{K}'' h_i^{-1}$ and

$$\chi = \sum_{i=1}^{s} \frac{1}{\#\Gamma''_i} \mathbf{1}_{G_\infty(1) \times h_i \mathrm{K}''}.$$

For $x = (y, g) \in \mathrm{G}(1)$ write $g = \delta_f h_i k$ with $\delta \in \Gamma$, $k \in \mathrm{K}''$, for the unique i with $g \in \Gamma_f h_i \mathrm{K}''$. Then $\gamma x \in G_\infty(1) \times h_j \mathrm{K}''$ forces $j = i$, and holds if and only if $\gamma_f \delta_f \in \Gamma''_i$; as $\gamma \mapsto \gamma_f$ is injective, $\sum_{\gamma \in \Gamma} \chi(\gamma x) = 1$. The quotient measure satisfies $\int_{\mathrm{G}(1)} \phi = \int_{[\mathrm{U}(\mathrm{I}_n)]} \sum_{\gamma \in \Gamma} \phi(\gamma x)\, dx$ for integrable ϕ; applied to $\phi = \chi f$ (bounded, with compact support), whose sum over Γ is f, it gives, with Fubini's theorem and the right K''-invariance of f in the second variable,

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} f = \sum_{i=1}^{s} \frac{1}{\#\Gamma''_i} \int_{G_\infty(1)} \int_{h_i \mathrm{K}''} f(y, g)\, d\mu_f(g)\, c_n\, dy = \frac{c_n}{[\mathbf{K}_0(n) : \mathrm{K}'']} \sum_{i=1}^{s} \frac{H(h_i)}{\#\Gamma''_i}.$$

By (1) for H, K and K'', the last sum is $[\mathrm{K} : \mathrm{K}'']\, \mathrm{CI}_{\mathrm{K}}(H)$, and $[\mathbf{K}_0(n) : \mathrm{K}''] = [\mathbf{K}_0(n) : \mathrm{K}][\mathrm{K} : \mathrm{K}'']$ gives (2). □

Lemma 6.4.75. *Let D be admissible data, ϑ an m-fold twist, χ_ϑ the character of K_ϑ of Definition 3.2.31, and $y \in \mathcal{A}_M(Y_0)$. Put $F_0 = y$ and, for $1 \le j \le m$, let F_j be lift j applied to F_{j-1}.*

(a) For $0 \le j \le m$ the function F_j is defined (the integral defining lift j of F_{j-1} converges absolutely at every point) and is a form of type e_{λ_j} on Y_j, where $\lambda_j = \frac{1}{2} p_{\mathrm{I},0,j}$.

(b) $F_m(x, gk) = \chi_\vartheta(k)\, F_m(x, g)$ for all $x \in G_\infty(1)$, $g \in G_f(n)$ and $k \in \mathrm{K}_\vartheta$.

(c) $\Theta_\vartheta y$ is an algebraic form of weight (κ_Y, e_Y) on the index set of Y_m, and $\Theta_\vartheta y(gk) = \chi_\vartheta(k)\,\Theta_\vartheta y(g)$ for all $g \in G_f(n)$ and $k \in \mathrm{K}_\vartheta$. In particular Θ_ϑ maps $\mathcal{T}$ into $\mathcal{A}_\vartheta(Y_m)$.

Proof. **Notation.** Write n_j for the index set of Y_j, $N_j = \#n_j$, and $\mathcal{L}$ for the set of level places of ϑ (the chosen places and the places of Q): distinct prime ideals of $\mathcal{O}_E$ with product $\mathfrak{t}$, containing the conjugate of none of their members ($\mathfrak{t}$ is a modulus, (TV2) of Definition 3.2.30 and (XD4)). Through the point of Y_j the integral elements of $\mathrm{U}(Y_j)(\mathbb{A}_f)$ form $\mathbf{K}_0(n_j)$; for such k and $w \in \mathcal{L}$ let $\bar{k}_w \in \mathrm{GL}_{n_j}(k_w)$ be the reduction of its component at w. The indices of n_j form block 0 (the r indices of Y_0) and blocks $1, \dots, j$ of size t, and the blocks of n_{j-1} are the blocks $0, \dots, j-1$ of n_j. For $1 \le l \le m$ let $\psi_l = (\omega_w^l \psi_w^l)_w$, ψ the tame part of ϑ: multiplying the identities of Definition 3.1.1 for μ_l^0 and ϑ^l, ψ_l is a tame part of ν_l, the tame part used for the character of K_ϑ in Definition 3.2.31, and $\psi_{l,w} = 1$ for $w \notin \mathcal{L}$ ($\omega_w = 1$ off the chosen places, $\psi_w = 1$ off Q). For $0 \le j \le m$ let $\mathrm{K}^{(j)}$ be the set of $k \in \mathbf{K}_0(n_j)$ with $\bar{k}_w = 1$ at the chosen places and $\bar{k}_w$ block upper triangular at the places of Q, and

$$\chi^{(j)}(k) = \prod_{w \in \mathcal{L}} \prod_{l=1}^{j} \psi_{l,w}(\det \bar{k}_w^{(l)}) \qquad (k \in \mathrm{K}^{(j)}),$$

$\bar{k}_w^{(l)}$ the diagonal block l of $\bar{k}_w$. Then $\mathrm{K}^{(m)} = \mathrm{K}_\vartheta$ and $\chi^{(m)} = \chi_\vartheta$ by Definition 3.2.31, while $\mathrm{K}^{(0)} = \mathrm{K}_M$ (one block, so no condition at Q) and $\chi^{(0)} = 1$.

Step 1: the data of lift j, and (a). Let $1 \le j \le m$, $\alpha_j = \nu_j \upsilon^{\lfloor N_{j-1}/2 \rfloor}$, $\beta_j = \nu_j \upsilon^{\lfloor N_j/2 \rfloor}$, $\varphi_j = \mathrm{mod}_{\mathfrak{t}}(\mathbf{1}_j^{\mathrm{inc}}, v_{H_j})$, and let L_j be the lift of Lemma 6.3.76 for $S = Y_{j-1}$, $T = Y_j$, the characters (α_j, β_j), the modulus $\mathfrak{t}$, $\Psi = \mathbf{1}_j^{\mathrm{inc}}$ and $P = H_j$; so lift j is $c_j L_j$ with c_j the index of Definition 3.2.31. By (GP6), α_j and β_j are the edge characters for $c = \mathrm{II}$, $l = j-1$ at the ranks N_{j-1} and N_j, of weights $\gamma_j = \gamma_{\mathrm{II},j-1}(N_{j-1})$ and $\gamma_j' = \gamma_{\mathrm{II},j-1}(N_j)$. The polynomial H_j is the joint harmonic (GP7) for the signs of $(\mathrm{I}, 0, j-1)$ and $(\mathrm{I}, 0, j)$, the weights (γ_j, γ_j') and the doubled parameters $(p_{\mathrm{I},0,j-1}, p_{\mathrm{I},0,j})$; this is the case $z = \mathrm{I}$, $o = a = 0$, $b = j-1$ of Lemma 6.4.15(b) ($b+1 \le m$), so v_{H_j} is an edge for the weights (γ_j, γ_j') from $e_{\lambda_{j-1}}$ to e_{λ_j}. Now (a) follows by induction on j. For $j = 0$, $y \in \mathcal{F}_\triangle^0(\mathrm{I}, 0)$ by Lemma 6.4.67(a), and by (TV2) these are the forms of type e_{λ_0} on Y_0. If F_{j-1} is a form of type $e_{\lambda_{j-1}}$ on Y_{j-1}, then by Lemma 6.3.76(1) the integral $L_j F_{j-1}(h)$ converges absolutely for every h and $L_j F_{j-1}$ is a form of type e_{λ_j} on Y_j; so is $F_j = c_j L_j F_{j-1}$.

Step 2: the law of one lift. Let $1 \le j \le m$, let X_0 be the $n_j \times n_{j-1}$ matrix with entry 1 at (a, a) for $a \in n_{j-1}$ and 0 elsewhere, and let $k \in \mathbf{K}_0(n_j)$, $k' \in \mathbf{K}_0(n_{j-1})$ with $\bar{k}_w X_0 = X_0 \bar{k}_w'$ for every $w \in \mathcal{L}$. We show that for every form G of type $e_{\lambda_{j-1}}$ on Y_{j-1}

$$L_j G(h(1,k)) = c(k,k')\, L_j(G(\cdot\,(1,k')))(h), \qquad c(k,k') = \prod_{w \in \mathcal{L}} \frac{\psi_{j,w}(\det \bar{k}_w)}{\psi_{j,w}(\det \bar{k}_w')}. \tag{6.101}$$

By Lemma 4.1.1(6) for $S = Y_{j-1}$, $T = Y_j$, the modulus $\mathfrak{t}$ (so $A = \mathcal{L}$), $\Phi = \mathbf{1}_j^{\mathrm{inc}}$ and the elements k' of $\mathrm{U}(S)$, k of $\mathrm{U}(T)$,

$$\omega_{\alpha_j,\beta_j}((1,k'),(1,k))\varphi_j = \alpha_j(\det k)\,\beta_j(\det k')^{-1}\,\mathrm{mod}_{\mathfrak{t}}(\Phi_{k',k}, v_{H_j}), \qquad \Phi_{k',k}(X) = \Phi(\bar{k}^{-1} X \bar{k}'),$$

the reductions modulo $\mathfrak{t}$ being the families $(\bar{k}_w)_w$, $(\bar{k}_w')_w$ under $R_{\mathfrak{t}} \cong \prod_{w \in \mathcal{L}} k_w$ (Chinese remainder theorem). As Φ is the indicator function of X_0, $\Phi_{k',k}$ is that of $\bar{k} X_0 \bar{k}'^{-1} = X_0$; so $\Phi_{k',k} = \Phi$. The determinants $u = \det k$ and $u' = \det k'$ lie in $\mathrm{U}(1)(\mathbb{A})$ (k, k' are unitary), with infinite components 1 and finite components integral units ($k^{\pm 1}$, $k'^{\pm 1}$ are integral). For such u, $\upsilon(u) = 1$ (υ has trivial tame part) and $\nu_j(u) = \prod_w \psi_{j,w}(u \bmod w) = \prod_{w \in \mathcal{L}} \psi_{j,w}(u \bmod w)$ (Definition 3.1.1; the

weight factor is 1 as the infinite components are 1). Since $\det k \bmod w = \det \bar{k}_w$, this gives $\alpha_j(\det k)\beta_j(\det k')^{-1} = c(k,k')$, and Lemma 6.3.76(3), with $\Psi' = \Psi$, gives (6.101).

Step 3: (b). We show by induction on j that $F_j(h(1,k)) = \chi^{(j)}(k)F_j(h)$ for all h and all $k \in \mathrm{K}^{(j)}$; for $j = m$ this is (b). For $j = 0$ it is the right invariance of $y \in \mathcal{A}_M(Y_0)$ under $\mathrm{K}_M = \mathrm{K}^{(0)}$. Let $1 \le j \le m$ and $k \in \mathrm{K}^{(j)}$. For $w \in \mathcal{L}$ the matrix $\bar{k}_w$ is block upper triangular (at the chosen places it is 1), so

$$\bar{k}_w = \begin{pmatrix} A_w & B_w \\ 0 & D_w \end{pmatrix},$$

with A_w the block on $n_{j-1} \times n_{j-1}$ and $D_w = \bar{k}_w^{(j)}$; hence $\det \bar{k}_w = \det A_w \det D_w$, A_w is invertible, $A_w = 1$ at the chosen places, A_w is block upper triangular for the blocks of n_{j-1} at the places of Q, and its diagonal blocks are $\bar{k}_w^{(l)}$, $0 \le l \le j-1$. The reduction map $\mathbf{K}_0(n_{j-1}) \to \prod_{w\in\mathcal{L}} \mathrm{GL}_{n_{j-1}}(k_w)$ is a homomorphism whose kernel has index $\prod_{w\in\mathcal{L}} \#\mathrm{GL}_{n_{j-1}}(k_w)$ by Lemma 6.4.76, so it is onto; choose k' with $\bar{k}'_w = A_w$ for $w \in \mathcal{L}$. Then $k' \in \mathrm{K}^{(j-1)}$, and $\bar{k}_w X_0$, the matrix of the columns n_{j-1} of $\bar{k}_w$, is $X_0 A_w = X_0 \bar{k}'_w$. By (a), (6.101) with $G = F_{j-1}$, the hypothesis of the induction and the linearity of L_j,

$$F_j(h(1,k)) = c_j\, c(k,k')\, L_j(\chi^{(j-1)}(k')F_{j-1})(h) = c(k,k')\, \chi^{(j-1)}(k')\, F_j(h).$$

Finally $\psi_{j,w}(\det \bar{k}_w)/\psi_{j,w}(\det A_w) = \psi_{j,w}(\det D_w)$, and the diagonal blocks of A_w are those of $\bar{k}_w$, so $c(k,k')\chi^{(j-1)}(k') = \chi^{(j)}(k)$.

Step 4: (c). Let $F = F_m$, $\rho = \rho_{\kappa_Y, e_Y}$, $v^+ = v_l^+$, $d = \#I_{\kappa_Y}$ and $\eta = \Theta_\vartheta y = F_l^\flat$, so $\eta(g) = d \int_{G_\infty(1)} F(x,g)\rho(x)v^+\,dx$; the integral exists, $x \mapsto F(x,g)$ and ρ being continuous on the compact group $G_\infty(1)$. By (a) and (ED2), F is left invariant under the rational points Γ of I_n and right invariant under an open subgroup K' of $G_f(n)$. Hence $\eta(gk) = \eta(g)$ for $k \in K'$. For $\gamma \in \Gamma$, $F(x, \gamma_f g) = F(\gamma_\infty^{-1}x, g)$; substituting $x = \gamma_\infty x'$ (the Haar measure of $G_\infty(1)$ is invariant) and using $\rho(\gamma_\infty x') = \rho(\gamma_\infty)\rho(x')$ (Lemma 4.6.10(c)),

$$\eta(\gamma_f g) = d \int_{G_\infty(1)} F(x', g)\, \rho(\gamma_\infty)\rho(x')v^+\,dx' = \rho(\gamma_\infty)\, \eta(g).$$

So η is an algebraic form of weight (κ_Y, e_Y) (WM7). By (b), $\eta(gk) = d \int F(x,gk)\rho(x)v^+dx = \chi_\vartheta(k)\eta(g)$ for $k \in \mathrm{K}_\vartheta$. For $y \in \mathcal{T} \subseteq \mathcal{A}_M(Y_0)$ this says that η lies in $\mathcal{A}_\vartheta(Y_m)$. □

Lemma 6.4.76. *Let $n \ge 1$, let A be a finite set of finite places of E containing the conjugate of none of its members, $\mathfrak{m} = \prod_{w\in A} w$, and $\mathbf{K}_A = \{k \in \mathbf{K}_0(n) : k_w \equiv 1 \bmod w$ for every $w \in A\}$. Then*

$$[\mathbf{K}_0(n) : \mathbf{K}_A] = \prod_{w\in A} \#\mathrm{GL}_n(k_w) = \#\mathrm{GL}_n(\mathcal{O}_E/\mathfrak{m}).$$

Proof. Let $\mathrm{red}\colon \mathbf{K}_0(n) \to \prod_{w\in A} \mathrm{GL}_n(k_w)$, $k \mapsto (k_w \bmod w)_w$, a homomorphism with kernel $\mathbf{K}_A$; so the index is the order of its image, and it suffices to show that red is onto. Let $(a_w)_{w\in A}$ be given. For $w \in A$ lift a_w entrywise to $g_w \in \mathrm{M}_n(\mathcal{O}_{E,w})$; $\det g_w$ reduces to $\det a_w \ne 0$, so $g_w \in \mathrm{GL}_n(\mathcal{O}_{E,w})$. Define $k \in \mathrm{GL}_n(\mathbb{A}_{E,f})$ by $k_w = g_w$ and $k_{\bar{w}} = \overline{(g_w^{-1})^{\mathsf{T}}}$ for $w \in A$ (the bar being the conjugation $E_w \to E_{\bar{w}}$), and $k_u = 1$ at the other finite places u; this is consistent, as $\bar{w} \notin A$ and $\bar{w} \ne w$ for $w \in A$. At the places w and $\bar{w}$ the condition $k^*k = 1$ reads $\overline{k_{\bar{w}}}^{\mathsf{T}} k_w = 1$ and $\overline{k_w}^{\mathsf{T}} k_{\bar{w}} = 1$, which hold by construction (the second is the conjugate transpose of the inverse of the first); elsewhere it is trivial. All components of k and of k^{-1} are integral, so $k \in \mathbf{K}_0(n)$, and $\mathrm{red}(k) = (a_w)$. Finally the places of A are distinct prime ideals, so $\mathcal{O}_E/\mathfrak{m} \cong \prod_{w\in A} k_w$ by the Chinese remainder theorem, and GL_n of a finite product of rings is the product of the GL_n. □

Lemma 6.4.77. *Let D be admissible data. The space $\mathcal{F}_{\mathfrak{b}}(m)$ is spanned by the forms φ whose algebraic form $\varphi^\flat$ satisfies, for every $g \in G_f(n_{\mathrm{II},0})$,*

$$\begin{aligned} &\mathrm{gau}_\iota(g, \varphi^\flat(g)) \le 1 && \text{for every prime identification } \iota, \\ &\|\sigma(\varphi^\flat(g))\|^2_{\kappa_{\mathrm{II}}} \le \exp(x^{99}b^2) && \text{for every field automorphism } \sigma \text{ of } \mathbb{C}. \end{aligned}$$

Proof. Throughout, $\|z\|$ is the operator norm of a complex matrix. We use three facts on Schur matrices, read off from (WM1)–(WM3).

(S1) Integrality and multiplicativity. By the Cauchy–Binet formula, for a set A of h rows $\Delta_{\tau,A}(zy) = \sum_B \det(z_\tau[A,B])\Delta_{\tau,B}(y)$, the sum over the sets B of h rows, where $z_\tau[A,B]$ is the submatrix on the rows A and the columns B. Hence $\Delta_T(zy) = \sum_{T'} \Lambda(z)_{TT'}\Delta_{T'}(y)$ for $T, T' \in \mathcal{C}_\kappa$, where $\Lambda(z) = \bigotimes_{(\tau,h,j)} \wedge^h z_\tau$ is the tensor product of the compound matrices $(\wedge^h z_\tau)_{A,B} = \det z_\tau[A,B]$. Writing $b_i = \sum_T c_{iT}\Delta_T$ with $c_{iT} \in \mathbb{Z}$ (as $b_i \in \nabla_\kappa$) and $\Delta_{T'} = \sum_j (F_\kappa)_{T'j} b_j$, and using the linear independence of the b_j, we get $S_\kappa(z) = c\,\Lambda(z)\,F_\kappa$ and

$$F_\kappa S_\kappa(z) = \Lambda(z) F_\kappa.$$

So the entries of $S_\kappa(z)$ are polynomials with integer coefficients in the entries of z, S_κ commutes with ring homomorphisms applied entrywise, and $S_\kappa(zz') = S_\kappa(z)S_\kappa(z')$ for square z, z' (expand $b_i(z(z'y))$ twice and compare coefficients; a polynomial identity over $\mathbb{Z}$, so valid over every commutative ring); in particular $S_\kappa(1) = 1$ and $S_\kappa(z)$ is invertible for invertible z. Likewise $\mathrm{ev}_\kappa(y)$ has integer polynomial coordinates $b_i(y)$.

(S2) Norms. As F_κ is real, $\|\xi\|_\kappa = \|F_\kappa \xi\|$ (euclidean norm). For a complex matrix z_τ with singular value decomposition $u\,\mathrm{diag}(s)\,u'$, the Cauchy–Binet formula gives $\wedge^h z_\tau = \wedge^h u \wedge^h \mathrm{diag}(s) \wedge^h u'$ with $\wedge^h u$, $\wedge^h u'$ unitary (as $\wedge^h(u^*) \wedge^h (u) = \wedge^h(u^*u) = 1$ and $\wedge^h(u^*) = (\wedge^h u)^*$) and $\wedge^h\mathrm{diag}(s)$ diagonal with entries products of h singular values; so $\| \wedge^h z_\tau\| \le \|z_\tau\|^h$, with equality of norms of vectors if z_τ is unitary. With $\beta_\tau = \sum_{1 \le h < N_{\mathrm{t}}} h\,\kappa(\tau,h)$ this gives

$$\|S_\kappa(z)\xi\|_\kappa = \|\Lambda(z)F_\kappa\xi\| \le \prod_\tau \|z_\tau\|^{\beta_\tau}\,\|\xi\|_\kappa, \qquad \|S_\kappa(u)\xi\|_\kappa = \|\xi\|_\kappa \text{ if all } u_\tau \text{ are unitary.}$$

(S3) Evaluation vectors. Enumerate $n = \{a_0 < \cdots < a_{N_{\mathrm{t}}-1}\}$ and let $y^0_{\tau,a_j,c} = 1$ if $c = j$ and 0 otherwise. The polynomials b_i involve only the columns $c < N_{\mathrm{t}} - 1$. For an array y let $z(y)_\tau$ be the $n \times n$ matrix whose column a_j is $(y_{\tau,a,j})_{a \in n}$; then $(z(y)y^0)_{\tau,a,c} = y_{\tau,a,c}$ for $c < N_{\mathrm{t}}$, hence $\mathrm{ev}_\kappa(y) = S_\kappa(z(y))\,\mathrm{ev}_\kappa(y^0)$. Moreover $F_\kappa \mathrm{ev}_\kappa(y^0) = (\Delta_T(y^0))_T$, and $\Delta_{\tau,A}(y^0)$ is 1 if $A = \{a_0, \dots, a_{h-1}\}$ and 0 otherwise; so $F_\kappa \mathrm{ev}_\kappa(y^0)$ is a standard basis vector and $\|\mathrm{ev}_\kappa(y^0)\|_\kappa = 1$.

Step 1: transport to algebraic forms. By (4) of Lemma 6.4.68, $y \mapsto y^\flat$ is a linear bijection of $\mathcal{F}(\mathrm{II}, 0, m)$ onto $\mathcal{A}$ with $y = F^l_{y^\flat}$. If y is fixed by K, so is $y^\flat$ (its definition (WM7) integrates $y(x,g)$ in x only), and if $\eta \in \mathcal{A}$ is fixed by K, so is F^l_η. Hence $y \mapsto y^\flat$ maps $\mathcal{F}_{\mathfrak{b}}(m)$ bijectively onto the space $\mathcal{A}^{\mathrm{K}}$ of the K-invariant algebraic forms, and it suffices to show that $\mathcal{A}^{\mathrm{K}}$ is spanned by forms η with $\mathrm{gau}_\iota(g, \eta(g)) \le 1$ and $\|\sigma(\eta(g))\|^2_\kappa \le \exp(x^{99}b^2)$ for all ι, σ, g; call such η *short*.

Step 2: delta forms. K is an open subgroup of $\mathbf{K}_0(n)$, the stabiliser in $G_f(n)$ of the lattice $\widehat{\mathcal{O}}_E^n$ of I_n, and every element of K is $\equiv 1$ modulo π_M, hence acts trivially on $\mathcal{O}^n_{E_w}/w$ for each chosen place w (there is one, π_M being a non-unit of norm p_0p_1). By Lemma 4.6.2 (c), $\Gamma_f \cap g\mathrm{K}g^{-1} = \{1\}$ for every $g \in G_f(n)$. For $g \in G_f(n)$ and $\xi \in \mathbb{V}_\kappa$ define $\delta_{g,\xi}(\gamma_f g k) = \rho_{\kappa,e}(\gamma_\infty)\xi$ ($\gamma \in \Gamma$, $k \in \mathrm{K}$) and $\delta_{g,\xi} = 0$ off $\Gamma_f g \mathrm{K}$. It is well defined: $\gamma_f g k = \gamma'_f g k'$ gives $\gamma_f'^{-1}\gamma_f = gk'k^{-1}g^{-1} \in \Gamma_f \cap g\mathrm{K}g^{-1}$, so $\gamma = \gamma'$. Clearly $\delta_{g,\xi} \in \mathcal{A}^{\mathrm{K}}$ and $\xi \mapsto \delta_{g,\xi}$ is linear. By

the finiteness of class numbers, (K) of Theorem A.4.1 applied to $\mathrm{U}(\mathrm{I}_n)$ over E^+ and the open compact subgroup K, there are finitely many $g_1,\dots,g_h$ with $G_f(n)=\bigcup_i \Gamma_f g_i \mathrm{K}$, the double cosets disjoint after removing repetitions; then every $\eta\in\mathcal{A}^{\mathrm{K}}$ equals $\sum_i \delta_{g_i,\eta(g_i)}$. It therefore suffices to find, for each $g\in G_f(n)$, vectors ξ spanning $\mathbb{V}_\kappa$ with $\delta_{g,\xi}$ short.

Step 3: the vectors. Fix $g\in G_f(n)$ and put $B_{\mathrm{s}}=6q_1 d(fN_{\mathrm{t}})^2$. By Lemma 4.6.5, applied to g and to g^{e_τ} ($\tau\in\Phi$), there are $Y,Y'_\tau\in\mathrm{GL}_n(E)$ with $g^{-1}Y$ and $g^{-e_\tau}Y'_\tau$ in $\mathrm{M}_n(\widehat{\mathcal{O}}_E)$ and all entries of $\eta(Y)$, $\eta(Y'_\tau)$ of absolute value at most B_{s}, for every embedding $\eta\colon E\to\mathbb{C}$. For an array y whose entries are roots of unity put

$$\xi_y=\prod_{\tau\in\Phi}\det\epsilon_\tau(Y'_\tau)\cdot S_\kappa\big(\epsilon(Y)\big)\,\mathrm{ev}_\kappa(y).$$

They span $\mathbb{V}_\kappa$. The matrix $\prod_\tau\det\epsilon_\tau(Y'_\tau)\,S_\kappa(\epsilon(Y))$ is invertible by (S1). If a linear form λ on $\mathbb{V}_\kappa$ vanishes on all $\mathrm{ev}_\kappa(y)$, the polynomial $\sum_i\lambda_i b_i$ vanishes on all arrays with entries in the infinite set of roots of unity; a polynomial vanishing on a product of infinite sets is 0 (induction on the number of variables), and the b_i are linearly independent, so $\lambda=0$.

Gauge. Let ι be a prime identification. By (S1) and since $f_{\iota,\tau}$ is a ring homomorphism agreeing with $\iota\circ\epsilon_\tau$ on E,

$$\prod_\tau\det f_{\iota,\tau}(g^{-1})^{e_\tau}\,S_\kappa\big(f_\iota(g^{-1})\big)\,\iota(\xi_y)=\prod_\tau\det f_{\iota,\tau}\big(g^{-e_\tau}Y'_\tau\big)\cdot S_\kappa\big(f_\iota(g^{-1}Y)\big)\,\mathrm{ev}_\kappa(\iota(y)).$$

The matrices $f_{\iota,\tau}(g^{-e_\tau}Y'_\tau)$ and $f_{\iota,\tau}(g^{-1}Y)$ have integral entries (the projection of an integral finite adele to E_w lies in $\mathcal{O}_{E_w}$, and the continuous extension of the embedding maps $\mathcal{O}_{E_w}$ into the valuation ring of $\overline{\mathbb{Q}}_\ell$), $\iota(y)$ has root-of-unity entries, and S_κ, ev_κ are integer polynomials; so $\mathrm{gau}_\iota(g,\xi_y)\le 1$.

Norm. Let σ be a field automorphism of $\mathbb{C}$. Each $\sigma\circ\epsilon_\tau$ is an embedding of E, and $\sigma(\mathrm{ev}_\kappa(y))=\mathrm{ev}_\kappa(\sigma(y))=S_\kappa(z(\sigma(y)))\mathrm{ev}_\kappa(y^0)$ by (S3), where $z(\sigma(y))_\tau$ has root-of-unity entries, so $\|z(\sigma(y))_\tau\|\le N_{\mathrm{t}}$; also $\|\sigma\epsilon_\tau(Y)\|\le N_{\mathrm{t}}B_{\mathrm{s}}$ and $|\det\sigma\epsilon_\tau(Y'_\tau)|\le\|\sigma\epsilon_\tau(Y'_\tau)\|^{N_{\mathrm{t}}}\le(N_{\mathrm{t}}B_{\mathrm{s}})^{N_{\mathrm{t}}}$. By (S1)–(S3), with $\beta=\sum_\tau\beta_\tau$ and $N_{\mathrm{t}}\le B_{\mathrm{s}}$,

$$\|\sigma(\xi_y)\|_\kappa^2\le\prod_\tau(N_{\mathrm{t}}B_{\mathrm{s}})^{2N_{\mathrm{t}}}\big(N_{\mathrm{t}}^2B_{\mathrm{s}}\big)^{2\beta_\tau}\le B_{\mathrm{s}}^{4fN_{\mathrm{t}}+6\beta}\le B_{\mathrm{s}}^{6(fN_{\mathrm{t}}+\beta)}.$$

Step 4: the delta forms are short. Let $h=\gamma_f g k$ with $\gamma\in\Gamma$, $k\in\mathrm{K}$; the value of δ_{g,ξ_y} at h is $\rho_{\kappa,e}(\gamma_\infty)\xi_y$ (at the other points it is 0). As $\iota(\rho_{\kappa,e}(\gamma_\infty)\xi)=\prod_\tau\det f_{\iota,\tau}(\gamma)^{e_\tau}S_\kappa(f_\iota(\gamma))\iota(\xi)$ and $h^{-1}=k^{-1}g^{-1}\gamma_f^{-1}$, (S1) gives

$$\prod_\tau\det f_{\iota,\tau}(h^{-1})^{e_\tau}S_\kappa\big(f_\iota(h^{-1})\big)\iota\big(\rho_{\kappa,e}(\gamma_\infty)\xi_y\big)=\prod_\tau\det f_{\iota,\tau}(k^{-1})^{e_\tau}S_\kappa\big(f_\iota(k^{-1})\big)\cdot\zeta,$$

ζ the vector of the gauge of ξ_y at g, whose coordinates are integral by Step 3. Since $k^{-1}\in\mathrm{GL}_n(\widehat{\mathcal{O}}_E)$, $f_{\iota,\tau}(k^{-1})$ is integral with unit determinant, so the gauge at h is at most 1. For σ, $\sigma(\rho_{\kappa,e}(\gamma_\infty)\xi_y)=\prod_\tau\det u_\tau^{e_\tau}S_\kappa(u)\sigma(\xi_y)$ with $u_\tau=(\sigma\epsilon_\tau)(\gamma)$; as E is a CM field, every embedding commutes with complex conjugation, so $\bar\gamma^{\mathsf{T}}\gamma=1$ gives $u_\tau^*u_\tau=1$, and by (S2) the norm equals $\|\sigma(\xi_y)\|_\kappa$. So δ_{g,ξ_y} is short once $B_{\mathrm{s}}^{6(fN_{\mathrm{t}}+\beta)}\le\exp(x^{99}b^2)$.

Step 5: the numerical bound. By (4) of Lemma 6.4.3 at $i=0$, $\beta\le br^4$. By (AD2), $r\le 3x^5$, $m\le 2\sqrt{x}$, $t=5r$, so $N_{\mathrm{t}}=r+1+m(t-1)\le 34x^{11/2}$ (Definition 3.2.28). By Lemma 4.3.5, $f\le q_1\le b$, $d\le b$, $\log b\ge 10$ and $x\ge 4$; by (AD1), $\log x\le 10^{-12}\log b$, so $x^{11/2}\le b^{1/2}$ and $34\le b^{1/2}$, whence $N_{\mathrm{t}}\le b$. Hence $B_{\mathrm{s}}\le 6b^6\le b^7$, $fN_{\mathrm{t}}+\beta\le 34bx^{11/2}+81bx^{20}\le 115\,bx^{20}$, and

$$6(fN_{\mathrm{t}}+\beta)\log B_{\mathrm{s}}\le 6\cdot 115\cdot 7\,x^{20}b\log b\le 4830\,x^{20}b^2\le x^{99}b^2,$$

as $x^{79}\ge 4^{79}$. By Steps 2–4 the short forms span $\mathcal{A}^{\mathrm{K}}$, and by Step 1 the lemma follows. □

Lemma 6.4.78. *Let D be admissible data. There is a branching pairing at (m,m).*

Proof. Write $n = n_{\mathrm{I},m}$, $n' = n_{\mathrm{II},m} = n \sqcup \{*\}$, $N = \#n$ (so $\#n' = N+1$), $(\kappa, e) = (\kappa_{\mathrm{II}}, e^{\det}_{\mathrm{II},m})$ in the rank $N+1$ with highest weights $\lambda_\tau(q) = \sum_{q<h\le N} \kappa(\tau,h)$ $(0 \le q \le N)$, $l' = l_{\mathrm{II},m} = -p_{\mathrm{II},m,m}$, and $(\kappa', e') = (\kappa_{\mathrm{I}}, e^{\det}_{\mathrm{I},m})$ in the rank N with highest weights λ'_τ, $l = l_{\mathrm{I},m} = -p_{\mathrm{I},m,m}$. By (3) of Lemma 6.4.3, l' and l are doubled Harish-Chandra parameters of (κ, e) and (κ', e'). For a doubled parameter l'' of a weight (κ'', e'') in a rank N'', the numbers $c_q = 2(e''_\tau + \lambda''_\tau(q)) + N'' - 1 - 2q$ $(0 \le q < N'')$ strictly decrease, so the injective map l''_τ is a bijection onto them and its q-th largest value (counted from $q=0$) is c_q.

Step 1: a weight with the parameter $p = -l$. Put $\kappa_0(\tau,h) = \kappa'(\tau, N-h)$ $(1 \le h < N)$ and $e_{0,\tau} = -e'_\tau - \lambda'_\tau(0)$. Its highest weight is $\lambda_{0,\tau}(q) = \sum_{0<h<N-q} \kappa'(\tau,h) = \lambda'_\tau(0) - \lambda'_\tau(N-1-q)$. The q-th largest value of $p_\tau = -l_\tau$ is minus the $(N-1-q)$-th largest value of l_τ:

$$-2(e'_\tau + \lambda'_\tau(N-1-q)) - (N-1) + 2(N-1-q) = 2(e_{0,\tau} + \lambda_{0,\tau}(q)) + N - 1 - 2q.$$

As p_τ is injective, p is a doubled Harish-Chandra parameter of (κ_0, e_0) on n.

Step 2: the values of p and l' alternate. Fix τ and put $K_j = 2\kappa_j(\tau)$ $(j \ge 1)$, so that $K_{j+1} = K_j + 2\Delta$ and $K_1 > 3\Delta$; moreover $\Delta > t + k + 1$. By (GP5) at the node (I, m, m) (here $\delta = 0$, as $2m$ is even; the base indices are $0, \dots, r-1 = k-2+m$), the values of p_τ are the $k-1$ numbers of $S = \{k-2, k-4, \dots, 2-k\}$ (base $i < k-1$, $2\varsigma_i = k-2-2i$), the numbers $b_0 = \Delta - K_1$ and $b_j = \Delta - K_{j+1} = -(K_j + \Delta)$ $(1 \le j < m$; base $i = k-1+j)$, and for $1 \le l \le m$ the blocks $U_l = \{K_l + t - 1 - 2c : 0 \le c < t\}$ (up) and $D_l = \{-K_l + t - 1 - 2c : 0 \le c < t\}$ (down). At (II, m, m) (base indices $0, \dots, r$, up blocks of length $t+1$, down blocks of length $t-1$), the values of $l'_\tau = -p_{\mathrm{II},m,m}(\tau)$ are the $k-1$ numbers of $S' = \{k-3, k-5, \dots, 1-k\}$, the numbers $b'_0 = K_1 - \Delta - 1$ and $b'_j = K_{j+1} - \Delta - 1 = K_j + \Delta - 1$ $(1 \le j \le m)$, and the blocks $U'_l = \{K_l + t - 2 - 2c : 0 \le c \le t-2\}$ and $D'_l = \{-K_l + t - 2c : 0 \le c \le t\}$. Writing $X > Y$ when every element of X exceeds every element of Y,

$$\begin{aligned} b'_m > U_m \cup U'_m > b'_{m-1} > \cdots > b'_1 > U_1 \cup U'_1 > b'_0 > S \cup S' \\ > b_0 > D'_1 \cup D_1 > b_1 > D'_2 \cup D_2 > \cdots > b_{m-1} > D'_m \cup D_m, \end{aligned}$$

and inside each group the two blocks are arithmetic progressions of step 2 whose lengths differ by one and whose centres agree (U_l, U'_l centred at K_l, of lengths t, $t-1$; S, S' of length $k-1$ with $S' = S - 1$; D'_l, D_l centred at $-K_l$, of lengths $t+1$, t), so their elements alternate, the group starting with U_l, S, D'_l and ending with U_l, S', D'_l respectively. Hence the $2N+1$ values, listed in decreasing order, alternate between l'_τ and p_τ, beginning and ending with a value of l'_τ: if $L'_0 > \cdots > L'_N$ are the values of l'_τ and $P_0 > \cdots > P_{N-1}$ those of p_τ, then $L'_q > P_q > L'_{q+1}$ for $0 \le q < N$.

Step 3: a horizontal strip. Put $\mu_q = e_\tau + \lambda_\tau(q)$ $(0 \le q \le N)$ and $\nu_q = e_{0,\tau} + \lambda_{0,\tau}(q)$ $(0 \le q < N)$, so $L'_q = 2\mu_q + N - 2q$ and $P_q = 2\nu_q + N - 1 - 2q$. The integer inequalities $L'_q > P_q$ and $P_q > L'_{q+1}$ give $2\mu_q > 2\nu_q - 1$ and $2\nu_q > 2\mu_{q+1} - 1$, so $\mu_{q+1} \le \nu_q \le \mu_q$. Put $d_q = \nu_q - \mu_{q+1}$, so $0 \le d_q \le \mu_q - \mu_{q+1} = \kappa(\tau, q+1)$, and define weights for the rank $N+1$ by $\kappa_1(\tau,h) = d_{h-1}$ and $\gamma(\tau,h) = \kappa(\tau,h) - d_{h-1}$ $(1 \le h \le N)$. Then $\kappa = \gamma + \kappa_1$; for $1 \le h < N$, $\kappa_1(\tau,h) + \gamma(\tau,h+1) = d_{h-1} + \mu_h - \mu_{h+1} - d_h = \nu_{h-1} - \nu_h = \kappa_0(\tau,h)$; and $e_\tau + \kappa_1(\tau,N) = e_\tau + \nu_{N-1} - \mu_N = \nu_{N-1} = e_{0,\tau}$, as $\mu_N = e_\tau$ and $\lambda_{0,\tau}(N-1) = 0$. Moreover $e_{0,\tau} = \nu_{N-1} \ge \mu_N = e_\tau$, so $\lambda_{0,\tau}(q) = \nu_q - e_{0,\tau} \le \mu_q - e_\tau = \lambda_\tau(q)$, and summing over q and τ (the number of boxes is the sum of the row lengths),

$$\sum_\tau \sum_{1 \le h < N} h\,\kappa_0(\tau,h) = \sum_\tau \sum_{q<N} \lambda_{0,\tau}(q) \le \sum_\tau \sum_{q \le N} \lambda_\tau(q) = B_0. \tag{6.102}$$

Step 4: the matrix. Number n as $1,\dots,N$ and $*$ as $N+1$. This identifies the polynomial rings of (WM1) for the rows n, n' with those for the rows $1,\dots,N$ and $1,\dots,N+1$; it carries products of minors to products of minors up to sign, hence ∇_κ to itself and the products Δ_T of increasing fillings to themselves up to sign. So it identifies the Weyl modules up to an integral change of coordinates with integral inverse (both standard bases being $\mathbb{Z}$-bases of ∇_κ), compatibly with the Schur matrices, and isometrically, since $\|\xi\|_\kappa^2 = \sum_T |\xi(\Delta_T)|^2$ by (WM3) with ξ read as a linear form on ∇_κ. Through it, Lemma 4.6.7 for Φ, $n_\tau = N$, (κ, e), γ, κ_1 and $q = 1$ (its κ_0, e_0 are ours by Step 3) gives an integer matrix br with rows I_{κ_0} and columns $I_{\mathrm{II},m}$ satisfying its (a)–(c), with $w_\tau = \sum_{1\le h\le N} \gamma(\tau, h)$. Lemma 6.4.73 for n, the weight (κ_0, e_0) with parameter p (Step 1) and (κ', e') with parameter $-p = l$ gives an integer matrix A with rows $I_{\mathrm{I},m}$ and columns I_{κ_0} satisfying its (1)–(4). Put $B = A\,\mathrm{br}$, an integer matrix with rows $I_{\mathrm{I},m}$ and columns $I_{\mathrm{II},m}$.

Step 5: (a) of (LQ6). Put $N_\tau = w_\tau + e_\tau$; as $0 \le w_\tau \le \sum_h \kappa(\tau, h) \le B_0$, $|N_\tau| \le B_0 + |e_\tau|$. Let S, R, f_τ, g, u, v', v be as in (a). From $\bar g^{\mathsf T} g = 1$, $\det g$ is a unit of S, so $f(g) \in \prod_\tau \mathrm{GL}_n(R)$, $s = (f_\tau(u))_\tau \in \prod_\tau R^\times$ and $f(\mathrm{diag}(g, u)) = \mathrm{diag}(f(g), s)$. By (a) of Lemma 4.6.7 and (1) of Lemma 6.4.73 over R,

$$\begin{aligned}\big(P_{\kappa',e'}(f(g))v'\big)^{\mathsf T} A\,\mathrm{br}\,P_{\kappa,e}(\mathrm{diag}(f(g),s))v &= \prod_\tau s_\tau^{N_\tau}\big(P_{\kappa',e'}(f(g))v'\big)^{\mathsf T} A\,P_{\kappa_0,e_0}(f(g))\,\mathrm{br}\,v\\ &= \prod_\tau f_\tau(u)^{N_\tau}\, v'^{\mathsf T} B v.\end{aligned}$$

Step 6: (b) of (LQ6). Let $M \ge B_0$, $v' \in \mathbb{V}_{\mathrm{I},m}$, $v \in \mathbb{V}_{\mathrm{II},m}$. By (4) of Lemma 6.4.73 for $\mathrm{br}\,v$ there is w' with $\|w'\|_{\kappa'} = \|\mathrm{br}\,v\|_{\kappa_0}$ and $v'^{\mathsf T} A\,\mathrm{br}\,v = \langle w', v'\rangle_{\kappa'}$. The form $\langle\cdot,\cdot\rangle_{\kappa'}$ is positive semidefinite ($G_{\kappa'} = F_{\kappa'}^{\mathsf T} F_{\kappa'}$), so by the Cauchy–Schwarz inequality and (b) of Lemma 4.6.7 with $L = M$ (admissible by (6.102)),

$$|v'^{\mathsf T} B v| \le \|w'\|_{\kappa'}\|v'\|_{\kappa'} = \|\mathrm{br}\,v\|_{\kappa_0}\|v'\|_{\kappa'} \le (M^M)^3 \|v'\|_{\kappa'}\|v\|_\kappa.$$

Step 7: (c) of (LQ6). Fix $g \in G_\infty(1)$ for n', let dy be the Haar probability measure of $G_\infty(1)$ for n, and define the linear map T from $\mathbb{V}_{\mathrm{II},m}$ to $\mathbb{V}_{\kappa_0}$ by

$$T\xi = \int_{G_\infty(1)} \rho_{\kappa_0,e_0}(y)\, v_p^+ \,\big\langle v_{l'}^+, \rho_{\kappa,e}(g^{-1})\,\rho_{\kappa,e}(\mathrm{diag}(y,1))^{-1}\xi\big\rangle_\kappa\, dy.$$

For $y_0 \in G_\infty(1)$, substituting $y = y_0 y'$ and using the left invariance of dy and the multiplicativity of ρ gives $T\rho_{\kappa,e}(\mathrm{diag}(y_0,1)) = \rho_{\kappa_0,e_0}(y_0)T$, that is $T\,P_{\kappa,e}(\mathrm{diag}(h,1)) = P_{\kappa_0,e_0}(h)\,T$ for every $h = \bar y_0 \in \prod_\tau \mathrm{U}(N)$; by (c) of Lemma 4.6.7, $T = c_g\,\mathrm{br}$ for some $c_g \in \mathbb{C}$, which depends only on g. Now let η, φ, u, K be as in (c), and $f(x) = F_\eta^l(x)\,F_\varphi^{l'}(\mathrm{diag}(x,(1,u))(g,1))$ on $\mathrm{G}(1)$ for n. For $x = (y,h)$, (2) of Lemma 6.4.73 (signs 1) gives $F_\eta^l(y,h) = \eta(h)^{\mathsf T} A \rho_{\kappa_0,e_0}(y) v_p^+$, and (WM7) gives $F_\varphi^{l'}(\mathrm{diag}(y,1)g, \mathrm{diag}(h,u)) = \langle v_{l'}^+, \rho_{\kappa,e}(g^{-1})\rho_{\kappa,e}(\mathrm{diag}(y,1))^{-1}\varphi(\mathrm{diag}(h,u))\rangle_\kappa$; hence

$$\int_{G_\infty(1)} f(y,h)\,dy = \eta(h)^{\mathsf T} A\,T\,\varphi(\mathrm{diag}(h,u)) = c_g\,F_u(h), \qquad F_u(h) = \eta(h)^{\mathsf T} B\,\varphi(\mathrm{diag}(h,u)).$$

The function f is continuous, and right invariant in the finite variable under the open subgroup of the $k \in \mathbf{K}_0(n)$ with $\eta(hk) = \eta(h)$ and $\varphi(h'\mathrm{diag}(k,1)) = \varphi(h')$ for all h, h' (as $\mathrm{diag}(hk,u) = \mathrm{diag}(h,u)\mathrm{diag}(k,1)$). It is left invariant under the rational points γ of I_n: $\mathrm{diag}(\gamma,1)$ is a rational point of $\mathrm{I}_{n'}$, so by (WM7)

$$\eta(\gamma_f h) = \rho_{\kappa',e'}(\gamma_\infty)\eta(h) \quad\text{and}\quad \varphi(\mathrm{diag}(\gamma_f h, u)) = \rho_{\kappa,e}(\mathrm{diag}(\gamma_\infty,1))\varphi(\mathrm{diag}(h,u)),$$

and $F^{l''}_{\eta''}(\gamma x) = F^{l''}_{\eta''}(x)$ for both forms, as $\rho((\gamma_\infty x_\infty)^{-1})\rho(\gamma_\infty) = \rho(x_\infty^{-1})$ by multiplicativity. By Step 5, B is an integer matrix with (a) of (LQ6), so by (i) of Lemma 6.4.79 F_u satisfies the hypotheses of (LQ3), and so does $c_g F_u$. By (2) of Lemma 6.4.74,

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} F^l_\eta(x)\, F^{l'}_\varphi\big(\mathrm{diag}(x,(1,u))(g,1)\big)\,dx = \frac{c_n}{[\mathbf{K}_0(n):\mathrm{K}]}\,\mathrm{CI}_\mathrm{K}(c_g F_u) = \frac{c_n c_g}{[\mathbf{K}_0(n):\mathrm{K}]}\,\mathrm{CI}_\mathrm{K}(F_u),$$

the last step by (1) of Lemma 6.4.74 (both class integrals computed at one level fixing F_u). This is (c) with $c = c_n c_g$, which depends only on g. So B is a branching pairing at (m,m). □

Lemma 6.4.79. *Let D be admissible data, $n = n_{\mathrm{I},m}$ and $n' = n_{\mathrm{II},m} = n \sqcup \{*\}$, as in (LQ6).*

(i) Let B be an integer matrix with rows $I_{\mathrm{I},m}$ and columns $I_{\mathrm{II},m}$ that satisfies (a) of (LQ6), let $\eta \in \mathcal{A}_{\mathrm{I},m}$, $\varphi \in \mathcal{A}_{\mathrm{II},m}$ and $u \in \mathrm{U}(1)(\mathbb{A}_f)$, and put

$$F(h) = \eta(h)^{\mathsf{T}} B\, \varphi(\mathrm{diag}(h,u)) \qquad (h \in G_f(n)).$$

Then $F(\gamma_f h) = F(h)$ for every rational point γ of I_n and every h; if η is right invariant under an open subgroup K_1 of $G_f(n)$ and φ under an open subgroup K_2 of $G_f(n')$, then F is right invariant under the open subgroup $\{k \in \mathrm{K}_1 : \mathrm{diag}(k,1) \in \mathrm{K}_2\}$. In particular F satisfies the hypotheses of (LQ3) for the index set n.

(ii) Let B be a branching pairing at (m,m), ϑ an m-fold twist, Ψ a function on the edge tuples for ϑ and $y = (y_\mathrm{I}, y_\mathrm{II})$ a pair with $y_z \in \mathcal{F}(z,0,m)$. For every edge tuple S for ϑ, both chains $\mathrm{Lc}^S_{z,m}(y_z)$ are defined and lie in $\mathcal{A}_{z,m}$, and the integrand $h \mapsto \mathrm{Lc}^S_{\mathrm{I},m}(y_\mathrm{I})(h)^{\mathsf{T}} B\, \mathrm{Lc}^S_{\mathrm{II},m}(y_\mathrm{II})(\mathrm{bp}_\vartheta(h))$ of (LQ7) is the function F of (i) for $\eta = \mathrm{Lc}^S_{\mathrm{I},m}(y_\mathrm{I})$, $\varphi = \mathrm{Lc}^S_{\mathrm{II},m}(y_\mathrm{II})$ and $u = \mathrm{flp}^m_\vartheta$. In particular $\mathrm{Ls}_B(\Psi, y)$ is defined.

Proof. Write $(\kappa', e') = (\kappa_\mathrm{I}, e^{\det}_{\mathrm{I},m})$ and $(\kappa, e) = (\kappa_\mathrm{II}, e^{\det}_{\mathrm{II},m})$ for the weights at (I,m,m) and (II,m,m), so that $\mathcal{A}_{\mathrm{I},m} = \mathcal{A}_n(\kappa', e')$ and $\mathcal{A}_{\mathrm{II},m} = \mathcal{A}_{n'}(\kappa, e)$ ((LQ1)). For $h \in G_f(n)$ the block matrix $\mathrm{diag}(h,u)$ lies in $G_f(n')$, as h is unitary for I_n and $u\bar{u} = 1$.

Step 1: left invariance in (i). Let γ be a rational point of I_n, that is $\gamma \in \mathrm{M}_n(E)$ with $\bar{\gamma}^{\mathsf{T}}\gamma = 1$; its infinite component γ_∞ is the family of the matrices $\tau(\gamma)$ ($\tau \in \Phi$). Then $\mathrm{diag}(\gamma, 1)$ is a rational point of $\mathrm{I}_{n'}$, with infinite component $\mathrm{diag}(\gamma_\infty, 1)$ and finite component $\mathrm{diag}(\gamma_f, 1)$, and $\mathrm{diag}(\gamma_f h, u) = \mathrm{diag}(\gamma_f, 1)\,\mathrm{diag}(h,u)$. By the transformation law (WM7) for η and for φ,

$$\eta(\gamma_f h) = P_{\kappa',e'}(\bar{\gamma}_\infty)\,\eta(h), \qquad \varphi(\mathrm{diag}(\gamma_f h, u)) = P_{\kappa,e}\big(\mathrm{diag}(\bar{\gamma}_\infty, 1)\big)\,\varphi(\mathrm{diag}(h,u)),$$

with $\bar{\gamma}_\infty$ the entrywise complex conjugate. Apply (a) of (LQ6) to the ring E with its complex conjugation, the field $R = \mathbb{C}$, the ring homomorphisms $f_\tau(x) = \overline{\tau(x)}$ ($\tau \in \Phi$), the matrix $g = \gamma$, the scalar $1 \in E$ in place of its unit, and $v' = \eta(h)$, $v = \varphi(\mathrm{diag}(h,u))$. As E is a CM field, $\overline{\tau(x)} = \tau(\bar{x})$, so $f(\gamma) = \bar{\gamma}_\infty$, $f(\mathrm{diag}(\gamma,1)) = \mathrm{diag}(\bar{\gamma}_\infty, 1)$ and $f_\tau(1) = 1$; hence

$$F(\gamma_f h) = \big(P_{\kappa',e'}(f(\gamma))\,v'\big)^{\mathsf{T}} B\, P_{\kappa,e}(f(\mathrm{diag}(\gamma,1)))\,v = v'^{\mathsf{T}} B v = F(h).$$

Step 2: right invariance in (i). By (WM7) every algebraic form is right invariant under some open subgroup, so open subgroups K_1, K_2 as in (i) exist. The map $k \mapsto \mathrm{diag}(k,1)$ is a continuous homomorphism $G_f(n) \to G_f(n')$, so $\mathrm{K}_3 = \{k \in \mathrm{K}_1 : \mathrm{diag}(k,1) \in \mathrm{K}_2\}$ is an open subgroup of $G_f(n)$. For $k \in \mathrm{K}_3$, $\eta(hk) = \eta(h)$ and $\mathrm{diag}(hk,u) = \mathrm{diag}(h,u)\,\mathrm{diag}(k,1)$, so $\varphi(\mathrm{diag}(hk,u)) = \varphi(\mathrm{diag}(h,u))$ and $F(hk) = F(h)$. With Step 1, F is a complex-valued function on $G_f(n)$, left invariant under the finite components of the rational points of I_n and right invariant under an open subgroup: these are the hypotheses of (LQ3).

Step 3: (ii). By (2) of Lemma 6.4.68, for both z and every edge tuple S for ϑ the chain $\mathrm{Lc}^{S}_{z,m}(y_z)$ is defined and lies in $\mathcal{A}_{z,m}$. The flip idele has norm one, $\mathrm{flp}_\vartheta\,\overline{\mathrm{flp}_\vartheta}=1$, so $u=\mathrm{flp}_\vartheta^{m}\in \mathrm{U}(1)(\mathbb{A}_f)$, and $\mathrm{bp}_\vartheta(h)=\mathrm{diag}(h,u)$ by (LQ7). So the integrand of (LQ7) for S is the function F of (i) for these η, φ, u, and a branching pairing is an integer matrix with rows $I_{\mathrm{I},m}$ and columns $I_{\mathrm{II},m}$ satisfying (a) of (LQ6). By (i) the integrand satisfies the hypotheses of (LQ3). Both conditions of (LQ7) hold for every S, so $\mathrm{Ls}_B(\Psi,y)$ is defined. □

On the last path every space is definite and every move is an algebraic theta lift. This group proves the three properties of the last path that the spanning statement uses (Proposition 6.4.80): every family of functions of edge tuples is proportional to the last-path sum; one integer $N\le\exp(x^{99}b^2)$ clears its denominators at every prime identification $\iota\mid\ell$ with ℓ prime to the modulus of the twist; and at the trivial twist its conjugates are at most $\exp(x^{200}b^2)$ times the geometric mean of the bounds for the two forms. The arithmetic input is the jet matrices of the algebraic lifts along the edges (Lemma 6.4.82), whose denominators are bounded by one integer and whose conjugates at the trivial twist are bounded as operators; in our reading their entries are homogeneous jets of theta functions with complex multiplication, of the kind studied in Section 4. For the integrality of theta functions with complex multiplication see [272, 159]. The class numbers of the levels are bounded in Lemma 6.4.86; for mass formulas of definite hermitian lattices see [97].

Proposition 6.4.80. *Let D be admissible data and B a branching pairing at (m,m); put $V_1=\#(\mathcal{O}_E/\mathfrak{b})^{2n_m}$ and $T_1=\#(\mathcal{O}_E/\mathfrak{b})^{8mn_m^2}$. On the last path:*

(a) for every family (Ψ_ϑ) of functions on edge tuples and every real point g of $\mathrm{U}(\tilde{Y}^m_m)$ there is $\beta\in\mathbb{C}$ such that for every m-fold twist ϑ, every conjugate form y on Y_m and every form φ on $\tilde{Y}^m_0$, the period of (Ψ_ϑ) at g on (ϑ,y,φ) is $\beta\,\mathrm{Ls}_B(\Psi_\vartheta,(y,\varphi))/[\mathbf{K}_0(n_{\mathrm{I},0}):\mathrm{K}_\vartheta(\mathrm{I},0)]$, $n_{\mathrm{I},0}$ the index set of Y_m and $\mathbf{K}_0$ the standard level of (VP1) of Definition 3.2.2;

(b) there is an integer $1\le N\le\exp(x^{99}b^2)$ such that $N\,\mathrm{Ls}_B(\Psi,y)$ is integral at ι for every m-fold twist ϑ, every prime identification $\iota\mid\ell$ with $\ell\nmid \mathrm{N}Q$, every path datum Ψ on the edges of the last path and every pair y fixed by the outer levels whose algebraic forms $y^\flat_z$ are integral at ι;

(c) for the trivial twist, every path datum Ψ of bound $V_1^{m^2}T_1$ on the edges of the last path, every pair y fixed by the outer levels, every field automorphism σ of $\mathbb{C}$ and all $M_z\ge0$ with $\|\sigma(y^\flat_z(g))\|^2_{\kappa_z}\le M_z$ for all g and $z\in\{\mathrm{I},\mathrm{II}\}$, $|\sigma(\mathrm{Ls}_B(\Psi,y))|\le\exp(x^{200}b^2)\sqrt{M_\mathrm{I}M_\mathrm{II}}$; and the class numbers of the levels $\mathrm{K}_1(z,i)$ $(0\le i\le m)$ of the trivial twist are at most $\exp(x^{99}b^2)$.

Proof. Write $n_z=n_{z,0}$, $n=n_{\mathrm{I},m}$ and, for an m-fold twist ϑ, $\mathrm{ix}_\vartheta(z,i)=[\mathbf{K}_0(n_{z,i}):\mathrm{K}_\vartheta(z,i)]$. For $(z,i)\ne(\mathrm{I},0)$ the level $\mathrm{K}_\vartheta(z,i)$ is the kernel of the reduction modulo $\mathfrak{b}$, so it and $\mathrm{ix}_\vartheta(z,i)$ do not depend on ϑ.

Step 1: the class integrals are defined. Let $y=(y_\mathrm{I},y_\mathrm{II})$ with $y_z\in\mathcal{F}(z,0,m)$ and let S be an edge tuple for ϑ supported on the edges of the last path. By (ii) of Lemma 6.4.79, for both z the chain $\mathrm{Lc}^{S}_{z,m}(y_z)$ is defined and lies in $\mathcal{A}_{z,m}$, the integrand

$$F_S(h)=\mathrm{Lc}^{S}_{\mathrm{I},m}(y_\mathrm{I})(h)^{\mathsf{T}}\,B\,\mathrm{Lc}^{S}_{\mathrm{II},m}(y_\mathrm{II})(\mathrm{bp}_\vartheta(h))$$

of (LQ7) on $G_f(n)$ satisfies the hypotheses of (LQ3), and $\mathrm{Ls}_B(\Psi,y)$ is defined for every function Ψ on the edge tuples. By (1) of Lemma 6.4.74, CI_K is linear on such functions (compute at a common open subgroup).

Step 2: the period is a multiple of Ls_B. Fix (Ψ_ϑ) and g. By (3) of Lemma 6.4.68 for $j = m$ and both z, the images of y and φ under the composites of the lift moves along the two halves of the last path with the matrices of S are $F_{\eta_S}^{l_{\mathrm{I},m}}$ and $F_{\eta'_S}^{l_{\mathrm{II},m}}$ with

$$\eta_S = \frac{c_{\mathrm{I},m}}{\mathrm{ix}_\vartheta(\mathrm{I},0)}\,\mathrm{Lc}^S_{\mathrm{I},m}(y), \qquad \eta'_S = \frac{c_{\mathrm{II},m}}{\mathrm{ix}_1(\mathrm{II},0)}\,\mathrm{Lc}^S_{\mathrm{II},m}(\varphi),$$

algebraic forms by Step 1. By (3.3) and (1) of Lemma 6.4.68, the period is the sum over the edge tuples S supported on the edges of the last path of $\Psi_\vartheta(S)$ times

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} F_{\eta_S}^{l_{\mathrm{I},m}}(x)\, F_{\eta'_S}^{l_{\mathrm{II},m}}(\mathrm{diag}(x,(1,\mathrm{flp}_\vartheta^m))(g,1))\,dx.$$

The flip idele has norm one, so $\mathrm{flp}_\vartheta^m \in \mathrm{U}(1)(\mathbb{A}_f)$; by (c) of (LQ6) for g (with its constant c_g, which depends only on g), $u = \mathrm{flp}_\vartheta^m$ and $\mathrm{K} = \mathrm{K}_\vartheta(\mathrm{I},m)$, and as $\mathrm{diag}(h,\mathrm{flp}_\vartheta^m) = \mathrm{bp}_\vartheta(h)$, the integral is

$$c_g\,\mathrm{ix}_1(\mathrm{I},m)^{-1}\mathrm{CI}_\mathrm{K}(h \mapsto \eta_S(h)^\mathsf{T} B\,\eta'_S(\mathrm{bp}_\vartheta(h))).$$

By linearity (Step 1),

$$\mathrm{per}_{\mathrm{last}}(\Psi;g)(\vartheta,y,\varphi) = \frac{\gamma_g}{\mathrm{ix}_\vartheta(\mathrm{I},0)}\,\mathrm{Ls}_B(\Psi_\vartheta,(y,\varphi)), \qquad \gamma_g = \frac{c_g\,c_{\mathrm{I},m}\,c_{\mathrm{II},m}}{\mathrm{ix}_1(\mathrm{II},0)\,\mathrm{ix}_1(\mathrm{I},m)}, \tag{6.103}$$

with γ_g independent of ϑ, y, φ; this is (a) with $\beta = \gamma_g$.

Step 3: the flip idele at a prime prime to $\mathrm{N}Q$. Let $\iota \mid \ell$ with $\ell \nmid \mathrm{N}Q$ and $\tau \in \Phi$. We show $\|f_{\iota,\tau}(M^b q_1\,\mathrm{flp}_\vartheta^{\pm 1})\| \le 1$. As $x^{q_1}-1 = \mathrm{cyc}_{q_1}(x)g(x)$ with $g \in \mathbb{Z}[x]$, $q_1\zeta^{q_1-1} = \mathrm{cyc}'_{q_1}(\zeta)g(\zeta)$, so by (WD2) $q_1\alpha$ and α^{-1} are integral finite adeles. The idele t_ϑ is integral and generates $\mathfrak{m}_\vartheta\widehat{\mathcal{O}}_E$, and $\mathrm{N}Q\,M^b \in \mathfrak{m}_\vartheta$ ($M^b = (\pi_M\bar\pi_M)^b$, and $\mathrm{N}w \in w$ for $w \in Q$); so $t_\vartheta^{-1}\mathrm{N}Q\,M^b$ is integral, and so is

$$a_+ = \mathrm{N}Q\,M^b q_1\,\mathrm{flp}_\vartheta = \left(t_\vartheta^{-1}\mathrm{N}Q\,M^b\right)\bar t_\vartheta\,\overline{q_1\alpha}\,\alpha^{-1},$$

and $a_- = \bar a_+ = \mathrm{N}Q\,M^b q_1\,\mathrm{flp}_\vartheta^{-1}$. The map $f_{\iota,\tau}$ carries integral adeles into the valuation ring of $\overline{\mathbb{Q}}_\ell$ and $\|f_{\iota,\tau}(\mathrm{N}Q)\| = 1$; this gives the claim.

Step 4: (b). Let N_τ ($\tau \in \Phi$) be the exponents of (a) of (LQ6) for B, so $|N_\tau| \le B_0 + |e^{\det}_{\mathrm{II},m}(\tau)| \le br^4 + 20b$ by (4), (5) of Lemma 6.4.3 for $z = \mathrm{II}$, $i = m$ (B_0 is the sum of (4) in the rank of (II,m,m)). Put $N = d_J^{2m}\prod_\tau (M^b q_1)^{m|N_\tau|}$, a positive integer depending only on D and B, with $\log N \le 2m\log d_J + fm(br^4+20b)\log(M^b q_1) \le x^{99}b^2$ by (2) of Lemma 6.4.86. Let ϑ, ι, Ψ, y be as in (b), and write $\mathrm{Ls}_B(\Psi,y) = \sum_t \zeta_t\, v_t'^\mathsf{T} B v_t$ as in Lemma 6.4.81, with $v'_t = \Pi^{\mathrm{I}}_t y^\flat_{\mathrm{I}}(g^{\mathrm{I}}_{t,0})$ and $v_t = \Pi^{\mathrm{II}}_t y^\flat_{\mathrm{II}}(g^{\mathrm{II}}_{t,0})$. By the integrality of $y^\flat_z$ and (1) of Lemma 6.4.82, applied m times along each half, $\mathrm{gau}_\iota(h, d_J^m v'_t) \le 1$ and $\mathrm{gau}_\iota(\mathrm{bp}_\vartheta(h), d_J^m v_t) \le 1$, $h = g^{\mathrm{I}}_{t,m}$. Put $w' = P_{\kappa_{\mathrm{I}},e^{\det}_{\mathrm{I},m}}(f_\iota(h^{-1}))\iota(d_J^m v'_t)$ and $w = P_{\kappa_{\mathrm{II}},e^{\det}_{\mathrm{II},m}}(f_\iota(\mathrm{bp}_\vartheta(h)^{-1}))\iota(d_J^m v_t)$, vectors with coordinates in the valuation ring. Apply (a) of (LQ6) with $S = \mathbb{A}_{E,f}$ (complex conjugation), $R = \overline{\mathbb{Q}}_\ell$, $f_\tau = f_{\iota,\tau}$, the unitary h^{-1} and $u = \mathrm{flp}_\vartheta^{-m}$; as $\mathrm{diag}(h^{-1},\mathrm{flp}_\vartheta^{-m}) = \mathrm{bp}_\vartheta(h)^{-1}$ and B has integer entries,

$$w'^\mathsf{T} B w = \prod_\tau f_{\iota,\tau}(\mathrm{flp}_\vartheta)^{-mN_\tau}\,\iota(d_J^{2m}\,v_t'^\mathsf{T} B v_t).$$

The left side has absolute value at most 1 (ultrametric inequality), and by Step 3

$$\|(M^b q_1)^{m|N_\tau|} f_{\iota,\tau}(\mathrm{flp}_\vartheta)^{mN_\tau}\| \le 1 \qquad \text{for every } \tau.$$

Hence $\|\iota(N\,v_t'^\mathsf{T} B v_t)\| \le 1$; as $\|\iota(\zeta_t)\| = 1$, the ultrametric inequality gives $\|\iota(N\,\mathrm{Ls}_B(\Psi,y))\| \le 1$.

Step 5: (c). Let $\vartheta = 1$ and Ψ, y, σ, M_z be as in (c). The space at a node (z,j,m) has rank at most $r+1+2mt < 2n_m$ ((GP), $n_m = r+1+mt$), so each of the $2m$ edges of the last path carries a matrix over $\mathcal{O}_E/\mathfrak{b}$ with at most $(2n_m)^2$ entries and T_1 bounds the number of edge tuples on the last path. By Lemma 6.4.81 with the bound $V_1^{m^2}T_1$ and (1) of Lemma 6.4.86, $\mathrm{Ls}_B(\Psi,y) = \sum_{t=1}^{T} \zeta_t v_t'^{\mathsf{T}} B v_t$ with $T \le V_1^{m^2}T_1^2 G^{2m+1}$. By (2) of Lemma 6.4.82, applied m times, $\|\sigma(v_t')\|_{\kappa_{\mathrm{I}}} \le G^m\sqrt{M_{\mathrm{I}}}$ and $\|\sigma(v_t)\|_{\kappa_{\mathrm{II}}} \le G^m\sqrt{M_{\mathrm{II}}}$. As B has integer entries, $\sigma(v_t'^{\mathsf{T}}Bv_t) = \sigma(v_t')^{\mathsf{T}}B\,\sigma(v_t)$, and by (b) of (LQ6) with $M = br^4 \ge B_0$ this has absolute value at most $((br^4)^{br^4})^3 G^{2m}\sqrt{M_{\mathrm{I}}M_{\mathrm{II}}}$. Summing, with $|\sigma(\zeta_t)| = 1$,

$$|\sigma(\mathrm{Ls}_B(\Psi,y))| \le V_1^{m^2}T_1^2G^{4m+1}\big((br^4)^{br^4}\big)^3\sqrt{M_{\mathrm{I}}M_{\mathrm{II}}} \le \exp(x^{200}b^2)\sqrt{M_{\mathrm{I}}M_{\mathrm{II}}}$$

by (3) of Lemma 6.4.86. The bound for the class numbers is (1) of Lemma 6.4.86. □

Lemma 6.4.81. *Let D be admissible data and B a branching pairing at (m,m). For an m-fold twist ϑ, an edge tuple S, $z \in \{\mathrm{I},\mathrm{II}\}$, $0 \le j < m$, $g \in G_f(n_{z,j})$ and $h \in G_f(n_{z,j+1})$ put*

$$J^S_{z,j}(g,h) = \mathrm{jm}\big(\omega_{\alpha,\beta}((1,g),(1,h))\,\varphi^S_{z,j}\big) \in \mathrm{M}_{I_{z,j+1}\times I_{z,j}}(\mathbb{C}).$$

Let ϑ be an m-fold twist, T_ϑ the number of edge tuples for ϑ supported on the edges of the last path, and

$$C_\vartheta = \prod_{j=0}^{m} \#(\Gamma_{n_{\mathrm{I},j}}\backslash G_f(n_{\mathrm{I},j})/\mathrm{K}_\vartheta(\mathrm{I},j)) \cdot \prod_{j=0}^{m-1} \#(\Gamma_{n_{\mathrm{II},j}}\backslash G_f(n_{\mathrm{II},j})/\mathrm{K}_\vartheta(\mathrm{II},j)),$$

the class sets taken for the finite components of the rational points. Let $N \in \mathbb{N}$, Ψ a path datum of bound N on the edges of the last path and y a pair fixed by the outer levels. Then there are an integer $0 \le T \le N\,T_\vartheta\,C_\vartheta$ and, for $1 \le t \le T$, a root of unity ζ_t, an edge tuple S_t and points $g^z_{t,j} \in G_f(n_{z,j})$ ($z \in \{\mathrm{I},\mathrm{II}\}$, $0 \le j \le m$) with $g^{\mathrm{II}}_{t,m} = \mathrm{bp}_\vartheta(g^{\mathrm{I}}_{t,m})$, such that

$$\mathrm{Ls}_B(\Psi,y) = \sum_{t=1}^{T} \zeta_t\,\big(\Pi^{\mathrm{I}}_t\,y^\flat_{\mathrm{I}}(g^{\mathrm{I}}_{t,0})\big)^{\mathsf{T}} B\,\big(\Pi^{\mathrm{II}}_t\,y^\flat_{\mathrm{II}}(g^{\mathrm{II}}_{t,0})\big),$$
$$\Pi^z_t = J^{S_t}_{z,m-1}(g^z_{t,m-1},g^z_{t,m})\cdots J^{S_t}_{z,0}(g^z_{t,0},g^z_{t,1}).$$

Proof. Fix ϑ, N, Ψ, y and write $\mathfrak{m} = \mathfrak{m}_\vartheta$, $\mathcal{S}$ for the set of edge tuples supported on the edges of the last path ($\#\mathcal{S} = T_\vartheta$), $G_{z,j} = G_f(n_{z,j})$, $\mathrm{K}_{z,j} = \mathrm{K}_\vartheta(z,j)$ and Γ for the finite components of the rational points. For $S \in \mathcal{S}$ write $L^S_{z,j} = \mathrm{Lc}^S_{z,j}(y_z)$; by (2) of Lemma 6.4.68 these chains are defined (so $\mathrm{Al}_{\vartheta,z,j}(\varphi^S_{z,j})$ is defined at $L^S_{z,j}$ for $j < m$, (LQ4), (LQ5)), they are algebraic forms, and $L^S_{z,j+1}(h) = \mathrm{CI}_{\mathrm{K}_{z,j}}(g \mapsto J^S_{z,j}(g,h)L^S_{z,j}(g))$, the integrands satisfying the hypothesis of (LQ3).

Step 1: free levels. Every $\mathrm{K}_{z,j}$ consists of elements of $\mathbf{K}_0(n_{z,j})$ that are $\equiv 1$ modulo $\mathfrak{b}$ (for $(\mathrm{I},0)$ modulo $\mathfrak{m}$, a multiple of $\mathfrak{b}$), hence act trivially on $\mathcal{O}^n_{E_w}/w$ for every chosen place w; by Lemma 4.6.2 (c), $\Gamma \cap g\mathrm{K}'g^{-1} = \{1\}$ for every open $\mathrm{K}' \subseteq \mathrm{K}_{z,j}$ and every g. So in (1) of Lemma 6.4.74 all $\#\Gamma'_h = 1$, and for such K' each double coset $\Gamma x\mathrm{K}_{z,j}$ is the disjoint union of the $[\mathrm{K}_{z,j} : \mathrm{K}']$ cosets $\Gamma xk\mathrm{K}'$, $k \in \mathrm{K}_{z,j}/\mathrm{K}'$.

Step 2: expansion. Choose open subgroups $\mathrm{K}'_{z,j} \subseteq \mathrm{K}_{z,j}$ and finite sets $\mathcal{R}'_{z,j}$ of representatives of $\Gamma\backslash G_{z,j}/\mathrm{K}'_{z,j}$ from the top down: first $\mathrm{K}'_{\mathrm{I},m}$ fixing the integrands

$$F_S(h) = L^S_{\mathrm{I},m}(h)^{\mathsf{T}} B L^S_{\mathrm{II},m}(\mathrm{bp}_\vartheta(h))$$

of Ls_B for all $S \in \mathcal{S}$, and $\mathcal{R}'_{\mathrm{I},m}$. (By (ii) of Lemma 6.4.79 each F_S satisfies the hypotheses of (LQ3) and $\mathrm{Ls}_B(\Psi,y)$ is defined; by (i) there, an open subgroup fixing F_S exists.) Then, for

$j = m-1, \dots, 0$, $\mathrm{K}'_{z,j}$ fixing the finitely many integrands $g \mapsto J^S_{z,j}(g,h)L^S_{z,j}(g)$ with $S \in \mathcal{S}$ and h in $\mathcal{R}'_{z,j+1}$ (with $h \in \mathrm{bp}_\vartheta(\mathcal{R}'_{\mathrm{I},m})$ for $(z,j+1) = (\mathrm{II},m)$), and $\mathcal{R}'_{z,j}$. Applying (1) of Lemma 6.4.74 at every class integral, with weights $w_{z,j} = [\mathrm{K}_{z,j} : \mathrm{K}'_{z,j}]^{-1}$,

$$\mathrm{Ls}_B(\Psi, y) = W \sum_{S \in \mathcal{S}} \Psi(S) \sum_x \Theta(S; x), \qquad W = \prod_{j=0}^{m} w_{\mathrm{I},j} \prod_{j=0}^{m-1} w_{\mathrm{II},j},$$

the inner sum over the tuples $x = (x_0, \dots, x_m; x''_0, \dots, x''_{m-1})$ with $x_j \in \mathcal{R}'_{\mathrm{I},j}$, $x''_j \in \mathcal{R}'_{\mathrm{II},j}$, where, with $x''_m = \mathrm{bp}_\vartheta(x_m)$,

$$\Theta(S;x) = \big(J^S_{\mathrm{I},m-1}(x_{m-1}, x_m) \cdots J^S_{\mathrm{I},0}(x_0, x_1)\, y^\flat_{\mathrm{I}}(x_0)\big)^{\mathsf{T}} \\ B\, \big(J^S_{\mathrm{II},m-1}(x''_{m-1}, x''_m) \cdots J^S_{\mathrm{II},0}(x''_0, x''_1)\, y^\flat_{\mathrm{II}}(x''_0)\big).$$

The same identity holds for every other choice of the representative sets (the summands are invariant functions of the classes).

Step 3: the jet matrices under integral points. Let $e = ((z,j,m),(z,j+1,m))$, $k \in \mathbf{K}_0(n_{z,j})$, $k' \in \mathbf{K}_0(n_{z,j+1})$ with infinite components 1, and $\bar{k}, \bar{k}'$ their reductions modulo $\mathfrak{m}$. For a finite point x and $f \in \mathcal{M}_{n,n'}$, $\omega_{\alpha,\beta}(x)(v \otimes f) = v \otimes \omega_{\alpha,\beta}(x)f$: by (WR6) $v \otimes f = \int v(y)\rho(\mathrm{rv}(y))f\, d\nu(y)$, $\omega_{\alpha,\beta}(x)$ is bounded and $\omega_{\alpha,\beta}(x)\rho(z)\omega_{\alpha,\beta}(x)^{-1} = \rho(xz) = \rho(z)$ for z with finite components 0 ((2) of Lemma 4.1.1). By (6) of Lemma 4.1.1 with Φ the indicator of $S(e)$, for which $\Phi_{k,k'}$ is the indicator of $\bar{k}'S(e)\bar{k}^{-1}$, and by the representation property,

$$J^S_{z,j}(gk, hk') = \alpha(\det k')\beta(\det k)^{-1}\, J^{S_{k,k'}}_{z,j}(g,h),$$

$S_{k,k'}$ the tuple with the matrix $\bar{k}'S(e)\bar{k}^{-1}$ on e and that of S elsewhere; indeed each entry of the jet matrix is $\theta(v_P \otimes \omega_{\alpha,\beta}((1,g),(1,h))\omega_{\alpha,\beta}((1,k),(1,k'))\varphi^S_{z,j})$. The characters α, β of (GP6) are $\mu^0_{j+1}(\vartheta^{j+1})^{[z]}$ times powers of v; their common tame part is trivial at the places not dividing $\mathfrak{m}$ (the tame part of v is trivial, that of μ^0_{j+1} lives at the chosen places, that of ϑ at Q), and for the row m the edge e is vertical exactly in the grid $\tilde{Y}$. So, for integral u with infinite components 1, $\alpha(u) = \beta(u) = \chi_e(u \bmod \mathfrak{m})$, and the factor is $\chi_e(\det \bar{k}'/\det \bar{k})$.

Step 4: invariance of the sum over S. Let $k_j \in \mathrm{K}_{\mathrm{I},j}$ $(0 \le j \le m)$, $k''_j \in \mathrm{K}_{\mathrm{II},j}$ $(0 \le j < m)$, and put $k''_m = \mathrm{diag}(k_m, 1)$, so that $\mathrm{bp}_\vartheta(x_m k_m) = \mathrm{bp}_\vartheta(x_m)k''_m$, and $k''_m \in \mathrm{K}_{\mathrm{II},m}$. Let g be the family of the reductions modulo $\mathfrak{m}$ of k_j at (I,j,m) and of k''_j at (II,j,m), and 1 at the other nodes. It is admissible in the sense of (PD2): at $(\mathrm{I},0,m)$ it is 1, at $(\mathrm{II},0,m)$ it lies in the reduction of the level, at (II,m,m) it is $g_{(\mathrm{I},m,m)} \oplus 1$, and at the other diagonal nodes it is $1 = 1 \oplus 1$. Write xk for the tuple $(x_j k_j; x''_j k''_j)$. As y is fixed by the outer levels, $y^\flat_z(x_0k_0) = y^\flat_z(x_0)$, and Step 3 on each of the $2m$ edges gives $\Theta(S; xk) = \epsilon_w(g)\,\Theta(g^{-1} \cdot S; x)$, w the edges of the last path. As $S \mapsto g \cdot S$ is a bijection of $\mathcal{S}$, (PD2) gives

$$\sum_{S \in \mathcal{S}} \Psi(S)\Theta(S; xk) = \sum_S \epsilon_w(g)\Psi(g \cdot S)\,\Theta(S; x) = \sum_{S \in \mathcal{S}} \Psi(S)\Theta(S; x).$$

Step 5: sum over classes. Let $\mathcal{R}_{z,j}$ be representatives of $\Gamma\backslash G_{z,j}/\mathrm{K}_{z,j}$ and, by Step 1, take $\mathcal{R}'_{z,j} = \{xk : x \in \mathcal{R}_{z,j},\ k \in \mathrm{K}_{z,j}/\mathrm{K}'_{z,j}\}$ (for a fixed set of coset representatives k). By Steps 2 and 4,

$$\mathrm{Ls}_B(\Psi, y) = W \sum_x \sum_k \sum_S \Psi(S)\Theta(S; xk) = \sum_x \sum_{S \in \mathcal{S}} \Psi(S)\,\Theta(S; x),$$

x now over the tuples with $x_j \in \mathcal{R}_{\mathrm{I},j}$, $x''_j \in \mathcal{R}_{\mathrm{II},j}$: there are C_ϑ of them, and the number of the k is W^{-1}. By (PD4), each $\Psi(S)$ is a sum of at most N roots of unity. Expanding gives at most $N\,T_\vartheta C_\vartheta$ terms $\zeta_t\Theta(S_t; x_t)$, and with $g^{\mathrm{I}}_{t,j} = (x_t)_j$, $g^{\mathrm{II}}_{t,j} = (x_t)''_j$ $(j < m)$, $g^{\mathrm{II}}_{t,m} = \mathrm{bp}_\vartheta(g^{\mathrm{I}}_{t,m})$, each $\Theta(S_t; x_t)$ is the asserted pairing. □

Lemma 6.4.82. *Let D be admissible data, $f = \#\Phi$ and $d_J = (M^b)^{2f(2n_m)^2}(M^b d)^{br^4}$. At the node (z,j,m) the gauge of (WM9) is taken for the weight $(\kappa_z, e^{\det}_{z,j})$. Then for every $z \in \{\mathrm{I},\mathrm{II}\}$, $0 \le j < m$, edge tuple S, $g \in G_f(n_{z,j})$, $h \in G_f(n_{z,j+1})$ and $v \in \mathbb{V}_{z,j}$:*

(1) for every m-fold twist ϑ and every prime identification $\iota \mid \ell$ with $\ell \nmid \mathrm{N}Q$,

$$\mathrm{gau}_\iota(h, d_J\, J^S_{z,j}(g,h)v) \le \mathrm{gau}_\iota(g,v);$$

(2) for the trivial twist and every field automorphism σ of $\mathbb{C}$,

$$\|\sigma(J^S_{z,j}(g,h)v)\|_{\kappa_z} \le \exp(x^{99}b^2)\,\|\sigma(v)\|_{\kappa_z},$$

σ applied coordinatewise.

Proof. Fix z, $0 \le j < m$, an m-fold twist ϑ, an edge tuple S, $g \in G_f(n_{z,j})$ and $h \in G_f(n_{z,j+1})$; all symbols below are local. Put $n = n_{z,j}$, $n' = n_{z,j+1}$, $N = \#n$, $N' = \#n'$, $R = NN'$, $\mathcal{C} = n' \times n$, $D = fR$, $N_0 = M^b$, $\kappa = \kappa_z$, and $B = \sum_\tau \sum_{1 \le h' < N'} h' \kappa(\tau, h')$. By (1) and (4) of Lemma 6.4.3 (at j and $j+1$), $N < N'$, $\kappa(\tau,h') = 0$ for $N < h' < N'$ and $B \le br^4$. The ranks of the nodes of the row m are at most $r + 1 + 2mt \le 2n_m$, so $R \le (2n_m)^2$.

Step 0: the space, the matrix and the datum. By (GP8) both I_n and $\mathrm{I}_{n'}$ have Gram matrix and point the identity, so $\mathrm{Hom}(\mathrm{I}_n, \mathrm{I}_{n'})$ is the standard definite space with index set $\mathcal{C}$ ((WR3)), the identity is a transporting element, and by Lemma 4.1.17 its theta functional $\theta_{n,n'}$ is the canonical functional θ_R of the standard definite space I_R on $\mathcal{C}$. Let α, β be the edge characters of (LQ4), of weights $e^{\det}_{z,j+1}$ and $\gamma' = \gamma_{z,j}(N')$ ((GP6) and (2) of Lemma 6.4.3), and put $F = \omega_{\alpha,\beta}((1,g),(1,h))\varphi^S_{z,j}$ and $J = J^S_{z,j}(g,h) = \mathrm{jm}(F)$. By (LQ4), $J_{i'i} = \theta_R(v_{P_{i'i}(\eta_P\,\cdot)} \otimes F)$, where $P_{i'i}$ is the entry of the rectangular Schur matrix $S_\kappa(X)$; by (WM2) each $P_{i'i}$ is homogeneous of degree B with integer coefficients (a minor on h' rows of Xy is homogeneous of degree h' in X). By (XD2), $F = c\,\omega(k)\varphi^S_{z,j}$ with $c = \alpha(\det h)\beta(\det g)^{-1}$ and $\omega(k)$ the Weil operator of the finite unitary transformation $k\colon X \mapsto hXg^{-1}$ of I_R; by Proposition 4.1.14, $\omega(k)\rho(\mathrm{fv}(u)) = \rho(\mathrm{fv}(ku))\omega(k)$ (the finite coordinates being $\mathbb{A}_{E,f}$-linear) and $\omega(k)$ preserves the span $\mathcal{M}_{\mathrm{fin}}$ of the finite Heisenberg translates of the vacuum v^0. Products of finite Heisenberg operators satisfy $\rho(\mathrm{fv}(x))\rho(\mathrm{fv}(x')) = \zeta\,\rho(\mathrm{fv}(x+x'))$ with ζ a value of the finite additive character (WD8), hence a root of unity (a continuous character of $\mathbb{A}_{E,f}$ is trivial on an open subgroup of each compact open subgroup, and every element lies in one).

Step 1: the edge datum as a combination of translated vacua. Let $A = \Sigma(\mathfrak{m}_\vartheta)$ and $T = R^{\mathcal{C}}_{\mathfrak{m}_\vartheta}$. By (LQ4), $\varphi^S_{z,j} = c_s^R\,\Phi^\natural \otimes_A v^0$, where Φ is the indicator function of the point $S(e_{z,j})$ of T. Apply Lemma 6.4.84 to the modulus $\mathfrak{m}_\vartheta$, the index set $\mathcal{C}$ with the signs $+1$ of I_R (Step 0) and $\Psi = \Phi$: it gives $\#T = \mathrm{N}(\mathfrak{m}_\vartheta)^R = (M^{fb}\,\mathrm{N}Q)^R$, as $\mathrm{N}_{E/\mathbb{Q}}(\pi_M) = M^f$, and vectors $u_\chi \in \mathbb{A}^{\mathcal{C}}_{E,f}$, one for each character χ of T, such that, after multiplication by c_s^R,

$$\varphi^S_{z,j} = \sum_\chi a_\chi\,\rho(\mathrm{fv}(u_\chi))\,c_s^R v^0, \qquad a_\chi = \frac{\overline{\chi(S(e_{z,j}))}}{\#T}, \qquad \sum_\chi |\sigma(a_\chi)| \le 1 \quad (\sigma \in \mathrm{Aut}(\mathbb{C})),$$

the bound by (a) of Lemma 6.4.84, as Φ takes the value 1 at one point and 0 elsewhere. Let $\ell \nmid \mathrm{N}Q$ be a prime and $w \in A$ a place above ℓ. Then $w \notin Q$ (each $w' \in Q$ lies above a prime dividing $\mathrm{N}w'$, hence $\mathrm{N}Q$), so $\mathfrak{m}_\vartheta \mathcal{O}_{E,w} = \pi_M^b \mathcal{O}_{E,w}$, and it contains $N_0 = M^b = \pi_M^b \bar\pi_M^b$ (Definition 2.3.4). By (b) of Lemma 6.4.84 with $\delta = N_0$, every $N_0 u_\chi$ is integral at every place above ℓ. With Step 0, $F = c\sum_\chi a_\chi\,\rho(\mathrm{fv}(ku_\chi))\,\omega(k)c_s^R v^0 \in \mathcal{M}_{\mathrm{fin}}$.

Step 2: values of characters of $\mathrm{U}(1)$**.** The edge characters α, β and the splitting character υ (Definition 3.2.12) are automorphic characters of $\mathrm{U}(1)$, and $\det g$, $\det h$, $\det k$ are finite adelic

elements u with $u\bar{u}=1$. By (a) of Lemma 6.4.85, $|\sigma(c)|=1$ for every $\sigma\in\mathrm{Aut}(\mathbb{C})$. If g,h and their inverses are integral at the places above ℓ, then so are k and k^{-1}, so $\det g$, $\det h$, $\det k$ are units at those places; as a prime identification $\iota\mid\ell$ followed by the inclusion of $\overline{\mathbb{Q}}_\ell$ in $\mathbb{C}_\ell$ is a ring homomorphism $\mathbb{C}\to\mathbb{C}_\ell$ (Definition 3.1.3), (b) of Lemma 6.4.85 shows that $\iota(c)$ and $\iota(\upsilon(1,\det k))$ are ℓ-adic units.

Step 3: a contraction bound for rectangular Schur matrices. For a family Y of complex $N'\times N$ matrices and $w\in\mathbb{V}_\kappa$ (rank N), $\|S_\kappa(Y)w\|_\kappa\le|Y|^B\|w\|_\kappa$, the left norm in the rank N' and $|Y|^2=\sum_\tau\sum_{b,a}|Y_{\tau,b,a}|^2$. Indeed, for a filling T' of κ in the rank N', the Cauchy–Binet formula expands each factor $\Delta_{A'}(Yy)$ of height $h'\le N$ as $\sum_A Y_\tau[A';A]\Delta_A(y)$ (A running over the h'-subsets of n; for $h'=N$ only $A=n$); comparing with (WM2) and using the uniqueness of coordinates there gives $F'_\kappa S_\kappa(Y)=\mathfrak{L}(Y)F_\kappa$, where F'_κ, F_κ are the filling matrices in the ranks N', N and $\mathfrak{L}(Y)$ is the matrix, in the standard wedge bases, of the tensor product over the factors of $\Lambda^{h'}Y_\tau$ ($h'<N$) and of $1\mapsto y_1\wedge\cdots\wedge y_N$ (the columns of Y_τ; $h'=N$). Each factor has operator norm at most $\|Y_\tau\|_{\mathrm{op}}^{h'}\le|Y|^{h'}$, so $\|S_\kappa(Y)w\|_\kappa=\|\mathfrak{L}(Y)F_\kappa w\|\le|Y|^B\|F_\kappa w\|=|Y|^B\|w\|_\kappa$ ((WM3)).

Step 4: clause (2). Let ϑ be the trivial twist and $\sigma\in\mathrm{Aut}(\mathbb{C})$. If σ does not fix K, replace it by $\mathrm{conj}\circ\sigma$, which fixes K; as the Gram matrices are real, complex conjugation of coordinates preserves both norms, so the claim for $\mathrm{conj}\circ\sigma$ gives it for σ. So let σ fix K, and let $t_\sigma,\epsilon_\sigma,\Theta=\Theta_{\sigma,F}$ be as in Lemma 4.2.16 for I_R and $F\in\mathcal{M}_{\mathrm{fin}}$ (Step 1). For $x\in\mathbb{A}^{\mathcal{C}}_{E,f}$, Steps 0 and 1 give $\theta_R(\rho(\mathrm{fv}(x))F)=c\sum_\chi a_\chi\zeta_\chi\,\mathcal{V}_R(x+ku_\chi,k)$ with roots of unity ζ_χ and $\mathcal{V}_R(x,k)=\theta_R(\rho(\mathrm{fv}(x))\omega(1,k)(c_s^Rv^0))$; by Steps 1, 2 and (2) of Lemma 6.4.83, $|\sigma\theta_R(\rho(\mathrm{fv}(x))F)|\le e^{A_R}$, $A_R=C_P(q_1(s)R+1)^2$. Since the $P_{i'i}$ have integer coefficients, (b) of Lemma 4.2.16 gives, coordinatewise,

$$\sigma(Jv)=\pi^{-D}\int_{\mathbb{C}^{\Phi\times\mathcal{C}}}S_\kappa\big(t_\sigma\bar{y}^{\epsilon_\sigma}\big)\,\sigma(v)\,e^{-|y|^2/2}\,\Theta(y)\,dy,$$

with $(t_\sigma\bar{y}^{\epsilon_\sigma})_\tau$ the $n'\times n$ matrix with entries $t_\sigma\overline{y_{\epsilon_\sigma(\tau),(b,a)}}$. By (a) of Lemma 4.2.16, $|\Theta|\le e^{A_R}$; by Step 3 and $|t_\sigma\bar{y}^{\epsilon_\sigma}|=|t_\sigma||y|=\Omega_s^{-1/2}|y|$,

$$\|\sigma(Jv)\|_\kappa\le e^{A_R}\,\Omega_s^{-B/2}\,\pi^{-D}\int|y|^Be^{-|y|^2/2}\,dy\;\|\sigma(v)\|_\kappa\le e^{A_R}\,4^D\,\big(2(B+1)\big)^{B/2}\,\Omega_s^{-B/2}\,\|\sigma(v)\|_\kappa,$$

using $|y|^Be^{-|y|^2/4}\le(2B)^{B/2}e^{-B/2}$ and $\pi^{-D}\int e^{-|y|^2/4}dy=4^D$ (for $B=0$, $\pi^{-D}\int e^{-|y|^2/2}dy=2^D$). Numerically, by Lemma 4.2.67: $n_m\le r+m(t+1)\le 3x^5+2\sqrt{x}(15x^5+1)\le x^6$, so $R\le 4x^{12}$; $f\le q_1\le x^{12}$, so $D\le 4x^{24}$ and $q_1R+1\le x^{25}$; $C_P\le\log x$ by (AD1), so $A_R\le x^{51}$ and $D\log 4\le x^{25}$. If $B\ge 1$: $B\le br^4\le 81bx^{20}$, $\log(2(B+1))\le\log(324\,b\,x^{20})\le 2\log b$ (as $x^{10^{12}}\le b$), $\log\Omega_s^{-1}\le\log\mathrm{rd}_E+|c_{\mathrm{CS}}(d)|\le 13\log x\le\log b$ (Lemma 5.2.13), and $\log b\le x^{1/100}$; so $\frac{B}{2}\big(\log(2(B+1))+\log\Omega_s^{-1}\big)\le\frac{3}{2}\cdot 81\,b\,x^{20}x^{1/100}\le bx^{22}$. Altogether the factor is at most $\exp(x^{51}+x^{25}+bx^{22})\le\exp(x^{99}b^2)$, which is (2).

Step 5: integrality at integral points. Let $\ell\nmid\mathrm{N}Q$, $\iota\mid\ell$, $\mathcal{O}_\iota=\{w\in\mathbb{C}:|\iota(w)|_\ell\le 1\}$, and suppose that g,h and their inverses are integral at the places above ℓ; then so are k and k^{-1}. Let $\mathcal{S}$ be the $\mathcal{O}_\iota$-span of the vectors $\rho(\mathrm{fv}(x))c_s^Rv^0$ with N_0x_w integral at every $w\mid\ell$, and $A_0=N_0^{fR}$. By Proposition 4.1.14 the finite operator $\omega(k)$ is the normalised finite kernel of Lemma 4.1.13, so $\omega(k)v^0=\frac{\Delta(k)}{I(k)}\sum_{y\in L/(L\cap k^{-1}L)}\zeta_y\,\rho(\mathrm{fv}(ky))v^0$ with $L=\widehat{\mathcal{O}}^{\mathcal{C}}_E$ and roots of unity ζ_y (the factor $s_L(ky)$ of Lemma 4.1.13 and the phase between its Heisenberg operator and $\rho(\mathrm{fv}(\cdot))$, both values of the finite additive character). Here $I(k)=[L:L\cap k^{-1}L]$ is prime to ℓ (the local indices above ℓ are 1), ky is integral above ℓ, and $\Delta(k)^2=I(k)\,\upsilon(1,\det k)^{-1}$ by $|\Delta(k)|^2=I(k)$ and $\overline{\Delta(k)}=\upsilon(1,\det k)\Delta(k)$, so $\iota(\Delta(k))$ is an ℓ-adic unit by Step 2. Together with Steps 0–2 ($\iota(c)$ a unit; $\iota(A_0a_\chi)\in\mathcal{O}_\iota$, as the ℓ-part of $\#T$ divides $M^{fbR}=A_0$; N_0ku_χ integral above ℓ; products of Heisenberg operators adding roots of unity) this gives $A_0F\in\mathcal{S}$.

By Proposition 4.2.35 with $C = \mathcal{C}$, $\delta = N_0$, $\zeta_{\mathrm{sc}} = 1$ and $Q = P_{i'i}$, and by Lemma 4.2.2 $(Q(\partial_Z)\mathscr{E}_{A_0F}(\eta_P Z)|_{Z=0} = \theta_R(v_{Q(\eta_P\cdot)} \otimes A_0F))$,

$$\left|\iota(A_0\,(N_0d)^B J_{i'i})\right|_\ell \le 1 \qquad \text{for all } i', i. \tag{M}$$

At such points the gauge is the maximum of the ℓ-adic absolute values of the coordinates, since $P_{\kappa,e}(f_\iota(g^{-1}))$ is an integral matrix with integral inverse $P_{\kappa,e}(f_\iota(g))$ (S_κ has integral polynomial entries, $\det f_\iota(g)$ is a unit). Hence, with $D_0 = A_0(N_0d)^B$, $\mathrm{gau}_\iota(h, D_0Jv) \le \mathrm{gau}_\iota(g, v)$.

Step 6: clause (1). Let g, h be arbitrary and $\ell \nmid \mathrm{N}Q$. Let R_ℓ be the set of places of E above ℓ, which is stable under conjugation. The set of $x \in \mathrm{G}(s_+) = G_\infty(s_+) \times G_f(n)$, s_+ the signs $+1$ on n (those of I_n), with $x_w \in g_w\mathrm{GL}_N(\mathcal{O}_{E,w})$ for every $w \in R_\ell$ is open and contains $(1, g)$; by Lemma 4.2.64 for I_n and R_ℓ it contains a product $\gamma'(1, k)$ with γ' a rational point of I_n and $k_w = 1$ for $w \in R_\ell$, so $\gamma'_w \in g_w\mathrm{GL}_N(\mathcal{O}_{E,w})$ there, and $\gamma = \gamma'^{-1}$ is a rational point of $\mathrm{U}(\mathrm{I}_n)$ with $\gamma_f g$ and its inverse integral above ℓ. In the same way there is a rational point δ of $\mathrm{U}(\mathrm{I}_{n'})$ with $\delta_f h$ and its inverse integral above ℓ. Write $J(g, h) = J^S_{z,j}(g, h)$. Since $(1, \gamma_f g) = \gamma \cdot (\gamma_\infty^{-1}, g)$, the rational invariance and the real part of the theta kernel $(\omega_{\alpha,\beta}, \theta_R)$ (Lemma 6.3.77) and (5) of Lemma 4.1.1 (all signs $+1$) give $J(\gamma_f g, \delta_f h)_{i'i} = \det(\bar\delta_\infty)^{e^{\det}_{z,j+1}} \det(\bar\gamma_\infty)^{-\gamma'} \theta_R(v_{Q'} \otimes F)$ with $Q'(X) = P_{i'i}(\eta_P\, \bar\delta_\infty X \bar\gamma_\infty^{-1})$ (for unitary x, $x^{-\mathsf{T}} = \bar x$ and $\det x^{-1} = \det \bar x$). By (WM2), $S_\kappa(zXw) = S_\kappa(z)S_\kappa(X)S_\kappa(w)\prod_\tau \det(w_\tau)^{\kappa(\tau,N)}$ for square z, w of sizes N', N (expand $b'_{i'}(zXwy)$ in three steps), and $e^{\det}_{z,j} = \gamma' + \kappa(\cdot, N)$ by (1) of Lemma 6.4.3; with $\rho_{\mathrm{s}} = \rho_{\kappa, e^{\det}_{z,j}}$, $\rho_{\mathrm{t}} = \rho_{\kappa, e^{\det}_{z,j+1}}$,

$$J(\gamma_f g, \delta_f h) = \rho_{\mathrm{t}}(\delta_\infty)\, J(g, h)\, \rho_{\mathrm{s}}(\gamma_\infty)^{-1}. \tag{N}$$

For a rational point γ, $f_{\iota,\tau}(\gamma_f) = \iota(\tau(\bar\gamma))$ and $\overline{\tau(\gamma)} = \tau(\bar\gamma)$ (E is CM), so $\iota(\rho_{\mathrm{s}}(\gamma_\infty)\xi) = P_{\kappa, e^{\det}_{z,j}}(f_\iota(\gamma_f))\iota(\xi)$, and multiplicativity of $P_{\kappa,e}$ and of f_ι gives $\mathrm{gau}_\iota(\gamma_f g, \rho_{\mathrm{s}}(\gamma_\infty)\xi) = \mathrm{gau}_\iota(g, \xi)$; likewise at the target. By these identities, (N) and Step 5 at the integral points $\gamma_f g$, $\delta_f h$,

$$\mathrm{gau}_\iota(h, D_0J(g, h)v) = \mathrm{gau}_\iota\big(\delta_f h, D_0J(\gamma_f g, \delta_f h)\rho_{\mathrm{s}}(\gamma_\infty)v\big) \le \mathrm{gau}_\iota(\gamma_f g, \rho_{\mathrm{s}}(\gamma_\infty)v) = \mathrm{gau}_\iota(g, v).$$

Finally $d_J/D_0 = N_0^{2f(2n_m)^2 - fR}(N_0d)^{br^4 - B}$ is a positive integer, as $R \le (2n_m)^2$ and $B \le br^4$, and multiplication by an integer does not increase an ℓ-adic gauge. This is (1). □

Lemma 6.4.83. *For every integer $N \ge 0$, let I_N be the standard positive hermitian space over E_s, with Gram matrix and framed point both the identity, and let $v_{0,N}$ be its unit vacuum. For arbitrary $x \in \mathbb{A}^N_{E_s,f}$ and $k \in G_f(N)$ put*

$$\mathcal{V}_N(x, k) = \theta_{I_N}(\rho(\mathrm{fv}\, x)\omega(1, k)(c_s^N v_{0,N})).$$

Then:

1. *For every prime ℓ and every ring homomorphism $\iota : \mathbb{C} \to \mathbb{C}_\ell$, $\|\iota(\mathcal{V}_N(x, k))\|_\ell \le 1$.*
2. *For every field automorphism σ of $\mathbb{C}$,*

$$|\sigma(\mathcal{V}_N(x, k))| \le \exp\big(C_P(q_1(s)N + 1)^2\big).$$

The choices of c_s, theta functional and vacuum are fixed before $N, x, k, \ell, \iota, \sigma$. Rank zero uses the empty tensor and has value 1. These assertions concern theta values in standard positive spaces; they assert neither a bound on raw coherent coefficients nor an arbitrary-signature statement.

Proof. Put $R = N$ and $q = q_1(s)$. Rank zero is immediate, so assume $R > 0$. Throughout the proof all spaces are standard positive and all theta values use the functional in the statement. The coherent action, its unitarity and covariance are Lemma 4.1.1; tensor theta factorization and rational invariance are Lemma 4.1.17. In normalized finite coordinates write $\mathsf{R}_f(x) = \rho(\mathrm{fv}\, x)$, $L = \widehat{\mathcal{O}}_E^R$. These coordinates are the canonical finite coordinates, with the fixed theta functional and vacuum scale.

We first identify its finite factor without any scalar ambiguity. A finite-part vector has coefficient $e^{-|x_\infty|^2/2}\varphi(x_f/\alpha)$ in the normalized coordinates of (WD6). For a finite unitary g, (WR3) gives a product integral. The real factor is

$$e^{-|x_\infty|^2/2}\pi^{-fR}\int_{\mathbb{C}^{fR}} e^{-|u|^2+\bar{x}_\infty\cdot u}\,du = e^{-|x_\infty|^2/2}.$$

The equality follows coordinatewise by angular integration of the exponential; its nonconstant holomorphic monomials have integral zero, and Gaussian domination justifies the expansion. The finite factor, with $L = \widehat{\mathcal{O}}_E^R$, is therefore exactly

$$(\Omega(g)\varphi)(z) = \Delta(g)\int \varphi(y)\psi_0(z^*gy/2)v_0(z-gy)\,d\mu(y), \qquad \mu(L) = 1,$$

where $\psi_0(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$, $v_0(z) = \psi_0(c_0 z^* z/2)\mathbf{1}_L(z)$ and $\Delta(g) = \upsilon_f(\det u_g)|\det u_g|_f^{-1/2}$, $u_g L = L \cap g^{-1}L$. This is the literal operator of Lemma 4.1.13. Thus its vacuum expansion and scalar identities apply to the selected action itself.

The hypotheses of Lemma 4.1.13 hold in these coordinates. Indeed $c_0 = (1-\jmath^{-1})/2 = (1+\sqrt{-d})/2 \in \mathcal{O}_K$. The prescribed ideal $\alpha\bar{\alpha} = \mathfrak{D}_{E/K}^{-1}$ and $\mathfrak{D}_{E/\mathbb{Q}} = \sqrt{-d}\mathfrak{D}_{E/K}$ show that $\jmath\alpha\bar{\alpha}$ generates the absolute inverse different locally, so the trace character has integral self-dual lattice $\widehat{\mathcal{O}}_E$. The splitting character is unitary and trivial on finite integral units. Also $\upsilon_f(\bar{t}) = \upsilon_f(t)^{-1}$: their product is its restriction to the norm idele $t\bar{t}$, and the quadratic character of E/F is trivial on local norms. These are precisely the character and lattice hypotheses of that lemma.

Finite integrality and positive rational transport. The rank-one property of the SAME c_s supplied by Proposition 4.2.1, with its fixed-scale specification, and exact tensor factorization give

$$\theta(\mathsf{R}_f(x)c_s^R v^0) = \prod_i c_s\theta_+(\mathsf{R}_f(x_i)v_+^0).$$

Every factor is integral at every prime under every embedding. For $k \in G_f(R)$ put $J = L\cap k^{-1}L$, $I = [L:J]$. The finite expansion just identified gives

$$\theta(\mathsf{R}_f(x)\omega(k)c_s^R v^0) = \frac{\Delta(k)}{I}\sum_{y\in L/J}\xi_{x,y}\theta(\mathsf{R}_f(x+ky)c_s^R v^0),$$

where every $\xi_{x,y}$ is a value of the finite additive character, hence a root of unity. In particular multiplying this expression by $I/\Delta(k)$ makes it integral at every prime. If k and its inverse are integral at the places above ℓ, then $\ell \nmid I$. The splitting-character value $\upsilon_f(\det k)$ is an ℓ-unit under every embedding: principalize a power of the determinant ideal, then divide its generator by its conjugate. The resulting norm-one element is a unit above ℓ, and the principal-idele character relation expresses a positive power of the character value as a root of unity times integral powers of its algebraic conjugates. Those conjugates are ℓ-units. Since $\upsilon_f(\det k)\Delta(k)^2 = I$, the factor $\Delta(k)/I$ is also an ℓ-unit. The ultrametric inequality proves integrality for such k.

For a general k, we justify the required rational approximation explicitly. Put $F = E^+$. At each $v \mid \ell$ choose a unitary u_v arbitrarily close to k_v^{-1} with $1+u_v$ invertible. This is possible

by multiplying k_v^{-1} by the scalar $(1+t_v\jmath)/(1-t_v\jmath)$ for sufficiently small $t_v \in F_v$, avoiding the finitely many zeros of its determinant. The Cayley matrix $B_v = (1-u_v)(1+u_v)^{-1}$ is skew hermitian. Such matrices form an F-linear space. Number-field weak approximation therefore supplies a single rational skew-hermitian B close to all B_v. Arrange that $1+B$ is invertible and put $\gamma = (1-B)(1+B)^{-1} \in U(I_R)(F)$. Then $\gamma_v k_v$ and its inverse are integral at all $v \mid \ell$.

There is no archimedean multiplier in this step. In (WR3) the negative block is empty, so its real multiplier is 1. Changing variables by the unitary γ_∞ preserves the Gaussian, the measure and the reproducing kernel, and gives $\omega(\gamma_\infty)v^0 = v^0$ exactly. It also fixes every finite translate of v^0. Rational theta invariance and Heisenberg covariance consequently give the exact identity

$$\theta(\mathsf{R}_f(x)\omega(1,k)c_s^R v^0) = \theta(\mathsf{R}_f(\gamma_f x)\omega(1,\gamma_f k)c_s^R v^0).$$

The integral-operator case applies to its right side at ℓ. Since ℓ and the embedding were arbitrary, this proves (1). This argument is why the assertion is restricted to the standard positive space.

Conjugate theta values. Apply Lemma 4.2.14(CT10) in rank $R = N$, with the SAME parameter pair P, field E_s, standard positive space I_R, fixed theta functional, finite coordinates, scale c_s and constant C_P as in the statement. Its hypotheses are exactly those already fixed here: $R \geq 1$, x is an arbitrary finite vector, and k is an arbitrary finite unitary element. Its conclusion applies to every automorphism σ of $\mathbb{C}$ and reads

$$\left|\sigma\theta_{\mathrm{I}_R}(\mathsf{R}_f(x)\omega(1,k)c_s^R v_{0,R})\right| \leq \exp\!\big(C_P(q_1(s)R+1)^2\big).$$

This theta value is precisely $\mathcal{V}_N(x,k)$ in the statement. In particular, this application retains the fixed scaled vacuum: the scalar bounded in (CT8) of that lemma is $\sigma(c_s^R)C_{\sigma,R,\mathcal{A}}$, rather than the unscaled transport scalar. The map and all its factors in that lemma are chosen before x and k; neither this application nor its bound reselects c_s or the theta normalization. The all-automorphism scope is expressly (CT10), so no extension of its semilinear-map assertion beyond automorphisms fixing K is needed. This proves (2). Rank zero was the empty tensor case at the start. □

Lemma 6.4.84. *Let $\mathfrak{m}$ be a modulus, $A = \Sigma(\mathfrak{m})$, C a finite index set, s signs on C, $T = R_{\mathfrak{m}}^C$ and $\widehat{T}$ the group of characters of T. Then $\#T = \mathrm{N}(\mathfrak{m})^{\#C}$, and there are vectors $u_\chi \in \mathbb{A}_{E,f}^C$ ($\chi \in \widehat{T}$), with components 0 at every place outside $\bar{A}$, such that for every function Ψ on T, in $\mathcal{M}_s$,*

$$\Psi^\natural \otimes_A v^0 = \sum_{\chi\in\widehat{T}} a_\chi(\Psi)\,\rho(\mathrm{fv}(u_\chi))\,v^0, \qquad a_\chi(\Psi) = \frac{1}{\#T}\sum_{X\in T}\Psi(X)\,\overline{\chi(X)}.$$

Moreover:

- *(a) $\sum_\chi |\sigma(a_\chi(\Psi))| \leq \sum_{X\in T}|\sigma(\Psi(X))|$ for every automorphism σ of $\mathbb{C}$;*
- *(b) if p is a prime and $\delta \geq 1$ an integer with $\delta \in \mathfrak{m}\mathcal{O}_{E,w}$ for every $w \in A$ above p, then every δu_χ has integral components at every place of E above p.*

Proof. Put $\psi_0(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$, $Q_A = \prod_{w\in A} E_w^C$ and $L_A = \prod_{w\in A}\mathcal{O}_{E,w}^C$. By Lemma 4.1.3, $\widehat{\mathcal{O}}_E^C$ is its own annihilator under $(u,x) \mapsto \psi_0(\bar{u}^{\mathsf{T}}x)$. Since A is the set of places of $\mathfrak{m}$, the reduction map identifies $L_A/\mathfrak{m}L_A$ with T (Chinese remainder theorem), and $\#T = \#(\mathcal{O}_E/\mathfrak{m})^{\#C} = \mathrm{N}(\mathfrak{m})^{\#C}$.

Step 1: the characters of T. Let $\bar{\mathfrak{m}}$ be the conjugate ideal and $U = \bar{\mathfrak{m}}^{-1}\widehat{\mathcal{O}}_E^C$. For $u \in U$ and $x \in L_A$ (read as a finite adelic vector with components 0 off A) put $\chi_u(x) = \psi_0(\bar{u}^{\mathsf{T}}x)$, a character of L_A. For $\mu \in \mathfrak{m}$ and $x \in L_A$, $\bar{u}^{\mathsf{T}}(\mu x) = \overline{(\bar{\mu}u)}^{\mathsf{T}}x$ with $\bar{\mu}u \in \widehat{\mathcal{O}}_E^C$, so $\chi_u(\mu x) = 1$ by

self-duality; as $\mathfrak{m}L_A$ is generated by such μx, χ_u is trivial on $\mathfrak{m}L_A$, and χ_u is a character of T; it is trivial when $u \in \widehat{\mathcal{O}}_E^C$. So $u \mapsto \chi_u$ is a homomorphism $U/\widehat{\mathcal{O}}_E^C \to \widehat{T}$. It is injective: as $\bar{\mathfrak{m}}^{-1}\mathcal{O}_{E,w'} = \mathcal{O}_{E,w'}$ for $w' \notin \bar{A}$, every class has a representative u with components 0 off $\bar{A}$; then $\bar{u}$ vanishes off A, so $\psi_0(\bar{u}^{\mathsf{T}}x) = \chi_u(x_A)$ for every $x \in \widehat{\mathcal{O}}_E^C$, and if $\chi_u = 1$ then u annihilates $\widehat{\mathcal{O}}_E^C$, so $u \in \widehat{\mathcal{O}}_E^C$. Both groups have $\mathrm{N}(\mathfrak{m})^{\#C}$ elements ($\#(\bar{\mathfrak{m}}^{-1}\widehat{\mathcal{O}}_E/\widehat{\mathcal{O}}_E) = \mathrm{N}(\bar{\mathfrak{m}}) = \mathrm{N}(\mathfrak{m})$, and $\widehat{T} \cong T$), so the map is bijective. For each $\chi \in \widehat{T}$ let $u_\chi \in U$ be the representative with components 0 off $\bar{A}$ of the class with $\chi_{u_\chi} = \chi$.

Step 2: the expansion. By Fourier inversion on the finite abelian group T, $\Psi = \sum_\chi a_\chi(\Psi)\chi$. Read as a function on Q_A, $\Psi^\natural$ is $x \mapsto \Psi(x \bmod \mathfrak{m})$ on L_A and 0 off L_A, so $\Psi^\natural = \sum_\chi a_\chi(\Psi)\,(\chi \circ \mathrm{red})\,\mathbf{1}_A$, with $\mathbf{1}_A$ the indicator of L_A. In the notation of (2) of Lemma 4.1.3, $(R_A(u_\chi)\mathbf{1}_A)(x) = \psi_0(\bar{u}_\chi^{\mathsf{T}}(2x + u_\chi)_A/2)\mathbf{1}_A(x + (u_\chi)_A) = \psi_0(\bar{u}_\chi^{\mathsf{T}}x_A)\mathbf{1}_A(x) = \chi(x \bmod \mathfrak{m})\mathbf{1}_A(x)$, because $(u_\chi)_A = 0$ (A contains no conjugate of its members). The map $\Psi' \mapsto \Psi' \otimes_A v^0$ is linear ((WR6): the section is linear), and by (2) and (3) of Lemma 4.1.3, $(R_A(u_\chi)\mathbf{1}_A) \otimes_A v^0 = \rho(\mathrm{fv}(u_\chi))(\mathbf{1}_A \otimes_A v^0) = \rho(\mathrm{fv}(u_\chi))v^0$. This gives the displayed identity.

Step 3: (a). The values of χ are roots of unity, so $|\sigma(\overline{\chi(X)})| = 1$ and $|\sigma(a_\chi(\Psi))| \le (\#T)^{-1}\sum_X |\sigma(\Psi(X))|$; summing over the $\#\widehat{T} = \#T$ characters gives (a).

Step 4: (b). The components of u_χ vanish except at the places $\bar{w}$, $w \in A$. A place of E above p at which u_χ does not vanish is therefore $\bar{w}$ with $w \in A$ above p; there $\delta \in \mathfrak{m}\mathcal{O}_{E,w}$ gives $\delta = \bar{\delta} \in \bar{\mathfrak{m}}\mathcal{O}_{E,\bar{w}}$, so $\delta(u_\chi)_{\bar{w}} \in \delta\bar{\mathfrak{m}}^{-1}\mathcal{O}_{E,\bar{w}}^C \subseteq \mathcal{O}_{E,\bar{w}}^C$. □

Lemma 6.4.85. *Let χ be an automorphic character of $\mathrm{U}(1)$ and let $u \in \mathbb{A}_{E,f}$ with $u\bar{u} = 1$, read as the element of $\mathrm{U}(1)(\mathbb{A})$ with components 1 at the infinite places. Then:*

(a) $|\sigma(\chi(u))| = 1$ for every automorphism σ of $\mathbb{C}$;

(b) if p is a prime such that the component of u at every place of E above p is a unit, then $|\iota(\chi(u))|_p = 1$ for every ring homomorphism $\iota\colon \mathbb{C} \to \mathbb{C}_p$.

Proof. **Step 1: the infinite part and an open subgroup in the kernel.** For $v \in \Phi$ the component group $\{z \in \mathbb{C} : z\bar{z} = 1\}$ is the circle, and the restriction of χ to it is a continuous character, so it is $z \mapsto z^{n(v)}$ for an integer $n(v)$. The restriction of χ to the finite part $\mathrm{U}(1)(\mathbb{A}_f) = \{u \in \mathbb{A}_{E,f} : u\bar{u} = 1\}$ is continuous, so some open subgroup U_1 of the compact open group $\mathrm{U}(1)(\widehat{\mathcal{O}}_F) = \mathrm{U}(1)(\mathbb{A}_f) \cap \widehat{\mathcal{O}}_E^\times$ is mapped into $\{z : |z| = 1,\ \mathrm{Re}\, z > 0\}$; its image is a subgroup of the circle contained in that arc, hence trivial. So χ is trivial on U_1.

Step 2: a power of u is rational up to U_1. By (K) of Theorem A.4.1 for the torus $G = \mathrm{U}(1)$ over F and $K_f = U_1$, the group $\mathrm{U}(1)(\mathbb{A})$ is the union of finitely many sets

$$\mathrm{U}(1)(F)x_i\mathrm{U}(1)(F_\infty)U_1;$$

projecting to the finite part, the abelian group $\mathrm{U}(1)(F)\backslash\mathrm{U}(1)(\mathbb{A}_f)/U_1$ is finite. Hence there are an integer $q \ge 1$, $\gamma \in E$ with $\gamma\bar{\gamma} = 1$ and $u_1 \in U_1$ with $u^q = \gamma_f u_1$, where γ_f is the finite part of the diagonal image of γ.

Step 3: the value. As χ is trivial on the diagonal image $(\gamma_\infty, \gamma_f)$ of γ and on U_1,

$$\chi(u)^q = \chi((1, \gamma_f)) = \chi((\gamma_\infty, 1))^{-1} = \prod_{v \in \Phi} v(\gamma)^{-n(v)},$$

$v(\gamma)$ the image of γ under the embedding chosen at v. So $\chi(u)$ is algebraic.

(a) For $\sigma \in \mathrm{Aut}(\mathbb{C})$ and $v \in \Phi$, $\sigma \circ v$ is an embedding of the CM field E into $\mathbb{C}$, so it commutes with complex conjugation and $|\sigma(v(\gamma))|^2 = (\sigma \circ v)(\gamma\bar{\gamma}) = 1$. Hence $|\sigma(\chi(u))|^q = |\sigma(\chi(u)^q)| = \prod_v |\sigma(v(\gamma))|^{-n(v)} = 1$, and $|\sigma(\chi(u))| = 1$.

(b) At every place w of E above p, $\gamma = u^q u_1^{-1}$ has a unit component (u_w is a unit by hypothesis, $u_{1,w}$ as $u_1 \in \widehat{\mathcal{O}}_E^\times$). For $v \in \Phi$, $\iota \circ v$ is an embedding of E into $\mathbb{C}_p$, and $|\iota(v(y))|_p$ is the absolute value of y at a place of E above p; so $|\iota(v(\gamma))|_p = 1$, and $|\iota(\chi(u))|_p^q = \prod_v |\iota(v(\gamma))|_p^{-n(v)} = 1$. □

Lemma 6.4.86. *Let D be admissible data, $f = \#\Phi$, $G = \exp(x^{99}b^2)$, $V_1 = \#(\mathcal{O}_E/\mathfrak{b})^{2n_m}$ and $T_1 = \#(\mathcal{O}_E/\mathfrak{b})^{8mn_m^2}$. Then:*

(1) for $z \in \{\mathrm{I}, \mathrm{II}\}$ and $0 \le j \le m$, the number of double cosets $\Gamma_{n_{z,j}} \backslash G_f(n_{z,j}) / \mathrm{K}_1(z,j)$ (for the finite components of the rational points) is at most G;

(2) $2m \log d_J + fm\,(br^4 + 20b) \log(M^b q_1) \le x^{99}b^2$;

(3) $V_1^{m^2}\, T_1^2\, G^{4m+1}\, \left((br^4)^{br^4}\right)^3 \le \exp(x^{200}b^2)$.

Proof. We use, from Lemma 4.2.67 and Lemma 2.3.6: $x \ge e^{6.4\cdot 10^{15}}$, $(\log b)^{100} \le x$, $x^{10^{12}} \le b$, $r \le 3x^5$, $m \le 2\sqrt{x}$, $t \le 15x^5$, $f \le q_1 \le x^{12}$, $\log M \le 22 \log b$, and $d \le C_P \le \log x$. Hence $n_m = r + 1 + mt \le 34x^{11/2}$ and every rank $N_{z,j}$ ($j \le m$) satisfies $N_{z,j} \le r + 1 + 2mt \le 2n_m \le 68x^{11/2}$. As $[E : K] = f$, the norm of π_M from E to $\mathbb{Q}$ is M^f, so $\#(\mathcal{O}_E/\mathfrak{b}) = M^{fb}$ and $\log \#(\mathcal{O}_E/\mathfrak{b}) = fb \log M \le 22x^{12} b \log b$. Below, $\log b \le x^{1/100}$ and $b \ge x^{10^{12}}$ absorb all factors x^c with $c \le 10$.

(1). Let $n = n_{z,j}$. The level $\mathrm{K}_1(z,j)$ is the kernel of the reduction $\mathbf{K}_0(n) \to \mathrm{GL}_n(\mathcal{O}_E/\mathfrak{b})$ ((LQ2), $\mathfrak{m}_1 = \mathfrak{b}$), so $[\mathbf{K}_0(n) : \mathrm{K}_1(z,j)] \le \#(\mathcal{O}_E/\mathfrak{b})^{(\#n)^2}$, and every double coset $\Gamma x \mathbf{K}_0(n)$ is the union of the at most $[\mathbf{K}_0(n) : \mathrm{K}_1(z,j)]$ double cosets $\Gamma x k \mathrm{K}_1(z,j)$, $k \in \mathbf{K}_0(n)/\mathrm{K}_1(z,j)$. By Lemma 4.6.4, applied with $1 \le \#n \le 2n_m$ to the standard definite space I_n and $\mathrm{K} = \mathbf{K}_0(n)$, the stabiliser of $\widehat{\mathcal{O}}_E^n$, which contains its principal congruence subgroup of level $\pi_M \pi_N$, the number of double cosets $\Gamma x \mathbf{K}_0(n)$ is at most $\exp(x^{30})$; so the logarithm of the number of double cosets for $\mathrm{K}_1(z,j)$ is at most

$$x^{30} + (68x^{11/2})^2 \cdot 22x^{12} b \log b \le x^{30} + 1.1 \cdot 10^5 x^{23} b \log b \le x^{99} b^2.$$

(2). With $\log d \le \log x$,

$$\begin{aligned} \log d_J &= 2f(2n_m)^2 b \log M + br^4(b \log M + \log d) \\ &\le 2.1 \cdot 10^5 x^{23} b \log b + 1782\, x^{20} b^2 \log b + 81 x^{20} b \log x \le 2000\, x^{20} b^2 \log b, \end{aligned}$$

so $2m \log d_J \le 8000\, x^{41/2} b^2 \log b \le x^{21} b^2$. Further $fm \le 2x^{25/2}$, $br^4 + 20b \le 82x^{20}b$ and $\log(M^b q_1) \le 22 b \log b + 12 \log x \le 23 b \log b$, so $fm(br^4 + 20b) \log(M^b q_1) \le 3772\, x^{65/2} b^2 \log b \le x^{33} b^2$. The sum is at most $2x^{33}b^2 \le x^{99}b^2$.

(3). The logarithm of the left side is $m^2 \log V_1 + 2 \log T_1 + (4m+1)x^{99}b^2 + 3br^4 \log(br^4)$. Here $m^2 \log V_1 = 2m^2 n_m f b \log M \le 4x \cdot 68x^{11/2} \cdot 22x^{12} b \log b \le 6000\, x^{37/2} b \log b$, $2 \log T_1 = 16 m n_m^2 f b \log M \le 16 \cdot 2\sqrt{x} \cdot 1156 x^{11} \cdot 22 x^{12} b \log b \le 9 \cdot 10^5 x^{47/2} b \log b$, $(4m+1)x^{99}b^2 \le 9x^{199/2}b^2$, and, as $\log(br^4) \le \log b + \log 81 + 20 \log x \le 2 \log b$, $3br^4 \log(br^4) \le 486\, x^{20} b \log b$. The total is at most $10\, x^{199/2} b^2 \le x^{200} b^2$. □

The next group moves periods from the first path to the last (Proposition 6.4.87), in m^2 turns, one at each position (i,j), with bound V^{m^2}, where $V(\vartheta) = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{2n_m}$, and with a constant whose absolute value is $\prod_{0 \le i,j < m} \tau_{ij}$ up to a norm power. A turn off the diagonal is the square law of a unit square (Lemma 6.4.89), an instance of the one-square identity, and costs one turn ratio. A turn on the diagonal also moves the meeting node of the two halves: two seesaws

in the sense of Kudla [171] compare the periods with periods over the subdiagonal space, and between them the line added at the diagonal is reversed by a Fourier transform (Lemma 6.4.94; see [322]).

Proposition 6.4.87. *Let D be admissible data and $V(\vartheta) = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{2n_m}$. There is a function c from the m-fold twists to $\mathbb{C}^\times$, of absolute value $\prod_{0\le i,j<m}\tau_{ij}$ up to a norm power, such that the first path transfers periods to the last path with bound V^{m^2} and constant c.*

Proof. **Step 1: transfers compose.** (i) $\Gamma \xrightarrow{1,1} \Gamma$ for every path Γ: given path data Ψ' of bound N on the edges of Γ, take $\Psi = \Psi'$. (ii) If $\Gamma' \xrightarrow{k,c} \Gamma$ and $k \le k'$ pointwise, then $\Gamma' \xrightarrow{k',c} \Gamma$, since a sum of at most kN roots of unity is a sum of at most $k'N$ of them (add zeros: 0 is the empty sum), so (PD4) passes to the larger bound and (PD1)–(PD3) do not involve it. (iii) If $\Gamma_1 \xrightarrow{k,c} \Gamma_2$ and $\Gamma_2 \xrightarrow{k',c'} \Gamma_3$, then $\Gamma_1 \xrightarrow{kk',cc'} \Gamma_3$: path data Ψ_1 of bound N on Γ_1 give Ψ_2 of bound kN on Γ_2 and then Ψ_3 of bound $k'kN$ on Γ_3; if $\Psi_3 \propto_{\Gamma_3} \Xi$, then $\Psi_2 \propto_{\Gamma_2} \Xi/c'$, and applying the first transfer to the function Ξ/c' gives $\Psi_1 \propto_{\Gamma_1} \Xi/(cc')$.

Step 2: one turn. For $s = (i,j)$ with $0 \le i,j < m$ let c_s be the function of Lemma 6.4.88 if $i \ne j$ and that of Lemma 6.4.93 if $i = j$; it has absolute value τ_{ij} up to a norm power. Every turn at s from a path Γ' to a path Γ gives $\Gamma' \xrightarrow{V,c_s} \Gamma$: for $i = j$ this is Lemma 6.4.93; for $i \ne j$, Lemma 6.4.88 gives bound 1, and $1 \le V$ because $V(\vartheta)$ is a positive integer, so Step 1 (ii) applies. The function c_s depends only on s, not on the path.

Step 3: the squares of a path. For a half p (a monotone path from $(0,m)$ to (l,l)) let $\mathrm{sq}(p)$ be the union, over the steps down $(a,b+1) \to (a,b)$ of p, of the sets $\{(i,b) : 0 \le i < a\}$. For a path Γ with $l = l(\Gamma)$ put

$$\Sigma(\Gamma) = [0,l)^2 \ \cup\ \mathrm{sq}(\Gamma_{\mathrm{I}}) \ \cup\ \{(j,i) : (i,j) \in \mathrm{sq}(\Gamma_{\mathrm{II}})\},$$

the unit squares between the first path and Γ, named by their least corner. Along a half the first index rises from 0 to l and the second falls from m to l, so every step down $(a,b+1) \to (a,b)$ has $a \le l \le b$ and $b+1 \le m$; hence

$$\mathrm{sq}(p) \subseteq [0,l) \times [l,m) \quad \text{for every half } p, \qquad \text{and} \qquad \Sigma(\Gamma) \subseteq [0,m)^2. \tag{B}$$

We prove three facts.

(C1) $\Sigma(\text{first}) = \emptyset$ and $\Sigma(\text{last}) = [0,m)^2$. The first path has $l = 0$ and halves whose steps down all lie in the column $a = 0$, so all sets $\{(i,b) : i < 0\}$ are empty. The last path has $l = m$ and halves without steps down.

(C2) If Γ has a turn at s to Γ_1, then $s \in [0,m)^2$, $s \notin \Sigma(\Gamma)$ and $\Sigma(\Gamma_1) = \Sigma(\Gamma) \cup \{s\}$. Suppose first that the two coordinates of s differ. By Lemma 6.4.92 (a), applied to the turn from Γ to Γ_1, there are z and $a < b < m$ (the (z,i',j') there), with $s = (a,b)$ if $z = \mathrm{I}$ and $s = (b,a)$ if $z = \mathrm{II}$, such that Γ_z is a path q to $(a,b+1)$, the steps $(a,b+1) \to (a,b) \to (a+1,b)$, and a path r from $(a+1,b)$ to (l,l); the half $(\Gamma_1)_z$ has the steps $(a,b+1) \to (a+1,b+1) \to (a+1,b)$ instead, $l(\Gamma_1) = l$, and the other half is unchanged. As $(a+1,b)$ is a node of Γ_z and along a half the first index rises from 0 to l while the second falls from m to l, $a+1 \le l \le b$. The steps down of q and r are unchanged; the old step down contributes $\{(i,b) : i < a\}$ and the new one $\{(i,b) : i < a+1\}$, so $\mathrm{sq}((\Gamma_1)_z) = \mathrm{sq}(\Gamma_z) \cup \{(a,b)\}$. Moreover $(a,b) \notin \mathrm{sq}(\Gamma_z)$: the steps down of q end in rows $\ge b+1$, those of r in rows $< b$, and the old corner gives only $i < a$. The other two parts of $\Sigma(\Gamma)$ do not contain s: an element of $[0,l)^2$ has both coordinates $< l \le b$, and by (B) an element of sq of the other half has first coordinate

$< l \le b$ (so after the exchange of coordinates for $z = \mathrm{I}$ its second coordinate is $< b$). This gives $s \notin \Sigma(\Gamma)$ and $\Sigma(\Gamma_1) = \Sigma(\Gamma) \cup \{s\}$. Suppose next that $s = (j, j)$. By Lemma 6.4.92 (b), $l(\Gamma) = j$, both halves are paths q_z (the u_z there) to $(j, j+1)$ followed by the step down to (j, j), and Γ_1 has $l = j + 1$ and halves q_z followed by the step right to $(j + 1, j + 1)$. Then $\mathrm{sq}(\Gamma_z) = \mathrm{sq}(q_z) \cup \{(i, j) : i < j\}$ and $\mathrm{sq}((\Gamma_1)_z) = \mathrm{sq}(q_z)$, and

$$[0, j + 1)^2 = [0, j)^2 \cup \{(i, j) : i < j\} \cup \{(j, i) : i < j\} \cup \{(j, j)\},$$

so $\Sigma(\Gamma_1) = \Sigma(\Gamma) \cup \{(j, j)\}$. Every step down of q_z lies in a column $a \le j$, so $\mathrm{sq}(q_z)$ has first coordinates $< j$; hence $(j, j) \notin \Sigma(\Gamma)$. In both cases $s \in \Sigma(\Gamma_1) \subseteq [0, m)^2$ by (B).

(C3) Every path $\Gamma \neq \mathrm{last}$ has a turn. If some half has a step down followed at once by a step right, that corner is a turn. Otherwise in each half all steps right precede all steps down, so each half is l steps right followed by $m - l$ steps down, $l = l(\Gamma)$. If $l = m$, both halves run along the row m and $\Gamma = \mathrm{last}$. If $l < m$, both halves end with the step down $(l, l + 1) \to (l, l)$, and the turn on the diagonal at (l, l) applies.

Step 4: from every path to the last. For a path Γ put $T(\Gamma) = [0, m)^2 \setminus \Sigma(\Gamma)$ and $c_T = \prod_{s \in T} c_s$. We show by strong induction on $k = \#T(\Gamma)$ that

$$\Gamma \xrightarrow{V^{\#T(\Gamma)},\, c_{T(\Gamma)}} \mathrm{last}$$

for every path Γ. If $\Gamma = \mathrm{last}$, then $T(\Gamma) = \emptyset$ by (C1), and Step 1 (i) gives the claim with bound $V^0 = 1$ and the empty product 1. Otherwise (C3) gives a turn at some s from Γ to a path Γ_1, and by (C2) $s \in T(\Gamma)$ and $T(\Gamma) = T(\Gamma_1) \cup \{s\}$ with $s \notin T(\Gamma_1)$; so $\#T(\Gamma_1) = k - 1$. By Step 2, $\Gamma \xrightarrow{V, c_s} \Gamma_1$; by the induction hypothesis, $\Gamma_1 \xrightarrow{V^{k-1}, c_{T(\Gamma_1)}} \mathrm{last}$; by Step 1 (iii), $\Gamma \xrightarrow{V^k,\, c_s c_{T(\Gamma_1)}} \mathrm{last}$, and $c_s c_{T(\Gamma_1)} = c_{T(\Gamma)}$. For $\Gamma = \mathrm{first}$, (C1) gives $T(\mathrm{first}) = [0, m)^2$, with m^2 elements: the first path transfers periods to the last with bound V^{m^2} and constant $c = \prod_{0 \le i, j < m} c_{ij}$, which takes values in $\mathbb{C}^\times$.

Step 5: the absolute value. For each $s = (i, j)$ there are $C_s \in \mathbb{R}$ and $k_s \in \mathbb{Z}$ with $|c_s(\vartheta)|^2 = C_s \, \mathrm{N}Q(\vartheta)^{k_s} \, \tau_{ij}(\vartheta)^2$ for every ϑ. Multiplying over the m^2 pairs,

$$|c(\vartheta)|^2 = \Big(\prod_s C_s\Big) \, \mathrm{N}Q(\vartheta)^{\sum_s k_s} \Big(\prod_{0 \le i, j < m} \tau_{ij}(\vartheta) \Big)^2,$$

so c has absolute value $\prod_{0 \le i, j < m} \tau_{ij}$ up to a norm power. □

Lemma 6.4.88. *Let D be admissible data and $0 \le i, j < m$ with $i \neq j$. There is a function c_{ij} from the m-fold twists to $\mathbb{C}^\times$, of absolute value τ_{ij} up to a norm power, such that for every turn at (i, j) from a path Γ' through the two grids to a path Γ, the path Γ' transfers periods to Γ with bound 1 and constant c_{ij}.*

Proof. For a monotone path u in the grid z and an edge tuple S let $\mathrm{fm}_u(S)$ be the composite, along u, of the moves by the matrices of S: the transposed move

$$\mathrm{mv}_{((z,a',b'),(z,a',b'+1))}(S((z, a', b'), (z, a', b' + 1)))$$

for a step down from $(a', b' + 1)$ to (a', b'), the lift move

$$\mathrm{mv}_{((z,a',b'),(z,a'+1,b'))}(S((z, a', b'), (z, a' + 1, b')))$$

for a step right from (a',b'); so $\mathrm{fm}_u(S)$ depends only on the matrices of S on the edges of u, and the map along a concatenation of two paths is the composite of the two maps.

Step 1: the square and the constant. Put $(z,i',j') = (\mathrm{I},i,j)$ if $i<j$ and $(z,i',j') = (\mathrm{II},j,i)$ if $i>j$; then $i'<j'<m$. Apply Lemma 6.4.89 to the grid z and the square at (i',j'). It gives $\kappa\in\mathbb{C}$, a bijection $\sigma\colon n_{(z,i',j')}\sqcup n_{(z,i'+1,j'+1)}\to n_{(z,i',j'+1)}\sqcup n_{(z,i'+1,j')}$ and a function c from the m-fold twists to $\mathbb{C}^\times$ of absolute value τ up to a norm power, where $\tau=\tau_{i'j'}=\tau_{ij}$ if $z=\mathrm{I}$ and $\tau=\tau_{j'i'}=\tau_{ij}$ if $z=\mathrm{II}$. Put $c_{ij}=c$; it depends only on (i,j).

Step 2: the shape of a turn at (i,j). Let Γ arise from Γ' by a turn at (i,j), and put $l=l(\Gamma')$. By Lemma 6.4.92 (a) there are monotone paths q from $(0,m)$ to $(i',j'+1)$ and r from $(i'+1,j')$ to (l,l) in the grid z with

$$\Gamma'_z = q,\ (i',j'{+}1)\to(i',j')\to(i'{+}1,j'),\ r;\qquad \Gamma_z = q,\ (i',j'{+}1)\to(i'{+}1,j'{+}1)\to(i'{+}1,j'),\ r,$$

while $\Gamma_{\neg z}=\Gamma'_{\neg z}$ and $l(\Gamma)=l$. In the notation of Lemma 6.4.91 (case $i\neq j$) this is $p=(z,i',j')$, $p_{\mathrm{a}}=(z,i',j'+1)$, $p_{\mathrm{b}}=(z,i'+1,j')$, $p^+=(z,i'+1,j'+1)$, $T=\emptyset$, $B=n_{p_{\mathrm{b}}}$; so σ is a bijection $n_p\sqcup n_{p^+}\to n_{p_{\mathrm{a}}}\sqcup B$, and the character $\chi_\square$ of Lemma 6.4.89 is the character $\chi_{\mathrm{c}}=(\chi_{(p,p_{\mathrm{a}})}\chi_{(p,p_{\mathrm{b}})})^{-1}$ of Lemma 6.4.91. By Lemma 6.4.92 (a), the edges of q, of r and of $\Gamma'_{\neg z}$ are the edges of both paths other than the four edges of the square, so they form the set $\mathcal{E}_0$ of Lemma 6.4.91 (1). Since $T=\emptyset$, the matrices $v(S)$ and v' are the empty matrix, $\mathrm{tr}(v'v)=0$, $\psi(0)=1$, and the sums over v and over v' in Lemma 6.4.91 (2), (3) have one term; the matrix $y(S)$ has the row blocks $y_1=S(p,p_{\mathrm{a}})$, $y_2=S(p,p_{\mathrm{b}})$, and $x(S)$ the column blocks $x_1=S(p_{\mathrm{a}},p^+)$, $x_2=S(p_{\mathrm{b}},p^+)$.

Step 3: the new path data. Let N be a function from the m-fold twists to $\mathbb{N}$ and $\Psi'=(\Psi'_\vartheta)$ a family of path data of bound $N(\vartheta)$ on the edges of Γ'. For each ϑ, Lemma 6.4.91, applied with σ, the trivial additive character and Ψ'_ϑ, gives a path datum Ψ_ϑ of bound $\#(R_\vartheta)^0N(\vartheta)=1\cdot N(\vartheta)$ on the edges of Γ satisfying (3).

Step 4: the two periods differ by κ/c_{ij}. Fix a real point g of $\mathrm{U}(\tilde{Y}_l^l)$ and a period triple (ϑ,y',φ). For an edge tuple S supported on $\mathcal{E}_0$ define a form $f_S\in\mathcal{F}(p_{\mathrm{a}})$ and a linear functional l_S on $\mathcal{F}(p_{\mathrm{b}})$ by

$$\begin{aligned} z=\mathrm{I}:&\quad f_S=\mathrm{fm}_q(S)\,y',\qquad l_S(w)=\langle \mathrm{fm}_r(S)\,w,\ \mathrm{fm}_{\Gamma'_{\mathrm{II}}}(S)\,\varphi\rangle_{l,g},\\ z=\mathrm{II}:&\quad f_S=\mathrm{fm}_q(S)\,\varphi,\qquad l_S(w)=\langle \mathrm{fm}_{\Gamma'_{\mathrm{I}}}(S)\,y',\ \mathrm{fm}_r(S)\,w\rangle_{l,g};\end{aligned}$$

l_S is linear because the moves are linear maps and $\langle\cdot,\cdot\rangle_{l,g}$, the integral of the product of its two arguments over $[\mathrm{U}(Y_l^l)]$, is linear in each argument. Let J be the set of pairs (f,l) of a form $f\in\mathcal{F}(p_{\mathrm{a}})$ and a linear functional l on $\mathcal{F}(p_{\mathrm{b}})$, let $L_{(f,l)}$, $L'_{(f,l)}$ be the functions L, L' of Lemma 6.4.89 for ϑ, f and l, and $F(S,v')=(f_S,l_S)$. Since f_S and l_S involve only the matrices of S on the edges of q, r and $\Gamma'_{\neg z}$, which lie in $\mathcal{E}_0$, we have $(f_S,l_S)=(f_{S_0},l_{S_0})$ for every edge tuple S. For S supported on the edges of Γ', the map along Γ'_z is $\mathrm{fm}_r(S)\,\mathrm{mv}_{(p,p_{\mathrm{b}})}(y_2)\,\mathrm{mv}_{(p,p_{\mathrm{a}})}(y_1)\,\mathrm{fm}_q(S)$, so the term of S in (3.3) for Γ' is $\Psi'_\vartheta(S)\,L'_{F(S_0,v')}(y(S))$; for S supported on the edges of Γ, the map along Γ_z is $\mathrm{fm}_r(S)\,\mathrm{mv}_{(p_{\mathrm{b}},p^+)}(x_2)\,\mathrm{mv}_{(p_{\mathrm{a}},p^+)}(x_1)\,\mathrm{fm}_q(S)$, so the term of S for Γ is $\Psi_\vartheta(S)\,L_{F(S_0,v'(S))}(x(S))$. By Lemma 6.4.89, for every $(f,l)\in J$, $\sum_y\Psi_1(y)L'_{(f,l)}(y)=\frac{\kappa}{c_{ij}(\vartheta)}\sum_x\Phi_1(x)L_{(f,l)}(x)$ whenever Φ_1, Ψ_1 are matched for $(\sigma,\chi_{\mathrm{c}})$ over R_ϑ. So Lemma 6.4.91 (3), with $C=\kappa/c_{ij}(\vartheta)$, gives

$$\mathrm{per}_{\Gamma'}(\Psi';g)(\vartheta,y',\varphi)=\frac{\kappa}{c_{ij}(\vartheta)}\,\mathrm{per}_{\Gamma}(\Psi;g)(\vartheta,y',\varphi).\tag{6.104}$$

Step 5: the transfer. Let Ξ be a function of period triples with $\Psi\propto_\Gamma\Xi$. The paths Γ' and Γ have the same index l, so their periods are taken at the same real points g of $\mathrm{U}(\tilde{Y}_l^l)$. For such g there is $\beta\in\mathbb{C}$ with $\mathrm{per}_\Gamma(\Psi;g)(\vartheta,y',\varphi)=\beta\,\Xi(\vartheta,y',\varphi)$ for all period triples, and by (6.104)

$$\mathrm{per}_{\Gamma'}(\Psi';g)(\vartheta,y',\varphi)=\kappa\beta\cdot\Xi(\vartheta,y',\varphi)/c_{ij}(\vartheta)$$

for all period triples, with $\kappa\beta$ independent of the triple. Hence

$$\Psi' \propto_{\Gamma'} \big((\vartheta, y', \varphi) \mapsto \Xi(\vartheta, y', \varphi)/c_{ij}(\vartheta)\big).$$

Together with Step 3 this says that Γ' transfers periods to Γ with bound 1 and constant c_{ij}. $\square$

Lemma 6.4.89. *For a node p let n_p be the index set of its basis; for an m-fold twist ϑ put $R_\vartheta = \mathcal{O}_E/\mathfrak{m}_\vartheta$; for an edge $e = (p, q)$ and a matrix X over R_ϑ with rows n_q and columns n_p let $\mathrm{mv}_e(X)$ be the move along e with matrix X: the lift move $\mathcal{F}(p) \to \mathcal{F}(q)$ if the first index changes along e, the transposed move $\mathcal{F}(q) \to \mathcal{F}(p)$ if the second index changes.*

Let D be admissible data, $z \in \{\mathrm{I}, \mathrm{II}\}$ and $0 \le i, j < m$. Write $p_{00} = (z, i, j)$, $p_{01} = (z, i, j+1)$, $p_{10} = (z, i+1, j)$, $p_{11} = (z, i+1, j+1)$, and put $\tau = \tau_{ij}$ if $z = \mathrm{I}$ and $\tau = \tau_{ji}$ if $z = \mathrm{II}$. There are $\kappa \in \mathbb{C}$ (possibly 0), a bijection $\sigma\colon n_{p_{00}} \sqcup n_{p_{11}} \to n_{p_{01}} \sqcup n_{p_{10}}$ and a function c from the m-fold twists to $\mathbb{C}^\times$, of absolute value τ up to a norm power, with the following property. Let ϑ be an m-fold twist, $f \in \mathcal{F}(p_{01})$ and l a linear functional on $\mathcal{F}(p_{10})$. For a matrix x over R_ϑ with rows $n_{p_{11}}$ and columns $n_{p_{01}} \sqcup n_{p_{10}}$, with column blocks x_1, x_2, and a matrix y over R_ϑ with rows $n_{p_{01}} \sqcup n_{p_{10}}$ and columns $n_{p_{00}}$, with row blocks y_1, y_2, put

$$L(x) = l\big(\mathrm{mv}_{(p_{10},p_{11})}(x_2)\,\mathrm{mv}_{(p_{01},p_{11})}(x_1)\,f\big), \qquad L'(y) = l\big(\mathrm{mv}_{(p_{00},p_{10})}(y_2)\,\mathrm{mv}_{(p_{00},p_{01})}(y_1)\,f\big).$$

Then

$$\sum_y \Psi(y)\,L'(y) = \frac{\kappa}{c(\vartheta)} \sum_x \Phi(x)\,L(x)$$

for all functions Φ of the matrices x and Ψ of the matrices y that are matched for $(\sigma, \chi_\square)$ over R_ϑ, where $\chi_\square = \big(\chi_{(p_{00},p_{01})}\,\chi_{(p_{00},p_{10})}\big)^{-1}$.

Proof. Fix D, z, i, j, and write $[z] = 0$ if $z = \mathrm{I}$, $[z] = 1$ if $z = \mathrm{II}$. By (GP5) the basis of the node (z, a, b) has $r + [z] + a(t + [z]) + b(t - [z])$ elements. Put $N_{ab} = \mathrm{rk}\, p_{ab}$; then

$$N_{11} = N_{00} + 2t, \qquad N_{00} + N_{11} = N_{01} + N_{10} = N_\square := 2r + 2[z] + (2i+1)(t+[z]) + (2j+1)(t-[z]),$$

and $N_\square$ is even, as $(2i+1)(t+[z]) + (2j+1)(t-[z]) \equiv 2t \pmod 2$. For a flag c, $l \ge 0$ and a rank N write $\mathrm{ec}_{c,l}(N)$ for the edge character of (GP6); its weight $\gamma_{c,l}(N)$ does not depend on the twist. Put $h = j + 1$ if $z = \mathrm{I}$ and $h = i + 1$ if $z = \mathrm{II}$, $\mu^\square = \mu^0_{i+1}\mu^0_{j+1}$, $\nu_\vartheta = (\mu^\square \vartheta^h)^{-1}$ for an m-fold twist ϑ, and $\mu_\square(v) = \kappa_{i+1}(v) + \kappa_{j+1}(v)$ for $v \in \Phi$.

Step 1: numerical facts. By Lemma 2.3.6, $\log x > 0$, so the integer x is at least 2. By (AD2), $m \le 2\sqrt{x}$ and $r \ge x^5$; hence $m + 1 \le 3\sqrt{x} \le x^5 \le r$ and $26m \le 52\sqrt{x} \le 12x^{35} \le 12r^7$. By (AD4), $\kappa(v) > 0$, so $\kappa_l(v) = \kappa(v) + (2l+1)r^8 \ge 3r^8$ for $l \ge 1$. By Lemma 2.3.6, $q_0 \ge 18480$, and $d \ge 1$, $s = 22(e+1)$, $m = 2^{e+1}$ by (AD2); so $q_2 \ge 2^{s+6} > 2^{e+2} = 2m$.

Step 2: the grid modulus. By Lemma 6.4.90, $\mathfrak{m}_\vartheta$ is a modulus with $\Sigma(\mathfrak{m}_\vartheta) = S_M \sqcup Q$, and so $\prod_{w \in \Sigma(\mathfrak{m}_\vartheta)} \mathrm{N}w = \mathrm{N}S_M \cdot \mathrm{N}Q$ with $\mathrm{N}S_M = \prod_{w \in S_M} \mathrm{N}w$.

Step 3: tameness and the character of the square. If two automorphic characters of $\mathrm{U}(1)$ have weights e, e' and tame parts ψ, ψ', their product has weight $e + e'$ and tame part $\psi\psi'$, and the inverse of the first has weight $-e$ and tame part ψ^{-1} (the defining formula of Definition 3.1.2). Let ψ be the tame part of ϑ. Then ν_ϑ has weight $\mu_\square$ (ϑ has weight 0) and tame part $\psi_\nu = (\omega^{i+j+2}\psi^h)^{-1}$. At a chosen place w, $\psi_w = 1$ (as $w \notin Q$) and $\omega_w^{i+j+2} \ne 1$, since ω_w has order q_2 and $2 \le i + j + 2 \le 2m < q_2$ (Step 1). At $w \in Q$, $\omega_w = 1$ and $\psi_w^h \ne 1$, since $1 \le h \le m$ and ϑ is an m-fold twist. At every other place both are trivial. So ν_ϑ is tame of weight $\mu_\square$ for $(\mathfrak{m}_\vartheta, \chi_\vartheta)$, where $\chi_\vartheta(u) = \prod_{w \in \Sigma(\mathfrak{m}_\vartheta)} \psi_{\nu,w}(u \bmod w)$ for $u \in R_\vartheta^\times$. By (GP6), of the two edges (p_{00}, p_{01}) (the second index changes, $l = j$) and (p_{00}, p_{10}) (the first

index changes, $l = i$), exactly one is vertical: the first if $z = \mathrm{I}$, the second if $z = \mathrm{II}$. So for $u \in R_\vartheta^\times$, $\chi_{(p_{00},p_{01})}(u)\chi_{(p_{00},p_{10})}(u) = \prod_w(\omega^{i+j+2}\psi^h)_w(u \bmod w)$, and $\chi_\square(u) = \chi_\vartheta(u)$. Matching (XD6) evaluates the character only at determinants of invertible matrices; hence functions are matched for $(\sigma, \chi_\square)$ if and only if they are matched for (σ, χ_ϑ).

Step 4: the data of the one-square identity. Apply Proposition 6.3.72 with: I the set of m-fold twists; $A' = p_{00}$, $A = p_{11}$, $U_1 = p_{01}$, $U_2 = p_{10}$, with index sets $n = n_{p_{00}}$, $n' = n_{p_{11}}$, $n_1 = n_{p_{01}}$, $n_2 = n_{p_{10}}$; $\sigma\colon n_{p_{00}} \sqcup n_{p_{11}} \to n_{p_{01}} \sqcup n_{p_{10}}$ any bijection (both sides have $N_\square$ elements); $t = 5r$; $\mu = \mu_\square$; for $\vartheta \in I$ the modulus $\mathfrak{m}_\vartheta$, the character χ_ϑ and ν_ϑ (Steps 2, 3); the characters

$$(a_1, b_1) = \big(\mathrm{ec}_{z,i}(N_{01}), \mathrm{ec}_{z,i}(N_{11})\big),\ (a_2, b_2) = \big(\mathrm{ec}_{\neg z,j}(N_{10}), \mathrm{ec}_{\neg z,j}(N_{11})\big),$$

$$(b_1', a_1') = \big(\mathrm{ec}_{\neg z,j}(N_{00}), \mathrm{ec}_{\neg z,j}(N_{01})\big),\ (b_2', a_2') = \big(\mathrm{ec}_{z,i}(N_{00}), \mathrm{ec}_{z,i}(N_{10})\big)$$

on the pairs (U_1, A), (U_2, A), (A', U_1), (A', U_2) (the first character at the first space); P_1, P_2, P_1', P_2' the joint harmonics (GP7) of the moves along (p_{01}, p_{11}), (p_{10}, p_{11}), (p_{00}, p_{01}), (p_{00}, p_{10}); and the types $e = e_{p_{11}}$, $e' = e_{p_{00}}$, $e_1 = e_{p_{01}}$, $e_2 = e_{p_{10}}$. The move along (p_{01}, p_{11}) is a lift move with $c = z$, $l = i$, along (p_{10}, p_{11}) a transposed move from p_{11} to p_{10} with $c = \neg z$, $l = j$, along (p_{00}, p_{01}) a transposed move from p_{01} to p_{00} with $c = \neg z$, $l = j$, and along (p_{00}, p_{10}) a lift move with $c = z$, $l = i$; by (GP6), (GP7) each uses at its two ends the characters and the joint harmonic listed above, and the indicator of its matrix modulo $\mathfrak{m}_\vartheta$. Hence the maps $\Theta_\vartheta(x)$, $\Theta'_\vartheta(y)$ of Proposition 6.3.72 are $\mathrm{mv}_{(p_{10},p_{11})}(x_2)\,\mathrm{mv}_{(p_{01},p_{11})}(x_1)$ and $\mathrm{mv}_{(p_{00},p_{10})}(y_2)\,\mathrm{mv}_{(p_{00},p_{01})}(y_1)$ from $\mathcal{F}(p_{01})$ to $\mathcal{F}(p_{10})$, and the functions L, L' there are those of the statement.

Step 5: (OS1). $\mathrm{rk}\,A = N_{11} = N_{00} + 2t = \mathrm{rk}\,A' + 2t$. By (GP4), with $M_z = m - j + [z]$, $\mathrm{neg}(U_1) = \mathrm{neg}(A) = \lfloor (M_z - 1)/2 \rfloor$ and $\mathrm{neg}(U_2) = \mathrm{neg}(A') = \lfloor M_z/2 \rfloor$; so $\mathrm{neg}(W) = \mathrm{neg}(A) + \mathrm{neg}(A') = \lfloor (M_z - 1)/2 \rfloor + \lfloor M_z/2 \rfloor = M_z - 1 \le m$. Hence $2\,\mathrm{neg}(W) + 2 \le 2m + 2 \le 2r \le N_{01} + N_{10} = \mathrm{rk}\,W$ by Step 1. Finally, as $i, j \le m - 1$,

$$\begin{aligned}\mathrm{rk}\,W = N_\square &\le 2r + 2 + (2m-1)(2t+1) \le 2r + 2 + 20mr + 2m \le 26mr \\ &\le 12r^8 \le 2\mu_\square(\upsilon) \le 2\mu_\square(\upsilon) + 2\,\mathrm{neg}(W)\end{aligned}$$

for every $\upsilon \in \Phi$, by Step 1.

Step 6: (OS2). The weights of the characters of each pair are the weights $\gamma_{c,l}(N)$ of (GP6), independent of ϑ. By Lemma 6.4.15 (d) for $(a, b) = (i, j+1)$, (b) with offset $o = 0$ for $(a, b) = (i+1, j)$, (b) with $o = 0$ for $(a, b) = (i, j)$ and (d) for $(a, b) = (i, j)$ (the ranges hold as $i, j < m$), the Fock vectors of P_1, P_2, P_1', P_2' are edges for the weights of the characters of their pairs, the first first, from $e_{p_{01}}$ to $e_{p_{11}}$, from $\bar{e}_{p_{10}}$ to $\bar{e}_{p_{11}}$, from $\bar{e}_{p_{00}}$ to $\bar{e}_{p_{01}}$ and from $e_{p_{00}}$ to $e_{p_{10}}$, that is from e_1 to e, from $\bar{e}_2$ to $\bar{e}$, from $\bar{e}'$ to $\bar{e}_1$ and from e' to e_2.

Step 7: (OS3). Let $N + N' = N_\square$, so $N \equiv N' \pmod 2$. If $z = \mathrm{I}$, then

$$\mathrm{ec}_{z,i}(N)\,\mathrm{ec}_{\neg z,j}(N') = \mu_{i+1}^0 \upsilon^{\lceil N/2 \rceil} \cdot \mu_{j+1}^0 \vartheta^{j+1} \upsilon^{\lfloor N'/2 \rfloor};$$

if $z = \mathrm{II}$, it is

$$\mu_{i+1}^0 \vartheta^{i+1} \upsilon^{\lfloor N/2 \rfloor} \cdot \mu_{j+1}^0 \upsilon^{\lceil N'/2 \rceil}.$$

In both cases $\lceil N/2 \rceil + \lfloor N'/2 \rfloor = \lfloor N/2 \rfloor + \lceil N'/2 \rceil = N_\square/2$, so the product is $\mu^\square \vartheta^h \upsilon^{N_\square/2}$. The base change of υ on $\mathrm{U}(1)(\mathbb{A})$ is $x \mapsto \upsilon(x/\bar{x}) = \upsilon(x)\upsilon(\bar{x})^{-1} = \upsilon(x)^2$ by (WD3). Hence, for characters α, β with $\alpha\beta = \mathrm{ec}_{z,i}(N)\,\mathrm{ec}_{\neg z,j}(N')$,

$$\alpha[N]\,\beta[N'] = \widetilde{\alpha\beta}\,\upsilon^{-N_\square} = \widetilde{\mu^\square \vartheta^h} = \tilde{\nu}_\vartheta^{-1}.$$

The four products of (OS3) are of this form, with (N, N') equal to (N_{01}, N_{10}), (N_{10}, N_{01}), (N_{11}, N_{00}) and (N_{00}, N_{11}) respectively, the character $\mathrm{ec}_{z,i}$ taken at N and $\mathrm{ec}_{\neg z,j}$ at N'.

Step 8: the square law. By Steps 4 to 7 the hypotheses of Proposition 6.3.72 hold. It gives $C > 0$, $\kappa \in \mathbb{C}$ (possibly 0), both independent of ϑ, and for each ϑ a number $c(\vartheta)$ with $|c(\vartheta)|^2 = C\, L_*(\mathfrak{m}_\vartheta, \nu_\vartheta; t) \neq 0$, so $c(\vartheta) \in \mathbb{C}^\times$, such that for every $f \in \mathcal{F}(p_{01})$ and every linear functional l on $\mathcal{F}(p_{10})$, $\sum_y \Psi(y)L'(y) = \frac{\kappa}{c(\vartheta)} \sum_x \Phi(x)L(x)$ whenever Φ, Ψ are matched for (σ, χ_ϑ), that is, by Step 3, for $(\sigma, \chi_\square)$.

Step 9: the absolute value of c. By (XD7) and Step 2, in the notation of Definition 4.2.4,

$$|c(\vartheta)|^2 = C\,(\mathrm{N}S_M\,\mathrm{N}Q)^{t^2} \prod_{\iota=1}^{t} \bigl|L^{S_M \cup Q}\bigl(\iota, (\mu^\square \vartheta^h)^{-1}\bigr)\bigr|^2.$$

For the trivial twist ($Q = \emptyset$, $\vartheta^h = 1$) this reads $0 \neq |c(1)|^2 = C\,(\mathrm{N}S_M)^{t^2} \prod_{\iota=1}^{t} |L^{S_M}(\iota, (\mu^\square)^{-1})|^2$; so $L^{S_M}(\iota, (\mu^\square)^{-1}) \neq 0$ for $1 \leq \iota \leq t$. As ϑ^h has modulus Q, the definition of the ratio gives $|L^{S_M \cup Q}(\iota, (\mu^\square \vartheta^h)^{-1})| = r_{(\mu^\square, \iota)}(\vartheta^h)\, |L^{S_M}(\iota, (\mu^\square)^{-1})|$, and therefore

$$|c(\vartheta)|^2 = |c(1)|^2\,(\mathrm{N}Q)^{t^2}\, F_{\mu^\square, t}(\vartheta^h)^2.$$

If $z = \mathrm{I}$, $F_{\mu^\square, t}(\vartheta^h) = F_{\mu^0_{i+1}\mu^0_{j+1}, t}(\vartheta^{\,j+1}) = \tau_{ij}(\vartheta)$; if $z = \mathrm{II}$, $F_{\mu^\square, t}(\vartheta^h) = F_{\mu^0_{j+1}\mu^0_{i+1}, t}(\vartheta^{\,i+1}) = \tau_{ji}(\vartheta)$. So c has absolute value τ up to a norm power, with the constant $|c(1)|^2$ and the exponent t^2. □

Lemma 6.4.90. *Let D be admissible data and ϑ an m-fold twist with modulus Q. Then $\mathfrak{m}_\vartheta$ is a modulus with $\Sigma(\mathfrak{m}_\vartheta) = S_M \sqcup Q$, and $\#R_{\mathfrak{m}_\vartheta} = \#(\mathcal{O}_E/\mathfrak{b}) \cdot \mathrm{N}Q$.*

Proof. **The places of $\mathfrak{m}_\vartheta$.** The prime ideals containing $\mathfrak{b} = \pi_M^b$ ($b \geq 1$) are those containing π_M, that is the chosen places, which lie above p_0 or p_1 since $\pi_M \bar{\pi}_M = p_0 p_1$ (AD5). The places of Q have norms prime to M (Definition 3.1.2), so they lie above no prime dividing M; hence $S_M \cap Q = \emptyset$, and the prime ideals dividing $\mathfrak{m}_\vartheta$ form the set $S_M \sqcup Q$, nonempty because π_M is not a unit ($\mathrm{N}_{K/\mathbb{Q}}(\pi_M) = p_0 p_1 > 1$). So $\mathfrak{m}_\vartheta = \prod_{w \in S_M \sqcup Q} w^{e_w}$ with all $e_w \geq 1$.

No two places are conjugate. The conjugate of a place above p_0 or p_1 lies above the same prime, so no place of Q is conjugate to a chosen place; and Q contains the conjugate of none of its members (Definition 3.1.2). Suppose that a chosen place w, above p_0 say, has its conjugate $\bar{w}$ (possibly w itself) among the chosen places. Then $\pi_M \in \bar{w}$, so $\bar{\pi}_M \in w$; thus π_M and $\bar{\pi}_M$, which lie in $\mathcal{O}_K$, lie in the prime $\mathfrak{p} = w \cap \mathcal{O}_K$ of K above p_0, and $\mathfrak{p} \nmid p_1$ as $p_0 \neq p_1$. Hence $v_\mathfrak{p}(p_0) = v_\mathfrak{p}(p_0 p_1) = v_\mathfrak{p}(\pi_M) + v_\mathfrak{p}(\bar{\pi}_M) \geq 2$, so p_0 ramifies in K. The discriminant of $K = \mathbb{Q}(\sqrt{-d})$ divides $4d$, so $p_0 \mid 4d$. But $q_2 = (q_0 d)^{s+6} \geq q_0 \geq 18480$ by Lemma 2.3.6, and $p_0 \equiv 1 \pmod{q_2^2}$ (AD5); so the prime p_0 is $\geq q_2^2 + 1 > 2$, hence odd, and $p_0 \equiv 1 \pmod{d}$ as $d \mid q_2$, hence $p_0 \nmid d$; so $p_0 \nmid 4d$. This contradiction (and the same argument for p_1) shows that $\Sigma(\mathfrak{m}_\vartheta) = S_M \sqcup Q$ contains the conjugate of none of its members. So $\mathfrak{m}_\vartheta$ is a modulus (XD4).

The order of the residue ring. The ideals $\mathfrak{b}$ and $w \in Q$ are pairwise coprime (their prime divisors are disjoint, and the $w \in Q$ are distinct primes), so by the Chinese remainder theorem $R_{\mathfrak{m}_\vartheta} = \mathcal{O}_E/\mathfrak{m}_\vartheta \cong \mathcal{O}_E/\mathfrak{b} \times \prod_{w \in Q} \mathcal{O}_E/w$, of order $\#(\mathcal{O}_E/\mathfrak{b}) \prod_{w \in Q} \mathrm{N}w = \#(\mathcal{O}_E/\mathfrak{b})\,\mathrm{N}Q$. □

Lemma 6.4.91. *For a node p let n_p be the index set of its basis, and for an m-fold twist ϑ put $R_\vartheta = \mathcal{O}_E/\mathfrak{m}_\vartheta$. Let D be admissible data, ϑ an m-fold twist, and let the path Γ through the two grids arise from the path Γ' by a turn at (i, j). Define nodes $p, \tilde{p}, p_\mathrm{a}, p_\mathrm{b}, p^+, \tilde{p}^+$, a finite set T and an index set B for the basis of p_b as follows.*

- *If $i \neq j$, let $(z, i', j') = (\mathrm{I}, i, j)$ if $i < j$ and $(z, i', j') = (\mathrm{II}, j, i)$ if $i > j$; put $p = \tilde{p} = (z, i', j')$, $p_\mathrm{a} = (z, i', j' + 1)$, $p_\mathrm{b} = (z, i' + 1, j')$, $p^+ = \tilde{p}^+ = (z, i' + 1, j' + 1)$, $T = \emptyset$ and $B = n_{p_\mathrm{b}}$.*

- *If $i = j$, put $p = (\mathrm{I}, j, j)$, $\tilde{p} = (\mathrm{II}, j, j)$, $p_\mathrm{a} = (\mathrm{I}, j, j+1)$, $p_\mathrm{b} = (\mathrm{II}, j, j+1)$, $p^+ = (\mathrm{I}, j+1, j+1)$, $\tilde{p}^+ = (\mathrm{II}, j+1, j+1)$; let T have one element, the added line, so that $n_{\tilde{p}} = n_p \sqcup T$ and $n_{\tilde{p}^+} = n_{p^+} \sqcup T$ through the decompositions of (GP2); and let $B = n_{(\mathrm{I},j+1,j)}$, numbering the basis of p_b through the renumbering of (GP3).*

In both cases $n_{\tilde{p}} = n_p \sqcup T$ and $n_{\tilde{p}^+} = n_{p^+} \sqcup T$. For an edge tuple S let $y(S)$ be the matrix with rows $n_{p_\mathrm{a}} \sqcup B$ and columns n_p whose row blocks are $S(p, p_\mathrm{a})$ and the columns n_p of $S(\tilde{p}, p_\mathrm{b})$; $v(S)$ the columns T of $S(\tilde{p}, p_\mathrm{b})$ (a $B \times T$ matrix); $x(S)$ the matrix with rows n_{p^+} and columns $n_{p_\mathrm{a}} \sqcup B$ whose column blocks are $S(p_\mathrm{a}, p^+)$ and the rows n_{p^+} of $S(p_\mathrm{b}, \tilde{p}^+)$; and $v'(S)$ the rows T of $S(p_\mathrm{b}, \tilde{p}^+)$ (a $T \times B$ matrix). Then:

(1) there is a set $\mathcal{E}_0$ of edges, containing none of the four edges (p, p_a), $(\tilde{p}, p_\mathrm{b})$, (p_a, p^+), $(p_\mathrm{b}, \tilde{p}^+)$, such that the edges of Γ' are $\mathcal{E}_0 \cup \{(p, p_\mathrm{a}), (\tilde{p}, p_\mathrm{b})\}$ and those of Γ are $\mathcal{E}_0 \cup \{(p_\mathrm{a}, p^+), (p_\mathrm{b}, \tilde{p}^+)\}$.

For an edge tuple S supported on $\mathcal{E}_0$ and matrices y, v, x, v' of the shapes above, let $S[y, v]$ be the tuple that agrees with S except at the two edges (p, p_a), $(\tilde{p}, p_\mathrm{b})$, where it is given by $y(S[y, v]) = y$ and $v(S[y, v]) = v$, and $S\langle x, v'\rangle$ the tuple that agrees with S except at the two edges (p_a, p^+), $(p_\mathrm{b}, \tilde{p}^+)$, where it is given by $x(S\langle x, v'\rangle) = x$ and $v'(S\langle x, v'\rangle) = v'$; for any tuple S let S_0 be the tuple equal to S on $\mathcal{E}_0$ and to 0 elsewhere. Let ψ be an additive character of R_ϑ, $\sigma\colon n_p \sqcup n_{p^+} \to n_{p_\mathrm{a}} \sqcup B$ a bijection, $\chi_\mathrm{c} = (\chi_{(p,p_\mathrm{a})}\chi_{(\tilde{p},p_\mathrm{b})})^{-1}$, $N \in \mathbb{N}$, and Ψ' a path datum of bound N on the edges of Γ'. Then there is a path datum Ψ of bound $\#(R_\vartheta)^{\#B \cdot \#T} N$ on the edges of Γ such that:

(2) for every edge tuple S supported on $\mathcal{E}_0$ and every $T \times B$ matrix v', the functions

$$x \longmapsto \Psi\big(S\langle x, v'\rangle\big) \qquad \text{and} \qquad y \longmapsto \sum_v \psi\big(\mathrm{tr}(v'v)\big)\, \Psi'\big(S[y, v]\big)$$

are matched for $(\sigma, \chi_\mathrm{c})$ over R_ϑ, the sum running over the $B \times T$ matrices v;

(3) for every set J, every $C \in \mathbb{C}$, every family $(L_\iota, L'_\iota)_{\iota \in J}$ of functions of the matrices x, resp. y, such that $\sum_y \Psi_1(y) L'_\iota(y) = C \sum_x \Phi_1(x) L_\iota(x)$ for all Φ_1, Ψ_1 matched for $(\sigma, \chi_\mathrm{c})$ over R_ϑ, and every function F from the pairs (S, v') (S supported on $\mathcal{E}_0$, v' a $T \times B$ matrix) to J,

$$\sum_S \Psi'(S) \sum_{v'} \psi\big(\mathrm{tr}(v'v(S))\big)\, L'_{F(S_0, v')}\big(y(S)\big) = C \sum_S \Psi(S)\, L_{F(S_0, v'(S))}\big(x(S)\big),$$

the sum on the left over the edge tuples supported on the edges of Γ', that on the right over those supported on the edges of Γ.

Proof. Write $R = R_\vartheta$, $n = n_{p_\mathrm{a}} \sqcup B$, and identify n with $n_p \sqcup n_{p^+}$ through σ; for $k \in \mathrm{GL}_n(R)$ let $k_\flat$ be the matrix of the columns n_p of k and $k^\sharp$ that of the rows n_{p^+} of k^{-1}. Thus y ranges over the $n \times n_p$ and x over the $n_{p^+} \times n$ matrices, and Φ, Ψ are matched for (σ, χ) if Φ vanishes off the matrices $k^\sharp$, Ψ off the matrices $k_\flat$, and $\Phi(k^\sharp) = \chi(\det k)\Psi(k_\flat)$ for all $k \in \mathrm{GL}_n(R)$. Values of multiplicative characters of R at units are roots of unity, as $R^\times$ is finite. Put $e_1 = (p, p_\mathrm{a})$, $e_2 = (\tilde{p}, p_\mathrm{b})$, $e_3 = (p_\mathrm{a}, p^+)$, $e_4 = (p_\mathrm{b}, \tilde{p}^+)$.

Step 1: the edges, clause (1). By Lemma 6.4.92 (a) (case $i \neq j$, with the nodes named there $(z, i', j') = p$, $(z, i', j'+1) = p_\mathrm{a}$, $(z, i'+1, j') = p_\mathrm{b}$, $(z, i'+1, j'+1) = p^+$) and (b) (case $i = j$), the edges of Γ' are $\mathcal{E}_0 \cup \{e_1, e_2\}$ and those of Γ are $\mathcal{E}_0 \cup \{e_3, e_4\}$, where $\mathcal{E}_0$ is the set of edges of the paths q, r, $\Gamma'_{\neg z}$, resp. u_I, u_II of that lemma, and contains none of $e_1, \ldots, e_4$; this is

(1), and $e_1 \neq e_2$, $e_3 \neq e_4$. No edge of $\mathcal{E}_0$ has p or $\tilde{p}$ as an endpoint: by monotonicity the nodes (a, b) of q have $b \geq j' + 1$, those of r have $a \geq i' + 1$, those of u_z have $b \geq j + 1$, and $\Gamma'_{\neg z}$ lies in the other grid. The nodes $p, \tilde{p}$ are not the starting nodes $(z, 0, m)$ (their second index is $< m$), and off the diagonal p is not a diagonal node.

Step 2: characters and vertical edges of the square. By (GP6) the character χ_e depends only on whether e is vertical and on the value at the source of the index that changes along e. Off the diagonal, e_1 and e_4 both change the second index, from j', and e_2, e_3 the first, from i', in the same grid; on the diagonal, e_1 (in the grid Y, second index) and e_4 (in the grid $\tilde{Y}$, first index) are vertical and change an index from j, while e_2 (grid $\tilde{Y}$, second index) and e_3 (grid Y, first index) are not vertical and change an index from j. Hence $\chi_{e_3} = \chi_{e_2}$, $\chi_{e_4} = \chi_{e_1}$, and in both cases exactly one of e_1, e_2 is vertical, the opposite edge e_4, resp. e_3, is vertical, and the other new edge is not (off the diagonal e_1, e_4 are vertical if $z = \mathrm{I}$ and e_2, e_3 if $z = \mathrm{II}$).

Step 3: two facts on matrices over R. (i) *Completion.* If y has a left inverse, then $y = k_\flat$ for some $k \in \mathrm{GL}_n(R)$. By the Chinese remainder theorem $R = \prod_w \mathcal{O}_E/w^{e_w}$ is a finite product of local rings, and a square matrix over R is invertible if and only if each component is; so let R be local with maximal ideal $\mathfrak{q}$. From $Ly = 1$ the reduction of y modulo $\mathfrak{q}$ has rank $\#n_p$; complete its columns by $\#n - \#n_p = \#n_{p^+}$ columns (the sizes match because σ is a bijection) to a basis of the residue space, lift them to R, and let k have the columns y at n_p and the lifts at n_{p^+}; its determinant is a unit, as its reduction is nonzero. (ii) *Transfer of left inverses.* Let $k \in \mathrm{GL}_n(R)$ and write $k_\flat$ in row blocks Y_1, Y_2 (rows n_{p_a}, B) and $k^\sharp$ in column blocks X_1, X_2 (columns n_{p_a}, B). If Y_1 has a left inverse, so has X_2; if Y_2 has a left inverse, so has X_1. For the first, let $LY_1 = 1$ and let s be the $n_p \times n$ matrix equal to L on the columns n_{p_a} and to 0 on the columns B; then $sk_\flat = 1$. The square matrix P with the rows s (at n_p) and $k^\sharp$ (at n_{p^+}) satisfies $Pk = \begin{pmatrix} 1 & * \\ 0 & 1 \end{pmatrix}$ in the blocks n_p, n_{p^+}, since $k^\sharp k$ is the rows n_{p^+} of 1; so $\det P \det k = 1$ and P is invertible. Reading $P^{-1}P = 1$ at the rows and columns B, where the rows s of P vanish, gives $MX_2 = 1$ for the block M of P^{-1} with rows B and columns n_{p^+}. The second is the same with the roles of the blocks exchanged.

Step 4: the Fourier transform of Ψ'. For S supported on $\mathcal{E}_0$ and a $T \times B$ matrix v' put $\hat{\Psi}'_{S,v'}(y) = \sum_v \psi(\mathrm{tr}(v'v))\, \Psi'(S[y, v])$. By Step 1 the map $(S, y, v) \mapsto S[y, v]$ is a bijection from the triples (S supported on $\mathcal{E}_0$) onto the tuples supported on the edges of Γ', with inverse $S \mapsto (S_0, y(S), v(S))$, and similarly $(S, x, v') \mapsto S\langle x, v' \rangle$ onto the tuples supported on the edges of Γ. We show:

(F1) if $\hat{\Psi}'_{S,v'}(y) \neq 0$, then $y = k_\flat$ for some $k \in \mathrm{GL}_n(R)$, and for such k and some v with $\Psi'(S[k_\flat, v]) \neq 0$ the vertical edges in $\mathcal{E}_0$ carry matrices of S with left inverses, and Y_1 has a left inverse if e_1 is vertical, Y_2 if e_2 is vertical;

(F2) $\chi_\mathrm{c}(\det h)\, \hat{\Psi}'_{S,v'}(yh) = \hat{\Psi}'_{S,v'}(y)$ for every $h \in \mathrm{GL}_{n_p}(R)$;

(F3) for every admissible family g, with $g_+ = g_{p^+}$, $\hat{g}$ the element $g_{p_\flat}$ written in the numbering B, $g_n = \mathrm{diag}(g_{p_\mathrm{a}}, \hat{g}) \in \mathrm{GL}_n(R)$ and the root of unity $A_g = \epsilon_{\mathcal{E}_0}(g)\, \chi_{e_1}(\det g_{p_\mathrm{a}})\, \chi_{e_2}(\det g_{p_\flat})$, one has $\hat{\Psi}'_{g \cdot S,\, v'\hat{g}}(y) = A_g^{-1}\, \hat{\Psi}'_{S,v'}(g_n y)$.

(F1): some v has $\Psi'(S[y, v]) \neq 0$; by (PD3) for Ψ' the vertical edges of Γ' carry left invertible matrices. These include the edges of $\mathcal{E}_0$ that are vertical and, by Step 2, e_1 or e_2. If e_1 is vertical, $Y_1 = S[y, v](e_1)$ has a left inverse; if e_2 is vertical, $(Y_2 \,|\, v) = S[y, v](e_2)$ has a left inverse L, and the rows n_p of L form a left inverse of Y_2. In both cases y has a left inverse (extend a left inverse of the block by 0), and Step 3 (i) applies. (F2): let g' be the family equal to h at p, to $h \oplus 1_T$ at $\tilde{p}$ (that is, h at $\tilde{p} = p$ off the diagonal) and to 1 elsewhere; it is admissible by Step 1. As no edge of $\mathcal{E}_0$

meets $p, \tilde{p}$, $g' \cdot S[y,v] = S[yh,v]$ and $\epsilon_{E(\Gamma')}(g') = \chi_{e_1}(\det h)^{-1}\chi_{e_2}(\det h)^{-1} = \chi_{\mathrm{c}}(\det h)$; (PD2) for Ψ' gives $\chi_{\mathrm{c}}(\det h)\Psi'(S[yh,v]) = \Psi'(S[y,v])$, and summing over v gives (F2). (F3): let g' be equal to g except at p and $\tilde{p}$, where it is 1; it is admissible by Step 1. Then $g' \cdot S[y,v] = (g \cdot S)[g_n^{-1}y, \hat{g}^{-1}v]$ and $\epsilon_{E(\Gamma')}(g') = A_g$, so (PD2) gives $\Psi'((g \cdot S)[g_n^{-1}y, \hat{g}^{-1}v]) = A_g^{-1}\Psi'(S[y,v])$. Substituting $v = \hat{g}^{-1}u$ in the sum defining $\hat{\Psi}'_{g\cdot S, v'\hat{g}}(g_n^{-1}y)$, $\mathrm{tr}(v'\hat{g}\hat{g}^{-1}u) = \mathrm{tr}(v'u)$, which gives (F3) after replacing y by $g_n y$.

Step 5: the match and the new datum. For S supported on $\mathcal{E}_0$ and v' define $\Phi_{S,v'}(x) = \chi_{\mathrm{c}}(\det k)\,\hat{\Psi}'_{S,v'}(k_\flat)$ if $x = k^\sharp$ for some $k \in \mathrm{GL}_n(R)$, and $\Phi_{S,v'}(x) = 0$ otherwise. This does not depend on k: if $k^\sharp = k'^\sharp$, the rows n_{p^+} of $M = k^{-1}k'$ are those of $k^\sharp k' = k'^\sharp k'$, that is $(0\ 1)$, so $M = \begin{pmatrix} h & * \\ 0 & 1 \end{pmatrix}$ with $\det h = \det M \in R^\times$, $k'_\flat = k_\flat h$ and $\det k' = \det k \det h$; by (F2), $\chi_{\mathrm{c}}(\det k')\hat{\Psi}'_{S,v'}(k'_\flat) = \chi_{\mathrm{c}}(\det k)\hat{\Psi}'_{S,v'}(k_\flat)$. By construction and (F1), $\Phi_{S,v'}$ and $\hat{\Psi}'_{S,v'}$ are matched for $(\sigma, \chi_{\mathrm{c}})$. Put

$$\Psi(S) = \Phi_{S_0,\, v'(S)}\big(x(S)\big)$$

for every edge tuple S. For S supported on $\mathcal{E}_0$, $(S\langle x, v'\rangle)_0 = S$, $v'(S\langle x, v'\rangle) = v'$ and $x(S\langle x, v'\rangle) = x$, so $x \mapsto \Psi(S\langle x, v'\rangle)$ is $\Phi_{S,v'}$; this is (2).

Step 6: Ψ is a path datum of bound $\#(R)^{\#B\cdot\#T}N$ on the edges of Γ. (PD1): $\Psi(S)$ depends only on S_0, $v'(S)$ and $x(S)$, that is on the matrices of S on $\mathcal{E}_0 \cup \{e_3, e_4\}$. (PD4): if $\Psi(S) \neq 0$, then $\Psi(S) = \chi_{\mathrm{c}}(\det k)\sum_v \psi(\mathrm{tr}(v'v))\Psi'(S_0[k_\flat, v])$ with $\#(R)^{\#B\cdot\#T}$ terms v; $\chi_{\mathrm{c}}(\det k)$ and the values of ψ are roots of unity (R is finite), each $\Psi'(\cdot)$ is a sum of at most N roots of unity, and a root of unity times such a sum is again one; so $\Psi(S)$ is a sum of at most $\#(R)^{\#B\cdot\#T}N$ roots of unity, and 0 is the empty sum. (PD3): let $\Psi(S) \neq 0$, so $x(S) = k^\sharp$ with $\hat{\Psi}'_{S_0,v'(S)}(k_\flat) \neq 0$. By (F1) the vertical edges of $\mathcal{E}_0$ carry left invertible matrices of S_0, hence of S, and Y_1 (if e_1 is vertical) or Y_2 (if e_2 is vertical) has a left inverse. By Step 3 (ii), X_2, resp. X_1, has a left inverse. By Step 2 the vertical new edge is e_4 in the first case and e_3 in the second. In the second, $S(e_3) = X_1$. In the first, $S(e_4)$ has the rows X_2 (at n_{p^+}) and $v'(S)$ (at T), and $(M \mid 0)$ is a left inverse of it if $MX_2 = 1$. (PD2): let g be admissible. At $\tilde{p}^+$, $g_{\tilde{p}^+} = g_{p^+} \oplus 1_T$ (admissibility on the diagonal; trivially off it), so $x(g \cdot S) = g_+^{-1}x(S)g_n$, $v'(g \cdot S) = v'(S)\hat{g}$ and $(g \cdot S)_0 = g \cdot S_0$. From (F3) and the definition of Φ: for $x = k^\sharp$, $\Phi_{g\cdot S_0, v'\hat{g}}(x) = \chi_{\mathrm{c}}(\det k)A_g^{-1}\hat{\Psi}'_{S_0,v'}((g_n k)_\flat) = A_g^{-1}\chi_{\mathrm{c}}(\det g_n)^{-1}\Phi_{S_0,v'}(xg_n^{-1})$, since $xg_n^{-1} = (g_n k)^\sharp$; and both sides vanish when x is not of the form $k^\sharp$, since then neither is xg_n^{-1}. Next, $g_+^{-1}k^\sharp = (kD^{-1})^\sharp$ for $D = \mathrm{diag}(1_{n_p}, g_+^{-1})$, with $(kD^{-1})_\flat = k_\flat$ and $\det(kD^{-1}) = \det k \det g_+$; so $\Phi_{S_0,v'}(g_+^{-1}x) = \chi_{\mathrm{c}}(\det g_+)\Phi_{S_0,v'}(x)$ for all x (both sides vanish off the matrices $k^\sharp$). Hence

$$\Psi(g \cdot S) = A_g^{-1}\,\chi_{\mathrm{c}}(\det g_n)^{-1}\chi_{\mathrm{c}}(\det g_+)\,\Psi(S).$$

On the other hand, by Step 1, $\det g_{\tilde{p}^+} = \det g_+$ and Step 2,

$$\epsilon_{E(\Gamma)}(g) = \epsilon_{\mathcal{E}_0}(g)\,\frac{\chi_{e_2}(\det g_+)}{\chi_{e_2}(\det g_{p_\mathrm{a}})}\,\frac{\chi_{e_1}(\det g_+)}{\chi_{e_1}(\det g_{p_\mathrm{b}})} = A_g\,\chi_{\mathrm{c}}(\det g_n)\,\chi_{\mathrm{c}}(\det g_+)^{-1},$$

using $\det g_n = \det g_{p_\mathrm{a}} \det g_{p_\mathrm{b}}$ and $\chi_{\mathrm{c}} = (\chi_{e_1}\chi_{e_2})^{-1}$. So $\epsilon_{E(\Gamma)}(g)\Psi(g \cdot S) = \Psi(S)$.

Step 7: clause (3). By the bijections of Step 4, the left side of (3) equals

$$\sum_S \sum_{v'} \sum_y \Big(\sum_v \psi(\mathrm{tr}(v'v))\Psi'(S[y,v])\Big) L'_{F(S,v')}(y) = \sum_S \sum_{v'} \sum_y \hat{\Psi}'_{S,v'}(y)\,L'_{F(S,v')}(y),$$

the sums over the tuples S supported on $\mathcal{E}_0$, the $T \times B$ matrices v' and the matrices y. For fixed S, v' the functions $\Phi_{S,v'}$, $\hat{\Psi}'_{S,v'}$ are matched (Step 5), so by hypothesis the inner sum is

$C\sum_x \Phi_{S,v'}(x)L_{F(S,v')}(x)$. As $\Phi_{S,v'}(x) = \Psi(S\langle x,v'\rangle)$, the bijection $(S,x,v') \mapsto S\langle x,v'\rangle$ turns $C\sum_S\sum_{v'}\sum_x \Phi_{S,v'}(x)L_{F(S,v')}(x)$ into the right side of (3). □

Lemma 6.4.92. *Let D be admissible data and let the path Γ through the two grids arise from the path Γ' by a turn at (i,j), $0 \le i,j < m$; put $l = l(\Gamma')$.*

(a) Let $i \ne j$, and let $(z,i',j') = (\mathrm{I},i,j)$ if $i < j$ and $(z,i',j') = (\mathrm{II},j,i)$ if $i > j$. Then $i' < j' < m$, $l(\Gamma) = l$, $\Gamma_{\neg z} = \Gamma'_{\neg z}$, and there are monotone paths q from $(0,m)$ to $(i',j'+1)$ and r from $(i'+1,j')$ to (l,l) in the grid z such that Γ'_z is q followed by the steps $(i',j'+1) \to (i',j') \to (i'+1,j')$ and by r, and Γ_z is q followed by the steps $(i',j'+1) \to (i'+1,j'+1) \to (i'+1,j')$ and by r. The edges of Γ' are those of $\mathcal{E}_0$ and $((z,i',j'),(z,i',j'+1))$, $((z,i',j'),(z,i'+1,j'))$; the edges of Γ are those of $\mathcal{E}_0$ and $((z,i',j'+1),(z,i'+1,j'+1))$, $((z,i'+1,j'),(z,i'+1,j'+1))$; here $\mathcal{E}_0$ is the set of edges of q, of r and of $\Gamma'_{\neg z}$, and contains none of these four edges.

(b) Let $i = j$. Then $l = j$, $l(\Gamma) = j+1$, and for each z there is a monotone path u_z from $(0,m)$ to $(j,j+1)$ in the grid z such that Γ'_z is u_z followed by the step down to (j,j) and Γ_z is u_z followed by the step right to $(j+1,j+1)$. The edges of Γ' are those of $\mathcal{E}_0$ and $((\mathrm{I},j,j),(\mathrm{I},j,j+1))$, $((\mathrm{II},j,j),(\mathrm{II},j,j+1))$; the edges of Γ are those of $\mathcal{E}_0$ and $((\mathrm{I},j,j+1),(\mathrm{I},j+1,j+1))$, $((\mathrm{II},j,j+1),(\mathrm{II},j+1,j+1))$; here $\mathcal{E}_0$ is the set of edges of u_{I} and u_{II}, and contains none of these four edges.

Proof. The edge of a step of a monotone path in the grid z is the pair of its two nodes with the smaller one first: a step down from $(a,b+1)$ to (a,b) has the edge $((z,a,b),(z,a,b+1))$, a step right from (a,b) to $(a+1,b)$ the edge $((z,a,b),(z,a+1,b))$; the edges of a monotone path are those of its steps, and the edges of a path through the two grids are those of its halves.

Nodes of a half. Along a half of a path with index l, from $(0,m)$ to (l,l), the first index never decreases and the second never increases; so every node (a,b) of the half has $0 \le a \le l \le b \le m$. If the half comes down to a node (a,b) and leaves it to the right, then $(a+1,b)$ is also a node of the half, so $a+1 \le l \le b$ and in particular $a < b$.

(a). By the definition of a turn, a turn at (i,j) either replaces a corner of a half (at the node (i,j) of the half in the grid Y, or at the node (j,i) of the half in the grid $\tilde{Y}$), or it is the turn on the diagonal, which requires $i = j$. So for $i \ne j$ it replaces a corner at which a half comes down to a node and leaves it to the right; by the preceding paragraph the node (a,b) of such a corner has $a < b$. The node (i,j) in the grid Y has this property only if $i < j$, the node (j,i) in the grid $\tilde{Y}$ only if $j < i$. Hence the corner is at the node (i',j') of the half Γ'_z, with $i' < j'$; the node $(i',j'+1)$ before it lies on the half, so $j'+1 \le m$. Write Γ'_z as q, the steps $(i',j'+1) \to (i',j') \to (i'+1,j')$, and r; the turn replaces the two middle steps by $(i',j'+1) \to (i'+1,j'+1) \to (i'+1,j')$ and changes nothing else, which gives the description of Γ_z, $\Gamma_{\neg z} = \Gamma'_{\neg z}$ and $l(\Gamma) = l$. The two replaced steps have the edges $((z,i',j'),(z,i',j'+1))$ and $((z,i',j'),(z,i'+1,j'))$, the two new steps the edges $((z,i',j'+1),(z,i'+1,j'+1))$ and $((z,i'+1,j'),(z,i'+1,j'+1))$. Every node (a,b) of q has $a \le i'$ and $b \ge j'+1$, every node of r has $a \ge i'+1$ and $b \le j'$. Each of the four edges has a node outside q (the node (i',j'), (i',j'), $(i'+1,j'+1)$, $(i'+1,j')$ respectively) and a node outside r (the node $(i',j'+1)$, (i',j'), $(i'+1,j'+1)$, $(i'+1,j'+1)$ respectively), so it is an edge neither of q nor of r; nor of $\Gamma'_{\neg z}$, whose edges lie in the other grid.

(b). For $i = j$ the turn is not at a corner, since the node (j,j) of a corner would have $j < j$; so it is the turn on the diagonal: $j = l$, both halves of Γ' end with a step down, necessarily from $(j,j+1)$ to (j,j), and Γ has index $j+1$ and both final steps replaced by the steps right

from $(j,j+1)$ to $(j+1,j+1)$. Let u_z be Γ'_z without its last step. The edges of the replaced and of the new steps are the four edges listed. Every node (a,b) of u_z has $a \le j$ and $b \ge j+1$, while each of the four edges has a node with $b = j$ (the node (j,j)) or with $a = j+1$ (the node $(j+1,j+1)$); so none of them is an edge of u_{I} or of u_{II}. □

Lemma 6.4.93. *Let D be admissible data, $0 \le j < m$, and $V(\vartheta) = \#(\mathcal{O}_E/\mathfrak{m}_\vartheta)^{2n_m}$ for every m-fold twist ϑ. There is a function c_{jj} from the m-fold twists to $\mathbb{C}^\times$, of absolute value τ_{jj} up to a norm power, such that for every turn at (j,j) from a path Γ' through the two grids to a path Γ, the path Γ' transfers periods to Γ with bound V and constant c_{jj}.*

Proof. **Step 1: the constant.** Apply Lemma 6.4.89 to the grid Y ($z = \mathrm{I}$) and the square at (j,j), with corners (I,j,j), $(\mathrm{I},j,j+1)$, $(\mathrm{I},j+1,j)$, $(\mathrm{I},j+1,j+1)$. It gives $\kappa \in \mathbb{C}$, a bijection $\sigma\colon n_{(\mathrm{I},j,j)} \sqcup n_{(\mathrm{I},j+1,j+1)} \to n_{(\mathrm{I},j,j+1)} \sqcup n_Z$ and a function c from the m-fold twists to $\mathbb{C}^\times$ of absolute value τ_{jj} up to a norm power. For each m-fold twist ϑ apply Lemma 6.4.94 to the space Z with its signs s, $\epsilon = (-1)^{j+1}$, $\beta = \chi^{\mathrm{h}}$, $\alpha' = \chi^{\mathrm{v}}_\vartheta$ and $k = f^j_\vartheta$; it gives an additive character ψ_ϑ of R_ϑ and $c_{\mathrm{ln}}(\vartheta) \in \mathbb{C}^\times$ with $|c_{\mathrm{ln}}(\vartheta)|^2 \,\#(R_\vartheta)^{\mathrm{rk}\,Z} = 1$. Take $D = \delta_w$ there, for an $n_Z \times 1$ matrix w, and $h = \rho(g)$. Then $\hat{D}(\varrho) = \psi_\vartheta(\mathrm{tr}(\varrho w)) = \sum_{w'} \psi_\vartheta(\mathrm{tr}(w'w))\,\delta_{w'}(\varrho)$, the sum over the $1 \times n_Z$ matrices w'; the datum $\mathrm{mod}_{\mathfrak{m}_\vartheta}(\cdot, v_{P'})$ and the theta kernel are linear in the function on matrices, and $-\epsilon = (-1)^j$, $k\,\mathrm{flp}_\vartheta = f^{j+1}_\vartheta$ since $f_\vartheta = \mathrm{flp}_\vartheta$ (Lemma 6.4.95). So, with P' the polynomial obtained from P by the substitution of Lemma 6.4.94 (it depends on P and on the signs of Z, not on ϑ),

$$K^{\mathrm{col}}_\vartheta[w,P](g) = c_{\mathrm{ln}}(\vartheta) \sum_{w'} \psi_\vartheta(\mathrm{tr}(w'w))\, K^{\mathrm{row}}_\vartheta[w',P'](g) \tag{6.105}$$

for all w, P and $g \in \mathrm{U}(\tilde{Y}^{j+1}_j)(\mathbb{A}_F)$. Put $c_{jj}(\vartheta) = c(\vartheta)/c_{\mathrm{ln}}(\vartheta) \in \mathbb{C}^\times$.

Step 2: the absolute value of c_{jj}. Let ϑ have modulus Q. By Lemma 6.4.90, $\#R_\vartheta = \#(\mathcal{O}_E/\mathfrak{b})\,\mathrm{N}Q$ with $\mathfrak{b} = \pi_M^b$. There are $C_1 \in \mathbb{R}$ and $n_1 \in \mathbb{Z}$ with $|c(\vartheta)|^2 = C_1(\mathrm{N}Q)^{n_1}\tau_{jj}(\vartheta)^2$ for all ϑ; hence

$$|c_{jj}(\vartheta)|^2 = |c(\vartheta)|^2\,\#(R_\vartheta)^{\mathrm{rk}\,Z} = C_1\,\#(\mathcal{O}_E/\mathfrak{b})^{\mathrm{rk}\,Z}\,(\mathrm{N}Q)^{n_1+\mathrm{rk}\,Z}\,\tau_{jj}(\vartheta)^2,$$

and c_{jj} has absolute value τ_{jj} up to a norm power.

Step 3: the shape of a turn at (j,j). Let Γ arise from Γ' by a turn at (j,j). By Lemma 6.4.92 (b), $l(\Gamma') = j$, the halves of Γ' are monotone paths u_z from $(0,m)$ to $(j,j+1)$ followed by the step down to (j,j), and Γ has index $j+1$ and the halves u_z followed by the step right to $(j+1,j+1)$. These are the paths Γ', Γ of Lemma 6.4.95, and in Lemma 6.4.91 (case $i = j$) $p = (\mathrm{I},j,j)$, $p_{\mathrm{a}} = (\mathrm{I},j,j+1)$, $p^+ = (\mathrm{I},j+1,j+1)$, $B = n_Z$, so σ is a bijection $n_p \sqcup n_{p^+} \to n_{p_{\mathrm{a}}} \sqcup B$. By Lemma 6.4.92 (b), the edges of u_{I} and u_{II} are the edges of both paths other than the four edges of the turn, so they form the set $\mathcal{E}_0$ of Lemma 6.4.91 (1). Finally the character $\chi_{\mathrm{c}} = (\chi_{(p,p_{\mathrm{a}})}\chi_{(\tilde{p},p_{\mathrm{b}})})^{-1}$ of Lemma 6.4.91 is the character $\chi_\square = (\chi_{((\mathrm{I},j,j),(\mathrm{I},j,j+1))}\chi_{((\mathrm{I},j,j),(\mathrm{I},j+1,j))})^{-1}$ of Step 1: by (GP6) the edges $(\tilde{p},p_{\mathrm{b}}) = ((\mathrm{II},j,j),(\mathrm{II},j,j+1))$ and $((\mathrm{I},j,j),(\mathrm{I},j+1,j))$ are both not vertical (in the grid $\tilde{Y}$ the first index stays, in the grid Y the second index stays) and the index that changes along each starts at j, so both have the character of the tame part of μ^0_{j+1}.

Step 4: the new path data. Let N be a function from the m-fold twists to $\mathbb{N}$ and $\Psi' = (\Psi'_\vartheta)$ a family of path data of bound $N(\vartheta)$ on the edges of Γ'. For each ϑ, Lemma 6.4.91, with ψ_ϑ, σ and Ψ'_ϑ, gives a path datum Ψ_ϑ of bound $\#(R_\vartheta)^{\mathrm{rk}\,Z}N(\vartheta)$ on the edges of Γ (here $\#B = \mathrm{rk}\,Z$, $\#T = 1$) satisfying (3). The node $(\mathrm{I},j+1,j)$ carries a space of rank $r+(2j+1)t$ (Definition 3.2.28) and $n_m = k+m(t+1) = r+1+mt$ (Definition 2.3.4); so $\mathrm{rk}\,Z = r+(2j+1)t \le r+(2m-1)t < 2(r+1+mt) = 2n_m$, and $\#R_\vartheta \ge 1$; so $\#(R_\vartheta)^{\mathrm{rk}\,Z} \le V(\vartheta)$. A sum of at most $\#(R_\vartheta)^{\mathrm{rk}\,Z}N(\vartheta)$ roots of unity is a sum of at most $V(\vartheta)N(\vartheta)$ roots of unity, and (PD1)–(PD3) do not involve the bound; hence Ψ_ϑ is a path datum of bound $V(\vartheta)N(\vartheta)$ on the edges of Γ.

Step 5: column periods are row periods. Fix a real point g_0 of $\mathrm{U}(Z)$, a polynomial P and a period triple (ϑ, y', φ). For an edge tuple S supported on $\mathcal{E}_0$ and a $1 \times n_Z$ matrix w' let $l_{S,w'}$ be the linear functional

$$l_{S,w'}(y'') = \int_{[\mathrm{U}(\tilde{Y}_j^{j+1})]} K_\vartheta^{\mathrm{row}}[w', P'](g)\, \varphi_S(g)\, y''(\rho(g)g_0)\, dg \qquad (y'' \in \mathcal{F}(\mathrm{I}, j+1, j)),$$

defined by Lemma 6.4.95 (1), and put $F(S, w') = (\mathrm{fm}_{u_\mathrm{I}}(S)y',\, l_{S,w'})$, an element of the set J of pairs (f, l) with $f \in \mathcal{F}(\mathrm{I}, j, j+1)$ and l a linear functional on $\mathcal{F}(\mathrm{I}, j+1, j)$. Since φ_S and $\mathrm{fm}_{u_\mathrm{I}}(S)$ involve only the matrices of S on the edges of u_II, u_I, which lie in $\mathcal{E}_0$, $F(S, w') = F(S_0, w')$ for every tuple S. For $(f, l) \in J$ let $L_{(f,l)}$, $L'_{(f,l)}$ be the functions L, L' of Lemma 6.4.89 for the square of Step 1, ϑ, f and l; by the definitions of $y_S^\pm$,

$$L'_{F(S_0,w')}(y(S)) = l_{S,w'}(y_S^-), \qquad L_{F(S_0,w')}(x(S)) = l_{S,w'}(y_S^+).$$

Insert (6.105) with $w = v(S)$ into the column period; the sum over w' is finite and each of its integrals converges absolutely by Lemma 6.4.95 (1), so it may be taken outside the integral:

$$C(\Psi'; g_0, P)(\vartheta, y', \varphi) = c_\mathrm{ln}(\vartheta) \sum_S \Psi'_\vartheta(S) \sum_{w'} \psi_\vartheta(\mathrm{tr}(w'v(S)))\, L'_{F(S_0,w')}(y(S)),$$

the sum over the edge tuples supported on the edges of Γ'. By Lemma 6.4.89 and Step 3, for every $(f, l) \in J$,

$$\sum_y \Psi_1(y) L'_{(f,l)}(y) = \frac{\kappa}{c(\vartheta)} \sum_x \Phi_1(x) L_{(f,l)}(x)$$

whenever Φ_1, Ψ_1 are matched for $(\sigma, \chi_\mathrm{c})$ over R_ϑ. So Lemma 6.4.91 (3), with $C = \kappa/c(\vartheta)$, turns the right side into

$$c_\mathrm{ln}(\vartheta) \frac{\kappa}{c(\vartheta)} \sum_S \Psi_\vartheta(S)\, l_{S,v'(S)}(y_S^+),$$

the sum over the tuples supported on the edges of Γ, which is $c_\mathrm{ln}(\vartheta)\frac{\kappa}{c(\vartheta)} R(\Psi; g_0, P')(\vartheta, y', \varphi)$. Thus

$$C(\Psi'; g_0, P)(\vartheta, y', \varphi) = \frac{\kappa}{c_{jj}(\vartheta)}\, R(\Psi; g_0, P')(\vartheta, y', \varphi). \tag{6.106}$$

Step 6: the transfer. Let Ξ be a function of period triples with $\Psi \propto_\Gamma \Xi$. Fix g_0 and P. By Lemma 6.4.95 (3), applied to g_0 and P', there is $\beta \in \mathbb{C}$ with $R(\Psi; g_0, P') = \beta\, \Xi$ on all period triples; by (6.106), $C(\Psi'; g_0, P)(\vartheta, y', \varphi) = \kappa\beta \cdot \Xi(\vartheta, y', \varphi)/c_{jj}(\vartheta)$ for all period triples, with $\kappa\beta$ independent of the triple. By Lemma 6.4.95 (2), applied to the function $(\vartheta, y', \varphi) \mapsto \Xi(\vartheta, y', \varphi)/c_{jj}(\vartheta)$, $\Psi' \propto_{\Gamma'} \Xi/c_{jj}$. With Step 4, Γ' transfers periods to Γ with bound V and constant c_{jj}, which by Step 2 has absolute value τ_{jj} up to a norm power. □

Lemma 6.4.94. *For $\epsilon \in \{\pm 1\}$ let ℓ_ϵ be the standard line of sign ϵ, a space with a point; by (GP8) these are the lines added in (GP2). Let S be a space with a point with signs s on an index set n, $\epsilon \in \{\pm 1\}$, ϑ an m-fold twist, β and α' automorphic characters of $\mathrm{U}(1)$, and $k \in G_f(1)$. There are an additive character ψ of $R_{\mathfrak{m}_\vartheta}$ and $C \in \mathbb{C}^\times$ with*

$$|C|^2 \cdot \#(R_{\mathfrak{m}_\vartheta})^{\#n} = 1$$

such that for every function D on the $n \times 1$ matrices over $R_{\mathfrak{m}_\vartheta}$, every polynomial P in the entries $X_{v,i,1}$ ($v \in \Phi$, $i \in n$) of such matrices and every $h \in \mathrm{G}(s)$,

$$\theta_{1,\beta}^{\ell_{-\epsilon},S}(\mathrm{mod}_{\mathfrak{m}_\vartheta}(D, v_P))((1,k),h) = C\, \theta_{\alpha',\upsilon}^{S,\ell_\epsilon}(\mathrm{mod}_{\mathfrak{m}_\vartheta}(\hat{D}, v_{P'}))(h, (1, k\,\mathrm{flp}_\vartheta)),$$

where $\hat{D}(\varrho) = \sum_y D(y)\,\psi(\mathrm{tr}(\varrho y))$ *for* $1 \times n$ *matrices* ϱ *(the sum over the* $n \times 1$ *matrices* y*),* P' *is the polynomial obtained from* P *by the substitution* $X_{v,i,1} \mapsto -\epsilon s_i\, X_{v,1,i}$*, and* $(1,k)$*,* $(1, k\,\mathrm{flp}_\vartheta)$ *are the points of* $\mathrm{G}(\pm\epsilon)$ *with infinite part* 1 *and finite parts* k*,* $k\,\mathrm{flp}_\vartheta$*.*

Proof. Throughout, ϵ, S (signs s on n), ϑ, β, α', k are fixed. Put $\mathfrak{m} = \mathfrak{m}_\vartheta$, $\Sigma = \Sigma(\mathfrak{m})$, $R = R_\mathfrak{m}$, $t = t_\vartheta$ (local in this proof), $\mathcal{O}_\Sigma = \prod_{w\in\Sigma} \mathcal{O}_{E,w}$ and $\psi_0(x) = \psi_{E,f}(\jmath\alpha\bar{\alpha}x)$. By Lemma 6.4.90, $\mathfrak{m}$ is a modulus, so Σ contains the conjugate of none of its members; hence for $w \in \Sigma$ the place $\bar{w}$ does not divide $\mathfrak{m}$ and $t_{\bar{w}} = 1$. As t generates $\mathfrak{m}\widehat{\mathcal{O}}_E$, $t_w\mathcal{O}_{E,w} = \mathfrak{m}\mathcal{O}_{E,w}$ for $w \in \Sigma$, so $R \cong \mathcal{O}_\Sigma/t\mathcal{O}_\Sigma$ (Chinese remainder theorem) and $\#R = \prod_{w\in\Sigma} |t_w|_w^{-1}$. By Lemma 4.1.3, $\widehat{\mathcal{O}}_E$ is its own annihilator under $(u,v) \mapsto \psi_0(\bar{u}v)$; in particular ψ_0 is trivial on $\widehat{\mathcal{O}}_E$. Put $c_\epsilon = c^\epsilon$, a unit of $\widehat{\mathcal{O}}_E$ with $c_\epsilon\bar{c}_\epsilon = (c\bar{c})^\epsilon = -1$, so $\bar{c}_\epsilon^{-1} = -c_\epsilon$. Write $p = x_{\ell_{-\epsilon}}$ and $p' = x_{\ell_\epsilon}$ for the standard points (ideles: 1, or the idele with components 1 at the infinite places and c at the finite places, for the signs $+1$, -1); then $p = (1, c_\epsilon)\,p'$ in both cases, $(1,y)$ denoting the idele with infinite components 1 and finite part y. Put

$$\gamma_\alpha = (1, \bar{\alpha}/\alpha), \qquad \gamma_t = (1, \bar{t}/t), \qquad \gamma_\alpha\,(1,k)\,\gamma_t = (1, k\,\mathrm{flp}_\vartheta),$$

elements of norm one, that is points of the unitary group $\mathrm{G}(\pm\epsilon) = \mathrm{U}(1)(\mathbb{A}_F)$ of a line. Let $\ell' = (\ell_\epsilon)_{\gamma_\alpha} = (\epsilon, p'\gamma_\alpha)$ be the moved line, and

$$\mathrm{H}_1 = \mathrm{Hom}(\ell_{-\epsilon}, S), \qquad \mathrm{H}_2 = \mathrm{Hom}(S, \ell'), \qquad \mathrm{H}_3 = \mathrm{Hom}(S, \ell_\epsilon).$$

The vectors of H_1 are $n \times 1$ matrices, those of H_2, H_3 are $1 \times n$ matrices; we index both by n. The sign of i in H_1 is $\sigma_i = -\epsilon s_i$, in H_2 and H_3 it is $-\sigma_i$; H_2 and H_3 have the same theta model $\mathcal{M}'$, and $\mathcal{M}$ denotes the theta model of H_1. Let $\hat{\sigma}_i \in \mathbb{A}_E$ be σ_i at the infinite places and 1 at the finite places.

Step 1: the coordinate flip. Let $\lambda = (1, -c_\epsilon\alpha/\bar{\alpha}) \in \mathbb{A}_E^\times$, so $\lambda\bar{\lambda}$ is 1 at the infinite and $c_\epsilon\bar{c}_\epsilon = -1$ at the finite places. For a $1 \times n$ adelic matrix Y let $\mathrm{fl}(Y)$ be the $n \times 1$ matrix with entries $\mathrm{fl}(Y)_i = \lambda\hat{\sigma}_i\bar{Y}_i$; in matrix form $\mathrm{fl}(Y) = \lambda\,\varepsilon_s\,Y^*\,\varepsilon_{-\epsilon}$, $\varepsilon_{-\epsilon}$ the sign idele of $\ell_{-\epsilon}$. It is additive, a homeomorphism, and has the following four properties.

(i) *Bicharacters.* $\overline{\mathrm{fl}(Y')_i}\,\hat{\sigma}_i\,\mathrm{fl}(Y)_i = \lambda\bar{\lambda}\,\hat{\sigma}_i\,Y_i'\bar{Y}_i = -\hat{\sigma}_i'Y_i'\bar{Y}_i$, where $\hat{\sigma}_i'$ is the sign of i in H_2 at the infinite places and 1 at the finite places. Hence the argument of ψ_E in $\beta_{\mathrm{H}_1}(\mathrm{fl}Y, \mathrm{fl}Y')$ is $-\frac{\jmath}{2}\sum_i \hat{\sigma}_i'Y_i'\bar{Y}_i = \overline{\frac{\jmath}{2}\sum_i \hat{\sigma}_i'\bar{Y}_i'Y_i}$, and $\beta_{\mathrm{H}_1}(\mathrm{fl}Y, \mathrm{fl}Y') = \beta_{\mathrm{H}_2}(Y, Y')$.

(ii) *Vacua.* At $v \in \Phi$, $|\mathrm{fl}(Y)_{i,v}| = |Y_{i,v}|$. At the finite places, for $Y = \alpha Z$, $\mathrm{fl}(\alpha Z)_i = -c_\epsilon(\alpha/\bar{\alpha})\bar{\alpha}\bar{Z}_i = \alpha(-c_\epsilon\bar{Z}_i)$; as c_ϵ is a unit, $\mathrm{fl}(Y)_f \in \alpha\widehat{\mathcal{O}}_E^n$ if and only if $Y_f \in \alpha\widehat{\mathcal{O}}_E^n$. On this set $\sum_i \overline{\mathrm{fl}(Y)_i}\mathrm{fl}(Y)_i = -\sum_i \bar{Y}_iY_i = -\alpha\bar{\alpha}q$ at the finite places, with $q = \sum_i \bar{Z}_iZ_i \in \widehat{\mathcal{O}}_E$, and the two finite vacuum phases of (WD5) differ by $\psi_{E,f}(c_0\jmath\alpha\bar{\alpha}q) = \psi_0(c_0q) = 1$, as c_0q is integral. So $e_n(\mathrm{fl}(Y)) = e_n(Y)$.

(iii) *Measures.* In the coordinates (u,z) of (WD6), fl is $u_{v,i} \mapsto \sigma_i\bar{u}_{v,i}$ at the infinite places and $z_i \mapsto -c_\epsilon\bar{z}_i$ at the finite places (by (ii)); these preserve Lebesgue measure, respectively $\widehat{\mathcal{O}}_E^n$ and its Haar measure. So fl carries μ_n to μ_n.

(iv) *Rational vectors.* Those of H_1 are $x_S^{-1}\xi p$ ($\xi \in E^{n\times 1}$), those of H_2 are $(p'\gamma_\alpha)^{-1}\eta x_S$ ($\eta \in E^{1\times n}$). From $x_S^*J_Sx_S = \varepsilon_s$ we get $\varepsilon_s x_S^* = x_S^{-1}J_S^{-1}$, and from the point of $\ell_{-\epsilon}$, $\varepsilon_{-\epsilon} = -\epsilon\bar{p}p$. Hence

$$\mathrm{fl}((p'\gamma_\alpha)^{-1}\eta x_S) = \lambda\,x_S^{-1}J_S^{-1}\eta^*\,\overline{p'\gamma_\alpha}^{-1}(-\epsilon)\bar{p}p = x_S^{-1}(-\epsilon J_S^{-1}\eta^*)p\cdot\lambda\,(1,\bar{c}_\epsilon)\,\gamma_\alpha,$$

using $\bar{p}/\bar{p}' = (1,\bar{c}_\epsilon)$ and $\bar{\gamma}_\alpha^{-1} = \gamma_\alpha$. The finite part of $\lambda(1,\bar{c}_\epsilon)\gamma_\alpha$ is $-c_\epsilon\bar{c}_\epsilon = 1$, its infinite part 1. As $\eta \mapsto -\epsilon J_S^{-1}\eta^*$ is a bijection of $E^{1\times n}$ onto $E^{n\times 1}$, fl maps the rational vectors of H_2 onto those of H_1.

Let $\mathrm{Fl}f = f \circ \mathrm{fl}$. By (i), (ii) and (iii), applied to the images under fl^{-1} of vectors of H_1, the additive homeomorphism fl^{-1} from the vectors of H_1 to those of H_2 satisfies the hypotheses of (1) of Lemma 6.3.65 for the signs of H_1 and of H_2, and $\mathrm{Fl}f = f \circ (\mathrm{fl}^{-1})^{-1}$. So Fl is a linear bijection of $\mathcal{M}$ onto $\mathcal{M}'$ preserving norm and inner product, $\mathrm{Fl}v^0 = v^0$, and $\mathrm{Fl}\,\rho(X) = \rho(\mathrm{fl}^{-1}X)\,\mathrm{Fl}$, that is $\mathrm{Fl}\,\rho(\mathrm{fl}(Y)) = \rho(Y)\,\mathrm{Fl}$. By (iv), fl^{-1} maps the rational vectors of H_1 onto those of H_2, so (3) of Lemma 6.3.65 (for $V = \mathrm{H}_1$, $V' = \mathrm{H}_2$, $\tau = \mathrm{fl}^{-1}$ and $\Pi = \mathrm{Fl}$) gives $z_0 \in \mathbb{C}$, $|z_0| = 1$, with

$$\theta_{\mathrm{H}_2}(\mathrm{Fl}f) = z_0\,\theta_{\mathrm{H}_1}(f) \qquad (f \in \mathcal{M}). \tag{6.107}$$

Step 2: the Weil operators. Let $g \in \mathrm{G}(-\epsilon)$ and $h \in \mathrm{G}(s)$. The pair map gives the operator $A\colon X \mapsto hXg^{-1} = g^{-1}hX$ of H_1 and, for the pair (h, g) of (S, ℓ'), the operator $B\colon Y \mapsto gYh^{-1}$ of H_2; on coordinate vectors indexed by n, $A = g^{-1}h$ and $B = gh^{-\mathsf{T}} = (A^{-1})^{\mathsf{T}}$. Since $h^*\varepsilon_s h = \varepsilon_s$ gives $\varepsilon_s h^{-*} = h\varepsilon_s$, and $\bar{g} = g^{-1}$,

$$\mathrm{fl}(BY) = \lambda\,\varepsilon_s h^{-*} Y^* \bar{g}\,\varepsilon_{-\epsilon} = g^{-1}h\,\mathrm{fl}(Y) = A\,\mathrm{fl}(Y).$$

The multipliers. Let $d = \det A = g^{-\#n} \det h$. The operator A lies in the group G of the signs $(\sigma_i)_{i\in n}$ of H_1 (it is a pair image), the signs of H_2 are $(-\sigma_i)_{i\in n}$, and $B = (A^{-1})^{\mathsf{T}}$; so (4) of Lemma 6.3.65 for $\delta = (\sigma_i)_{i\in n}$ gives $\Delta_{\mathrm{H}_2}(B) = \upsilon(d)\,\Delta_{\mathrm{H}_1}(A)$, and

$$\frac{\Delta_{\mathrm{H}_1}(A)}{\Delta_{\mathrm{H}_2}(B)} = \upsilon(d)^{-1} = \upsilon(g)^{\#n}\,\upsilon(\det h)^{-1}.$$

Intertwining. As $\mathrm{fl}(BY) = A\,\mathrm{fl}(Y)$ for every vector Y of H_2, $\mathrm{fl}^{-1}(AX) = B\,\mathrm{fl}^{-1}(X)$ for every vector X of H_1, and (2) of Lemma 6.3.65 gives

$$\mathrm{Fl}\,\omega(A) = \frac{\Delta_{\mathrm{H}_1}(A)}{\Delta_{\mathrm{H}_2}(B)}\,\omega(B)\,\mathrm{Fl}.$$

With (WR4) this reads, for the pair operators with trivial characters,

$$\mathrm{Fl}\,\omega_{1,1}^{\ell_{-\epsilon},S}(g,h) = \omega_{\upsilon^{\#n},\upsilon}^{S,\ell'}(h,g)\,\mathrm{Fl}. \tag{6.108}$$

Step 3: the reversed kernel on the standard line. The point of H_2 is that of H_3 composed with $\Lambda\colon Y \mapsto \gamma_\alpha Y$, the image of $(1, \gamma_\alpha)$ under the pair map of (S, ℓ_ϵ); so $\mathrm{H}_2 = (\mathrm{H}_3)_\Lambda$ and its rational vectors are Λ^{-1} of those of H_3. If k_3 is a transporting element of H_3 (WR3), then $k_3\Lambda$ is one of H_2, so by Lemma 4.1.17 (independence of the transporting element) and the multiplicativity of ω (Proposition 4.1.14), $\theta_{\mathrm{H}_2} = \theta_{\mathrm{H}_3} \circ \omega(\Lambda)$. Hence for automorphic characters a, a' and $F \in \mathcal{M}'$, by (WR4) and $\omega(\Lambda)\omega_{1,1}^{S,\ell_\epsilon}(h,g) = \omega_{1,1}^{S,\ell_\epsilon}(h,\gamma_\alpha g)$,

$$\theta_{a,a'}^{S,\ell'}(F)(h,g) = a(g)\,a'(\det h)^{-1}\,\theta_{\mathrm{H}_3}\big(\omega_{1,1}^{S,\ell_\epsilon}(h,\gamma_\alpha g)F\big) = a(\gamma_\alpha)^{-1}\,\theta_{a,a'}^{S,\ell_\epsilon}(F)(h,\gamma_\alpha g).$$

Combining with (6.107) and (6.108): for $f \in \mathcal{M}$, $g \in \mathrm{G}(-\epsilon)$, $h \in \mathrm{G}(s)$,

$$\theta_{1,1}^{\ell_{-\epsilon},S}(f)(g,h) = z_0^{-1}\,\theta_{\mathrm{H}_2}\big(\mathrm{Fl}\,\omega_{1,1}^{\ell_{-\epsilon},S}(g,h)f\big) = z_0^{-1}\,\upsilon(\gamma_\alpha)^{-\#n}\,\theta_{\upsilon^{\#n},\upsilon}^{S,\ell_\epsilon}(\mathrm{Fl}f)(h,\gamma_\alpha g). \tag{6.109}$$

Step 4: Fock vectors. At the infinite places fl^{-1} sends X to Y with $Y_i = \sigma_i \bar{X}_i$; as κ_v is real, $\mathrm{fl}^{-1}(\mathrm{rv}(y)) = \mathrm{rv}(y^\sharp)$ with $y^\sharp_{v,1,i} = \sigma_i \bar{y}_{v,i,1}$, and $y \mapsto y^\sharp$ preserves ν. By Step 1, $\mathrm{Fl}\rho(\mathrm{rv}(y)) = \rho(\mathrm{rv}(y^\sharp))\mathrm{Fl}$, and Fl is a bounded linear map, so it passes under the integral of (WR6): for a Fock vector v of H_1 and $f \in \mathcal{M}$, substituting $y' = y^\sharp$,

$$\mathrm{Fl}(v \otimes f) = \int v(y)\,\rho(\mathrm{rv}(y^\sharp))\,\mathrm{Fl}f\,d\nu(y) = v^\flat \otimes \mathrm{Fl}f, \qquad v^\flat(y') = v(y),\ y_{v,i,1} = \sigma_i \bar{y}'_{v,1,i}.$$

For $v = v_P$: $e^\infty(y) = e^\infty(y')$; if $\sigma_i = 1$, the coordinate $\zeta(y)_{v,i,1} = \bar{y}_{v,i,1} = y'_{v,1,i} = \zeta(y')_{v,1,i}$ (the sign of $(1,i)$ in H_2 is -1); if $\sigma_i = -1$, $\zeta(y)_{v,i,1} = y_{v,i,1} = -\bar{y}'_{v,1,i} = -\zeta(y')_{v,1,i}$. So $\zeta(y)_{v,i,1} = \sigma_i\,\zeta(y')_{v,1,i} = -\epsilon s_i\,\zeta(y')_{v,1,i}$, and $v_P^\flat = v_{P'}$. By Proposition 4.1.14, $\omega(\Lambda')\rho(z)\omega(\Lambda')^{-1} = \rho(\Lambda' z)$; for Λ' the pair image of $((1,\gamma'),1)$, γ' finite, $\Lambda'\mathrm{rv}(y) = \mathrm{rv}(y)$, so likewise

$$\omega_{1,1}^{\ell_{-\epsilon},S}((1,\gamma'),1)(v\otimes f) = v\otimes \omega_{1,1}^{\ell_{-\epsilon},S}((1,\gamma'),1)f. \tag{6.110}$$

Step 5: class indicators. For $y\in R^{n\times 1}$ fix a lift $\tilde{y}\in\mathcal{O}_\Sigma^n$, let q_y be the finite vector with components $-t_w^{-1}\tilde{y}_w$ at $w\in\Sigma$ and 0 elsewhere, and $\varphi_y = \rho(\mathrm{fv}(q_y))v^0\in\mathcal{M}$; let δ_y be the indicator of $\{y\}$.

(a) By (2) and (3) of Lemma 4.1.3 (with $A=\Sigma$, $\mathbf{1}_\Sigma\otimes_\Sigma v^0 = v^0$), $\varphi_y = \Psi_y\otimes_\Sigma v^0$ with $\Psi_y(x) = \psi_0(\sum_i \overline{(q_y)_i}(2x+q_y)_{\Sigma,i}/2)\mathbf{1}_\Sigma(x+q_y) = \mathbf{1}_\Sigma(x - t^{-1}\tilde{y})$, the phase being 1 because $\bar{q}_y$ is supported on $\bar{\Sigma}$, which is disjoint from Σ. Apply (1) of Lemma 4.1.16 to the pair $(\ell_{-\epsilon},S)$, $A=\Sigma$, trivial characters, the finite point $\bar{t}/t$ of $\ell_{-\epsilon}$ (unitary, 1 outside $\Sigma\cup\bar{\Sigma}$) and 1 of S. At $w\in\Sigma$, $(\bar{t}/t)_w = \overline{t_{\bar{w}}}/t_w = t_w^{-1}$; so $\Psi'_y(X) = \Psi_y(X\bar{t}/t) = 1$ if and only if $t_w^{-1}(X_w - \tilde{y}_w)$ is integral for all $w\in\Sigma$, that is $\Psi'_y = \delta_y^\natural$. The scalar is $\upsilon(\delta_t)^{\#n}|\delta_t|^{\#n/2}$, δ_t the idele with components t_w^{-1} at $w\in\Sigma$ and 1 elsewhere ($1[p] = \upsilon^{-p}$), and $|\delta_t| = \#R$. With $A_\vartheta = \upsilon(\delta_t)^{\#n}(\#R)^{\#n/2}$, $|A_\vartheta|^2 = (\#R)^{\#n}$,

$$\omega_{1,1}^{\ell_{-\epsilon},S}(\gamma_t,1)\,\varphi_y = A_\vartheta\,\delta_y^\natural\otimes_\Sigma v^0.$$

(b) By (ii), $\mathrm{fl}^{-1}(\mathrm{fv}(q)) = \mathrm{fv}(c_\epsilon\bar{q}^{\mathsf{T}})$ ($\alpha q = \alpha(-c_\epsilon)\bar{Z}$ gives $Z = -\bar{c}_\epsilon^{-1}\bar{q} = c_\epsilon\bar{q}$). So, by Step 1, $\mathrm{Fl}\varphi_y = \rho(\mathrm{fv}(r_y))v^0$ with $r_y = c_\epsilon\bar{q}_y^{\mathsf{T}}$, supported on $\bar{\Sigma}$, and $\bar{r}_y = \bar{c}_\epsilon q_y^{\mathsf{T}}$. By (2), (3) of Lemma 4.1.3 for H_3 (whose theta model is $\mathcal{M}'$), $\mathrm{Fl}\varphi_y = \hat{\Psi}_y\otimes_\Sigma v^0$ with, as $(r_y)_\Sigma = 0$,

$$\hat{\Psi}_y(x) = \psi_0\Big(\sum_i(\bar{r}_y)_i x_{\Sigma,i}\Big)\mathbf{1}_\Sigma(x) = \psi_0\Big(-\bar{c}_\epsilon t^{-1}\sum_i \tilde{y}_i x_{\Sigma,i}\Big)\mathbf{1}_\Sigma(x).$$

Define $\psi(a \bmod t\mathcal{O}_\Sigma) = \psi_0(-\bar{c}_\epsilon t^{-1}a)$ for $a\in\mathcal{O}_\Sigma$, read as the finite adele with components a_w at Σ and 0 elsewhere. It is well defined, since for $a\in t\mathcal{O}_\Sigma$ the argument is integral and ψ_0 is trivial on $\widehat{\mathcal{O}}_E$, and it is an additive character of R; it depends only on ϵ and ϑ. For x integral at Σ with $x_\Sigma \bmod \mathfrak{m} = \varrho$, $\sum_i \tilde{y}_i x_{\Sigma,i}$ lifts $\mathrm{tr}(\varrho y)$. Hence $\hat{\Psi}_y = \hat{\delta}_y^\natural$ with $\hat{\delta}_y(\varrho) = \psi(\mathrm{tr}(\varrho y))$.

Step 6: conclusion. Fix y. By (XD5), Step 5 (a) and (6.110),

$$\mathrm{mod}_{\mathfrak{m}}(\delta_y, v_P) = v_P\otimes(\delta_y^\natural\otimes_\Sigma v^0) = A_\vartheta^{-1}\,\omega_{1,1}^{\ell_{-\epsilon},S}(\gamma_t,1)\,(v_P\otimes\varphi_y).$$

By (WR4),

$$\omega_{1,\beta}((1,k),h) = \beta((1,k))^{-1}\omega_{1,1}((1,k),h),$$

and $\omega_{1,1}((1,k),h)\omega_{1,1}(\gamma_t,1) = \omega_{1,1}((1,k)\gamma_t,h)$ (the pair map is a homomorphism and ω is multiplicative, Proposition 4.1.14). Hence, by (6.109), Step 4 and Step 5 (b),

$$\theta_{1,\beta}^{\ell_{-\epsilon},S}(\mathrm{mod}_{\mathfrak{m}}(\delta_y,v_P))((1,k),h) = \frac{\theta_{1,1}^{\ell_{-\epsilon},S}(v_P\otimes\varphi_y)((1,k)\gamma_t,h)}{A_\vartheta\,\beta((1,k))} = \frac{\theta^{S,\ell_\epsilon}_{\upsilon^{\#n},\upsilon}(\mathrm{mod}_{\mathfrak{m}}(\hat{\delta}_y,v_{P'}))(h,g_1)}{A_\vartheta\,\beta((1,k))\,z_0\,\upsilon(\gamma_\alpha)^{\#n}},$$

with $g_1 = \gamma_\alpha(1,k)\gamma_t = (1, k\,\mathrm{flp}_\vartheta)$, since $\mathrm{Fl}(v_P\otimes\varphi_y) = v_{P'}\otimes(\hat{\delta}_y^\natural\otimes_\Sigma v^0)$. By (WR4),

$$\theta^{S,\ell_\epsilon}_{\upsilon^{\#n},\upsilon}(F)(h,g_1) = \upsilon(g_1)^{\#n}\alpha'(g_1)^{-1}\theta^{S,\ell_\epsilon}_{\alpha',\upsilon}(F)(h,g_1).$$

Put

$$C = \frac{\upsilon(g_1)^{\#n}}{A_\vartheta\,\beta((1,k))\,z_0\,\upsilon(\gamma_\alpha)^{\#n}\,\alpha'(g_1)},$$

which does not depend on y, P, h and has $|C|^2 = |A_\vartheta|^{-2} = (\#R)^{-\#n}$, all other factors having modulus one; so $C \neq 0$ and $|C|^2\,\#(R)^{\#n} = 1$. Then the identity of the statement holds for $D = \delta_y$. A general D is $\sum_y D(y)\delta_y$, and $\hat{D} = \sum_y D(y)\hat{\delta}_y$; the maps $D \mapsto D^\natural \mapsto D^\natural \otimes_\Sigma v^0$ ((1) of Lemma 4.1.3: the datum does not depend on the section), $v \otimes \cdot$, the Weil operators and the theta functionals are linear, so both sides are linear in D, and the identity holds for every D, every P and every h, with the same ψ and C. □

Lemma 6.4.95. *Let D be admissible data and $0 \leq j < m$. Let $Z = Y_j^{j+1}$, the space at the node $(\mathrm{I}, j+1, j)$, with index set n_Z, and let $\rho\colon \mathrm{U}(\tilde{Y}_j^{j+1})(\mathbb{A}_F) \to \mathrm{U}(Z)(\mathbb{A}_F)$ be the isomorphism given by the renumbering of (GP3). For an m-fold twist ϑ let $f_\vartheta = \mathrm{flp}_\vartheta$, and let $\chi^{\mathrm{h}} = \mu_{j+1}^0 \upsilon^{\lceil \mathrm{rk}\, Z/2 \rceil}$ and $\chi_\vartheta^{\mathrm{v}} = \mu_{j+1}^0 \vartheta^{j+1} \upsilon^{\lfloor \mathrm{rk}\, Z/2 \rfloor}$ be the edge characters of (GP6) for $l = j$ and $N = \mathrm{rk}\, Z$. For an $n_Z \times 1$ matrix w and a $1 \times n_Z$ matrix w' over R_ϑ, polynomials P in the entries $X_{v,i,1}$ and P' in the entries $X_{v,1,i}$ ($v \in \Phi$, $i \in n_Z$), and $g \in \mathrm{U}(\tilde{Y}_j^{j+1})(\mathbb{A}_F)$ put*

$$K_\vartheta^{\mathrm{col}}[w,P](g) = \theta_{1,\chi^{\mathrm{h}}}^{\ell_{(-1)^j},Z}\big(\mathrm{mod}_{\mathfrak{m}_\vartheta}(\delta_w, v_P)\big)\big((1, f_\vartheta^j), \rho(g)\big),$$
$$K_\vartheta^{\mathrm{row}}[w',P'](g) = \theta_{\chi_\vartheta^{\mathrm{v}},\upsilon}^{Z,\ell_{(-1)^{j+1}}}\big(\mathrm{mod}_{\mathfrak{m}_\vartheta}(\delta_{w'}, v_{P'})\big)\big(\rho(g), (1, f_\vartheta^{j+1})\big),$$

δ denoting the indicator of one matrix. For a monotone path u in the grid z and an edge tuple S let $\mathrm{fm}_u(S)$ be the composite along u of the moves by the matrices of S (the transposed move for a step down, the lift move for a step right). Let u_{I}, u_{II} be monotone paths from $(0,m)$ to $(j, j+1)$ in the grids Y and $\tilde{Y}$; let Γ' be the path with index j whose halves are u_z followed by the step down to (j,j), and Γ the path with index $j+1$ whose halves are u_z followed by the step right to $(j+1, j+1)$. For a period triple (ϑ, y', φ) and an edge tuple S put $\varphi_S = \mathrm{fm}_{u_{\mathrm{II}}}(S)\varphi \in \mathcal{F}(\mathrm{II}, j, j+1)$ and

$$y_S^- = \mathrm{mv}_{((\mathrm{I},j,j),(\mathrm{I},j+1,j))}\big(y_2(S)\big)\,\mathrm{mv}_{((\mathrm{I},j,j),(\mathrm{I},j,j+1))}\big(y_1(S)\big)\,\mathrm{fm}_{u_{\mathrm{I}}}(S)\,y',$$
$$y_S^+ = \mathrm{mv}_{((\mathrm{I},j+1,j),(\mathrm{I},j+1,j+1))}\big(x_2(S)\big)\,\mathrm{mv}_{((\mathrm{I},j,j+1),(\mathrm{I},j+1,j+1))}\big(x_1(S)\big)\,\mathrm{fm}_{u_{\mathrm{I}}}(S)\,y',$$

both in $\mathcal{F}(\mathrm{I}, j+1, j)$. For families $\Psi' = (\Psi'_\vartheta)$, $\Psi = (\Psi_\vartheta)$ of functions of edge tuples, a real point g_0 of $\mathrm{U}(Z)$ (read in $\mathrm{U}(Z)(\mathbb{A}_F)$ with finite part 1) and polynomials P, P' as above define the column period *and the* row period

$$C(\Psi'; g_0, P)(\vartheta, y', \varphi) = \sum_S \Psi'_\vartheta(S) \int_{[\mathrm{U}(\tilde{Y}_j^{j+1})]} K_\vartheta^{\mathrm{col}}[v(S), P](g)\,\varphi_S(g)\,y_S^-\big(\rho(g)g_0\big)\,dg,$$

$$R(\Psi; g_0, P')(\vartheta, y', \varphi) = \sum_S \Psi_\vartheta(S) \int_{[\mathrm{U}(\tilde{Y}_j^{j+1})]} K_\vartheta^{\mathrm{row}}[v'(S), P'](g)\,\varphi_S(g)\,y_S^+\big(\rho(g)g_0\big)\,dg,$$

the sums over the edge tuples supported on the edges of Γ', resp. of Γ. Then:

(1) for every m-fold twist ϑ, all w, w', P, P' as above, every $\varphi'' \in \mathcal{F}(\mathrm{II}, j, j+1)$ and every $y'' \in \mathcal{F}(\mathrm{I}, j+1, j)$, the functions

$$g \mapsto K_\vartheta^{\mathrm{col}}[w,P](g)\,\varphi''(g)\,y''(\rho(g)g_0),$$
$$g \mapsto K_\vartheta^{\mathrm{row}}[w',P'](g)\,\varphi''(g)\,y''(\rho(g)g_0)$$

are functions on $[\mathrm{U}(\tilde{Y}_j^{j+1})]$ whose integrals converge absolutely; in particular the column and row periods are defined;

(2) if for every g_0 and every P there is $\beta \in \mathbb{C}$ with $C(\Psi'; g_0, P)(\vartheta, y', \varphi) = \beta\,\Xi(\vartheta, y', \varphi)$ for all period triples, then $\Psi' \propto_{\Gamma'} \Xi$;

(3) if $\Psi \propto_\Gamma \Xi$, then for every g_0 and every P' there is $\beta \in \mathbb{C}$ with $R(\Psi; g_0, P')(\vartheta, y', \varphi) = \beta\, \Xi(\vartheta, y', \varphi)$ for all period triples.

Proof. Fix D and $j < m$. Write $p = (\mathrm{I}, j, j)$, $p_Z = (\mathrm{I}, j+1, j)$, $p^+ = (\mathrm{I}, j+1, j+1)$, $\tilde{p} = (\mathrm{II}, j, j)$, $q = (\mathrm{II}, j, j+1)$, $\tilde{p}^+ = (\mathrm{II}, j+1, j+1)$, N_x for the rank of the space at a node x, $\ell_- = \ell_{(-1)^j}$, $\ell_+ = \ell_{(-1)^{j+1}}$, and $\mathrm{ec}_{c,l}(N)$ for the edge character of (GP6). For a monotone path, an edge tuple S and a period triple (ϑ, y', φ) put $u_S = \mathrm{mv}_{(p,(\mathrm{I},j,j+1))}(y_1(S))\,\mathrm{fm}_{u_\mathrm{I}}(S) y' \in \mathcal{F}(p)$ and $U_S = \mathrm{mv}_{((\mathrm{I},j,j+1),p^+)}(x_1(S))\,\mathrm{fm}_{u_\mathrm{I}}(S) y' \in \mathcal{F}(p^+)$, so that y_S^- is the lift move of u_S along (p, p_Z) with $y_2(S)$ and y_S^+ the transposed move of U_S along (p_Z, p^+) with $x_2(S)$.

Step 0: spaces, kernels, heights, types.

(a) *Identifications.* By (GP2) and (GP8) there is a sign-preserving bijection $e_-\colon n_{\tilde{p}} \to n_p \sqcup \{*\}$ (the decomposition $n_{\tilde{p}} = n_p \sqcup T$) with $\tilde{Y}_j^j = (Y_j^j \oplus \ell_-)^{e_-}$: for $j = 0$ this is (GP8) with e_- the identity, the added line being the base index r; for $j \geq 1$ both $\tilde{Y}_j^j$ and $Y_j^j \oplus \ell_-$ are standard spaces (the orthogonal sum of standard spaces is standard), and a standard space renumbered by a sign-preserving bijection is the standard space of the renumbered signs. Likewise $\tilde{Y}_{j+1}^{j+1} = (Y_{j+1}^{j+1} \oplus \ell_+)^{e_+}$ $(j+1 \geq 1)$, and $\tilde{Y}_j^{j+1} = Z^{e_0}$ with e_0 the renumbering of (GP3), $\rho(g^{e_0}) = g$. Write $\iota_\pm(h,k) = \mathrm{diag}(h,k)^{e_\pm}$; this is the inclusion of (GP2) used in (3.3), and, real and finite components commuting, the integrand of $\langle u, v\rangle_{l,g}$ there is $u(h)\, v(\iota(h, (1, \mathrm{flp}_\vartheta^l))(g,1))$.

(b) *Characters.* By (GP6), for the pair (x, x') of an edge in the notation of (XD2) (Hom of the end with the smaller indices into the other), the character on x' is the edge character at the rank N_x and the character on x the one at $N_{x'}$. The ranks are $N_p = r + 2jt$, $N_{\tilde{p}} = N_p + 1$, $N_q = N_{p_Z} = r + (2j+1)t$, $N_{p^+} = r + 2(j+1)t$, $N_{\tilde{p}^+} = N_{p^+} + 1$, with N_p, N_{p^+} odd. Hence: the edge $(\tilde{p}, q)$ (transposed move, $c = \mathrm{I}$, $l = j$) has $\mathrm{ec}_{\mathrm{I},j}(N_{\tilde{p}}) = \mu_{j+1}^0 \upsilon^{(N_p+1)/2} = \mathrm{ec}_{\mathrm{I},j}(N_p)$ on q and χ^h on $\tilde{p}$; the edge (p, p_Z) (lift move) has $\mathrm{ec}_{\mathrm{I},j}(N_p)$ on Z and χ^h on p; the edge $(q, \tilde{p}^+)$ (lift move, $c = \mathrm{II}$) has $\chi_\vartheta^\mathrm{v}$ on $\tilde{p}^+$ and $\mathrm{ec}_{\mathrm{II},j}(N_{\tilde{p}^+}) = \mathrm{ec}_{\mathrm{II},j}(N_{p^+})\,\upsilon$ on q (as $\lfloor N_{\tilde{p}^+}/2 \rfloor = \lfloor N_{p^+}/2 \rfloor + 1$); the edge (p_Z, p^+) (transposed move) has $\chi_\vartheta^\mathrm{v}$ on p^+ and $\mathrm{ec}_{\mathrm{II},j}(N_{p^+})$ on Z.

(c) *Splitting.* Read matrices and polynomials on $q \times \tilde{p}$ and $\tilde{p}^+ \times q$ entries through $e_0, e_\pm$ as in Lemma 6.4.91; so $S(\tilde{p}, q) = (y_2(S) \,|\, v(S))$ and $S(q, \tilde{p}^+) = \binom{x_2(S)}{v'(S)}$. For polynomials A in the variables of $n_Z \times n_p$ (resp. $n_{p^+} \times n_Z$) entries and B in those of $n_Z \times \{*\}$ (resp. $\{*\} \times n_Z$) entries, let Q_{AB} be the polynomial of the $q \times \tilde{p}$ (resp. $\tilde{p}^+ \times q$) entries obtained from AB by (4) of Lemma 6.4.96. Then (3), (4) of Lemma 6.4.96, Lemma 6.4.97 (a), (b) and (b) above give, with $\kappa_{X,Q}^e$ the theta kernel of the moves along an edge e with the datum $\mathrm{mod}_{\mathfrak{m}_\vartheta}(\delta_X, v_Q)$ and the characters of (b), for $h \in \mathrm{G}$ of p, resp. of p^+, $k \in G_f(1)$ and $g \in \mathrm{U}(\tilde{Y}_j^{j+1})(\mathbb{A}_F)$:

$$\kappa^{(\tilde{p},q)}_{(X_1|X_2),Q_{AB}}(\iota_-(h,(1,k)), g) = \kappa^{(p,p_Z)}_{X_1,A}(h, \rho(g)) \cdot \theta^{\ell_-,Z}_{1,\chi^\mathrm{h}}(\mathrm{mod}_{\mathfrak{m}_\vartheta}(\delta_{X_2}, v_B))((1,k), \rho(g)), \tag{6.111}$$

$$\kappa^{(q,\tilde{p}^+)}_{\binom{X_1}{X_2},Q_{AB}}(g, \iota_+(h,(1,k))) = \theta^{Z,\ell_+}_{\chi_\vartheta^\mathrm{v},\upsilon}(\mathrm{mod}_{\mathfrak{m}_\vartheta}(\delta_{X_2}, v_B))(\rho(g), (1,k)) \cdot \kappa^{(p_Z,p^+)}_{X_1,A}(\rho(g), h). \tag{6.112}$$

In (6.111) the target characters multiply, $\mathrm{ec}_{\mathrm{I},j}(N_p) \cdot 1$, and the source character χ^h is common; in (6.112) the target character $\chi_\vartheta^\mathrm{v}$ is common and the source characters multiply, $\mathrm{ec}_{\mathrm{II},j}(N_{p^+})\,\upsilon$. The indicator $\delta_{(X_1|X_2)}$ is $\delta_{X_1} \otimes \delta_{X_2}$. For $k = \mathrm{flp}_\vartheta^j$, resp. $\mathrm{flp}_\vartheta^{j+1}$, and $(X_2, B) = (v(S), P)$, resp. $(v'(S), P')$, the line factors are $K_\vartheta^\mathrm{col}[v(S), P](g)$ and $K_\vartheta^\mathrm{row}[v'(S), P'](g)$.

(d) *Heights.* For spaces with points V, V' and $h \in \mathrm{G}$ of V, h' of V', the lattice of $(V \oplus V')_{\mathrm{diag}(h,h')}$ is the product of the lattices of V_h, $V'_{h'}$ and the euclidean norm of a pair dominates that of each entry, so

$$\lambda_{V\oplus V'}(\mathrm{diag}(h,h')) = \min(\lambda_V(h), \lambda_{V'}(h')) \quad \text{and} \quad \mathrm{ht}_{V\oplus V'}(\mathrm{diag}(h,h')) \le \mathrm{ht}_V(h)\,\mathrm{ht}_{V'}(h').$$

With (1) of Lemma 6.4.96:

$$\mathrm{ht}_{\tilde{Y}^j_j}(\iota_-(h,(1,k))) \le c_k\,\mathrm{ht}_{Y^j_j}(h), \qquad \mathrm{ht}_{\tilde{Y}^{j+1}_{j+1}}(\iota_+(h,(1,k))) \le c_k\,\mathrm{ht}_{Y^{j+1}_{j+1}}(h)$$

with $c_k = \mathrm{ht}_{\ell_\pm}((1,k))$, and $\mathrm{ht}_Z(\rho(g)) = \mathrm{ht}_{\tilde{Y}^{j+1}_j}(g)$; ρ carries rational points to rational points and the measure to the measure.

(e) *Types.* By Lemma 6.4.15 (d) the Fock vectors of the joint harmonics $H_{(p,p_Z)}$ and $H_{(q,\tilde{p}^+)}$ of the lift moves along (p,p_Z) and $(q,\tilde{p}^+)$ ($j<m$) are edges for the weights of their characters from e_p to e_{p_Z} and from e_q to $e_{\tilde{p}^+}$; by Lemma 6.4.15 (b) ($o=0$, $a=j+1$, $b=j$) that of the transposed move along (p_Z,p^+) is an edge from $\bar{e}_{p_Z}$ to $\bar{e}_{p^+}$, hence a half edge for the reversed real part from e_{p^+} to e_{p_Z}. By (a) of (ED4) and the invariance of (ED1) under complex conjugation, e_p, e_q, e_{p^+} are cusp kernels of order 0; so by Lemma 6.3.75 the grid forms at p, q, p^+ decrease rapidly: $\sup|F|\,\mathrm{ht}^A < \infty$ for every A. Grid forms are bounded (ED2).

(f) *Bounds.* By Proposition 4.1.14 the Heisenberg operators are isometric and strongly continuous for the L^1 norm, so the integral of (WR6) gives $\|v\otimes f\| \le \|v\|\,\|f\|$ ($\|v\|$ the $L^1(\nu)$ norm). By Lemma 6.2.28, every theta kernel above satisfies $|\theta(v\otimes f)(g,h)| \le Y\|v\|\|f\|(\mathrm{ht}(g)\mathrm{ht}(h))^A$ with Y, A depending only on the two spaces. By Theorem 4.2.18 the quotients $[\mathrm{U}(V)]$ have finite volume; by Lemma 6.3.77 the kernels are invariant under rational points in each variable, continuous, and have real part $\Omega_{\gamma,\gamma'}$, the real Weil representation for the weights (γ,γ') of their characters, which acts by bounded operators of the Fock model (Proposition 4.1.14).

Step 1: (1). Let $\varphi'' \in \mathcal{F}(q)$, $y'' \in \mathcal{F}(p_Z)$. The function $F(g) = K^{\mathrm{col}}_\vartheta[w,P](g)\varphi''(g)y''(\rho(g)g_0)$ is continuous and left invariant under the rational points of $\tilde{Y}^{j+1}_j$ (by (d), (f) and the invariance of φ'', y''). By (f) and (d), $|K^{\mathrm{col}}_\vartheta[w,P](g)| \le C\,\mathrm{ht}_{\tilde{Y}^{j+1}_j}(g)^A$; by (e), $|\varphi''(g)|\mathrm{ht}(g)^A$ is bounded; y'' is bounded. So F is bounded on the quotient, which has finite volume, and its integral converges absolutely. The same holds for K^{row}. This is (1); in particular every summand of C and R is defined.

Step 2: (2). Let Ξ satisfy the hypothesis, and fix a real point g of $\mathrm{U}(\tilde{Y}^j_j)$ and Ψ'. For an edge tuple S on Γ', a period triple $x=(\vartheta,y',\varphi)$ and v in the Fock model $\mathcal{F}_1$ of $\mathrm{Hom}(\tilde{Y}^j_j,\tilde{Y}^{j+1}_j)$ let $f_S = \delta^{\natural}_{S(\tilde{p},q)} \otimes_{\Sigma(\mathfrak{m}_\vartheta)} v^0$ and

$$\Lambda_{S,x}(v) = \int_{[\mathrm{U}(Y^j_j)]} u_S(h) \int_{[\mathrm{U}(\tilde{Y}^{j+1}_j)]} \theta^{\tilde{p},q}(v\otimes f_S)\big(\iota_-(h,(1,\mathrm{flp}^j_\vartheta)),g'\big)\,\varphi_S(g')\,dg'\,dh,$$

the kernel with the characters of $(\tilde{p},q)$. By (d), (e), (f) the integrand is bounded by $C_S\|v\|$ on the product of the two quotients, of finite volume; so the double integral converges absolutely, Fubini's theorem applies, and $\Lambda_{S,x}$ is a continuous linear functional on $\mathcal{F}_1$ with $|\Lambda_{S,x}(v)| \le C'_S\|v\|$. Put $L_x = \sum_S \Psi'_\vartheta(S)\Lambda_{S,x}$, the sum over the tuples supported on the edges of Γ'.

(i) *The period.* The half Γ'_{I} carries y' to u_S, and Γ'_{II} carries φ to the transposed move of φ_S along $(\tilde{p},q)$, whose value at $\tilde{x}$ is $\int \kappa^{(\tilde{p},q)}_{S(\tilde{p},q),H}(\tilde{x},g')\varphi_S(g')\,dg'$, H its joint harmonic (Lemma 6.3.76

(1)). At $\tilde{x} = \iota_-(h,(1,\mathrm{flp}_\vartheta^j))(g,1)$, the homomorphism property and the real part (f) give $\kappa(\tilde{x},g') = \theta^{\tilde{p},q}(w\otimes f_S)(\iota_-(h,(1,\mathrm{flp}_\vartheta^j)),g')$ with $w=\Omega(g,1)v_H\in\mathcal{F}_1$. So by (a) and (3.3), $\mathrm{per}_{\Gamma'}(\Psi';g)(x)=L_x(w)$ for every x.

(ii) *Products.* Let A, B be as in (c) (column case) and $Q=Q_{AB}$. By (6.111) and Fubini,

$$\Lambda_{S,x}(v_Q)=\int_{[\mathrm{U}(\tilde{Y}_j^{j+1})]} K_\vartheta^{\mathrm{col}}[v(S),B](g')\,\varphi_S(g')\,(L_Au_S)(\rho(g'))\,dg',$$

where L_A is the lift of Lemma 6.3.76 for the pair (Y_j^j,Z) with the characters of (p,p_Z), the datum $\delta_{y_2(S)}$ and the polynomial A. By (e) and (4) of Lemma 6.3.76 for $P=H_{(p,p_Z)}$, there is a continuous compactly supported a_A on G_∞ of Z, depending only on the weights, the types and A, with $L_Au_S=R(a_A)y_S^-$, i.e. $(L_Au_S)(\rho(g'))=\int a_A(z)\,y_S^-(\rho(g')(z,1))\,dz$. As y_S^- is bounded and $K^{\mathrm{col}}\varphi_S$ integrable (Step 1), Fubini gives, after summing over S,

$$L_x(v_Q)=\int_{G_\infty} a_A(z)\,C(\Psi';z,B)(x)\,dz \qquad \text{for every period triple } x,$$

$z\mapsto a_A(z)C(\Psi';z,B)(x)$ being integrable. By hypothesis $C(\Psi';z,B)=\beta_z\Xi$ for every z. If $\Xi=0$, then $L_x(v_Q)=0$ for all x. Otherwise fix x_0 with $\Xi(x_0)\neq0$; then $C(\Psi';z,B)(x)=\Xi(x)\,C(\Psi';z,B)(x_0)/\Xi(x_0)$, and $L_x(v_Q)=\beta_{AB}\Xi(x)$ with $\beta_{AB}=\Xi(x_0)^{-1}\int a_AC(\Psi';z,B)(x_0)\,dz$.

(iii) *Closure.* Let $\mathcal{V}$ be the set of $v\in\mathcal{F}_1$ for which some β satisfies $L_x(v)=\beta\,\Xi(x)$ for all x. If $\Xi=0$ it is $\bigcap_x\ker L_x$; otherwise it is $\bigcap_x\ker\bigl(L_x-\Xi(x)\Xi(x_0)^{-1}L_{x_0}\bigr)$. In both cases it is a closed linear subspace. By (ii) it contains $v_{Q_{AB}}$ for all A, B; every monomial in the variables of the $n_Z\times(n_p\sqcup\{*\})$ entries is such a product, so by linearity of $Q\mapsto v_Q$ it contains the Fock vectors of all polynomials, which are dense by Lemma 6.3.29. So $\mathcal{V}=\mathcal{F}_1\ni w$, and by (i) $\mathrm{per}_{\Gamma'}(\Psi';g)=\beta\,\Xi$. As g was arbitrary, $\Psi'\propto_{\Gamma'}\Xi$.

Step 3: (3). Let $\Psi\propto_\Gamma\Xi$, and fix g_0, P'. For a tuple S on Γ, a triple x and v in the Fock model $\mathcal{F}_2$ of $\mathrm{Hom}(Z,Y_{j+1}^{j+1})$ put $f'_S=\delta^{\natural}_{x_2(S)}\otimes_{\Sigma(\mathfrak{m}_\vartheta)}v^0$ and

$$M_{S,x}(v)=\int_{[\mathrm{U}(\tilde{Y}_j^{j+1})]} K_\vartheta^{\mathrm{row}}[v'(S),P'](g')\,\varphi_S(g')\int_{[\mathrm{U}(Y_{j+1}^{j+1})]}\theta^{Z,p^+}(v\otimes f'_S)(\rho(g'),h)\,U_S(h)\,dh\,dg',$$

the kernel with the characters of (p_Z,p^+). As in Step 2, by (d), (e), (f), the integrand is bounded by $C_S\|v\|$ on a product of quotients of finite volume, so $M_{S,x}$ is a continuous linear functional and Fubini applies; put $M_x=\sum_S\Psi_\vartheta(S)M_{S,x}$, the sum over the tuples supported on the edges of Γ.

(i) *The row period.* $y_S^+(\rho(g')g_0)=\int\kappa^{(p_Z,p^+)}_{x_2(S),H'}(\rho(g')(g_0,1),h)U_S(h)\,dh$, H' the joint harmonic of the transposed move; by the real part (f), $\kappa(\rho(g')(g_0,1),h)=\theta^{Z,p^+}(w'\otimes f'_S)(\rho(g'),h)$ with $w'=\Omega(g_0,1)v_{H'}\in\mathcal{F}_2$. So $R(\Psi;g_0,P')(x)=M_x(w')$.

(ii) *Polynomials.* Let A be a polynomial in the variables of the $n_{p^+}\times n_Z$ entries and $Q=Q_{AP'}$ (row case of (c)). By (6.112) with $k=\mathrm{flp}_\vartheta^{j+1}$ and Fubini,

$$M_{S,x}(v_A)=\int_{[\mathrm{U}(Y_{j+1}^{j+1})]}U_S(h)\,(L_Q\varphi_S)\bigl(\iota_+(h,(1,\mathrm{flp}_\vartheta^{j+1}))\bigr)\,dh,$$

L_Q the lift of Lemma 6.3.76 for the pair $(\tilde{Y}_j^{j+1},\tilde{Y}_{j+1}^{j+1})$ with the characters of $(q,\tilde{p}^+)$, the datum $\delta_{S(q,\tilde{p}^+)}$ and the polynomial Q. By (e) and (4) of Lemma 6.3.76 for $P=H_{(q,\tilde{p}^+)}$, $L_Q\varphi_S=R(a_Q)V_S$ with a_Q continuous, compactly supported and independent of S and ϑ, V_S the lift move of φ_S along $(q,\tilde{p}^+)$ with $S(q,\tilde{p}^+)$, which is the image of φ along Γ_{II}; U_S is the image of y' along Γ_{I}. By Fubini (U_S rapidly decreasing, V_S bounded) and (3.3) with (a),

$$M_x(v_A)=\int_{G_\infty}a_Q(z)\,\mathrm{per}_\Gamma(\Psi;z)(x)\,dz,$$

z running over the real points of $\mathrm{U}(\tilde{Y}_{j+1}^{j+1})$. By hypothesis $\mathrm{per}_\Gamma(\Psi;z)=\beta_z\Xi$ for every z, and as in Step 2 (ii), $M_x(v_A)=\beta_A\Xi(x)$ for all x, with β_A independent of x.

(iii) *Closure.* As in Step 2 (iii), the set of $v\in\mathcal{F}_2$ with $M_x(v)=\beta\Xi(x)$ for all x and some β is a closed subspace; it contains every v_A, hence $\mathcal{F}_2$ by Lemma 6.3.29, hence w'. By (i), $R(\Psi;g_0,P')=\beta\,\Xi$ on all period triples. □

Lemma 6.4.96. *Let $e\colon n'\to n$ be a bijection of finite index sets and P_e the $n'\times n$ matrix with entries $(P_e)_{i'i}=1$ if $i=e(i')$ and 0 otherwise, so that $(P_eu)_{i'}=u_{e(i')}$ and $P_e^{-1}=P_e^{\mathsf T}$. For a space with a point $V=(J_V,x_V)$ with signs s on n put $V^e=(P_eJ_VP_e^{\mathsf T},P_ex_VP_e^{\mathsf T})$; for $g\in\mathrm{G}(s)$ put $g^e=P_egP_e^{\mathsf T}$; for a function f on $\mathbb{A}_E^n$ put $f^e=f\circ P_e^{\mathsf T}$, a function on $\mathbb{A}_E^{n'}$.*

(1) V^e is a space with a point with signs $s\circ e$, and $g\mapsto g^e$ is an isomorphism of topological groups $\mathrm{G}(s)\to\mathrm{G}(s\circ e)$ which carries the measure of $\mathrm{G}(s)$ to that of $\mathrm{G}(s\circ e)$ and Γ_V onto Γ_{V^e}, with $\det g^e=\det g$ and $\mathrm{ht}_{V^e}(g^e)=\mathrm{ht}_V(g)$.

(2) $f\mapsto f^e$ is a linear isometry of $\mathcal{M}_s$ onto $\mathcal{M}_{s\circ e}$ with $(v^0)^e=v^0$, $\rho(P_ez)f^e=(\rho(z)f)^e$ $(z\in\mathbb{A}_E^n)$, $\omega_{s\circ e}(g^e)f^e=(\omega_s(g)f)^e$ and $\theta_{V^e}(f^e)=\theta_V(f)$.

(3) Let S, T be spaces with points with signs s on n_S and s' on n_T, and $e_S\colon n_S'\to n_S$, $e_T\colon n_T'\to n_T$ bijections; write $e_T\times e_S$ for the bijection $(a',b')\mapsto(e_T(a'),e_S(b'))$ of $n_T'\times n_S'$ onto $n_T\times n_S$. Then $\mathrm{Hom}(S^{e_S},T^{e_T})=\mathrm{Hom}(S,T)^{e_T\times e_S}$, and for all automorphic characters α,β of $\mathrm{U}(1)$, $\varphi\in\mathcal{M}_{S,T}$, $g\in\mathrm{G}(s)$ and $h\in\mathrm{G}(s')$,

$$\theta_{\alpha,\beta}^{S^{e_S},T^{e_T}}\big(\varphi^{e_T\times e_S}\big)\big(g^{e_S},h^{e_T}\big)=\theta_{\alpha,\beta}^{S,T}(\varphi)(g,h).$$

(4) In the situation of (3), for a modulus $\mathfrak{m}$, a function Φ on the $n_T\times n_S$ matrices over $R_{\mathfrak{m}}$ and a polynomial Q in the variables $X_{v,a,b}$ $(v\in\Phi,\ a\in n_T,\ b\in n_S)$,

$$\mathrm{mod}_{\mathfrak{m}}(\Phi,v_Q)^{e_T\times e_S}=\mathrm{mod}_{\mathfrak{m}}(\Phi',v_{Q'}),\qquad \Phi'(X')=\Phi(P_{e_T}^{\mathsf T}X'P_{e_S}),$$

where Q' is obtained from Q by the substitution $X_{v,e_T(a'),e_S(b')}\mapsto X_{v,a',b'}$.

Proof. **(1).** With $P=P_e$, $(Px_VP^{\mathsf T})^*(PJ_VP^{\mathsf T})(Px_VP^{\mathsf T})=Px_V^*J_Vx_VP^{\mathsf T}=P\varepsilon_sP^{\mathsf T}=\varepsilon_{s\circ e}$, and $PJ_VP^{\mathsf T}$ is hermitian over E; so V^e is a space with a point with signs $s\circ e$. Conjugation by P is a homeomorphic group isomorphism of GL carrying $\{g:g^*\varepsilon_sg=\varepsilon_s\}$ onto $\{g:g^*\varepsilon_{s\circ e}g=\varepsilon_{s\circ e}\}$, preserving determinants, the integral finite points and the rational points: $\Gamma_{V^e}=(Px_VP^{\mathsf T})^{-1}P\,\mathrm{U}(V)(F)\,P^{\mathsf T}(Px_VP^{\mathsf T})=P\Gamma_VP^{\mathsf T}$. Measures: at a real place, $S(PyP^{\mathsf T})=PS(y)P^{\mathsf T}$ entrywise in Definition 3.2.1 (both entries are indexed by the pair $(e(a),e(b))$), so $D(PyP^{\mathsf T})=PD(y)P^{\mathsf T}$ for $PJP^{\mathsf T}$, the Cayley charts are intertwined by conjugation, and $y\mapsto PyP^{\mathsf T}$ preserves Lebesgue measure and $|\det D|$; at the finite places conjugation is an automorphism of the unimodular group $G_f(n)\cong G_f(n')$ carrying $G_f(n)\cap\mathrm{GL}_n(\widehat{\mathcal{O}}_E)$ onto $G_f(n')\cap\mathrm{GL}_{n'}(\widehat{\mathcal{O}}_E)$, hence Haar measure of mass one there to the same. Heights: $(V^e)_{g^e}=(PJ_VP^{\mathsf T},P(x_Vg)P^{\mathsf T})$, its lattice is P applied to the lattice of V_g, and $((Px_VgP^{\mathsf T})^{-1}Pu)_\infty=P((x_Vg)^{-1}u)_\infty$ has the same euclidean norm as $((x_Vg)^{-1}u)_\infty$. So the infima λ of (VP4) of Definition 3.2.2 agree, and $\mathrm{ht}_{V^e}(g^e)=\mathrm{ht}_V(g)$.

(2). The bicharacter, the vacuum and the vacuum measure of (WD5), (WD6) are sums, products and product measures over the coordinates, so $\beta_{s\circ e}(Px,Py)=\beta_s(x,y)$, $e_{n'}(Px)=e_n(x)$ and P carries μ_n to $\mu_{n'}$. Substituting $y=P^{\mathsf T}y'$ in the identity (WD7) shows that $f^e\in\mathcal{M}_{s\circ e}$ when $f\in\mathcal{M}_s$, with the same L^1 norm; the inverse is $f'\mapsto f'\circ P$. Directly from the definitions, $(v^0)^e=e_{n'}=v^0$ and $(\rho(z)f)^e(x')=\beta_s(z,P^{\mathsf T}x')f(P^{\mathsf T}x'-z)=\beta_{s\circ e}(Pz,x')f^e(x'-$

Pz). For $g \in \mathrm{G}(s)$ the negative block of g_v^e is a permutation conjugate of that of g_v, and $\widehat{\mathcal{O}}_E^{n'} \cap (g_f^e)^{-1}\widehat{\mathcal{O}}_E^{n'} = P(\widehat{\mathcal{O}}_E^n \cap g_f^{-1}\widehat{\mathcal{O}}_E^n)$, so PuP^{T} serves for g^e in (WR3) when u serves for g; hence $\Delta_{s\circ e}(g^e) = \Delta_s(g)$, and substituting $y = P^{\mathsf{T}}y'$ in the integral (WR3) gives $\omega_{s\circ e}(g^e)f^e = (\omega_s(g)f)^e$. *Standard spaces.* Let V_s be the standard space of signs s; then V_s^e is the standard space $V_{s\circ e}$ (diagonal Gram matrix and point, permuted). The functional $\Theta(f') = \theta_{V_s}(f' \circ P)$ on $\mathcal{M}_{s\circ e}$ is bounded, and invariant under $\rho(\gamma')$ for the rational vectors γ' of $V_{s\circ e}$, which are the $P\gamma$ with γ rational for V_s. By (WC1), for $x \in \mathbb{A}_E^n$, $\Theta(\rho(Px)v^0) = \theta_{V_s}(\rho(x)v^0) = \prod_{i\in n}\theta_{s_i}(\rho(x_i)v^0) = \prod_{i'\in n'}\theta_{s_{e(i')}}(\rho((Px)_{i'})v^0) = \theta_{V_{s\circ e}}(\rho(Px)v^0)$. By Lemma 4.1.7 the bounded rational-Heisenberg-invariant functionals on $\mathcal{M}_{s\circ e}$ form a line, so $\Theta = c\,\theta_{V_{s\circ e}}$; as $\theta_{V_{s\circ e}}$ is normalized, $\theta_{V_{s\circ e}}(\rho(x')v^0) \neq 0$ for some x', and comparing there gives $c = 1$. So $\theta_{V_{s\circ e}}(f^e) = \theta_{V_s}(f)$. *General spaces.* Let k be a transporting element of V (WR3). For $u \in E^n$ with $kx_V^{-1}u = x_{V_s}^{-1}u_1$, $k^e(Px_V P^{\mathsf{T}})^{-1}(Pu) = P\,kx_V^{-1}u = (Px_{V_s}P^{\mathsf{T}})^{-1}(Pu_1)$; so k^e is a transporting element of V^e for $V_{s\circ e}$. By Lemma 4.1.17 (independence of the transporting element) and what precedes,

$$\theta_{V^e}(f^e) = \theta_{V_{s\circ e}}\big(\omega_{s\circ e}(k^e)f^e\big) = \theta_{V_{s\circ e}}\big((\omega_s(k)f)^e\big) = \theta_{V_s}(\omega_s(k)f) = \theta_V(f).$$

(3). Write $P_S = P_{e_S}$, $P_T = P_{e_T}$. The matrix of $e_T \times e_S$ on $n'_T \times n'_S$ matrices is $X \mapsto P_T X P_S^{\mathsf{T}}$, that is $P_T \otimes P_S$ on coordinates. By (VP5) of Definition 3.2.2, $\mathrm{Hom}(S^{e_S}, T^{e_T})$ has matrix $(P_T J_T P_T^{\mathsf{T}}) \otimes ((P_S J_S P_S^{\mathsf{T}})^{-1})^{\mathsf{T}} = (P_T \otimes P_S)(J_T \otimes (J_S^{-1})^{\mathsf{T}})(P_T \otimes P_S)^{\mathsf{T}}$, the same for the point, and the signs $s'(e_T(a'))s(e_S(b'))$; this is $\mathrm{Hom}(S,T)^{e_T\times e_S}$. The pair map sends (g^{e_S}, h^{e_T}) to $X \mapsto P_T h P_T^{\mathsf{T}} X P_S g^{-1} P_S^{\mathsf{T}}$, which is the conjugate $(h\otimes(g^{-1})^{\mathsf{T}})^{e_T\times e_S}$ of the pair image of (g,h), and $\det g^{e_S} = \det g$, $\det h^{e_T} = \det h$. So by (2) for $\mathrm{Hom}(S,T)$ and $e_T \times e_S$, $\omega_{\alpha,\beta}(g^{e_S}, h^{e_T})\varphi^{e_T\times e_S} = (\omega_{\alpha,\beta}(g,h)\varphi)^{e_T\times e_S}$, and applying $\theta_{\mathrm{Hom}(S,T)^{e_T\times e_S}}$ gives (3) by the last identity of (2).

(4). Write $\pi(X') = P_T^{\mathsf{T}} X' P_S$ for $n'_T \times n'_S$ matrices X' and put $\iota = n_T \times n_S$, $\iota' = n'_T \times n'_S$. By (4) of Lemma 4.1.3, for $A = \Sigma(\mathfrak{m})$ the datum $\mathrm{mod}_{\mathfrak{m}}(\Phi, v_Q) = v_Q \otimes (\Phi^\natural \otimes_A v^0)$ is the function whose value is the product of v_Q at the normalized real coordinates, of $\mathcal{I}_A(\Phi^\natural)$ at the scaled finite coordinates at A, and of the finite vacuum at the other finite coordinates. Each factor is compatible with the permutation π of the coordinates: the finite vacuum and $\mathbf{1}_A$ are products over the coordinates; $R_A(\pi^{-1}z)\mathbf{1}_A = (R_A(z)\mathbf{1}_A)\circ\pi$ by the formula of Lemma 4.1.3 (the sum $\bar{y}^{\mathsf{T}}(2x+y)_A$ is over the coordinates), and π preserves the Haar measure of Q_A, so $\mathcal{I}_A(\Phi^\natural \circ \pi) = \mathcal{I}_A(\Phi^\natural)\circ\pi$, where $\Phi^\natural \circ \pi = (\Phi')^\natural$ as reduction modulo $\mathfrak{m}$ and integrality are entrywise; and $v_Q \circ \pi = v_{Q'}$, since e^∞ is invariant and the coordinate ζ of (WR5) at (v, a', b') is the coordinate at $(v, e_T(a'), e_S(b'))$, whose sign is the same. Hence $\mathrm{mod}_{\mathfrak{m}}(\Phi, v_Q)\circ\pi = \mathrm{mod}_{\mathfrak{m}}(\Phi', v_{Q'})$, which is (4), as $f^{e_T\times e_S} = f\circ\pi$. □

Lemma 6.4.97. *Let $\mathfrak{m}$ be a modulus and α, β, β' automorphic characters of* $\mathrm{U}(1)$*; write* $\mathrm{diag}(g_1, g_2)$ *for block diagonal elements.*

(a) (Columns.) Let S_1, S_2, T be spaces with points with signs s_1 on n_1, s_2 on n_2, s' on n_T. Let Φ_i be a function on the $n_T \times n_i$ matrices over $R_{\mathfrak{m}}$ and A, B polynomials in the variables $X_{v,a,b}$ with $a \in n_T$ and $b \in n_1$, resp. $b \in n_2$; put $(\Phi_1 \otimes \Phi_2)(X_1 \mid X_2) = \Phi_1(X_1)\Phi_2(X_2)$ on $n_T \times (n_1 \sqcup n_2)$ matrices. Then

$$\mathrm{mod}_{\mathfrak{m}}(\Phi_1 \otimes \Phi_2, v_{AB}) = \mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_A) \boxtimes^{\mathrm{sc}} \mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_B) \in \mathcal{M}_{S_1\oplus S_2, T},$$

and for $g_i \in \mathrm{G}(s_i)$, $h \in \mathrm{G}(s')$,

$$\theta^{S_1\oplus S_2,T}_{\beta\beta',\alpha}\big(\mathrm{mod}_{\mathfrak{m}}(\Phi_1\otimes\Phi_2, v_{AB})\big)\big(\mathrm{diag}(g_1,g_2), h\big) = \theta^{S_1,T}_{\beta,\alpha}\big(\mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_A)\big)(g_1,h)\,\theta^{S_2,T}_{\beta',\alpha}\big(\mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_B)\big)(g_2,h).$$

(b) (Rows.) Let S, T_1, T_2 be spaces with points with signs s on n_S, s_1 on n_1, s_2 on n_2. Let Φ_i be a function on the $n_i \times n_S$ matrices over $R_{\mathfrak{m}}$ and A, B polynomials in the variables $X_{v,a,b}$ with $b \in n_S$ and $a \in n_1$, resp. $a \in n_2$; put $(\Phi_1 \otimes \Phi_2)\binom{X_1}{X_2} = \Phi_1(X_1)\Phi_2(X_2)$. Then $\mathrm{mod}_{\mathfrak{m}}(\Phi_1 \otimes \Phi_2, v_{AB}) = \mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_A) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_B)$, and for $g \in \mathrm{G}(s)$, $h_i \in \mathrm{G}(s_i)$,

$$\theta^{S,T_1\oplus T_2}_{\alpha,\beta\beta'}(\mathrm{mod}_{\mathfrak{m}}(\Phi_1 \otimes \Phi_2, v_{AB}))(g, \mathrm{diag}(h_1, h_2)) = \theta^{S,T_1}_{\alpha,\beta}(\mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_A))(g, h_1)\, \theta^{S,T_2}_{\alpha,\beta'}(\mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_B))(g, h_2).$$

Proof. **The data.** We prove (a); (b) is the same with rows in place of columns. Put $A_0 = \Sigma(\mathfrak{m})$, $\iota_i = n_T \times n_i$ and $\iota = n_T \times (n_1 \sqcup n_2) = \iota_1 \sqcup \iota_2$. By (4) of Lemma 4.1.3, for a function Φ on the matrices over $R_{\mathfrak{m}}$ with these index sets and a polynomial Q, the datum $\mathrm{mod}_{\mathfrak{m}}(\Phi, v_Q) = v_Q \otimes (\Phi^\natural \otimes_{A_0} v^0)$ is the function whose value at a vector is the product of three factors: v_Q at its normalized real coordinates, $\mathcal{I}_{A_0}(\Phi^\natural)$ at its scaled finite coordinates at A_0, and the finite vacuum at its other finite coordinates. Each factor for $(\Phi_1 \otimes \Phi_2, AB)$ on ι is the product of the factors for (Φ_1, A) on ι_1 and for (Φ_2, B) on ι_2:

- the Fock coordinates ζ of (WR5) are coordinatewise and the signs of $\mathrm{Hom}(S_1 \oplus S_2, T)$ restrict to those of $\mathrm{Hom}(S_i, T)$ on ι_i ((WR6), context), and e^∞ is a product over the coordinates, so $v_{AB} = v_A \cdot v_B$;
- integrality at A_0 and reduction modulo $\mathfrak{m}$ are entrywise, so $(\Phi_1 \otimes \Phi_2)^\natural = \Phi_1^\natural \otimes \Phi_2^\natural$ on $Q^\iota_{A_0} = Q^{\iota_1}_{A_0} \times Q^{\iota_2}_{A_0}$; the function $R_{A_0}(z)\mathbf{1}_{A_0}$ of Lemma 4.1.3 is the product of the corresponding functions for the two blocks of z (its phase is a sum over the coordinates and $\mathbf{1}_{A_0}$ a product), and the Haar measure of $Q^\iota_{A_0}$ is the product measure; so by Fubini (all functions are locally constant with compact support) $\mathcal{I}_{A_0}(\Psi_1 \otimes \Psi_2)(z_1, z_2) = \mathcal{I}_{A_0}(\Psi_1)(z_1)\mathcal{I}_{A_0}(\Psi_2)(z_2)$;
- the finite vacuum (WD5) is a product over the coordinates.

Hence $\mathrm{mod}_{\mathfrak{m}}(\Phi_1 \otimes \Phi_2, v_{AB})(x) = \mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_A)(x|_{\iota_1})\,\mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_B)(x|_{\iota_2})$, which is the source product of (WR6).

The kernels. By (d) of Lemma 6.3.52 for $f = \mathrm{mod}_{\mathfrak{m}}(\Phi_1, v_A)$ and $f' = \mathrm{mod}_{\mathfrak{m}}(\Phi_2, v_B)$, the theta kernel of the source product at $(\mathrm{diag}(g_1, g_2), h)$ is the product of the two theta kernels, with the characters as displayed; for (b), the target product and the target part of (d) of Lemma 6.3.52. □

The last group proves deep-level vanishing (Lemma 6.4.98), which makes the flat restriction onto: at a suitable real point ω, the restrictions of discrete series forms of very deep level from $Y_0 \oplus \langle 1 \rangle$ to Y_0 detect every form of principal level. It is the case $V = Y_0$ of a criterion for framed hermitian spaces (Proposition 6.4.99). Its hypothesis at ω, that the pairing of the Flensted-Jensen coefficients [81] of the two parameters is not small against the volume of a ball, holds by Lemma 6.4.109, which rests on Laplace's method for periods of two discrete series coefficients (Theorem 5.7.21, Section 5).

The proof of the criterion is a halving argument for the supremum S of a form y orthogonal to the restrictions. High in the cusp, a bounded form of large-gap type is at most $S/2$, by a cusp estimate (Lemma 6.4.100). Away from the cusp, Poincaré series of the discrete series kernel at deep level [234] pair with the form through their identity-coset term, and Schur orthogonality for square-integrable representations [163, 119], with the lower bound at ω, gives again $|y| \le S/2$ (Lemma 6.4.103). Hence $S \le S/2$ and $y = 0$. For the reduction theory behind the division into the cusp and its complement see [37, 33].

Lemma 6.4.98. *Let D be admissible data, let s_v be the signs of Y_0 at $v \in \Phi$, give $\tilde{Y}_0^0 = Y_0 \oplus \langle 1 \rangle$ the frame of Y_0 followed by the added basis vector, and let $\lambda'(v) = -\frac{1}{2} p_{\mathrm{II},0,0}(v)$ be the Harish-Chandra parameter of $\tilde{Y}_0^0$ at v. There is a real point $\omega \in \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}(s_v, 1))$ of $\mathrm{U}(\tilde{Y}_0^0)$ with the following property: if $y \in \mathcal{A}_M(Y_0)$ satisfies*

$$\int_{\mathrm{U}(Y_0)(E^+)\backslash \mathrm{U}(Y_0)(\mathbb{A})} y(x)\, \overline{\varphi\big((x \oplus 1)\,\omega\big)}\, dx = 0$$

for every form φ on $\tilde{Y}_0^0$ of type λ' and level $\mathrm{K}(\pi_M^b)$ (the grid forms at the node $(\mathrm{II}, 0, 0)$ of the deep level), then $y = 0$.

Proof. Put $V = Y_0$, so $n = r$ and $Z = \tilde{Y}_0^0 = V \oplus \langle 1 \rangle$, and $\lambda(v) = \varsigma(v) = \lambda_{\mathrm{I}}(v)$, $\lambda'(v) = -\lambda_{\mathrm{II}}(v)$. Choose

$$A = r^4, \quad L = 20b, \quad a_{\mathrm{p}} = 20(2r+1)^2, \quad \beta = M^{\lceil x \rceil/2}, \quad R = \beta^{20A(f+1)}, \quad h = r^7.$$

We verify the hypotheses of Proposition 6.4.99, finding ω with Lemma 6.4.109.

Sizes used. By Lemma 4.2.67, Lemma 5.2.13, Proposition 2.3.5 and Lemma 2.3.6: $x \geq e^{6.4\cdot 10^{15}}$, $x^5 \leq r \leq 3x^5$, $m \leq 2\sqrt{x}$, $f \leq q_1 \leq x^{12}$, $q_1 d \leq x^{13}$, $\mathrm{rd}_E \leq x^{12}$, $\log M \leq 22 \log b$, $(\log b)^{100} \leq x$, $x^{10^{12}} \leq b$ and $x^{10^6} \leq x_1 \leq b^{10^{-6}}$; by (AD5), $M \geq b^{20}$; by (AD4), $b/x_1 \leq \kappa(v) \leq b$. By (AD2), $\Delta^2 = 4r^{16} \leq 4 \cdot 3^{16} x^{80} \leq x^{81} \leq x_1$; since $x_1^2 \leq b$, this gives $\Delta^2 \leq x_1 \leq b/x_1 \leq \kappa(v)$. So $r < \Delta \leq \Delta^2 \leq \kappa(v)$ and $\kappa_0(v) = \kappa(v) + \frac{\Delta}{2} \leq b + \frac{b}{2} \leq 2b$. Also $\log \beta \leq x \log M \leq 22x \log b \leq 22x^{1.01}$ and $\beta \geq M^{x/2} \geq b^{10x}$.

Gaps and entries. By (GP5), $2\lambda(v)$ has the entries $2\varsigma_i(v)$, $0 \leq i \leq r-1$, and $2\lambda'(v)$ the entries $-(2\varsigma_i(v)+1)$, $0 \leq i \leq r$; they are distinct (the sequence $\varsigma_i(v)$ is strictly decreasing), the first are even and $r-1$ is even, the second are odd and $(r+1)-1 = r$ is odd (AD2). The base index i has the sign $+1$ for $i \leq k-1$ and $(-1)^a$ for $i = k-1+a$. If two indices have different signs, then either both are $\geq k-1$, or one is $\leq k-2$ and the other is $k-1+a$ with $a \geq 1$. In the first case $|\varsigma_i - \varsigma_j|$ is a positive multiple of Δ; in the second $\varsigma_i - \varsigma_{k-1+a} \geq 1 - \frac{k}{2} - \frac{\Delta}{2} + \kappa_{a+1} \geq \kappa + \Delta - k \geq \Delta$. So opposite-sign entries of $\lambda(v)$, and of $\lambda'(v)$, differ by at least $\Delta = 2r^8$, which exceeds $500(r+1)^3 + \max(4A, h) = 500(r+1)^3 + \max(4r^4, r^7)$. Hence $2\lambda(v)$ has large gap $4A$ and large gap h for s_v, and $2\lambda'(v)$ has large gap $2A$ and large gap h for $(s_v, +1)$, the signs of Z (the added index r has the sign $(-1)^m = +1$ by (GP5)). Every entry has absolute value at most $\max(k,\ 2\kappa_{m+1}(v) - \Delta + 1) = 2\kappa(v) + (2m+2)\Delta + 1 \leq 5b \leq L$, since $(2m+2)\Delta \leq 2\Delta^2 \leq 2\kappa(v) \leq 2b$.

Deep-level sizes for rank r. So $(A, L, a_{\mathrm{p}}, \beta, R)$ satisfy the deep-level size conditions for rank r.

The real point. Fix $v \in \Phi$ and apply Lemma 6.4.109 with $n = r$, $\varepsilon = s_v$, $l = 2\lambda(v)$, $l' = 2\lambda'(v)$, $X = \{0, \ldots, k-2\}$, $M = m$ (even), $e = e_{\mathrm{I}}$, $e' = e_{\mathrm{II}}$, $B = \kappa_0(v) \geq 1$, β, h and L. Hypothesis 1 is Lemma 5.7.20 for $z = \mathrm{I}$ (for $\frac{1}{2}l = \varsigma(v)$) and for $z = \mathrm{II}$ (for $-\frac{1}{2}l' = \lambda_{\mathrm{II}}(v)$), the domains being $X \sqcup \{0, \ldots, m-1\}$ and $X \sqcup \{0, \ldots, m\}$ since $2\varrho + 2 = m$. Hypotheses 2 and 3 were checked above. Hypothesis 4: $\beta \geq 10^{12}$; $2r + 1 + L \leq 21b + 1 \leq \beta$; $(r+1)^4 (6\kappa_0(v))^{2m+2} \leq b\,(12b)^{2m+2} \leq b^{4m+5} \leq b^{10x} \leq \beta$; and $10^{30}\big((2r+1)^2 \log \beta\big)^3 \leq 10^{30}(9r^2 \cdot 22x^{1.01})^3 \leq 10^{37} r^6 x^{3.03} \leq r^7 = h$ since $r \geq x^5$. So there is $\omega_v \in \mathrm{U}(\mathrm{diag}(s_v, 1))$ with $\|\omega_v\|^2 \leq \beta$ and

$$\mathrm{vol}\{r' \in \mathrm{U}(\mathrm{diag}\, s_v) : \|r' - 1\| \leq 1\} \leq \beta^{a_{\mathrm{p}}} \Big| \int c_{\lambda(v)}(r')\, \overline{c_{\lambda'(v)}\big(\omega_v^{-1}(r' \oplus 1)\omega_v\big)}\, dr' \Big|,$$

as $20(2n+1)^2 = a_{\mathrm{p}}$. Put $\omega = (\omega_v)_{v\in\Phi}$.

Conclusion. The forms of principal level $\mathcal{A}_M(Y_0)$ are the forms on V of type $\varsigma = \lambda$ and level $\mathrm{K}(\pi_M)$: the type condition of Definition 3.2.16 is (DZ2) for $\lambda = \varsigma$, and $\mathrm{K}_M = \mathrm{K}(\pi_M)$ because

$\pi_M\mathcal{O}_E$ is the product of the chosen places, each with exponent one (by Lemma 4.2.66(3), the $2f$ chosen places divide π_M and the product of their norms is $M^f = \mathrm{N}_{E/\mathbb{Q}}(\pi_M)$). All hypotheses of Proposition 6.4.99 hold for V, λ, λ', $(A, L, a_{\mathrm{p}}, \beta, R)$ and ω, so every $y \in \mathcal{A}_M(Y_0)$ with the stated orthogonality vanishes. □

Proposition 6.4.99. *Let D be admissible data, V a hermitian space over E of rank $n \geq 1$ with a frame and signs s_v, and $Z = V \oplus \langle 1 \rangle$ with the frame of V followed by the added basis vector. Let $A, L, a_{\mathrm{p}} \in \mathbb{N}$ and $\beta, R > 0$ satisfy the deep-level size conditions for rank n. Let λ, λ' be such that, for every $v \in \Phi$, $2\lambda(v)$ has large gap $4A$ for s_v with entries of absolute value at most L, and $2\lambda'(v)$ has large gap $2A$ for $(s_v, +1)$. Let $\omega \in \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}(s_v, 1))$ satisfy, for every v, $\|\omega_v\|^2 \leq \beta$ and*

$$\mathrm{vol}\{r \in \mathrm{U}(\mathrm{diag}\, s_v) : \|r - 1\| \leq 1\} \leq \beta^{a_{\mathrm{p}}} \Big| \int_{\mathrm{U}(\mathrm{diag}\, s_v)} c_{\lambda(v)}(r)\, \overline{c_{\lambda'(v)}(\omega_v^{-1}(r \oplus 1)\omega_v)}\, dr \Big|.$$

If y is a form on V of type λ and level $K(\pi_M)$ such that

$$\int_{\mathrm{U}(V)(E^+)\backslash \mathrm{U}(V)(\mathbb{A})} y(x)\, \overline{\varphi\big((x \oplus 1)\,\omega\big)}\, dx = 0$$

for every form φ on Z of type λ' and level $K(\pi_M^b)$, then $y = 0$.

Proof. **Levels.** Since π_M divides $M = \pi_M\bar{\pi}_M$ and π_M^b in $\mathcal{O}_E$, every element of $K(M)$ or of $K(\pi_M^b)$ is congruent to 1 modulo π_M, so $K(M) \subseteq K(\pi_M)$ and $K(\pi_M^b) \subseteq K(\pi_M)$. Hence y has level $K(M)$ and level $K(\pi_M^b)$.

Halving. Let $S \geq 0$ with $|y(g)| \leq S$ for all $g \in \mathrm{U}(V)(\mathbb{A})$, and let $x \in \mathrm{U}(V)(\mathbb{A})$. If $\lambda_V(x) < \theta_{\mathrm{cs}}$, then $|y(x)| \leq S/2$ by Lemma 6.4.100, applied to y with level $K(M)$; its hypotheses are among ours. If $\lambda_V(x) \geq \theta_{\mathrm{cs}}$, then $|y(x)| \leq S/2$ by Lemma 6.4.103, applied to y with level $K(\pi_M^b)$ and the same ω, whose hypotheses are ours (the orthogonality being the displayed one). So every bound S of $|y|$ on $\mathrm{U}(V)(\mathbb{A})$ gives the bound $S/2$.

Conclusion. A form is bounded (DZ2); let $S_0 = \sup|y| < \infty$. By induction, $2^{-j}S_0$ bounds $|y|$ for every $j \geq 0$, so $y = 0$. □

Lemma 6.4.100. *Let D be admissible data, V a hermitian space over E of rank $n \geq 1$ with a frame and signs s_v ($v \in \Phi$), and let $A, L, a_{\mathrm{p}} \in \mathbb{N}$ and $\beta, R > 0$ satisfy the deep-level size conditions for rank n. Let $\lambda = (\lambda(v))_{v\in\Phi}$ be such that $2\lambda(v)$ has large gap $4A$ for s_v and entries of absolute value at most L, for every v. Let y be a form on V of type λ and level $K(M)$, and $S \geq 0$ with $|y(g)| \leq S$ for all $g \in \mathrm{U}(V)(\mathbb{A})$. If $x \in \mathrm{U}(V)(\mathbb{A})$ and $\lambda_V(x) < \theta_{\mathrm{cs}}$, then $|y(x)| \leq S/2$.*

Proof. Write $G_\infty = \prod_v G_v$, $G_v = \mathrm{U}(\mathrm{diag}\, s_v)$, $c_v = c_{\lambda(v)}$, $d_v = d_{\lambda(v)}$, $D_0 = \prod_v d_v$, $\psi(z) = \prod_v \overline{c_v(z_v)}$, so $e_\lambda = D_0\psi$, and

$$\mathrm{dc}(z) = \prod_v \Big(\frac{2}{\|z_v\|}\Big)^{2A}, \qquad \mathrm{mj}(z) = D_0\,\mathrm{dc}(z) \qquad (z \in G_\infty).$$

From the size conditions $\beta \geq 2000$, $R \geq \beta^{20A(f+1)} \geq \beta$, $f \leq \beta$ and $100(n + L + 1)^5 \leq \beta$. Put $\delta = R^{-2} \in (0, 1]$.

Step 1: local bounds. By Lemma 5.7.38(1) (gap $500n^3 + 4A \geq 4A$), $|c_v| \leq 1$, $|c_v(z)| \leq (2/\|z\|)^{4A}$ and $\overline{c_v(z)} = c_v(z^{-1})$; hence $|\psi(z)| \leq \mathrm{dc}(z)^2$. By Lemma 5.7.38(3) with $c = 2A > 8n^2$ and entries at most L, mj is integrable with

$$\int_{G_\infty} \mathrm{mj} = \prod_v \int_{G_v} d_v\Big(\frac{2}{\|z\|}\Big)^{2A} dz \leq T^f, \qquad T = 8\big(2000(n + L + 1)^6\big)^{2n^2} 2^{2A};$$

in particular e_λ is integrable ($|e_\lambda| \le D_0 \,\mathrm{dc}^2 \le 2^{2Af}\mathrm{mj}$).

Step 2: the kernel varies slowly. Let $u \in G_\infty$ with $\max_v \|u_v - 1\| \le \delta$ and $z \in G_\infty$. At each v, $\overline{c_v(u_v^{-1}z_v)} - \overline{c_v(z_v)} = c_v(z_v^{-1}u_v) - c_v(z_v^{-1})$, of modulus at most $100(n+L+1)^5\|u_v - 1\| \le \beta\delta$ by Lemma 5.7.38(2). As all factors have modulus at most 1, $|\prod_v a_v - \prod_v b_v| \le \sum_v |a_v - b_v|$ gives $|\psi(u^{-1}z) - \psi(z)| \le f\beta\delta \le \beta^2\delta$. Combining with $|\psi| \le \mathrm{dc}^2$,

$$|\psi(u^{-1}z) - \psi(z)|^2 \le \beta^2\delta\big(\mathrm{dc}(u^{-1}z)^2 + \mathrm{dc}(z)^2\big) \le \beta^2 R^{-2}\big(\mathrm{dc}(u^{-1}z) + \mathrm{dc}(z)\big)^2,$$

so $|e_\lambda(u^{-1}z) - e_\lambda(z)| \le (\mathrm{mj}(u^{-1}z) + \mathrm{mj}(z))\,\beta/R$.

Step 3: the oscillation. By the type condition (DZ2), $y(g') = \int e_\lambda(z) y(g'(z,1))\,dz$ for every g'. For u as in Step 2, substituting $z \mapsto u^{-1}z$ (left invariance) in the expression for $y(x(u,1))$,

$$y(x(u,1)) - y(x) = \int_{G_\infty} \big(e_\lambda(u^{-1}z) - e_\lambda(z)\big)\, y(x(z,1))\,dz,$$

hence, by Steps 1 and 2 and the left invariance of dz,

$$|y(x(u,1)) - y(x)| \le S\,\frac{\beta}{R}\int (\mathrm{mj}(u^{-1}z) + \mathrm{mj}(z))dz \le 2S\,\frac{\beta}{R}\,T^f \le \frac{S}{2},$$

the last step because $T \le 8\beta^{2n^2}2^{2A} \le \beta^{1+2n^2+2A} \le \beta^{3A}$ ($2n^2+1 \le A$) and $4\beta\cdot\beta^{3Af} \le \beta^{3Af+2} \le \beta^{20A(f+1)} \le R$.

Step 4: the cusp. Apply Lemma 6.4.101 with $M_0 = M$, the given y (its large gap $4A$ implies large gap 0), $\delta = R^{-2}$, $g = x$ and $C = S/2$: the hypothesis $\lambda_V(x) < \theta_{\mathrm{cs}} = (\delta/(Mc_{\mathrm{cs}}(n)^2))^n$ is ours, and the oscillation bound is Step 3. So $|y(x)| \le S/2$. □

Lemma 6.4.101. *Let D be admissible data, V a hermitian space over E of rank $n \ge 1$ with a frame and signs s_v, and λ such that $2\lambda(v)$ has large gap 0 for s_v (gap $500n^3$) for every $v \in \Phi$. Let $M_0 \ge 1$ be an integer, y a form on V of type λ and level $K(M_0)$, $0 < \delta \le 1$, $g \in \mathrm{U}(V)(\mathbb{A})$ and $C \ge 0$, and assume*

$$\lambda_V(g) < \Big(\frac{\delta}{M_0\, c_{\mathrm{cs}}(n)^2}\Big)^n \quad \text{and} \quad |y(g(u,1)) - y(g)| \le C \ \text{ for all } u \in G_\infty \text{ with } \max_{v\in\Phi}\|u_v - 1\| \le \delta.$$

Then $|y(g)| \le C$.

Proof. With its frame, V is a framed space of rank n with signs s, the same at every $v \in \Phi$ (Definition 5.6.3), $\mathrm{U}(V)(\mathbb{A}) = G_\infty \times G_f$, and the principal level $\mathrm{K}(M_0)$ of (DZ2) is the principal level $\mathrm{K}_f(M_0)$ of (FT5); $\lambda_V(g)$ is the first minimum of (VP4) of Definition 3.2.2 of this framed space at g.

Step 1: the type kernel is a cusp kernel. By hypothesis each $2\lambda(v)$ has gap $500n^3 = 500n^3 + 0$ for s, so by Lemma 5.6.21 with $N = n$ and $B = 0$ the type kernel e_λ is a cusp kernel of order 0 on G_∞. The form y is continuous, bounded, left invariant under Γ_V, right invariant under $\mathrm{K}_f(M_0)$, and $R(e_\lambda)y = y$ by (FT2), (FT3) and (DZ2).

Step 2: an integer in the different. Put $N_D = q_1 d$, a positive rational integer; by Lemma 6.4.102, N_D lies in the different $\mathfrak{D}_E$ of E. With $N = n$ and this N_D, the constant $\kappa = 8fn\,\mathrm{rd}_E + 48n^6f^2N_D + 1$ of (i) of Proposition 5.8.13 is $c_{\mathrm{cs}}(n)$ of (DZ4) ($f = \#\Phi = [E^+ : \mathbb{Q}]$).

Step 3: a cusp frame. As $\lambda_V(g) < (\delta/(M_0c_{\mathrm{cs}}(n)^2))^n$, $M_0 \ge 1$ and $0 < \delta \le 1$, (i) of Proposition 5.8.13 gives a nonzero isotropic subspace $A \subseteq V$ with $N_A(\mathbb{A}_{E^+})\, g \subseteq N_A(E^+)\, g\, Z_\delta\, \mathrm{K}_f(M_0)$.

Step 4: the oscillation bound. Apply (ii) of Lemma 5.8.9 to $U = V$, the cusp kernel $e = e_\lambda$ of order 0, $F = y$ (left invariant under $N_A(E^+) \subseteq \Gamma_V$), $J = \mathrm{K}_f(M_0)$, this δ and g, the point $1 \in G_\infty$ and $D = C$: the hypothesis $|y(g(z,1)) - y(g)| \le C$ for $z \in Z_\delta$ is the assumed oscillation bound (with $u = z$). Hence $|y(g)| \le C$. □

Lemma 6.4.102. *For admissible data D, the positive integer $q_1 d$ lies in $\mathfrak{D}_E$.*

Proof. Put $N = q_1 d$ and let ζ_N be a primitive N-th root of unity. By (1) of Lemma 4.2.66, $E \subseteq L = \mathbb{Q}(\zeta_N)$. The ring of integers of L is $\mathbb{Z}[\zeta_N]$, so the different $\mathfrak{D}_L$ of $L/\mathbb{Q}$ is generated by $\mathrm{cyc}_N'(\zeta_N)$, cyc_N the cyclotomic polynomial. Differentiating $x^N - 1 = \mathrm{cyc}_N(x)h(x)$ with $h \in \mathbb{Z}[x]$ at ζ_N gives $N\zeta_N^{N-1} = \mathrm{cyc}_N'(\zeta_N)h(\zeta_N)$, so $N \in \mathfrak{D}_L$. By the transitivity of differents, $\mathfrak{D}_L = \mathfrak{D}_{L/E}\,\mathfrak{D}_E\mathcal{O}_L \subseteq \mathfrak{D}_E\mathcal{O}_L$, and as $\mathcal{O}_L$ is faithfully flat over $\mathcal{O}_E$, $\mathfrak{D}_E\mathcal{O}_L \cap \mathcal{O}_E = \mathfrak{D}_E$. Hence $N \in \mathfrak{D}_E\mathcal{O}_L \cap E = \mathfrak{D}_E$ (classical facts on differents and cyclotomic fields, cited in passing). $\square$

Lemma 6.4.103. *Let D be admissible data, V a hermitian space over E of rank $n \geq 1$ with a frame and signs s_v, and $Z = V \oplus \langle 1\rangle$ with the frame of V followed by the added basis vector (signs $(s_v, +1)$); write $x \mapsto x \oplus 1$ for the embedding $\mathrm{U}(V) \to \mathrm{U}(Z)$. Let $A, L, a_{\mathrm{p}} \in \mathbb{N}$ and $\beta, R > 0$ satisfy the deep-level size conditions for rank n. Let $\lambda = (\lambda(v))$ and $\lambda' = (\lambda'(v))$ be such that, for every $v \in \Phi$, $2\lambda(v)$ has large gap $4A$ for s_v with entries of absolute value at most L, and $2\lambda'(v)$ has large gap $2A$ for $(s_v, +1)$. Let $\omega = (\omega_v) \in \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}(s_v, 1))$ satisfy, for every v, $\|\omega_v\|^2 \leq \beta$ and*

$$\mathrm{vol}\{r \in \mathrm{U}(\mathrm{diag}\, s_v) : \|r - 1\| \leq 1\} \leq \beta^{a_{\mathrm{p}}} \Big| \int_{\mathrm{U}(\mathrm{diag}\, s_v)} c_{\lambda(v)}(r)\, \overline{c_{\lambda'(v)}(\omega_v^{-1}(r \oplus 1)\omega_v)}\, dr \Big|.$$

Let y be a form on V of type λ and level $K(\pi_M^b)$, $S \geq 0$ with $|y| \leq S$ on $\mathrm{U}(V)(\mathbb{A})$, and assume

$$\int_{\mathrm{U}(V)(E^+)\backslash \mathrm{U}(V)(\mathbb{A})} y(x)\, \overline{\varphi((x \oplus 1)\,\omega)}\, dx = 0$$

for every form φ on Z of type λ' and level $K(\pi_M^b)$. If $x \in \mathrm{U}(V)(\mathbb{A})$ and $\lambda_V(x) \geq \theta_{\mathrm{cs}}$, then $|y(x)| \leq S/2$.

Proof. Write $G_\infty = \prod_v \mathrm{U}(\mathrm{diag}\, s_v)$, $G'_\infty = \prod_v \mathrm{U}(\mathrm{diag}(s_v, 1))$, $\tilde{x} = x \oplus 1$, $\mathfrak{b} = \pi_M^b$, $\Gamma_Z = \mathrm{U}(Z)(E^+)$, $\mathrm{vol}_v = \mathrm{vol}\{r \in \mathrm{U}(\mathrm{diag}\, s_v) : \|r - 1\| \leq 1\} > 0$ (the set contains a neighbourhood of 1), $c_\lambda(u) = \prod_v c_{\lambda(v)}(u_v)$, $d_v = d_{\lambda(v)}$ and $D' = \prod_v d_{\lambda'(v)} > 0$ (formal degrees of discrete series are positive, Theorem A.5.18). From the size conditions, $\beta \geq 2000 \geq 16$ and $R \geq \beta^{20A(f+1)} \geq \beta$. For $\alpha \in G'_\infty$ put $\psi_\alpha(r) = \phi_{\alpha,\omega}(r \oplus 1)$ $(r \in G_\infty)$ and

$$Y_\alpha(x') = \int_{G_\infty} \psi_\alpha(r)\, y(x'(r, 1))\, dr \qquad (x' \in \mathrm{U}(V)(\mathbb{A})).$$

Step 1: the Poincaré series are orthogonal to y. Fix $\alpha \in G'_\infty$ and put

$$P_\alpha(g) = \phi_{\alpha,\omega}(g_\infty)\mathbf{1}_{K_Z(\mathfrak{b})}(g_f)$$

on $\mathrm{U}(Z)(\mathbb{A})$. Since $e_{\lambda'}(u) = \prod_v d_{\lambda'(v)}\overline{c_{\lambda'(v)}(u_v)}$, we have $\phi_{\alpha,\omega}(u) = D'^{-1} e_{\lambda'}(\alpha^{-1}u\omega)$. Apply Lemma 6.4.107 to Z $(N = n + 1)$, $B = 2A > 8(n+1)^2$, λ', $a = \mathfrak{b}$ and $c = (\alpha, 1)^{-1}\tilde{x}^{-1}$: there is a form Q on Z of type λ' and level $K_Z(\mathfrak{b})$ with

$$\overline{Q(g')} = \sum_\gamma e_{\lambda'}((c\gamma g')_\infty)\mathbf{1}_{K_Z(\mathfrak{b})}((c\gamma g')_f).$$

For $g' = (h \oplus 1)(\omega, 1)$ one has $(c\gamma g')_\infty = \alpha^{-1}(\tilde{x}^{-1}\gamma(h \oplus 1))_\infty\omega$ and $(c\gamma g')_f = (\tilde{x}^{-1}\gamma(h \oplus 1))_f$, so

$$\sum_{\gamma\in\Gamma_Z} P_\alpha(\tilde{x}^{-1}\gamma(h \oplus 1)) = D'^{-1}\,\overline{Q((h \oplus 1)\omega)}.$$

Multiplying by $y(h)$ and integrating over $\Gamma_V\backslash \mathrm{U}(V)(\mathbb{A})$ gives 0, by the orthogonality hypothesis for $\varphi = Q$.

Step 2: the smoothing is small. Apply Lemma 6.4.104 with $F = y$ (bounded and measurable, left invariant under Γ_V, of level $K_V(\mathfrak{b})$, $|y| \le S$), $a = \mathfrak{b}$, $R_0 = M^{b/2}$ in place of its R (indeed $|\mathfrak{b}|_v = M^{b/2}$ at every v), the given A, λ', α, ω, x, and $d = R$. Its hypotheses hold: $8(n+1)^2 < A$ and $2f(n+1)+2 \le A$ are size conditions; $d = R \ge \beta \ge \max(10, f)$; and, as $\lambda_V(x) \ge \theta_{\mathrm{cs}}$, $M^{b/2} \ge R^{3n+2}$ and $Mc_{\mathrm{cs}}(n)^2 \le \beta \le R$,

$$R_0\lambda_V(x) \ge R^{3n+2}\, R^{-2n}\big(Mc_{\mathrm{cs}}(n)^2\big)^{-n} \ge R^{n+2}R^{-n} = d^2.$$

By Step 1 the period in that lemma is 0; dividing by $\mathrm{vol}(K_V(\mathfrak{b})) > 0$,

$$|Y_\alpha(x)| \le C_{\mathrm{sl}}(\alpha,\omega)\, S\, \frac{10}{R} \qquad (\alpha \in G'_\infty). \tag{6.113}$$

Step 3: moving a real translation into α. Let $u \in G_\infty$. Substituting $r' = ur$ (left invariance of dr) and using $\omega^{-1}(u^{-1} \oplus 1) = ((u \oplus 1)\omega)^{-1}$,

$$Y_\omega(x(u,1)) = \int \phi_{\omega,\omega}\big((u^{-1}r' \oplus 1)\big) y\big(x(r',1)\big)\, dr' = Y_{(u\oplus 1)\omega}(x),$$

so $|Y_\omega(x(u,1))| \le C_{\mathrm{sl}}((u\oplus 1)\omega,\omega) S \cdot 10/R$ by (6.113). Since $\|u_v \oplus 1\| = \|u_v\|$ (as $\|u_v\| \ge 1$) and $\|\omega_v\|^2 \le \beta$,

$$C_{\mathrm{sl}}((u\oplus 1)\omega,\omega) \le \prod_{v\in\Phi} \big(2\|u_v\|^2\beta^2\big)^A 16^A \mathrm{vol}_v.$$

Step 4: the average. By Lemma 5.7.38(1) with $c = 4A$ and the gap $500n^3 + 4A$ of $2\lambda(v)$, $|e_\lambda(u)| \le \prod_v d_v (2/\|u_v\|)^{4A}$, which is integrable by Lemma 5.7.38(3) ($4A > 8n^2$, entries at most L); so e_λ is integrable, and ψ_ω is integrable by Lemma 6.4.104. By Fubini (y bounded) and Lemma 6.4.108 (with $g = x$),

$$\begin{aligned}\int_{G_\infty} e_\lambda(u)\, Y_\omega\big(x(u,1)\big)\, du &= \int_{G_\infty} \psi_\omega(r)\Big(\int_{G_\infty} e_\lambda(u)\, y\big(x(u,1)(r,1)\big)\, du\Big) dr \\ &= \eta\, y(x), \qquad \eta = \int_{G_\infty} \psi_\omega(r) c_\lambda(r)\, dr.\end{aligned}$$

By Fubini on $G_\infty = \prod_v G_v$, $\eta = \prod_v \int c_{\lambda(v)}(r)\overline{c_{\lambda'(v)}(\omega_v^{-1}(r\oplus 1)\omega_v)}\, dr$, so $|\eta| \ge \beta^{-a_{\mathrm{p}} f} \prod_v \mathrm{vol}_v$ by the hypothesis on ω.

Step 5: the bound. By Steps 3 and 4, and $2^{2A}\cdot 2^A \cdot 16^A\beta^{2A} \le (2\beta)^{3A}$ (as $16 \le \beta$),

$$|e_\lambda(u)|\, |Y_\omega(x(u,1))| \le S\, \frac{10}{R}\, (2\beta)^{3Af} \prod_v \mathrm{vol}_v \cdot \prod_v d_v\Big(\frac{2}{\|u_v\|}\Big)^{2A}.$$

Integrating, with Lemma 5.7.38(3) for $c = 2A > 8n^2$ at each place and $T = 8(2000(n+L+1)^6)^{2n^2}2^{2A}$,

$$\beta^{-a_{\mathrm{p}} f}\Big(\prod_v \mathrm{vol}_v\Big)|y(x)| \le |\eta\, y(x)| \le S\, \frac{10}{R}\, (2\beta)^{3Af}\, T^f \prod_v \mathrm{vol}_v.$$

Now $T \le 8\beta^{2n^2}2^{2A} \le \beta^{1+2n^2+2A}$ and $(2\beta)^{3A} \le \beta^{6A}$, and $a_{\mathrm{p}} \le A-1$, $2n^2 \le A-1$, so $\beta^{a_{\mathrm{p}}}(2\beta)^{3A}T \le \beta^{10A}$ and $16\beta\,(\beta^{a_{\mathrm{p}}}(2\beta)^{3A}T)^f \le \beta^{10Af+2} \le \beta^{20A(f+1)} \le R$. Hence $|y(x)| \le S\cdot 10/(16\beta) \le S/2$. □

Lemma 6.4.104. *Let V be a hermitian space over E of rank $n \geq 1$ with a frame and signs s_v, and $Z = V \oplus Ee$ with $\langle e, e\rangle = 1$ and the frame of V followed by e; write $h \mapsto h \oplus 1$ for $\mathrm{U}(V) \to \mathrm{U}(Z)$, $\Gamma_V = \mathrm{U}(V)(E^+)$, $\Gamma_Z = \mathrm{U}(Z)(E^+)$, $G_\infty(V) \times G_f(V)$ and $G_\infty(Z) \times G_f(Z)$ the frame decompositions, and $K_V(a)$, $K_Z(a)$ the principal levels. Fix Haar measures dr on $G_\infty(V)$ (a product over $v \in \Phi$) and dk on $G_f(V)$, put $dh = dr\,dk$ on $\mathrm{U}(V)(\mathbb{A})$, and let $\dot{dh}$ be the quotient measure on $\Gamma_V\backslash\mathrm{U}(V)(\mathbb{A})$ for which $\int_{\mathrm{U}(V)(\mathbb{A})} u\,dh = \int \sum_{\delta\in\Gamma_V} u(\delta h)\,\dot{dh}$ for integrable u. Let $0 \neq a \in \mathcal{O}_E$ and $R \geq 0$ with $R \leq |a|_v$ for all $v \in \Phi$; let $A \in \mathbb{N}$ with $8(n+1)^2 < A$ and $2f(n+1) + 2 \leq A$; let λ' be such that $2\lambda'(v)$ has large gap $2A$ for $(s_v, +1)$; let $\alpha, \omega \in G_\infty(Z)$. For $g \in \mathrm{U}(Z)(\mathbb{A})$ put $P(g) = \phi_{\alpha,\omega}(g_\infty)\,\mathbf{1}_{K_Z(a)}(g_f)$. Let F be a bounded measurable function on $\mathrm{U}(V)(\mathbb{A})$, left invariant under Γ_V and right invariant under $K_V(a)$, with $|F| \leq S$. Let $x \in \mathrm{U}(V)(\mathbb{A})$ and $d \geq \max(10, f)$ with $d^2 \leq R\lambda_V(x)$. Then $\psi(r) = \phi_{\alpha,\omega}(r \oplus 1)$ is integrable on $G_\infty(V)$, the function $h \mapsto \sum_{\gamma\in\Gamma_Z} P\big((x\oplus 1)^{-1}\gamma(h\oplus 1)\big)F(h)$ is integrable on $\Gamma_V\backslash\mathrm{U}(V)(\mathbb{A})$, and*

$$\Big|\int \sum_{\gamma\in\Gamma_Z} P\big((x\oplus 1)^{-1}\gamma(h\oplus 1)\big)F(h)\,\dot{dh} - \mathrm{vol}(K_V(a))\int_{G_\infty(V)} \psi(r)F\big(x(r,1)\big)\,dr\Big| \leq \mathrm{vol}(K_V(a))\,C_{\mathrm{sl}}(\alpha,\omega)\,S\,\frac{10}{d}.$$

Proof. Write $\tilde{x} = x \oplus 1$, $X = \prod_{v\in\Phi} \mathbb{C}^{n+1}$ with its Euclidean norm (a real space of dimension $2f(n+1)$), and for $u \in Z$ let $c_x(u) = \tilde{x}^{-1}c(u) \in \mathbb{A}_E^{n+1}$ be its coordinates at $\tilde{x}$, $c_x(u)_\infty \in X$ their infinite part. For $g \in G_\infty(Z)$ every factor satisfies $\|g_v\| \geq 1$, since $g_v^{-1} = J_v g_v^* J_v$ with $J_v = \mathrm{diag}(s_v, 1)$ gives $\|g_v^{-1}\| = \|g_v\|$ and $1 \leq \|g_v\|\|g_v^{-1}\|$.

Step 1: integrability of ψ and of the kernels. By Lemma 6.4.105 with $g = 1$ and $t = 1$ (each $\|r_v \oplus 1\| \geq 1$), ψ is integrable. Let $g \in \mathrm{U}(Z)(\mathbb{A})$ with $g_f \in K_Z(a)$. For $h \in \mathrm{U}(V)(\mathbb{A})$, $g_f(h_f \oplus 1) \in K_Z(a)$ if and only if $h_f \oplus 1 \in K_Z(a)$, if and only if $h_f \in K_V(a)$; so $P(g(h\oplus 1)) = \phi_{\alpha,\omega}(g_\infty(h_\infty \oplus 1))\mathbf{1}_{K_V(a)}(h_f)$ and, by Fubini,

$$\int_{\mathrm{U}(V)(\mathbb{A})} \big|P\big(g(h\oplus 1)\big)\big|\,dh = \mathrm{vol}(K_V(a))\int_{G_\infty(V)} \big|\phi_{\alpha,\omega}\big(g_\infty(r\oplus 1)\big)\big|\,dr \leq \mathrm{vol}(K_V(a))\,C_{\mathrm{sl}}(\alpha,\omega)\,t^{-A} \tag{6.114}$$

whenever $0 < t \leq \prod_v \|g_v(r_v \oplus 1)\|$ for all r (Lemma 6.4.105); $t = 1$ is always allowed.

Step 2: the cosets that contribute. The map $h \mapsto h\oplus 1$ identifies Γ_V with the stabiliser of e in Γ_Z: an isometry fixing e preserves $V = e^\perp$. Choose a set Σ of representatives of $\Gamma_Z/(\Gamma_V \oplus 1)$ containing 1, so that $\gamma = \sigma(\delta \oplus 1)$ with unique $\sigma \in \Sigma$, $\delta \in \Gamma_V$. Let $\Sigma' \subseteq \Sigma$ be the set of σ for which some $k_\sigma \in \mathrm{U}(V)(\mathbb{A})$ has $(\tilde{x}^{-1}\sigma(k_\sigma \oplus 1))_f \in K_Z(a)$; fix such k_σ, with $k_1 = x$. If $\sigma \notin \Sigma'$, every term $P(\tilde{x}^{-1}\sigma(\delta\oplus 1)(h\oplus 1))$ vanishes. For $\sigma \in \Sigma$ let $y_\sigma = \sigma e \in Z$; then $y_\sigma = y_{\sigma'}$ implies $\sigma^{-1}\sigma' e = e$, so $\sigma^{-1}\sigma' \in \Gamma_V \oplus 1$ and $\sigma = \sigma'$. Put $p_\sigma = c_x(y_\sigma)_\infty \in X$.

Step 3: separation. Let $\sigma \neq \sigma'$ in Σ' and $g = \tilde{x}^{-1}\sigma(k_\sigma \oplus 1)$, $g' = \tilde{x}^{-1}\sigma'(k_{\sigma'} \oplus 1)$. As $(k \oplus 1)$ fixes the last coordinate vector, $c_x(y_\sigma) = g\,c(e)$ is the last column of the matrix of g, and likewise for σ'; since $g_f, g'_f \in K_Z(a)$, the finite parts of $c_x(y_\sigma)$ and $c_x(y_{\sigma'})$ are congruent to the last coordinate vector modulo $a\widehat{\mathcal{O}}_E$. Hence $u = a^{-1}(y_\sigma - y_{\sigma'}) \in Z$ is nonzero with $c_x(u)_f \in \widehat{\mathcal{O}}_E^{n+1}$. Write $u = u_V + ce$ with $u_V \in V$, $c \in E$; then $c_x(u) = (x^{-1}c(u_V), c)$, so $c \in \mathcal{O}_E$ and $x^{-1}c(u_V)$ has integral finite part. If $c \neq 0$, some $|c|_v \geq 1$ by the product formula, so $\|c_x(u)_\infty\| \geq 1$; if $c = 0$, then $u_V \neq 0$ and $\|c_x(u)_\infty\| \geq \lambda_V(x)$. In both cases $\|c_x(u)_\infty\| \geq \lambda_V(x)$, and since $|a|_v \geq R$ at every v,

$$\|p_\sigma - p_{\sigma'}\| = \|a\,c_x(u)_\infty\| \geq R\lambda_V(x) \geq d^2.$$

Also $p_1 = c(e)_\infty$ has norm $\sqrt{f} \leq d$.

Step 4: the terms. Let $\sigma \in \Sigma'$, $\sigma \neq 1$; then $\|p_\sigma\| \geq d^2 - d \geq d^2/2 > 0$. For $h \in \mathrm{U}(V)(\mathbb{A})$ let $g_h = \tilde{x}^{-1}\sigma(k_\sigma h \oplus 1)$. Its last column at the infinite places is p_σ, so $\|p_\sigma\| \leq \sum_v \|(g_h)_v\| \leq f \prod_v \|(g_h)_v\| \leq d \prod_v \|(g_h)_v\|$, using $\|(g_h)_v\| \geq 1$. Apply (6.114) to $g = g_1 = \tilde{x}^{-1}\sigma(k_\sigma \oplus 1)$ with $t = \|p_\sigma\|/d$, and substitute $h \mapsto k_\sigma h$ (left invariance of dh):

$$\int_{\mathrm{U}(V)(\mathbb{A})} \bigl|P(\tilde{x}^{-1}\sigma(h \oplus 1))F(h)\bigr|\, dh \leq \mathrm{vol}(K_V(a))\, C_{\mathrm{sl}}(\alpha,\omega)\, S\Bigl(\frac{d}{\|p_\sigma\|}\Bigr)^A.$$

For $\sigma = 1$ the same integral is finite by (6.114) with $t = 1$.

Step 5: summing the terms. The points p_σ, $\sigma \in \Sigma' \setminus \{1\}$, have norms and mutual distances at least $d^2/2$, and $\dim_{\mathbb{R}} X + 2 = 2f(n+1) + 2 \leq A$; by Lemma 6.4.106 with $\delta = d^2/2$,

$$\sum_{\sigma \in \Sigma' \setminus \{1\}} \Bigl(\frac{d}{\|p_\sigma\|}\Bigr)^A \leq d^A \Bigl(\frac{10}{d^2}\Bigr)^A = \Bigl(\frac{10}{d}\Bigr)^A \leq \frac{10}{d},$$

as $d \geq 10$ and $A \geq 1$.

Step 6: unfolding. By Steps 4 and 5, $\sum_{\sigma \in \Sigma'} \int |P(\tilde{x}^{-1}\sigma(h \oplus 1))F(h)|\, dh < \infty$. Since $F(\delta h) = F(h)$ for $\delta \in \Gamma_V$, the defining property of $d\dot{h}$ and Tonelli's theorem give that

$$\sum_{\sigma \in \Sigma'} \sum_{\delta \in \Gamma_V} |P(\tilde{x}^{-1}\sigma(\delta h \oplus 1))F(h)|$$

is integrable on the quotient, and, with Step 2 and Fubini,

$$\int \sum_{\gamma \in \Gamma_Z} P(\tilde{x}^{-1}\gamma(h \oplus 1))F(h)\, d\dot{h} = \sum_{\sigma \in \Sigma'} \int_{\mathrm{U}(V)(\mathbb{A})} P(\tilde{x}^{-1}\sigma(h \oplus 1))F(h)\, dh.$$

This proves the integrability claim.

Step 7: the identity coset. For $\sigma = 1$ substitute $h = xh'$:

$$P(h' \oplus 1)F(xh') = \psi(h'_\infty)\mathbf{1}_{K_V(a)}(h'_f)F(x(h'_\infty, h'_f)),$$

and $F(x(h'_\infty, h'_f)) = F(x(h'_\infty, 1))$ for $h'_f \in K_V(a)$ by right invariance; Fubini gives the term

$$\mathrm{vol}(K_V(a)) \int_{G_\infty(V)} \psi(r)F(x(r,1))\, dr.$$

The difference in the statement is the sum over $\sigma \in \Sigma' \setminus \{1\}$, bounded by Steps 4 and 5 by $\mathrm{vol}(K_V(a))C_{\mathrm{sl}}(\alpha,\omega)S \cdot 10/d$. □

Lemma 6.4.105. *Let $n \geq 1$, $s_v \in \{\pm 1\}^n$ for $v \in \Phi$, $G_\infty = \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}\, s_v)$ and $G'_\infty = \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}(s_v, 1))$, each factor with a Haar measure dr_v, $r \mapsto r \oplus 1$ the block embedding, and $\|\cdot\|$ the operator norm. Let $A \in \mathbb{N}$ with $8(n+1)^2 < A$, and let $\lambda' = (\lambda'(v))$ be such that $2\lambda'(v)$ has large gap $2A$ for $(s_v, +1)$. For $\alpha, \omega \in G'_\infty$ put*

$$\phi_{\alpha,\omega}(g) = \prod_{v\in\Phi} \overline{c_{\lambda'(v)}(\alpha_v^{-1} g_v \omega_v)},$$

$$C_{\mathrm{sl}}(\alpha,\omega) = \prod_{v\in\Phi} \bigl(2(\|\alpha_v\|\,\|\omega_v\|)^2\bigr)^A\, 16^A\, \mathrm{vol}\{r \in \mathrm{U}(\mathrm{diag}\, s_v) : \|r - 1\| \leq 1\}.$$

Let $g \in G'_\infty$ and $t > 0$ with $t \leq \prod_{v\in\Phi} \|g_v(r_v \oplus 1)\|$ for every $r \in G_\infty$. Then $r \mapsto \phi_{\alpha,\omega}(g(r \oplus 1))$ is integrable on G_∞ and

$$\int_{G_\infty} \bigl|\phi_{\alpha,\omega}(g(r \oplus 1))\bigr|\, dr \leq C_{\mathrm{sl}}(\alpha,\omega)\, t^{-A}.$$

Proof. **Step 1: two norm facts.** For $x \in \mathrm{U}(\mathrm{diag}\,\epsilon)$ (any signs ϵ), $x^{-1} = \mathrm{diag}(\epsilon)\,\bar{x}^{\mathsf{T}}\mathrm{diag}(\epsilon)$, so $\|x^{-1}\| = \|x\|$. Hence, with $X_v = \alpha_v^{-1} g_v(r_v \oplus 1)\omega_v$, the identity $g_v(r_v \oplus 1) = \alpha_v X_v \omega_v^{-1}$ gives $\|g_v(r_v \oplus 1)\| \le \|\alpha_v\|\,\|X_v\|\,\|\omega_v\|$.

Step 2: pointwise decay. For each v, $2\lambda'(v) \in \mathbb{Z}^{n+1}$ has large gap $2A$ for $(s_v, +1)$, i.e. gap $500(n+1)^3 + 2A \ge 2A$, so (1) of Lemma 5.7.38 (rank $n+1$, $c = 2A$) gives $|c_{\lambda'(v)}(u)| \le (2/\|u\|)^{2A}$ for all u. With Step 1,

$$\begin{aligned}|\phi_{\alpha,\omega}(g(r \oplus 1))| &\le \prod_{v\in\Phi} \Big(\frac{2\|\alpha_v\|\|\omega_v\|}{\|g_v(r_v \oplus 1)\|}\Big)^{2A} \\ &= \prod_{v\in\Phi} (2(\|\alpha_v\|\|\omega_v\|)^2)^A \Big(\frac{2}{\|g_v(r_v \oplus 1)\|}\Big)^{A} \cdot \Big(\prod_{v\in\Phi} \|g_v(r_v \oplus 1)\|\Big)^{-A}.\end{aligned}$$

By hypothesis the last factor is at most t^{-A}.

Step 3: the slice integral at one place. Fix v and let $H = \mathrm{U}(\mathrm{diag}\, s_v)$ with its Haar measure dr_v (right invariant; H is unimodular, so the measure is also inversion invariant), and $j(r) = r \oplus 1 \in \mathrm{U}(\mathrm{diag}(s_v, 1))$, a continuous homomorphism which is a closed embedding, hence proper. By Step 1, $\|g_v(r \oplus 1)\| = \|(r^{-1} \oplus 1)g_v^{-1}\|$; substituting $r \mapsto r^{-1}$ and applying (ii) of Lemma 5.6.32 with $S = H$, $N = n+1$, $y = g_v^{-1}$ and $c = A > 8(n+1)^2$,

$$\int_H \Big(\frac{2}{\|g_v(r \oplus 1)\|}\Big)^A dr_v = \int_H \Big(\frac{2}{\|j(r)g_v^{-1}\|}\Big)^A dr_v \le 16^A \,\mathrm{vol}\{r \in H : \|r - 1\| \le 1\},$$

the volume being finite by the same item.

Step 4: conclusion. The function $r \mapsto \phi_{\alpha,\omega}(g(r \oplus 1))$ is continuous ($c_{\lambda'(v)}$ is continuous) and, by Step 2, dominated by t^{-A} times a product over v of nonnegative functions of r_v alone; by Tonelli's theorem for the product measure and Step 3 the dominating function is integrable, with integral at most $t^{-A}\prod_v (2(\|\alpha_v\|\|\omega_v\|)^2)^A 16^A \mathrm{vol}\{\|r-1\| \le 1\} = C_{\mathrm{sl}}(\alpha,\omega)\,t^{-A}$. Hence the slice is integrable with the stated bound. □

Lemma 6.4.106. *Let X be a real normed space of finite dimension D, let $\delta > 0$, and let $(p_i)_{i\in I}$ be a family in X with $\|p_i - p_j\| \ge \delta$ for $i \ne j$ and $\|p_i\| \ge \delta$ for all i. For every integer $A \ge D+2$ the series $\sum_{i\in I} \|p_i\|^{-A}$ converges and*

$$\sum_{i\in I} \|p_i\|^{-A} \le \Big(\frac{5}{\delta}\Big)^A.$$

Proof. **Counting.** Fix a Haar measure μ on X (a Lebesgue measure in a basis); $\mu(B(c,\rho)) = \rho^D \mu(B(0,1))$ for every closed ball, by translation invariance and homogeneity, and $0 < \mu(B(0,1)) < \infty$. For $t \ge 0$ let $N(t) = \#\{i : \|p_i\| \le t\}$. The balls $B(p_i, \delta/2)$ are pairwise disjoint up to boundaries, of measure zero, by the triangle inequality, and for $\|p_i\| \le t$ they lie in $B(0, t + \delta/2)$. Comparing measures, $N(t)(\delta/2)^D \le (t + \delta/2)^D$, so $N(t)$ is finite and

$$N(t) = 0 \quad (t < \delta), \qquad N(t) \le \Big(\frac{2t+\delta}{\delta}\Big)^D \le \Big(\frac{3t}{\delta}\Big)^D \quad (t \ge \delta).$$

In particular I is countable.

Layer cake. For each i, $\|p_i\|^{-A} = \int_{\|p_i\|}^{\infty} At^{-A-1}\,dt$. Summing over i and interchanging sum and integral (Tonelli; all terms are nonnegative),

$$\sum_i \|p_i\|^{-A} = \int_0^\infty At^{-A-1} N(t)\,dt \le A\Big(\frac{3}{\delta}\Big)^D \int_\delta^\infty t^{D-A-1}\,dt = \frac{A}{A-D}\,3^D\delta^{-A},$$

which is finite since $A - D \geq 2$.

The constant. As $A-D \geq 2$ and $D \leq A$, $\frac{A}{A-D}3^D \leq \frac{A}{2}\,3^A \leq 5^A$, the last inequality because $(5/3)^A \geq 1 + \frac{2A}{3} \geq \frac{A}{2}$ (Bernoulli's inequality). □

Lemma 6.4.107. *Let Z be a hermitian space over E of rank $N \geq 1$ with a frame and signs t_v ($v \in \Phi$), $\Gamma_Z = \mathrm{U}(Z)(E^+)$, and let $B \in \mathbb{N}$ with $8N^2 < B$. Let λ' be such that $2\lambda'(v)$ has large gap B for t_v for every v. Let $0 \neq a \in \mathcal{O}_E$ and $c \in \mathrm{U}(Z)(\mathbb{A})$. Then for every $g \in \mathrm{U}(Z)(\mathbb{A})$ the series*

$$\sum_{\gamma \in \Gamma_Z} e_{\lambda'}((c\gamma g)_\infty)\, \mathbf{1}_{K(a)}((c\gamma g)_f)$$

converges absolutely, and there is a form Q on Z of type λ' and level $K(a)$ whose complex conjugate is this series, as a function of g.

Proof. With its frame Z is a framed space of rank N whose signs are the same at every place (Definition 5.6.3), $\mathrm{U}(Z)(\mathbb{A}) = G_\infty \times G_f$, and Γ_Z is read through the frames. Write $e = e_{\lambda'}$ and $K = K(a)$, an open compact subgroup of G_f; put $\kappa(y) = e(y_\infty)\mathbf{1}_K(y_f)$ for $y \in G_\infty \times G_f$.

Step 1: the kernel. Each $2\lambda'(v)$ has gap $500N^3 + B$ for the signs, so by Lemma 5.6.21 e is a cusp kernel of order B: an idempotent kernel with $e(y^{-1}) = \overline{e(y)}$ and $\sup_y |e(y)|\,\|y\|_\infty^B < \infty$ (EK4 (b)).

Step 2: absolute convergence, uniformly in g. As K is a group and $e(y^{-1}) = \overline{e(y)}$, $|\kappa(c\gamma g)| = |\kappa(g^{-1}\gamma^{-1}c^{-1})|$. Apply (ii) of Proposition 5.8.22 with $\varphi = \mathbf{1}_K$ (locally constant, compactly supported), $k = e$, $j = 0$, $B \geq 8N^2 + 1$, $r = 1$ (admissible since $\|y_v\| \geq 1$ for every $y_v \in \mathrm{U}(\operatorname{diag} t)$, as $\|y_v^{-1}\| = \|y_v\|$, so $\|y\|_\infty \geq 1$), the points g and $x = c^{-1}$, and $Z = \Gamma_Z$; after the bijection $\gamma \mapsto \gamma^{-1}$ of Γ_Z it gives

$$\sum_{\gamma \in \Gamma_Z} |\kappa(c\gamma g)| = \sum_{\gamma \in \Gamma_Z} |\kappa(g^{-1}\gamma c^{-1})| \leq C' \lambda_Z(c^{-1})^{-4fN^2} =: C_0 < \infty$$

for every g, with C_0 independent of g. So the series $P(g) = \sum_\gamma \kappa(c\gamma g)$ converges absolutely, $|P| \leq C_0$, and, since $\overline{\kappa(y)} = \kappa(y^{-1})$, $\overline{P(g)} = \sum_\gamma \kappa(g^{-1}\gamma^{-1}c^{-1}) = \sum_\gamma \kappa(g^{-1}\gamma c^{-1}) =: F(g)$, an absolutely convergent sum (reindexing by $\gamma \mapsto \gamma^{-1}$).

Step 3: invariance. Each term of F is continuous in g, so F is measurable, and $|F| \leq C_0$. For $\delta \in \Gamma_Z$, $F(\delta g) = \sum_\gamma \kappa(g^{-1}\delta^{-1}\gamma c^{-1}) = F(g)$ by the bijection $\gamma \mapsto \delta\gamma$. For $u \in K$, $\kappa(u^{-1}g^{-1}\gamma c^{-1}) = \kappa(g^{-1}\gamma c^{-1})$ since $\mathbf{1}_K(u^{-1}y_f) = \mathbf{1}_K(y_f)$; so $F(g(1,u)) = F(g)$.

Step 4: reproduction by e. For g fixed, by Tonelli's theorem and Step 2 at the points $g(h,1)$,

$$\int_{G_\infty} \sum_\gamma |e(h)\,\kappa((h,1)^{-1}g^{-1}\gamma c^{-1})|\,dh \leq C_0 \int_{G_\infty} |e| < \infty,$$

so sum and integral may be exchanged in $R(e)F(g) = \int e(h)F(g(h,1))\,dh$. For each γ, with $y = g^{-1}\gamma c^{-1}$, the identity of (EK3) at $x = 1$ gives $\int e(h)\,e(h^{-1}y_\infty)\,dh = e(y_\infty)$, hence $R(e)F = F$.

Step 5: continuity and conclusion. By Step 3, Lemma 5.8.29 applies to the bounded measurable, left Γ_Z-invariant, right K-invariant function F: $R(e)F$ is continuous; by Step 4 it is F. Hence $Q = F$ is continuous, bounded, left invariant under Γ_Z, right invariant under $K(a)$ and satisfies $R(e_{\lambda'})Q = Q$ with $e_{\lambda'}$ integrable: a form of type λ' and level $K(a)$ ((FT2), (DZ2)), and $\overline{Q(g)} = P(g)$ is the series of the statement. □

Lemma 6.4.108. *Let V be a hermitian space over E with a frame and signs s_v, $\lambda = (\lambda(v))_{v\in\Phi}$ Harish-Chandra parameters for the groups $\mathrm{U}(\operatorname{diag} s_v)$ such that e_λ is integrable on G_∞, and put*

$c_\lambda(x) = \prod_{v\in\Phi} c_{\lambda(v)}(x_v)$ *for* $x \in G_\infty$. *If* y *is a form on* V *of type* λ, *then for all* $g \in \mathrm{U}(V)(\mathbb{A})$ *and* $x \in G_\infty$

$$\int_{G_\infty} e_\lambda(z)\, y(g\,(z,1)(x,1))\, dz = c_\lambda(x)\, y(g).$$

Proof. **The local kernels.** Fix $v \in \Phi$ and write $G_v = \mathrm{U}(\mathrm{diag}\, s_v)$, $c_v = c_{\lambda(v)}$, $d_v = d_{\lambda(v)}$ and $e_v = d_v\overline{c_v}$, so that $e_\lambda(z) = \prod_v e_v(z_v)$. By definition c_v is a diagonal matrix coefficient of a unit vector w of the discrete series $(\sigma, \mathcal{H})$ of G_v with parameter $\lambda(v)$, and $d_v^{-1} = \int_{G_v} |c_v|^2$. With inner products linear in the second argument, $c_v(g) = \langle w, \sigma(g)w\rangle$ or $c_v(g) = \langle \sigma(g)w, w\rangle$; we treat the first case, the second being the same computation with all coefficients conjugated. Schur's orthogonality relations (Theorem A.5.18, applicable since σ is irreducible, unitary and has a square-integrable coefficient) give, with $a = b = a' = b' = w$, that the formal degree of σ is d_v, and in general

$$\int_{G_v} \langle b, \sigma(z)a\rangle\, \overline{\langle b', \sigma(z)a'\rangle}\, dz = d_v^{-1}\langle a', a\rangle\langle b, b'\rangle.$$

For $x, u \in G_v$, unitarity gives $\overline{c_v(x^{-1}z^{-1}u)} = \langle \sigma(u)w, \sigma(z)\sigma(x)w\rangle$, so, with $b = \sigma(u)w$, $a = \sigma(x)w$, $b' = a' = w$,

$$\begin{aligned} K_{v,x}(u) := \int_{G_v} e_v(z)\, e_v(x^{-1}z^{-1}u)\, dz &= d_v^2 \int_{G_v} \langle \sigma(u)w, \sigma(z)\sigma(x)w\rangle\, \overline{\langle w, \sigma(z)w\rangle}\, dz \\ &= d_v\langle w, \sigma(x)w\rangle\langle \sigma(u)w, w\rangle = c_v(x)\, e_v(u). \end{aligned}$$

Each e_v is integrable, since $\int |e_\lambda| = \prod_v \int |e_v| < \infty$ and every factor is positive. By Fubini on the product $G_\infty = \prod_v G_v$, for $x \in G_\infty$

$$\int_{G_\infty} e_\lambda(z)\, e_\lambda(x^{-1}z^{-1}u)\, dz = \prod_v K_{v,x_v}(u_v) = c_\lambda(x)\, e_\lambda(u) \qquad (u \in G_\infty).$$

The form. Let $f(u) = y(g(u,1))$ for $u \in G_\infty$; it is bounded and measurable, and the type condition (DZ2) says $\int e_\lambda(h) f(uh)\, dh = f(u)$ for every u. Hence $f(zx) = \int e_\lambda(h) f(zxh)\, dh$, and

$$\begin{aligned} \int e_\lambda(z) f(zx)\, dz &= \iint e_\lambda(z) e_\lambda(h) f(zxh)\, dh\, dz \\ &= \int f(u)\Big(\int e_\lambda(z) e_\lambda(x^{-1}z^{-1}u)\, dz\Big) du = c_\lambda(x) \int e_\lambda(u) f(u)\, du, \end{aligned}$$

where the interchange and the substitution $u = zxh$ (left invariance of dh) are justified by $\iint |e_\lambda(z)||e_\lambda(h)| \sup|f|\, dh\, dz < \infty$. The last integral is $f(1) = y(g)$ by the type condition at $u = 1$, and $f(zx) = y(g(z,1)(x,1))$. □

Lemma 6.4.109. *Let* $n \geq 1$, $\varepsilon \in \{\pm 1\}^n$ *and* $\varepsilon' = (\varepsilon, +1) \in \{\pm 1\}^{n+1}$; *let* $l \in \mathbb{Z}^n$ *and* $l' \in \mathbb{Z}^{n+1}$, *let* X *be a finite set,* $M \geq 0$ *an even integer, and* $e\colon X \sqcup \{0, \dots, M-1\} \to \{1, \dots, n\}$, $e'\colon X \sqcup \{0, \dots, M\} \to \{1, \dots, n+1\}$ *bijections. Let* $B \geq 1$ *and* $\beta \geq 10^{12}$ *be reals and* $h, L \in \mathbb{N}$. *Assume:*

1. l *is steep for* (ε, e, B), *and* $-l'$ *is steep for* (ε', e', B);
2. l *has large gap* h *for* ε *and* l' *has large gap* h *for* ε';
3. $|l_a| \leq L$ *and* $|l'_{a'}| \leq L$ *for all entries;*
4. $2n + 1 + L \leq \beta$, $(n+1)^4(6B)^{2M+2} \leq \beta$ *and* $10^{30}\big((2n+1)^2 \log\beta\big)^3 \leq h$.

Then there is $y \in \mathrm{U}(\operatorname{diag}\varepsilon')$ with $\|y\|^2 \le \beta$ such that, for any Haar measure dg on $\mathrm{U}(\operatorname{diag}\varepsilon)$,

$$\operatorname{vol}\{g \in \mathrm{U}(\operatorname{diag}\varepsilon) : \|g-1\| \le 1\} \le \beta^{20(2n+1)^2}\Big|\int_{\mathrm{U}(\operatorname{diag}\varepsilon)} c_{l/2}(g)\,\overline{c_{l'/2}(y^{-1}(g\oplus 1)y)}\,dg\Big|,$$

where $\|\cdot\|$ is the operator norm and $g \oplus 1 = \operatorname{diag}(g,1)$.

Proof. Write $\Omega = \{1,\dots,n\}$, $* = n+1$, $\Omega' = \Omega \sqcup \{*\}$, $J = \operatorname{diag}(\varepsilon)$, $J' = \operatorname{diag}(\varepsilon')$, $(b_i)_{i\in\Omega'}$ for the standard basis of $\mathbb{C}^{n+1}$, $\mu = \mu_l$ and $\nu = \mu_{l'}$. As l' has a gap, $\mu_{-l'} = -\nu$ (Lemma 5.6.27 (iii)). So the hypotheses (1) say: $\varepsilon_{e(x)} = 1$ and $\mu(e(x)) = 0$ for $x \in X$, $\varepsilon_{e(i)} = (-1)^i$ and $i \mapsto \mu(e(i))$ is strictly decreasing on $\{0,\dots,M-1\}$ with values in $[-3B,-B]$; $\varepsilon'_{e'(x)} = 1$ and $\nu(e'(x)) = 0$ for $x \in X$, $\varepsilon'_{e'(a)} = (-1)^a$ and $a \mapsto \nu(e'(a))$ is strictly increasing on $\{0,\dots,M\}$ with values in $[B,3B]$.

Nodes and Lagrange weights. Put $\tau_k = \nu(e'(M-k))$ for $0 \le k \le M$ and $\tau_{M+1+k} = \mu(e(k))$ for $0 \le k < M$. The first $M+1$ decrease strictly in $[B,3B]$, the last M decrease strictly in $[-3B,-B]$; so $\tau_0 > \tau_1 > \cdots > \tau_{2M}$ are integers with $|\tau_k - \tau_{k'}| \le 6B$. For $0 \le k \le 2M$ the product $\prod_{k'\ne k}(\tau_k - \tau_{k'})$ has exactly k negative factors, so $c_k = \big|\prod_{k'\ne k}(\tau_k-\tau_{k'})\big|^{1/2} \ge 1$ satisfies $c_k^2 = (-1)^k \prod_{k'\ne k}(\tau_k-\tau_{k'})$, and Lagrange interpolation at the $2M+1$ nodes gives, for every polynomial π of degree at most $2M$,

$$[\text{coefficient of } \tau^{2M} \text{ in } \pi] = \sum_{k\le 2M} \frac{\pi(\tau_k)}{\prod_{k'\ne k}(\tau_k-\tau_{k'})} = \sum_{k\le 2M} (-1)^k \frac{\pi(\tau_k)}{c_k^2}. \tag{6.115}$$

For $0 \le a \le M$ put

$$d_a = \frac{(-1)^a}{c_a}\prod_{k<M}(\tau_a - \tau_{M+1+k}), \qquad \pi_a(\tau) = d_a \prod_{k\le M,\,k\ne a}(\tau-\tau_k), \qquad \rho_{ka} = \frac{\pi_a(\tau_{M+1+k})}{c_{M+1+k}} \quad (k<M).$$

By the formula for c_a^2, $\pi_a(\tau_{a'}) = \delta_{aa'}c_a$ for $a,a' \le M$. The polynomial $\pi_a\pi_{a'}$ has degree $2M$ and leading coefficient $d_ad_{a'}$, so (6.115) gives $\sum_{k\le 2M}(-1)^k\pi_a(\tau_k)\pi_{a'}(\tau_k)/c_k^2 = d_ad_{a'}$; the terms with $k \le M$ add up to $(-1)^a\delta_{aa'}$, and those with $k = M+1+k'$ are $-(-1)^{k'}\rho_{k'a}\rho_{k'a'}$ because M is even. Hence

$$\sum_{k<M}(-1)^k\rho_{ka}\rho_{ka'} + d_ad_{a'} = (-1)^a\delta_{aa'} \qquad (a,a' \le M). \tag{6.116}$$

Sizes: $d_a^2 = \prod_{k<M}|\tau_a-\tau_{M+1+k}| / \prod_{k\le M,k\ne a}|\tau_a-\tau_k| \le (6B)^M$, as the nodes are distinct integers; and since $c_{M+1+k}^2 \ge |\tau_{M+1+k}-\tau_a|\prod_{k'\le M,k'\ne a}|\tau_{M+1+k}-\tau_{k'}|$, $\rho_{ka}^2 \le d_a^2\prod_{k'\le M,k'\ne a}|\tau_{M+1+k}-\tau_{k'}| \le (6B)^{2M}$.

The point y. Let y be the real $\Omega'\times\Omega'$ matrix with columns

$$y\,b_{e'(x)} = b_{e(x)} \quad (x\in X), \qquad y\,b_{e'(a)} = \sum_{k<M}\rho_{k,M-a}\,b_{e(k)} + d_{M-a}\,b_* \quad (0\le a\le M);$$

this defines y because e' is a bijection onto Ω'. The columns $b_{e(x)}$ are distinct basis vectors of sign $+1$ that do not occur in the other columns; and by (6.116), with $\varepsilon_{e(k)} = (-1)^k$ and $\varepsilon'_* = 1$, the J'-product of the columns at $e'(a)$ and $e'(a')$ is $(-1)^{M-a}\delta_{aa'} = (-1)^a\delta_{aa'} = \varepsilon'_{e'(a)}\delta_{aa'}$. So $y^*J'y = J'$ and $y \in \mathrm{U}(\operatorname{diag}\varepsilon')$; in particular $\|y^{-1}\| = \|y\|$ (Lemma 5.6.30 (i)). Every entry of y has absolute value at most $(6B)^M$, so $\|y\|^2 \le \|y\|_{\mathrm{HS}}^2 \le (n+1)^2(6B)^{2M} \le (n+1)^4(6B)^{2M+2} \le \beta$.

The weights are conjugate. We show that the rows with index in Ω of $y\operatorname{diag}(\nu)\,y^{-1}$ are those of the $\Omega\times\Omega'$ matrix $(\operatorname{diag}(\mu) \mid v)$, for the column v at $*$ with $v_{e(x)} = 0$ and $v_{e(k)} = -\prod_{k'\le M}(\tau_{M+1+k}-\tau_{k'})/c_{M+1+k}$; equivalently, row $r \in \Omega$ of $y\operatorname{diag}(\nu)$ equals $\mu(r)$ times row r

of y plus v_r times row $*$ of y. In a column $e'(x)$ both sides vanish, as $\nu(e'(x))=0$, $\mu(e(x))=0$ and $y_{*,e'(x)}=0$. In a column $e'(a)$ and a row $e(x)$ both sides vanish. In a column $e'(a)$ and a row $e(k)$, where $\nu(e'(a))=\tau_{M-a}$ and $\mu(e(k))=\tau_{M+1+k}$, the difference of the two sides is, with $a'=M-a$,

$$(\tau_{a'}-\tau_{M+1+k})\rho_{ka'}-v_{e(k)}d_{a'}=0,$$

because $(\tau_{a'}-\tau)\pi_{a'}(\tau)=-d_{a'}\prod_{k'\le M}(\tau-\tau_{k'})$. Consequently, for every $\Omega\times\Omega$ matrix Z,

$$\operatorname{tr}\bigl(\operatorname{diag}(\nu)\,y^{-1}(Z\oplus 0)\,y\bigr)=\operatorname{tr}\bigl(y\operatorname{diag}(\nu)\,y^{-1}(Z\oplus 0)\bigr)=\operatorname{tr}\bigl(\operatorname{diag}(\mu)Z\bigr). \tag{6.117}$$

Laplace's method. Let dg be a Haar measure on $S=\mathrm{U}(\operatorname{diag}\varepsilon)$; it is right invariant (the group is unimodular) and finite on compact sets. Let $j=(j_1,j_2)$, $j_1(g)=g$, $j_2(g)=y^{-1}(g\oplus 1)y$, a homomorphism to $\mathrm{U}(\operatorname{diag}\varepsilon)\times\mathrm{U}(\operatorname{diag}\varepsilon')$ with j_1 proper and j_2 continuous, and $\varphi=0$. Note $j_2(g)-1=y^{-1}((g-1)\oplus 0)y$. We check that these data form a Laplace datum, that is (LA1)–(LA4) of Definition 5.7.2, for $\mathfrak{n}=\Omega$, $\mathfrak{m}=\Omega'$, the signs ε,ε', the vectors l and $k=l'$, the bijection e, the map $\tau=e'|_X$, and B,β,L,h.

(LA1) is hypothesis (1) for l.

(LA2) $\varphi=0$ is additive with real part 0; by (6.117), $\operatorname{tr}(\operatorname{diag}(\mu)(j_1(g)-1))-\operatorname{tr}(\operatorname{diag}(\nu)(j_2(g)-1))=0$; and $\operatorname{tr}(j_2(g)-1)=\operatorname{tr}((g-1)\oplus 0)=\operatorname{tr}(j_1(g)-1)$.

(LA3) $\varepsilon'_{e'(x)}=1$ and $\nu(e'(x))=0$; $\nu\ge 0$ on Ω', with values 0 or in $[B,3B]$, so $\nu\le 3B$ everywhere. For a unitary $X\times X$ matrix u let $g=1+\iota_e(u-1)\iota_e^*$; it is unitary and equals 1 off the block $e(X)\times e(X)$, where $J=1$, so $g\in\mathrm{U}(\operatorname{diag}\varepsilon)$. Since $yb_{e'(x)}=b_{e(x)}$ and the row of y at $e(x)$ is $b^{\mathsf T}_{e'(x)}$ (the other columns vanish at $e(x)$), $y^{-1}b_{e(x)}=b_{e'(x)}$ and $b^{\mathsf T}_{e(x')}y=b^{\mathsf T}_{e'(x')}$; hence $j_2(g)-1=\iota_\tau(u-1)\iota_\tau^*$ and $j_1(g)-1=\iota_e(u-1)\iota_e^*$.

(LA4) is hypotheses (2), (3), (4), with $\#\mathfrak{n}+\#\mathfrak{m}=2n+1$.

Theorem 5.7.21 gives that $g\mapsto c_{l/2}(g)\overline{c_{l'/2}(j_2(g))}$ is integrable and

$$\operatorname{vol}\{g:\|g\|\le\beta+1,\ \|j_2(g)\|\le\beta+1\}\le\beta^{20(2n+1)^2}\Bigl|\int_{\mathrm{U}(\operatorname{diag}\varepsilon)}c_{l/2}(g)\,\overline{c_{l'/2}(y^{-1}(g\oplus 1)y)}\,dg\Bigr|.$$

If $\|g-1\|\le 1$, then $\|g\|\le 2\le\beta+1$ and $\|j_2(g)-1\|\le\|y^{-1}\|\,\|g-1\|\,\|y\|\le\|y\|^2\le\beta$, so $\|j_2(g)\|\le\beta+1$. Hence the set on the left contains $\{g:\|g-1\|\le 1\}$, which proves the lemma. □

6.5 The norm of the chain of lifts

The proof of Theorem C compares $Z(\vartheta)=\det(\Theta_\vartheta^*\Theta_\vartheta)$ with $Z(1)$ along a regular family, and this section factors their ratio into pieces whose heights can be bounded one by one (Proposition 6.5.1). The Gram operator of the chain is, up to a scalar, the product of the Gram operators of the m single lifts, the j-th taken at ϑ^j, and each of these is a Rallis series; the scalar has modulus a fixed constant times a power of $\mathrm{N}Q$ times the product of the chain ratios $q_{ij}(\vartheta)$. Taking determinants on the target forms gives

$$\frac{Z(\vartheta)}{Z(1)}=\Bigl((\mathrm{N}Q)^{e/2}\prod_{1\le i<j\le m}q_{ij}(\vartheta)\Bigr)^{d_\mathcal{T}}\ \prod_{j=1}^{m}\frac{Z_j(\vartheta)}{Z_j(1)}.$$

The chain ratios have small height along a family with small ratios (Lemma 6.1.5), and the volumes of the single lifts are bounded one lift at a time in Section 6.6 (Theorem 6.6.6). The

injectivity of the chain, and so $Z(\vartheta) > 0$, comes out of the same computation. The organisation follows [259].

The tool throughout is the Rallis inner product formula [237, 238], the basis of the doubling method [231]; for theta lifts along Witt towers see [236]. In Weil's convergent range [323] it was proved by Li for cusp forms [187], and beyond that range it rests on the regularised Siegel–Weil formula [176, 139, 94, 331]. The pairs here are in the convergent range, but the forms are rapidly decreasing rather than cuspidal, so the form used is proved at the end of the section (Theorem 6.5.13).

Proposition 6.5.1. *There are $C > 0$, $e \in \mathbb{Z}$ and a function c from the m-fold twists to $\mathbb{C}$ such that for every m-fold twist ϑ with modulus Q:*

1. $|c(\vartheta)| = C\,(\mathrm{N}Q)^{e/2} \prod_{1\le i<j\le m} q_{ij}(\vartheta)$;
2. $\Theta_\vartheta^*\Theta_\vartheta = c(\vartheta)\, c_Q^m\, R^{\mathcal{T}}_{1,\vartheta} R^{\mathcal{T}}_{2,\vartheta^2} \cdots R^{\mathcal{T}}_{m,\vartheta^m}$ *on* $\mathcal{T}$;
3. Θ_ϑ *is injective,* $Z(\vartheta) > 0$, *and* $Z_j(\vartheta) > 0$ *for* $1 \le j \le m$;
4. *with the same* e,
$$\frac{Z(\vartheta)}{Z(1)} = \Big((\mathrm{N}Q)^{e/2} \prod_{1\le i<j\le m} q_{ij}(\vartheta)\Big)^d \prod_{j=1}^m \frac{Z_j(\vartheta)}{Z_j(1)}.$$

Proof. **Step 1: the operator identity.** By Lemma 6.5.2 there are c, $C_0 \in \mathbb{R}$ and $k \in \mathbb{Z}$ with $|c(\vartheta)|^2 = C_0(\mathrm{N}Q)^k f(\vartheta)^2$ and $\langle \Theta_\vartheta x, \Theta_\vartheta y\rangle = c(\vartheta) c_Q^m \langle x, R_\vartheta y\rangle$ for all $x, y \in \mathcal{T}$. By the definition of the adjoint, $\langle x, \Theta_\vartheta^*\Theta_\vartheta y\rangle = \langle x, c(\vartheta) c_Q^m R_\vartheta y\rangle$ for all x, which is (2) for this c.

Step 2: the modulus of c. At the trivial twist $Q = \emptyset$, $\mathrm{N}Q = 1$ and $f(1) = 1$, since $q_{ij}(1) = 1$ for all $i < j$ by Lemma 6.1.7(c). If $c(1) = 0$, then $\langle \Theta_1 y, \Theta_1 y\rangle = 0$, so $\Theta_1 y = 0$ and $y = 0$ by the injectivity in Lemma 6.5.2: $\mathcal{T} = 0$. Then both sides of (2) are 0 for every function c, and (1)–(4) hold with $C = 1$, $e = 0$, $c = f$ ((4) reads $1 = 1$, the empty determinants being 1). If $c(1) \neq 0$, then $C_0 = |c(1)|^2 > 0$, and as $f \ge 0$,
$$|c(\vartheta)| = |c(1)|\,(\mathrm{N}Q)^{k/2} f(\vartheta);$$
this is (1) with $C = |c(1)|$ and $e = k$.

Step 3: positivity. Θ_ϑ is injective by Lemma 6.5.2, so $Z(\vartheta) = \det(\Theta_\vartheta^*\Theta_\vartheta)$, the Gram determinant of the images of an orthonormal basis, is > 0. $Z_j(\vartheta) > 0$ by Proposition 6.5.9(1). This is (3).

Step 4: the factorisation. Taking determinants in (2) on the d-dimensional space $\mathcal{T}$ and using Proposition 6.5.9(3) for each j (the powers ϑ^j have the modulus Q, so the same c_Q),
$$Z(\vartheta) = \big(c(\vartheta)c_Q^m\big)^d \prod_{j=1}^m \det R^{\mathcal{T}}_{j,\vartheta^j} = \Big(\frac{c(\vartheta)}{A_1\cdots A_m}\Big)^d \prod_{j=1}^m (A_j c_Q)^d \det R^{\mathcal{T}}_{j,\vartheta^j} = \Big(\frac{c(\vartheta)}{A_1\cdots A_m}\Big)^d \prod_{j=1}^m Z_j(\vartheta).$$
$Z(\vartheta)$ and the $Z_j(\vartheta)$ are positive reals, so taking absolute values and (1),
$$Z(\vartheta) = \big(C'(\mathrm{N}Q)^{e/2} f(\vartheta)\big)^d \prod_{j=1}^m Z_j(\vartheta), \qquad C' = \frac{C}{|A_1\cdots A_m|} > 0.$$
At $\vartheta = 1$ this reads $Z(1) = C'^{\,d} \prod_j Z_j(1)$, by Step 2. Dividing gives (4). □

The factorisation is the Gram form of the chain (Lemma 6.5.2). It is not computed lift by lift. The lifts and descents form the twisted triangle of Definition 3.2.30, and the abstract triangle lemma (Lemma 6.4.59) reduces the Gram form of a weighted chain to the product of the Gram operators of the first arrows, given that the squares commute up to the chain ratios (Proposition 6.4.11) and that the first lift of each row is injective with a Rallis series as Gram form (Lemma 6.4.58). The ratio of group orders that the lemma produces cancels against the index of the last level (Lemma 6.5.8).

The single lift is the subject of Proposition 6.5.9: it is injective, its Gram operator is a nonzero constant independent of the twist times c_Q times a Rallis series, and the series preserves the good forms, so that $Z_j(\vartheta)$ is a determinant of a Rallis series on the target forms. The passage from the good forms on W_j to the target forms is the comparison of Section 5 (Proposition 5.8.55, Proposition 5.8.4). The block datum is sharp: its matrix coefficient is its norm on a principal congruence subgroup and 0 off it (Lemma 6.5.10). Sharpness turns the Rallis inner product formula (Theorem 6.5.13) into a series (Lemma 6.5.12); for cusp forms the formula is Li's theorem [187], and the form used here is proved with the Siegel–Weil formula of the convergent range [280, 323] (see [231, 190]). The Rallis series converges absolutely, preserves automorphy and level, and is injective on bounded forms (Proposition 6.5.4); its summability uses neighbour steps of lattices, as in Kneser's method of neighbours [166]. For injectivity of theta liftings in general see [237].

Lemma 6.5.2. *For an m-fold twist ϑ let $R_\vartheta = R^{\mathcal{T}}_{1,\vartheta} R^{\mathcal{T}}_{2,\vartheta^2} \cdots R^{\mathcal{T}}_{m,\vartheta^m}$. There is a function c from the m-fold twists to $\mathbb{C}$ with absolute value $\prod_{1\le i<j\le m} q_{ij}$ up to a norm power such that*

$$\langle \Theta_\vartheta x, \Theta_\vartheta y\rangle = c(\vartheta)\, c_Q^m \,\langle x, R_\vartheta y\rangle \qquad (x, y \in \mathcal{T})$$

for every m-fold twist ϑ with modulus Q. Moreover the chain of lifts is injective on the forms of level J_M on Y_0; in particular Θ_ϑ is injective.

Proof. Write $N_n(\vartheta) = \#\mathrm{GL}_{n_n}(R_\vartheta)$ and $X_\vartheta = \mathrm{Wc}^0_{\vartheta,\mathrm{I},m}$.

Step 0: the relation and the base forms. $\mathcal{M}(1,1)$ holds ($C=1$, $n=0$), $\mathcal{M}(c,g)$ and $\mathcal{M}(c',g')$ give $\mathcal{M}(cc', gg')$ (multiply the two identities), and $\mathcal{M}(c,1)$ holds for every $c(\vartheta) = C'(\mathrm{N}Q)^{k'}$ with $C' \in \mathbb{C}$, $k' \in \mathbb{Z}$ (take $C = |C'|^2$, $n = 2k'$). By (a) of Lemma 6.4.67, $\mathcal{A}_M(Y_0) \subseteq \mathcal{F}^0_\triangle(\mathrm{I}, 0)$; its forms are right invariant under K_M, the integral elements reducing to 1 at the chosen places, which in the coordinates of the point of Y_0 (the space with a point of (VP3) of Definition 3.2.2, in the basis of Y_0, given by its fixed frame) is the base level $\mathrm{K}^{\mathrm{bs}}_{\mathrm{I}}$ (the fixed frame of Y_0, (XF1) of Definition 3.2.15, is $L_0 g$ with g integral and $g \equiv 1$ at the chosen places, (HP5) of Definition 3.2.13, so integrality and the reductions at the chosen places are the same in both bases). Hence

$$\mathcal{T} \subseteq \mathcal{A}_M(Y_0) \subseteq \mathcal{F}^{\mathrm{bs}}_{\mathrm{I}}.$$

If $\mathcal{F}^{\mathrm{bs}}_{\mathrm{I}} = 0$, then $\mathcal{T} = 0$ and $\mathcal{A}_M(Y_0) = 0$, both claims hold with $c = 0$ (which has absolute value $\prod q_{ij}$ up to a norm power with $C = 0$), and nothing remains. Assume from now on $\mathcal{F}^{\mathrm{bs}}_{\mathrm{I}} \neq 0$.

Step 1: the abstract triangle. Fix left pairs $\Phi_{i,n}$ at the positions (i,n) with $i+n<m$ ((c) of Lemma 6.4.15) and take the data of Proposition 6.4.11 for $z = \mathrm{I}$: $\mathcal{H}_{i,n} = \mathcal{F}^i_\triangle(\mathrm{I}, n)$, $a^\vartheta_{i,n} = \mathrm{Tl}^i_{\vartheta,\mathrm{I},n}$, the descents $b^\vartheta_{i,n}$, $w_\vartheta(n) = N_n(\vartheta)$, $V_0 = \mathcal{F}^{\mathrm{bs}}_{\mathrm{I}}$ and the inclusions u_i. By (a) and (b) of Proposition 6.4.11, (Qu1)–(Qu3), (Qx1) and (Qx2) hold with $f_{r,k} = q_{rk}$. The weighted chain of row 0 of the abstract triangle is the weighted chain of (TV3): $X^\vartheta_{0,n} = \mathrm{Wc}^0_{\vartheta,\mathrm{I},n}$, both being defined by $X_{0,0} = \mathrm{id}$ and $X_{0,n+1} = N_n(\vartheta)\,\mathrm{Tl}^0_{\vartheta,\mathrm{I},n} \circ X_{0,n}$.

Step 2: (Qx3). Let $U_0 = \mathcal{T}$, $s\colon \mathcal{T} \to V_0$ the inclusion (Step 0) and $S_\vartheta(i) = R^{\mathcal{T}}_{i+1,\vartheta^{\,i+1}}$ for $i < m$, an endomorphism of $\mathcal{T}$ by (3) of Proposition 6.5.9. For $i < m$ the map $a^\vartheta_{i,0} \circ u_i$ is the

first lift a_ϑ of row i of Lemma 6.4.58, since $u_i x$ is x read on the adelic group of $V^i_{\mathrm{I},0}$, the copy of x (TV5). By (a) of Lemma 6.4.58 (with $z = \mathrm{I}$; its $y \in \mathcal{F}^{\mathrm{bs}}_{\mathrm{I}}$ is our $s(y)$, its x our $x \in V_0$) and Lemma 6.5.3,

$$w_\vartheta(0)\langle a^\vartheta_{i,0} u_i x,\ a^\vartheta_{i,0} u_i\, s(y)\rangle = \frac{A_{\mathrm{I},i}}{\#\mathrm{M}_{n_1\times n_0}(R_\vartheta)}\,\langle x,\ R_{\Sigma_\vartheta}\, y\rangle = C_i(\vartheta)\,\langle x,\ s(S_\vartheta(i)y)\rangle,$$

with $C_i(\vartheta) = A_{\mathrm{I},i}/\#\mathrm{M}_{n_1\times n_0}(R_\vartheta)$, the Petersson product being that of $V^0_{\mathrm{I},0} = Y_0$. As $\mathrm{N}Q$ is prime to M (Definition 3.1.2), the ideals $\pi_M\mathcal{O}_E$ and $\prod_{w\in Q} w$ are coprime, so $\#R_\vartheta = \#(\mathcal{O}_E/\pi_M\mathcal{O}_E)\cdot \mathrm{N}Q$ and $C_i(\vartheta) = A_{\mathrm{I},i}\,\#(\mathcal{O}_E/\pi_M\mathcal{O}_E)^{-r(r+t)}(\mathrm{N}Q)^{-r(r+t)}$; as $A_{\mathrm{I},i}$ does not depend on ϑ, $\mathcal{M}(C_i, 1)$ by Step 0. So (Qx3) holds.

Step 3: the Gram form of the weighted chain. By (2) of Lemma 6.4.59 for $i = 0$, $n = m$, there is κ_0 with $\mathcal{M}(\kappa_0, \prod_{0<r<k\le m} q_{rk})$ such that, since $S_\vartheta(0)\cdots S_\vartheta(m-1) = R^{\mathcal{T}}_{1,\vartheta}R^{\mathcal{T}}_{2,\vartheta^2}\cdots R^{\mathcal{T}}_{m,\vartheta^m} = R_\vartheta$,

$$\langle X_\vartheta x,\ X_\vartheta y\rangle_{Y_m} = \kappa_0(\vartheta)\,\frac{N_0(\vartheta)\,N_1(\vartheta)^m}{N_m(\vartheta)}\,\langle x, R_\vartheta y\rangle \qquad (x, y \in \mathcal{T}),$$

the product on the left being the Petersson product of $V^0_{\mathrm{I},m} = Y_m$.

Step 4: the chain. By Lemma 6.5.7 and Lemma 6.5.8, with $C > 0$, $k \in \mathbb{Z}$ independent of ϑ and $d = \dim W_{\lambda^\circ}$,

$$\begin{aligned}\langle \Theta_\vartheta x, \Theta_\vartheta y\rangle &= [\mathbf{K}_0 : \mathrm{K}_\vartheta]\, d\,\langle X_\vartheta x, X_\vartheta y\rangle_{Y_m}\\ &= C(\mathrm{N}Q)^k c_Q^m \frac{N_m(\vartheta)}{N_0(\vartheta)N_1(\vartheta)^m}\cdot d\cdot \kappa_0(\vartheta)\frac{N_0(\vartheta)N_1(\vartheta)^m}{N_m(\vartheta)}\langle x, R_\vartheta y\rangle.\end{aligned}$$

The group orders cancel (they are positive integers). Put $c(\vartheta) = C\,d\,(\mathrm{N}Q)^k\kappa_0(\vartheta)$. Then

$$\langle \Theta_\vartheta x, \Theta_\vartheta y\rangle = c(\vartheta)\, c_Q^m\,\langle x, R_\vartheta y\rangle,$$

and $\mathcal{M}(c, \prod_{1\le i<j\le m} q_{ij})$ by Step 0 (multiplicativity, with $\mathcal{M}(Cd(\mathrm{N}Q)^k, 1)$).

Step 5: injectivity. By (1) of Lemma 6.4.59 (for $i = 0$, $n = m$), X_ϑ is injective on $V_0 \supseteq \mathcal{A}_M(Y_0)$. Let $y \in \mathcal{A}_M(Y_0)$ with $\Theta_\vartheta y = 0$, Θ_ϑ the chain on all of $\mathcal{A}_M(Y_0)$. By (b) of Lemma 6.4.67, $X_\vartheta y = F^{p_{\mathrm{I},0,m}}_{\Theta_\vartheta y} = F^{p_{\mathrm{I},0,m}}_0 = 0$, as F^l_η is linear in η; so $y = 0$. Hence the chain is injective on the forms of level $\mathrm{K}_M = J_M$, and in particular on $\mathcal{T}$. □

Lemma 6.5.3. *Let D be admissible data, $0 \le i < m$ and ϑ an m-fold twist, and let R_{Σ_ϑ} be the Rallis series of Lemma 6.4.58 for $z = \mathrm{I}$ and the row i. Then $R_{\Sigma_\vartheta} y = R^{\mathcal{T}}_{i+1,\vartheta^{i+1}}\, y$ for every $y \in \mathcal{T}$.*

Proof. Write $j = i+1$, $\vartheta' = \vartheta^j$ and $O = O_{j,\vartheta'}$; ϑ' has the modulus Q of ϑ (Definition 3.1.2).

Step 1: the data of the two series agree. The series R_{Σ_ϑ} is formed for $(S, T, \beta, \Sigma) = (V^i_{\mathrm{I},0}, V^i_{\mathrm{I},1}, b_\vartheta, \Sigma_\vartheta)$ and $R^{\mathcal{T}}_{j,\vartheta'}$ for $(W_j, \mathrm{I}_{r+t}, \chi'_O, \Sigma)$. (a) Ranks: S and W_j have rank r, and T and I_{r+t} have rank $N_1 = r+t$, since n_1 is n_0 with one down block of length t (GP5). (b) Characters: b_ϑ is the edge character with $c = \mathrm{II}$, $l = i$ at the rank N_1, that is $\mu^0_{i+1}\vartheta^{i+1}\upsilon^{\lfloor (r+t)/2\rfloor}$ (GP6), and $\chi'_O = \mu^0_j\vartheta'\upsilon^{\lfloor (r+t)/2\rfloor}$; they are equal. (c) Places: the places dividing $\mathfrak{t}_\vartheta(\mathrm{I}) = \pi_M\prod_{w\in Q} w$ are the chosen places and the places of Q, which are the places $M_O \cup Q_O$ of the level system of O (LF4); so $\Sigma_\vartheta = \Sigma$. (d) Groups and representatives: through the points of the spaces, $\mathrm{U}(S)(\mathbb{A}_F)$, $\mathrm{U}(W_j)(\mathbb{A}_F)$ and $\mathrm{U}(Y_0)(\mathbb{A}_F)$ are written as groups $\mathrm{G}(\cdot) = G_\infty(\cdot)\times G_f(r)$ with the same finite part $G_f(r)$ ((VP1), (VP2) of Definition 3.2.2; S and Y_0 have the same adelic group of matrices

by (TV1)), and the groups K_Σ of Proposition 6.5.4 are formed in $G_f(r)$ from the components K_v of $\mathbf{K}_0(r)$ (Lemma 6.5.6). So the cosets q and their fixed representatives u_q, which have components 1 off Σ, are the same for both series, and both act on functions y on $\mathrm{U}(Y_0)(\mathbb{A}_F)$ by $y \mapsto \sum_q \mathrm{mc}(u_q)\, y(\cdot\, u_q)$, with the vacuum coefficient of the respective pair.

Step 2: the vacuum coefficient depends only on the ranks, the character and Σ. Let (S,T) be spaces with points with signs s on n and s' on n', β a character and $\gamma \in G_f(n)$ with components 1 off the places above Σ. By (WR4) with $\alpha = 1$ and $g = (1,\gamma)$, $h = 1$,

$$\mathrm{mc}_{\beta,\Sigma}(\gamma) = \beta(\det\gamma)^{-1}\langle v^0,\ \omega_\varepsilon(k_\gamma)\, v^0\rangle, \qquad k_\gamma = 1_{n'} \otimes (\gamma^{-1})^{\mathsf{T}},$$

with $\varepsilon = s' \otimes s$ on $\iota = n' \times n$ and $k_\gamma \in \mathrm{G}(\varepsilon)$ the finite element $X \mapsto X\gamma^{-1}$ (infinite components 1). By (WR3) and (WD7), with $N = \#\iota$,

$$\langle v^0, \omega_\varepsilon(k) v^0\rangle = \Delta_\varepsilon(k) \iint \overline{e_N(x)}\, e_N(y)\, \beta_\varepsilon(ky,x)\, e_N(x-ky)\, d\mu_N(y)\, d\mu_N(x) \qquad (k = k_\gamma).$$

Here $\Delta_\varepsilon(k) = v(\det u)|\det u|^{-1/2}$ does not depend on ε, since $k_v = 1$ at the infinite places. In the integrand ε enters only through the infinite part of $\beta_\varepsilon(ky,x) = \psi_E(\frac{\jmath}{2}\bar{x}^{\mathsf{T}} S\, ky)$ (S is 1 at the finite places, (WD6)), which, as $(ky)_\infty = y_\infty$, is $\prod_{v\in\Phi,\, a\in\iota} \exp(-2\pi i \,\mathrm{Re}(\jmath_v \varepsilon_a \bar{x}_{a,v} y_{a,v}))$ by (WD4). Substitute $x_{a,v} \mapsto \bar{x}_{a,v}$, $y_{a,v} \mapsto \bar{y}_{a,v}$ in the infinite coordinates (a,v) with $\varepsilon_a = -1$. This preserves μ_N (Lebesgue measure on these coordinates, scaled by the real κ_v, (WD6)), e_N and $e_N(x-ky)$ (they depend on the infinite coordinates through $|x_{a,v}|^2$, $|x_{a,v}-y_{a,v}|^2$, (WD5)), and the finite coordinates, on which k acts; and it replaces $\mathrm{Re}(\jmath_v\varepsilon_a\bar{x}_{a,v}y_{a,v})$ by $\mathrm{Re}(\jmath_v\varepsilon_a x_{a,v}\bar{y}_{a,v}) = \mathrm{Re}(\bar{\jmath}_v\varepsilon_a\bar{x}_{a,v}y_{a,v}) = \mathrm{Re}(\jmath_v\cdot(-\varepsilon_a)\bar{x}_{a,v}y_{a,v})$, as $\bar{\jmath} = -\jmath$ (WD1). So the integral for ε equals the integral for the constant sign $+1$ on ι. The integrand is integrable (a Gaussian in the infinite coordinates times a bounded function of compact support in the finite ones), so the substitution is legitimate. Finally a bijection $\iota \to \iota'$ of index sets with the constant sign transports e_N, μ_N, β_{+1} and k_γ to the same objects for ι'. Hence $\mathrm{mc}_{\beta,\Sigma}(\gamma)$ depends only on $\#n$, $\#n'$, β and γ.

Step 3: conclusion. By Step 1 (a)–(c) and Step 2, $\mathrm{mc}_{b_\vartheta,\Sigma_\vartheta}(u_q)$ for the pair $(V^i_{\mathrm{I},0}, V^i_{\mathrm{I},1})$ equals $\mathrm{mc}_{\chi'_O,\Sigma}(u_q)$ for the pair (W_j, I_{r+t}), for every representative u_q. With Step 1 (d) the two series agree term by term on every function y on $\mathrm{U}(Y_0)(\mathbb{A}_F)$; by (1) of Proposition 6.5.4 (applicable as $2r < r+t$) both converge absolutely for bounded y, in particular for $y \in \mathcal{T}$, and so $R_{\Sigma_\vartheta} y = R^{\mathcal{T}}_{i+1,\vartheta^{\,i+1}} y$. □

Proposition 6.5.4. *Let S, T be spaces with $2\,\mathrm{rk}\,S < \mathrm{rk}\,T$, β an automorphic character of $\mathrm{U}(1)$ and Σ a set of finite places of F. Let K_Σ be the group of $g \in \mathrm{U}(S)(\mathbb{A}_{F,f})$ with $g_v \in K_v$ for $v \in \Sigma$, and K'_Σ the group of $k \in \prod_v K_v$ with $k_v = 1$ for $v \notin \Sigma$. For each coset $q \in \mathrm{U}(S)(\mathbb{A}_{F,f})/K_\Sigma$ fix a representative u_q with $(u_q)_v = 1$ for $v \notin \Sigma$. For a function y on $\mathrm{U}(S)(\mathbb{A}_F)$ the **Rallis series** is*

$$(R_\Sigma y)(g) = \sum_q \mathrm{mc}_{\beta,\Sigma}(u_q)\, y(g u_q) \qquad (g \in \mathrm{U}(S)(\mathbb{A}_F)).$$

Then:

1. *$\sum_q |\mathrm{mc}_{\beta,\Sigma}(u_q)| < \infty$. Hence for y bounded and measurable the series converges absolutely and uniformly, $\sup|R_\Sigma y| \le (\sum_q |\mathrm{mc}_{\beta,\Sigma}(u_q)|)\sup|y|$, and for y moreover left invariant under $\mathrm{U}(S)(F)$, y' integrable on $[\mathrm{U}(S)]$ and $x \in \mathrm{U}(S)(\mathbb{A}_F)$,*

$$\sum_q \mathrm{mc}_{\beta,\Sigma}(u_q)\, \langle y',\, y(\cdot\, x\, u_q)\rangle_S = \langle y',\, (R_\Sigma y)(\cdot\, x)\rangle_S,$$

the series converging absolutely.

2. *Suppose* $\beta(\det k) = 1$ *for all* $k \in K'_\Sigma$. *Let* y *be bounded, continuous, left invariant under* $\mathrm{U}(S)(F)$, *right invariant under* K'_Σ *and under some open subgroup of* $\mathrm{U}(S)(\mathbb{A}_{F,f})$. *Then* $R_\Sigma y$ *has the same four properties;* R_Σ *commutes with right translation by* $\mathrm{U}(S)(F \otimes \mathbb{R})$ *and with convolution on the right by integrable functions on* $\mathrm{U}(S)(F \otimes \mathbb{R})$; *and if* y *is right invariant under a subgroup* J *with* $K'_\Sigma \le J \le K_\Sigma$, *so is* $R_\Sigma y$.

3. *Under the hypothesis on* β *of (2), a bounded function* y, *right invariant under* K'_Σ, *with* $R_\Sigma y = 0$ *is* 0.

Proof. **Step 1: the coefficients.** $\langle v^0, v^0\rangle = 1$: For $\gamma \in G_f(n)$ supported on a set A of finite places, by the definition in Lemma 6.5.6

$$\mathrm{mc}_{\beta,A}(\gamma) = \mathrm{mc}(\gamma) := \langle v^0, \omega((1,\gamma),1)v^0\rangle,$$

which does not depend on A. By (5) of Lemma 6.2.33 (with $A = \emptyset$), v^0 is a vacuum above every set of places. Three properties:

(i) $|\mathrm{mc}(\gamma)| = I(\gamma)^{-m/2}$. By (WR4),

$$\omega((1,\gamma),1) = \beta(\det\gamma)^{-1}\omega_{s'\otimes s}(g') \quad \text{with} \quad g' = 1 \otimes (\gamma^{-1})^{\mathsf{T}},$$

the map $X \mapsto X\gamma^{-1}$ of $m\times n$ matrices, whose infinite components are 1. By Lemma 6.2.13(1),(2) applied to g'^{-1}, and the inner-product preservation and inverse law of Lemma 4.1.1(2), the coefficients of $\omega_{s'\otimes s}(g')$ and $\omega_{s'\otimes s}(g'^{-1})$ against v^0 are complex conjugates. Hence $|\mathrm{mc}(\gamma)| = |\Delta_{s'\otimes s}(g'^{-1})|^{-1}$, and by (WR3)

$$|\Delta_{s'\otimes s}(g'^{-1})| = |\det u|^{-1/2} = [\widehat{\mathcal{O}}_E^{mn} : \widehat{\mathcal{O}}_E^{mn} \cap g'\widehat{\mathcal{O}}_E^{mn}]^{1/2}$$

(the other factors have modulus 1, and $|\det u| = [\widehat{\mathcal{O}}_E^{mn} : u\widehat{\mathcal{O}}_E^{mn}]^{-1}$). As g' acts on each of the m rows by $x^{\mathsf{T}} \mapsto (\gamma^{-1})^{\mathsf{T}}x^{\mathsf{T}}$ and $(\gamma^{-1})^{\mathsf{T}} = \bar\gamma$ ($\gamma^*\gamma = 1$), this index is $[L : L \cap \bar\gamma L]^m = I(\gamma)^m$, complex conjugation preserving $\widehat{\mathcal{O}}_E$.

(ii) If γ is supported on A_1 and γ' on A_2, $A_1 \cap A_2 = \emptyset$, then $\mathrm{mc}(\gamma\gamma') = \mathrm{mc}(\gamma)\mathrm{mc}(\gamma')$: Lemma 6.5.6 with $\Sigma = A_1$, $\varphi = v^0$ and $g = (1,\gamma')$ (whose components above A_1 are $1 \in K_v$).

(iii) If $\beta(\det k) = 1$ for $k \in K'_\Sigma$, then $\mathrm{mc}(k\gamma k') = \mathrm{mc}(\gamma)$ for $k, k' \in K'_\Sigma$: by (4) of Lemma 6.2.33 (with $A = \emptyset$), $v^0 = v_1 \otimes v^0$, so by (6) of Lemma 4.1.1 $\omega((1,k),1)v^0 = \beta(\det k)^{-1}v^0 = v^0$, and ω is unitary by (2) there.

Step 2: one place. Let v be a finite place of F and $s_v = \#\mathrm{St}_v \cdot \mathrm{N}w^{-m/2}$. By Lemma 6.5.5(c) and $m \ge 2n+1$: if v splits, $s_v \le 2\frac{\mathrm{N}w}{\mathrm{N}w-1}\mathrm{N}w^{n-1}\mathrm{N}w^{-n-1/2} \le 3\,\mathrm{N}v^{-3/2}$; if v is inert, $s_v \le \mathrm{N}v\frac{\mathrm{N}w}{\mathrm{N}w-1}\mathrm{N}w^{n-1}\mathrm{N}w^{-n-1/2} \le 2\,\mathrm{N}v^{-2}$. As $\mathrm{N}w \ge 316$, $s_v \le 1/50$ in both cases. Since at most $[F:\mathbb{Q}]$ places lie above a prime p, each with $\mathrm{N}v \ge p$, $\sum_v s_v \le 3[F:\mathbb{Q}]\sum_p p^{-3/2} < \infty$. By Lemma 6.5.5(b), I is constant on the cosets $c \in G_v/K_v$ (here $K_v = G_v \cap \mathbf{K}_0(n)$), $I(c) = 1$ only for the trivial coset c_0, and $\rho \in \mathrm{St}_v$ acts on G_v/K_v by left multiplication, injectively. Put $S_v = \sum_{c\in G_v/K_v} I(c)^{-m/2}$ and $S_v(N) = \sum_{I(c)\le N} I(c)^{-m/2}$ (sums of nonnegative terms). For $c \ne c_0$ choose $\rho_c \in \mathrm{St}_v$ with $\mathrm{N}w\, I(\rho_c c) \le I(c)$; then $I(c)^{-m/2} \le \mathrm{N}w^{-m/2}I(\rho_c c)^{-m/2}$, $I(\rho_c c) < I(c)$, and $c \mapsto (\rho_c, \rho_c c)$ is injective. Hence

$$S_v(N) \le 1 + \mathrm{N}w^{-m/2}\sum_{\rho\in\mathrm{St}_v}\sum_{I(c')\le N-1} I(c')^{-m/2} = 1 + s_v S_v(N-1),$$

and by induction on N (with $S_v(0) = 0$), $S_v(N) \le (1 - s_v)^{-1}$. So $S_v \le (1 - s_v)^{-1}$ and $S_v - 1 \le s_v/(1 - s_v) \le 2s_v$.

Step 3: (1). Let $A \subseteq \Sigma$ and K_A be defined as K_Σ. The map $gK_A \mapsto (g_v K_v)_{v\in A}$ is a bijection from $G_f(n)/K_A$ onto the families $(c_v)_{v\in A}$, $c_v \in G_v/K_v$, with $c_v = c_0$ for almost all v ($G_f(n)$ is the restricted product of the G_v with respect to the K_v). For a representative u_q supported on A, $I(u_q) = \prod_v I(c_v)$ by Lemma 6.5.5(b), so by Step 1 (i), with finite partial products and monotone limits,

$$\sum_q |\mathrm{mc}(u_q)| = \prod_{v\in A} S_v \le \exp\Big(2\sum_{v\in A} s_v\Big) < \infty, \qquad \sum_{q\neq q_0} |\mathrm{mc}(u_q)| \le \exp\Big(2\sum_{v\in A} s_v\Big) - 1, \qquad (*)$$

q_0 the trivial coset. For $A = \Sigma$ this is the summability in (1). For y bounded and measurable, $|\mathrm{mc}(u_q)y(gu_q)| \le |\mathrm{mc}(u_q)| \sup|y|$, so the series converges absolutely and uniformly (Weierstrass), with the stated bound. If moreover y is left invariant under $\mathrm{U}(S)(F)$ and y' is integrable on $[\mathrm{U}(S)]$, each $g \mapsto y(gxu_q)$ is bounded, measurable and left invariant, and $\sum_q \int_{[\mathrm{U}(S)]} |y'(g)|\,|\mathrm{mc}(u_q)|\,|y(gxu_q)|\,dg \le \sup|y| \sum_q |\mathrm{mc}(u_q)| \int |y'| < \infty$; Fubini gives the identity of (1).

Step 4: (2). Assume $\beta(\det k) = 1$ for $k \in K'_\Sigma$, and let y be bounded and right invariant under K'_Σ. *Independence of the representatives:* two representatives of q supported on Σ differ by $k \in K_\Sigma$ supported on Σ, i.e. $k \in K'_\Sigma$, and both mc (Step 1 (iii)) and $y(g\,\cdot)$ are unchanged; the same holds for every $A \subseteq \Sigma$. *Right invariance under K'_Σ:* for $k \in K'_\Sigma$, $q \mapsto kq$ permutes $G_f(n)/K_\Sigma$ and ku_q is a representative of kq supported on Σ, so $(R_\Sigma y)(gk) = \sum_q \mathrm{mc}(ku_q)y(gku_q) = (R_\Sigma y)(g)$ by Step 1 (iii) and the independence. *A level:* if y is right invariant under an open subgroup U, it contains a product $\prod_v U_v$ of open subgroups with $U_v = K_v$ for almost all v; let $U' = \prod_{v\in\Sigma} K_v \times \prod_{v\notin\Sigma} U_v$, open. For $k \in U'$ write $k = k_\Sigma k^\Sigma$ (components above Σ, resp. off Σ); $k^\Sigma \in U$ commutes with every u_q, so $(R_\Sigma y)(gk) = \sum_q \mathrm{mc}(u_q)y(gk_\Sigma u_q k^\Sigma) = (R_\Sigma y)(gk_\Sigma) = (R_\Sigma y)(g)$, as $k_\Sigma \in K'_\Sigma$. *A level J with $K'_\Sigma \le J \le K_\Sigma$:* for $j \in J$, $j_\Sigma \in K'_\Sigma \le J$, so $j^\Sigma = j_\Sigma^{-1} j \in J$, and the same computation applies. *The other properties:* each term is continuous and left invariant under $\mathrm{U}(S)(F)$ when y is, and the convergence is uniform, so $R_\Sigma y$ is bounded, continuous and left invariant. Right translation by $(x, 1)$, $x \in \mathrm{U}(S)(F \otimes \mathbb{R})$, commutes with every $(1, u_q)$, hence with R_Σ; for integrable k on $\mathrm{U}(S)(F\otimes\mathbb{R})$, $\int k(x) \sum_q \mathrm{mc}(u_q)y(g(x,1)u_q)\,dx = \sum_q \mathrm{mc}(u_q) \int k(x)y(gu_q(x,1))\,dx$ by Fubini, the double series–integral of absolute values being at most $\sup|y| \sum_q |\mathrm{mc}(u_q)| \int |k|$.

Step 5: (3). Let $\mathcal{B}$ be the Banach space of bounded functions on $\mathrm{U}(S)(\mathbb{A}_F)$ right invariant under K'_Σ, with the supremum norm. For $A \subseteq \Sigma$, R_A maps $\mathcal{B}$ to $\mathcal{B}$: it is right invariant under K'_A by Step 4 (the hypothesis on β holds on $K'_A \subseteq K'_\Sigma$), and under $K'_{\Sigma\setminus A}$, whose elements commute with the u_q supported on A; and $K'_\Sigma = K'_A K'_{\Sigma\setminus A}$. The trivial coset may be represented by 1, with $\mathrm{mc}(1) = 1$, so $R_A = \mathrm{id} + N_A$ with $\|N_A\| \le \sum_{q\neq q_0} |\mathrm{mc}(u_q)|$. *Multiplicativity:* if $A = A_1 \sqcup A_2 \subseteq \Sigma$, then $u_{q_1}u_{q_2}$ (q_i cosets of K_{A_i}) runs once through a system of representatives of $G_f(n)/K_A$ supported on A (Step 3), $\mathrm{mc}(u_{q_1}u_{q_2}) = \mathrm{mc}(u_{q_1})\mathrm{mc}(u_{q_2})$ by Step 1 (ii), and by absolute convergence and the independence of representatives, $R_{A_1}(R_{A_2}y) = R_A y$ for $y \in \mathcal{B}$. *Conclusion:* choose a finite $T \subseteq \Sigma$ with $\sum_{v\in\Sigma\setminus T} s_v \le 1/10$ (Step 2). By $(*)$, $\|N_{\Sigma\setminus T}\| \le e^{1/5} - 1 < 1/4$, and for $v \in T$, $\|N_{\{v\}}\| \le S_v - 1 \le 2s_v \le 1/25$. An operator $\mathrm{id} + N$ with $\|N\| < 1$ is injective, since $\|y + Ny\| \ge (1 - \|N\|)\|y\|$. By multiplicativity, $R_\Sigma = R_{\{v_1\}} \circ \cdots \circ R_{\{v_k\}} \circ R_{\Sigma\setminus T}$ for $T = \{v_1, \ldots, v_k\}$, a composition of injective operators of $\mathcal{B}$; so $R_\Sigma y = 0$ implies $y = 0$. □

Lemma 6.5.5. *Let $n \ge 1$, $L = \widehat{\mathcal{O}}_E^n$, and for $\gamma \in G_f(n)$ put $I(\gamma) = [L : L \cap \gamma L]$. For a finite place v of F let G_v be the group of $\gamma \in G_f(n)$ whose components at the finite places of E not above v are 1. Then:*

(a) every finite place of F is unramified in E, and $\mathrm{N}w \geq 316$ for every finite place w of E;

(b) $I(\gamma)$ is a positive integer, $I(\gamma) = 1$ if and only if $\gamma \in \mathbf{K}_0(n)$, $I(\kappa\gamma\kappa') = I(\gamma)$ for $\kappa, \kappa' \in \mathbf{K}_0(n)$, and $I(\gamma\gamma') = I(\gamma)I(\gamma')$ whenever at every finite place of E one of γ, γ' has component 1;

(c) for every finite place v of F there is a finite set $\mathrm{St}_v \subseteq G_v$ such that for every $\gamma \in G_v \setminus \mathbf{K}_0(n)$ some $\rho \in \mathrm{St}_v$ satisfies $\mathrm{N}w \cdot I(\rho\gamma) \leq I(\gamma)$ (w a place above v), and

$$\#\mathrm{St}_v \leq 2\,\frac{\mathrm{N}w^n - 1}{\mathrm{N}w - 1} \quad \text{if } v \text{ splits in } E,$$
$$\#\mathrm{St}_v \leq \mathrm{N}v\,\frac{\mathrm{N}w^n - 1}{\mathrm{N}w - 1} \quad \text{if } v \text{ is inert in } E \text{ (then } \mathrm{N}w = \mathrm{N}v^2\text{).}$$

Proof. **Step 1: (a).** The primitive 5040-th root of unity ζ gives $i = \zeta^{1260}$ and $\zeta_3 = \zeta^{1680}$ in E; as F is totally real, $i, \sqrt{-3} \notin F$, so $E = F(i) = F(\sqrt{-3})$. The extension $F(i)/F$ is unramified at the finite places not above 2, and $F(\sqrt{-3})/F$ at those not above 3 (the discriminants of X^2+1 and X^2+X+1 are -4 and -3), so E/F is unramified at every finite place. If w has residue characteristic p, the group $\mu_{N'}$ of N'-th roots of unity, N' the prime-to-p part of $5040 = 2^4 \cdot 3^2 \cdot 5 \cdot 7$, injects into $k_w^\times$ ($X^{N'} - 1$ is separable mod p), so $\mathrm{N}w - 1 \geq N' \geq 315$.

Step 2: (b). $L \cap \gamma L$ is a lattice, so the index is a positive integer, and $I(\gamma) = \prod_w [L_w : L_w \cap \gamma_w L_w]$. If $\kappa, \kappa' \in \mathbf{K}_0(n)$ then $\kappa' L = L$ and $\kappa L = L$, so $L \cap \kappa\gamma\kappa' L = \kappa(L \cap \gamma L)$ and $I(\kappa\gamma\kappa') = I(\gamma)$. The product rule follows from the product formula over the places. If $\gamma \in \mathbf{K}_0(n)$ then $I(\gamma) = 1$. Conversely, if $I(\gamma) = 1$ then $L \subseteq \gamma L$, i.e. $\gamma^{-1} = \bar\gamma^{\mathsf T}$ has integral entries; complex conjugation preserves $\widehat{\mathcal{O}}_E$, so γ has integral entries, $\gamma L \subseteq L$, hence $\gamma L = L$ and $\gamma \in \mathbf{K}_0(n)$.

Step 3: v split, $v = w\bar w$. Here G_v is identified with $\mathrm{GL}_n(E_w)$ by $\gamma \mapsto \gamma_w$: given $a \in \mathrm{GL}_n(E_w)$, the element with components a at w, $\overline{(a^{-1})^{\mathsf T}}$ at $\bar w$ and 1 elsewhere lies in G_v, and every element of G_v is of this form. For a lattice $M \subset E_w^n$ let $M^\vee = \{y : y^{\mathsf T} x \in \mathcal{O}\ \forall x \in M\}$; then $L_w^\vee = L_w$, $(aL_w)^\vee = (a^{-1})^{\mathsf T} L_w$, $M^{\vee\vee} = M$, $(M \cap M')^\vee = M^\vee + M'^\vee$, and $[M : M'] = [M'^\vee : M^\vee]$ for $M' \subseteq M$. For $\gamma \in G_v$ and $M = \gamma_w L_w$, the conjugate of $\gamma_{\bar w} L_{\bar w}$ is $(\gamma_w^{-1})^{\mathsf T} L_w = M^\vee$, and

$$[L_w : L_w \cap M^\vee] = [L_w + M : L_w] = [M : L_w \cap M], \qquad \text{so} \qquad I(\gamma) = [L_w : L_w \cap M]\,[M : L_w \cap M],$$

and symmetrically $I(\gamma) = [L_{\bar w} : L_{\bar w} \cap M']\,[M' : L_{\bar w} \cap M']$ for $M' = \gamma_{\bar w} L_{\bar w}$. *The steps.* For each line $\ell \subset L_w/\varpi L_w = k_w^n$ (ϖ a uniformiser of E_w) let $L_\ell = L_w + \varpi^{-1}\mathcal{O}\tilde\ell$, $\tilde\ell \in L_w$ a lift of a generator (independent of the lift), choose $a_\ell \in \mathrm{GL}_n(E_w)$ with $a_\ell L_\ell = L_w$, and let $\rho_\ell \in G_v$ have component a_ℓ at w; define ρ'_ℓ in the same way at $\bar w$. St_v is the set of these $2(\mathrm{N}w^n - 1)/(\mathrm{N}w - 1)$ elements. *The step lowers I.* Let $\gamma \in G_v \setminus \mathbf{K}_0(n)$ and $M = \gamma_w L_w$; then $M \neq L_w$ (otherwise γ_w and $\gamma_{\bar w} = \overline{(\gamma_w^{-1})^{\mathsf T}}$ are integral). Suppose first $M \not\subseteq L_w$. Take $y \in M \setminus L_w$ and the least $k \geq 1$ with $\varpi^k y \in L_w$; then $x = \varpi^{k-1} y \in M \setminus L_w$ and $\varpi x \in L_w \setminus \varpi L_w$. Let ℓ be the line of ϖx; then $L_\ell = L_w + \mathcal{O}x$ and $[L_\ell : L_w] = \mathrm{N}w$. Put $D = L_\ell \cap M \supseteq (L_w \cap M) + \mathcal{O}x$; as $x \notin L_w$ and $\varpi x \in L_w \cap M$, $[D : L_w \cap M] \geq \mathrm{N}w$. Applying a_ℓ^{-1}, which preserves indices,

$$I(\rho_\ell\gamma) = [L_\ell : D]\,[M : D] = \frac{[L_\ell : L_w][L_w : L_w \cap M]}{[D : L_w \cap M]} \cdot \frac{[M : L_w \cap M]}{[D : L_w \cap M]} \leq \frac{I(\gamma)}{\mathrm{N}w}.$$

If $M \subseteq L_w$, then $M \subsetneq L_w$, so $M^\vee \supsetneq L_w$ and $M' = \overline{M^\vee} \not\subseteq L_{\bar w}$; the same argument at $\bar w$, with the symmetric formula for I, gives ℓ with $I(\rho'_\ell\gamma) \leq I(\gamma)/\mathrm{N}w$.

Step 4: v inert, w the place above v. E_w/F_v is an unramified quadratic extension, $\mathrm{N}w = \mathrm{N}v^2$; fix a uniformiser $\varpi \in F_v$ (also one of E_w). Let $h(x,y) = y^* x$ on E_w^n and $M^\# =$

$\{y : h(x,y) \in \mathcal{O}\ \forall x \in M\}$; $L_w^{\#} = L_w$, $M^{\#\#} = M$, $(M \cap M')^{\#} = M^{\#} + M'^{\#}$ and $[M : M'] = [M'^{\#} : M^{\#}]$. G_v is the unitary group of h (component at w). For $\gamma \in G_v$, $M = \gamma L_w$ satisfies $M^{\#} = M$, and $I(\gamma) = [L_w : L_w \cap M]$. Call a lattice L_1 a *neighbour* if $L_1^{\#} = L_1$ and $[L_w : L_w \cap L_1] = \mathrm{N}w$. *Neighbours are moved to* L_w. Let $L_1^{\#} = L_1$. The form $h \bmod \varpi$ on $L_1/\varpi L_1$ is a nondegenerate hermitian form over k_w. A nondegenerate hermitian form $\bar{h}$ over k_w has an anisotropic vector: otherwise polarisation gives $\bar{h}(a,b) + \bar{h}(b,a) = 0$, and with ca in place of a, $(c - \bar{c})\bar{h}(a,b) = 0$ for all $c \in k_w$, so $\bar{h} = 0$. Lift it to $e \in L_1$; $h(e,e) \in \mathcal{O}_{F_v}^{\times}$, and as E_w/F_v is unramified the norm $\mathcal{O}^{\times} \to \mathcal{O}_{F_v}^{\times}$ is surjective, so some $c \in \mathcal{O}^{\times}$ gives $h(ce,ce) = 1$. Then $L_1 = \mathcal{O}ce \oplus \{z \in L_1 : h(z,ce) = 0\}$ (write $z = h(z,ce)ce + (z - h(z,ce)ce)$), the second summand is again self-dual in the orthogonal complement, and by induction L_1 has an h-orthonormal basis $f_1, \dots, f_n$. The matrix ρ with $\rho f_i = e_i$ (the standard basis) preserves h, so $\rho \in G_v$ and $\rho L_1 = L_w$. For every neighbour $L_1 \neq L_w$ fix such ρ_{L_1}; St_v is the set of these. *Counting.* Let $L_1 \neq L_w$ be a neighbour and $L_0 = L_w \cap L_1$. L_w/L_0 has order $\mathrm{N}w$, so it is $\cong k_w$ and $\varpi L_w \subseteq L_0$: L_0 corresponds to a hyperplane of k_w^n, at most $(\mathrm{N}w^n - 1)/(\mathrm{N}w - 1)$ choices. Given L_0: $L_0^{\#} = L_w + L_1$, $[L_0^{\#} : L_w] = [L_w : L_0] = \mathrm{N}w$, so $V = L_0^{\#}/L_0$ has order $\mathrm{N}w^2$; $\varpi L_1 \subseteq L_0$ ($[L_1 : L_0] = [L_w : L_0]$, as L_1, L_w are self-dual), so ϖ kills V and V is a k_w-plane. As $L_0^{\#} \subseteq \varpi^{-1} L_0$, $h(L_0^{\#}, L_0^{\#}) \subseteq \varpi^{-1}\mathcal{O}$, and $\bar{h}(a,b) = \varpi h(a,b) \bmod \varpi$ is a well-defined hermitian form on V; it is nondegenerate, since $h(a, L_0^{\#}) \subseteq \mathcal{O}$ forces $a \in L_0^{\#\#} = L_0$. The self-dual lattices L' with $L_0 \subset L' \subset L_0^{\#}$ and $[L' : L_0] = \mathrm{N}w$ give isotropic lines L'/L_0 of V, distinct lattices giving distinct lines. In a basis e, f of V with $\bar{h}(e,f) = 0$ (an anisotropic e and its orthogonal), $\bar{h}(e,e) = \alpha$, $\bar{h}(f,f) = \beta \in k_v^{\times}$, the isotropic lines are those of $xe + f$ with $x\bar{x} = -\beta/\alpha$; the norm $k_w^{\times} \to k_v^{\times}$ is surjective with fibres of size $\mathrm{N}v + 1$, so there are $\mathrm{N}v + 1$ isotropic lines, one of which is L_w/L_0. So at most $\mathrm{N}v$ neighbours $L_1 \neq L_w$ contain L_0, which gives the bound for $\#\mathrm{St}_v$. *The step lowers* I. Let $\gamma \in G_v \setminus \mathbf{K}_0(n)$ and $M = \gamma L_w$. Then $M \not\subseteq L_w$: otherwise $M = M^{\#} \supseteq L_w^{\#} = L_w$, so $M = L_w$. As in Step 3 pick $x \in M \setminus L_w$ with $\varpi x \in L_w$. The map $L_w \to \varpi^{-1}\mathcal{O}/\mathcal{O}$, $z \mapsto h(z,x) \bmod \mathcal{O}$, is well defined ($h(z, \varpi x) = \varpi h(z,x) \in \mathcal{O}$) and $\mathcal{O}$-linear; it is nonzero, since $\varpi x \notin \varpi L_w = \varpi L_w^{\#}$ gives $z \in L_w$ with $h(z, \varpi x) \notin \varpi\mathcal{O}$; so its kernel L_0 has index $\mathrm{N}w$. Let $L_1 = L_0 + \mathcal{O}x$. Then $h(x,x) \in \mathcal{O}$ ($x \in M = M^{\#}$), $h(L_0, x) \subseteq \mathcal{O}$ and $h(L_0, L_0) \subseteq \mathcal{O}$, so $L_1 \subseteq L_1^{\#}$; $x \notin L_0$ and $\varpi x \in L_0$, so $[L_1 : L_0] = \mathrm{N}w$; then $[L_1^{\#} : L_0] = [L_0^{\#} : L_0]/[L_0^{\#} : L_1^{\#}] = \mathrm{N}w^2/\mathrm{N}w = [L_1 : L_0]$, whence $L_1 = L_1^{\#}$. As $x \in L_1 \setminus L_w$ and $[L_1 : L_0] = \mathrm{N}w$ has no intermediate $\mathcal{O}$-lattices, $L_w \cap L_1 = L_0$; so $L_1 \neq L_w$ is a neighbour. Moreover $L_w \cap M \subseteq L_0$ ($h(z,x) \in \mathcal{O}$ for $z, x \in M$), and $L_1 \cap M \supseteq (L_w \cap M) + \mathcal{O}x$ with $[(L_w \cap M) + \mathcal{O}x : L_w \cap M] = \mathrm{N}w$. With $\rho = \rho_{L_1}$,

$$I(\rho\gamma) = [L_1 : L_1 \cap M] \leq \frac{[L_1 : L_0]\,[L_0 : L_w \cap M]}{\mathrm{N}w} = \frac{[L_w : L_w \cap M]}{\mathrm{N}w} = \frac{I(\gamma)}{\mathrm{N}w},$$

using $[L_0 : L_w \cap M] = [L_w : L_w \cap M]/\mathrm{N}w$. By Step 1 every finite place of F is split or inert, which completes (c). □

Lemma 6.5.6. *Let S, T be spaces, $n = \mathrm{rk}\, S$, β an automorphic character of $\mathrm{U}(1)$ and $\omega = \omega_{1,\beta}$. Let Σ be a set of finite places of F and, for $v \in \Sigma$, K_v the component at v of $\mathbf{K}_0(n)$, the stabiliser of the standard lattice. For $\gamma \in G_f(n)$ whose components at the finite places not above Σ are 1 put*

$$\mathrm{mc}_{\beta,\Sigma}(\gamma) = \langle v^0,\ \omega((1,\gamma),1)\, v^0 \rangle,$$

the ***vacuum coefficient****. Let $\varphi \in \mathcal{M}_{S,T}$ be a vacuum above Σ. Then for every such γ and every $g \in \mathrm{U}(S)(\mathbb{A}_F)$ with $g_v \in K_v$ for all $v \in \Sigma$,*

$$\langle \varphi, \omega((1,\gamma)g,1)\varphi \rangle = \mathrm{mc}_{\beta,\Sigma}(\gamma)\, \langle \varphi, \omega(g,1)\varphi \rangle.$$

Proof. **Step 1: $u = \omega(g,1)\varphi$ is a vacuum above Σ.** Let $y \in \widehat{\mathcal{O}}_E^N$ have components 0 at the finite places not above Σ. By (WD8), $\rho_f(y) = c(y)\rho(\mathrm{fv}(y))$ with $c(y) = \psi_{E,f}(\jmath\alpha\bar{\alpha}\frac{c_0}{2}y^*y)$ and $\mathrm{fv}(y) = (0, \alpha y)$. By (2) of Lemma 4.1.1, $\omega_{s'\otimes s}(g')^{-1}\rho(z)\,\omega_{s'\otimes s}(g') = \rho(g'^{-1}z)$, and the scalar $\beta(\det g)^{-1}$ cancels in the conjugation. As $\mathrm{fv}(y)$ has archimedean part 0 and the finite part of g'^{-1} is linear, $g'^{-1}\mathrm{fv}(y) = \mathrm{fv}(y_1)$ with $y_1 = g_f'^{-1}y$; g_f' is unitary for the standard form, so $y_1^*y_1 = y^*y$ and $c(y_1) = c(y)$. At the places above Σ, $g_v \in K_v$, so $g_f'^{-1}$ is integral there, and y_1 is again integral with components 0 off the places above Σ. Hence $\omega(g,1)^{-1}\rho_f(y)\,\omega(g,1) = \rho_f(y_1)$ and $\rho_f(y)u = \omega(g,1)\rho_f(y_1)\varphi = u$.

Step 2: the factorisation. By (2) of Lemma 4.1.1, $\omega((1,\gamma)g,1)\varphi = \omega((1,\gamma),1)u = \beta(\det\gamma)^{-1}\omega_{s'\otimes s}(\gamma')u$ with $\gamma' = 1\otimes(\gamma^{-1})^{\mathsf{T}}$, whose components are 1 at the infinite places and at the finite places not above Σ. As φ and u are vacua above Σ, (7) of Lemma 6.2.33 gives

$$\langle\varphi, \omega((1,\gamma)g,1)\varphi\rangle = \beta(\det\gamma)^{-1}\langle v^0, \omega_{s'\otimes s}(\gamma')v^0\rangle\langle\varphi,u\rangle = \mathrm{mc}_{\beta,\Sigma}(\gamma)\,\langle\varphi,\omega(g,1)\varphi\rangle.$$

□

Lemma 6.5.7. *Let D be admissible data and ϑ an m-fold twist, and write $X_\vartheta = \mathrm{Wc}^0_{\vartheta,\mathrm{I},m}$. For all $x, y \in \mathcal{T}$,*

$$\langle\Theta_\vartheta x, \Theta_\vartheta y\rangle = [\mathbf{K}_0 : \mathrm{K}_\vartheta]\cdot\dim W_{\lambda^\circ}\cdot\langle X_\vartheta x,\ X_\vartheta y\rangle_{Y_m}.$$

Proof. Let $p = p_{\mathrm{I},0,m}$, which is the doubled Harish-Chandra parameter $l = 2\lambda(Y_m)$ of (κ_Y, e_Y) used by the chain in Definition 3.2.31 , and $d = \#I_{\kappa_Y} = \dim W_{\lambda^\circ}$. Let $x, y \in \mathcal{T}$ and $\eta = \Theta_\vartheta x$, $\eta' = \Theta_\vartheta y$, elements of $\mathcal{A}_\vartheta(Y_m)$ by Lemma 6.4.75(c): algebraic forms of weight (κ_Y, e_Y) with $\eta(gk) = \chi(k)\eta(g)$ and $\eta'(gk) = \chi(k)\eta'(g)$ for $k \in \mathrm{K}_\vartheta$, χ the character of K_ϑ of Definition 3.2.31, whose values are values of characters of finite groups and so have modulus 1. The group K_ϑ is an open subgroup of $\mathbf{K}_0(n)$ (it contains the elements congruent to 1 modulo the level places). By (WM3), the summand of (TL1) is $\eta(g_c)^*G_W\eta'(g_c) = \langle\eta(g_c),\eta'(g_c)\rangle_{\kappa_Y}$, so (TL1) is the class sum for K_ϑ of $h \mapsto \langle\eta(h),\eta'(h)\rangle_{\kappa_Y}$, which is constant on the double cosets by (c) of Lemma 6.4.72. By that lemma,

$$\langle\Theta_\vartheta x, \Theta_\vartheta y\rangle = [\mathbf{K}_0(n) : \mathrm{K}_\vartheta]\cdot d\cdot\langle F^p_\eta, F^p_{\eta'}\rangle_{\mathrm{I}_n}.$$

Since $x, y \in \mathcal{A}_M(Y_0)$, Lemma 6.4.67(b) gives $F^p_\eta = X_\vartheta x$ and $F^p_{\eta'} = X_\vartheta y$, and $\mathrm{I}_n = Y_m$; this is the assertion. □

Lemma 6.5.8. *Let D be admissible data. For an m-fold twist ϑ put $N_n(\vartheta) = \#\mathrm{GL}_{n_n}(R_\vartheta)$ for the triangle $z = \mathrm{I}$ ($\#n_n = r + nt$). There are $C > 0$ and $k \in \mathbb{Z}$, independent of ϑ, such that for every m-fold twist ϑ with modulus Q*

$$[\mathbf{K}_0 : \mathrm{K}_\vartheta] = C\,(\mathrm{N}Q)^k\,c_Q^m\,\frac{N_m(\vartheta)}{N_0(\vartheta)\,N_1(\vartheta)^m}.$$

Proof. **Step 1: the residue ring.** The primes $p_0 \neq p_1$ are $\equiv 1 \pmod{q_2^2}$ ((AD5)), hence prime to d and to every prime factor of q_1 (all of which divide q_0, as $2, 3 \mid q_0$, and so divide $q_2 = (q_0 d)^{s+6}$; Definition 2.3.1); so they are unramified in $E = K(\zeta_{q_1})$. As $\pi_M\bar{\pi}_M = p_0p_1$ in $\mathcal{O}_K$, neither p_ϵ is inert in K, so $\pi_M\mathcal{O}_K$, and hence $\pi_M\mathcal{O}_E$, is a product of distinct primes; these are the chosen places, each with exponent 1. With (TV2) and $\mathrm{N}Q$ prime to M, $R_\vartheta = \prod_{w\in P} k_w$ for P the set of chosen places and places of Q, and $N_n(\vartheta) = \prod_{w\in P}\#\mathrm{GL}_{r+nt}(k_w)$.

Step 2: the index as a product. The places of P are distinct and none is the conjugate of itself or of another ((DP1) of Definition 3.2.23, for the level system of (LF4) of Definition 3.2.26);

so each lies over a place of F split in E, the component of the unitary group at that place is $\mathrm{GL}_N(E_w)$, $N = r+mt$, that of $\mathbf{K}_0$ is $\mathrm{GL}_N(\mathcal{O}_{E,w})$, and reduction maps $\mathbf{K}_0$ onto $\prod_{w\in P}\mathrm{GL}_N(k_w)$. As K_ϑ is the inverse image of $\prod_{w\ \mathrm{chosen}}\{1\}\times\prod_{w\in Q}P_w$, $P_w\subseteq\mathrm{GL}_N(k_w)$ the block upper triangular group,

$$[\mathbf{K}_0:\mathrm{K}_\vartheta]=\prod_{w\ \mathrm{chosen}}\#\mathrm{GL}_N(k_w)\cdot\prod_{w\in Q}[\mathrm{GL}_N(k_w):P_w].$$

Step 3: the local factors. Let $q=\mathrm{N}w$ and write $\#\mathrm{GL}_a$ for $\#\mathrm{GL}_a(\mathbb{F}_q)$. The group P_w is the semidirect product of the block diagonal group with the block unipotent group, so $\#P_w=\#\mathrm{GL}_r\,(\#\mathrm{GL}_t)^m q^e$ with $e=rmt+t^2m(m-1)/2$ (the number of entries above the diagonal blocks). The matrices of GL_{r+t} fixing the first r basis vectors form a group of order $\prod_{i=r}^{r+t-1}(q^{r+t}-q^i)=q^{rt}\#\mathrm{GL}_t$, whose index is the number $\prod_{i=0}^{r-1}(q^{r+t}-q^i)=q^{(r+t)r}f(q)$ of $(r+t)\times r$ matrices of rank r; so $\#\mathrm{GL}_{r+t}=q^{(r+t)r+rt}f(q)\,\#\mathrm{GL}_t$. Hence, for $w\in Q$,

$$[\mathrm{GL}_N:P_w]=\frac{\#\mathrm{GL}_N}{\#\mathrm{GL}_r(\#\mathrm{GL}_t)^m q^e}=q^k\left(q^{rt}f(q)\right)^m\frac{\#\mathrm{GL}_N}{\#\mathrm{GL}_r\,(\#\mathrm{GL}_{r+t})^m},$$
$$k=m(r+t)r-e=mr^2-t^2m(m-1)/2,$$

and for a chosen place w, $\#\mathrm{GL}_N(k_w)=C_w\,\#\mathrm{GL}_N(k_w)/(\#\mathrm{GL}_r(k_w)\#\mathrm{GL}_{r+t}(k_w)^m)$ with $C_w=\#\mathrm{GL}_r(k_w)\#\mathrm{GL}_{r+t}(k_w)^m$.

Step 4: conclusion. Multiplying over P and using Step 1 ($N_0=\prod_P\#\mathrm{GL}_r(k_w)$, $N_1=\prod_P\#\mathrm{GL}_{r+t}(k_w)$, $N_m=\prod_P\#\mathrm{GL}_N(k_w)$), $\prod_{w\in Q}q_w^k=(\mathrm{N}Q)^k$ and $\prod_{w\in Q}(q_w^{rt}f(q_w))^m=c_Q^m$, the formula holds with $C=\prod_{w\ \mathrm{chosen}}C_w>0$ and k as above, both independent of ϑ. □

Proposition 6.5.9. *Let $1\le j\le m$, and for a tame character ϑ let $\Theta^{\mathrm{pr}}_{j,\vartheta}$ be the theta lift of the descent pair at ϑ on $\mathcal{A}^{\mathrm{pr}}(W_j)$, so that $\Theta_{j,\vartheta}$ is its restriction to the good forms. Let $R_{j,\vartheta}$ be the* ***Rallis series*** *on $\mathcal{A}^{\mathrm{pr}}(W_j)$,*

$$R_{j,\vartheta}\,y=\sum_q \mathrm{mc}_{j,\vartheta}(q)\,\rho(q)y,$$

q over $\mathrm{U}(W_j)(\mathbb{A}_f)$ modulo the points integral at the places outside $S_M\cup Q$ and their conjugates, $\mathrm{mc}_{j,\vartheta}(q)$ the matrix coefficient of the unramified vector of the Weil representation for the second character of the pair (the one twisting the action of $\mathrm{U}(W_j)$, read with the rank $r+t$ of V^{def}, as in (XD2) of Definition 3.2.22). Put

$$c_Q=(\mathrm{N}Q)^{rt}\prod_{w\in Q}\prod_{i=t+1}^{t+r}(1-(\mathrm{N}w)^{-i}).$$

Then:

1. *for every tame ϑ, $\Theta^{\mathrm{pr}}_{j,\vartheta}$ is injective; hence $\Theta_{j,\vartheta}$ is injective and $Z_j(\vartheta)>0$ for every m-fold twist ϑ;*
2. *there is $A_j\in\mathbb{C}\setminus\{0\}$, independent of ϑ, with $(\Theta^{\mathrm{pr}}_{j,\vartheta})^*\Theta^{\mathrm{pr}}_{j,\vartheta}=A_j\,c_Q\,R_{j,\vartheta}$ for every tame ϑ with modulus Q;*
3. *$R_{j,\vartheta}$ preserves the good forms, and for every m-fold twist ϑ with modulus Q,*

$$Z_j(\vartheta)=(A_j\,c_Q)^{d_\mathcal{T}}\,\det(R^{\mathcal{T}}_{j,\vartheta^j}),$$

where $R^{\mathcal{T}}_{j,\vartheta}$ is the Rallis series of the j-th pair acting on the target forms $\mathcal{T}=\mathcal{A}^{\mathrm{good}}(Y_0)$.

Proof. **Step 1: the block datum is sharp.** The finite datum F of the descent pair (block function at $S_M \cup Q$, vacuum elsewhere) is sharp for J_M off $(S_M \cup Q) \cup \overline{(S_M \cup Q)}$ in the sense of Lemma 6.5.12, with mass

$$c_\Psi = \frac{\#\prod_{w\in Q} \mathrm{GL}_r(k_w) \cdot (\mathrm{N}Q)^{tr}}{\#\{(r+t)\times r \text{ matrices mod } \pi_M Q\} \cdot \#\prod_{w\in S_M} \mathrm{GL}_r(k_w)}.$$

This is Lemma 6.5.10 for $O = O_{j,\vartheta}$ (ranks $r < r+t$, $S_O = S_M \cup Q$, $J_O = J_M$, $c_\Psi = c_O$): (a), (b′) and (4) of Lemma 6.2.33 give (SH1) of Lemma 6.5.12 with S_0 the places of F below $S_M \cup Q$, (c) gives (SH2) for the character $b = \chi'_O$, (d) gives (SH3) ($S_M \neq \emptyset$), and (e) gives (SH4).

Step 2: Rallis' formula and the algebraic forms. Let $O = O_{j,\vartheta}$, $n = r+t$, $\xi_O = v_{l_O}^+$ ((LF5), (DP11)), $v = v_{\mathrm{Har}_O(\xi_O)}$, a Schwartz vector ((XD3) of Definition 3.2.22), so that $\mathrm{J}_O(\xi_O) = v \otimes \Upsilon(O)$ (DP8). By Lemma 6.5.11, O fits the parameter $l = 2\varsigma$ on W_j, and by Lemma 6.4.15(e), v is an edge, for the weights $\gamma = r_-(O)$ and $\gamma' = \lfloor n/2 \rfloor + \mathrm{wt}_O$, from $e_\varsigma = e_{l/2}$, the type of the forms of $\mathcal{A}^{\mathrm{pr}}(W_j)$ (Definition 3.2.16), to $e_{l_O/2}$. These are the weights of $\chi_O = \upsilon^{r_-(O)}$ and $\chi'_O = \mu_O \upsilon^{\lfloor n/2 \rfloor}$ (υ has weight 1, $\mu_O = \mu_j^0 \vartheta$ has weight $\mathrm{wt}_O = -\kappa_j$), and they do not depend on ϑ, nor do O's weight (κ_O, e_O), l_O and Har_O ((LF4) and (DP3), (DP8), (DP11): the twist enters only through μ_O and the level system). By Lemma 6.5.12, applied to $S = W_j$, $T = \mathrm{I}_n$, the edge v, the characters $(a,b) = (\chi_O, \chi'_O)$, $J = J_M$, the places S_0 of F below $S_M \cup Q$ and $F = \Upsilon(O)$, sharp by Step 1 with mass c_Ψ, there is $A \neq 0$ depending only on W_j, I_n, v, the weights and e_ς (so not on ϑ), such that the lift $L = L_{v\otimes\Upsilon(O)}$ maps $\mathcal{A}^{\mathrm{pr}}(W_j)$ to forms of type $e_{l_O/2}$ on I_n, is injective on $\mathcal{A}^{\mathrm{pr}}(W_j)$ (its forms are right invariant under J_M), and $\langle Lx, Ly\rangle_{\mathrm{I}_n} = A\, c_\Psi \langle x, R_{j,\vartheta} y\rangle$ for $x, y \in \mathcal{A}^{\mathrm{pr}}(W_j)$, $R_{j,\vartheta}$ being the Rallis series of $(W_j, \mathrm{I}_n, \chi'_O, \Sigma)$, Σ the finite places of F off S_0. By (LF5), $\Theta^{\mathrm{pr}}_{j,\vartheta} y$ is the algebraic form $(Ly)^\flat_{l_O}$ attached to Ly, an element of $\mathrm{Form}(O)$. By Lemma 6.4.70, $Ly = F^{l_O}_\eta$ for an algebraic form η of weight (κ_O, e_O), and by Lemma 6.4.72(b), $\eta = (Ly)^\flat_{l_O} = \Theta^{\mathrm{pr}}_{j,\vartheta} y$; so $Ly = F^{l_O}_{\Theta^{\mathrm{pr}}_{j,\vartheta} y}$. In particular $\Theta^{\mathrm{pr}}_{j,\vartheta} y = 0$ forces $Ly = 0$ and $y = 0$, which is (1); and since $Z_j(\vartheta)$ is the Gram determinant of the images of an orthonormal basis under an injective map, $Z_j(\vartheta) > 0$. The elements of $\mathrm{Form}(O)$ transform under $\mathbf{K}(O)$ by the character $\tilde{\eta}_O$, whose values have modulus 1 (values of characters of finite groups), and the inner product of $\mathrm{Form}(O)$ is the class sum for $\mathbf{K}(O)$ of the Gram pairings (DP5); so Lemma 6.4.72(c) gives

$$\langle \Theta^{\mathrm{pr}}_{j,\vartheta} x, \Theta^{\mathrm{pr}}_{j,\vartheta} y\rangle = [\mathbf{K}_0(n) : \mathbf{K}(O)] \cdot \delta \cdot \langle Lx, Ly\rangle_{\mathrm{I}_n} = [\mathbf{K}_0(n) : \mathbf{K}(O)] \cdot \delta \cdot A\, c_\Psi \langle x, R_{j,\vartheta} y\rangle,$$

$\delta = \dim \mathbb{V}_O$, independent of ϑ.

Step 3: the constant. For a place w, the number of $(r+t)\times r$ matrices of rank r over k_w is

$$\prod_{i=0}^{r-1} (q_w^{r+t} - q_w^i) = q_w^{(r+t)r} f(q_w), \qquad f(q) = \prod_{i=t+1}^{t+r} (1 - q^{-i}), \quad q_w = \mathrm{N}w.$$

Reduction maps $\mathbf{K}_0(n)$ onto $\prod_{w\in S_M\cup Q} \mathrm{GL}_n(k_w)$ (the places are split and pairwise non-conjugate, (DP1)), so $[\mathbf{K}_0(n) : \mathbf{K}(O)] = \prod_w [\mathrm{GL}_n(k_w) : \mathbf{L}(O)_w]$ (DP4). At $w \in S_M$, $\mathbf{L}(O)_w$ is the stabiliser S'_w of the r basis vectors in the image of inc, of index the number above. At $w \in Q$, $\mathbf{L}(O)_w$ is the stabiliser P_w of the span of the other t basis vectors, of order $\#\mathrm{GL}_r(k_w)\#\mathrm{GL}_t(k_w) q_w^{rt}$, while $\#S'_w = \prod_{i=r}^{n-1}(q_w^n - q_w^i) = q_w^{rt}\#\mathrm{GL}_t(k_w)$; so $[\mathrm{GL}_n(k_w) : P_w]\,\#\mathrm{GL}_r(k_w) = [\mathrm{GL}_n(k_w) : S'_w]$. Hence $[\mathbf{K}_0(n) : \mathbf{K}(O)] \cdot \#\prod_{w\in Q} \mathrm{GL}_r(k_w) = \prod_{w\in S_M\cup Q} q_w^{(r+t)r} f(q_w)$. Dividing by the number $\prod_{w\in S_M\cup Q} q_w^{(r+t)r}$ of matrices modulo $\pi_M Q$,

$$[\mathbf{K}_0(n) : \mathbf{K}(O)]\, c_\Psi = \Big(\prod_{w\in S_M} \frac{f(q_w)}{\#\mathrm{GL}_r(k_w)} \Big) \cdot (\mathrm{N}Q)^{rt} \prod_{w\in Q} f(q_w) = c_M\, c_Q,$$

with $c_M \neq 0$ (as $q_w^i \neq 1$ for $i \geq 1$) depending only on the chosen places. So $A_j = A\,\delta\,c_M \neq 0$ does not depend on ϑ, and $\langle \Theta x, \Theta y\rangle = A_j c_Q \langle x, R_{j,\vartheta} y\rangle$ for all x, y, which is (2) by the definition of the adjoint.

Step 4: determinants. If $u\colon U \to U'$ is linear between finite-dimensional inner product spaces with $\langle ux, uy\rangle = a\langle x, Sy\rangle$ for an endomorphism S of U, then $u^*u = aS$ and $\det(u^*u) = a^{\dim U} \det S$. The target parameter has gap Δ for Y_0 and for W_j, and $\dim \mathcal{A}^{\mathrm{good}}(W_j) = d_{\mathcal{T}}$, by Proposition 5.8.4(iii). The series $R_{j,\vartheta}$ is given on W_j and on Y_0 by the same summable family of Hecke translates (Step 2), so by Proposition 5.8.55 it is a spherical Hecke operator T_a away from the level on both spaces, preserves the good forms, and has the same determinant on the good forms of W_j and on $\mathcal{T} = \mathcal{A}^{\mathrm{good}}(Y_0)$. The powers ϑ^j have the modulus Q of ϑ, so c_Q is the same; apply the rule to $u = \Theta_{j,\vartheta^j}$ on the good forms of W_j with $a = A_j c_Q$ and $S = R_{j,\vartheta^j}$, which gives (3). □

Lemma 6.5.10. *Let O be a descent pair over E for ranks $r < n$, $S_O = M_O \cup Q_O$, $\bar{S}_O$ the set of conjugates of its places, $F = \Upsilon(O)$, and*

$$J_O = \{k \in \mathbf{K}_0(r) :\ k_w \equiv 1 \pmod{w} \text{ for all } w \in M_O\},$$
$$c_O = \frac{\prod_{w\in Q_O} \#\mathrm{GL}_r(k_w) \cdot (\mathrm{N}Q_O)^{(n-r)r}}{\prod_{w\in S_O} (\mathrm{N}w)^{nr} \cdot \prod_{w\in M_O} \#\mathrm{GL}_r(k_w)},$$

with $\mathrm{N}Q_O = \prod_{w\in Q_O} \mathrm{N}w$. Then:

(a) $[\mathbf{K}_0(r) : J_O] = \prod_{w\in M_O} \#\mathrm{GL}_r(k_w)$ *and* $\langle F, F\rangle = [\mathbf{K}_0(r) : J_O]\, c_O \neq 0$*;*

(b) $P^{A'}F = F$ *for every finite set A' of finite places containing the conjugate of none of its members with $(A' \cup \bar{A}') \cap (S_O \cup \bar{S}_O) = \emptyset$;*

(b′) *F is a vacuum above the set of finite places of F below no place of S_O, in the sense of (7) of Lemma 6.2.33;*

(c) *for every $k \in G_f(r)$ with $k_w \in \mathrm{GL}_r(\mathcal{O}_{E,w})$ at all finite places $w \notin S_O \cup \bar{S}_O$,*

$$\langle F,\ \omega_O((1,k),1)\,F\rangle = \begin{cases} \langle F, F\rangle & \text{if } k \in J_O, \\ 0 & \text{otherwise;} \end{cases}$$

(d) *for every $w \in S_O$ and every finite adelic $n \times r$ matrix x with $\Phi_O(x) \neq 0$, the matrix x_w over E_w is integral and has a left inverse over $\mathcal{O}_{E,w}$; in particular, if $S_O \neq \emptyset$, every datum $v \otimes F$ (v a Fock vector) is Φ_O at the places of S_O times a datum at the other places, with $\Phi_O(x) \neq 0$ only if x_w has a left inverse;*

(e) $\omega_O((1,k),(1,k'))F = F$ *for all $k \in \mathbf{K}_0(r)$ and $k' \in \mathbf{K}_0(n)$ whose components at the places of S_O reduce to 1; these form open subgroups.*

Proof. **Step 0: reductions and the vacuum.** The places of S_O are distinct and none is the conjugate of itself or of another (DP1); so each $w \in S_O$ lies over a place v of F split in E, distinct w lie over distinct v, and the component of $G_f(r)$ at v is identified, by projection to w, with $\mathrm{GL}_r(E_w)$ (the condition $g^*g = 1$ determines the component at $\bar{w}$), the component of $\mathbf{K}_0(r)$ with $\mathrm{GL}_r(\mathcal{O}_{E,w})$. Hence $(\mathrm{red}_w)_{w\in M_O}\colon \mathbf{K}_0(r) \to \prod_{w\in M_O} \mathrm{GL}_r(k_w)$ is surjective with kernel J_O, which gives the index in (a). If $S_O \neq \emptyset$ let $\mathfrak{m} = \prod_{w\in S_O} w$, a modulus with $\Sigma(\mathfrak{m}) = S_O$; by the Chinese remainder theorem $R_{\mathfrak{m}} = \prod_{w\in S_O} k_w$, Ψ_O is a function on $n \times r$ matrices over $R_{\mathfrak{m}}$, and

$\Phi_O = \Psi_O^\natural$ in the notation of (6) of Lemma 4.1.1. If $S_O = \emptyset$, Ψ_O is the empty product 1, $\Phi_O = 1$ and $F = 1 \otimes_\emptyset v^0 = v^0$, since $\mathcal{T}_\emptyset$ is spanned by $\tau_0 = 1$ and $P^\emptyset$ is the identity (WR6). Finally $\langle v^0, v^0\rangle = 1$:

Step 1: inner products of data modulo $\mathfrak{m}$. Let $S_O \neq \emptyset$ and Ψ_1, Ψ_2 be functions on $n \times r$ matrices over $R_\mathfrak{m}$, and $N_\mathfrak{m} = \#\mathrm{M}_{n\times r}(R_\mathfrak{m}) = \prod_{w\in S_O}(\mathrm{N}w)^{nr}$. Then

$$\langle \Psi_1^\natural \otimes_{S_O} v^0,\ \Psi_2^\natural \otimes_{S_O} v^0\rangle = \frac{1}{N_\mathfrak{m}} \sum_X \overline{\Psi_1(X)}\, \Psi_2(X).$$

Indeed, by (1) and (2) of Lemma 6.2.33 and Step 0 the left side is $\langle \Psi_1^\natural, \Psi_2^\natural\rangle_{S_O}$. The integrand vanishes unless x is integral at S_O, so the integral is over $\widehat{\mathcal{O}}_E^{nr}$, of mass 1, of a function of x mod $\mathfrak{m}$; reduction is a surjective continuous homomorphism of compact groups $\widehat{\mathcal{O}}_E^{nr} \to \mathrm{M}_{n\times r}(R_\mathfrak{m})$, so it carries the Haar probability measure to the uniform measure, which gives the right side.

Step 2: (a). Let $S_O \neq \emptyset$. For $X = (X_w)_{w\in S_O}$, $|\Psi_O(X)|^2$ is 1 if $X_w = \mathrm{Inc}_O$ for all $w \in M_O$ and the inc-rows of X_w are invertible for all $w \in Q_O$, and 0 otherwise: the values of a character of the finite group $k_w^\times$ have modulus 1, and its value at 0 is 0. An $n \times r$ matrix over k_w with invertible inc-rows is an element of $\mathrm{GL}_r(k_w)$ on the inc-rows and arbitrary on the other $n - r$ rows. So

$$\sum_X |\Psi_O(X)|^2 = \prod_{w\in Q_O} \#\mathrm{GL}_r(k_w)\,(\mathrm{N}w)^{(n-r)r},$$

and by Step 1, $\langle F, F\rangle$ is this number divided by $N_\mathfrak{m}$, which is $[\mathbf{K}_0(r) : J_O]\, c_O$; it is positive. If $S_O = \emptyset$, $\langle F, F\rangle = \langle v^0, v^0\rangle = 1 = c_O$ and $J_O = \mathbf{K}_0(r)$.

Step 3: (b) and (b′). If $S_O \neq \emptyset$, (b) is (3) of Lemma 6.2.33 with $A = S_O$; if $S_O = \emptyset$ it is (2) there. A vector $y \in \widehat{\mathcal{O}}_E^{nr}$ has components 0 at the places not above the places of F below no place of S_O exactly when its components at $S_O \cup \bar{S}_O$ are 0; so (b′) is (5) of Lemma 6.2.33 with $A = S_O$ (with $A = \emptyset$, $\Psi = 1$ if $S_O = \emptyset$).

Step 4: the integral points. Let $k \in \mathbf{K}_0(r)$ and write $\bar{k} = (\mathrm{red}_w k)_{w\in S_O}$. Then $u = \det k$ lies in $\mathrm{U}(1)(\mathbb{A})$ (as $k^*k = 1$), has infinite components 1 and unit finite components, and $u \bmod w = \det(\mathrm{red}_w k)$. As μ_O has tame part $(\psi_{O,w})$ with $\psi_{O,w} = 1$ off S_O (DP2), $\mu_O(u) = \prod_{w\in S_O} \psi_{O,w}(\det \mathrm{red}_w k)$ (the weight factor is 1), and $v(u) = \prod_{v\in\Phi} u_v/|u_v| = 1$ by (WD3). So

$$\chi'_O(\det k) = \prod_{w\in S_O} \psi_{O,w}(\det \mathrm{red}_w k).$$

By (4) of Lemma 6.2.33, $F = v_1 \otimes F$ for the real vacuum v_1; so (6) of Lemma 4.1.1 (with $v = v_1$, $\alpha = \chi_O$, $\beta = \chi'_O$, $k' = 1$; for $S_O = \emptyset$ its last sentence) and (4) of Lemma 6.2.33 again give

$$\omega_O((1,k),1)F = \chi'_O(\det k)^{-1}\, \Psi_{O,k}^\natural \otimes_{S_O} v^0, \qquad \Psi_{O,k}(X) = \Psi_O(X\bar{k}).$$

If $k \in J_O$: at $w \in M_O$, $X_w \,\mathrm{red}_w k = X_w$ and $\psi_{O,w}(\det \mathrm{red}_w k) = 1$; at $w \in Q_O$ the inc-rows of $X_w \,\mathrm{red}_w k$ are those of X_w times $\mathrm{red}_w k$, so $\psi_{O,w}$ of their determinant is

$$\psi_{O,w}(\det \text{inc-rows}(X_w))\, \psi_{O,w}(\det \mathrm{red}_w k)$$

(both sides 0 if the inc-rows are singular). Hence $\Psi_{O,k} = \chi'_O(\det k)\Psi_O$, so $\omega_O((1,k),1)F = F$ and the coefficient is $\langle F, F\rangle$. *If $k \notin J_O$* (then $S_O \supseteq M_O \neq \emptyset$): by Step 1 the coefficient is $\chi'_O(\det k)^{-1} N_\mathfrak{m}^{-1} \sum_X \overline{\Psi_O(X)}\Psi_O(X\bar{k})$, and every term vanishes: if $\Psi_O(X) \neq 0 \neq \Psi_O(X\bar{k})$, then for $w \in M_O$ both X_w and $X_w \,\mathrm{red}_w k$ equal Inc_O, and since $\mathrm{Inc}_O^\mathsf{T}\mathrm{Inc}_O = 1_r$ (inc_O is injective), $\mathrm{red}_w k = \mathrm{Inc}_O^\mathsf{T} X_w \,\mathrm{red}_w k = 1$; so $k \in J_O$, a contradiction.

Step 5: (d). Let $w \in S_O$ and $\Phi_O(x) \neq 0$. Then x is integral at w, and $X_w = x_w \bmod w$ satisfies $\Psi_O(X) \neq 0$. If $w \in M_O$, $X_w = \mathrm{Inc}_O$, so $B = \mathrm{Inc}_O^{\mathsf{T}} x_w \in \mathrm{M}_r(\mathcal{O}_{E,w})$ reduces to 1_r and is invertible over $\mathcal{O}_{E,w}$. If $w \in Q_O$, $\psi_{O,w}(\det \text{inc-rows}(X_w)) \neq 0$, so the inc-rows B of x_w have unit determinant and $B \in \mathrm{GL}_r(\mathcal{O}_{E,w})$. In both cases $B^{-1}\mathrm{Inc}_O^{\mathsf{T}}$ is an integral left inverse of x_w (the inc-rows of x_w are $\mathrm{Inc}_O^{\mathsf{T}} x_w$). The last assertion is the definition of the datum $v \otimes (\Phi_O \otimes_{S_O} v^0)$ in (WR6).

Step 6: (c) for $k \notin \mathbf{K}_0(r)$. Let $k \in G_f(r) \setminus \mathbf{K}_0(r)$ with $k_w \in \mathrm{GL}_r(\mathcal{O}_{E,w})$ for $w \notin S_O \cup \bar{S}_O$; as $k \notin \mathbf{K}_0(r)$, $S_O \neq \emptyset$. Write $k = k_1 k_2$ in $G_f(r)$, where k_1 has the components of k at the places of F below S_O and 1 elsewhere, and k_2 has components 1 there and those of k elsewhere. Then $k_2 \in J_O$, so $\omega_O((1,k_2),1)F = F$ by Step 4, and by (2) of Lemma 4.1.1, $\omega_O((1,k),1)F = \omega_O((1,k_1),1)F$. As k_1 is 1 outside $S_O \cup \bar{S}_O$, (4) of Lemma 4.1.1 (with $A = S_O$, $h = 1$) gives a scalar c with $\omega_O((1,k_1),1)F = c\,\Phi' \otimes_{S_O} v^0$, $\Phi'(x) = \Phi_O(xk_1) \in \mathcal{T}_{S_O}$. By (1), (2) of Lemma 6.2.33 and Step 0, $\langle F, \omega_O((1,k),1)F\rangle = c\,\langle \Phi_O, \Phi'\rangle_{S_O}$, and the integrand $\overline{\Phi_O(x)}\Phi_O(xk_1)$ vanishes everywhere. Otherwise, for each $w \in S_O$ both x_w and $(xk_1)_w = x_w k_w$ are integral with integral left inverses L, L' (Step 5); then $k_w = L\,x_w k_w$ and $k_w^{-1} = L' x_w$ are integral, so $k_w \in \mathrm{GL}_r(\mathcal{O}_{E,w})$, and the component at $\bar{w}$, determined by k_w through $k^*k = 1$, is integral too. With the hypothesis off $S_O \cup \bar{S}_O$, k would be integral at every finite place, i.e. $k \in \mathbf{K}_0(r)$, a contradiction. So the coefficient is 0. Together with Step 4 this proves (c).

Step 7: (e). Let k, k' be as in (e). As in Step 4 ($F = v_1 \otimes F$ and (6) of Lemma 4.1.1, now with k'), $\omega_O((1,k),(1,k'))F = \chi_O(\det k')\chi'_O(\det k)^{-1}\,\Psi^{\natural}_{O,k,k'} \otimes_{S_O} v^0$ with $\Psi_{O,k,k'}(X) = \Psi_O(\bar{k'}^{-1} X \bar{k}) = \Psi_O(X)$, the reductions being 1. By the formula of Step 4, $\chi'_O(\det k) = \prod_{w \in S_O} \psi_{O,w}(1) = 1$, and $\chi_O(\det k') = \upsilon(\det k')^{r_-(O)} = 1$ by (WD3), $\det k'$ having infinite components 1 and unit finite components. So F is fixed. The two groups contain the kernels of the reductions $\mathbf{K}_0 \to \prod_{w \in S_O} \mathrm{GL}(k_w)$, which are open. □

Lemma 6.5.11. *Let D be admissible data, $1 \leq j \leq m$ and ϑ a tame character. The descent pair $O_{j,\vartheta}$ fits the parameter $l = (l_\tau)_{\tau \in \Phi}$ given by $l_\tau(c) = 2\varsigma(\tau)_{\mathrm{num}(c)}$ for the basis vectors c of W_j.*

Proof. Fix $\tau \in \Phi$ and write $O = O_{j,\vartheta}$, $n = r + t$, $r_+ = r_+(O)$, $r_- = r_-(O)$, $t' = \frac{t-1}{2}$ and $\varsigma(i) = \varsigma_\tau(i)$ for $i \geq 0$ (with the extension of (LF4) for $i \geq r$). By (LF4) and (HP4), $r_+ = k + j - 1$ and $r_- = r - r_+ = m - j$ (recall $r = k + m - 1$), and $\mathrm{wt}_O(\tau) = -\kappa_j(\tau)$, the weight of $\mu_j^0\vartheta$. Since $r + t = 6r$ is even, $\lfloor n/2 \rfloor = \frac{r+t}{2}$; r and $t = 5r$ are odd. For $i \geq 0$ put

$$\sigma(i) = \varsigma(i) + \kappa_j(\tau).$$

Sizes. By (AD1) and Definition 2.3.3, $C_P \geq 6$, so $\log x \geq 100 \log\log b \geq 6 \cdot 10^{14}$; hence $r \geq x^5 \geq 10$ by (AD2), and $\frac{\Delta}{2} = r^8$ exceeds k, t and $t' + 1$, and $4r^8 \geq 343000\, r^3$. Since $\kappa_j - \kappa_{j'} = (j - j')\Delta$, the values of σ are

$$\sigma(i) = \kappa_j(\tau) + \tfrac{k}{2} - 1 - i \quad (0 \leq i \leq k-2), \qquad \sigma(k - 2 + j') = \tfrac{\Delta}{2} + (j - j')\Delta \quad (j' \geq 1),$$

the second formula covering both the entries $\frac{\Delta}{2} - \kappa_{j'}$ of $\varsigma(\tau)$ ($1 \leq j' \leq m$) and the extension ($j' = i + 2 - k \geq m + 1$). Hence:

(1) σ is a strictly decreasing sequence of integers: the steps are 1 among the first $k - 1$ values, $\sigma(k-2) - \sigma(k-1) = \kappa(\tau) + \Delta - \frac{k}{2} + 1 > 0$, and Δ afterwards;

(2) $\sigma(i) \geq \frac{\Delta}{2} > t' + 1$ for $i < r_+$ and $\sigma(i) \leq -\frac{\Delta}{2} < -t' - 1$ for $i \geq r_+$ (here $j' \leq j$, respectively $j' \geq j + 1$, and $j \geq 1$).

Note that $\varsigma(h-1)-\max(\varsigma(h),t'-\kappa_j)=\sigma(h-1)-\max(\sigma(h),t')$ and $\min(\varsigma(r-h-1),-\kappa_j-t')-\varsigma(r-h)=\min(\sigma(r-h-1),-t')-\sigma(r-h)$, so (LF4) reads $\kappa^+(\tau,h)=(\sigma(h-1)-\max(\sigma(h),t')-1)^+$ and $\kappa^-(\tau,h)=(\min(\sigma(r-h-1),-t')-\sigma(r-h)-1)^+$ for $1\le h<n$.

The column counts. Let $1\le h<n$. By (1) and (2):

(P1) for $h<r_+$, $\sigma(h)>t'$, so $\kappa^+(\tau,h)=\sigma(h-1)-\sigma(h)-1\ge 0$;

(P2) for $h=r_+$, $\sigma(r_+)<t'$ and $\sigma(r_+-1)>t'+1$, so $\kappa^+(\tau,r_+)=\sigma(r_+-1)-t'-1\ge 0$;

(P3) for $h>r_+$, $\sigma(h-1)<t'$, so $\kappa^+(\tau,h)=0$.

For κ^- put $i=r-h$. If $h\ge r$, both arguments are read as 0 and $\kappa^-(\tau,h)=(\min(\sigma(0),-t')-\sigma(0)-1)^+=0$ since $\sigma(0)>0$. If $1\le i\le r_+-1$, then $\sigma(i)>0\ge\min(\sigma(i-1),-t')$, so $\kappa^-(\tau,h)=0$. The remaining cases have $i\ge r_+$, that is $h\le r-r_+=r_-$:

(M1) for $h=r_-$ (so $i=r_+$; only if $r_-\ge 1$), $\sigma(r_+-1)>0$, so $\kappa^-(\tau,r_-)=-t'-\sigma(r_+)-1\ge 0$;

(M2) for $1\le h\le r_--1$ (so $i\ge r_++1$), $\sigma(i-1)<-t'$, so $\kappa^-(\tau,h)=\sigma(r-h-1)-\sigma(r-h)-1\ge 0$.

In particular $\kappa^+(\tau,h)=0$ for $r_+<h<n$ (P3) and $\kappa^-(\tau,h)=0$ for $r_-<h<n$; this is (iii).

(ii). By (1), $\varsigma(\tau)$ is strictly decreasing in the number, so $l_\tau(c)<l_\tau(c')$ if and only if $\mathrm{num}(c')<\mathrm{num}(c)$. For c of sign $+1$ the vectors c' of sign $+1$ with $l_\tau(c)<l_\tau(c')$ are those with $\mathrm{num}(c')<\mathrm{num}(c)$; as the numbers of sign $+1$ are $0,\dots,r_+-1$, there are $\mathrm{num}(c)=\mathrm{ord}(c)$ of them. For c of sign -1 the vectors c' of sign -1 with $-l_\tau(c)<-l_\tau(c')$ are those with $\mathrm{num}(c')>\mathrm{num}(c)$; the numbers of sign -1 being $r_+,\dots,r-1$, there are $r-1-\mathrm{num}(c)=\mathrm{ord}(c)$ of them.

The parameter l_O. Define $g(a)$ for $1\le a\le n$ by

$$\begin{aligned}
&g(a)=2\sigma(a-1)\ (a\le r_+),\\
&g(a)=2(t'-(a-1-r_+))\ (r_+<a\le r_++t),\\
&g(a)=2\sigma(a-1-t)\ (a>r_++t).
\end{aligned}$$

As $a-1-t$ runs over $r_+,\dots,r-1$ in the last range and $\{2(t'-b):0\le b<t\}=[t]$, the set of values of g is $\{2\sigma(i):0\le i<r\}\cup[t]$. We show

$$l_{O,\tau}(a)-2r_-+r=g(a)\qquad(1\le a\le n).\tag{6.118}$$

By (DP11), $l_{O,\tau}(a)=2(e_O(\tau)+\lambda_{O,\tau}(a-1))+n-1-2(a-1)$, and $\lambda_{O,\tau}(a-1)-\lambda_{O,\tau}(a)=\kappa_O(\tau,a)=\kappa^+(\tau,a)+\kappa^-(\tau,n-a)$ for $1\le a<n$ (head of Definition 3.2.19, (DP3)). Hence

$$l_{O,\tau}(a)-l_{O,\tau}(a+1)=2\kappa^+(\tau,a)+2\kappa^-(\tau,n-a)+2\qquad(1\le a<n).$$

We compare with $g(a)-g(a+1)$, using (iii) for the vanishing terms:

- $a<r_+$: $g(a)-g(a+1)=2(\sigma(a-1)-\sigma(a))=2\kappa^+(\tau,a)+2$ by (P1), and $n-a>r_-$;
- $a=r_+$: $g(a)-g(a+1)=2\sigma(r_+-1)-2t'=2\kappa^+(\tau,r_+)+2$ by (P2), and $n-a=r_-+t>r_-$;
- $r_+<a<r_++t$: $g(a)-g(a+1)=2$, $\kappa^+(\tau,a)=0$ and $n-a>r_-$;
- $a=r_++t<n$ (so $r_-\ge 1$ and $n-a=r_-$): $g(a)-g(a+1)=-2t'-2\sigma(r_+)=2\kappa^-(\tau,r_-)+2$ by (M1), and $\kappa^+(\tau,a)=0$;

- $r_+ + t < a < n$: with $i = a - t \in [r_+ + 1, r - 1]$ and $h = n - a = r - i \le r_- - 1$, $g(a) - g(a+1) = 2(\sigma(i-1) - \sigma(i)) = 2\kappa^-(\tau, h) + 2$ by (M2), and $\kappa^+(\tau, a) = 0$.

So both sides of (6.118) have the same steps, and it suffices to check $a = n$. As $\lambda_{O,\tau}(n-1) = 0$ (an empty sum), $l_{O,\tau}(n) = 2e_O(\tau) - (n-1)$ with $e_O(\tau) = -\sum_{1 \le h < n} \kappa^-(\tau, h)$. If $r_- = 0$, then $\kappa^-(\tau, \cdot) = 0$, $r_+ = r$, and $l_{O,\tau}(n) + r = 1 - t = g(n)$. If $r_- \ge 1$, then by (M1), (M2) and telescoping,

$$\sum_{1 \le h < n} \kappa^-(\tau, h) = (\sigma(r_+) - \sigma(r-1) - (r_- - 1)) + (-t' - \sigma(r_+) - 1) = -\sigma(r-1) - r_- - t',$$

so $l_{O,\tau}(n) - 2r_- + r = 2\sigma(r-1) + 2r_- + (t-1) - (r+t-1) - 2r_- + r = 2\sigma(r-1) = g(n)$. This proves (6.118).

(i). Apply (WM8) with the index sets $\{1, \dots, r\}$ (signs ε_O, $N = r$) and $\{1, \dots, n\}$ (signs $\mathbf{1}_n$, $N' = n$), and the weights $\gamma = r_-$, $\gamma' = \frac{r+t}{2} - \kappa_j(\tau)$. The shifted entries are

$$\tilde{l}_\tau(c) = l_\tau(c) - 2\gamma' + n = 2\sigma(\mathrm{num}(c)), \qquad \tilde{l}_{O,\tau}(a) = l_{O,\tau}(a) - 2r_- + r = g(a).$$

(a) l_τ is injective by (1); its values are even, and $r - 1$ is even. If c, c' have the signs $+1$, -1, then $\mathrm{num}(c) < r_+ \le \mathrm{num}(c')$ and, by (2), $l_\tau(c) - l_\tau(c') = 2(\sigma(\mathrm{num}(c)) - \sigma(\mathrm{num}(c'))) \ge 2\Delta = 4r^8 \ge 2 \cdot 500(r+n)^3$, as $(r+n)^3 = 343r^3$. So l_τ has gap $500(r+n)^3$ for ε_O. The map $l_{O,\tau}$ is strictly decreasing, hence injective, with $l_{O,\tau}(a) \equiv n - 1 \pmod 2$, and $\mathbf{1}_n$ takes one value; so it has every gap for $\mathbf{1}_n$. (b) $N = r \le N'$, and by (6.118) the set $\tilde{l}_{O,\tau}(\{1, \dots, n\})$ is the set of values of g, which is $\{2\sigma(i) : 0 \le i < r\} \cup [t] = \tilde{l}_\tau(\{1, \dots, r\}) \cup [n - r]$, since num is a bijection onto $\{0, \dots, r-1\}$. (c) The signs $\mathbf{1}_n$ are all $+1$. By (2), $\tilde{l}_\tau(c) = 2\sigma(\mathrm{num}(c))$ is positive when $\mathrm{num}(c) < r_+$, that is when $\varepsilon_O(c) = +1$, and negative otherwise, when $\varepsilon_O(c) = -1$. So (c) holds. Hence $(l_\tau, l_{O,\tau})$ satisfies the block rule for the weights $(r_-, \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau))$ and the signs $(\varepsilon_O, \mathbf{1}_n)$ at every $\tau \in \Phi$, which is (i). □

Lemma 6.5.12. *Let S, T be spaces with signs s on n and s' on n', $2\#n < \#n'$, let $\gamma, \gamma' \colon \Phi \to \mathbb{Z}$, e a type on S, e' a type on T, and $v \in \mathcal{F}_{S,T}$ a Schwartz vector that is an edge for the weights (γ, γ') from e to e'. Let dx be the Haar measure of (ED1) on $G_\infty(s)$, dk the Haar measure on $G_f(n)$ giving $\mathbf{K}_0(n)$ mass 1, $\lambda_S > 0$ the constant with $dg = \lambda_S \, dx \, dk$ for the Haar measure dg on $\mathrm{U}(S)(\mathbb{A}_F) = \mathrm{G}(s)$ inducing the quotient measure of $[\mathrm{U}(S)]$, and*

$$A = \mathrm{vol}([\mathrm{U}(T)]) \, \lambda_S \int_{G_\infty(s)} \langle v, \Omega_{\gamma,\gamma'}(x, 1) v \rangle \, \frac{\overline{e(x)}}{e(1)} \, dx.$$

*Let a, b be automorphic characters of $\mathrm{U}(1)$ of weights γ, γ', S_0 a finite set of finite places of F, Σ the set of the other finite places of F, $J \subseteq G_f(n)$ an open subgroup and $c \in \mathbb{C}$. Let $F \in \mathcal{M}_{S,T}$ be **sharp for J off S_0 with mass** c:*

(SH1) $\langle F, F \rangle \ne 0$, $c = \langle F, F \rangle / [\mathbf{K}_0(n) : J \cap \mathbf{K}_0(n)]$, $v_1 \otimes F = F$, *and F is a vacuum above Σ;*

(SH2) for every $k \in G_f(n)$ with $k_v \in K_v$ for all $v \in \Sigma$, $\langle F, \omega_{1,b}((1,k),1) F \rangle$ is $\langle F, F \rangle$ if $k \in J \cap \mathbf{K}_0(n)$ and 0 otherwise;

(SH3) either all signs of S agree, or $F = \Psi \otimes_A v^0$ for a finite set A of finite places of E containing the conjugate of none of its members, a place $w \in A$ and some $\Psi \in \mathcal{T}_A$ with $\Psi(x) \ne 0$ only if the $\#n' \times \#n$ matrix x_w has a left inverse;

(SH4) $\omega_{a,b}((1,k),(1,k')) F = F$ for all k, k' in some open subgroups of $G_f(n)$, $G_f(n')$.

Let $L = L_{v\otimes F}$ be the lift of (ED3) for the theta kernel $(\omega_{a,b}, \theta_{\mathrm{Hom}(S,T)})$. Then $A \neq 0$; L maps forms of type e on S to forms of type e' on T; L is injective on the forms of type e that are right invariant under J; and for every such form y and every form y' of type e on S,

$$\langle Ly', Ly\rangle_T = A\, c\, \langle y', R_\Sigma y\rangle_S = \sum_q A\, c\, \mathrm{mc}_{b,\Sigma}(u_q)\, \langle y',\, y(\,\cdot\, u_q)\rangle_S,$$

the series absolutely convergent, R_Σ the Rallis series of (S, T, b, Σ) and q running over

$$\mathrm{U}(S)(\mathbb{A}_{F,f})/K_\Sigma.$$

Proof. **Step 0: preliminaries.**

(i) By Lemma 6.3.77, $(\omega_{a,b}, \theta_{\mathrm{Hom}(S,T)})$ is a theta kernel for (S, T) on $\mathrm{Hom}(S, T)$ with real part Ω, and L is the theta lift Θ_φ of Theorem 6.5.13 for $(\alpha, \beta) = (a, b)$.

(ii) By (ED4)(a), e is a cusp kernel of order 0, in particular an integrable idempotent kernel. Forms of type e are continuous, bounded, left invariant under Γ_S, have a level (ED2), and are rapidly decreasing in the height: $\sup |F|\, \mathrm{ht}_S^N < \infty$ for every N, by Lemma 6.3.75 for the cusp kernel e of order 0; so they satisfy the decay hypothesis of Theorem 6.5.13, which is stated in this height form. They are integrable on $[\mathrm{U}(S)]$, which has finite volume.

(iii) φ is a datum whose Fock vector is a Schwartz vector, and it is clean: under the first alternative of (SH3) this is (DC1) of Theorem 6.5.13; under the second, $\varphi = v \otimes (\Psi \otimes_A v^0)$ is the datum of (v, Ψ) at A ((WR6)), and Ψ, a combination of the functions τ_y, is a Schwartz–Bruhat function of the components at A; this is (DC2).

(iv) For $x \in G_\infty(s)$ and $k \in G_f(n)$, $\langle \varphi, \omega_{a,b}((x,k),1)\varphi\rangle = \langle v, \Omega(x,1)v\rangle\, \langle F, \omega_{1,b}((1,k),1)F\rangle$. Indeed $a(\det 1) = 1$, so $\omega_{a,b}(g,1) = \omega_{1,b}(g,1)$; by (5) of Lemma 4.1.1, $\omega_{a,b}((x,k),1)\varphi = (\Omega(x,1)v)\otimes(\omega_{1,b}((1,k),1)F)$; by (6) of Lemma 6.2.33 the inner product is $\langle v, \Omega(x,1)v\rangle\langle v_1 \otimes F, v_1 \otimes \omega_{1,b}((1,k),1)F\rangle$; and $v_1 \otimes \omega_{1,b}((1,k),1)F = \omega_{1,b}((1,k),1)(v_1 \otimes F) = \omega_{1,b}((1,k),1)F$ by (5) of Lemma 4.1.1 at $x = 1$ and (SH1).

(v) For $x \in G_\infty(s)$, $|\langle v, \Omega(x,1)v\rangle| \leq \langle v, v\rangle$: $\Omega(x,1)$ is a scalar of modulus 1 (determinants of the unitary matrices x_v) times the unitary operator $\omega_\varepsilon^\infty(\cdot)$ ((2) of Lemma 4.1.1). As e is integrable, the integral defining A converges absolutely; it is not 0 by (ED4)(b), and $\mathrm{vol}([\mathrm{U}(T)]) > 0$, $\lambda_S > 0$; so $A \neq 0$.

Step 1: the character b is unramified on K'_Σ, and $K'_\Sigma \subseteq J$. Let $k \in K'_\Sigma$ (integral, with components 1 off Σ). By Lemma 6.5.6 applied to F (a vacuum above Σ by (SH1)) with $\gamma = k$ and $g = 1$, $\langle F, \omega_{1,b}((1,k),1)F\rangle = \mathrm{mc}(k)\langle F, F\rangle$. By (WR4), $\mathrm{mc}(k) = b(\det k)^{-1}\langle v^0, \omega_{s'\otimes s}(k')v^0\rangle$ with $k' = 1 \otimes (k^{-1})^{\mathsf{T}}$, and $\omega_{s'\otimes s}(k')v^0 = \omega_{1,1}((1,k),1)(v_1 \otimes v^0) = v^0$ by (6) of Lemma 4.1.1 and (4) of Lemma 6.2.33; so $\mathrm{mc}(k) = b(\det k)^{-1}$ (as $\langle v^0, v^0\rangle = 1$), of modulus 1. Hence the coefficient is not 0, and (SH2) gives $k \in J \cap \mathbf{K}_0(n)$ and $\mathrm{mc}(k)\langle F, F\rangle = \langle F, F\rangle$, i.e. $b(\det k) = 1$. So the hypotheses of (2) and (3) of Proposition 6.5.4 hold for $\beta = b$, and every J-invariant function is K'_Σ-invariant.

Step 2: L maps forms of type e to forms of type e'. By (SH4) and (5) of Lemma 4.1.1 at real points 1, $\omega_{a,b}((1,k),(1,k'))\varphi = v \otimes \omega_{a,b}((1,k),(1,k'))F = \varphi$ for k' in an open subgroup U' of $G_f(n')$, so for a form y of type e and $h \in \mathrm{G}(s')$,

$$Ly(h(1,k')) = \int \theta(\omega_{a,b}(g,h)\omega_{a,b}(1,(1,k'))\varphi)y(g)\, dg = Ly(h)\,:$$

Ly has the level U'. By (ED4)(c), applied to the half edge v, the theta kernel of Step 0 (i), $f = F$ and y, Ly is a form of type e' on T.

Step 3: the Rallis integral, cut into cosets. Let y be a J-invariant form of type e and y' a form of type e. By Step 0 (ii), (iii) and Theorem 6.5.13,

$$\langle Ly', Ly\rangle_T = \mathrm{vol}([\mathrm{U}(T)]) \int_{\mathrm{G}(s)} \langle \varphi, \omega_{a,b}(g,1)\varphi\rangle \, \langle y', R(g)y\rangle_S \, dg,$$

absolutely convergent. With $dg = \lambda_S \, dx \, dk$ and Fubini, for almost every x the function

$$h_x(k) = \langle \varphi, \omega_{a,b}((x,k),1)\varphi\rangle \langle y', R((x,k))y\rangle_S$$

is integrable on $G_f(n)$, and $\langle Ly', Ly\rangle_T = \mathrm{vol}([\mathrm{U}(T)])\lambda_S \iint h_x(k)\, dk\, dx$. The group K_Σ is open, so $G_f(n) = \bigsqcup_q u_q K_\Sigma$ is a countable disjoint union of open cosets, and by left invariance of dk, $\int h_x = \sum_q \int_{K_\Sigma} h_x(u_q\kappa)\, d\kappa$, absolutely convergent. For $\kappa \in K_\Sigma$, Step 0 (iv), Lemma 6.5.6 applied to F (with $\gamma = u_q$, supported on Σ, and $g = (1,\kappa)$, $\kappa_v \in K_v$ for $v \in \Sigma$) and (SH2) give

$$\langle \varphi, \omega_{a,b}((x,u_q\kappa),1)\varphi\rangle = \langle v, \Omega(x,1)v\rangle \, \mathrm{mc}(u_q) \, \langle F, F\rangle \, \mathbf{1}_{J\cap \mathbf{K}_0(n)}(\kappa),$$

and for $\kappa \in J$, $y(g(x,u_q\kappa)) = y(g(x,1)(1,u_q))$ by the J-invariance of y. As $dk(J \cap \mathbf{K}_0(n)) = [\mathbf{K}_0(n) : J \cap \mathbf{K}_0(n)]^{-1}$,

$$\int_{K_\Sigma} h_x(u_q\kappa)\, d\kappa = c \, \langle v, \Omega(x,1)v\rangle \, \mathrm{mc}(u_q) \, \big\langle y', y(\,\cdot\,(x,1)u_q)\big\rangle_S,$$

and summing over q with (1) of Proposition 6.5.4 (y bounded, measurable and left invariant, y' integrable), $\int h_x = c \, \langle v, \Omega(x,1)v\rangle \, \langle y', z(\,\cdot\,(x,1))\rangle_S$ with $z = R_\Sigma y$.

Step 4: the real integral. By Step 1, (2) of Proposition 6.5.4 applies to y (bounded, continuous, left invariant, right invariant under $K'_\Sigma \subseteq J$ and under an open subgroup): z is bounded, continuous, left invariant under Γ_S, has a level, and $R(e)z = R_\Sigma(R(e)y) = z$, as R_Σ commutes with convolution by the integrable e and $R(e)y = y$. So z is a form of type e, and by Lemma 6.3.78 (e an idempotent kernel), $\langle y', z(\,\cdot\,(x,1))\rangle_S = \frac{\overline{e(x)}}{e(1)}\langle y', z\rangle_S$. Hence, by Step 0 (v),

$$\langle Ly', Ly\rangle_T = \mathrm{vol}([\mathrm{U}(T)])\, \lambda_S \, c \, \langle y', z\rangle_S \int \langle v, \Omega(x,1)v\rangle \frac{\overline{e(x)}}{e(1)}\, dx = A \, c \, \langle y', R_\Sigma y\rangle_S.$$

By (1) of Proposition 6.5.4 at $x = 1$, $\langle y', R_\Sigma y\rangle_S = \sum_q \mathrm{mc}(u_q)\langle y', y(\,\cdot\,u_q)\rangle_S$, absolutely convergent; this is the displayed formula.

Step 5: injectivity. Let y be a J-invariant form of type e with $Ly = 0$, and $z = R_\Sigma y$, a form of type e by Step 4. The formula with $y' = z$ gives $0 = \langle Lz, Ly\rangle_T = A \, c \, \langle z, z\rangle_S$. Here $A \neq 0$ (Step 0 (v)) and $c \neq 0$ (SH1), so $\int_{[\mathrm{U}(S)]} |z|^2 = 0$; z is continuous and the quotient measure gives positive mass to the image of every nonempty open set, so $z = 0$. As y is bounded and right invariant under K'_Σ, (3) of Proposition 6.5.4 gives $y = 0$. □

This group proves the Rallis inner product formula in the form used for the single lifts (Theorem 6.5.13): for spaces with $2\,\mathrm{rk}\, S < \mathrm{rk}\, T$, rapidly decreasing functions y, y' on $[\mathrm{U}(S)]$ and Schwartz data φ, φ' with φ clean,

$$\big\langle \Theta_{\varphi'} y', \Theta_\varphi y\big\rangle_T = \mathrm{vol}([\mathrm{U}(T)]) \int_{\mathrm{U}(S)(\mathbb{A}_F)} \langle \varphi', \omega(g,1)\varphi\rangle \, \langle y', R(g)y\rangle_S \, dg,$$

both sides converging absolutely. The formula goes back to Rallis [237, 238] and the doubling method [231], through the Siegel–Weil formula [280, 323]; for unitary groups see [187, 121, 139,

190, 331, 94]. In Li's theorem the forms are cusp forms; here they are rapidly decreasing, and the cleanness of the datum takes the place of cuspidality.

The proof doubles the space, computes the integral over $[\mathrm{U}(T)]$ by the Siegel–Weil formula on the theta model (Proposition 6.5.15), and uses cleanness to select the Lagrangians: a Lagrangian with a nonzero term is the graph of a rational isometry (Lemma 6.5.14), whose term is a matrix coefficient of the Weil representation, so that the sum unfolds to the integral over $\mathrm{U}(S)(\mathbb{A}_F)$. The Siegel–Weil formula is proved in the group: the terms are summable by the convergence of Siegel Eisenstein series [184, 208], a uniform majorant comes from Weil's convergence criterion [323, 139], and Weil's identity in the convergent range (Theorem A.4.28; see also [121]) is carried to the theta model by the comparison in every rational polarisation (Lemma 6.5.22). That comparison is derived from Weil's theta transform and metaplectic group [322], Kudla's splitting [172] and the Stone–von Neumann theorem in Mackey's form [195].

Theorem 6.5.13. *Let S, T be spaces with $2\operatorname{rk} S < \operatorname{rk} T$, let α, β be automorphic characters of $\mathrm{U}(1)$, and write $\omega = \omega_{\alpha,\beta}$, $\theta = \theta^{S,T}_{\alpha,\beta}$. Let dg be the Haar measure on $\mathrm{U}(S)(\mathbb{A}_F)$ whose quotient by the counting measure on $\mathrm{U}(S)(F)$ is the measure of $[\mathrm{U}(S)]$; let $\langle\cdot,\cdot\rangle$ be the L^2 inner product on data, $\langle F, F'\rangle_V = \int_{[\mathrm{U}(V)]} \overline{F(x)}\, F'(x)\, dx$ for functions on $[\mathrm{U}(V)]$ (both conjugate-linear in the first argument), and R right translation. For a datum φ and a function y on $[\mathrm{U}(S)]$ the theta lift is*

$$(\Theta_\varphi y)(h) = \int_{[\mathrm{U}(S)]} \theta(\varphi)(g,h)\, y(g)\, dg \qquad (h \in \mathrm{U}(T)(\mathbb{A}_F)).$$

Let φ, φ' be finite sums of data whose Fock vectors are Schwartz vectors, and suppose that φ is clean*: either*

(DC1) *all signs of S agree; or*

(DC2) *there are a set A of finite places of E containing no two conjugate places, a place $w \in A$ and a Schwartz–Bruhat function Ψ of the components above A of $x \in \operatorname{Hom}(S,T)(\mathbb{A}_E)$, with $\Psi(x) \neq 0$ only if the $\operatorname{rk} T \times \operatorname{rk} S$ matrix x_w over E_w has a left inverse, such that φ is Ψ at the places of A times a datum at the other places.*

Let y, y' be continuous functions on $\mathrm{U}(S)(\mathbb{A}_F)$, left invariant under $\mathrm{U}(S)(F)$, right invariant under an open subgroup of $\mathrm{U}(S)(\mathbb{A}_{F,f})$, and rapidly decreasing in the height: for every $N \geq 0$, $|y|\,\mathrm{ht}_S^N$ and $|y'|\,\mathrm{ht}_S^N$ are bounded on $\mathrm{U}(S)(\mathbb{A}_F)$. Then:

1. *the function $(g', g, h) \mapsto \overline{y'(g')\,\theta(\varphi')(g',h)}\; y(g)\,\theta(\varphi)(g,h)$ is integrable on $[\mathrm{U}(S)] \times [\mathrm{U}(S)] \times [\mathrm{U}(T)]$, and $g \mapsto \langle \varphi', \omega(g,1)\varphi\rangle\, \langle y', R(g)y\rangle_S$ is integrable on $\mathrm{U}(S)(\mathbb{A}_F)$;*
2. $$\big\langle \Theta_{\varphi'} y',\, \Theta_\varphi y \big\rangle_T = \operatorname{vol}([\mathrm{U}(T)]) \int_{\mathrm{U}(S)(\mathbb{A}_F)} \big\langle \varphi', \omega(g,1)\varphi \big\rangle\, \big\langle y', R(g)y \big\rangle_S\, dg.$$

Proof. The argument is the doubling method of [238] in the form of [187], Section 2, with cleanness in place of cuspidality. Let s on n and s' on n' be the signs of S and T, so $\#n' > 2\#n$, and write $\omega = \omega_{\alpha,\beta}$, $\theta = \theta^{S,T}_{\alpha,\beta}$, $\Theta = \Theta_S$. Let $W = S \oplus S^-$, with signs $s \sqcup (-s)$ on $n \sqcup n$ and matrix $J_W = \operatorname{diag}(J_S, -J_S)$, let $c = c_{S,T}$ be as in Lemma 6.4.56 (stated with the conjugate cj of (WR7)), and $\mathrm{dbl} = \mathrm{dbl}_c$ the doubled datum of (WR7): $\mathrm{dbl}(\varphi_1, \varphi_1') = \varphi_1 \boxtimes^{\mathrm{sc}} c\,\mathrm{cj}\,\varphi_1' \in \mathcal{M}_{W,T}$ for $\varphi_1, \varphi_1' \in \mathcal{M}_{S,T}$ ((1) of Lemma 6.4.56). Under (DC2), Ψ is read as the function $x \mapsto \Psi(x_A)$ of finite adelic matrices, an element of $\mathcal{T}_A$ by Lemma 6.2.22, and "φ is Ψ at the places of A times a datum at the other places" means $\varphi = \Psi \otimes_A \varphi_0$ for some $\varphi_0 \in \mathcal{M}_{S,T}$.

Step 1: the doubling identity for theta kernels. For $\varphi_1, \varphi_1' \in \mathcal{M}_{S,T}$ and $h \in \mathrm{G}(s')$,

$$\theta^{W,T}_{\upsilon^{\#n},1}(\mathrm{dbl}(\varphi_1,\varphi_1'))(1,h) = \Theta(\omega(1,h)\varphi_1)\,\overline{\Theta(\omega(1,h)\varphi_1')}. \tag{6.119}$$

Put $\alpha' = \alpha^{-1}\upsilon^{\#n}$ and $\beta' = \beta^{-1}\upsilon^{\#n'}$, so $\alpha\alpha' = \upsilon^{\#n}$. By (a) of Lemma 6.3.52 for $S_1 = S$, $S_2 = S^-$, the characters α, α' on the side of T and 1 on the side of the source, and $g_1 = g_2 = 1$,

$$\omega^{W,T}_{\upsilon^{\#n},1}(1,h)\,\mathrm{dbl}(\varphi_1,\varphi_1') = \omega^{S,T}_{\alpha,1}(1,h)\varphi_1 \boxtimes^{\mathrm{sc}} \omega^{S^-,T}_{\alpha',1}(1,h)\,c\,\mathrm{cj}\,\varphi_1',$$

and at the point $(1,h)$ the character of the source is irrelevant (WR4), so the factors are $\omega(1,h)\varphi_1$ and $c\,\omega^{S^-,T}_{\alpha',\beta'}(1,h)\,\mathrm{cj}\,\varphi_1' = c\,\mathrm{cj}\,\omega(1,h)\varphi_1'$ ((2) of Lemma 6.4.56). By (c) of Lemma 6.3.52 the theta functional of $\mathrm{Hom}(W,T)$ at this product is $\Theta(\omega(1,h)\varphi_1)\,\Theta_{S^-}(c\,\mathrm{cj}\,\omega(1,h)\varphi_1')$, and the second factor is $\overline{\Theta(\omega(1,h)\varphi_1')}$ by (3) of Lemma 6.4.56. This is (6.119). For $g, g' \in \mathrm{G}(s)$ put $\varphi^{\mathrm{d}}_{g,g'} = \mathrm{dbl}(\omega(g,1)\varphi, \omega(g',1)\varphi')$; as ω is a representation of $\mathrm{G}(s)\times\mathrm{G}(s')$ ((2) of Lemma 4.1.1), $\omega(1,h)\omega(g,1) = \omega(g,h)$, and (6.119) becomes

$$\theta^{W,T}_{\upsilon^{\#n},1}(\varphi^{\mathrm{d}}_{g,g'})(1,h) = \theta(\varphi)(g,h)\,\overline{\theta(\varphi')(g',h)}. \tag{6.120}$$

Step 2: the Siegel–Weil formula and the graphs. W has the splitting $(k,l,\emptyset)$ over the zero space $V_\emptyset$ ((MX13) of Definition 4.1.18) along a copy p of n with $k = \begin{pmatrix} 1 \\ -1 \end{pmatrix}$ and $l = \frac{1}{2}\begin{pmatrix} J_S^{-1} \\ J_S^{-1} \end{pmatrix}$: $k^* J_W k = J_S - J_S = 0$, $l^* J_W l = \frac{1}{4}(J_S^{-1} - J_S^{-1}) = 0$, $l^* J_W k = \frac{1}{2} + \frac{1}{2} = 1$ (J_S is hermitian), and $\#(n \sqcup n) = 2\#p$. As $\#n' > 2\#p$, Proposition 6.5.15 applies to (W,T): $M = \sum_L \|Z_L\| < \infty$, and for every g, g' the function $h \mapsto \theta^{W,T}_{\upsilon^{\#n},1}(\varphi^{\mathrm{d}}_{g,g'})(1,h)$ is integrable on $[\mathrm{U}(T)]$ with integral $\mathrm{vol}([\mathrm{U}(T)])\sum_L Z_L(\varphi^{\mathrm{d}}_{g,g'})$. By Lemma 6.5.14, applied to φ (whose hypotheses are (DC1), resp. (DC2) in the form above), g and the datum $\omega(g',1)\varphi'$, every rational Lagrangian L with $Z_L(\varphi^{\mathrm{d}}_{g,g'}) \neq 0$ is $\{(\delta_0 y, y) : y \in E^n\}$ for a unique $\delta_0 \in \mathrm{U}(S)(F)$; substituting $y = -u$, it is $L_\delta = \{(\delta^{-1}u, -u)\}$ for $\delta = -\delta_0^{-1} \in \mathrm{U}(S)(F)$. Conversely each L_δ is a graph of this kind, and $\delta \mapsto L_\delta$ is injective (L_δ determines the linear map $u \mapsto \delta^{-1}u$). Hence $\sum_L Z_L(\varphi^{\mathrm{d}}_{g,g'}) = \sum_{\delta\in\mathrm{U}(S)(F)} Z_{L_\delta}(\varphi^{\mathrm{d}}_{g,g'})$, and by Lemma 6.5.23 and the invariance of the inner product under $\omega(g',1)$ ((2) of Lemma 4.1.1; the characters have modulus one),

$$Z_{L_\delta}(\varphi^{\mathrm{d}}_{g,g'}) = \langle \omega(g',1)\varphi',\, \omega(x_S^{-1}\delta x_S, 1)\,\omega(g,1)\varphi\rangle = \langle \varphi',\, \omega(g'^{-1}\gamma g, 1)\varphi\rangle, \qquad \gamma = x_S^{-1}\delta x_S.$$

As δ runs over $\mathrm{U}(S)(F)$, γ runs over Γ_S once. With (6.120), for all $g, g' \in \mathrm{G}(s)$,

$$\int_{[\mathrm{U}(T)]} \theta(\varphi)(g,h)\,\overline{\theta(\varphi')(g',h)}\,dh = \mathrm{vol}([\mathrm{U}(T)])\sum_{\gamma\in\Gamma_S}\langle \varphi', \omega(g'^{-1}\gamma g,1)\varphi\rangle, \tag{6.121}$$

the integrand integrable and the series absolutely convergent, $|Z_{L_\delta}(\varphi^{\mathrm{d}}_{g,g'})| \le \|Z_{L_\delta}\|\,\|\varphi^{\mathrm{d}}_{g,g'}\|$.

Step 3: bounds in the heights. The L^1 norm of a source product is the product of the norms (the measure of $\mathrm{Hom}(W,T)$ is the product of those of the two factors, (WR6), and Tonelli), cj is isometric ((1) of Lemma 6.4.56) and $|c| = 1$; so $\|\varphi^{\mathrm{d}}_{g,g'}\| = \|\omega(g,1)\varphi\|\,\|\omega(g',1)\varphi'\|$. With N of (2) of Proposition 6.5.15 for (W,T) and (6.120), and with Step 2,

$$\int_{[\mathrm{U}(T)]} |\theta(\varphi)(g,h)|\,|\theta(\varphi')(g',h)|\,dh \le \|N\|_1\,P(g,g'), \qquad \sum_{\gamma\in\Gamma_S}\big|\langle \varphi', \omega(g'^{-1}\gamma g,1)\varphi\rangle\big| \le M\,P(g,g'),$$

where $P(g,g') = \|\omega(g,1)\varphi\|\,\|\omega(g',1)\varphi'\|$ and $\|N\|_1 = \int_{[\mathrm{U}(T)]} N < \infty$. Both left sides are unchanged when g and g' are replaced by $\gamma_1 g$ and $\gamma_2 g'$ with $\gamma_1, \gamma_2 \in \Gamma_S$: the first because

$\theta(\varphi)(\gamma_1 g, h) = \theta(\varphi)(g,h)$ (Lemma 6.2.5), the second by the substitution $\gamma \mapsto \gamma_2\gamma\gamma_1^{-1}$ of Γ_S. Let Y, A be the constants of Lemma 6.2.28 for (S,T), and by its clause (2) choose $\gamma_1, \gamma_2 \in \Gamma_S$ with

$$\|\omega(\gamma_1 g, 1)\varphi\| \le Y \mathrm{ht}_S(g)^A \|\varphi\| \quad \text{and} \quad \|\omega(\gamma_2 g', 1)\varphi'\| \le Y \mathrm{ht}_S(g')^A \|\varphi'\|.$$

With $K = \max(\|N\|_1, M)\, Y^2 \|\varphi\|\, \|\varphi'\|$ this gives, for all $g, g' \in \mathrm{G}(s)$,

$$\begin{aligned} \int_{[\mathrm{U}(T)]} |\theta(\varphi)(g,h)\, \theta(\varphi')(g',h)|\, dh &\le K\, \mathrm{ht}_S(g)^A \mathrm{ht}_S(g')^A, \\ \sum_{\gamma \in \Gamma_S} |\langle \varphi', \omega(g'^{-1}\gamma g, 1)\varphi\rangle| &\le K\, \mathrm{ht}_S(g)^A \mathrm{ht}_S(g')^A. \end{aligned} \tag{6.122}$$

Step 4: integration; proof of the first half of (1). By the decay hypothesis there are B, B' with $|y|\, \mathrm{ht}_S^A \le B$ and $|y'|\, \mathrm{ht}_S^A \le B'$ on $\mathrm{G}(s)$. The functions

$$(g', g, h) \mapsto \overline{y'(g')\theta(\varphi')(g',h)}\, y(g)\theta(\varphi)(g,h)$$

are continuous ((2) of Lemma 4.1.1, Θ bounded) and left invariant under $\Gamma_S \times \Gamma_S \times \Gamma_T$ (the invariance of y, y' and Lemma 6.2.5), so they are functions on $[\mathrm{U}(S)] \times [\mathrm{U}(S)] \times [\mathrm{U}(T)]$. By Tonelli and (6.122) the integral of their absolute value is at most $K\, B\, B'\, \mathrm{vol}([\mathrm{U}(S)])^2$, which is finite since $[\mathrm{U}(S)]$ has finite volume (Theorem 4.2.18; for $\#n = 0$ the group is trivial). This is the first half of (1). For every h the integral defining $(\Theta_\varphi y)(h)$ converges absolutely, as $|\theta(\varphi)(g,h)| \le Y\|\varphi\|(\mathrm{ht}_S(g)\mathrm{ht}_T(h))^A$ ((1) of Lemma 6.2.28) and $|y|\mathrm{ht}_S^A \le B$; by Fubini and (6.121),

$$\begin{aligned} \langle \Theta_{\varphi'} y', \Theta_\varphi y\rangle_T &= \int_{[\mathrm{U}(S)]^2} \overline{y'(g')}\, y(g) \int_{[\mathrm{U}(T)]} \overline{\theta(\varphi')(g',h)}\, \theta(\varphi)(g,h)\, dh\, dg\, dg' \\ &= \mathrm{vol}([\mathrm{U}(T)]) \int_{[\mathrm{U}(S)]^2} \overline{y'(g')}\, y(g) \sum_{\gamma \in \Gamma_S} \langle \varphi', \omega(g'^{-1}\gamma g, 1)\varphi\rangle\, dg\, dg'. \end{aligned}$$

Step 5: unfolding; proof of the second half of (1) and of (2). The quotient measure of $[\mathrm{U}(S)]$ is defined by $\int_{[\mathrm{U}(S)]} \sum_{\gamma\in\Gamma_S} \Phi(\gamma g)\, dg = \int_{\mathrm{G}(s)} \Phi(x)\, dx$ for nonnegative measurable Φ, hence for integrable Φ, and dx is left invariant. Fix g' and apply this to $\Phi(x) = y(x)\langle \varphi', \omega(g'^{-1}x, 1)\varphi\rangle$, then substitute $x \mapsto g'x$: as $y(\gamma g) = y(g)$,

$$\int_{[\mathrm{U}(S)]} y(g) \sum_{\gamma\in\Gamma_S} \langle \varphi', \omega(g'^{-1}\gamma g, 1)\varphi\rangle\, dg = \int_{\mathrm{G}(s)} y(g'x)\, \langle \varphi', \omega(x,1)\varphi\rangle\, dx,$$

first for the absolute values, which by (6.122) and $|y|\mathrm{ht}_S^A \le B$ gives a finite value at most $K\, B\, \mathrm{vol}([\mathrm{U}(S)])\, \mathrm{ht}_S(g')^A$, then as stated. Multiplying by $\overline{y'(g')}$, the function

$$(g', x) \mapsto \overline{y'(g')}\, y(g'x) \langle \varphi', \omega(x,1)\varphi\rangle$$

is integrable on $[\mathrm{U}(S)] \times \mathrm{G}(s)$ (its integral in absolute value is at most $K\, B\, B'\, \mathrm{vol}([\mathrm{U}(S)])^2$; it is invariant under $g' \mapsto \gamma g'$), and Fubini gives

$$\langle \Theta_{\varphi'} y', \Theta_\varphi y\rangle_T = \mathrm{vol}([\mathrm{U}(T)]) \int_{\mathrm{G}(s)} \langle \varphi', \omega(x,1)\varphi\rangle \int_{[\mathrm{U}(S)]} \overline{y'(g')}\, y(g'x)\, dg'\, dx.$$

The inner integral is $\langle y', R(x)y\rangle_S$, and the integrability of the function of (g', x) shows that $x \mapsto \langle \varphi', \omega(x,1)\varphi\rangle \langle y', R(x)y\rangle_S$ is integrable on $\mathrm{G}(s) = \mathrm{U}(S)(\mathbb{A}_F)$, with dx the measure dg of the statement. This is the second half of (1), and the display is (2). $\square$

Lemma 6.5.14. *Let S, T be spaces with signs s on n and s' on n', α, β automorphic characters of $\mathrm{U}(1)$, $\omega = \omega_{\alpha,\beta}$, and $W = S \oplus S^-$, with matrix $\mathrm{diag}(J_S, -J_S)$, so that $W(E) = S(E) \oplus S^-(E) = E^n \oplus E^n$. Let $\varphi, \varphi' \in \mathcal{M}_{S,T}$ and suppose that either all signs of S agree, or there are a finite set A of finite places of E containing the conjugate of none of its members, a place $w \in A$, a function $\Psi \in \mathcal{T}_A$ with $\Psi(x) \neq 0$ only if the $n' \times n$ matrix x_w over E_w has a left inverse, and $\varphi_0 \in \mathcal{M}_{S,T}$ with $\varphi = \Psi \otimes_A \varphi_0$. Let $g \in \mathrm{U}(S)(\mathbb{A}_F)$ and $\varphi_{\mathrm{d}} = \mathrm{dbl}_{c_{S,T}}(\omega(g,1)\varphi, \varphi')$. If L is a rational Lagrangian of W with $Z_L(\varphi_{\mathrm{d}}) \neq 0$, then*

$$L \cap (S \oplus 0) = 0 = L \cap (0 \oplus S^-),$$

and there is a unique $\delta \in \mathrm{U}(S)(F)$ with $L = \{(\delta y, y) : y \in S(E)\}$.

Proof. **Step 1: standard properties used.** The following are properties of the Weil and Heisenberg representations ([322]; for unitary dual pairs [121], Section 1):

(a) for $g \in \mathrm{U}(S)(\mathbb{A}_F)$ and $h \in \mathrm{Hom}(S,T)(\mathbb{A}_E)$, $\omega(g,1)\,\varrho(h)\,\omega(g,1)^{-1} = \varrho(h \circ g^{-1})$ (the splitting characters only multiply $\omega(g,1)$ by a scalar);

(b) for $h \in \mathrm{Hom}(S,T)(\mathbb{A}_E)$, the Heisenberg operator of $(h,0) \in \mathrm{Hom}(W,T)(\mathbb{A}_E)$ acts on a doubled datum through its first factor: $\varrho_W((h,0))$ applied to the doubled datum of (φ_1, φ_1') is the doubled datum of $(\varrho(h)\varphi_1, \varphi_1')$;

(c) the term Z_L is invariant under $\varrho_W(k)$ for every $k \in \mathrm{Hom}(W,T)(\mathbb{A}_E)$ vanishing on L: write $Z_L(d) = (\omega_W(\gamma)d)(0)$ in the Schrödinger model on $\mathrm{Hom}(W^+,T)(\mathbb{A}_E)$ of a polarisation $W = W^+ \oplus W^-$, with $\gamma \in \mathrm{U}(W)(F)$ and $\gamma^{-1}W^+ = L$; then $\omega_W(\gamma)\varrho_W(k)\omega_W(\gamma)^{-1} = \varrho_W(k \circ \gamma^{-1})$, and $k \circ \gamma^{-1}$ vanishes on W^+, so it acts in this model by multiplication by a character of value 1 at 0;

(d) at a finite place v split as $w\bar{w}$, the operator $\varrho(h)$ of an h whose only nonzero component is at $\bar{w}$ acts in the Schrödinger model by multiplication by $x_w \mapsto \psi_{\mathrm{add},v}(B_v(h_{\bar{w}}, x_w))$, where B_v is the restriction of the symplectic form to $\mathrm{Hom}(S,T)(E_{\bar{w}}) \times \mathrm{Hom}(S,T)(E_w)$, a perfect pairing. For h of rank one, $h(x) = z\langle x, u\rangle_S$ ($z \in T(E_{\bar{w}})$, $u \in S(E_w)$), one has $B_v(h, x_w) = \lambda_v(z, x_w u)$ with $\lambda_v \colon T(E_{\bar{w}}) \times T(E_w) \to F_v$ a perfect F_v-bilinear pairing (the trace of the form of T multiplied by the fixed purely imaginary element defining the symplectic form).

Step 2: $L \cap (S \oplus 0) = 0$. Suppose $(u,0) \in L$ with $u \in S(E)$, $u \neq 0$. Since L is isotropic, $\langle u, u\rangle_S = 0$. If all signs of S agree, then at every real place the form of S is definite; as $S(E)$ embeds in its completions, S is anisotropic and $u = 0$, a contradiction. Otherwise $\varphi = \Psi \otimes_A \varphi_0$ as in the statement; every $w' \in A$ lies over a split place, A containing no two conjugate places; Ψ, a finite combination of the functions τ_y of (WR6), is a locally constant, compactly supported function of $x_A = (x_{w'})_{w' \in A}$; and $\Psi(x_A) \neq 0$ only if x_{w_0} has a left inverse, $w_0 \in A$ the place of the statement, over v_0. Define the linear functional $\ell(\varphi_1) = Z_L(\varphi_{\mathrm{d},\varphi_1})$, $\varphi_{\mathrm{d},\varphi_1}$ the doubled datum of $(\omega(g,1)\varphi_1, \varphi')$. For $z \in T(\mathbb{A}_E)$ let $k_z \in \mathrm{Hom}(S,T)(\mathbb{A}_E)$ be $k_z(x) = z\langle x, u\rangle_S$, and $h_z = k_z \circ g$, i.e. $h_z(x) = z\langle x, u_g\rangle_S$ with $u_g = g^{-1}u$. The map $(x,y) \mapsto k_z(x) = z\langle (x,y), (u,0)\rangle_W$ vanishes on L, because $(u,0) \in L$ and L is isotropic. By (a), (b), (c),

$$\ell(\varrho(h_z)\varphi_1) = Z_L\big(\varrho_W((k_z,0))\,\varphi_{\mathrm{d},\varphi_1}\big) = \ell(\varphi_1) \qquad \text{for all } z \text{ and } \varphi_1.$$

Now take z with only one nonzero component, at $\bar{w}_0$. The component u_{g,w_0} is nonzero, since g is invertible and $u \neq 0$. For x_A in the support of Ψ, x_{w_0} is injective, so $x_{w_0}u_{g,w_0} \neq 0$, and as λ_{v_0} is perfect and ψ_{add,v_0} is nontrivial there is z with $\psi_{\mathrm{add},v_0}(\lambda_{v_0}(z, x_{w_0}u_{g,w_0})) \neq 1$. By (d), $\varrho(h_z)$

multiplies data by the locally constant function $\chi_z(x_{w_0}) = \psi_{\mathrm{add},v_0}(\lambda_{v_0}(z, x_{w_0}u_{g,w_0}))$; it acts at the place v_0 only, and commutes with multiplication by functions of x_A. The support of Ψ is compact and Ψ is locally constant, so $\Psi = \sum_j c_j \mathbf{1}_{B_j}$, a finite sum over pairwise disjoint compact open boxes B_j, each so small that χ_{z_j} is constant on B_j with value $\epsilon_j \neq 1$ for a suitable z_j; the functions $x \mapsto \mathbf{1}_{B_j}(x_A)$ lie in $\mathcal{T}_A$ by Lemma 6.2.22, and $\Psi \mapsto \Psi \otimes_A \varphi_0$ is linear (WR6), so $\varphi = \sum_j c_j\, \mathbf{1}_{B_j} \otimes_A \varphi_0$. Then $\varrho(h_{z_j})(\mathbf{1}_{B_j} \otimes_A \varphi_0) = \epsilon_j\, \mathbf{1}_{B_j} \otimes_A \varphi_0$, and the invariance gives $\ell(\mathbf{1}_{B_j} \otimes_A \varphi_0) = \epsilon_j\, \ell(\mathbf{1}_{B_j} \otimes_A \varphi_0)$, so $\ell(\mathbf{1}_{B_j} \otimes_A \varphi_0) = 0$ for every j, and $Z_L(\varphi_{\mathrm{d}}) = \ell(\varphi) = 0$, a contradiction. Hence $L \cap (S \oplus 0) = 0$.

Step 3: L is a graph. By Step 2 the projection $L \to S$, $(x, y) \mapsto y$ onto the second summand is injective; as $\dim L = \operatorname{rk} S$ it is bijective, so $L = \{(\delta y, y) : y \in S(E)\}$ for a unique E-linear map $\delta\colon S(E) \to S(E)$. The form of W vanishes on L: $\langle \delta y, \delta y' \rangle_S = \langle y, y' \rangle_S$ for all y, y', so δ is an isometry of the nondegenerate space S, hence invertible and $\delta \in \mathrm{U}(S)(F)$. Finally $L \cap (0 \oplus S^-) = \{(\delta y, y) : \delta y = 0\} = 0$. □

Proposition 6.5.15. *Let W be a space with a point with signs on an index set m_W, p an index set with $\#m_W = 2\#p$ such that W has a splitting over the zero space $V_\emptyset$ along p, and T a space with a point with signs t on n_T and $\#n_T > 2\#p$. Then every rational Lagrangian L of W is split along p, so that its term $Z_L\colon \mathcal{M}_{W,T} \to \mathbb{C}$ is defined, and:*

1. *the operator norms satisfy $\sum_L \|Z_L\| < \infty$, the sum over the rational Lagrangians of W;*
2. *there is a measurable function $N\colon [\mathrm{U}(T)] \to [0, \infty]$ with finite integral such that*

$$|\theta^{W,T}_{\upsilon^{\#p},1}(d)(1, h)| \leq N(\Gamma_T h)\, \|d\|$$

   for all $h \in \mathrm{G}(t)$ and $d \in \mathcal{M}_{W,T}$;
3. *for every $d \in \mathcal{M}_{W,T}$ the function $h \mapsto \theta^{W,T}_{\upsilon^{\#p},1}(d)(1, h)$ is integrable on $[\mathrm{U}(T)]$ and*

$$\int_{[\mathrm{U}(T)]} \theta^{W,T}_{\upsilon^{\#p},1}(d)(1, h)\, dh = \mathrm{vol}([\mathrm{U}(T)]) \sum_L Z_L(d).$$

Proof. **The terms.** By hypothesis W has a splitting D_0 over $V_\emptyset$ along p. By (1) of Lemma 6.5.16, every rational Lagrangian L of W is split along p, so Z_L is defined (MX13); by (3) of Lemma 6.5.16, $Z_D = Z_L$ for every splitting $D = (k, l, \emptyset)$ of W over $V_\emptyset$ along p with $kE^p = L$.

Clause (1) is Lemma 6.5.17, and **clause (2)** is Lemma 6.5.18.

Clause (3). Let $d \in \mathcal{M}_{W,T}$. The function $h \mapsto \theta^{W,T}_{\upsilon^{\#p},1}(d)(1, h) = \theta_{\mathrm{Hom}(W,T)}(\omega_{\upsilon^{\#p},1}(1, h)d)$ is continuous on $\mathrm{G}(t)$ ((2) of Lemma 4.1.1; the theta functional is bounded) and invariant under left translation by Γ_T (Lemma 6.2.5), hence a measurable function on $[\mathrm{U}(T)]$; by clause (2) it is dominated by $N\, \|d\|$, so it is integrable. The series $\sum_L Z_L(d)$ converges absolutely, since $|Z_L(d)| \leq \|Z_L\|\, \|d\|$ and clause (1). The identity of clause (3) is Lemma 6.5.21. □

Lemma 6.5.16. *Let W be a space with a point with signs on an index set m_W, p an index set with $\#m_W = 2\#p$, $D_0 = (k_0, l_0, i_0)$ a splitting of W over the zero space $V_\emptyset$ along p (i_0 empty), $L_0 = k_0E^p$, and $\mathrm{Stab}(L_0) = \{\delta \in \mathrm{U}(W)(F) : \delta L_0 = L_0\}$. Let T be a space with a point.*

1. *For every rational Lagrangian L of W there is $\delta \in \mathrm{U}(W)(F)$ with $\delta L_0 = L$; for every such δ, $(\delta k_0, \delta l_0, i_0)$ is a splitting of W over $V_\emptyset$ along p with $\delta k_0 E^p = L$; in particular every rational Lagrangian of W is split along p. The map $\delta \mapsto \delta L_0$ induces a bijection from $\mathrm{U}(W)(F)/\mathrm{Stab}(L_0)$ onto the set of rational Lagrangians of W.*

2. *For $\delta \in \mathrm{U}(W)(F)$, all automorphic characters α, β of $\mathrm{U}(1)$ and $d \in \mathcal{M}_{W,T}$,*

$$Z_{\delta L_0}(d) = Z_{L_0}(\omega_{\alpha,\beta}(x_W^{-1}\delta^{-1}x_W, 1)\, d).$$

3. *For every splitting $D = (k, l, i_0)$ of W over $V_\emptyset$ along p, $Z_D = Z_{kE^p}$.*

Proof. **(1).** The form h_W is nondegenerate (J_W is invertible). Let L be a rational Lagrangian; L and L_0 have dimension $\#p$ (for L_0: k_0 has a left inverse $l_0^* J_W$, as $l_0^* J_W k_0 = 1$) and h_W vanishes on both ($k_0^* J_W k_0 = 0$). So every E-linear bijection $\sigma\colon L_0 \to L$ is an isometry between subspaces of (E^{m_W}, h_W), and by Witt's extension theorem (Theorem A.6.7) it extends to some $\delta \in \mathrm{U}(W)(F)$; then $\delta L_0 = L$. For any $\delta \in \mathrm{U}(W)(F)$ with $\delta L_0 = L$, the matrices $k = \delta k_0$, $l = \delta l_0$ satisfy $k^* J_W k = k_0^* J_W k_0 = 0$, $l^* J_W l = 0$, $l^* J_W k = 1$, the conditions on i_0 are empty and $\#m_W = 0 + 2\#p$; so (k, l, i_0) is a splitting of W over $V_\emptyset$ along p, with $kE^p = \delta L_0 = L$. Conversely every δL_0, $\delta \in \mathrm{U}(W)(F)$, is a rational Lagrangian (δ preserves h_W and dimensions). The map $\delta \mapsto \delta L_0$ is constant exactly on the cosets $\delta\mathrm{Stab}(L_0)$, by the definition of $\mathrm{Stab}(L_0)$, and it is onto by the first sentence; this is the bijection.

(3). Let $L = kE^p$, split along p by D, and $D_L = (k', l', i_0)$ the splitting fixed in (MX13), so $k'E^p = L$ and $k^* J_W k' = 0$ (L is isotropic). By (2) of Lemma 6.2.25 it suffices that the splittings of $\mathrm{Hom}(W, T)$ induced by D and D_L satisfy the same condition (their third frames are empty). Their k-frames are $\tilde{k} = J_T^{-1} \otimes (k^* J_W)^{\mathsf{T}}$, $\tilde{k}' = J_T^{-1} \otimes (k'^* J_W)^{\mathsf{T}}$ and the matrix of $\mathrm{Hom}(W, T)$ is $J_T \otimes (J_W^{-1})^{\mathsf{T}}$ (VP5); with $J_T^* = J_T$ and $J_W^{\mathsf{T}} = \overline{J_W}$,

$$\tilde{k}^*(J_T \otimes (J_W^{-1})^{\mathsf{T}})\tilde{k}' = J_T^{-1} \otimes \overline{k^* J_W}\, \overline{J_W^{-1}}\, J_W^{\mathsf{T}}\, \overline{k'} = J_T^{-1} \otimes \overline{k^* J_W k'} = 0.$$

So $Z_D = Z_{D_L} = Z_L$.

(2). Let $g = x_W^{-1}\delta x_W$, an element of Γ_W (VP2). By (1) and (3), $Z_{\delta L_0}$ and Z_{L_0} are the zero terms along the splittings of $\mathrm{Hom}(W, T)$ over $\mathrm{Hom}(V_\emptyset, T)$ induced by $(\delta k_0, \delta l_0, i_0)$ and by D_0. Their adelic k-frames are $b \mapsto x_T^{-1} J_T^{-1}\, b\, k^* J_W\, x_W$ for $k = \delta k_0$ and $k = k_0$ (the point of $\mathrm{Hom}(W, T)$ is $x_T \otimes (x_W^{-1})^{\mathsf{T}}$). As $\delta^* J_W = J_W \delta^{-1}$,

$$x_T^{-1} J_T^{-1}\, b\, (\delta k_0)^* J_W\, x_W = X_b\, g^{-1}, \qquad X_b = x_T^{-1} J_T^{-1}\, b\, k_0^* J_W\, x_W.$$

For $g' \in \mathrm{G}(s)$ the pair element of $(g', 1)$ is $Y \mapsto Y g'^{-1}$ (VP5) and the scalar $\beta(\det g')^{-1}$ cancels under conjugation, so (2) of Lemma 4.1.1 gives $\omega(g', 1)\rho(Y)\omega(g', 1)^{-1} = \rho(Y g'^{-1})$. With $g' = g$ and Lemma 6.2.5 ($g \in \Gamma_W$),

$$\theta(\rho(X_b g^{-1})d) = \theta(\omega(g, 1)\rho(X_b)\omega(g^{-1}, 1)d) = \theta(\rho(X_b)\, \omega(g^{-1}, 1)d).$$

The canonical theta functional of $\mathrm{Hom}(V_\emptyset, T)$ is the identity (WC1, rank 0), so by (MX4) both terms are the means of these functions over $b \in \mathrm{M}_{n' \times p}(\mathbb{A}_E)/\mathrm{M}_{n' \times p}(E)$, and $Z_{\delta L_0}(d) = Z_{L_0}(\omega(g^{-1}, 1)d)$ with $g^{-1} = x_W^{-1}\delta^{-1}x_W$. □

Lemma 6.5.17. *Let W be a space with a point with signs on an index set m_W, p an index set with $\#m_W = 2\#p$ such that W has a splitting over the zero space $V_\emptyset$ along p, and T a space with a point with signs t on n_T and $\#n_T > 2\#p$. Then every rational Lagrangian of W is split along p, and $\sum_L \|Z_L\| < \infty$, the sum over the rational Lagrangians L of W of the operator norms.*

Proof. If $p = \emptyset$, then W has rank 0, its only rational Lagrangian is 0, and its term is a bounded functional on $\mathcal{M}_{W,T} = \mathbb{C}$; the sum has one term. Let $p \neq \emptyset$. Fix a splitting $D_0 = (k_0, l_0, i_0)$ of W over $V_\emptyset$ along p, $L_0 = k_0 E^p$, adelic frames $k_\mathbb{A} = x_W^{-1} k_0$, $l_\mathbb{A} = x_W^{-1} l_0$, and $\mathrm{Stab}(L_0)$ as

in Lemma 6.5.16. By (1) and (3) of Lemma 6.5.16 every rational Lagrangian of W is split along p, and $Z_{L_0} = Z_{D_0}$ is the zero term along the splitting of $\mathrm{Hom}(W,T)$ induced by D_0. Let $\mathrm{G}_{L_0} = \{u \in \mathrm{G}(s) : uk_{\mathbb{A}} = k_{\mathbb{A}} m_u \text{ for some } m_u \in \mathrm{GL}_p(\mathbb{A}_E)\}$; then $m_u = \mathrm{pr}_k\, u\, k_{\mathbb{A}}$ ($\mathrm{pr}_k k_{\mathbb{A}} = l_0^* J_W k_0 = 1$), so $u \mapsto |\det m_u|$ is a continuous homomorphism $\mathrm{G}_{L_0} \to (0,\infty)$, and $\iota(\mathrm{G}_{L_0})$ is the group $\mathrm{Stab}(L_0)(\mathbb{A}_F)$ of adelic points of the stabiliser $\mathrm{Stab}(L_0)$ of L_0 in $\mathrm{U}(W)$ (an algebraic group over F whose rational points form the group $\mathrm{Stab}(L_0)$ of Lemma 6.5.16); m_u is the matrix, in the basis k_0, of the action of $\iota(u)$ on $L_0 \otimes \mathbb{A}_E$.

Step 1: an Iwasawa decomposition. By (1) of Lemma 6.2.46 there is $g_D \in \mathrm{G}(s)$ at which D_0 is adapted in the basis 1: $g_D^{-1}(l_{\mathbb{A}} \,|\, k_{\mathbb{A}})$ has orthonormal columns at the infinite places and entries in $\widehat{\mathcal{O}}_E$ at the finite places. So D_0 is a base-adapted splitting of the moved space $W_{g_D} = (J_W, x_W g_D)$ (same signs), whose adelic frames are $g_D^{-1} l_{\mathbb{A}}$, $g_D^{-1} k_{\mathbb{A}}$. Let $K = K_\infty(s) \times \mathbf{K}_0(m_W)$, a compact subgroup of $\mathrm{G}(s)$. For $g \in \mathrm{G}(s)$, Lemma 6.6.88 for W_{g_D} and D_0 writes $g_D^{-1} g = \mathrm{rad}'(c,b)\,\mathrm{lev}'(m,g_0)\,\kappa$ with $\kappa \in K$, the elements formed with the frames of W_{g_D} (here c and g_0 are empty). By (MX2), $\mathrm{lev}'(m,g_0)$ sends $g_D^{-1} k_{\mathbb{A}}$ to $g_D^{-1} k_{\mathbb{A}} m$, and $\mathrm{rad}'(c,b)$ fixes it (pr_l and pr_i of W_{g_D} vanish on it, by the relations of (MX1)). Hence

$$g = u\, g_D \kappa, \qquad u = g_D\, \mathrm{rad}'(c,b)\,\mathrm{lev}'(m,g_0)\, g_D^{-1} \in \mathrm{G}_{L_0}, \quad m_u = m, \quad \kappa \in K. \tag{6.123}$$

Put $H(g) = |\det m_u|$ for any such decomposition: if $u_1 g_D \kappa_1 = u_2 g_D \kappa_2$, then $u_2^{-1} u_1 \in \mathrm{G}_{L_0} \cap g_D K g_D^{-1}$, a compact group, on which the continuous homomorphism $|\det m.|$ is 1; so H is well defined, and $H(ug) = |\det m_u|\, H(g)$ for $u \in \mathrm{G}_{L_0}$.

Step 2: the norm of a translated term. Let $C_K = \sup_{\kappa \in K} \|\omega(g_D\kappa, 1)\|$. It is finite: $\mathcal{M}_{W,T}$ is a Banach space ((1) of Lemma 4.1.10), for each d the map $\kappa \mapsto \omega(g_D\kappa,1)d$ is continuous on the compact set K ((2) of Lemma 4.1.1), hence bounded, and the uniform boundedness principle applies. The zero term Z_{L_0} along the induced splitting is bounded ((7) of Lemma 4.1.1). By the law of the zero term in (2) of Lemma 6.2.45 (its case $x = 0$, with $\alpha = \beta = 1$, $h = 1$; g_0 is trivial and $\omega_{1,1}(g_0,1)$ is the identity of $\mathcal{M}_{V_\emptyset,T} = \mathbb{C}$, and the character there has modulus one), $|Z_{L_0}(\omega(u,1)F)| = |\det m_u|^{n'/2} |Z_{L_0}(F)|$ for $u \in \mathrm{G}_{L_0}$, $F \in \mathcal{M}_{W,T}$. With (6.123) and as ω is a representation,

$$\big\|Z_{L_0} \circ \omega(g,1)\big\| \le C_K\, \|Z_{L_0}\|\, H(g)^{n'/2} \qquad (g \in \mathrm{G}(s)). \tag{6.124}$$

Step 3: from Lagrangians to cosets. By Lemma 6.5.16, $\delta \mapsto \delta L_0$ is a bijection from $\mathrm{U}(W)(F)/\mathrm{Stab}(L_0)$ onto the rational Lagrangians, and $Z_{\delta L_0} = Z_{L_0} \circ \omega(x_W^{-1}\delta^{-1} x_W, 1)$. As $\delta \mapsto \delta^{-1}$ carries left cosets to right cosets, with (6.124),

$$\begin{aligned}\sum_L \|Z_L\| &= \sum_{\gamma \in \mathrm{Stab}(L_0)\backslash \mathrm{U}(W)(F)} \big\|Z_{L_0} \circ \omega(x_W^{-1}\gamma x_W, 1)\big\| \\ &\le C_K\, \|Z_{L_0}\| \sum_{\gamma \in \mathrm{Stab}(L_0)\backslash \mathrm{U}(W)(F)} H(x_W^{-1}\gamma x_W)^{n'/2}.\end{aligned}$$

Step 4: convergence of the Siegel Eisenstein series. The space (E^{m_W}, h_W) is hermitian of dimension $2n$ and Witt index n (L_0 is isotropic of dimension n), and $\mathrm{Stab}(L_0)$ is the stabiliser of the maximal isotropic subspace L_0. Let K_1 be a maximal compact subgroup of $\mathrm{U}(W)(\mathbb{A}_F)$ with $\mathrm{U}(W)(\mathbb{A}_F) = \mathrm{Stab}(L_0)(\mathbb{A}_F) K_1$ (it exists, cited in passing as the standard Iwasawa decomposition), and $H_1(pk) = |\det a(p)|$ for $p \in \mathrm{Stab}(L_0)(\mathbb{A}_F)$, $k \in K_1$, $a(p)$ the action of p on $L_0 \otimes \mathbb{A}_E$; it is well defined because $|\det a|$ is 1 on the compact group $\mathrm{Stab}(L_0)(\mathbb{A}_F) \cap K_1$. Then $f_z(pk) = H_1(pk)^{z+n/2}$ is a K_1-finite flat section of $\mathrm{Ind}(|\det a|^z)$ with $\mu = 1$ and $f_0 = 1$ on K_1, and Theorem A.4.29 gives that $\sum_{\gamma \in \mathrm{Stab}(L_0)\backslash \mathrm{U}(W)(F)} H_1(\gamma)^{z+n/2}$ converges for real $z > n/2$. Take $z = (n'-n)/2$, which exceeds $n/2$ as $n' > 2n$: $\sum_\gamma H_1(\gamma)^{n'/2} < \infty$. Finally compare H and H_1. By Step 1, $\mathrm{U}(W)(\mathbb{A}_F) = \mathrm{Stab}(L_0)(\mathbb{A}_F) K_2$ with $K_2 = \iota(g_D K g_D^{-1})$, and $H(x_W^{-1} y x_W) = |\det a(p)|$

for $y = pk$, $p \in \mathrm{Stab}(L_0)(\mathbb{A}_F)$, $k \in K_2$, since m_u is the matrix of $a(\iota(u))$. If $y = pk = p_1k_1$ with $k \in K_2$, $k_1 \in K_1$, then $p_1^{-1}p = k_1k^{-1} \in \mathrm{Stab}(L_0)(\mathbb{A}_F) \cap K_1K_2$, a compact set ($K_1K_2$ is compact, $\mathrm{Stab}(L_0)(\mathbb{A}_F)$ closed), on which the continuous function $|\det a|$ is at most some $c_1 \geq 1$. Hence $H(x_W^{-1}yx_W) \leq c_1H_1(y)$, and

$$\sum_\gamma H(x_W^{-1}\gamma x_W)^{n'/2} \leq c_1^{n'/2} \sum_\gamma H_1(\gamma)^{n'/2} < \infty.$$

With Step 3 this proves $\sum_L \|Z_L\| < \infty$. □

Lemma 6.5.18. *Let W be a space with a point with signs on an index set m_W, p an index set with $\#m_W = 2\#p$ such that W has a splitting over the zero space $V_\emptyset$ ((MX13) of Definition 4.1.18) along p, and T a space with a point with signs t on n_T and $\#n_T > 2\#p$. There is a measurable function $N\colon [\mathrm{U}(T)] \to [0,\infty]$ with finite integral such that $|\theta^{W,T}_{\upsilon^{\#p},1}(d)(1,h)| \leq N(\Gamma_T h)\,\|d\|$ for all $h \in \mathrm{G}(t)$ and $d \in \mathcal{M}_{W,T}$.*

Proof. **Step 1: the case $p = \emptyset$.** Then $\#m_W = 0$, so $\mathrm{Hom}(W,T)$ has the empty index set, $\mathcal{M}_{W,T} = \mathbb{C}$ with $\|d\| = |d|$, its canonical theta functional is the identity (WC1), and $\omega(1,h)$ is the identity ($\upsilon^0 = 1$, and the Weil representation of the empty sign vector is trivial, (WR3)). So $|\theta^{W,T}_{1,1}(d)(1,h)| = \|d\|$ and $N = 1$ works, $\mathrm{vol}([\mathrm{U}(T)])$ being finite by Theorem 4.2.18 (trivial for $n' = \emptyset$). From now on $p \neq \emptyset$, and then $n' \neq \emptyset$.

Step 2: the theta kernel as a sum of slices. Fix a splitting $D = (k,l,i)$ of W over $V_\emptyset$ along p (i empty), with Hom slices $d[x] \in \mathcal{M}_{V_\emptyset,T} = \mathbb{C}$ for adelic $n' \times p$ matrices x. The canonical theta functional of $\mathrm{Hom}(V_\emptyset, T)$ is the identity (WC1, rank 0), so by (5) of Lemma 6.2.44, for every $F \in \mathcal{M}_{W,T}$,

$$\theta_{\mathrm{Hom}(W,T)}(F) = \sum_{\xi \in \mathrm{M}_{n' \times p}(E)} F[x_T^{-1}\xi],$$

absolutely convergent. By (2) of Lemma 6.2.45 with $g = 1$, $m = 1$, $g_0 = 1$, $\alpha = \beta = 1$ (there the matrix W is empty, $B = \mathrm{pr}_k l_{\mathbb{A}} = l^* J_W l = 0$, and the character is 1 at $\det m = 1$), and since $\omega_{1,1}(1,h)$ is the identity on the rank-0 model $\mathcal{M}_{V_\emptyset,T}$,

$$(\omega(1,h)d)[x] = d[h^{-1}x] \qquad (h \in \mathrm{G}(t)).$$

With (WC4), for all h and d,

$$|\theta^{W,T}_{\upsilon^{\#p},1}(d)(1,h)| = \Big|\sum_\xi d[h^{-1}x_T^{-1}\xi]\Big| \leq \sum_{\xi \in \mathrm{M}_{n' \times p}(E)} |d[h^{-1}x_T^{-1}\xi]|. \tag{6.125}$$

Step 3: Hom slices are slices of the induced splitting. Let $D_T = (k', l', i')$ be the splitting of $\mathrm{Hom}(W,T)$ over $\mathrm{Hom}(V_\emptyset, T)$ along $n' \times p$ induced by D, a splitting of a space with a point along a nonempty index set. Its adelic frame is $l'_{\mathbb{A}} = (x_T^{-1} \otimes x_W^{\mathsf{T}})(1 \otimes (l^* J_W)^{\mathsf{T}})$, which sends an adelic $n' \times p$ matrix X to $x_T^{-1} X\, l^* J_W x_W = x_T^{-1} X\, \mathrm{pr}_k$, because $\mathrm{pr}_k = l^*_{\mathbb{A}}\varepsilon = l^* x_W^{-*}\varepsilon = l^* J_W x_W$ ($x_W^* J_W x_W = \varepsilon$, ε the adelic sign matrix of W). Hence the slice of d along D_T at X, $Z_{D_T}(\rho(l'_{\mathbb{A}}X)d)$, is the Hom slice $d[x_T^{-1}X]$ (MX4).

Step 4: the majorant. Let $B \subseteq \mathbb{A}_E^{n' \times p}$ and M be the compact set and the constant of Lemma 6.5.19 for D_T. For $h \in \mathrm{G}(t)$ the map $\phi_h(\xi) = x_T h^{-1} x_T^{-1}\xi$ is a homomorphism $\mathrm{M}_{n' \times p}(E) \to \mathbb{A}_E^{n' \times p}$, and $d[h^{-1}x_T^{-1}\xi]$ is the slice of d along D_T at $\phi_h(\xi)$ by Step 3. By (6.125) and Lemma 6.5.19,

$$|\theta^{W,T}_{\upsilon^{\#p},1}(d)(1,h)| \leq M \cdot \#\phi_h^{-1}(B) \cdot \|d\| = M\, N_B(h)\, \|d\|,$$

with N_B the count of Lemma 6.5.20. By that lemma ($\#n' > 2\#p$) N_B is invariant under Γ_T, measurable, and has finite integral over $[\mathrm{U}(T)]$. So $N(\Gamma_T h) = M\,N_B(h)$ is the required function. □

Lemma 6.5.19. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set, and (k,l,i) a splitting of V over V_0 along p, with slices $f[x] \in \mathcal{M}_{s_0}$ ($f \in \mathcal{M}_s$, $x \in \mathbb{A}_E^p$). There are a compact set $B \subseteq \mathbb{A}_E^p$ and $M \geq 0$ such that for every abelian group I, every group homomorphism $\phi\colon I \to \mathbb{A}_E^p$ and every $f \in \mathcal{M}_s$*

$$\sum_{\xi\in I} \|f[\phi(\xi)]\| \leq M \cdot \#\phi^{-1}(B) \cdot \|f\|.$$

Proof. **Step 1: a pointwise bound for the slices.** By (1) of Lemma 6.2.46 there is $g \in \mathrm{G}(s)$ at which the splitting is adapted in the basis 1. The slice maps $\Pi_x\colon f \mapsto f[x] = Z(\rho(l_{\mathbb{A}}x)f)$ are bounded and linear (Z is bounded by (7) of Lemma 4.1.1 and $\rho(l_{\mathbb{A}}x)$ is an isometry), and by the second display of (1) of Lemma 6.2.44 they satisfy the hypothesis of (2) of Lemma 6.2.46. Hence, with $u = \omega_s(g)v^0$, there is $C \in \mathbb{C}$ with $u[x] = C\,|e_p(x)|^2 v^0$ for all $x \in \mathbb{A}_E^p$. Let $f \in \mathcal{M}_s$ and $h = \omega_s(g^{-1})f$. By (1) of Lemma 6.2.12, $h = \int h(z)\rho(z)v^0\,d\mu_n(z)$ as a Bochner integral; applying the bounded operator $\omega_s(g)$ and $\omega_s(g)\rho(z) = \rho(gz)\omega_s(g)$ ((2) of Lemma 4.1.1), and then the bounded map Π_y,

$$f[y] = \int h(z)\,(\rho(gz)u)[y]\,d\mu_n(z) \qquad (y \in \mathbb{A}_E^p).$$

Write $gz = l_{\mathbb{A}}a_z + i_{\mathbb{A}}w_z + k_{\mathbb{A}}b_z$ with $a_z = \mathrm{pr}_l(gz)$, $w_z = \mathrm{pr}_i(gz)$, $b_z = \mathrm{pr}_k(gz)$. By (1) of Lemma 6.2.44, $(\rho(gz)u)[y]$ is a number of modulus one times $\rho(w_z)u[y+a_z]$, and $\rho(w_z)$ is an isometry; so $\|(\rho(gz)u)[y]\| = |C|\,|e_p(y+a_z)|^2\,\|v^0\|$ and

$$\|f[y]\| \leq |C|\,\|v^0\| \int |h(z)|\,|e_p(y+a_z)|^2\,d\mu_n(z) \qquad (y \in \mathbb{A}_E^p). \tag{6.126}$$

Step 2: summation. Let I, ϕ be as in the statement and $K(\phi) = \sup_{a\in\mathbb{A}_E^p} \sum_{\xi\in I} |e_p(\phi(\xi)+a)|^2 \in [0,\infty]$. Summing (6.126) over $y = \phi(\xi)$ and exchanging sum and integral (Tonelli),

$$\begin{aligned}\sum_{\xi\in I} \|f[\phi(\xi)]\| &\leq |C|\,\|v^0\| \int |h(z)| \sum_{\xi\in I} |e_p(\phi(\xi)+a_z)|^2\,d\mu_n(z)\\ &\leq |C|\,\|v^0\|\,K(\phi)\,\|h\| \leq |C|\,\|v^0\|\,\|\omega_s(g^{-1})\|\,K(\phi)\,\|f\|.\end{aligned}$$

Step 3: $K(\phi)$ is at most a constant times a count. By (WD5),

$$|e_p(x)|^2 = \exp(-Q(x_\infty))\,\mathbf{1}[x_f \in \alpha\widehat{\mathcal{O}}_E^p] \quad \text{with} \quad Q(y) = 2\pi \sum_{j\in p}\sum_{v\in\Phi} \mathrm{Im}(\jmath_v)|y_{j,v}|^2,$$

a positive definite quadratic form on $\mathbb{C}^{\Phi\times p} = \mathbb{R}^{2r\#p}$ ($\mathrm{Im}\,\jmath_v > 0$, (WD1)); so $Q(y) \geq c_Q|y|^2$ for some $c_Q > 0$. Let $D = [0,1]^{2r\#p}$ and, for $t \in \mathbb{Z}^{2r\#p}$, $c_t = \sup_{y\in t+D} e^{-Q(y)}$. On $t+D$, $|y| \geq |t| - \sqrt{2r\#p}$, so $c_t \leq \exp(-c_Q \max(0, |t| - \sqrt{2r\#p})^2)$ and $K_0 = \sum_t c_t < \infty$. Put $B_0 = \{x : x_\infty \in D,\ x_f \in \alpha\widehat{\mathcal{O}}_E^p\}$ and

$$B = B_0 - B_0 = \{x : x_\infty \in [-1,1]^{2r\#p},\ x_f \in \alpha\widehat{\mathcal{O}}_E^p\},$$

compact ($\alpha\widehat{\mathcal{O}}_E^p$ is a compact group). As the translates $t+D$ cover $\mathbb{R}^{2r\#p}$, $|e_p(x)|^2 \le \sum_t c_t \mathbf{1}_{t+B_0}(x)$, where t translates the archimedean coordinates. Hence for every a

$$\sum_{\xi\in I} |e_p(\phi(\xi)+a)|^2 \le \sum_t c_t \,\#\{\xi\in I : \phi(\xi)\in t+B_0-a\} \le K_0\,\#\phi^{-1}(B) :$$

if ξ_0 lies in the set counted, then $\xi \mapsto \xi-\xi_0$ maps it injectively into $\phi^{-1}(B)$, as $\phi(\xi-\xi_0) = \phi(\xi)-\phi(\xi_0) \in B_0 - B_0$. So $K(\phi) \le K_0\,\#\phi^{-1}(B)$, and the statement holds with this B and $M = |C|\,\|v^0\|\,\|\omega_s(g^{-1})\|\,K_0$, which depend only on the splitting. □

Lemma 6.5.20. *Let T be a space with a point with signs t on n', p an index set with $\#n' > 2\#p$, and $B \subseteq \mathrm{M}_{n'\times p}(\mathbb{A}_E)$ a compact set. For $h \in \mathrm{G}(t)$ put*

$$N_B(h) = \#\{\xi \in \mathrm{M}_{n'\times p}(E) :\ x_T h^{-1} x_T^{-1}\,\xi \in B\}.$$

Then $N_B(\gamma h) = N_B(h)$ for $\gamma \in \Gamma_T$, N_B is measurable, and $\int_{[\mathrm{U}(T)]} N_B(h)\,dh < \infty$.

Proof. **Step 1: invariance and measurability.** For $\gamma\in\Gamma_T$, $\gamma' = x_T\gamma x_T^{-1} \in \mathrm{U}(T)(F) \subseteq \mathrm{GL}_{n'}(E)$ and $x_T(\gamma h)^{-1}x_T^{-1}\xi = h'^{-1}\gamma'^{-1}\xi$; as $\xi\mapsto\gamma'^{-1}\xi$ is a bijection of $\mathrm{M}_{n'\times p}(E)$, $N_B(\gamma h) = N_B(h)$. For each ξ the set $\{h : h'^{-1}\xi \in B\}$ is closed (B is compact, hence closed, and $h\mapsto h'^{-1}\xi$ is continuous), so $N_B = \sum_\xi \mathbf{1}_{\{h:h'^{-1}\xi\in B\}}$ is a countable sum of measurable functions.

Step 2: the case $p = \emptyset$. Then $\mathrm{M}_{n'\times p}$ has one element, $N_B \le 1$, and $\int_{[\mathrm{U}(T)]} N_B \le \mathrm{vol}([\mathrm{U}(T)]) < \infty$ by Theorem 4.2.18 (for $n' = \emptyset$ the group is trivial). From now on $\#p \ge 1$.

Step 3: domination by a Schwartz–Bruhat function. The projections of B to the archimedean and to the finite components are compact. So there is $R>0$ with $|y_{v,ij}| \le R$ for all $y\in B$, $v\in\Phi$, $i\in n'$, $j\in p$, and, as $\mathbb{A}_{E,f}$ is the increasing union of the open subgroups $u^{-1}\widehat{\mathcal{O}}_E$ ($u\ge 1$ an integer), there is u_0 with $y_f \in u_0^{-1}\widehat{\mathcal{O}}_E^{n'\times p}$ for all $y\in B$. Read $\mathrm{M}_{n'\times p}(\mathbb{A}_E)$ as $T(\mathbb{A}_E)^p = T^p(\mathbb{A}_F)$, the space of p-tuples of vectors of the hermitian space $T = (E^{n'}, J_T)$. For the Schrödinger model of the Weil representation of the pair $(\mathrm{U}(W'),\mathrm{U}(T))$, W' a skew-hermitian space of dimension $2\#p$ and Witt index $\#p$ with a polarisation, on $\mathcal{S}(T^p(\mathbb{A}_F))$, let $\varphi_0 = \bigotimes_v \varphi_{0,v}$ with $\varphi_{0,v}$ the vector of the constant polynomial of the Fock model at $v\in\Phi$ and $\varphi_{0,f} = \mathbf{1}[y_f \in u_0^{-1}\widehat{\mathcal{O}}_E^{n'\times p}]$. Each $\varphi_{0,v}$ is a Gaussian $\exp(-q_v(y_v))$ with q_v a positive definite real quadratic form on $\mathrm{M}_{n'\times p}(\mathbb{C})$ (the Fock vacuum in a Schrödinger model, cited in passing: [322]; for unitary dual pairs [121], Section 1), and $\varphi_{0,f}$ is fixed by an open subgroup of the compact group $K_{G,f}$, hence K_G-finite. With $C_B = \exp(\sum_{v\in\Phi}\max_{|y_{ij}|\le R} q_v(y))$ we get $\mathbf{1}_B \le C_B\,\varphi_0$ pointwise, and $\varphi_0 \ge 0$.

Step 4: Weil's criterion. In this model $\mathrm{U}(T)(\mathbb{A}_F)$ acts linearly: $|(\omega(1,h')\varphi_0)(x)| = \varphi_0(h'^{-1}x)$ (the factor is a unitary character of $\det h'$). Hence, by Step 3,

$$N_B(h) \le C_B \sum_{\xi\in T^p(F)} \varphi_0(h'^{-1}\xi) = C_B \sum_{\xi\in T^p(F)} |(\omega(1,h')\varphi_0)(\xi)|.$$

The hypotheses of Theorem A.4.27 hold for $V = T$ of dimension $m = \#n'$ and Witt index r, and $n = \#p \ge 1$: $m > 2n > n$, and $r \le m/2$ (an isotropic subspace has dimension at most $m/2$), so $m - r \ge m/2 > n$; a Hecke character χ of E with $\chi|_{\mathbb{A}_F^\times} = \eta^m$ exists (classical, cited in passing), and φ_0 is K_G-finite with archimedean component a polynomial vector of the Fock model. Its item (1) at $g=1$, absolute convergence of the theta integral, gives $\int_{[\mathrm{U}(T)]}\sum_\xi |(\omega(1,h')\varphi_0)(\xi)|\,dh' < \infty$ for the Haar measure of total mass 1 on $\mathrm{U}(T)(F)\backslash\mathrm{U}(T)(\mathbb{A}_F)$. The measure of $\mathrm{G}(t)$ is a Haar measure (a product of Cayley measures, which are Haar measures, and a Haar measure of $G_f(n')$, (VP1) of Definition 3.2.2), so its image under $h\mapsto h'$ is a Haar measure of $\mathrm{U}(T)(\mathbb{A}_F)$, and the quotient measure of $[\mathrm{U}(T)]$ is a positive multiple of the measure used there. Therefore $\int_{[\mathrm{U}(T)]} N_B(h)\,dh < \infty$. □

Lemma 6.5.21. *Let W be a space with a point with signs on an index set m_W, p an index set with $\#m_W = 2\#p$ such that W has a splitting over the zero space $V_\emptyset$ along p, and T a space with a point with signs t on n_T and $\#n_T > 2\#p$. For every $d \in \mathcal{M}_{W,T}$ the function $h \mapsto \theta^{W,T}_{\upsilon^{\#p},1}(d)(1,h)$ is integrable on $[\mathrm{U}(T)]$, the family $(Z_L(d))_L$ is absolutely summable, and*

$$\int_{[\mathrm{U}(T)]} \theta^{W,T}_{\upsilon^{\#p},1}(d)(1,h)\,dh = \mathrm{vol}([\mathrm{U}(T)]) \sum_L Z_L(d),$$

the sum over the rational Lagrangians L of W.

Proof. Write $\mathcal{M} = \mathcal{M}_{W,T}$, $\theta = \theta_{\mathrm{Hom}(W,T)}$, $\omega = \omega_{\upsilon^{\#p},1}$, so that $\theta^{W,T}_{\upsilon^{\#p},1}(d)(1,h) = \theta(\omega(1,h)d)$, and $m = \#n_T$.

Reduction to smooth vectors. By (1) of Lemma 6.5.16 every rational Lagrangian is split along p, so each Z_L is defined. The function $h \mapsto \theta(\omega(1,h)d)$ is continuous on $\mathrm{G}(t)$ ((2) of Lemma 4.1.1, θ bounded) and left invariant under Γ_T (Lemma 6.2.5), hence a measurable function on $[\mathrm{U}(T)]$; by Lemma 6.5.18 it is dominated by $N\|d\|$ with N integrable, so it is integrable. By Lemma 6.5.17, $\sum_L |Z_L(d)| \le \big(\sum_L \|Z_L\|\big)\|d\| < \infty$. The volume $v = \mathrm{vol}([\mathrm{U}(T)])$ is finite and positive by Theorem 4.2.18 ($[\mathrm{U}(T)]$ is $\mathrm{U}(T)(F)\backslash\mathrm{U}(T)(\mathbb{A}_F)$ through the point, (VP2) of Definition 3.2.2). Hence

$$\Lambda_1(d) = \int_{[\mathrm{U}(T)]} \theta(\omega(1,h)d)\,dh, \qquad \Lambda_2(d) = v\sum_L Z_L(d)$$

are linear functionals on $\mathcal{M}$ with $|\Lambda_1(d)| \le \|N\|_1\|d\|$ and $|\Lambda_2(d)| \le v\sum_L \|Z_L\|\,\|d\|$, so both are continuous. By (1) of Lemma 6.5.22 (for $S = W$) the smooth vectors $\mathcal{M}^\infty$ are dense in $\mathcal{M}$; it therefore suffices to prove $\Lambda_1(d) = \Lambda_2(d)$ for $d \in \mathcal{M}^\infty$.

The polarisation adapted to the splitting. Let $D_0 = (k_0, l_0, \emptyset)$ be the splitting of W over $V_\emptyset$ along p of the hypothesis, $L_0 = k_0E^p$, and $\mathrm{Stab}(L_0) \subset \mathrm{U}(W)(F)$ its stabiliser. By (MX1), $k_0^*J_Wk_0 = l_0^*J_Wl_0 = 0$, $l_0^*J_Wk_0 = 1$, the matrix $(l_0 \mid k_0)$ is invertible, and

$$J_W^{-1} = k_0l_0^* + l_0k_0^*.$$

The rational vectors of $\mathrm{Hom}(W,T)$ are $x_T^{-1}ux_W$ with $u \in \mathrm{M}_{n_T\times m_W}(E)$, and

$$B(x_T^{-1}ux_W, x_T^{-1}u'x_W) = \mathrm{Tr}_{E/F}(\jmath\,\mathrm{tr}(J_W^{-1}u'^*J_Tu))$$

($x_W\varepsilon x_W^* = J_W^{-1}$, $x_T^{-*}\varepsilon x_T^{-1} = J_T$ by (VP2) of Definition 3.2.2). Put

$$\mathbb{Y} = \{x_T^{-1}ux_W : uk_0 = 0\}, \qquad \mathbb{X} = \{x_T^{-1}ux_W : ul_0 = 0\}.$$

By the display, $\mathrm{tr}(J_W^{-1}u'^*J_Tu) = \mathrm{tr}(k_0^*u'^*J_Tul_0) + \mathrm{tr}(l_0^*u'^*J_Tuk_0)$, which vanishes if $uk_0 = u'k_0 = 0$ or if $ul_0 = u'l_0 = 0$; and $u \mapsto (ul_0, uk_0)$ is a bijection onto pairs of $n_T \times p$ matrices, under which $\mathbb{Y}$ and $\mathbb{X}$ are the pairs $(c,0)$ and $(0,c)$. So $(\mathbb{X},\mathbb{Y})$ is a polarisation in the sense of Lemma 6.5.22; let $\Lambda = \Lambda_{\mathbb{X}}\colon \mathcal{M}^\infty \to \mathcal{S}(\mathbb{X}_\mathbb{A})$ be the bijection of (2) of Lemma 6.5.22 for $S = W$, $\alpha = \upsilon^{\#p}$, $\beta = 1$.

The classical data. The splitting characters of $\omega^\mathbb{X}$ are $\beta[m] = \upsilon^{-m}$ on $\mathrm{U}(W)$ and $\alpha[\#m_W] = \alpha[2\#p]$ on $\mathrm{U}(T)$. Since $\upsilon(\bar{x}) = \upsilon(x)^{-1}$ (WD3), the base change of $\alpha = \upsilon^{\#p}$ is $\tilde{\alpha}(x) = \upsilon(x/\bar{x})^{\#p} = \upsilon(x)^{2\#p}$, so $\alpha[2\#p] = 1$. On $\mathbb{A}_F^\times$, υ is a character of $\mathbb{A}_F^\times/F^\times$ with $\upsilon^2 = 1$, trivial on the norms ($\upsilon(y\bar{y}) = 1$), and nontrivial (the idele equal to -1 at one infinite place and to 1 elsewhere has value -1 by (WD3)); by class field theory $\mathbb{A}_F^\times/F^\times\mathrm{N}(\mathbb{A}_E^\times)$ has order 2 with nontrivial character η, so $\upsilon|_{\mathbb{A}_F^\times} = \eta$ and $\chi = \upsilon^{-m}$ satisfies $\chi|_{\mathbb{A}_F^\times} = \eta^m$. In the dictionary of Lemma 4.1.2 (the tensor map $\mathcal{A}(v\otimes z) = \bar{v}\,\bar{z}^\mathsf{T}$ from the hermitian space $V = (E^{n_T}, h_V)$ and the

skew-hermitian space $W' = (E^{m_W}, h_W)$ of its statement, the pair (g,h) acting as $(\overline{g^{-\mathsf{T}}}, \bar{h})$), a pure tensor gives $\mathcal{A}(v\otimes z)k_0 = \bar{v}\,(\bar{z}^{\mathsf{T}}k_0)$, so $\mathcal{A}$ maps $V\otimes L$ into $\{u : uk_0 = 0\}$ and $V\otimes L'$ into $\{u : ul_0 = 0\}$, and the dimensions agree ($\#n_T \cdot \#p$); hence $\mathbb{Y} = \mathcal{A}(V\otimes L)$ and $\mathbb{X} = \mathcal{A}(V\otimes L')$ with

$$L = J_W k_0 E^p, \qquad L' = J_W l_0 E^p,$$

complementary maximal isotropic subspaces of W', and $g \mapsto \overline{g^{-\mathsf{T}}}$ maps $\mathrm{Stab}(L_0)$ onto the stabiliser $P(F)$ of L and $\mathrm{U}(W)(F)$ onto $\mathrm{U}(W')(F)$.

Thus the data of Theorem A.4.28 are: the hermitian space V of dimension m, the skew-hermitian space W' of dimension $2\#p$ and Witt index $\#p$, the Lagrangians $\mathbb{X} = V\otimes L'$, $\mathbb{Y} = V\otimes L$, the character χ, the trivial character on $\mathrm{U}(V)$, and $\omega = \omega^{\mathbb{X}}$; and $m > 2\#p$ by hypothesis.

The terms as values of a section. Let $d \in \mathcal{M}^\infty$. By (3) of Lemma 6.5.16, $Z_{L_0} = Z_{D_0}$. The splitting of $\mathrm{Hom}(W,T)$ induced by D_0 has k-frame $J_T^{-1}\otimes(k_0^* J_W)^{\mathsf{T}}$ (MX1), so its adelic frame sends $b \in \mathbb{A}_E^{n_T\times p}$ to $y_b = x_T^{-1}J_T^{-1}bk_0^* J_W x_W$; the space over which it splits has rank 0, its canonical functional is the identity of $\mathbb{C}$ (WC1), and (MX4) reads

$$Z_{L_0}(d) = \int_{\mathbb{A}_E^{n_T\times p}/E^{n_T\times p}} \theta(\rho(y_b)d)\,db.$$

Since $u = J_T^{-1}bk_0^*J_W$ satisfies $uk_0 = 0$ and $ul_0 = J_T^{-1}b$, the map $b\mapsto y_b$ is an $\mathbb{A}_F$-linear bijection of $\mathbb{A}_E^{n_T\times p}$ onto $\mathbb{Y}_{\mathbb{A}}$ carrying $E^{n_T\times p}$ onto $\mathbb{Y}$, hence the invariant probability measure of the first quotient to that of $\mathbb{Y}_{\mathbb{A}}/\mathbb{Y}$. By (4) of Lemma 6.5.22,

$$Z_{L_0}(d) = (\Lambda d)(0).$$

For $\delta \in \mathrm{U}(W)(F)$ put $g_\delta = x_W^{-1}\delta^{-1}x_W \in \Gamma_W$. By (2) of Lemma 6.5.16, (1) and (2) of Lemma 6.5.22,

$$Z_{\delta L_0}(d) = Z_{L_0}\big(\omega(g_\delta,1)d\big) = \big(\Lambda\,\omega(g_\delta,1)d\big)(0) = \big(\omega^{\mathbb{X}}(g_\delta,1)\Lambda d\big)(0).$$

By (1) of Lemma 6.5.16, $\delta\mapsto \delta L_0$ is a bijection of $\mathrm{U}(W)(F)/\mathrm{Stab}(L_0)$ onto the rational Lagrangians; with $\gamma = \delta^{-1}$ and the identification of the previous paragraph,

$$\sum_L Z_L(d) = \sum_{\gamma\in \mathrm{Stab}(L_0)\backslash \mathrm{U}(W)(F)} \big(\omega^{\mathbb{X}}(x_W^{-1}\gamma x_W,1)\Lambda d\big)(0) = E(1,\Lambda d),$$

the Eisenstein series of (1) of Theorem A.4.28 for $\Phi = \Lambda d$ (both series converge absolutely, by Lemma 6.5.17 and by (1) of Theorem A.4.28, and they have the same terms).

The theta integral. For $h\in \mathrm{G}(t)$, $\omega(1,h)d \in \mathcal{M}^\infty$ and, by (3) and (2) of Lemma 6.5.22,

$$\theta(\omega(1,h)d) = \theta_{\mathbb{X}}\big(\Lambda\omega(1,h)d\big) = \sum_{x\in\mathbb{X}} \big(\omega^{\mathbb{X}}(1,h)\Lambda d\big)(x).$$

Through the point and $h\mapsto \bar{h}$, $[\mathrm{U}(T)]$ is $\mathrm{U}(V)(F)\backslash\mathrm{U}(V)(\mathbb{A}_F)$ and $v^{-1}dh$ is the invariant probability measure. Hence (3) of Theorem A.4.28 at $g=1$ gives

$$\sum_L Z_L(d) = E(1,\Lambda d) = v^{-1}\int_{[\mathrm{U}(T)]} \theta(\omega(1,h)d)\,dh,$$

that is $\Lambda_2(d) = \Lambda_1(d)$ for $d\in\mathcal{M}^\infty$. By the reduction, $\Lambda_1 = \Lambda_2$ on $\mathcal{M}$, which is the identity of the statement. □

Lemma 6.5.22. *Let S, T be spaces with points with signs s on n and s' on n', α, β automorphic characters of $\mathrm{U}(1)$, $\mathcal{M} = \mathcal{M}_{S,T}$ and $\theta = \theta_{\mathrm{Hom}(S,T)}$. Read the vectors of $\mathbb{A}_E^{n'\times n}$ as $n' \times n$ matrices, so that the rational vectors of $\mathrm{Hom}(S,T)$ are $H_E = \{x_T^{-1} u x_S : u \in \mathrm{M}_{n'\times n}(E)\}$. Let ψ_F be the character of $\mathbb{A}_F/F$ with $\psi_E = \psi_F \circ \mathrm{Tr}_{E/F}$, and*

$$B(z,w) = \mathrm{Tr}_{E/F}\big(\jmath\,\mathrm{tr}(\varepsilon_s w^* \varepsilon_{s'} z)\big) \qquad (z, w \in \mathbb{A}_E^{n'\times n}).$$

*A **polarisation** is a pair $(\mathbb{X}, \mathbb{Y})$ of F-subspaces of H_E with $H_E = \mathbb{X} \oplus \mathbb{Y}$ and $B(\mathbb{X},\mathbb{X}) = B(\mathbb{Y},\mathbb{Y}) = 0$; $\mathbb{X}_\mathbb{A}$, $\mathbb{Y}_\mathbb{A}$ denote the $\mathbb{A}_F$-submodules of $\mathbb{A}_E^{n'\times n}$ they span, $\mathbb{X}_\mathbb{A}$ carries the Haar measure with $\mathrm{vol}(\mathbb{X}_\mathbb{A}/\mathbb{X}) = 1$, and $\mathbb{Y}_\mathbb{A}/\mathbb{Y}$ its invariant probability measure. For a polarisation, $\rho^\mathbb{X}$ is the Schrödinger realisation on $L^2(\mathbb{X}_\mathbb{A})$ of Theorem A.5.3 for the character ψ_F and the pairing $B|_{\mathbb{X}_\mathbb{A}\times\mathbb{Y}_\mathbb{A}}$, $\theta_\mathbb{X}(\varphi) = \sum_{q\in\mathbb{X}} \varphi(q)$ for $\varphi \in \mathcal{S}(\mathbb{X}_\mathbb{A})$, and $\omega^\mathbb{X}(g,h)$ ($g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$) is the Weil representation $\omega_{\psi_F,\chi}$ of Theorem A.5.4 on $\mathcal{S}(\mathbb{X}_\mathbb{A})$ of the dual pair $(\mathrm{U}(S),\mathrm{U}(T))$ in the symplectic group of (H_E, B), with the splitting characters $\beta[\#n']$ on $\mathrm{U}(S)$ and $\alpha[\#n]$ on $\mathrm{U}(T)$, as in Lemma 4.1.2; here $\mathrm{G}(s)$, $\mathrm{G}(s')$ are identified with $\mathrm{U}(S)(\mathbb{A}_F)$, $\mathrm{U}(T)(\mathbb{A}_F)$ through the points. Let $\mathcal{M}^\infty$ be the set of $f \in \mathcal{M}$ for which $z \mapsto \rho(z)f$ is locally constant in the finite components of z and infinitely differentiable in its archimedean components. Then:*

1. *$\mathcal{M}^\infty$ is dense in $\mathcal{M}$, and $\rho(z)\mathcal{M}^\infty \subset \mathcal{M}^\infty$, $\omega_{\alpha,\beta}(g,h)\mathcal{M}^\infty \subset \mathcal{M}^\infty$ for all $z \in \mathbb{A}_E^{n'\times n}$, $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$;*
2. *for every polarisation $(\mathbb{X},\mathbb{Y})$ there is a linear bijection $\Lambda_\mathbb{X}\colon \mathcal{M}^\infty \to \mathcal{S}(\mathbb{X}_\mathbb{A})$ with*

$$\Lambda_\mathbb{X}\,\rho(z) = \rho^\mathbb{X}(z)\,\Lambda_\mathbb{X}, \qquad \Lambda_\mathbb{X}\,\omega_{\alpha,\beta}(g,h) = \omega^\mathbb{X}(g,h)\,\Lambda_\mathbb{X}$$

   for all z, g, h;

3. *$\theta(\rho(z)f) = \theta_\mathbb{X}(\rho^\mathbb{X}(z)\Lambda_\mathbb{X} f)$ for all z and $f \in \mathcal{M}^\infty$; in particular $\theta = \theta_\mathbb{X} \circ \Lambda_\mathbb{X}$ on $\mathcal{M}^\infty$;*
4. *$\displaystyle\int_{\mathbb{Y}_\mathbb{A}/\mathbb{Y}} \theta(\rho(y)f)\,dy = (\Lambda_\mathbb{X} f)(0)$ for every $f \in \mathcal{M}^\infty$.*

Proof. Write $\psi = \psi_F$, $\omega = \omega_{\alpha,\beta}$, $\mathbb{A}^N = \mathbb{A}_E^{n'\times n}$. Throughout, θ is a theta functional of $\mathrm{Hom}(S,T)$ in the sense of (WD9) by Lemma 4.1.17: bounded, and $\theta(\rho(q)f) = \theta(f)$ for $q \in H_E$.

The form. B is $\mathbb{A}_F$-bilinear and alternating, and $\beta_{s'\otimes s}(z,w) = \psi(\frac{1}{2}B(z,w))$. Indeed $\bar{w}^\mathsf{T} S z = \mathrm{tr}(\varepsilon_s w^* \varepsilon_{s'} z)$ for the sign matrix S of $\mathrm{Hom}(S,T)$ in (WD6), so

$$\beta_{s'\otimes s}(z,w) = \psi_E(\tfrac{\jmath}{2}\,\mathrm{tr}(\varepsilon_s w^* \varepsilon_{s'} z)) = \psi(\tfrac{1}{2}B(z,w));$$

and $B(w,z) = \mathrm{Tr}_{E/F}(\jmath\,\overline{\mathrm{tr}(\varepsilon_s w^* \varepsilon_{s'} z)}) = -B(z,w)$ because $\bar{\jmath} = -\jmath$. For $z = x_T^{-1} u x_S$, $w = x_T^{-1} u' x_S$ with u, u' rational,

$$B(z,w) = \mathrm{Tr}_{E/F}\big(\jmath\,\mathrm{tr}(J_S^{-1} u'^* J_T u)\big) \in F,$$

by $x_S \varepsilon_s x_S^* = J_S^{-1}$ and $x_T^{-*} \varepsilon_{s'} x_T^{-1} = J_T$ ((VP2) of Definition 3.2.2); so B is an F-valued nondegenerate alternating form on the F-space H_E, and $\mathbb{A}^N = H_E \otimes_F \mathbb{A}_F$ since the point is invertible. For a polarisation, B restricts to a perfect pairing $\mathbb{X} \times \mathbb{Y} \to F$, and $\mathbb{A}^N = \mathbb{X}_\mathbb{A} \oplus \mathbb{Y}_\mathbb{A}$. By (1) of Lemma 4.1.10 and the formula of Theorem A.5.3 the two families of operators have the same cocycle:

$$\rho(z)\rho(w) = \psi\big(\tfrac{1}{2}B(z,w)\big)\rho(z+w), \qquad \rho^\mathbb{X}(z)\rho^\mathbb{X}(w) = \psi\big(\tfrac{1}{2}B(z,w)\big)\rho^\mathbb{X}(z+w). \tag{1}$$

Consequently $\rho(w)\rho(z) = \psi(B(w,z))\rho(z)\rho(w)$.

Item (1). If $f \in \mathcal{M}^\infty$, then $\rho(w)\rho(z)f = \psi(B(w,z))\rho(z)\rho(w)f$ is smooth in the archimedean and locally constant in the finite components of w ($\rho(z)$ is bounded, and $w \mapsto \psi(B(w,z))$ is a character of this kind), so $\rho(z)f \in \mathcal{M}^\infty$. For $q = (g,h)$ with pair map P, (2) of Lemma 4.1.1 gives $\rho(z)\omega(q)f = \omega(q)\rho(P^{-1}z)f$; P^{-1} is $\mathbb{A}_E$-linear and preserves components, and $\omega(q)$ is bounded, so $\omega(q)f \in \mathcal{M}^\infty$. Density (Gårding): let dz be a Haar measure on $\mathbb{A}^N$ and $\kappa = \kappa_\infty \otimes \mathrm{vol}(K)^{-1}\mathbf{1}_K$ with $\kappa_\infty \geq 0$ smooth, compactly supported, of integral 1 on the archimedean part, and K a compact open subgroup of the finite part. For $f \in \mathcal{M}$ put $\rho(\kappa)f = \int \kappa(z)\rho(z)f\,dz$, a Bochner integral in $\mathcal{M}$ (ρ is strongly continuous and isometric by (1) of Lemma 4.1.10). By (1) and $B(z',z') = 0$,

$$\rho(z')\rho(\kappa)f = \int \kappa(z-z')\,\psi(\tfrac{1}{2}B(z',z))\rho(z)f\,dz.$$

The integrand is smooth in the archimedean part of z', with derivatives bounded uniformly for z' in a compact set and z in the compact support, so differentiation under the integral is allowed; and for z' in a compact open subgroup $K' \subset K$ of the finite part so small that $\psi(\frac{1}{2}B(K',C)) = 1$, C the finite projection of the support, the integrand does not depend on the finite part of z'. Hence $\rho(\kappa)f \in \mathcal{M}^\infty$. Since $\|\rho(\kappa)f - f\| \leq \int \kappa(z)\|\rho(z)f - f\|\,dz$, choosing κ_∞ and K with supports shrinking to 0 gives $\rho(\kappa)f \to f$ by strong continuity.

Theta functions. Let $\mathcal{H}_B$ be the space of measurable functions Θ on $\mathbb{A}^N$, modulo null functions, with $\Theta(w+q) = \psi(\frac{1}{2}B(w,q))\Theta(w)$ for $q \in H_E$ and almost all w, and with $\|\Theta\|^2 = \int_{\mathbb{A}^N/H_E} |\Theta|^2$ finite (the invariant probability measure; $|\Theta|$ is H_E-periodic). For $w' \in \mathbb{A}^N$ put $(R(w')\Theta)(w) = \psi(\frac{1}{2}B(w,w'))\Theta(w+w')$; $R(w')$ is a unitary operator of $\mathcal{H}_B$.

Let π be a family of linear operators on a vector space with the cocycle (1) and λ a linear functional with $\lambda \circ \pi(q) = \lambda$ for $q \in H_E$. Then $\Theta_v(w) = \lambda(\pi(w)v)$ satisfies

$$\Theta_v(w+q) = \psi(\tfrac{1}{2}B(w,q))\Theta_v(w), \qquad \Theta_{\pi(w')v} = R(w')\Theta_v, \tag{2}$$

because $\pi(w+q) = \psi(-\frac{1}{2}B(q,w))\pi(q)\pi(w)$ and $\pi(w)\pi(w') = \psi(\frac{1}{2}B(w,w'))\pi(w+w')$.

The theta model. For $f \in \mathcal{M}$ let $\vartheta_{\mathcal{M}}f(w) = \theta(\rho(w)f)$, a continuous function (ρ strongly continuous, θ bounded). By (2) and (2) of Lemma 4.1.10, $\vartheta_{\mathcal{M}}$ is a linear map $\mathcal{M} \to \mathcal{H}_B$ with $\langle \vartheta_{\mathcal{M}}f, \vartheta_{\mathcal{M}}f' \rangle = \langle f, f' \rangle$ and $\vartheta_{\mathcal{M}}\rho(w') = R(w')\vartheta_{\mathcal{M}}$.

A Schrödinger model. Let $(\mathbb{X},\mathbb{Y})$ be a polarisation. For $q = q_1 + q_2 \in H_E$ ($q_1 \in \mathbb{X}$, $q_2 \in \mathbb{Y}$) and $\varphi \in \mathcal{S}(\mathbb{X}_\mathbb{A})$, $\theta_\mathbb{X}(\rho^\mathbb{X}(q)\varphi) = \sum_{a\in\mathbb{X}} \psi(B(a,q_2) + \frac{1}{2}B(q_1,q_2))\varphi(a+q_1) = \theta_\mathbb{X}(\varphi)$, as $B(a,q_2), \frac{1}{2}B(q_1,q_2) \in F$. For $u \in \mathbb{X}_\mathbb{A}$, $v \in \mathbb{Y}_\mathbb{A}$,

$$\vartheta_\mathbb{X}\varphi(u+v) := \theta_\mathbb{X}(\rho^\mathbb{X}(u+v)\varphi) = \psi(\tfrac{1}{2}B(u,v)) \sum_{a\in\mathbb{X}} \psi(B(a,v))\varphi(u+a) = \psi(\tfrac{1}{2}B(u,v))\, Z_\psi\varphi(u,v),$$

with Weil's theta transform Z_ψ of Theorem A.5.5 for $X = \mathbb{X}$, $Y = \mathbb{Y}$ and the pairing B. The map $G \mapsto [\, u+v \mapsto \psi(\frac{1}{2}B(u,v))G(u,v)\,]$ is a unitary isomorphism of the space $\mathcal{H}_\beta$ of Theorem A.5.5 onto $\mathcal{H}_B$: it preserves $|G|$, the product of the probability measures on $\mathbb{X}_\mathbb{A}/\mathbb{X}$ and $\mathbb{Y}_\mathbb{A}/\mathbb{Y}$ is the invariant probability measure of $\mathbb{A}^N/H_E$, and the two quasi-periodicities correspond.

By Theorem A.5.5, $\vartheta_\mathbb{X}$ therefore extends from $\mathcal{S}(\mathbb{X}_\mathbb{A})$ to a unitary isomorphism $\vartheta_\mathbb{X}\colon L^2(\mathbb{X}_\mathbb{A}) \to \mathcal{H}_B$, and for Schwartz φ the displayed function is its continuous representative. By (2) for $\pi = \rho^\mathbb{X}$ on $\mathcal{S}(\mathbb{X}_\mathbb{A})$ (which $\rho^\mathbb{X}$ preserves) and by continuity, $\vartheta_\mathbb{X}\rho^\mathbb{X}(w') = R(w')\vartheta_\mathbb{X}$ on $L^2(\mathbb{X}_\mathbb{A})$. Put

$$\Lambda^0_\mathbb{X} = \vartheta_\mathbb{X}^{-1} \circ \vartheta_{\mathcal{M}}\colon \mathcal{M} \to L^2(\mathbb{X}_\mathbb{A});$$

it is linear, preserves inner products and satisfies $\Lambda^0_\mathbb{X}\rho(w') = \rho^\mathbb{X}(w')\Lambda^0_\mathbb{X}$.

The polarisation of the comparison. Apply Lemma 4.1.2 to S, T, α, β and the theta functional θ. Read in the coordinates of the point (under which its form is B by the display

above), it supplies a polarisation $(\mathbb{X}_1, \mathbb{Y}_1)$, a linear bijection $\Lambda_1 \colon \mathcal{M}^\infty \to \mathcal{S}(\mathbb{X}_{1,\mathbb{A}})$ with $\Lambda_1\rho(z) = \rho^{\mathbb{X}_1}(z)\Lambda_1$ and $\Lambda_1\omega(q) = \omega^{\mathbb{X}_1}(q)\Lambda_1$, and a constant $c_1 \neq 0$ with $\theta = c_1\,\theta_{\mathbb{X}_1} \circ \Lambda_1$ on $\mathcal{M}^\infty$. For $f \in \mathcal{M}^\infty$ and every w, since $\rho(w)f \in \mathcal{M}^\infty$ by (1),

$$\vartheta_{\mathcal{M}} f(w) = c_1\,\theta_{\mathbb{X}_1}(\Lambda_1\rho(w)f) = c_1\,\theta_{\mathbb{X}_1}(\rho^{\mathbb{X}_1}(w)\Lambda_1 f) = c_1\,\vartheta_{\mathbb{X}_1}(\Lambda_1 f)(w),$$

hence $\Lambda^0_{\mathbb{X}_1} = c_1\Lambda_1$ on $\mathcal{M}^\infty$.

Change of polarisation. Let $(\mathbb{X}, \mathbb{Y})$ be any polarisation and $\Psi = \vartheta_{\mathbb{X}}^{-1}\vartheta_{\mathbb{X}_1}$, a unitary isomorphism $L^2(\mathbb{X}_{1,\mathbb{A}}) \to L^2(\mathbb{X}_{\mathbb{A}})$ with $\Psi\rho^{\mathbb{X}_1}(w) = \rho^{\mathbb{X}}(w)\Psi$ and $\Lambda^0_{\mathbb{X}} = \Psi\Lambda^0_{\mathbb{X}_1}$. We show $\Psi\mathcal{S}(\mathbb{X}_{1,\mathbb{A}}) = \mathcal{S}(\mathbb{X}_{\mathbb{A}})$. Choose an F-basis (e_i) of $\mathbb{X}_1$ and the basis (f_i) of $\mathbb{Y}_1$ with $B(e_i, f_j) = \delta_{ij}$, and likewise (e_i'), (f_i') for $(\mathbb{X}, \mathbb{Y})$; the F-linear map σ with $\sigma e_i = e_i'$, $\sigma f_i = f_i'$ preserves B and H_E, and we extend it $\mathbb{A}_F$-linearly. Then:

- $\Psi_0\varphi = \varphi \circ \sigma^{-1}|_{\mathbb{X}_{\mathbb{A}}}$ maps $\mathcal{S}(\mathbb{X}_{1,\mathbb{A}})$ onto $\mathcal{S}(\mathbb{X}_{\mathbb{A}})$ (σ is defined over F), is unitary (σ carries the Haar measure of $\mathbb{X}_{1,\mathbb{A}}$ with quotient volume 1 to that of $\mathbb{X}_{\mathbb{A}}$), satisfies $\theta_{\mathbb{X}} \circ \Psi_0 = \theta_{\mathbb{X}_1}$ ($\sigma\mathbb{X}_1 = \mathbb{X}$), and $\Psi_0\rho^{\mathbb{X}_1}(w) = \rho^{\mathbb{X}}(\sigma w)\Psi_0$ (insert $B(\sigma\cdot, \sigma\cdot) = B$ in the formula of Theorem A.5.3).
- With $(C_\sigma\Theta)(w) = \Theta(\sigma^{-1}w)$, a unitary operator of $\mathcal{H}_B$ (σ preserves B, H_E and the invariant probability measure of the compact group $\mathbb{A}^N/H_E$), the first item gives $\vartheta_{\mathbb{X}}(\Psi_0\varphi)(w) = \theta_{\mathbb{X}}(\Psi_0\rho^{\mathbb{X}_1}(\sigma^{-1}w)\varphi) = \vartheta_{\mathbb{X}_1}\varphi(\sigma^{-1}w)$, that is $\vartheta_{\mathbb{X}}\Psi_0 = C_\sigma\vartheta_{\mathbb{X}_1}$ on $\mathcal{S}(\mathbb{X}_{1,\mathbb{A}})$, hence on L^2.
- $U = \vartheta_{\mathbb{X}}^{-1}C_\sigma^{-1}\vartheta_{\mathbb{X}}$ is unitary with $U\rho^{\mathbb{X}}(w)U^{-1} = \rho^{\mathbb{X}}(\sigma^{-1}w)$, because $C_\sigma^{-1}R(w)C_\sigma = R(\sigma^{-1}w)$. So (σ^{-1}, U) belongs to the metaplectic group of Theorem A.5.3, and U maps $\mathcal{S}(\mathbb{X}_{\mathbb{A}})$ onto itself.

Hence $\Psi = \vartheta_{\mathbb{X}}^{-1}C_\sigma^{-1}\vartheta_{\mathbb{X}}\Psi_0 = U\Psi_0$ maps $\mathcal{S}(\mathbb{X}_{1,\mathbb{A}})$ onto $\mathcal{S}(\mathbb{X}_{\mathbb{A}})$.

Item (2). Put $\Lambda_{\mathbb{X}} = \Lambda^0_{\mathbb{X}}|_{\mathcal{M}^\infty} = c_1\Psi\Lambda_1$. It is a linear bijection of $\mathcal{M}^\infty$ onto $\mathcal{S}(\mathbb{X}_{\mathbb{A}})$, and it intertwines ρ with $\rho^{\mathbb{X}}$ (both sides on $\mathcal{M}^\infty$, which ρ preserves by (1)). For the Weil representations, $\Lambda_{\mathbb{X}}\omega(q) = c_1\Psi\omega^{\mathbb{X}_1}(q)\Lambda_1 = \Psi\omega^{\mathbb{X}_1}(q)\Psi^{-1}\Lambda_{\mathbb{X}}$ on $\mathcal{M}^\infty$ (by (1), $\omega(q)$ preserves $\mathcal{M}^\infty$). By Theorem A.5.3 for the two realisations, $(\sigma', U') \mapsto (\sigma', \Psi U'\Psi^{-1})$ identifies the metaplectic group of the realisation on $L^2(\mathbb{X}_{1,\mathbb{A}})$ with that of the realisation on $L^2(\mathbb{X}_{\mathbb{A}})$ over the identity of the symplectic group; it does not depend on the unitary equivalence Ψ, which is unique up to a scalar by (i) of Theorem A.5.9 ($\rho^{\mathbb{X}_1}$ is generated by the translations and the characters $\psi(B(\cdot, v))$ of $\mathbb{X}_{1,\mathbb{A}}$, and $v \mapsto \psi(B(\cdot, v))$ identifies $\mathbb{Y}_{1,\mathbb{A}}$ with the dual group). Under this identification the metaplectic group, Kudla's splitting (i) of Theorem A.5.4 and the Weil representation (ii) of Theorem A.5.4 on the Schwartz space of an arbitrary Lagrangian are one and the same; hence $\Psi\omega^{\mathbb{X}_1}(q)\Psi^{-1} = \omega^{\mathbb{X}}(q)$, and $\Lambda_{\mathbb{X}}\omega(q) = \omega^{\mathbb{X}}(q)\Lambda_{\mathbb{X}}$.

Item (3). For $f \in \mathcal{M}^\infty$, $\vartheta_{\mathbb{X}}(\Lambda_{\mathbb{X}}f) = \vartheta_{\mathcal{M}}f$ in $\mathcal{H}_B$. Both $w \mapsto \theta_{\mathbb{X}}(\rho^{\mathbb{X}}(w)\Lambda_{\mathbb{X}}f)$ ($\Lambda_{\mathbb{X}}f$ is Schwartz, so this is $\psi(\frac{1}{2}B(u,v))Z_\psi(\Lambda_{\mathbb{X}}f)(u,v)$, continuous by Theorem A.5.5) and $w \mapsto \theta(\rho(w)f)$ are continuous; they agree almost everywhere, hence everywhere.

Item (4). For $y \in \mathbb{Y}_{\mathbb{A}}$, item (3) and the display above give $\theta(\rho(y)f) = Z_\psi(\Lambda_{\mathbb{X}}f)(0, y)$. The inverse formula of Theorem A.5.5, which holds pointwise for Schwartz functions, gives $\int_{\mathbb{Y}_{\mathbb{A}}/\mathbb{Y}} Z_\psi(\Lambda_{\mathbb{X}}f)(0,y)\,dy = (\Lambda_{\mathbb{X}}f)(0)$. □

Lemma 6.5.23. *Let S, T be spaces with points with signs s on n and s' on n', and $W = S \oplus S^-$, with signs $s \sqcup (-s)$ on $n \sqcup n$ and matrix* $\mathrm{diag}(J_S, -J_S)$. *For $\delta \in \mathrm{GL}_n(E)$ with $\delta^* J_S \delta = J_S$ let*

$$L_\delta = \{(\delta^{-1}u, -u) : u \in E^n\},$$

a rational Lagrangian of W. Then for all $f, f' \in \mathcal{M}_{S,T}$ and all automorphic characters α, β of $\mathrm{U}(1)$,

$$Z_{L_\delta}(\mathrm{dbl}_{c_{S,T}}(f, f')) = \langle f',\, \omega_{\alpha,\beta}(x_S^{-1}\delta x_S, 1)\, f\rangle.$$

Proof. Fix δ, f, f', α, β as in the statement and put $g_\delta = x_S^{-1}\delta x_S \in \Gamma_S$ and $\varphi_{\mathrm{d}} = \mathrm{dbl}_{c_{S,T}}(f, f') = f \boxtimes^{\mathrm{sc}} c_{S,T}\,\mathrm{cj}f'$ (WR7), a vector of $\mathcal{M}_{W,T}$ since $\mathrm{cj}f' \in \mathcal{M}_{S^-,T}$ ((1) of Lemma 6.4.56).

Step 1: L_δ is the Lagrangian of a splitting of W over the zero space. Let p be a copy of n and

$$k = \begin{pmatrix} \delta^{-1} \\ -1 \end{pmatrix}, \qquad l = \frac{1}{2}\begin{pmatrix} \delta^{-1} \\ 1 \end{pmatrix} J_S^{-1},$$

$(n \sqcup n) \times p$ matrices over E, and i the empty $(n \sqcup n) \times \emptyset$ matrix. With $J_W = \mathrm{diag}(J_S, -J_S)$, $J_S^* = J_S$ and $(\delta^{-1})^* J_S \delta^{-1} = J_S$ (which follows from $\delta^* J_S \delta = J_S$):

$$\begin{aligned} k^* J_W k &= (\delta^{-1})^* J_S \delta^{-1} - J_S = 0, \\ l^* J_W l &= \tfrac{1}{4} J_S^{-1}\big((\delta^{-1})^* J_S \delta^{-1} - J_S\big) J_S^{-1} = 0, \\ l^* J_W k &= \tfrac{1}{2} J_S^{-1}\big((\delta^{-1})^* J_S \delta^{-1} + J_S\big) = 1, \end{aligned}$$

the conditions on i are empty, and $\#(n \sqcup n) = 0 + 2\#p$. So $D_\delta = (k, l, i)$ is a splitting of W over the zero space $V_\emptyset$ along p, and $kE^p = \{(\delta^{-1}u, -u) : u \in E^n\} = L_\delta$. In particular L_δ has dimension $\#p$ and h_W vanishes on it ($k^* J_W k = 0$), so it is a rational Lagrangian of W, split along p, and by (3) of Lemma 6.5.16, Z_{L_δ} is the zero term Z along the splitting of $\mathrm{Hom}(W, T)$ over $\mathrm{Hom}(V_\emptyset, T)$ induced by D_δ.

Step 2: the term as a mean over adelic matrices. The space $\mathrm{Hom}(V_\emptyset, T)$ has the empty index set $n' \times \emptyset$; so $\mathcal{M}_{V_\emptyset,T} = \mathbb{C}$, $\rho(0) = 1$, and its canonical theta functional is the identity (WC1, rank 0). The induced splitting has k-frame $J_T^{-1} \otimes (k^* J_W)^{\mathsf{T}}$ (MX1), and the point of $\mathrm{Hom}(W, T)$ is $x_T \otimes (x_W^{-1})^{\mathsf{T}}$; so its adelic k-frame sends an adelic $n' \times p$ matrix b to $\tilde{k}_{\mathbb{A}} b = x_T^{-1} J_T^{-1}\, b\, k^* J_W\, x_W$. By (MX4), as $n_0 = \emptyset$,

$$Z_{L_\delta}(\varphi_{\mathrm{d}}) = \int_{\mathrm{M}_{n' \times p}(\mathbb{A}_E)/\mathrm{M}_{n' \times p}(E)} \theta_{\mathrm{Hom}(W,T)}\big(\rho(\tilde{k}_{\mathbb{A}} b)\, \varphi_{\mathrm{d}}\big)\, db.$$

Now $k^* J_W = \big((\delta^{-1})^* J_S \mid J_S\big)$ in column blocks indexed by the two copies of n, and $(\delta^{-1})^* J_S = J_S \delta$ because $\delta^* J_S \delta = J_S$. With $X_b = x_T^{-1} J_T^{-1}\, b\, J_S\, x_S$, an adelic $n' \times n$ matrix, and since the scalar idele c commutes with matrices,

$$\tilde{k}_{\mathbb{A}} b = \big(x_T^{-1} J_T^{-1} b J_S \delta x_S \mid x_T^{-1} J_T^{-1} b J_S\, c\, x_S\big) = \big(X_b\, g_\delta \mid c\, X_b\big). \tag{6.127}$$

Step 3: the integrand. For adelic $n' \times n$ matrices z_1, z_2, $F_1 \in \mathcal{M}_{S,T}$ and $F_2 \in \mathcal{M}_{S^-,T}$, $\rho\big((z_1 \mid z_2)\big)(F_1 \boxtimes^{\mathrm{sc}} F_2) = \rho(z_1)F_1 \boxtimes^{\mathrm{sc}} \rho(z_2)F_2$. By (6.127) and (c) of Lemma 6.3.52 (source sums $S \oplus S^-$, constant 1),

$$\theta_{\mathrm{Hom}(W,T)}\big(\rho(\tilde{k}_{\mathbb{A}} b)\, \varphi_{\mathrm{d}}\big) = \theta\big(\rho(X_b g_\delta) f\big) \cdot c_{S,T}\, \theta_{\mathrm{Hom}(S^-,T)}\big(\rho(cX_b)\, \mathrm{cj}f'\big).$$

By (1) of Lemma 6.4.56 with $z = X_b$,

$$\mathrm{cj}\, \rho(X_b) = \rho(\sigma_c^{-1} X_b)\, \mathrm{cj} = \rho(cX_b)\, \mathrm{cj},$$

since $\sigma_c^{-1} x = (x_\infty, c\, x_f) = c\, x$; so by (3) of Lemma 6.4.56 the second factor is

$$c_{S,T}\theta_{\mathrm{Hom}(S^-,T)}(\mathrm{cj}\, \rho(X_b) f') = \overline{\theta(\rho(X_b) f')}.$$

For the first factor: for $g \in \mathrm{G}(s)$ the pair element of $(g, 1)$ is $Y \mapsto Yg^{-1}$ (VP5), and the scalars $\alpha(\det 1)\beta(\det g)^{-1}$ cancel under conjugation, so (2) of Lemma 4.1.1 gives $\omega(g, 1)\rho(Y)\omega(g, 1)^{-1} =$

$\rho(Yg^{-1})$ for every adelic $n' \times n$ matrix Y. With $g = g_\delta^{-1}$, $\rho(X_b g_\delta) = \omega(g_\delta^{-1}, 1)\rho(X_b)\omega(g_\delta, 1)$, and as $g_\delta^{-1} \in \Gamma_S$, Lemma 6.2.5 gives

$$\theta\big(\rho(X_b g_\delta) f\big) = \theta\big(\rho(X_b)\,\omega(g_\delta, 1) f\big).$$

Hence

$$\theta_{\mathrm{Hom}(W,T)}\big(\rho(\tilde{k}_{\mathbb{A}} b)\,\varphi_{\mathrm{d}}\big) = \overline{\theta(\rho(X_b) f')}\;\theta\big(\rho(X_b)\,\omega(g_\delta, 1) f\big). \tag{6.128}$$

Step 4: change of variables and the Plancherel identity. The map $b \mapsto X_b$ is a continuous additive automorphism of $\mathrm{M}_{n' \times n}(\mathbb{A}_E)$, with inverse $X \mapsto J_T x_T\, X\, x_S^{-1} J_S^{-1}$, and it maps $\mathrm{M}_{n' \times n}(E)$ onto $\{x_T^{-1} u\, x_S : u \in \mathrm{M}_{n' \times n}(E)\}$ (as $b \mapsto J_T^{-1} b J_S$ is a bijection of $\mathrm{M}_{n' \times n}(E)$), which is the set $\mathrm{Hom}(S,T)(E)$ of rational vectors of $\mathrm{Hom}(S,T)$, its point being $x_T \otimes (x_S^{-1})^{\mathsf{T}}$. So it induces an isomorphism of compact groups $\mathrm{M}_{n' \times p}(\mathbb{A}_E)/\mathrm{M}_{n' \times p}(E) \to \mathbb{A}_E^{n' \times n}/\mathrm{Hom}(S,T)(E)$, which carries the invariant probability measure to the invariant probability measure (uniqueness of normalised Haar measure). The canonical functional θ is a theta functional of $\mathrm{Hom}(S,T)$ in the sense of (WD9) by Lemma 4.1.17; by (2) of Lemma 4.1.10 the function $x \mapsto \overline{\theta(\rho(x) f')}\,\theta(\rho(x)\omega(g_\delta, 1) f)$ is a continuous function on $\mathbb{A}_E^{n' \times n}/\mathrm{Hom}(S,T)(E)$ with mean $\langle f', \omega(g_\delta, 1) f\rangle$. With Step 2 and (6.128),

$$Z_{L_\delta}(\varphi_{\mathrm{d}}) = \int_{\mathbb{A}_E^{n' \times n}/\mathrm{Hom}(S,T)(E)} \overline{\theta(\rho(x) f')}\;\theta\big(\rho(x)\,\omega(g_\delta, 1) f\big)\,dx = \big\langle f',\, \omega_{\alpha,\beta}(x_S^{-1}\delta x_S, 1)\, f\big\rangle.$$

□

6.6 The cost of one lift

This section bounds the volumes of the single lifts, one lift at a time (Theorem 6.6.6): along a regular family θ, the family $\iota \mapsto Z_j(1)/Z_j(\theta(\iota))$ has height at most $d_{\mathcal{T}}\, k\,(\log b \cdot \beta_{\mathrm{den}} - h_{\mathrm{dir}})$, with h_{dir} the direction amount (Definition 2.4.2) and β_{den} the denominator budget (Definition 3.2.34).

The volume at a twist is compared with its value at the trivial twist through a comparison operator (Definition 6.6.1). This is a family U_ϑ that, on the lifts, is the Hecke ratio $\rho_j(\vartheta) = \Gamma_j(\vartheta)/\Gamma_j(1)$ of products of partial Hecke L-values [128] times one positive operator independent of ϑ; it maps lifts to forms orthogonal to the false lifts, keeps integrality away from $\mathrm{N}Q$, and changes conjugate norms at the trivial twist by a bounded factor. Its compression Δ to the space of lifts satisfies $Z_j(\vartheta)\,\Delta(\vartheta) = C\rho_j(\vartheta)^d$ (Lemma 6.6.7), so that

$$\frac{Z_j(1)}{Z_j(\theta(\iota))} = \frac{\Delta(\theta(\iota)^j)}{\Delta(1)} \cdot \rho_j\big(\theta(\iota)^j\big)^{-d}, \qquad d = d_{\mathcal{T}}.$$

The first factor is bounded by the clearing condition of the regular family and the size of $\Delta(1)$; the second by the heights of the Hecke ratios (Proposition 6.7.1, Section 6.7), where L-values are realised as squared norms of lifts from $\mathrm{U}(1)$. The rest of the section proves the abstract comparison, constructs comparison operators (Proposition 6.6.13) and proves that the periods of false lifts vanish (Proposition 6.6.81). The integrality that a regular family carries is established in Section 7. The architecture follows [259]; for the arithmetic of automorphic forms on unitary groups, the background of the comparison, see [273, 274].

Definition 6.6.1. Fix $1 \le j \le m$ and let S_0 be the set of chosen places.

The exchange pairs. The three **exchange pairs** of the j-th lift are the critical pairs

$$p_j^* = (\mu_j^0 \upsilon^{n_*},\, z_*), \qquad p_j^{\pm} = (\upsilon^{-z_\pm} \chi_M^{\pm j},\, z_\pm),$$

where $n_* = j + (t - 11m - 1)/2$, $z_* = 7\lfloor m/2 \rfloor + k/2$, $z_+ = m$ and $z_- = \lfloor m/2 \rfloor$; their tame parts are ω^j, ω^j and ω^{-j}. Put $s_* = s_+ = 1$ and $s_- = -1$.

The Hecke value product. For a twist ϑ with modulus Q the **Hecke value product** of the j-th lift is

$$\Gamma_j(\vartheta) = \prod_{i \in \{*,+,-\}} L_*(S_0 \cup Q,\ (\nu_i\, \vartheta^{s_i})^{-1};\ z_i), \qquad p_j^i = (\nu_i, z_i), \tag{6.129}$$

and $\rho_j(\vartheta) = \Gamma_j(\vartheta)/\Gamma_j(1)$ is its **Hecke ratio**.

Comparison operators. A **comparison operator** for the j-th lift is a family $U = (U_\vartheta)$, one $\mathbb{C}$-linear operator U_ϑ on $\mathcal{A}_{j,\vartheta}(V^{\mathrm{def}})$ for each twist ϑ, such that:

(CO1) $\rho_j(\vartheta) \neq 0$ for every twist ϑ;

(CO2) there is an operator U° on $\mathcal{A}^{\mathrm{good}}(W_j)$, independent of ϑ, with $\langle y, U^\circ y\rangle > 0$ for $y \neq 0$ and

$$\langle \Theta_{j,\vartheta} y',\, U_\vartheta\, \Theta_{j,\vartheta} y\rangle = \rho_j(\vartheta)\, \langle y', U^\circ y\rangle \qquad \text{for all twists } \vartheta \text{ and } y, y' \in \mathcal{A}^{\mathrm{good}}(W_j);$$

(CO3) for every twist ϑ and every $z \in \mathcal{L}_{j,\vartheta}$, the form $U_\vartheta z$ is orthogonal to the false lifts for $(e_0, \mathcal{L}_{j,\vartheta}^{\perp})$;

(CO4) for every twist ϑ, every prime $\ell \nmid \mathrm{N}Q$ and every embedding $\mathbb{C} \to \mathbb{C}_\ell$, U_ϑ maps the forms integral at that embedding to forms integral at it;

(CO5) $\|U_1\varphi\|_\sigma^2 \leq \exp(6\, f\, m\, b\, (\log b)^2)\, \|\varphi\|_\sigma^2$ for every $\varphi \in \mathcal{A}_{j,1}(V^{\mathrm{def}})$ and every automorphism σ of $\mathbb{C}$.

For a comparison operator U, the **compression** $\mathrm{pr}\, U_\vartheta$ is the operator $z \mapsto \mathrm{pr}_\vartheta(U_\vartheta z)$ on $\mathcal{L}_{j,\vartheta}$, with pr_ϑ the orthogonal projection onto $\mathcal{L}_{j,\vartheta}$.

Definition 6.6.2. Let O be a descent pair for ranks $r < n$. Let $\varpi_O \in \mathbb{A}_{E,f}^\times$ be a fixed idele whose component at each chosen place w generates $w\mathcal{O}_{E,w}$ and which is 1 elsewhere; $R_2 = \mathcal{O}_E/\mathfrak{M}_O^2$ with $\mathfrak{M}_O = \prod_{w \in M_O} w$, and $\bar{\varpi}$ the class of ϖ_O in R_2. For an embedding u of index sets, I_u is the inclusion matrix, whose column j is the basis vector $e_{u(j)}$.

(GU1) Divided splittings. For finite index sets N, m, a and an embedding $z\colon \{1,\dots,r\} \hookrightarrow m$, a **divided splitting** $\mathcal{V}$ consists of a bijection $\varepsilon\colon N \sqcup m \to \{1,\dots,n\}$, an embedding $\phi_{\mathcal{V}}\colon \{1,\dots,r\} \hookrightarrow N$ with $\varepsilon(\phi_{\mathcal{V}}(i)) = \mathrm{inc}_O(i)$ for all i, and an embedding $a \hookrightarrow N$ (the **divided embedding**), such that $\kappa_O^+(\tau, h) = 0$ for $|N| \leq h < n$ and $\kappa_O^-(\tau, h) = 0$ for $|m| \leq h < n$. For an $n \times r$ matrix x, x_N and x_m are its rows $\varepsilon(N)$ and $\varepsilon(m)$. Its **loss** is $\mathrm{loss}(\mathcal{V}) = \sum_{\tau \in \Phi}(|a| \sum_{h<|N|} \kappa_O^+(\tau,h) + |m| \sum_{h<|m|} \kappa_O^-(\tau,h))$.

(GU2) Divided lattices. A **divided lattice** L is a point $\gamma_L \in G_f(n)$ with components 1 outside the chosen places and their conjugates such that every entry of $\varpi_O \gamma_L^{-1}$ is integral. Its **reduced inverse** $G_L \in \mathrm{M}_n(R_2)$ is the reduction of $\varpi_O \gamma_L^{-1}$, and its **Weil scalar** is $\beta_L = \chi_O[r](\delta)/|\delta|^{r/2}$, where δ is the idele equal to $\det \gamma_L$ at the chosen places and to 1 elsewhere.

(GU3) The congruence group and block normalisation. For an $a \times N$ matrix s over R_2, $[s; \bar{\varpi}]$ is the $(a \sqcup N) \times N$ matrix with s stacked over $\bar{\varpi}\cdot 1$. $\mathrm{C}(\mathcal{V}) = \{A \in \mathrm{GL}_r(R_2) : A\bar{\varpi} = \bar{\varpi}\}$. An $n \times r$ matrix x over R_2 is **block normalised for** s if $x_m = I_z$ and $[s; \bar{\varpi}]\, x_N = [s; \bar{\varpi}]\, I_{\phi_{\mathcal{V}}}$.

(GU4) Glued lattices. A divided lattice L is **glued for** s if (1) for every $n \times r$ matrix x over R_2 with $G_L x = \bar{\varpi}\,\mathrm{Inc}_O$ there is exactly one $A \in \mathrm{C}(\mathcal{V})$ with xA block normalised for s; (2) if xA is block normalised for s for some $A \in \mathrm{C}(\mathcal{V})$, then $G_L x = \bar{\varpi}\,\mathrm{Inc}_O$; and (3) there is $J \in \mathrm{GL}_N(R_2)$ such that $\bar{\varpi}$ times the product of the columns $\varepsilon(N)$ of G_L with J vanishes in every column outside the image of the divided embedding.

(GU5) Delta forms. For $x \in G_f(n)$ and $v \in \mathbb{V}_{\kappa_O}$, the **delta form** $\delta_x(v) \in \mathrm{Form}(O)$ is

$$\delta_x(v)(y) = \sum_{\gamma} \tilde{\eta}_O(x^{-1}\gamma y)\,\rho_O(\gamma)^{-1} v \qquad (y \in G_f(n)),$$

the sum over the rational points γ of $\mathrm{U}(\mathrm{I}_n)$ with $x^{-1}\gamma y \in \mathbf{K}(O)$.

(GU6) Cartan product and product forms. Fix an integral left inverse C'_O of the matrix C_O of (DP8). For y of weight κ_O^+ in the rows N and η of weight κ_O^- in the rows m, the **Cartan product** is $y \cdot \eta = C'_O(S_{\kappa_O^+}(\iota_N)\,y \otimes S_{\kappa_O^-}(\iota_m)\,\eta)$, of weight κ_O, where ι_N, ι_m are the $n \times N$ and $n \times m$ matrices formed by the columns $\varepsilon(N)$, $\varepsilon(m)$ of the identity. For a divided lattice L, $h = (h_1, h_2) \in G_f(N) \times G_f(m)$ and such y, the **product form** is the linear map $\eta \mapsto \mathrm{pr}_{\mathcal{V},L}(h; y)(\eta) = \delta_{\mathrm{diag}_\varepsilon(h_1,h_2)\gamma_L}(y \cdot \eta)$, $\mathrm{diag}_\varepsilon$ the block diagonal embedding along ε.

Definition 6.6.3. Throughout, c, N and m are finite index sets, and $W(O)$ of a descent pair O of rank r has the index set $\{1, \dots, r\}$.

(KN1) Reduction modulo a modulus; levels of subgroups. Let $\mathfrak{m} = \prod_{w \in \Sigma(\mathfrak{m})} w^{e_w}$ be a modulus, so that $R_\mathfrak{m} = \prod_{w \in \Sigma(\mathfrak{m})} \mathcal{O}_{E,w}/w^{e_w}\mathcal{O}_{E,w}$ by the Chinese remainder theorem. For $k \in \mathbf{K}_0(N)$, $\mathrm{red}_\mathfrak{m}(k) \in \mathrm{GL}_N(R_\mathfrak{m})$ is the matrix whose image in $\mathrm{GL}_N(\mathcal{O}_{E,w}/w^{e_w}\mathcal{O}_{E,w})$ is the reduction of the component of k at w (read in $\mathrm{GL}_N(\mathcal{O}_{E,w})$ as for red_w), for every $w \in \Sigma(\mathfrak{m})$. For a subgroup H of $\mathrm{GL}_N(R_\mathfrak{m})$ the **level of** H is

$$\mathbf{K}_\mathfrak{m}[H] = \{k \in \mathbf{K}_0(N) :\ \mathrm{red}_\mathfrak{m}(k) \in H\}.$$

(KN2) Row stabilisers and column data. Let $\phi\colon R \to S$ be a homomorphism of commutative rings, $\Lambda \in \mathrm{M}_{c \times N}(S)$ and $u\colon \{1, \dots, r\} \hookrightarrow N$ an embedding; $\phi(A)$ is the entrywise image of a matrix A. The **row stabiliser** $\mathrm{Stab}_\phi(\Lambda, u)$ is the subgroup of the $A \in \mathrm{GL}_N(R)$ whose columns of index outside $u(\{1, \dots, r\})$ are those of the identity matrix and which satisfy $\Lambda\,\phi(A) = \Lambda$. For a multiplicative character χ of R (a homomorphism of multiplicative monoids $R \to \mathbb{C}$ that vanishes on the nonunits), the **column datum** is the function on $\mathrm{M}_{N \times r}(R)$

$$\mathrm{cd}_{\chi,\phi,\Lambda,u}(\sigma) = \chi(\det \sigma_u) \ \text{ if } \ \Lambda\,\phi(\sigma) = \Lambda\, I_u, \qquad \mathrm{cd}_{\chi,\phi,\Lambda,u}(\sigma) = 0 \ \text{ otherwise,}$$

where σ_u is the $r \times r$ matrix whose row c' is the row $u(c')$ of σ.

(KN3) Row-fixing levels. Let O be a descent pair of rank r with $M_O \neq \emptyset$, and $\mathfrak{Q}_O = \prod_{w \in Q_O} w$; then $\mathfrak{M}_O^2$ and $\mathfrak{M}_O^2\mathfrak{Q}_O$ are moduli, and $\mathrm{red}_0\colon R_{\mathfrak{M}_O^2\mathfrak{Q}_O} \to R_{\mathfrak{M}_O^2}$ is the reduction. The **residue character** of O is the multiplicative character ψ_O^{res} of $R_{\mathfrak{M}_O^2\mathfrak{Q}_O}$ with $\psi_O^{\mathrm{res}}(x) = \prod_{w \in M_O \cup Q_O} \psi_{O,w}(x \bmod w)$ for units x and $\psi_O^{\mathrm{res}}(x) = 0$ for nonunits. For $\Lambda \in \mathrm{M}_{c \times m}(R_{\mathfrak{M}_O^2})$ and an embedding $u\colon \{1, \dots, r\} \hookrightarrow m$ the **row-fixing level** is

$$\mathbf{K}_O[\Lambda, u] = \mathbf{K}_{\mathfrak{M}_O^2\mathfrak{Q}_O}[\mathrm{Stab}_{\mathrm{red}_0}(\Lambda, u)] \subseteq \mathbf{K}_0(m).$$

(KN4) Kernel vectors. Let O be a descent pair of rank r, b an automorphic character of $\mathrm{U}(1)$, $\mathfrak{m}$ a modulus, Ψ a function on $\mathrm{M}_{m\times r}(R_{\mathfrak{m}})$ and κ a weight in rank $|m|$ with rows m, with standard basis $(b_i)_{i\in I_\kappa}$; the letter substitution Let_{-1} of (DP8) is read with the rows in m, so that it takes values in $\mathbb{C}[x]_{m\times r}$. For $g\in \mathrm{U}(W(O))(\mathbb{A})$ and $h\in G_f(m)$ the **kernel vector** $\mathrm{kv}_{O,b;\mathfrak{m}}[\Psi;\kappa](g,h)\in\mathbb{V}_\kappa$ has the coordinates

$$\mathrm{kv}_{O,b;\mathfrak{m}}[\Psi;\kappa](g,h)_i=\overline{\theta^{W(O),\mathrm{I}_m}_{\chi_O,b;\mathfrak{m}}\big[\Psi,\mathrm{Let}_{-1}(b_i)\big](g,h)}\qquad(i\in I_\kappa).$$

(KN5) Coset kernel sums. Let O, $\mathfrak{Q}_O$, red_0 and ψ^{res}_O be as in (KN3), b an automorphic character of $\mathrm{U}(1)$, $\Lambda\in\mathrm{M}_{c\times m}(R_{\mathfrak{M}^2_O})$, $u\colon\{1,\dots,r\}\hookrightarrow m$ an embedding, and y a function from $G_f(m)$ to the Weyl module $\mathbb{V}_{\kappa^+_O}$ of the weight κ^+_O in rank $|m|$ with rows m (its values $\kappa^+_O(\tau,h')$, $1\le h'<|m|$); Let_1 is read with the rows in m. For $g\in\mathrm{U}(W(O))(\mathbb{A})$ the **coset kernel sum** is the sum (6.22) over the double cosets of $\mathrm{U}(\mathrm{I}_m)(F)\backslash G_f(m)/\mathbf{K}_O[\Lambda,u]$, evaluated at their fixed representatives h,

$$\mathrm{cks}_{O,b}(\Lambda,u;y)(g)=\sum_{h\bmod \mathbf{K}_O[\Lambda,u]}^{\mathrm{cl}}\theta^{W(O),\mathrm{I}_m}_{\chi_O,b;\mathfrak{M}^2_O\mathfrak{Q}_O}\Big[\mathrm{cd}_{\psi^{\mathrm{res}}_O,\mathrm{red}_0,\Lambda,u},\ \mathrm{Let}_1\big(\mathrm{Pol}_{\kappa^+_O}(y(h))\big)\Big](g,h).$$

(KN6) Point lifts and point forms. Let O be a descent pair for ranks $r<n$, $Y=(Y_w)_{w\in M_O}$ with $Y_w\in\mathrm{M}_{n\times r}(k_w)$, and $u\colon\{1,\dots,r\}\hookrightarrow\{1,\dots,n\}$ an embedding. A **point lift** for (Y,u) is an element $k\in\mathbf{K}_0(n)$ such that: its component is 1 at every finite place w with $w\notin M_O\cup Q_O$ and $\bar w\notin M_O\cup Q_O$; $\mathrm{red}_w(k)\,\mathrm{Inc}_O=Y_w$ for every $w\in M_O$; and, for every $w\in Q_O$ and $1\le c'\le r$, the row $u(c')$ of $\mathrm{red}_w(k)$ is the row $\mathrm{inc}_O(c')$ of the identity matrix. For $h\in G_f(n)$, $v\in\mathbb{V}_O$ and a point lift k for (Y,u), the delta form $\delta_{hk}(v)\in\mathrm{Form}(O)$ of (GU5) is the **point form** of v at h for k.

Definition 6.6.4. Let $1\le j\le m$, let ϑ be a twist, $O=O_{j,\vartheta}$ and $n=r+t$. The weights $\kappa^\pm_O$ do not involve ϑ ((LF4)), and $\mathfrak{M}=\mathfrak{M}_O=\pi_M\mathcal{O}_E$, the product of the chosen places, does not involve ϑ either. The basis of W_j is indexed by $\mathcal{R}=\{1,\dots,r\}$, read in $\{1,\dots,n\}$ through inc_O as the first r indices.

(TG1) Index sets and spaces. Put $\mathcal{A}^-_j=\{1,\dots,j\}$, $\mathcal{A}^+_j=\{1,\dots,3m-j\}$, $\mathcal{B}^\flat=\{1,\dots,6m+1\}$ and

$$\mathcal{B}_j=\mathcal{R}\sqcup\mathcal{A}^-_j\sqcup\mathcal{A}^+_j\sqcup\mathcal{B}^\flat,\qquad\mathcal{B}^\circ=\mathcal{R}\sqcup\{1,\dots,t-9m-1-r\},\qquad\mathcal{B}^{\mathrm{c}}=\{1,\dots,2m\}\sqcup\{1,\dots,m\},$$

so that $|\mathcal{B}_j|=r+9m+1$, $|\mathcal{B}^\circ|=t-9m-1$ and $|\mathcal{B}^{\mathrm{c}}|=3m$. The **first factor space** is $V''_j=\mathrm{I}_{\mathcal{B}_j}$, the **second factor space** is $V^\circ=\mathrm{I}_{\mathcal{B}^\circ}$, and $W^\flat=\mathrm{I}_{\mathcal{B}^\flat}$.

(TG2) The gluing splitting. Fix, independently of ϑ, a bijection of $(\mathcal{A}^-_j\sqcup\mathcal{A}^+_j\sqcup\mathcal{B}^\flat)\sqcup\mathcal{B}^\circ$ onto $\{r+1,\dots,n\}$ and an embedding $d_j\colon\mathcal{B}^{\mathrm{c}}\hookrightarrow\mathcal{B}_j$. Let $\varepsilon_j\colon\mathcal{B}_j\sqcup\mathcal{B}^\circ\to\{1,\dots,n\}$ be the identity on $\mathcal{R}\subseteq\mathcal{B}_j$ and the fixed bijection on the other indices, let $\phi_j\colon\mathcal{R}\hookrightarrow\mathcal{B}_j$ and $z_j\colon\mathcal{R}\hookrightarrow\mathcal{B}^\circ$ be the inclusions of $\mathcal{R}$. The **gluing splitting** of the j-th lift is $\mathcal{V}_j=(\varepsilon_j,\phi_j,d_j)$; with $\mathcal{B}_j$, $\mathcal{B}^\circ$, $\mathcal{B}^{\mathrm{c}}$ and z_j in the roles of N, m, a and z of (GU1), it is a divided splitting for $O_{j,\vartheta}$ exactly when $\kappa^+_O(\tau,h)=0$ for $|\mathcal{B}_j|\le h<n$ and $\kappa^-_O(\tau,h)=0$ for $|\mathcal{B}^\circ|\le h<n$, for all $\tau\in\Phi$.

(TG3) Classes and choices. For a finite index set $\mathcal{B}$, the **classes** of $\mathrm{I}_{\mathcal{B}}$ at the principal level are the double cosets $\mathrm{U}(\mathrm{I}_{\mathcal{B}})(F)\backslash G_f(\mathcal{B})/\mathbf{K}_{\mathfrak{M}^2}[\{1\}]$; $\mathrm{Cl}^\flat$ and Cl° are those of $W^\flat$ and of

V°, with fixed representatives $x_{\mathfrak{c}}$. Put $\Delta' = \frac{\Delta}{2} - \frac{t+1}{2}$. A **choice** for the j-th lift is a triple $i = (\Lambda_i, \mathfrak{c}_i, \lambda_i)$ of a matrix $\Lambda_i \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times \mathcal{B}_j}(\mathcal{O}_E/\mathfrak{M}^2)$, a class $\mathfrak{c}_i \in \mathrm{Cl}^\flat$ and a family $\lambda_i = (\lambda_{i,\tau})_{\tau \in \Phi}$ of maps $\lambda_{i,\tau} \colon \{1, \dots, \Delta'\} \times \{1, \dots, 2m\} \to \mathcal{B}^\flat$ (lists of rows). Mem_j is the finite set of choices.

(TG4) Tables. Let $\mathbb{V}_j^-$ be the Weyl module of the weight κ_O^- in rank $|\mathcal{B}^\circ|$ with rows $\mathcal{B}^\circ$, with the Gram form $\langle , \rangle_{\kappa_O^-}$. The **space of tables** Tab_j is the orthogonal sum of copies of $\mathbb{V}_j^-$, one for each pair $(i, \mathfrak{c}) \in \mathrm{Mem}_j \times \mathrm{Cl}^\circ$; its elements are the families $\zeta = (\zeta_{i,\mathfrak{c}})$, with $\langle \zeta, \zeta' \rangle = \sum_{i,\mathfrak{c}} \langle \zeta_{i,\mathfrak{c}}, \zeta'_{i,\mathfrak{c}} \rangle_{\kappa_O^-}$, and for $\sigma \in \mathrm{Aut}(\mathbb{C})$, $\|\zeta\|_\sigma^2 = \sum_{i,\mathfrak{c}} \|\sigma(\zeta_{i,\mathfrak{c}})\|_{\kappa_O^-}^2$, σ applied to the coordinates.

(TG5) Gluing levels. For $\Lambda \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times \mathcal{B}_j}(\mathcal{O}_E/\mathfrak{M}^2)$ the **gluing level** is the row-fixing level of $O_{j,\vartheta}$

$$\mathbf{J}_\vartheta(\Lambda) = \mathbf{K}_O\big[[\Lambda; \bar{\varpi}],\, \phi_j\big] \subseteq \mathbf{K}_0(\mathcal{B}_j),$$

with $[\Lambda; \bar{\varpi}]$ the $(\mathcal{B}^{\mathrm{c}} \sqcup \mathcal{B}_j) \times \mathcal{B}_j$ matrix of (GU3).

(TG6) Gluing maps. Suppose that $\mathcal{V}_j$ is a divided splitting for $O_{j,\vartheta}$. Let $L = (L_i)_{i \in \mathrm{Mem}_j}$ be divided lattices of $O_{j,1}$ (they are divided lattices of $O_{j,\vartheta}$, since (GU2) reads only the chosen places), and let $\varphi'' = (\varphi''_i)_{i \in \mathrm{Mem}_j}$ be functions $\varphi''_i \colon G_f(\mathcal{B}_j) \to \mathbb{V}_j^+$, the Weyl module of κ_O^+ in rank $|\mathcal{B}_j|$ with rows $\mathcal{B}_j$. The **gluing map** $\mathrm{gl}_\vartheta[L, \varphi''] \colon \mathrm{Tab}_j \to \mathrm{Form}(O_{j,\vartheta})$ is

$$\mathrm{gl}_\vartheta[L, \varphi''](\zeta) = M^{\mathrm{loss}(\mathcal{V}_j)} \sum_{(i,\mathfrak{c}) \in \mathrm{Mem}_j \times \mathrm{Cl}^\circ} \sum_{x \bmod \mathbf{J}_\vartheta(\Lambda_i)}^{\mathrm{cl}} \mathrm{pr}_{\mathcal{V}_j, L_i}\big((x, x_{\mathfrak{c}}); \varphi''_i(x)\big)(\zeta_{i,\mathfrak{c}}),$$

the inner sum (6.22) over the double cosets $\mathrm{U}(V_j'')(F) \backslash G_f(\mathcal{B}_j) / \mathbf{J}_\vartheta(\Lambda_i)$ at fixed representatives x; it is linear in ζ.

Definition 6.6.5. Let $1 \le j \le m$, ϑ a tame character, $O = O_{j,\vartheta}$ and $O^1 = O_{j,1}$ (the weights $\kappa_O^\pm = \kappa_{O^1}^\pm$ do not involve ϑ), and $r_+ = k + j - 1$. For a finite index set $\mathcal{B}$, $\mathrm{I}_{\mathcal{B}}$ is the standard definite space and $\mathrm{I}_{\mathcal{B}}^-$ the standard space of signs -1 on $\mathcal{B}$; a finite point of a definite group is read as the adelic point with infinite components 1. For $\tau \in \Phi$ and $z \in E$, $\tau(z)$ is the image of z under the embedding chosen at τ, applied entrywise to matrices. The two blocks of $\mathcal{B}^{\mathrm{c}} = \{1, \dots, 2m\} \sqcup \{1, \dots, m\}$ are written $(1, a)$ and $(2, a)$; S^{c} is the standard space on $\mathcal{B}^{\mathrm{c}}$ with signs $+1$ on the first and -1 on the second block.

(XE1) Characters. Put $e_j = j + \lfloor (t + k - 1)/2 \rfloor$. The **twisted level character**, the **first-factor character** and the **untwisted carrier character** are

$$\chi'_{j,\vartheta} = \chi_M^j\, \vartheta, \qquad \nu''_{j,\vartheta} = \mu_j^0 \vartheta\, \upsilon^{e_j}, \qquad \nu_j^\flat = \mu^\flat\, \upsilon^{e_j - j\Delta};$$

the **carrier character** is $\nu_j^\flat \upsilon^m = \mu^\flat \upsilon^{m + e_j - j\Delta}$.

(XE2) Trace characters. Let $\varpi_{\mathfrak{M}^2}$ be the finite idele with component π_M^2 at the places dividing $\mathfrak{M}$ and 1 at the other finite places. The **primitive character** of $R_{\mathfrak{M}^2}$ is $\psi_{\mathfrak{M}^2}(x \bmod \mathfrak{M}^2) = \psi_{E,f}\big(\jmath \alpha \bar{\alpha}\, \varpi_{\mathfrak{M}^2}^{-1} x\big)$ for $x \in \widehat{\mathcal{O}}_E$, and for $\Lambda \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times \mathcal{B}_j}(R_{\mathfrak{M}^2})$ the **trace character** is the function $\psi_\Lambda(y) = \psi_{\mathfrak{M}^2}(\mathrm{tr}(y\Lambda))$ on $\mathrm{M}_{\mathcal{B}_j \times \mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{M}^2})$.

(XE3) Padding, determinant index and the padded minor product. The **padded space** is $W_j \oplus \mathrm{I}_{\mathcal{A}_j^-}^- \oplus \mathrm{I}_{\mathcal{A}_j^+}$ on $\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+$, and $W'_j = W_j \oplus \mathrm{I}_{\mathcal{A}_j^-}^- \oplus \mathrm{I}_{\mathcal{A}_j^+} \oplus \mathrm{I}_{\mathcal{B}^\flat}$, on $\mathcal{B}_j$ (orthogonal

sums). The **negative rows** are $\mathrm{ng}_j(i) = i \in \mathcal{A}_j^-$ for $1 \le i \le j$ and $\mathrm{ng}_j(i)$ the basis vector of W_j of number $k + i - 2$ for $j < i \le m$. For $1 \le h < r_+$ and $1 \le a \le 2m$ the **positive row** $\mathrm{ps}_j(h,a)$ is the basis vector of W_j of number $h + a - 1$ if $h + a - 1 < r_+$, and the element a of $\mathcal{A}_j^+$ otherwise. The **determinant index** at $\tau \in \Phi$ is

$$D_j(\tau) = \{(h,c) : 1 \le h < r_+,\ 1 \le c \le \kappa_O^+(\tau,h)\} \sqcup \{1,\dots,\Delta'\}.$$

In the variables $x_{\tau,a,b}$ ($a \in \mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+$, $b \in \mathcal{B}^{\mathrm{c}}$) let $y_\tau^- = (x_{\tau,\mathrm{ng}_j(i),(2,i')})_{1\le i,i'\le m}$ and $y_{\tau,h} = (x_{\tau,\mathrm{ps}_j(h,a),(1,a')})_{1\le a,a'\le 2m}$. The **padded minor product** is

$$P_j = \prod_{\tau\in\Phi} \det(y_\tau^-)^{\#D_j(\tau)+|\mathcal{B}_j|+m} \prod_{\tau\in\Phi} \prod_{1\le h<r_+} \det(y_{\tau,h})^{\kappa_O^+(\tau,h)}.$$

(XE4) The carrier and its coefficients. The **carrier polynomial** is

$$P^\circ = \prod_{\tau\in\Phi} \det\big((x_{\tau,(2,i),i'})_{1\le i,i'\le m}\big)^{2m} \in \mathbb{C}[x]_{\mathcal{B}^{\mathrm{c}}\times\{1,\dots,m\}},$$

and the **carrier** is the function on the adelic group of S^{c}

$$\varphi^\circ(x) = \int_{[\mathrm{U}(\mathrm{I}^-_{\{1,\dots,m\}})]} \theta^{\mathrm{I}^-_{\{1,\dots,m\}},S^{\mathrm{c}}}_{v^m,1}\big(v_{P^\circ}\otimes v^0\big)(g,x)\,dg,$$

with the quotient measure. For an automorphic character β of $\mathrm{U}(1)$ the **carrier coefficient** is the function on $G_f(\mathcal{B}^{\mathrm{c}})$

$$\mathsf{a}_\beta(h) = \sum_{g \bmod \mathbf{K}_0(\{1,\dots,m\})}^{\mathrm{cl}} \theta^{\mathrm{I}_{\{1,\dots,m\}},\mathrm{I}_{\mathcal{B}^{\mathrm{c}}}}_{\beta,1}\big(v_1\otimes v^0\big)(g,h).$$

(XE5) Short row families and choice functions. A **short row family** is a family $Y = (Y_{\mathfrak{c}})_{\mathfrak{c}\in\mathrm{Cl}^\flat}$ of matrices $Y_{\mathfrak{c}} \in \mathrm{GL}_{\mathcal{B}^\flat}(E)$ such that $x_{\mathfrak{c}}^{-1}Y_{\mathfrak{c}}^{\mathsf{T}}$ has entries in $\widehat{\mathcal{O}}_E$ and $|\psi(Y_{\mathfrak{c},ab})| \le M^4$ for every ring homomorphism $\psi\colon E \to \mathbb{C}$ and all a,b. In (XE5)–(XE7) a short row family Y is fixed and the dependence on it is not written. For a choice i the **flat determinant product** is

$$P_i^\flat = \prod_{\tau\in\Phi}\prod_{k=1}^{\Delta'} \det\Big(\tau(Y_{\mathfrak{c}_i})[\lambda_{i,\tau}(k,\cdot)]\ (x_{\tau,b,(1,a)})_{b\in\mathcal{B}^\flat,\,1\le a\le 2m}\Big) \in \mathbb{C}[x]_{\mathcal{B}_j\times\mathcal{B}^{\mathrm{c}}},$$

where $\tau(Y_{\mathfrak{c}_i})[\lambda_{i,\tau}(k,\cdot)]$ is the $2m \times \mathcal{B}^\flat$ matrix whose row a is the row $\lambda_{i,\tau}(k,a)$ of $\tau(Y_{\mathfrak{c}_i})$, and P_j is read in $\mathbb{C}[x]_{\mathcal{B}_j\times\mathcal{B}^{\mathrm{c}}}$ through the inclusion of its rows in $\mathcal{B}_j$. The **choice function** of i is the function on $\mathrm{U}(W_j)(\mathbb{A})$

$$\mathsf{F}_i(g) = \int_{[\mathrm{U}(S^{\mathrm{c}})]} \varphi^\circ(x)\ \theta^{S^{\mathrm{c}},W_j'}_{v^m,\nu_j^\flat v^m;\mathfrak{M}^2}\big[\psi_{\Lambda_i},\ P_jP_i^\flat\big]\big(x,(g,1,x_{\mathfrak{c}_i})\big)\,dx,$$

with the quotient measure, $(g,1,x_{\mathfrak{c}_i})$ the block diagonal point with components g on $\mathcal{R}$, 1 on $\mathcal{A}_j^- \sqcup \mathcal{A}_j^+$ and $x_{\mathfrak{c}_i}$ on $\mathcal{B}^\flat$.

(XE6) Line series. Put $\mathcal{B}_j^{\mathrm{add}} = \mathcal{A}_j^+ \sqcup \mathcal{B}^\flat \sqcup \mathcal{B}^{\mathrm{c}}$, $W_j^{\mathrm{add}} = \mathrm{I}_{\mathcal{B}_j^{\mathrm{add}}}$ and $\mathcal{L}_j = \{0,\dots,r_+-1\} \sqcup \mathcal{B}_j^{\mathrm{add}}$, and fix, independently of ϑ, a bijection $\epsilon_j\colon \{1,\dots,2m\} \sqcup \mathcal{B}_j \to \mathcal{L}_j$. For a choice i, $\tau \in \Phi$ and $d \in D_j(\tau)$ the **constant rows** $\mathsf{c}_{i,\tau,d}$ form the complex $2m \times \mathcal{L}_j$ matrix whose row a is:

for $d = (h, c)$, the unit vector at the column $h + a - 1 \in \{0, \dots, r_+ - 1\}$ if $h + a - 1 < r_+$ and at the column $a \in \mathcal{A}_j^+$ otherwise; for $d \in \{1, \dots, \Delta'\}$, the row $\lambda_{i,\tau}(d, a)$ of $\tau(Y_{\mathfrak{c}_i})$ in the columns $\mathcal{B}^\flat$ and 0 in the other columns. Let $\Pi_i = \Delta^{\mathrm{id}}(\epsilon_j; \mathsf{c}_i) \in \mathbb{C}[x]_{\mathcal{B}_j \times \mathcal{L}_j}$ be the product of stacked determinants (6.23) whose index sets p, a, m, n, l there are $\{1, \dots, 2m\}$, $\mathcal{B}_j$, $\mathcal{L}_j$, $\mathcal{L}_j$, $\emptyset$, with the identity of $\mathcal{L}_j$ and ϵ_j as its bijections, $\iota_\tau = D_j(\tau)$ and the matrices $\mathsf{c}_{i,\tau,d}$. For $l \in I_{\kappa_O^+}$ (the standard basis of $\mathbb{V}_j^+$, rows $\mathcal{B}_j$) the **line coordinate** is

$$\mathrm{lc}_{i,l} = h_{\kappa_O^+}^{-1} \langle b_l, \Pi_i \rangle_{\mathrm{F}} \in \mathbb{C}[x]_{\mathcal{B}_j \times \mathcal{B}_j^{\mathrm{add}}},$$

the Fock pairing taken in the variables $x_{\tau,b,c}$ with $c \in \{0, \dots, r_+ - 1\}$ (in which b_l is written, $y_{\tau,b,c} \mapsto x_{\tau,b,c}$), the variables of the columns $\mathcal{B}_j^{\mathrm{add}}$ being coefficients, and $h_{\kappa_O^+}$ the hook number in rank $|\mathcal{B}_j|$. For $\Lambda \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times \mathcal{B}_j}(R_{\mathfrak{M}^2})$ the **added datum** is the function on $\mathrm{M}_{\mathcal{B}_j \times \mathcal{B}_j^{\mathrm{add}}}(R_{\mathfrak{M}^2 \mathfrak{Q}_O})$

$$\Psi_\Lambda^{\mathrm{add}}(z) = \sum_{\gamma \in \mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{M}^2})} \psi_\Lambda\big(\mathrm{red}_0(z^{\mathrm{c}})\, \gamma\big)$$

if the columns of z on $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat$ are those of the inclusion matrix of $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat$ in $\mathcal{B}_j$, and $\Psi_\Lambda^{\mathrm{add}}(z) = 0$ otherwise; z^{c} is the $\mathcal{B}_j \times \mathcal{B}^{\mathrm{c}}$ block of z. Let $\mathbf{1}_j^-$ be the indicator function of the inclusion matrix of $\mathcal{A}_j^-$ in $\mathcal{B}_j$ over $R_{\mathfrak{M}^2 \mathfrak{Q}_O}$. The **line series** $\Upsilon_{\vartheta,i} \colon G_f(\mathcal{B}_j) \to \mathbb{V}_j^+$ has the coordinates

$$\Upsilon_{\vartheta,i}(h)_l = \theta^{\mathrm{I}_{\mathcal{A}_j^-}^-, \mathrm{I}_{\mathcal{B}_j}}_{\upsilon^j, \nu''_{j,\vartheta}; \mathfrak{M}^2 \mathfrak{Q}_O} [\mathbf{1}_j^-, 1](1, h) \sum_{c \bmod \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})}^{\mathrm{cl}} \mathsf{a}_{\chi'_{j,\vartheta}}(c)\, \theta^{W_j^{\mathrm{add}}, \mathrm{I}_{\mathcal{B}_j}}_{\nu''_{j,\vartheta}, \nu''_{j,\vartheta}; \mathfrak{M}^2 \mathfrak{Q}_O} [\Psi_{\Lambda_i}^{\mathrm{add}}, \mathrm{lc}_{i,l}]\big((1, x_{\mathfrak{c}_i}, c), h\big)$$

($l \in I_{\kappa_O^+}$), with $(1, x_{\mathfrak{c}_i}, c)$ the block diagonal point on $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat \sqcup \mathcal{B}^{\mathrm{c}}$.

(XE7) The theta kernel pairing and the comparison form. For a function $\zeta \colon \mathrm{Cl}^\circ \to \mathbb{V}_j^-$ the **theta kernel pairing** is the function on $\mathrm{U}(W_j)(\mathbb{A})$

$$\mathrm{tt}_j(\zeta)(g) = \sum_{\mathfrak{c} \in \mathrm{Cl}^\circ} \theta^{W_j, V^\circ}_{\chi_{O^1}, \upsilon^{\lfloor m/2 \rfloor - j}; \mathfrak{M}^2} \Big[\mathbf{1}_{z_j},\ \mathrm{Let}_{-1}\big(\mathrm{Pol}_{\kappa_O^-}(\overline{\zeta(\mathfrak{c})})\big)\Big](g, x_{\mathfrak{c}}),$$

where $\mathbf{1}_{z_j}$ is the indicator function of the inclusion matrix of z_j over $R_{\mathfrak{M}^2}$, $\overline{\zeta(\mathfrak{c})}$ has the conjugate coordinates and Let_{-1} is read with the rows in $\mathcal{B}^\circ$. For $c'' \in \mathbb{C}^\times$ the **first factors with scale** c'' are $\varphi''_{\vartheta,i}(h) = \overline{c''\, \Upsilon_{\vartheta,i}(h)}$ (conjugate coordinates), $i \in \mathrm{Mem}_j$. When $\mathcal{V}_j$ is a divided splitting for O and $L = (L_i)_{i \in \mathrm{Mem}_j}$ are divided lattices of O^1, the **comparison form** of the j-th lift is the gluing map

$$\mathrm{gl}_{j,\vartheta}[L; c''] = \mathrm{gl}_\vartheta\big[L, (\varphi''_{\vartheta,i})_{i \in \mathrm{Mem}_j}\big] \colon \mathrm{Tab}_j \to \mathrm{Form}(O).$$

Theorem 6.6.6. *Let D be admissible data, θ a regular family of m-fold twists, and $1 \le j \le m$. Then the family $\iota \mapsto Z_j(1)/Z_j(\theta(\iota))$ has height at most*

$$d_{\mathcal{T}}\, k \big(\log b \cdot \beta_{\mathrm{den}} - h_{\mathrm{dir}}\big).$$

Proof. Let $d = \dim \mathcal{A}^{\mathrm{good}}(W_j)$; then $d = d_{\mathcal{T}}$ by Proposition 5.8.4(iii). Put $A = f\,m\,b\,(\log b)^2$ and $\xi_\iota = \theta(\iota)^j$, a twist with the modulus of $\theta(\iota)$.

The ratio as a quotient of compressions. By Proposition 6.6.13 there is a comparison operator U for the j-th lift; put $\Delta(\vartheta) = \det(\mathrm{pr}\, U_\vartheta)$. By Lemma 6.6.7(a) there is $C \neq 0$ with $\det(\Theta^*_{j,\vartheta}\Theta_{j,\vartheta})\Delta(\vartheta) = C\rho_j(\vartheta)^d$ for every twist ϑ, and $\Delta(\vartheta) \neq 0$, $\rho_j(\vartheta) \neq 0$. At $\vartheta = \xi_\iota$ the left side is $Z_j(\theta(\iota))\Delta(\xi_\iota)$; at $\vartheta = 1$, where $\rho_j(1) = 1$ and $1^j = 1$, it is $Z_j(1)\Delta(1) = C$. Dividing,

$$\frac{Z_j(1)}{Z_j(\theta(\iota))} = \frac{\Delta(\xi_\iota)}{\Delta(1)} \cdot \rho_j(\xi_\iota)^{-d}.$$

The first factor. Since θ is regular, (RW) gives a denominator bound $(\beta(\ell))_\ell$ for (θ, j): by (DB1), $\sum_{\ell\in T}\beta(\ell) \leq \beta_{\mathrm{den}}$ for every finite set T of primes, and by (DB2) and (DL1), for every $\iota \mid \ell$ the clearing condition (DL1) holds for ξ_ι at ι for j with $\beta(\ell)$; by (SR1), ℓ is prime to the norm of the modulus of ξ_ι. By Lemma 6.6.7(b), $\|\iota(\Delta(\xi_\iota))\| \leq e^{dr\beta(\ell)}$, and by Lemma 6.6.7(c), $|\sigma(\Delta(1))| \leq e^{3dA}$ for every automorphism σ of $\mathbb{C}$. So (HG1)–(HG3) hold for the family $\Delta(\xi_\iota)/\Delta(1)$ with $H = \Delta(1)$, $\alpha = 3dA$ and $h_\ell = dr\beta(\ell)/\log\ell$, and this family has height at most $3dA + dr\beta_{\mathrm{den}}$.

The second factor. By Proposition 6.7.1(c) the family $\rho_j(\xi_\iota)^{-1}$ has height at most $10mx_1 + k(6\beta_{\mathrm{den}} - h_{\mathrm{dir}})$, so its d-th power has height at most d times this (Lemma 3.1.8).

Conclusion. Heights add under products (Lemma 3.1.8), so by the displayed quotient the family $Z_j(1)/Z_j(\theta(\iota))$ has height at most

$$d\Big(3A + r\beta_{\mathrm{den}} + 10mx_1 + k\big(6\beta_{\mathrm{den}} - h_{\mathrm{dir}}\big)\Big) \leq d\,k\,\big(\log b \cdot \beta_{\mathrm{den}} - h_{\mathrm{dir}}\big),$$

the inequality being the scale inequality Lemma 6.1.6(v). Monotonicity of heights finishes the proof. □

The abstract comparison (Lemma 6.6.7) is linear algebra on the space of lifts, except for one point: the projection to the lifts does not increase any conjugate norm on forms orthogonal to the false lifts, although the conjugate norms are not the norms for which it is orthogonal. This comes from a lemma on idempotents that are self-adjoint for a family of pairings (Lemma 6.6.8), applied with the good idempotent and the Hecke polynomial at the lift root at a split place; in the relevant space, the forms orthogonal to the lifts are exactly the false lifts, which is why orthogonality to them is the hypothesis. That a single lift is killed by this Hecke polynomial (Lemma 6.6.10) follows by moving the polynomial through the theta integral (Lemma 6.6.11), where a factor vanishes at the lift root. The Hecke polynomials are those of the Satake isomorphism [248, 109]; for the compatibility of the theta correspondence with the unramified Hecke algebras see [134, 236, 173, 205].

Lemma 6.6.7. *Let $1 \leq j \leq m$, let $d = \dim \mathcal{A}^{\mathrm{good}}(W_j)$, let U be a comparison operator for the j-th lift, and put $\Delta(\vartheta) = \det(\mathrm{pr}\, U_\vartheta)$ for every twist ϑ.*

(a) There is $C \in \mathbb{C}\setminus\{0\}$ such that $\det(\Theta^*_{j,\vartheta}\Theta_{j,\vartheta})\,\Delta(\vartheta) = C\,\rho_j(\vartheta)^d$ for every twist ϑ. In particular $\Delta(\vartheta) \neq 0$.

(b) Let ϑ be a twist, $\iota \mid \ell$ a prime identification with $\ell \nmid \mathrm{N}Q$, and $\beta \in \mathbb{R}$ such that (DL1) holds for ϑ at ι for j with β. Then $\|\iota(\Delta(\vartheta))\| \leq e^{dr\beta}$.

(c) $|\sigma(\Delta(1))| \leq \exp\big(3\,d\,f\,m\,b\,(\log b)^2\big)$ for every automorphism σ of $\mathbb{C}$.

(d) If $y \in \mathcal{A}_{j,\vartheta}(V^{\mathrm{def}})$ is orthogonal to the false lifts for $(e_0, \mathcal{L}^\perp_{j,\vartheta})$, then $\|\mathrm{pr}_\vartheta y\|_\sigma \leq \|y\|_\sigma$ for every automorphism σ of $\mathbb{C}$.

Proof. Write $\Theta = \Theta_{j,\vartheta}$, $R = \mathcal{L}_{j,\vartheta}$ and $\mathrm{pr} = \mathrm{pr}_\vartheta$. The lift Θ is injective (single lift, Proposition 6.5.9), so $\dim R = d$.

Part (a). Since Θ^* vanishes on $R^\perp$, we have $\Theta^* U_\vartheta \Theta = \Theta^* \,\mathrm{pr}\, U_\vartheta \Theta = (\Theta^*\Theta) \circ (\Theta^{-1} \circ \mathrm{pr}\, U_\vartheta \circ \Theta)$, where $\Theta^{-1}\colon R \to \mathcal{A}^{\mathrm{good}}(W_j)$ is the inverse of the isomorphism onto R. The second factor is conjugate to $\mathrm{pr}\, U_\vartheta$ on R, so

$$\det(\Theta^* U_\vartheta \Theta) = \det(\Theta^*\Theta)\, \Delta(\vartheta).$$

By (CO2), $\langle y', \Theta^* U_\vartheta \Theta y\rangle = \langle \Theta y', U_\vartheta \Theta y\rangle = \rho_j(\vartheta)\langle y', U^\circ y\rangle$ for all y, y', so $\Theta^* U_\vartheta \Theta = \rho_j(\vartheta) U^\circ$ and its determinant is $\rho_j(\vartheta)^d \det U^\circ$. The operator U° has trivial kernel, since $\langle y, U^\circ y\rangle > 0$ for $y \neq 0$; so $C = \det U^\circ \neq 0$. With (CO1), $\Delta(\vartheta) \neq 0$.

Part (b). Let Λ be the operator given by (DL1); here $\dim \mathcal{L}_{j,\vartheta} = d$, so $\|\iota(\det \Lambda)\| \geq e^{-dr\beta}$, and $T = \Lambda \circ \mathrm{pr}\, U_\vartheta$, an operator on R. Let α be an eigenvalue of T with eigenvector $z \neq 0$. There is $c \in \mathbb{C}^\times$ such that cz is integral at ι and $\|\iota(\mu)\| \leq 1$ whenever μcz is integral at ι: the values of z at the finitely many class representatives have finitely many coordinates, and c is the inverse of a coordinate of largest ι-adic size. By (CO4) the form $U_\vartheta(cz)$ is integral at ι, and by (CO3) it is orthogonal to the false lifts. Hence $T(cz) = \Lambda(\mathrm{pr}\, U_\vartheta(cz)) = \alpha cz$ is integral at ι, and $\|\iota(\alpha)\| \leq 1$. As $\det T$ is the product of the eigenvalues of T with multiplicity and ι is a ring isomorphism, $\|\iota(\det \Lambda)\|\, \|\iota(\Delta(\vartheta))\| = \|\iota(\det T)\| \leq 1$, and the bound on $\det \Lambda$ gives $\|\iota(\Delta(\vartheta))\| \leq e^{dr\beta}$.

Part (c). Let α be an eigenvalue of $\mathrm{pr}\, U_1$ with eigenvector $z \in R \setminus \{0\}$. By (CO3) the form $U_1 z$ is orthogonal to the false lifts, so by part (d) and (CO5)

$$|\sigma(\alpha)|^2\, \|z\|_\sigma^2 = \|\mathrm{pr}\, U_1 z\|_\sigma^2 \leq \|U_1 z\|_\sigma^2 \leq \exp\bigl(6fmb(\log b)^2\bigr)\|z\|_\sigma^2.$$

Here $\|z\|_\sigma > 0$, since the Gram matrix of (TW4) of Definition 3.1.4 is positive definite and σ maps the nonzero coordinate vector of z to a nonzero vector. So $|\sigma(\alpha)| \leq \exp(3fmb(\log b)^2)$, and $|\sigma(\Delta(1))|$, the product of the d numbers $|\sigma(\alpha)|$ over the eigenvalues with multiplicity, is at most $\exp(3dfmb(\log b)^2)$.

Part (d). Let $\mathcal{A} = \mathcal{A}_{j,\vartheta}(V^{\mathrm{def}})$, and let w, the pairings $\langle\cdot,\cdot\rangle_\sigma$ with $\|y\|_\sigma^2 = \langle y, y\rangle_\sigma$ and the operator $B = H_w(\lambda_w)$ be those of Lemma 6.6.9. Each $\langle\cdot,\cdot\rangle_\sigma$ is biadditive, since σ is additive; it satisfies $\langle v, u\rangle_\sigma = \overline{\langle u, v\rangle_\sigma}$ and $\langle u, u\rangle_\sigma \geq 0$, since G is rational, hermitian and positive definite; and $\langle\cdot,\cdot\rangle_1$ is the Petersson product, a positive definite hermitian form. As y is orthogonal to the false lifts for $(e_0, R^\perp)$, it is orthogonal to $\mathcal{F}_w(e_0, R^\perp) = e_0\mathcal{A} \cap \ker B \cap R^\perp$. By Lemma 6.6.9(a), $R \subseteq e_0\mathcal{A} \cap \ker B$, and (b), (c) of the same lemma are the hypotheses (i), (ii) of Lemma 6.6.8 for $\Pi = e_0$ and B. So Lemma 6.6.8, with $\mathcal{H} = \mathcal{A}$, $Z = R$ and the automorphisms of $\mathbb{C}$ as index set, gives $\|\mathrm{pr}\, y\|_\sigma \leq \|y\|_\sigma$ for every σ, as pr is the orthogonal projection onto R for the Petersson product. □

Lemma 6.6.8. *Let $\mathcal{H}$ be a finite-dimensional complex vector space and $(\langle\cdot,\cdot\rangle_\sigma)_{\sigma\in I}$ a family of biadditive maps $\mathcal{H} \times \mathcal{H} \to \mathbb{C}$, indexed by a set I, with $\langle v, u\rangle_\sigma = \overline{\langle u, v\rangle_\sigma}$ and $\langle u, u\rangle_\sigma \geq 0$ for all u, v (they need not be $\mathbb{C}$-sesquilinear), such that I contains an element 1 for which $\langle\cdot,\cdot\rangle_1$ is a positive definite hermitian form, linear in the second variable; write $\|y\|_\sigma^2 = \langle y, y\rangle_\sigma$, and let* pr *be the orthogonal projection onto a subspace for $\langle\cdot,\cdot\rangle_1$. Let Π and B be linear operators on $\mathcal{H}$ such that for every $\sigma \in I$:*

(i) $\Pi^2 = \Pi$ *and* $\langle \Pi u, v\rangle_\sigma = \langle u, \Pi v\rangle_\sigma$ *for all* $u, v \in \mathcal{H}$;

(ii) $\langle Bv, z\rangle_\sigma = 0$ *for all* $v \in \mathcal{H}$ *and all* $z \in \ker B$.

Let Z be a subspace of $\Pi\mathcal{H} \cap \ker B$, let $Z^\perp$ be its orthogonal complement for $\langle\cdot,\cdot\rangle_1$, and let $y \in \mathcal{H}$ satisfy $\langle y, f\rangle_1 = 0$ for every $f \in \Pi\mathcal{H} \cap \ker B \cap Z^\perp$. Then $\|\mathrm{pr}_Z\, y\|_\sigma \leq \|y\|_\sigma$ for every $\sigma \in I$.

Proof. Write $\perp$ for orthogonal complements for the positive definite form $\langle\cdot,\cdot\rangle_1$, and put $K = \Pi\mathcal{H} \cap \ker B$.

The complement of K is $\ker\Pi + B\mathcal{H}$. If $\Pi u = 0$, then $\langle u, \Pi v\rangle_1 = \langle \Pi u, v\rangle_1 = 0$ by (i), so $\ker\Pi \subseteq (\Pi\mathcal{H})^\perp$; as Π is idempotent, $\mathcal{H} = \Pi\mathcal{H} \oplus \ker\Pi$, so both spaces have dimension $\dim\mathcal{H} - \dim\Pi\mathcal{H}$ and $(\Pi\mathcal{H})^\perp = \ker\Pi$. By (ii) at $\sigma = 1$, $B\mathcal{H} \subseteq (\ker B)^\perp$, and $\dim B\mathcal{H} = \dim\mathcal{H} - \dim\ker B = \dim(\ker B)^\perp$, so $(\ker B)^\perp = B\mathcal{H}$. For subspaces of a finite-dimensional space with a positive definite hermitian form, $(U \cap U')^\perp = U^\perp + U'^\perp$; hence $K^\perp = \ker\Pi + B\mathcal{H}$.

The part of y off Z lies in $K^\perp$. Put $z = \mathrm{pr}_Z\, y \in Z$ and $x = y - z \in Z^\perp$. Every $f \in K$ is $f = \mathrm{pr}_Z f + (f - \mathrm{pr}_Z f)$ with $\mathrm{pr}_Z f \in Z \subseteq K$, so $f - \mathrm{pr}_Z f \in K \cap Z^\perp$. Now $\langle x, \mathrm{pr}_Z f\rangle_1 = 0$ as $x \in Z^\perp$, and $\langle x, f - \mathrm{pr}_Z f\rangle_1 = \langle y, f - \mathrm{pr}_Z f\rangle_1 - \langle z, f - \mathrm{pr}_Z f\rangle_1 = 0$, by the hypothesis on y and because $z \in Z$. So $x \in K^\perp$, and $x = u + Bv$ with $\Pi u = 0$ and $v \in \mathcal{H}$.

x is orthogonal to Z for every form. Let $\sigma \in I$ and $z' \in Z$. Since $z' \in \Pi\mathcal{H}$ and Π is idempotent, $\Pi z' = z'$, so $\langle u, z'\rangle_\sigma = \langle u, \Pi z'\rangle_\sigma = \langle \Pi u, z'\rangle_\sigma = 0$ by (i); and $\langle Bv, z'\rangle_\sigma = 0$ by (ii), since $z' \in \ker B$. Hence $\langle x, z\rangle_\sigma = 0$, and $\langle z, x\rangle_\sigma = \overline{\langle x, z\rangle_\sigma} = 0$.

Pythagoras. For every $\sigma \in I$,

$$\|y\|_\sigma^2 = \langle z + x, z + x\rangle_\sigma = \|z\|_\sigma^2 + \|x\|_\sigma^2 \geq \|z\|_\sigma^2,$$

by biadditivity, $\langle z, x\rangle_\sigma = \langle x, z\rangle_\sigma = 0$ and $\langle x, x\rangle_\sigma \geq 0$. So $\|\mathrm{pr}_Z\, y\|_\sigma \leq \|y\|_\sigma$. □

Lemma 6.6.9. *Let $1 \leq j \leq m$, let ϑ be a tame character with modulus Q, $O = O_{j,\vartheta}$, $\mathcal{A} = \mathrm{Form}(O)$ and $\mathcal{L} = \mathcal{L}_{j,\vartheta}$. Fix representatives $h_1, \ldots, h_C$ of the double cosets*

$$\mathrm{U}(\mathrm{I}_n)(E)\backslash G_f(n)/\mathbf{K}(O),$$

let $\mathrm{co}(y) = (y(h_1), \ldots, y(h_C))$ for $y \in \mathcal{A}$, and G the block diagonal matrix with blocks $(\#\Gamma_{h_c})^{-1} G_{\kappa_O}$, so that $\langle y, y'\rangle = \mathrm{co}(y)^* G\, \mathrm{co}(y')$. For an automorphism σ of $\mathbb{C}$ put $\langle y, y'\rangle_\sigma = \sigma(\mathrm{co}(y))^*\, G\, \sigma(\mathrm{co}(y'))$, σ applied to the coordinates, and $\|y\|_\sigma^2 = \langle y, y\rangle_\sigma$. There are infinitely many finite places w of E with $w \neq \bar{w}$ and $w, \bar{w} \notin S_O$, and for every such w:

(a) $\mathcal{L} \subseteq [e_0]\mathcal{A} \cap \ker H_w(X_*(w))$;

(b) $[e_0]$ *is an idempotent of* $\mathcal{A}$, *and* $\langle [e_0]u, v\rangle_\sigma = \langle u, [e_0]v\rangle_\sigma$ *for all* $u, v \in \mathcal{A}$ *and every* σ;

(c) $\langle H_w(X_*(w))v, z\rangle_\sigma = 0$ *for all* $v \in \mathcal{A}$, *all* $z \in \ker H_w(X_*(w))$ *and every* σ.

Proof. Write $K = \mathbf{K}(O)$, $\Gamma = \mathrm{U}(\mathrm{I}_n)(E)$ (a discrete subgroup of $G_f(n)$, the infinite part of $\mathrm{U}(\mathrm{I}_n)$ being compact), $R(x)y(h) = y(hx)$, and $\rho = \rho_{\kappa_O, e_O}$. A form is determined by its values at the h_c, as $y(\gamma h_c k) = \tilde{\eta}_O(k)\rho(\gamma)y(h_c)$; so co is injective, and G is rational and positive definite because $G_{\kappa_O} = F^{\mathsf{T}} F$ with F an integer matrix of full column rank. Hence $\langle u, u\rangle_\sigma > 0$ for $u \neq 0$, since $\sigma(\mathrm{co}(u)) \neq 0$.

Split places. The rational primes that split completely in the Galois closure of E are infinite in number (Chebotarev's density theorem). Above such a p every place w of E has trivial decomposition group, so complex conjugation, which is nontrivial on E, moves w: $w \neq \bar{w}$. Only finitely many of these places meet $S_O \cup \bar{S}_O$.

A coefficient field. Let $\mathcal{K} \subset \mathbb{C}$ be the compositum of the Galois closure of E and of $\mathbb{Q}(\mu_N)$, $N = \#\bar{G} \cdot \prod_{v \in S_O}(\mathrm{N}v - 1)$. It is a CM field, Galois over $\mathbb{Q}$, so complex conjugation is central in its Galois group: $\sigma(\bar{x}) = \overline{\sigma(x)}$ for $x \in \mathcal{K}$ and every σ; hence $\sigma(M^*) = \sigma(M)^*$ for matrices M over $\mathcal{K}$. Let $T = \sum_x a_x R(x)$ be a finite sum with $a_x \in \mathcal{K}$ and $x \in G_f(n)$ that maps $\mathcal{A}$ to itself. Writing $h_c x = \gamma h_{c'} k'$ with $\gamma \in \Gamma$, $k' \in K$, we get $y(h_c x) = \tilde{\eta}_O(k')\rho(\gamma)y(h_{c'})$; the values of $\tilde{\eta}_O$ are

roots of unity of order dividing $\prod_v(\mathrm{N}v-1)$, and the entries of $\rho(\gamma)=\prod_\tau \det(\bar\gamma_\tau)^{e_O(\tau)}S_{\kappa_O}(\bar\gamma)$ are integral polynomials in the conjugates of the entries of the $\tau(\gamma)$, all in $\mathcal{K}$. So $\mathrm{co}(Ty)=M_T\,\mathrm{co}(y)$ with a matrix M_T over $\mathcal{K}$. This applies to $[g]=\prod_{v\in M_O}\psi_{O,v}(\det g_v)\,R(k_g)$ $(g\in\bar G)$, to the $T_{w,i}$, and to $R(z)$ for central $z\in G_f(n)$.

Part (a). By (LF5), $\mathcal{L}=\Theta_{j,\vartheta}(e_0\,\mathcal{A}_M(W_j))$. By Lemma 6.6.10(i), extended linearly to $\mathbb{C}[\bar G]$, $\Theta_{j,\vartheta}(e_0y)=[e_0]\Theta_{j,\vartheta}(y)\in[e_0]\mathcal{A}$, and by Lemma 6.6.10(ii) it lies in $\ker H_w(X_*(w))$.

Part (b). The action $[\cdot]$ of $\bar G$ on $\mathcal{A}$ is a representation, so $[e_0]$ is an idempotent, e_0 being one. Each $[g]$ preserves $\langle\,,\rangle$: $|\psi_{O,v}|=1$, and k_g normalises K with $\tilde\eta_O(k_g^{-1}kk_g)=\tilde\eta_O(k)$ (at $v\in M_O$ the reduction $\mathrm{diag}(g_v,1)$ conjugates the stabiliser of Inc_O into itself, at Q_O the reduction is 1), so $h\mapsto hk_g$ permutes the double cosets with $\#\Gamma_{hk_g}=\#\Gamma_h$. Hence $M_g^*GM_g=G$, i.e. $M_g^*G=GM_{g^{-1}}$ for $M_g=M_{[g]}$, and applying σ entrywise, $\sigma(M_g)^*G=G\,\sigma(M_{g^{-1}})$. Write $e_0=\sum_g c_g g$. By Definition 3.2.16, c_g is a sum of products of the numbers $\frac{\Xi_c(1)}{|\mathrm{GL}_r(k_v)|}\overline{\Xi_c(g_v)}$; the Ξ_c are virtual characters, so their values lie in $\mathbb{Q}(\mu_{\#\bar G})\subseteq\mathcal{K}$ and $\Xi_c(g^{-1})=\overline{\Xi_c(g)}$; hence $c_{g^{-1}}=\overline{c_g}$ and $\overline{\sigma(c_{g^{-1}})}=\sigma(c_g)$. Therefore

$$\sigma(M_{e_0})^*G=\sum_g\overline{\sigma(c_g)}\,G\,\sigma(M_{g^{-1}})=G\sum_g\overline{\sigma(c_{g^{-1}})}\,\sigma(M_g)=G\,\sigma(M_{e_0}),$$

which is $\langle[e_0]u,v\rangle_\sigma=\langle u,[e_0]v\rangle_\sigma$.

The adjoints of the Hecke operators. Let μ be the right invariant measure on $\Gamma\backslash G_f(n)$ with μ the quotient of the Haar measure giving K volume 1 by the counting measure. For left Γ-invariant functions f right invariant under an open compact K',

$$\int f\,d\mu=\mathrm{vol}(K')\sum_{[h]\in\Gamma\backslash G_f(n)/K'}f(h)/\#(\Gamma\cap hK'h^{-1});$$

so $\langle y,y'\rangle=\int\langle y(h),y'(h)\rangle_{\kappa_O}\,d\mu(h)$, and the right hand side defines a pairing B of all left Γ-equivariant, locally constant functions $G_f(n)\to\mathbb{V}_O$ with $B(R(x)f,f')=B(f,R(x^{-1})f')$. Let $K_w=\iota_w(\mathrm{GL}_n(\mathcal{O}_{E,w}))\subseteq K$ (its elements have reductions 1 at S_O and $\tilde\eta_O=1$ on them), so the forms are K_w-invariant. For $u,v\in\mathcal{A}$ the number $B(u,R(x)v)$ depends only on K_wxK_w. Since $\iota_w(\delta_i)^{-1}=z\,\iota_w(\delta'_{n-i})$ with $z=\iota_w(\varpi_w^{-1}1_n)$ central and $\delta'_{n-i}=\mathrm{diag}(1_i,\varpi_w1_{n-i})$ in the double coset of δ_{n-i}, and the numbers of left cosets in the double cosets of δ_i and δ_{n-i} are equal (both are the number of i-dimensional subspaces of k_w^n), we get

$$\langle T_{w,i}u,v\rangle=\#R_i\,B(u,R(\iota_w(\delta_i)^{-1})v)=\langle u,T_i'v\rangle,\qquad T_i'=R(z)\,T_{w,n-i}.$$

$R(z)$ maps $\mathcal{A}$ to itself, z being central. The operators $T_{w,i}$ and T_i' commute with each other on $\mathcal{A}$: on K_w-invariant vectors they are the action of the spherical Hecke algebra of $\mathrm{GL}_n(E_w)$, which is commutative (Satake), and $R(z)$ is central.

Part (c). Put $H=H_w(X)$ with $X=X_*(w)$, $q=\mathrm{N}w$, $X'=\sigma^{-1}(\overline{\sigma(X)})$ and $H'=\sum_i(-X')^iq^{i(i-1)/2}T_i'$. From $\langle T_{w,i}u,v\rangle=\langle u,T_i'v\rangle$ we get $M^*_{T_{w,i}}G=GM_{T_i'}$, and applying σ, $\sigma(M_{T_{w,i}})^*G=G\sigma(M_{T_i'})$. As $\sigma(M_H)=\sum_i(-\sigma X)^iq^{i(i-1)/2}\sigma(M_{T_{w,i}})$ and $\sigma(X')=\overline{\sigma(X)}$,

$$\sigma(M_H)^*G=\sum_i\big(-\overline{\sigma(X)}\big)^iq^{i(i-1)/2}G\,\sigma(M_{T_i'})=G\,\sigma(M_{H'}),$$

that is, $\langle Hx,y\rangle_\sigma=\langle x,H'y\rangle_\sigma$ for all $x,y\in\mathcal{A}$. H and H' commute. Let $Hz=0$. Then $\langle H'z,H'z\rangle_\sigma=\langle HH'z,z\rangle_\sigma=\langle H'Hz,z\rangle_\sigma=0$, so $H'z=0$, and $\langle Hv,z\rangle_\sigma=\langle v,H'z\rangle_\sigma=0$. □

Lemma 6.6.10. *Let $1\le j\le m$, let ϑ be a tame character with modulus Q, and $O=O_{j,\vartheta}$; its chosen places are those of the data, so $\mathrm{GL}_r^{\mathrm{ch}}(O)=\bar G$. Then:*

(i) $\Theta_{j,\vartheta}(g\cdot y)=[g]\,\Theta_{j,\vartheta}(y)$ *for every* $g\in\bar G$ *and* $y\in\mathcal{A}_M(W_j)$*;*

(ii) $H_w(X_*(w))\,\Theta_{j,\vartheta}(y)=0$ *for every* $y\in\mathcal{A}_M(W_j)$ *and every finite place* w *of* E *with* $w\neq\bar w$ *and* $w,\bar w\notin S_O$*.*

Proof. Write $n=r+t$, $W=W_j$, $\mathrm{J}=\mathrm{J}_O(\xi_O)$, and let $\mathfrak{m}=\prod_{w\in S_O}w$, a modulus by (DP1) ($S_O$ contains the chosen places), so that $R_{\mathfrak{m}}=\prod_{w\in S_O}k_w$. By (DP7), (DP8) and (XD5), $\mathrm{J}=\mathrm{mod}_{\mathfrak{m}}(\Psi_O,v_{\mathrm{Har}_O(\xi_O)})$. Let $\gamma=r_-(O)$ and $\gamma'=\lfloor n/2\rfloor+\mathrm{wt}_O$ be the weights of χ_O and χ'_O. By Lemma 6.5.11, O fits the parameter $l=2\varsigma$ (read on the basis of W), and $r\geq 1$; by Lemma 6.4.15(e), $v_{\mathrm{Har}_O(\xi_O)}$ is an edge for (γ,γ') from $e=e_\varsigma$ to $e'=e_{l_O/2}$. So Lemma 6.3.76 applies to $(S,T)=(W,\mathrm{I}_n)$, $(\alpha,\beta)=(\chi_O,\chi'_O)$, $\mathfrak{m}$, Ψ_O and $P=\mathrm{Har}_O(\xi_O)$, with $\kappa(u,h)=\theta^{W,\mathrm{I}_n}_{\chi_O,\chi'_O}(\mathrm{J})(u,h)=\theta_O(\omega_O(u,h)\mathrm{J})$; its lift L satisfies $\Theta_{j,\vartheta}(y)=(Ly)^\flat$ by (LF5). For $k'\in G_f(n)$ write $R(k')F=F(\cdot\,(1,k'))$; by (WM7), $(R(k')F)^\flat=R(k')F^\flat$.

The block datum at integral points. Let $k\in\mathbf{K}_0(r)$ and $k'\in\mathbf{K}_0(n)$ have reductions $\bar k_w$, $\bar k'_w$ at $w\in S_O$. By (6) of Lemma 4.1.1 for the modulus $\mathfrak{m}$,

$$\omega_O((1,k),(1,k'))\mathrm{J}=\chi_O(\det k')\,\chi'_O(\det k)^{-1}\,\mathrm{mod}_{\mathfrak{m}}(\Psi_O(\bar k'^{-1}\cdot\bar k),\,v_{\mathrm{Har}_O(\xi_O)}).\tag{1}$$

Here $\chi_O(\det k')=1$: $\det k'$ has unit finite components and infinite components 1, so $\upsilon(\det k')=1$ by (WD3) of Definition 3.2.12; likewise $\upsilon(\det k)=1$, so $\chi'_O(\det k)=\mu_O(\det k)=\prod_w\psi_{O,w}(\det k\bmod w)$ by the definition of the tame part, the factors with $w\notin S_O$ being 1.

(i). Let $g=(g_w)_{w\in M_O}\in\bar G$. Choose $k\in\mathbf{K}_0(r)$ with $\bar k_w=g_w$ for $w\in M_O$ and $\bar k_w=1$ for $w\in Q_O$, and $k'\in\mathbf{K}_0(n)$ with $\bar k'_w=1$ for $w\in Q_O$ and, for $w\in M_O$, $\bar k'_w$ acting as g_w on the span of the basis vectors in the image of inc_O and as the identity on the others (reduction at finitely many split places is surjective onto the product of the groups $\mathrm{GL}(k_w)$). Then $\bar k'_w\mathrm{Inc}_O=\mathrm{Inc}_O\,g_w$ for $w\in M_O$, so $\bar k'^{-1}_wX\bar k_w=\mathrm{Inc}_O$ if and only if $X=\mathrm{Inc}_O$, and the families at Q_O are unchanged: $\Psi_O(\bar k'^{-1}\cdot\bar k)=\Psi_O$. With $c_g=\prod_{w\in M_O}\psi_{O,w}(\det g_w)$, (1) reads $\omega_O((1,k),(1,k'))\mathrm{J}=c_g^{-1}\mathrm{J}$. By (3) of Lemma 6.3.76 (with $\Psi'=\Psi_O$, $c=c_g^{-1}$), $Ly(h(1,k'))=c_g^{-1}L(y(\cdot\,(1,k)))(h)$. As $g\cdot y=y(\cdot\,(1,k))$ (Definition 3.2.16),

$$\Theta_{j,\vartheta}(g\cdot y)=\big(L(g\cdot y)\big)^\flat=c_g\,R(k')(Ly)^\flat=c_g\,R(k')\,\Theta_{j,\vartheta}(y)=[g]\,\Theta_{j,\vartheta}(y)$$

by (DP5).

(ii). Let w be a finite place with $w\neq\bar w$, $w,\bar w\notin S_O$, $q=\mathrm{N}w=\mathrm{N}\bar w$, $X_*=X_*(w)$, and $y\in\mathcal{A}_M(W)$. The group K_w consists of elements of $\mathbf{K}_0(n)$ with components 1 outside $\{w,\bar w\}$; it is also the group $K_{\bar w}$ of the place $\bar w$. For $k'\in K_w$, (1) with $k=1$ and trivial reductions at S_O gives $\omega_O(1,(1,k'))\mathrm{J}=\mathrm{J}$, so Ly is right invariant under K_w. Put $G=H^{\mathrm{I}_n}_w(X_*)\,Ly$. By (DP10), $H_w(X_*)$ acts on $\mathrm{Form}(O)$ by the same combination of right translations, so $H_w(X_*)\Theta_{j,\vartheta}(y)=G^\flat$, and it suffices to show $G=0$.

By (1) of Lemma 6.3.76, Ly is a form of type e' on I_n; G is a finite combination of right translates of Ly by elements of $G_f(n)$, hence a form of type e' ((3) of Lemma 6.3.76), and right invariant under K_w (a double coset $D=K\delta K$ is stable under left multiplication by $K=\mathrm{GL}_n(\mathcal{O}_{E,w})$). So $y'=\bar G$ is a form of type $\bar e'$, continuous, left invariant under the rational points, with a level and right invariant under $K_{\bar w}=K_w$, and $F'=H^{\mathrm{I}_n}_{\bar w}(X_*)y'$ is a form of type $\bar e'$ as well.

Transposition of the Hecke operators. Let μ be the Haar measure of $\mathrm{GL}_n(E_w)$ with $\mu(K)=1$ and $D_i=K\mathrm{diag}(\varpi_w1_i,1_{n-i})K$. For right K_w-invariant f, $(T_{w,i}f)(h)=\int_{D_i}f(h\iota_w(x))\,d\mu(x)$, ι_w the embedding at w. As D_i is compact, $[\mathrm{U}(\mathrm{I}_n)]$ compact (Theorem A.4.5) and y', Ly continuous

and bounded, Fubini's theorem, the right invariance of the quotient measure and the invariance of μ under $x \mapsto x^{-1}$ ($\mathrm{GL}_n(E_w)$ is unimodular) give

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} y'\,(T_{w,i}Ly) = \int_{[\mathrm{U}(\mathrm{I}_n)]} Ly(h) \int_{D_i^{-1}} y'(h\iota_w(x))\,d\mu(x)\,dh = \int_{[\mathrm{U}(\mathrm{I}_n)]} (T_{\bar{w},i}y')\,Ly.$$

Summing with the coefficients $(-X_*)^i q^{\binom{i}{2}}$: $\int y'\,G = \int F' \cdot Ly$.

Adjointness and the vanishing factor. By (2) of Lemma 6.3.76 (forms y of type e on W and F' of type $\bar{e}'$ on I_n), $\int_{[\mathrm{U}(\mathrm{I}_n)]} F' \cdot Ly = \int_{[\mathrm{U}(W)]} y \cdot L^{\mathsf{t}}F'$. By (WR4) of Definition 3.2.18, $\kappa(u,h) = \chi_O'(\det u)^{-1}\theta^{W,\mathrm{I}_n}_{\chi_O,1}(\mathrm{J})(u,h)$, so $L^{\mathsf{t}}F' = \chi_O'(\det\cdot)^{-1}F_{F'}$ with $F_{y''}(u) = \int \theta^{W,\mathrm{I}_n}_{\chi_O,1}(\mathrm{J})(u,h)y''(h)\,dh$ the function of Lemma 6.6.11. Apply Lemma 6.6.11 at the place $\bar{w}$ (whose conjugate is w), to $S = W$ of rank r, $T = \mathrm{I}_n$ of rank $r+t$, $a = \chi_O$, the datum J and y'. Its hypotheses hold: the base change of $\chi_O = \upsilon^{r-(O)}$ is unramified at w (for a unit x of E_w read as an idele, $x/\bar{x}$ has unit finite components and infinite components 1, so $\upsilon(x/\bar{x}) = 1$); J is the vacuum at w and $\bar{w}$, since for an integral z supported at $\{w,\bar{w}\}$, disjoint from $S_O \cup \bar{S}_O$, $\rho_f(z)$ fixes $\Phi_O \otimes_{S_O} v^0$ by (5) of Lemma 6.2.33 and commutes with the real Heisenberg operators $\rho(\mathrm{rv}(\cdot))$ of (WR6) (the bicharacter of vectors with disjoint supports is 1, by (WD6)), hence with $v \otimes (\cdot)$; and y' is as required. Its constant is $\alpha = \chi_O[r](\varpi_w)q^{r/2} = \chi_{O,w}\{r\}$ (DP10), and

$$F_{F'} = \prod_{j=0}^{t-1}(1 - q^j\chi_{O,w}\{r\}X_*) \cdot H^W_{\bar{w}}(q^t\alpha\beta^{-1}X_*)F_{y'} = 0,$$

since $t - 1 = n - r - 1$ and $X_* = (\chi_{O,w}\{r\}q^{n-r-1})^{-1}$ make the factor $j = t-1$ vanish. Hence $L^{\mathsf{t}}F' = 0$ and

$$\int_{[\mathrm{U}(\mathrm{I}_n)]} |G|^2 = \int y'\,G = \int_{[\mathrm{U}(W)]} y \cdot L^{\mathsf{t}}F' = 0.$$

As $|G|^2$ is continuous and nonnegative on the compact quotient, whose measure charges every nonempty open set, $G = 0$. □

Lemma 6.6.11. *For a space V of rank n, a finite place $w \neq \bar{w}$ and $X \in \mathbb{C}$, let $H^V_w(X) = \sum_{i=0}^n (-X)^i(\mathrm{N}w)^{\binom{i}{2}}T_{w,i}$, acting on functions on $\mathrm{U}(V)(\mathbb{A}_F)$ that are right invariant under K_w. Let S be a space of rank n_S, T a standard definite space of rank $n_T = n_S + k$ with $k \geq 0$, w a finite place of E with $w \neq \bar{w}$, $q = \mathrm{N}w$, and a an automorphic character of $\mathrm{U}(1)$ whose base change $\tilde{a}$ is unramified at $\bar{w}$. Let $\varphi \in \mathcal{M}_{S,T}$ be a datum that is the* vacuum at w and $\bar{w}$*: $\rho_f(z)\varphi = \varphi$ for every integral finite adelic $n_T \times n_S$ matrix z whose components outside $\{w,\bar{w}\}$ are 0 (ρ_f the finite Heisenberg operators of (WD8) of Definition 3.2.12). Let y be a continuous function on $\mathrm{U}(T)(\mathbb{A}_F)$, left invariant under $\mathrm{U}(T)(F)$, right invariant under an open subgroup of $\mathrm{U}(T)(\mathbb{A}_{F,f})$ and under K_w. Put*

$$F_y(g) = \int_{[\mathrm{U}(T)]} \theta^{S,T}_{a,1}(\varphi)(g,h)\,y(h)\,dh \qquad (g \in \mathrm{U}(S)(\mathbb{A}_F)).$$

Let $\varpi_{\bar{w}}$ be an idele with a uniformiser of $E_{\bar{w}}$ at $\bar{w}$ and 1 elsewhere, $a[n_S] = \tilde{a}\,\upsilon^{-n_S}$ the space character of a in rank n_S, and

$$\alpha = a[n_S](\varpi_{\bar{w}})\,q^{n_S/2}, \qquad \beta = \upsilon(\varpi_{\bar{w}})^{-n_T}\,q^{n_T/2}$$

(independent of the uniformiser; $|\alpha| = q^{n_S/2}$, $|\beta| = q^{n_T/2}$). Then F_y is right invariant under K_w, and for every $X \in \mathbb{C}$

$$F_{H^T_w(X)y} = \prod_{j=0}^{k-1}(1 - q^j\alpha X) \cdot H^S_w(q^k\alpha\beta^{-1}X)F_y.$$

Proof. Throughout, $A = \{\bar{w}\}$; it contains the conjugate of none of its members. Write $\omega = \omega_{a,1}$, so $\theta_{a,1}^{S,T}(\varphi)(g,h) = \theta(\omega(g,h)\varphi)$ with $\theta = \theta_{\mathrm{Hom}(S,T)}$, and $\omega(g,h)\omega(g',h') = \omega(gg',hh')$ by (2) of Lemma 4.1.1; for finite elements we write $\omega(g,1)$, $\omega(1,h)$ for $\omega((1,g),(1,1))$, $\omega((1,1),(1,h))$. Complex conjugation is a ring isomorphism $E_w \to E_{\bar{w}}$ carrying $\mathcal{O}_w$ onto $\mathcal{O}_{\bar{w}}$; for a matrix γ over E_w, $\bar{\gamma}$ is the matrix over $E_{\bar{w}}$. The residue field k of $\bar{w}$ has q elements; for an integral matrix x over $E_{\bar{w}}$, $\bar{x}$ (in this proof) denotes its reduction modulo $\bar{w}$ and $r(x)$ the rank of the reduction. For $m \geq 0$ let $\mathrm{K} = \mathrm{GL}_m(\mathcal{O}_w)$, $D_i^{(m)} = \mathrm{K}\delta_i\mathrm{K}$, and recall that $\iota_w(\gamma)$ has component γ at w and $(\bar{\gamma}^{\mathsf{T}})^{-1}$ at $\bar{w}$. We use three classical facts: (C1) by the elementary divisor theorem, $\gamma\mathrm{K} \mapsto \gamma\mathcal{O}_w^m$ is a bijection from $D_i^{(m)}/\mathrm{K}$ onto the lattices L with $\varpi_w\mathcal{O}_w^m \subseteq L \subseteq \mathcal{O}_w^m$ and $[\mathcal{O}_w^m : L] = q^i$, and from $(D_i^{(m)})^{-1}/\mathrm{K}$ onto the lattices with $\mathcal{O}_w^m \subseteq L \subseteq \varpi_w^{-1}\mathcal{O}_w^m$ and $[L : \mathcal{O}_w^m] = q^i$; (C2) a vector space of dimension N over k has $\binom{N}{i}_q$ subspaces of dimension i (Gaussian binomial coefficient, 0 for $i > N$), and $\prod_{l=0}^{N-1}(1+q^l t) = \sum_{i=0}^{N} q^{\binom{i}{2}}\binom{N}{i}_q t^i$ (the q-binomial theorem); (C3) $\mathrm{GL}_m(E_w)$ is unimodular, and $[\mathrm{U}(T)]$ is compact because T is definite.

Step 1: the vacuum and the action at $\bar{w}$. For an integral $y \in \mathbb{A}_{E,f}^{n_T \times n_S}$, $y_{A\cup\bar{A}}$ is integral with components 0 outside $\{w,\bar{w}\}$, so $\rho_f(y_{A\cup\bar{A}})\varphi = \varphi$ and, averaging, $P^A\varphi = \varphi$ ((WR6)). By Lemma 6.6.12, $\varphi = \mathbf{1}_A \otimes_A \varphi$. For a function Ψ on $\mathrm{M}_{n_T\times n_S}(E_{\bar{w}})$ we read it as the function $x \mapsto \Psi(x_{\bar{w}})$ of finite adelic matrices. Let $g \in G_f^{(n_S)}$, $h \in G_f^{(n_T)}$ have components 1 outside $\{w,\bar{w}\}$. By (4) of Lemma 4.1.1 (for $\alpha = a$, $\beta = 1$, so $\beta[n_T] = \upsilon^{-n_T}$),

$$\begin{aligned} \omega(g,1)\omega(1,h)\varphi = a[n_S](\det_A h)\,\upsilon^{n_T}(\det_A g)\,|\det_A g|^{n_T/2}\,|\det_A h|^{-n_S/2}\;\Psi'\otimes_A\varphi,\\ \Psi'(x) = \mathbf{1}_A(h_{\bar{w}}^{-1}x\,g_{\bar{w}}), \end{aligned} \tag{1}$$

where $\mathbf{1}_A$ is the indicator of the integral matrices. The characters $\tilde{a}$ (by hypothesis) and υ (by (WD3)) are trivial on the ideles with a unit at $\bar{w}$ and 1 elsewhere; so for an idele d with component of valuation j at $\bar{w}$ and 1 elsewhere, $a[n_S](d) = a[n_S](\varpi_{\bar{w}})^j$ and $\upsilon(d) = \upsilon(\varpi_{\bar{w}})^j$, $\varpi_{\bar{w}}$ the idele with a uniformiser at $\bar{w}$ and 1 elsewhere. Put

$$\alpha = a[n_S](\varpi_{\bar{w}})\,q^{n_S/2}, \qquad \beta = \upsilon(\varpi_{\bar{w}})^{-n_T}\,q^{n_T/2};$$

$|\alpha| = q^{n_S/2}$ and $|\beta| = q^{n_T/2}$, as automorphic characters of $\mathrm{U}(1)$ and υ take values of modulus 1, and they depend only on a, w, n_S, n_T. For $k_1 \in \mathrm{GL}_{n_S}(\mathcal{O}_w)$, $k_2 \in \mathrm{GL}_{n_T}(\mathcal{O}_w)$ the determinants at $\bar{w}$ of $\iota_w(k_1)$, $\iota_w(k_2)$ are units, the scalar in (1) is 1 and $\Psi' = \mathbf{1}_A$; hence

$$\omega(\iota_w(k_1),1)\varphi = \varphi, \qquad \omega(1,\iota_w(k_2))\varphi = \varphi. \tag{2}$$

Step 2: invariance of F_y and the T-side. By (2),

$$F_y(g\iota_w(k_1)) = \int \theta(\omega(g,h)\omega(\iota_w(k_1),1)\varphi)y(h)\,dh = F_y(g)\,:$$

F_y is right invariant under K_w. Fix g and put $\Phi(h) = \theta(\omega(g,h)\varphi)$, a continuous function on $\mathrm{U}(T)(\mathbb{A}_F)$ (bounded functional, continuous representation), left invariant under $\mathrm{U}(T)(F)$ by Lemma 6.2.5 and, by (2), right invariant under K_w; right translates of Φ and of y keep the left invariance, so all integrals below are over $[\mathrm{U}(T)]$. Let μ be the Haar measure of $\mathrm{GL}_{n_T}(E_w)$ with $\mu(\mathrm{K}) = 1$. For a right K-invariant y and a set R_i of representatives of D_i/K ($D_i = D_i^{(n_T)}$), $\sum_{\gamma\in R_i} y(h\iota_w(\gamma)) = \int_{D_i} y(h\iota_w(x))\,d\mu(x)$. As D_i is compact, $[\mathrm{U}(T)]$ compact and all functions continuous, Fubini's theorem, the right invariance of the quotient measure and the invariance of

μ under $x \mapsto x^{-1}$ (C3) give

$$F_{T_{w,i}y}(g) = \int_{D_i}\int \Phi(h)\, y(h\iota_w(x))\, dh\, d\mu(x) = \int y(h) \int_{D_i^{-1}} \Phi(h\iota_w(x))\, d\mu(x)\, dh$$
$$= \int \theta\Big(\omega(g,h) \sum_{\varepsilon\in R_i'} \omega(1,\iota_w(\varepsilon))\varphi\Big) y(h)\, dh,$$

with R_i' a set of representatives of D_i^{-1}/K, using the right K-invariance of Φ and linearity of θ.

For $\varepsilon \in R_i'$, $h = \iota_w(\varepsilon)$ has $h_{\bar w}^{-1} = \bar\varepsilon^{\mathsf T}$ and $\det_A h = \overline{\det \varepsilon}^{\,-1}$, of valuation i at $\bar w$; by (1) $\omega(1,\iota_w(\varepsilon))\varphi = \alpha^i\, \mathbf{1}_A(\bar\varepsilon^{\mathsf T}\cdot) \otimes_A \varphi$. A matrix x over $E_{\bar w}$ has $\bar\varepsilon^{\mathsf T} x$ integral exactly when its columns lie in the dual lattice $L^* = \{c : c^{\mathsf T} L \subseteq \mathcal{O}_{\bar w}\}$ of $L = \bar\varepsilon \mathcal{O}_{\bar w}^{n_T}$. By (C1), transported by conjugation, L runs once over the lattices with $\mathcal{O} \subseteq L \subseteq \varpi^{-1}\mathcal{O}$, $[L:\mathcal{O}] = q^i$, so L^* runs once over the lattices with $\varpi\mathcal{O} \subseteq L^* \subseteq \mathcal{O}$, $[\mathcal{O}:L^*] = q^i$, that is over the subspaces $V = L^*/\varpi\mathcal{O}$ of k^{n_T} of dimension $n_T - i$. The columns of x lie in L^* iff x is integral and $\operatorname{im}\bar x \subseteq V$. By (C2), applied to $k^{n_T}/\operatorname{im}\bar x$ (dimension $n_T - r(x)$),

$$\sum_{\varepsilon\in R_i'} \mathbf{1}_A(\bar\varepsilon^{\mathsf T} x) = \mathbf{1}_A(x) \begin{pmatrix} n_T - r(x) \\ i \end{pmatrix}_q.$$

By linearity of $\Psi \mapsto \Psi \otimes_A \varphi$ and (C2) with $t = -\alpha X$,

$$\sum_{i=0}^{n_T} (-X)^i q^{\binom{i}{2}} \sum_{\varepsilon\in R_i'} \omega(1,\iota_w(\varepsilon))\varphi = P_T \otimes_A \varphi, \qquad P_T(x) = \mathbf{1}_A(x) \prod_{l=0}^{n_T - r(x) - 1} (1 - q^l \alpha X). \tag{3}$$

Step 3: the S-side. Let R_i be a set of representatives of $D_i^{(n_S)}/\mathrm{GL}_{n_S}(\mathcal{O}_w)$. Then $(T_{w,i}F_y)(g) = \sum_{\gamma\in R_i} F_y(g\iota_w(\gamma)) = \int \theta(\omega(g,h)\sum_\gamma \omega(\iota_w(\gamma),1)\varphi) y(h)\, dh$. For $\gamma \in R_i$, $g' = \iota_w(\gamma)$ has $g'_{\bar w} = (\bar\gamma^{\mathsf T})^{-1}$ and $\det_A g'$ of valuation $-i$, so by (1) $\omega(\iota_w(\gamma),1)\varphi = \beta^i\, \mathbf{1}_A(\cdot\,(\bar\gamma^{\mathsf T})^{-1}) \otimes_A \varphi$. Now $x(\bar\gamma^{\mathsf T})^{-1}$ is integral iff $\bar\gamma^{-1}x^{\mathsf T}$ is, iff the columns of $x^{\mathsf T}$ lie in $M = \bar\gamma \mathcal{O}_{\bar w}^{n_S}$; by (C1) M runs once over the lattices with $\varpi\mathcal{O} \subseteq M \subseteq \mathcal{O}$ of index q^i, i.e. over the subspaces $M/\varpi\mathcal{O}$ of k^{n_S} of dimension $n_S - i$, and the condition says that x is integral and $\operatorname{im}\bar x^{\mathsf T} \subseteq M/\varpi\mathcal{O}$. As $\operatorname{rank}\bar x^{\mathsf T} = r(x)$, (C2) gives, for every $Y \in \mathbb{C}$,

$$\sum_{i=0}^{n_S} (-Y)^i q^{\binom{i}{2}} \sum_{\gamma\in R_i} \omega(\iota_w(\gamma),1)\varphi = P_S \otimes_A \varphi, \qquad P_S(x) = \mathbf{1}_A(x) \prod_{l=0}^{n_S - r(x) - 1} (1 - q^l \beta Y). \tag{4}$$

Step 4: comparison. Take $Y = q^k \alpha\beta^{-1} X$, so $q^l \beta Y = q^{k+l}\alpha X$. Since $r(x) \le n_S$ and $n_T - r(x) = k + (n_S - r(x))$, splitting the product in P_T after its first k factors gives $P_T = \prod_{j=0}^{k-1}(1 - q^j\alpha X)\, P_S$. Summing the formula of Step 2 over i with the coefficients $(-X)^i q^{\binom{i}{2}}$ and using (3), then (4) and Step 3,

$$F_{H_w^T(X)y}(g) = \int \theta(\omega(g,h)(P_T \otimes_A \varphi)) y(h)\, dh$$
$$= \prod_{j=0}^{k-1} (1 - q^j\alpha X) \int \theta(\omega(g,h)(P_S \otimes_A \varphi)) y(h)\, dh$$
$$= \prod_{j=0}^{k-1} (1 - q^j\alpha X)\, (H_w^S(Y)F_y)(g).$$

□

Lemma 6.6.12. *Let s be signs on n and A a finite set of finite places of E containing the conjugate of none of its members. Then $\mathbf{1}_A \in \mathcal{T}_A$ and $\mathbf{1}_A \otimes_A f = P^A f$ for every $f \in \mathcal{M}_s$.*

Proof. The function $\mathbf{1}_A$ depends only on the components at A, where it is the indicator of $\prod_{w\in A} \mathcal{O}_{E,w}^n$, a compact open subset of Q_A; so $\mathbf{1}_A$ is locally constant with compact support on Q_A, and $\mathbf{1}_A \in \mathcal{T}_A$ by (1) of Lemma 4.1.3. (Directly: $\mathbf{1}_A = \tau_0$ in (WR6).) The identity $\mathbf{1}_A \otimes_A f = P^A f$ is the last assertion of (1) of Lemma 4.1.3; it rests on the independence of $\Psi \otimes_A f$ from the chosen section proved there, which gives $\mathbf{1}_A \otimes_A f = \tau_0 \otimes_A f = \rho(\mathrm{fv}(0)) P^A f = P^A f$. □

The comparison operator is built from a seesaw: $U_\vartheta = n_0 \,\mathrm{gl}_\vartheta \mathrm{gl}_\vartheta^*$, with gl_ϑ the comparison form of the j-th lift, a gluing map from tables to forms (Proposition 6.6.13). The seesaw identity of the gluing (Lemma 6.6.29) gives numbers c'_ϑ, with $\Gamma_j(\vartheta)|c'_\vartheta|^2$ independent of ϑ, and one map Θ° independent of the twist such that $c'_\vartheta \,\mathrm{gl}_\vartheta^* \circ \Theta_{j,\vartheta} = \Theta^\circ$. So on the lifts U_ϑ is $\rho_j(\vartheta)$ times a fixed operator, positive as soon as Θ° is injective. Orthogonality to the false lifts, integrality and size follow from Lemma 6.6.39 and Lemma 6.6.16.

Integrality is measured here by the chosen group order N_{ch}, one of the quantities of the clearing bound (Definition 6.6.15), which is printed at this point together with the defect bounds it rests on (Definition 6.6.14). The clearing bound also contains an odd-class integer X_{odd}, of which only a size bound is assumed. Section 7 fixes it through the odd Sha bound (Theorem 7.2.8) and uses the clearing bound for the denominators of Ribet's element (Theorem 7.6.6).

The L-values enter through the third exchange (Proposition 6.6.36), which rests on the explicit matching of Section 6.3 and on the carrier, a theta integral over a negative definite unitary group of rank m; the carrier is not zero, by the Rallis inner product formula and the injectivity of the Rallis series (Lemma 6.6.64). For seesaw dual pairs see [171]; identities that move a theta integral across a seesaw are the mechanism of the Rallis inner product formula and the doubling method [231]. Orthogonality to the false lifts uses Green's theory of the characters of the finite general linear groups [106] (Lemma 6.6.42).

The injectivity of Θ° is the statement that products span (Proposition 6.6.44), proved by isolation at a peak. A peak of a holomorphic form is not deep in a cusp (Lemma 6.6.58); away from the cusps a combination of the choice functions is close to a fixed function that does not vanish at 1 (Lemma 6.6.61); and the isolation estimate (Lemma 6.6.80) then forces the form to vanish. Its inputs are the holomorphic model functions, which are Flensted-Jensen's functions of the holomorphic chamber [163, 81], reduction theory to locate the cusps [37, 33], and the Fock model [14]. That the good forms on W_j are not zero is Theorem B (Theorem 5.1.2), for the Poincaré map fixed in Section 5, through the equality of dimensions (Proposition 5.8.4).

Proposition 6.6.13. *Let D be admissible data. For every $1 \le j \le m$ there is a comparison operator for the j-th lift.*

Proof. Fix $1 \le j \le m$. Let Y, c'', L, n_0 be as in Lemma 6.6.16; for a twist ϑ let $\mathrm{gl}_\vartheta = \mathrm{gl}_{j,\vartheta}[L; c'']$, formed with Y, and

$$U_\vartheta = n_0 \,\mathrm{gl}_\vartheta \,\mathrm{gl}_\vartheta^* \quad \text{on } \mathcal{A}_{j,\vartheta}(V^{\mathrm{def}}) = \mathrm{Form}(O_{j,\vartheta}).$$

The hypotheses of Lemma 6.6.29 and Lemma 6.6.39 hold for (Y, c'', L); let C, c'_ϑ, c_i° and Θ° be as in Lemma 6.6.29. For $\zeta \in \mathrm{Tab}_j$ write $\zeta_i \colon \mathfrak{c} \mapsto \zeta_{i,\mathfrak{c}}$. The pairing $\mathrm{tt}_j(\zeta')$ is conjugate-linear in ζ' (each kernel of (XE7) is linear in its polynomial, and $\mathrm{Pol}_{\kappa_O^-}$, Let_{-1} are linear), so $\mathrm{tt}_j(0) = 0$.

Step 1: Θ° is injective. Let $\Theta^\circ y = 0$. Fix $i \in \mathrm{Mem}_j$ and $\zeta' \colon \mathrm{Cl}^\circ \to \mathbb{V}_j^-$, and let $\zeta \in \mathrm{Tab}_j$ have $\zeta_i = \zeta'$ and $\zeta_{i'} = 0$ for $i' \ne i$. By (iii) of Lemma 6.6.29,

$$0 = \langle \zeta, \Theta^\circ y \rangle = c_i^\circ \int_{[\mathrm{U}(W_j)]} y \,\mathsf{F}_i \,\mathrm{tt}_j(\zeta'),$$

and $c_i^\circ \neq 0$. As i and ζ' are arbitrary, Proposition 6.6.44 (for the short row family Y) gives $y = 0$.

Step 2: (CO1). By (iii) of Proposition 5.8.4 and Theorem 5.1.2, applied to the parameters fixed above (the Poincaré map, the seesaw constant and the divisibility errors), whose map satisfies the hypothesis of that theorem (the two moment bounds) by Proposition 5.6.48, the hypothesis of which it satisfies by Lemma 5.6.33 (ii), $\dim \mathcal{A}^{\mathrm{good}}(W_j) = d_{\mathcal{T}} \geq 1$; take $y_0 \neq 0$, so $\Theta^\circ y_0 \neq 0$ by Step 1. If $c'_\vartheta = 0$ for some twist ϑ, (ii) of Lemma 6.6.29 gives $\Theta^\circ = 0$; so $c'_\vartheta \neq 0$ for every ϑ. By (i) there, $C = \Gamma_j(1)|c'_1|^2 \neq 0$ and $\Gamma_j(\vartheta) = C/|c'_\vartheta|^2$, so

$$\rho_j(\vartheta) = \frac{\Gamma_j(\vartheta)}{\Gamma_j(1)} = \frac{|c'_1|^2}{|c'_\vartheta|^2} \neq 0.$$

Step 3: (CO2). Let $U^\circ = n_0|c'_1|^{-2}\,\Theta^{\circ *}\Theta^\circ$ on $\mathcal{A}^{\mathrm{good}}(W_j)$ (the adjoint for the Petersson product and the inner product of Tab_j, both spaces being finite-dimensional); it does not depend on ϑ, and $\langle y, U^\circ y\rangle = n_0|c'_1|^{-2}\|\Theta^\circ y\|^2 > 0$ for $y \neq 0$ by Step 1. By (ii) of Lemma 6.6.29, $\mathrm{gl}^*_\vartheta \Theta_{j,\vartheta} y = c'^{-1}_\vartheta \Theta^\circ y$, so for $y, y' \in \mathcal{A}^{\mathrm{good}}(W_j)$

$$\langle \Theta_{j,\vartheta} y', U_\vartheta \Theta_{j,\vartheta} y\rangle = n_0 \langle \mathrm{gl}^*_\vartheta \Theta_{j,\vartheta} y', \mathrm{gl}^*_\vartheta \Theta_{j,\vartheta} y\rangle = \frac{n_0}{|c'_\vartheta|^2}\langle \Theta^\circ y', \Theta^\circ y\rangle = \rho_j(\vartheta)\,\langle y', U^\circ y\rangle,$$

by Step 2.

Step 4: (CO3). Let $z = \Theta_{j,\vartheta} y \in \mathcal{L}_{j,\vartheta}$; then $U_\vartheta z = n_0 c'^{-1}_\vartheta\, \mathrm{gl}_\vartheta(\Theta^\circ y)$. Let w be a finite place with $w \neq \bar{w}$, neither w nor $\bar{w}$ a place of $O_{j,\vartheta}$, and $\varphi \in \mathcal{F}_w(e_0, \mathcal{L}^\perp_{j,\vartheta})$. With $\zeta = \mathrm{gl}^*_\vartheta \varphi$, (iii) of Lemma 6.6.29 and Lemma 6.6.39 give

$$\langle \varphi, \mathrm{gl}_\vartheta(\Theta^\circ y)\rangle = \langle \zeta, \Theta^\circ y\rangle = \sum_i c_i^\circ \int_{[\mathrm{U}(W_j)]} y\, \mathsf{F}_i\, \mathrm{tt}_j(\zeta_i) = 0.$$

So $U_\vartheta z$ is orthogonal to $\mathcal{F}_w(e_0, \mathcal{L}^\perp_{j,\vartheta})$ for every such w, i.e. orthogonal to the false lifts for $(e_0, \mathcal{L}^\perp_{j,\vartheta})$.

Step 5: (CO4), (CO5). These are (a) and (b) of Lemma 6.6.16.

Hence $U = (U_\vartheta)$ is a comparison operator for the j-th lift. □

Definition 6.6.14. Let D be admissible data and put $h = \Delta/2 = r^8$.

CM sign. For a complex embedding $\sigma\colon E \to \mathbb{C}$, $\mathrm{sg}(\sigma) = 1$ if $\sigma = \iota_0 \circ g$ for some $g \in \mathrm{Gal}(E/K)$ (the embedding chosen at its place) and $\mathrm{sg}(\sigma) = -1$ otherwise. For a complex embedding σ, $\kappa_j(\sigma)$ means κ_j at the place of σ. For a prime ℓ, an isomorphism $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$, an embedding $e\colon E \to \overline{\mathbb{Q}}_\ell$ and $g \in G_\ell$, put $\sigma_{e,g} = \iota^{-1} \circ g^{-1} \circ e$.

Main-summand weight systems. Let $1 \leq r' \leq r$ and $t' \leq t$. A family $J = (J(\sigma))_\sigma$ of finite multisets of integers, indexed by the complex embeddings σ of E, is a **main-summand weight system** of rank r' and length t' if

(DW1) there is $j \leq m$ such that for every σ and every $u \in J(\sigma)$: either $\Delta \leq 4|u|$ and $|u| \leq 2m\Delta$ (a *low* jump), or $|\mathrm{sg}(\sigma)\, u + \kappa_j(\sigma)| \leq t$ (a *high* jump);

(DW2) for every σ, $k \cdot \#\{u \in J(\sigma) : |u| \leq 2h^2\} \leq r'm$;

(DW3) for every σ, $\#\{u \in J(\sigma) : u < 0\} + \#\{u \in J(\bar{\sigma}) : u < 0\} \leq r'$,

multisets counted with multiplicity and $\bar{\sigma}$ the complex conjugate of σ. The **far window start** at σ for $j \leq m$ is $S_j(\sigma) = \kappa_j(\sigma) - 2t$ (a non-negative integer, as $\kappa_j(\sigma) \geq h = r^8 > 2t$).

Loss and defect bounds. For a prime ℓ, the **crystalline loss** is

$$\lambda_\ell = v_\ell\Big((2b)!\cdot\Big(\prod_{\max(b-30h^3,0)<a\le b+30h^3} a\Big)^{h^3}\Big),$$

the **defect bound** and the **local defect bound** are

$$\mathrm{db}_\ell = 10^6\,\frac{m}{k}\,(b\,v_\ell(M)+\lambda_\ell), \qquad \mathrm{loc}_\ell = 4f\,\mathrm{db}_\ell, \tag{6.130}$$

non-negative reals.

Definition 6.6.15. Let D be admissible data and ℓ a prime. Write $h=\Delta/2=r^8$ (the **half gap**).

(CX1) Chosen group order. $N_{\mathrm{ch}}=\prod_w \#\mathrm{GL}_{rt}(k_w)$, the product over the chosen places w of E, with k_w the residue field at w.

(CX2) Twist error. $e'_\ell=(4f+3)\,r\,v_\ell(N_{\mathrm{ch}})+2^{-\ell}$.

(CX3) Odd-class integer. The **odd-class integer** of D is an integer X_{odd} depending on D alone with

$$1\le X_{\mathrm{odd}}\le 2^{4(q_1d+t+3)^{27}}\,\#\mathrm{Cl}(E),$$

where $\#\mathrm{Cl}(E)$ is the class number of E; this definition uses no other property of it.

(CX4) Denominator error.

$$e_\ell = t\,v_\ell(X_{\mathrm{odd}})+(8ft+2+(4t+1)h^{22}+h)\,v_\ell(N_{\mathrm{ch}}).$$

(CX5) Clearing bound.

$$\beta_\ell=\mathrm{loc}_\ell+(1+2t)\,e'_\ell+e_\ell+v_\ell(N_{\mathrm{ch}}).$$

In (CX4) the term $t\,v_\ell(X_{\mathrm{odd}})$ pays for the odd classes (and, at $e=0$, the class group), $((4t+1)h^{22}+h)v_\ell(N_{\mathrm{ch}})$ for the triangle, and the rest for the principal level, the idempotent and the automorphisms.

Lemma 6.6.16. *Let $1\le j\le m$. There are a short row family Y, a number $c''\in\mathbb{C}^\times$, divided lattices $L=(L_i)_{i\in\mathrm{Mem}_j}$ of $O_{j,1}$ with L_i glued for Λ_i, and an integer $n_0\ge 1$, such that $\mathcal{V}_j$ is a divided splitting for $O_{j,\vartheta}$ for every twist ϑ and, with $\mathrm{gl}_\vartheta=\mathrm{gl}_{j,\vartheta}[L;c'']$ formed with Y and $U_\vartheta=n_0\,\mathrm{gl}_\vartheta\mathrm{gl}_\vartheta^*$ on $\mathrm{Form}(O_{j,\vartheta})$:*

(a) for every twist ϑ, every prime $\ell\nmid \mathrm{N}Q$ and every embedding $\mathbb{C}\to\mathbb{C}_\ell$, U_ϑ maps the forms integral at that embedding to forms integral at it;

(b) $\|U_1\varphi\|_\sigma^2\le\exp\big(6fmb(\log b)^2\big)\|\varphi\|_\sigma^2$ for every $\varphi\in\mathrm{Form}(O_{j,1})$ and every automorphism σ of $\mathbb{C}$.

Proof. Fix j and write $\kappa^-=\kappa^-_{O_{j,1}}$ in rank $|\mathcal{B}^\circ|$, $h=h_{\kappa^-}\ge 1$, $E=fmb(\log b)^2$.

Step 1: the divided splitting. By (TG2) we must show, for every τ and every twist (the weights do not involve it), $\kappa^+_O(\tau,h')=0$ for $|\mathcal{B}_j|\le h'<n$ and $\kappa^-_O(\tau,h')=0$ for $|\mathcal{B}^\circ|\le h'<n$. First, $18m+5<2r$:

So $|\mathcal{B}^\circ| = 5r - 9m - 1 > r$. For $i \geq r$ the extended entry is $\varsigma_\tau(i) = \frac{\Delta}{2} - \kappa_{i+2-k}(\tau)$ with $i + 2 - k \geq m + 1 > j$, and $\kappa_{j'} = \kappa_j + (j' - j)\Delta$, so $\varsigma_\tau(i) \leq -\frac{\Delta}{2} - \kappa_j(\tau) < \frac{t-1}{2} - \kappa_j(\tau)$. If $h' \geq |\mathcal{B}_j| = r + 9m + 1$, then $h' - 1 \geq r$, so $\varsigma_\tau(h' - 1) - \max(\varsigma_\tau(h'), \frac{t-1}{2} - \kappa_j(\tau)) - 1 < 0$ and $\kappa_O^+(\tau, h') = 0$. If $h' \geq |\mathcal{B}^\circ| > r$, both arguments $r - h' - 1$ and $r - h'$ are negative and read as 0, so $\kappa_O^-(\tau, h') = (\min(\varsigma_\tau(0), -\kappa_j(\tau) - \frac{t-1}{2}) - \varsigma_\tau(0) - 1)^+ = 0$. Hence $\mathcal{V}_j$ is a divided splitting for every $O_{j,\vartheta}$.

Step 2: the choices. Let Y and c'' be as in Lemma 6.6.17. For each $i \in \mathrm{Mem}_j$, Lemma 6.6.24 (for $O_{j,1}$, the divided splitting $\mathcal{V}_j$ of Step 1 and $s = \Lambda_i$) gives a divided lattice L_i glued for Λ_i. Put $n_0 = N_{\mathrm{ch}} h^2$, a positive integer, $\mathrm{gl}_\vartheta = \mathrm{gl}_{j,\vartheta}[L; c'']$ and $U_\vartheta = n_0 \mathrm{gl}_\vartheta \mathrm{gl}_\vartheta^*$. By Steps 1 and 2 the hypotheses of Lemma 6.6.25 hold.

Step 3: frames. Let $(f_a)_{a \in A}$ be tables with $\sum_a \langle f_a, \zeta \rangle f_a = h^2 \zeta$ for all $\zeta \in \mathrm{Tab}_j$. For $\Xi \in \mathrm{Form}(O_{j,\vartheta})$, applied to $\zeta = \mathrm{gl}_\vartheta^* \Xi$ and since $\langle f_a, \mathrm{gl}_\vartheta^* \Xi \rangle = \langle \mathrm{gl}_\vartheta f_a, \Xi \rangle$,

$$U_\vartheta \Xi = N_{\mathrm{ch}} h^2 \, \mathrm{gl}_\vartheta (h^{-2} \textstyle\sum_a \langle \mathrm{gl}_\vartheta f_a, \Xi \rangle f_a) = \sum_{a \in A} c_a \, \mathrm{gl}_\vartheta f_a, \qquad c_a = N_{\mathrm{ch}} \langle \mathrm{gl}_\vartheta f_a, \Xi \rangle. \tag{6.131}$$

Step 4: (a). Let ϑ, $\ell \nmid \mathrm{N}Q$ and ι be given and let Ξ be integral at ι. Take the frame of (a) of Lemma 6.6.27 for ℓ. For every ring homomorphism $\iota' \colon \mathbb{C} \to \mathbb{C}_\ell$ the conjugated values $\overline{(f_a)}_{i,\mathfrak{c}}$ have gauge at most 1 at $x_\mathfrak{c}$ for $\iota' \circ c$; applied with $\iota' = \iota$ and with $\iota' = \iota \circ c$ (for which $\iota' \circ c = \iota$), (a) of Lemma 6.6.25 shows that every $\mathrm{gl}_\vartheta f_a$ is integral at ι and at $\iota \circ c$. By Lemma 6.6.28 (with Ξ there $\mathrm{gl}_\vartheta f_a$ and Ξ' there Ξ), $|\iota(c_a)|_\ell \leq 1$. The conditions defining integrality at ι are bounds $|\cdot|_\ell \leq 1$ on coordinates that depend linearly on the form, so by the ultrametric inequality the forms integral at ι are closed under sums and under multiplication by numbers c with $|\iota(c)|_\ell \leq 1$. By (6.131), $U_\vartheta \Xi$ is integral at ι.

Step 5: (b). Take $\vartheta = 1$ and the frame of (b) of Lemma 6.6.27. For an automorphism σ of $\mathbb{C}$ let $\sigma' = c \circ \sigma \circ c$; then $\sigma(\bar{z}) = \overline{\sigma'(z)}$ for $z \in \mathbb{C}$. The weights $1/\#\Gamma_h$ and the Gram matrix are rational, so for $u, v \in \mathrm{Form}(O_{j,1})$, $\sigma(\langle u, v \rangle)$ is the class sum of $\overline{\sigma'(u(h))}^{\mathsf{T}} G_{\kappa_O} \sigma(v(h))$, and the Cauchy–Schwarz inequality for this positive semidefinite hermitian form gives $|\sigma(\langle u, v \rangle)| \leq \|u\|_{\sigma'} \|v\|_\sigma$. With (b) of Lemma 6.6.25 for σ' and $\|f_a\|_{\sigma'} \leq h$,

$$|\sigma(c_a)| \leq N_{\mathrm{ch}} \, \|\mathrm{gl}_1 f_a\|_{\sigma'} \, \|\Xi\|_\sigma \leq N_{\mathrm{ch}} \, e^E h \, \|\Xi\|_\sigma.$$

By (6.131), $U_1 \Xi = \mathrm{gl}_1 \zeta$ with $\zeta = \sum_a c_a f_a$, and as σ is additive and multiplicative on coordinates, the triangle inequality gives $\|\zeta\|_\sigma \leq \sum_a |\sigma(c_a)| \, \|f_a\|_\sigma \leq \#A \, N_{\mathrm{ch}} h^2 e^E \|\Xi\|_\sigma$. By (b) of Lemma 6.6.25 and (c) of Lemma 6.6.27 (with $\#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) \geq 1$),

$$\|U_1 \Xi\|_\sigma^2 \leq e^{2E} \|\zeta\|_\sigma^2 \leq e^{4E} \big(\#A \, N_{\mathrm{ch}} h^2\big)^2 \|\Xi\|_\sigma^2 \leq e^{6E} \|\Xi\|_\sigma^2 = \exp\big(6 f m b (\log b)^2\big) \|\Xi\|_\sigma^2.$$

□

Lemma 6.6.17. *Let $1 \leq j \leq m$. There are a short row family Y and $c'' \in \mathbb{C}^\times$ such that the first factors $\varphi''_{\vartheta,i}$ with scale c'', formed with Y, satisfy:*

(i) for every twist ϑ with modulus Q, every $i \in \mathrm{Mem}_j$, every $h \in G_f(\mathcal{B}_j)$, every prime $\ell \nmid \mathrm{N}Q$ and every ring homomorphism $\iota \colon \mathbb{C} \to \mathbb{C}_\ell$: $\mathrm{gau}_\iota\big(h, \varphi''_{\vartheta,i}(h)\big) \leq 1$;

(ii) for every $i \in \mathrm{Mem}_j$, every $h \in G_f(\mathcal{B}_j)$ and every automorphism σ of $\mathbb{C}$: $\big\|\sigma\big(\varphi''_{1,i}(h)\big)\big\|_{\kappa_O^+}^2 \leq \exp\big(f m b (\log b)^2\big)$, σ applied to the coordinates.

Proof. Fix j, write $\kappa = \kappa^+_{O_{j,1}}$ (the weight of $\mathbb{V}^+_j$, free of the twist), $\mathfrak{M} = \pi_M\mathcal{O}_E$, $\#D_j = \sum_\tau \#D_j(\tau)$, and for a twist ϑ with modulus Q put $\mathfrak{n}_\vartheta = \mathfrak{M}^2\prod_{w\in Q} w$ (so $\mathfrak{n}_1 = \mathfrak{M}^2$). For an element or matrix z write $\bar z$ for its complex conjugate (entrywise).

Step 0: the choices. Let Y be a short row family (Lemma 6.6.18), and d, H as in (a) of Lemma 6.6.21. By Lemma 6.6.20 choose $c_0, c_1, c_2 \in \mathbb{C}^\times$ for the pairs of index sets $(\{1,\dots,m\}, \mathcal{B}^{\mathrm{c}})$, $(\mathcal{A}^-_j, \mathcal{B}_j)$, $(\mathcal{B}^{\mathrm{add}}_j, \mathcal{B}_j)$ and the degrees 0, 0, d, and by Lemma 6.4.55 let c_3, $|c_3| = 1$, be the constant for $(S,T) = (\mathrm{I}_{\mathcal{A}^-_j}, \mathrm{I}_{\mathcal{B}_j})$. Put

$$c'' = N^2_{\mathrm{ch}}\, c_0\, \bar c_1\, c_2\, H\, c_3 \neq 0.$$

These choices depend only on j and D.

Step 1: the first factor as a double class sum. Fix a twist ϑ with modulus Q, a choice i and $h \in G_f(\mathcal{B}_j)$; write $\chi' = \chi'_{j,\vartheta}$, $\nu'' = \nu''_{j,\vartheta}$, $b' = \nu''^{-1}\upsilon^{|\mathcal{B}_j|}$, $\mathfrak{n} = \mathfrak{n}_\vartheta$ (the modulus $\mathfrak{M}^2\mathfrak{O}_O$ of (XE6)), $Y = Y_{\mathfrak{c}_i}$, $x = x_{\mathfrak{c}_i}$. Let $u \in R^\times_{\mathfrak{n}}$ be the unit of Lemma 6.4.55 and $\Psi_1(X) = \mathbf{1}^-_j(uX)$, a function with values 0, 1. By Lemma 6.4.55 for $S = \mathrm{I}_{\mathcal{A}^-_j}$ (rank j), $T = \mathrm{I}_{\mathcal{B}_j}$, the characters 1, b', the function Ψ_1 and $P = 1$, whose right side has the characters υ^j, $b'^{-1}\upsilon^{|\mathcal{B}_j|} = \nu''$ and the function $\overline{\Psi_1(u^{-1}X)} = \mathbf{1}^-_j(X)$,

$$\theta^{\mathrm{I}^-_{\mathcal{A}^-_j},\mathrm{I}_{\mathcal{B}_j}}_{\upsilon^j,\nu'';\mathfrak{n}}\big[\mathbf{1}^-_j, 1\big](1,h) = \overline{c_3\,\kappa_1(h)}, \qquad \kappa_1(h) = \theta^{\mathrm{I}_{\mathcal{A}^-_j},\mathrm{I}_{\mathcal{B}_j}}_{1,b';\mathfrak{n}}[\Psi_1, 1](1,h).$$

By (XD5), $\mathrm{mod}_{\mathfrak{M}^2}(1,v_1) = v_1 \otimes (\mathbf{1}_A \otimes_A v^0) = v_1 \otimes v^0$ ($A = \Sigma(\mathfrak{M}^2)$; Lemma 6.6.12 and (2) of Lemma 6.2.33), so by (XE4) $\mathsf{a}_{\chi'}(g_2) = \sum^{\mathrm{cl}}_{g_1} k_0(g_1,g_2)$ with $k_0(g_1,g_2) = \theta^{\mathrm{I}_{\{1,\dots,m\}},\mathrm{I}_{\mathcal{B}^{\mathrm{c}}}}_{\chi',1;\mathfrak{M}^2}[1,1](g_1,g_2)$, the class sum over $g_1 \bmod \mathbf{K}_0(\{1,\dots,m\})$. For a polynomial $P \in \mathbb{C}[x]_{\mathcal{B}_j\times\mathcal{B}^{\mathrm{add}}_j}$ and $g \in G_f(\mathcal{B}^{\mathrm{add}}_j)$ write $\theta_g(P) = \theta^{W^{\mathrm{add}}_j,\mathrm{I}_{\mathcal{B}_j}}_{\nu'',\nu'';\mathfrak{n}}[\Psi^{\mathrm{add}}_{\Lambda_i}, P](g,h)$, linear in P, and for $g_2 \in G_f(\mathcal{B}^{\mathrm{c}})$ let $\bar g_2 = (1,x,g_2)$ be the block diagonal point on $\mathcal{A}^+_j \sqcup \mathcal{B}^\flat \sqcup \mathcal{B}^{\mathrm{c}}$ and $u_{g_2} = (c_2\,\theta_{\bar g_2}(H\mathrm{lc}_{i,l}))_{l\in I_\kappa}$. With the class-sum weights ω_{g_1}, ω_{g_2} of (6.22) (positive rationals) and $s(g_1,g_2) = c_0 k_0(g_1,g_2)\,\overline{c_1\kappa_1(h)}$, (XE6) and $c_3\bar c_3 = 1$ give

$$\varphi''_{\vartheta,i}(h) = \overline{c''\,\Upsilon_{\vartheta,i}(h)} = \sum_{g_2}\sum_{g_1}(N_{\mathrm{ch}}\omega_{g_2})(N_{\mathrm{ch}}\omega_{g_1})\,\overline{s(g_1,g_2)}\;\overline{u_{g_2}}, \tag{6.132}$$

the sums over the fixed representatives g_2 of the classes of $\mathrm{I}_{\mathcal{B}^{\mathrm{c}}}$ at $\mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$ and g_1 of those of $\mathrm{I}_{\{1,\dots,m\}}$ at $\mathbf{K}_0(\{1,\dots,m\})$. By Lemma 6.7.9 ($m$, $3m \le rt$ by Lemma 6.6.22) the numbers $N_{\mathrm{ch}}\omega$ are positive integers.

Step 2: three facts on the gauge. Let ℓ be a prime, $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism and $\mathrm{gau} = \mathrm{gau}_\iota$ for the weight $(\kappa,0)$ on $\mathcal{B}_j$. (G1) $\mathrm{gau}(h,a\xi) = |\iota(a)|\,\mathrm{gau}(h,\xi)$ and $\mathrm{gau}(h,\sum_k n_k\xi_k) \le \max_k \mathrm{gau}(h,\xi_k)$ for integers n_k: $\iota(a\xi) = \iota(a)\iota(\xi)$, the map is linear, and $|\cdot|_\ell$ is ultrametric with $|n|_\ell \le 1$. (G2) For a rational point γ of $\mathrm{I}_{\mathcal{B}_j}$, $\mathrm{gau}(\gamma_f h, \rho_{\kappa,0}(\gamma)\xi) = \mathrm{gau}(h,\xi)$: for $y \in E$, $f_{\iota,\tau}(y) = \iota(\tau(\bar y)) = \iota(\overline{\tau(y)})$ (the embedding of the CM type commutes with conjugation), so $f_\iota(\gamma_f) = \iota(\overline{\tau(\gamma)})_\tau$, and as S_κ has integral polynomial entries, $\iota(\rho_{\kappa,0}(\gamma)\xi) = \iota(S_\kappa(\overline{\tau(\gamma)})\xi) = S_\kappa(f_\iota(\gamma_f))\iota(\xi)$; then $S_\kappa(f_\iota((\gamma_f h)^{-1}))S_\kappa(f_\iota(\gamma_f)) = S_\kappa(f_\iota(h^{-1}))$ by the multiplicativity of f_ι and of S_κ ((a) of Lemma 4.6.10). (G3) If the components of h at the places above ℓ are integral invertible, then $\mathrm{gau}(h,\xi) \le \max_k|\iota(\xi_k)|$: the place inducing $f_{\iota,\tau}$ lies above ℓ, so $f_\iota(h^{-1})$ has entries of absolute value at most 1, and so has $S_\kappa(f_\iota(h^{-1}))$.

Step 3: rational translation of definite kernels. Let $S = \mathrm{I}_L$, $T = \mathrm{I}_N$ be standard definite spaces (for instance $W^{\mathrm{add}}_j = \mathrm{I}_{\mathcal{B}^{\mathrm{add}}_j}$), α, β automorphic characters of weights e_α, e_β, γ_S, γ_T rational points of S, T, g, h' finite points and P a polynomial. Then

$$\theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Psi,P](\gamma_{S,f}g, \gamma_{T,f}h') = \prod_{\tau\in\Phi}\det\tau(\gamma_T)^{-e_\alpha(\tau)}\det\tau(\gamma_S)^{e_\beta(\tau)}\;\theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Psi, P^{A,B}](g,h'), \tag{6.133}$$

with $A_\tau = \tau(\gamma_T)^{-1}$, $B_\tau = \tau(\gamma_S)$ and $P^{A,B}$ the substitution $x_\tau \mapsto A_\tau^{\mathsf{T}} x_\tau B_\tau^{\mathsf{T}}$. Indeed, by Lemma 6.2.5 the left side is the kernel at the points with infinite components $x = \tau(\gamma_S)^{-1}$, $y = \tau(\gamma_T)^{-1}$ and finite components g, h'; by (1) of Lemma 6.3.71 it is the kernel at (g, h') of $\mathrm{mod}_{\mathfrak{m}}(\Psi, \Omega_{e_\alpha, e_\beta}(x,y)v_P)$; by (5) of Lemma 4.1.1, all signs being $+1$,

$$\Omega_{e_\alpha,e_\beta}(x,y)v_P = \prod_\tau \det(y_\tau)^{e_\alpha(\tau)} \det(x_\tau)^{-e_\beta(\tau)} v_{P'}$$

with P' the substitution $x_\tau \mapsto y_\tau^{\mathsf{T}} x_\tau (x_\tau^{-1})^{\mathsf{T}}$, which is $P^{A,B}$.

Step 4: integrality of the three factors. Let ϑ, i, h be as in Step 1, $\ell \nmid \mathrm{N}Q$ a prime, $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, $\iota' = \iota \circ \bar{\cdot}$, also a ring homomorphism, and R the set of places of E above ℓ. By Lemma 4.2.64 (with the set R), for every finite point h_0 of a standard space there is a rational point δ with $\delta_f h_0$ integral invertible at R: the points whose components at the places $w \in R$ lie in $(h_0)_w$ times the integral invertible matrices form an open neighbourhood of $(1, h_0)$, so it contains some $\gamma(1,k)$ with γ rational and k trivial at R, and $\delta = \gamma^{-1}$ works. The number $q = \mathrm{N}Q$ satisfies $qM^2 \in \mathfrak{n}$ ($M \in \mathfrak{M}$, and $\mathrm{N}w \in w$). The characters 1, χ' (weight 0), b' and ν'' have weights and tame parts, and ν'' has the weight $-\#D_j(\tau)$: by (XE1), $\nu'' \upsilon^m = \chi' \nu_j^\flat \upsilon^m$, which has the weight $m - \#D_j(\tau)$ by (b) of Lemma 6.6.23, and υ has weight 1 ((ii) of Lemma 3.2.11). (a) $|\iota'(c_0 k_0(g_1,g_2))| \le 1$. Choose rational δ_1, δ_2 with $\delta_{1,f} g_1$, $\delta_{2,f} g_2$ integral invertible at R. By (6.133) with $P = 1$ and both characters of weight 0, $k_0(g_1,g_2) = k_0(\delta_{1,f} g_1, \delta_{2,f} g_2)$, and (i) of Lemma 6.6.20 with $q = 1$ ($M^2 \in \mathfrak{M}^2$), $\Psi = 1$ and ι' gives the claim. (b) $|\iota(c_1 \kappa_1(h))| \le 1$. Choose a rational δ' of $\mathrm{I}_{\mathcal{B}_j}$ with $\delta'_f h$ integral invertible at R; by (6.133) with $\gamma_S = 1$, $P = 1$ and the target character 1, $\kappa_1(h) = \kappa_1(\delta'_f h)$, and (i) of Lemma 6.6.20 with $q = \mathrm{N}Q$, Ψ_1 (values 0, 1) and ι gives the claim. (c) $\mathrm{gau}_\iota(h, \overline{u_{g_2}}) \le 1$. Choose rational points γ_1 of $W^\flat$, γ_2 of $\mathrm{I}_{\mathcal{B}^c}$ and γ' of $\mathrm{I}_{\mathcal{B}_j}$ with $\gamma_{1,f} x$, $\gamma_{2,f} g_2$, $\gamma'_f h$ integral invertible at R, put $\Gamma = \mathrm{diag}(1, \gamma_1, \gamma_2)$, a rational point of W_j^{add} with $\Gamma_f \bar{g}_2$ integral invertible at R, and $Y' = Y\gamma_1^{\mathsf{T}} \in \mathrm{M}_{\mathcal{B}^\flat}(E)$. Let $A_\tau = \tau(\gamma')^{-1}$, $U_\tau = \tau(\gamma_1)$, $V_\tau = \tau(\gamma_2)$, $B_\tau = \mathrm{diag}(1, U_\tau, V_\tau) = \tau(\Gamma)$; then $\tau(Y') = \tau(Y) U_\tau^{\mathsf{T}}$. Let $u'_k = c_2\, \theta^{W_j^{\mathrm{add}}, \mathrm{I}_{\mathcal{B}_j}}_{\nu'', \nu''; \mathfrak{n}}[\Psi^{\mathrm{add}}_{\Lambda_i}, H\mathrm{lc}_{i,k}[Y']](\Gamma_f \bar{g}_2, \gamma'_f h)$. By (6.133) (both weights $-\#D_j(\tau)$), linearity in the polynomial and (c) of Lemma 6.6.21,

$$\begin{aligned}\sum_k S_\kappa(A)_{lk} u'_k &= \prod_\tau \det \tau(\gamma')^{\#D_j(\tau)} \det \tau(\Gamma)^{-\#D_j(\tau)} \cdot c_2\, \theta_{\bar{g}_2}\Big(\big(\textstyle\sum_k S_\kappa(A)_{lk} H\mathrm{lc}_{i,k}[Y']\big)^{A,B} \Big) \\ &= c_2\, \theta_{\bar{g}_2}(H\mathrm{lc}_{i,l}[Y]),\end{aligned}$$

as $\det A_\tau = \det \tau(\gamma')^{-1}$ and $\det B_\tau = \det \tau(\Gamma)$; that is, $u_{g_2} = S_\kappa(A) u'$. Hence $\overline{u_{g_2}} = S_\kappa(\bar{A})\overline{u'} = \rho_{\kappa,0}(\gamma'^{-1})\overline{u'}$, and by (G2) and (G3), $\mathrm{gau}(h, \overline{u_{g_2}}) = \mathrm{gau}(\gamma'_f h, \overline{u'}) \le \max_k |\iota'(u'_k)|$. Now apply (i) of Lemma 6.6.20 for $(\mathcal{B}_j^{\mathrm{add}}, \mathcal{B}_j, d)$ with c_2, $q = \mathrm{N}Q$ and ι': the values of $\Psi^{\mathrm{add}}_{\Lambda_i}$ are 0 or sums of values of the additive character $\psi_{\mathfrak{M}^2}$, roots of unity, so they are integral at every ring homomorphism into every $\mathbb{C}_{\ell'}$; the points are integral invertible at R; $H\mathrm{lc}_{i,k}[Y']$ is homogeneous of degree d with coefficients in the subring $\{z : |\iota'(z)| \le 1\}$ of $\mathbb{C}$ by (a) of Lemma 6.6.21, because $Y'^{\mathsf{T}} = (\gamma_{1,f} x)(x^{-1} Y^{\mathsf{T}})$ has entries in E integral at every place above ℓ ((XE5): $x^{-1}Y^{\mathsf{T}}$ is integral), and $|\iota'(\tau(y))| \le 1$ for such y, $\iota' \circ \tau$ being an embedding of E into $\mathbb{C}_\ell$ that induces a place above ℓ. So $|\iota'(u'_k)| \le 1$ for all k.

Step 5: (i). By (6.132), (G1) and Step 4,

$$\mathrm{gau}_\iota(h, \varphi''_{\vartheta,i}(h)) \le \max_{g_1,g_2} |\iota(\overline{c_0 k_0})|\, |\iota(c_1\kappa_1(h))|\, \mathrm{gau}_\iota(h, \overline{u_{g_2}}) \le 1,$$

since $\iota(\bar{z}) = \iota'(z)$.

Step 6: (ii). Let $\vartheta = 1$ (so $Q = \emptyset$, $\mathfrak{n} = \mathfrak{M}^2$), $\sigma \in \mathrm{Aut}(\mathbb{C})$ and $\sigma' = \sigma \circ \bar{\cdot} \in \mathrm{Aut}(\mathbb{C})$. For $w \in \mathbb{C}^{I_\kappa}$, $\|w\|_\kappa = \max\{|f^{\mathsf{T}} w| : f \in \mathbb{C}^{I_\kappa},\ \bar{f}^{\mathsf{T}} G_\kappa^{-1} f \le 1\}$: G_κ is real symmetric and positive

definite ((b) of Lemma 4.6.10), $f^{\mathsf T}w = \langle G_\kappa^{-1}\bar f, w\rangle_\kappa$ and $\|G_\kappa^{-1}\bar f\|_\kappa^2 = \bar f^{\mathsf T}G_\kappa^{-1}f$, so this is the Cauchy–Schwarz inequality, with equality for $f = \overline{G_\kappa w}/\|w\|_\kappa$. By the first two assertions of Lemma 6.6.22, the ranks m, $3m$, j, $|\mathcal B_j|$, $|\mathcal B_j^{\mathrm{add}}| = 12m+1-j$ are at most Δ and $d \le M$; and $M^2 \in \mathfrak M^2$. By (ii) of Lemma 6.6.20 with $A=1$ and $B=1$ ($\Psi = 1$ or Ψ_1, $P=1$), $|\sigma'(c_0k_0)| \le e^{x_1}$ and $|\sigma'(\overline{c_1\kappa_1(h)})| = |\sigma(c_1\kappa_1(h))| \le e^{x_1}$. For f with $\bar f^{\mathsf T}G_\kappa^{-1}f \le 1$ let $Q_f = \sum_l \sigma'^{-1}(f_l)H\mathrm{lc}_{i,l}$, homogeneous of degree d; then $f^{\mathsf T}\sigma'(u_{g_2}) = \sigma'(c_2\theta_{\bar g_2}(Q_f))$, and for z with $|\sigma'(z_u)| \le M^4$ for all u, $|\sigma'(Q_f(z))| = |f^{\mathsf T}(\sigma'(H\mathrm{lc}_{i,l}(z)))_l| \le H\,M^{9(12m+1)\#D_j/2}$ by the duality and (b) of Lemma 6.6.21 ($|\sigma'(\tau(Y_{ab}))| \le M^4$ by (XE5)). The values of $\Psi_{\Lambda_i}^{\mathrm{add}}$ have all conjugates of absolute value at most $\#\mathrm{GL}_{3m}(\mathcal O_E/\mathfrak M^2)$. So (ii) of Lemma 6.6.20 and the duality give $\|\sigma'(u_{g_2})\|_\kappa \le e^{x_1}\,\#\mathrm{GL}_{3m}(\mathcal O_E/\mathfrak M^2)\,H\,M^{9(12m+1)\#D_j/2}$. The number of classes of $\mathrm I_{\mathcal B^{\mathrm c}}$ at $\mathbf K_0(\mathcal B^{\mathrm c})$ and of $\mathrm I_{\{1,\dots,m\}}$ at $\mathbf K_0(\{1,\dots,m\})$ is at most $e^{x^{30}}$ each (Lemma 4.6.4, m, $3m \le 2n_m$), and the weights ω are at most 1. By (6.132), applying σ coordinatewise ($\sigma(\bar z) = \sigma'(z)$) and the triangle inequality,

$$\|\sigma(\varphi''_{1,i}(h))\|_\kappa \le N_{\mathrm{ch}}^2\, e^{2x^{30}}\, e^{3x_1}\,\#\mathrm{GL}_{3m}(\mathcal O_E/\mathfrak M^2)\,H\,M^{9(12m+1)\#D_j/2},$$

and with $H \le d^{3d}$, $d \le (10m+1)\#D_j$, the last assertion of Lemma 6.6.22 gives (ii). □

Lemma 6.6.18. *For admissible data D there is a short row family $Y = (Y_{\mathfrak c})_{\mathfrak c\in \mathrm{Cl}^\flat}$.*

Proof. Write $N = \#\mathcal B^\flat = 6m+1$ and fix a class $\mathfrak c \in \mathrm{Cl}^\flat$, with representative $x = x_{\mathfrak c} \in G_f(\mathcal B^\flat)$.

Step 1: the framed space and its lattice. By (VP3) of Definition 3.2.2 the standard definite space $W^\flat = \mathrm I_{\mathcal B^\flat}$ (matrix 1, point 1, signs $s = +1$ on $\mathcal B^\flat$) is a framed hermitian space $U = (E^{\mathcal B^\flat}, h)$, $h(u,u') = u'^*u$, with the standard basis as frame at every $v \in \Phi$ and the identity of $\mathbb A_{E,f}^{\mathcal B^\flat}$ as isometry (a framed space of rank N in the sense of (FT1)), and $\lambda_U(g)$ is the first minimum of (VP4) for both readings. Its group is $\mathrm G(s)$, $g = (1,x) \in \mathrm G(s)$, and its coordinate map is $c_U(u) = u$, that is $(\tau(u))_{\tau\in\Phi}$ at the infinite places and u at the finite places; so, by (VP4),

$$L_g = \{u \in E^{\mathcal B^\flat} : x^{-1}u \in \widehat{\mathcal O}_E^{\mathcal B^\flat}\}, \qquad |u|_g^2 = \sum_{\tau\in\Phi}\sum_{b\in\mathcal B^\flat} |\tau(u_b)|^2.$$

Step 2: $\lambda_U(g) = 1$. Let $0 \ne u \in L_g$ and $y = x^{-1}u \in \widehat{\mathcal O}_E^{\mathcal B^\flat}$. As $x^*x = 1$ and x is square, $xx^* = 1$, so $a := u^*u = y^*x^*xy = y^*y$ in $\mathbb A_{E,f}$; the entries of y and of $\bar y$ are integral, so $a \in E \cap \widehat{\mathcal O}_E = \mathcal O_E$. Since $\bar a = a$, $a \in \mathcal O_{E^+}$, and $\tau(a) = \sum_b |\tau(u_b)|^2 > 0$ for every $\tau \in \Phi$ ($u \ne 0$ and τ is injective). The restrictions of the $\tau \in \Phi$ to E^+ are its f real embeddings, so $\prod_{\tau\in\Phi}\tau(a) = N_{E^+/\mathbb Q}(a)$ is a positive integer, hence at least 1. By the inequality of arithmetic and geometric means,

$$|u|_g^2 = \sum_{\tau\in\Phi}\tau(a) \ge f\Big(\prod_{\tau\in\Phi}\tau(a)\Big)^{1/f} \ge f \ge 1.$$

So the infimum in (VP4) is at least 1, and $\lambda_U(g) = 1$.

Step 3: a short basis. By Lemma 6.4.102, $N_{\mathfrak D} = q_1 d$ is a positive integer in the different $\mathfrak D_E$. By Lemma 6.6.19 for U, this $N_{\mathfrak D}$ and the point g, there is a basis $u_1,\dots,u_N$ of U over E with $u_k \in L_g$ and $|u_k|_g \le fNq_1d$ (Step 2). Number the basis by $\mathcal B^\flat$ and let $Y_{\mathfrak c} \in \mathrm M_{\mathcal B^\flat}(E)$ be the matrix whose row k is $u_k^{\mathsf T}$. Then $Y_{\mathfrak c} \in \mathrm{GL}_{\mathcal B^\flat}(E)$, and the columns of $x^{-1}Y_{\mathfrak c}^{\mathsf T}$ are the vectors $x^{-1}u_k \in \widehat{\mathcal O}_E^{\mathcal B^\flat}$, so $x^{-1}Y_{\mathfrak c}^{\mathsf T}$ has entries in $\widehat{\mathcal O}_E$.

Step 4: the entries are small. Every ring homomorphism $\psi\colon E \to \mathbb C$ is τ or $\bar\tau$ for some $\tau \in \Phi$ (E is totally complex and Φ contains one embedding of each conjugate pair), and

$|\bar\tau(z)| = |\tau(z)|$. So for all k, b, $|\psi(Y_{\mathfrak{c},kb})| = |\tau(u_{k,b})| \le |u_k|_g \le fNq_1d$. By Lemma 4.2.67 (items 2–5: $f \le x^{12}$, $q_1d \le x^{13}$, $m \le 2\sqrt{x}$, $x \ge e^{6.4\cdot 10^{15}}$, $x^{10^{12}} \le b$) and (AD5),

$$fNq_1d \le x^{12} \cdot 13\sqrt{x} \cdot x^{13} \le x^{26} \le b \le p_0p_1 = M \le M^4.$$

Doing this for every $\mathfrak{c} \in \mathrm{Cl}^\flat$ (a finite set) gives the short row family $Y = (Y_\mathfrak{c})_\mathfrak{c}$. □

Lemma 6.6.19. *Let E be a CM field with totally real subfield E^+, $f = [E^+ : \mathbb{Q}]$ and different $\mathfrak{D}_E$, and let $N_\mathfrak{D}$ be a positive integer with $N_\mathfrak{D} \in \mathfrak{D}_E$. Let $N \ge 1$ and let U be a framed space of rank N over E, with real group G_∞^U and $G^U = G_\infty^U \times G_f$. For $g \in G^U$ let*

$$L_g = \{u \in U : \ (g^{-1}c(u))_f \in \widehat{\mathcal{O}}_E^N\}, \qquad |u|_g = \|(g^{-1}c(u))_\infty\|,$$

$c(u) \in \mathbb{A}_E^N$ the coordinate vector of u and $\|\cdot\|$ the Euclidean norm on $\prod_v \mathbb{C}^N$. Then for every $g \in G^U$ there is a basis $u_1, \dots, u_N$ of U over E with $u_j \in L_g$ and

$$|u_j|_g \le f\, N\, N_\mathfrak{D}\ \lambda_U(g)^{-1} \qquad (1 \le j \le N).$$

Proof. Let $L_{g,\infty}$, $\langle\,,\rangle$ and σ be as in Lemma 5.8.15, and let β be the $\mathbb{R}$-linear extension of $u \mapsto (g^{-1}c(u))_\infty$ to $U \otimes_\mathbb{Q} \mathbb{R}$, so $|u|_g = \|\beta(u)\|$. Put $n = 2fN$. By (iii) of Lemma 5.8.15, $L_{g,\infty}$ is a lattice of rank n in $\prod_v \mathbb{C}^N$, so $\lambda_1(L_{g,\infty}) = \min\{|u|_g : 0 \ne u \in L_g\} > 0$ and $\lambda_U(g) = \min(1, \lambda_1(L_{g,\infty}))$.

Step 1: $\lambda_1(L_{g,\infty}^*) \ge 2\lambda_1(L_{g,\infty})/N_\mathfrak{D}$. By (iv) of Lemma 5.8.15 a nonzero vector of $L_{g,\infty}^*$ is $\sigma\beta(w)$ with $0 \ne w \in 2\mathfrak{D}_E^{-1}L_g$. As $N_\mathfrak{D} \in \mathfrak{D}_E$, $N_\mathfrak{D}\mathfrak{D}_E^{-1} \subseteq \mathcal{O}_E$, so $\frac{N_\mathfrak{D}}{2}w \in N_\mathfrak{D}\mathfrak{D}_E^{-1}L_g \subseteq L_g$ (L_g is an $\mathcal{O}_E$-module by (i) of Lemma 5.8.15), and $\frac{N_\mathfrak{D}}{2}w \ne 0$. Hence $\lambda_1(L_{g,\infty}) \le |\frac{N_\mathfrak{D}}{2}w|_g = \frac{N_\mathfrak{D}}{2}\|\beta(w)\| = \frac{N_\mathfrak{D}}{2}\|\sigma\beta(w)\|$, σ being an isometry.

Step 2: transference. By Banaszczyk's transference theorem [12], $\lambda_n(L_{g,\infty})\lambda_1(L_{g,\infty}^*) \le n$; with Step 1,

$$\lambda_n(L_{g,\infty}) \le \frac{n\,N_\mathfrak{D}}{2\lambda_1(L_{g,\infty})} = \frac{fNN_\mathfrak{D}}{\lambda_1(L_{g,\infty})} \le \frac{fNN_\mathfrak{D}}{\lambda_U(g)}.$$

So there are $u_1', \dots, u_n' \in L_g$ with $|u_k'|_g \le fNN_\mathfrak{D}\lambda_U(g)^{-1}$ and $\beta(u_1'), \dots, \beta(u_n')$ linearly independent over $\mathbb{R}$. Their E-span W is U: otherwise $\beta(W \otimes_\mathbb{Q} \mathbb{R})$ would contain them and have real dimension $2f \dim_E W < n$. Choose $u_1, \dots, u_N$ among the u_k' forming an E-basis. □

Lemma 6.6.20. *Let D be admissible data, L, N finite index sets and $\delta \ge 0$ an integer. There is $c \in \mathbb{C}^\times$ such that for all automorphic characters α, β of $\mathrm{U}(1)$ that have a weight and a tame part, every modulus $\mathfrak{m}$, every function Ψ on $\mathrm{M}_{N\times L}(R_\mathfrak{m})$, every $Q \in \mathbb{C}[x]_{N\times L}$ homogeneous of degree δ and all $g \in G_f(L)$, $h \in G_f(N)$, the number $\kappa = c\,\theta_{\alpha,\beta;\mathfrak{m}}^{\mathrm{I}_L,\mathrm{I}_N}[\Psi, Q](g,h)$ satisfies:*

- *(i) let $q \ge 1$ be an integer with $qM^2 \in \mathfrak{m}$, and suppose $|\iota'(\Psi(X))| \le 1$ for every X, every prime $\ell \nmid q$ and every ring homomorphism $\iota' \colon \mathbb{C} \to \mathbb{C}_\ell$; then for every prime $p \nmid q$ and every ring homomorphism $\iota \colon \mathbb{C} \to \mathbb{C}_p$: if the components of g and of h at every place of E above p are integral invertible matrices and every coefficient a of Q has $|\iota(a)| \le 1$, then $|\iota(\kappa)| \le 1$;*
- *(ii) suppose $|L| \le \Delta$, $|N| \le \Delta$, $\delta \le M$ and $M^2 \in \mathfrak{m}$; let $A \in \mathbb{N}$ with $|\sigma'(\Psi(X))| \le A$ for all $\sigma' \in \mathrm{Aut}(\mathbb{C})$ and all X, let $\sigma \in \mathrm{Aut}(\mathbb{C})$, and let $B \in \mathbb{R}$ with $|\sigma(Q(z))| \le B$ for every $z \in \mathbb{C}^{\Phi\times N\times L}$ with $|\sigma(z_i)| \le M^4$ for all i; then $|\sigma(\kappa)| \le e^{x_1}AB$.*

Proof. Write $C = N \times L$, $R = \#C = |N||L|$, and define

$$c = M^{4fR}\, c_s^R\, (M^2 d\, \eta_P)^\delta \in \mathbb{C}^\times,$$

which depends only on L, N, δ and D. Fix $\alpha, \beta, \mathfrak{m}, \Psi, Q, g, h$ as in the statement, put $A_0 = \Sigma(\mathfrak{m})$ and $\theta_0 = \theta^{\mathrm{I}_L,\mathrm{I}_N}_{\alpha,\beta;\mathfrak{m}}[\Psi, Q](g,h)$, so $\kappa = c\,\theta_0$.

Step 0: the kernel as a theta value of one finite datum. By (VP5), $\mathrm{Hom}(\mathrm{I}_L, \mathrm{I}_N)$ has matrix 1, point 1 and signs $+1$ on C: it is the standard definite space I_C, the identity is a transporting element, and by Lemma 4.1.17 its theta functional is the canonical functional θ_C of I_C. By (WR4), $\omega_{\alpha,\beta}((1,g),(1,h)) = c'\,\omega_+(k)$ with $c' = \alpha(\det h)\beta(\det g)^{-1}$, $\omega_+ = \omega_s$ for $s = +1$ on C, and $k \in G_f(C)$ the map $X \mapsto hXg^{-1}$. By (5) of Lemma 4.1.1 at the real points 1 (and $\Omega_{\gamma,\gamma'}(1,1) = 1$),

$$\theta_0 = \theta_C(v_Q \otimes F), \qquad F = c'\,\omega_+(k)\big(\Psi^\natural \otimes_{A_0} v^0\big).$$

By Lemma 6.4.84 for $\mathfrak{m}$, C, the signs $+1$ and the function Ψ on $T = R_{\mathfrak{m}}^C = \mathrm{M}_{N\times L}(R_{\mathfrak{m}})$, $\Psi^\natural \otimes_{A_0} v^0 = \sum_\chi a_\chi \rho(\mathrm{fv}(u_\chi))v^0$. By Proposition 4.1.14, $\omega_+(k)\rho(\mathrm{fv}(u)) = \rho(\mathrm{fv}(ku))\omega_+(k)$ (the finite coordinates are $\mathbb{A}_{E,f}$-linear and k has trivial infinite part), and $\omega_+(k)$ preserves the span $\mathcal{M}_{\mathrm{fin}}$ of the vectors $\rho(\mathrm{fv}(t))v^0$. Hence

$$c_s^R F = c' \sum_\chi a_\chi\, \rho(\mathrm{fv}(ku_\chi))\, \omega_+(k)\big(c_s^R v^0\big) \in \mathcal{M}_{\mathrm{fin}}. \tag{6.134}$$

Products of finite Heisenberg operators satisfy $\rho(\mathrm{fv}(x))\rho(\mathrm{fv}(x')) = \zeta\rho(\mathrm{fv}(x+x'))$ with ζ a value of the finite additive character of (WD8), hence a root of unity (a continuous character of $\mathbb{A}_{E,f}$ has finite image on every compact open subgroup, and every element lies in one). The finite points $\det g$, $\det h$ satisfy $u\bar{u} = 1$; by (a) of Lemma 6.4.85, $|\sigma(c')| = 1$ for every $\sigma \in \mathrm{Aut}(\mathbb{C})$.

Step 1: (i). Let q, $p \nmid q$, ι be as in (i), suppose the components of g, h above p are integral invertible and the coefficients of Q lie in $\mathcal{O}_\iota = \{z \in \mathbb{C} : |\iota(z)|_p \le 1\}$. Let $\mathcal{S}$ be the $\mathcal{O}_\iota$-span of the vectors $\rho(\mathrm{fv}(x))c_s^R v^0$ with $M^2 x_w \in \mathcal{O}_{E,w}^C$ for every place $w \mid p$, and put $F_0 = M^{4fR} c_s^R F$. We show $F_0 \in \mathcal{S}$.

- The components of k and k^{-1} above p are integral, and $\det g$, $\det h$ are units above p; by (b) of Lemma 6.4.85, $\iota(c')$ is a p-adic unit.
- By Proposition 4.1.14 the restriction of $\omega_+(k)$ to $\mathcal{M}_{\mathrm{fin}}$ is the normalised finite kernel of Lemma 4.1.13 in the scaled finite coordinates, so $\omega_+(k)v^0 = \frac{\Delta(k)}{I(k)} \sum_{y \in L_0/J(k)} \zeta_y\, \rho(\mathrm{fv}(ky))v^0$, with $L_0 = \widehat{\mathcal{O}}_E^C$, $J(k) = L_0 \cap k^{-1}L_0$ and roots of unity ζ_y (the factor $s_L(ky)$ of Lemma 4.1.13 and the phase between its Heisenberg operator and $\rho(\mathrm{fv}(\cdot))$ are values of continuous characters of $\mathbb{A}_{E,f}$). The index $I(k) = [L_0 : J(k)]$ is the product of the local indices, the one at w a power of the residue characteristic of w and equal to 1 at $w \mid p$; so $p \nmid I(k)$. By Lemma 4.1.13, $\Delta(k)\overline{\Delta(k)} = I(k)$ and $\overline{\Delta(k)} = \upsilon_f(\det k)\Delta(k)$, so $\Delta(k)^2 = I(k)\,\upsilon_f(\det k)^{-1}$, where $\upsilon_f(\det k)$ is the value of the splitting character, an automorphic character of U(1) ((LF2) of Definition 3.2.26), at the finite point $\det k$, a unit above p; by (b) of Lemma 6.4.85 $\iota(\Delta(k))$ is a p-adic unit, and so is $\iota(\Delta(k)/I(k))$.
- $a_\chi = (\#T)^{-1}\sum_X \Psi(X)\overline{\chi(X)}$, where $|\iota(\Psi(X))|_p \le 1$ ($p \nmid q$) and the $\chi(X)$ are roots of unity. Since $qM^2 \in \mathfrak{m}$, $\mathfrak{m}$ divides $qM^2\mathcal{O}_E$, so $\mathrm{N}(\mathfrak{m})$ divides $\mathrm{N}(qM^2\mathcal{O}_E) = (qM^2)^{2f}$ and $\#T = \mathrm{N}(\mathfrak{m})^R$ divides $q^{2fR}M^{4fR}$; as $p \nmid q$, $|\iota(M^{4fR}/\#T)|_p \le 1$. So $M^{4fR}a_\chi \in \mathcal{O}_\iota$.
- For $w \in A_0$ above p, q is a unit at w, so $M^2 \in \mathfrak{m}\mathcal{O}_{E,w}$; by (b) of Lemma 6.4.84 with $\delta = M^2$, $M^2 u_\chi$ is integral above p. Hence $M^2 k(u_\chi + y)$ is integral above p for $y \in L_0$.

Inserting $\omega_+(k)v^0$ into (6.134) and combining the Heisenberg operators gives

$$F_0 = \sum_{\chi,y} z_{\chi,y}\, \rho(\mathrm{fv}(k(u_\chi + y)))\, c_s^R v^0$$

with $z_{\chi,y} \in \mathcal{O}_\iota$, so $F_0 \in \mathcal{S}$. Put $\zeta_{\mathrm{sc}} = M^2 d$ if $\delta \geq 1$ and $\zeta_{\mathrm{sc}} = 1$ if $\delta = 0$. As Q is homogeneous of degree δ, $Q(\zeta_{\mathrm{sc}}\eta_P\,\cdot) = (M^2 d\eta_P)^\delta Q$; by linearity of the datum in both arguments and Lemma 4.2.2 for I_C,

$$\kappa = M^{4fR}(M^2 d\eta_P)^\delta\, \theta_C(v_Q \otimes c_s^R F) = \theta_C(v_{Q(\zeta_{\mathrm{sc}}\eta_P\cdot)} \otimes F_0) = Q(\partial_Z)\mathscr{E}_{F_0}(\zeta_{\mathrm{sc}}\eta_P Z)\big|_{Z=0}.$$

By Proposition 4.2.35 for the coordinate set C, the element $M^2 \in \mathcal{O}_K$ in the role of its δ, the module $\mathcal{S}$ and the homogeneous $Q \in \mathcal{O}_\iota[Z]$, $|\iota(\kappa)|_p \leq |\iota(\zeta_{\mathrm{sc}}/(M^2 d))|_p^\delta = 1$ (for $\delta \geq 1$ the ratio is 1; for $\delta = 0$ the exponent is 0). This is (i).

Step 2: reduction of (ii) to automorphisms over K. Let the hypotheses of (ii) hold for σ. As K is imaginary quadratic, σ or $\sigma'' = \bar{\cdot} \circ \sigma$ fixes K; since $|\sigma''(z)| = |\sigma(z)|$ for all z, the hypotheses of (ii) hold for σ'' with the same A, B, and $|\sigma''(\kappa)| = |\sigma(\kappa)|$. So we may assume that σ fixes K.

Step 3: the Gaussian integral. Put $Q'(Z) = Q(M^2 dZ)$ and $F' = c_s^R F \in \mathcal{M}_{\mathrm{fin}}$, so that $\kappa = M^{4fR}\theta_C(v_{Q'(\eta_P\cdot)} \otimes F')$. Let t_σ, ϵ_σ and $\Theta = \Theta_{\sigma,F'}$ be as in Lemma 4.2.16 for I_C; with $D_0 = fR$,

$$\sigma(\kappa) = M^{4fR}\,\pi^{-D_0} \int_{\mathbb{C}^{\Phi\times C}} Q'^\sigma\big(t_\sigma \bar{y}^{\epsilon_\sigma}\big)\, e^{-|y|^2/2}\, \Theta(y)\, dy.$$

The polynomial. $Q'^\sigma(w) = Q^\sigma(M^2 dw)$, as σ fixes $\mathbb{Q}$. If $|w_i| \leq M^4$ for all i, then $z = \sigma^{-1}(w)$ (coordinatewise) has $|\sigma(z_i)| \leq M^4$, so $|Q^\sigma(w)| = |\sigma(Q(z))| \leq B$; in particular $B \geq 0$. As Q^σ is homogeneous of degree δ, $Q^\sigma(w) = (\rho_w/M^4)^\delta Q^\sigma(M^4 w/\rho_w)$ for $w \neq 0$, $\rho_w = \max_i |w_i|$, and $Q^\sigma(0) = 0$ if $\delta \geq 1$; so $|Q^\sigma(w)| \leq B(\max_i |w_i|/M^4)^\delta$ for all w ($0^0 = 1$). For $w = M^2 dt_\sigma \bar{y}^{\epsilon_\sigma}$, $\max_i |w_i| \leq M^2 d|t_\sigma||y| = M^2 d\,\Omega_s^{-1/2}|y|$, so $|Q'^\sigma(t_\sigma \bar{y}^{\epsilon_\sigma})| \leq B\big(d\,\Omega_s^{-1/2}|y|/M^2\big)^\delta$. *The theta values.* By (a) of Lemma 4.2.16, $|\Theta(y)| \leq \sup_x |\sigma(\theta_C(\rho(\mathrm{fv}(x))F'))|$. By (6.134) and Step 0, $\theta_C(\rho(\mathrm{fv}(x))F') = c' \sum_\chi a_\chi \zeta_{x,\chi}\, \mathcal{V}_R(x + ku_\chi, k)$ with roots of unity $\zeta_{x,\chi}$ and $\mathcal{V}_R(x,k) = \theta_C(\rho(\mathrm{fv}(x))\omega_+(k)(c_s^R v^0))$, the value of Lemma 6.4.83 for I_C. By (2) of Lemma 6.4.83, $|\sigma(c')| = 1$ and (a) of Lemma 6.4.84,

$$|\Theta(y)| \leq \sum_\chi |\sigma(a_\chi)|\, e^{A_R} \leq \#T \cdot A \cdot e^{A_R}, \qquad A_R = C_P(q_1 R + 1)^2.$$

The moment. For $\delta \geq 1$,

$$|y|^\delta e^{-|y|^2/4} \leq (2\delta)^{\delta/2} e^{-\delta/2} \qquad (\text{maximum at } |y|^2 = 2\delta),$$

and $\pi^{-D_0} \int e^{-|y|^2/4} dy = 4^{D_0}$; so

$$\pi^{-D_0} \int |y|^\delta e^{-|y|^2/2} dy \leq (2\delta)^{\delta/2} 4^{D_0},$$

which also holds for $\delta = 0$ ($2^{D_0} \leq 4^{D_0}$). Altogether

$$|\sigma(\kappa)| \leq M^{4fR}\, \#T\, 4^{fR}\, e^{A_R}\, A\, B\, \Big(\frac{\sqrt{2\delta}\, d\,\Omega_s^{-1/2}}{M^2}\Big)^\delta.$$

Step 4: the sizes. By Lemma 4.2.67 (items 1–5): $d \leq C_P \leq \log\log b \leq \log x$ (with (AD1)), $x \geq e^{6.4\cdot 10^{15}}$, $(\log b)^{100} \leq x$, $x^{10^{12}} \leq b$, $r \leq 3x^5$, $f \leq q_1 \leq x^{12}$, $\log M \leq 22 \log b$;

by (2) of Lemma 5.2.13, $\Omega_s^{-1} = \mathrm{rd}_E e^{-c_{\mathrm{CS}}(d)}/(2\pi) \le x^{13}$; by (AD5), $M \ge b^{20}$. As $\delta \le M$, $\sqrt{2\delta}\, d\, \Omega_s^{-1/2} \le \sqrt{2M}\, x^7 \le M^2$, so the last factor is at most 1. Since $M^2 \in \mathfrak{m}$, $\mathrm{N}(\mathfrak{m})$ divides $\mathrm{N}(M^2\mathcal{O}_E) = M^{4f}$, so $\#T \le M^{4fR}$. As $|L|, |N| \le \Delta = 2r^8$, $R \le 4r^{16} \le 4 \cdot 3^{16} x^{80} \le x^{81}$, so $fR \le x^{93}$ and $q_1 R + 1 \le 2x^{93}$. Hence

$$\log(M^{8fR} 4^{fR} e^{A_R}) \le 8fR \cdot 22\, x^{1/100} + 2fR + 4x^{186} \log x \le x^{95} + x^{187} \le x^{10^6} \le x_1,$$

the last step by (AD1). So $|\sigma(\kappa)| \le e^{x_1} AB$, which is (ii). □

Lemma 6.6.21. *Let $1 \le j \le m$ and $\kappa^+ = \kappa^+_{O_{j,1}}$. For a choice i, a matrix $Y \in \mathrm{M}_{\mathcal{B}^\flat}(E)$ and $l \in I_{\kappa^+}$, let $\mathrm{lc}_{i,l}[Y] \in \mathbb{C}[x]_{\mathcal{B}_j \times \mathcal{B}_j^{\mathrm{add}}}$ be the line coordinate of (XE6) formed with Y in place of $Y_{\mathfrak{c}_i}$ in the constant rows, and put $\#D_j = \sum_{\tau \in \Phi} \#D_j(\tau)$, the number of determinants. Then:*

(a) there are integers d and H with $0 \le d \le (10m+1)\#D_j$ and $0 < H \le d^{3d}$ ($0^0 = 1$) such that for every choice i, every $Y \in \mathrm{M}_{\mathcal{B}^\flat}(E)$ and every l, the polynomial $H\,\mathrm{lc}_{i,l}[Y]$ is homogeneous of degree d and its coefficients lie in every subring of $\mathbb{C}$ that contains all the numbers $\tau(Y_{ab})$ ($\tau \in \Phi$, $a, b \in \mathcal{B}^\flat$);

(b) for every ring endomorphism φ of $\mathbb{C}$, every choice i, every Y with $|\varphi(\tau(Y_{ab}))| \le M^4$ for all τ, a, b and every $z \in \mathbb{C}^{\Phi \times \mathcal{B}_j \times \mathcal{B}_j^{\mathrm{add}}}$ with $|\varphi(z_u)| \le M^4$ for all u,

$$\big\| \big(\varphi(\mathrm{lc}_{i,l}[Y](z))\big)_{l \in I_{\kappa^+}} \big\|_{\kappa^+}^2 \le \big(M^9\big)^{(12m+1)\#D_j};$$

(c) let $A_\tau \in \mathrm{M}_{\mathcal{B}_j}(\mathbb{C})$, $U_\tau \in \mathrm{M}_{\mathcal{B}^\flat}(\mathbb{C})$ and $V_\tau \in \mathrm{M}_{\mathcal{B}^\mathrm{c}}(\mathbb{C})$ ($\tau \in \Phi$), let $B_\tau = \mathrm{diag}(1, U_\tau, V_\tau)$ on $\mathcal{B}_j^{\mathrm{add}} = \mathcal{A}_j^+ \sqcup \mathcal{B}^\flat \sqcup \mathcal{B}^\mathrm{c}$, and let $Y, Y' \in \mathrm{M}_{\mathcal{B}^\flat}(E)$ satisfy $\tau(Y') = \tau(Y)\, U_\tau^\mathsf{T}$ for every τ. For a polynomial P let $P^{A,B}$ be P after the substitution $x_\tau \mapsto A_\tau^\mathsf{T} x_\tau B_\tau^\mathsf{T}$ of the $\mathcal{B}_j \times \mathcal{B}_j^{\mathrm{add}}$ matrices of variables $x_\tau = (x_{\tau,b,c})$. Then for every choice i and every l

$$\Big(\sum_{k \in I_{\kappa^+}} S_{\kappa^+}(A)_{lk}\, \mathrm{lc}_{i,k}[Y'] \Big)^{A,B} = \prod_{\tau \in \Phi} \big(\det A_\tau\, \det B_\tau\big)^{\#D_j(\tau)}\, \mathrm{lc}_{i,l}[Y].$$

Proof. **The coordinates reconstruct the determinant product over its coefficient ring.** Fix j. Put $n_{\mathrm{row}} = |\mathcal{B}_j|$, $r_+ = k + j - 1$, and $\kappa = \kappa^+$. The weight formulas (LF4) give

$$\kappa(\tau, h) = 0 \quad (h < k-1 \text{ or } h > r_+), \qquad \kappa(\tau, r_+) = \Delta'. \tag{1}$$

Indeed consecutive entries before position $k-1$ differ by one. At r_+ the difference in (LF4) is $\Delta/2 - (t+1)/2 = \Delta'$; afterwards the preceding target entry is already below the truncation threshold, since $\kappa_{j+1} = \kappa_j + \Delta$. In particular

$$n_{\mathrm{row}} - h \le 10m + 1 \quad \text{whenever } \kappa(\tau, h) > 0. \tag{2}$$

Here $n_{\mathrm{row}} = r + 9m + 1$ and $k - 1 = r - m$.

We use the following coefficient-ring description, valid for arbitrary Y, not just a short row family. For a determinant of height $h < r_+$, its constant rows are zero in columns $0, \dots, h-1$, and row $a+1$, for $0 \le a < r_+ - h$, is the unit row in column $h + a$. These rows exist since $r_+ - h \le j \le m \le 2m$. Subtracting the appropriate multiples of these rows from each variable row clears its entries in columns $h, \dots, r_+ - 1$. This operation leaves all added-column entries unchanged. Expansion along the first h columns now expresses this determinant as a combination of their height-h minors with coefficients involving only added variables and entries

of $\tau(Y)$. The extra determinants have height r_+; all their constant entries in these first columns vanish, so the same expansion needs no clearing. All signs are the original Laplace signs.

Let $R \subseteq \mathbb{C}$ be any subring containing the entries of every $\tau(Y)$, and put

$$R_{\mathrm{add}} = R[x_{\tau,b,c} : c \in \mathcal{B}_j^{\mathrm{add}}].$$

Products of the preceding expansions have exactly $\kappa(\tau, h)$ minors of each height. The integral standard-basis property (WM1) therefore gives

$$\Pi_i[Y] = \sum_l a_l \, \widehat{b}_l, \qquad a_l \in R_{\mathrm{add}}, \tag{3}$$

where $\widehat{b}_l$ is b_l renamed to the first r_+ columns. No column of greater height occurs, so no b_l involves a later column.

Write G_κ for the filling Gram matrix and H_κ for the matrix of ordinary bilinear Fock pairings of the b_l. By Lemma 4.6.9, $H_\kappa G_\kappa = G_\kappa H_\kappa = h_\kappa I$. The scalar is nonzero. The definition of the line coordinates, pairing only the first-column variables, gives

$$\mathbf{lc}_i[Y] = h_\kappa^{-1} H_\kappa (a_l)_l = G_\kappa^{-1} (a_l)_l, \qquad \mathrm{Pol}_\kappa(\mathbf{lc}_i[Y]) = \Pi_i[Y]. \tag{4}$$

These equalities hold over the complex polynomial coefficient ring. The pairing used here has $\langle X^\alpha, X^\beta \rangle_{\mathrm{F}} = \mathbf{1}_{\alpha=\beta} \alpha!$, with no coefficient conjugation. Thus (4) uses precisely the normalization in (XE6).

Homogeneity and a denominator depending on the complementary degree. Set

$$d_{\mathrm{add}} = \sum_\tau \sum_{1 \le h < n_{\mathrm{row}}} (n_{\mathrm{row}} - h) \kappa(\tau, h). \tag{5}$$

In a cleared determinant of height h, every nonzero term uses exactly h variable entries from the first h columns and $n_{\mathrm{row}} - h$ variable entries from the added columns. The other entries are constant. Its added degree is therefore $n_{\mathrm{row}} - h$. Formula (3) is homogeneous of added degree d_{add}: decomposition by added degree and linear independence of the $\widehat{b}_l$ show that each a_l is homogeneous of that degree. Equation (4) proves the same for the line coordinates. This includes the zero polynomial. By (1)–(2),

$$0 \le d_{\mathrm{add}} \le (10m + 1) \# D_j. \tag{6}$$

For the required denominator use the complementary weight $\kappa^\vee(\tau, h) = \kappa(\tau, n_{\mathrm{row}} - h)$. Its number of boxes is exactly d_{add}. We give the integral Gram comparison explicitly. In each square block of variables let w_0 reverse the columns and let $c_\tau = \sum_h \kappa(\tau, h)$. On the span of the products of minors of weight κ consider

$$\mathcal{D}_\kappa P(X) = \prod_\tau \det(X_\tau)^{c_\tau} \, P(X_\tau^{-\mathsf{T}} w_0). \tag{7}$$

Although written on the invertible-matrix open set, this is polynomial on that span: the complementary-minor identity for the inverse transpose sends each flag minor of height h, after multiplication by $\det X_\tau$, to a signed flag minor on the complementary rows and the first $n_{\mathrm{row}} - h$ columns. This identity follows directly from the adjugate formula, or by expanding a determinant in its specified rows. Reversing the columns only supplies a sign. Consequently (7) bijects the products of minors of κ and of $\kappa^\vee$, up to signs. Applying the complementary operation again gives a fixed sign times the original polynomial, since $(X^{-\mathsf{T}} w_0)^{-\mathsf{T}} w_0 = X$. It is therefore an isomorphism of their integral spans.

Let T be its matrix in the two integral standard bases; T and T^{-1} have integer entries. Complementing every column filling gives a signed permutation matrix P of the filling tensors. If the rows of T give the coefficients of $\mathcal{D}_\kappa b_l$, comparison of the expansions of every product of minors gives

$$F_\kappa T = P F_{\kappa^\vee}, \qquad T^{\mathsf{T}} G_\kappa T = G_{\kappa^\vee}. \tag{8}$$

Put $H_{\mathrm{dual}} = h_{\kappa^\vee}$. Applying Lemma 4.6.9 to the complementary weight in (8) yields

$$H_{\mathrm{dual}} G_\kappa^{-1} = T H_{\kappa^\vee} T^{\mathsf{T}} \in \mathrm{M}_{I_\kappa}(\mathbb{Z}). \tag{9}$$

Here the $H_{\kappa^\vee}$ on the right is the Fock-pairing matrix, not the scalar H_{dual}. Equations (3)–(4) and (9) prove that every coefficient of $H_{\mathrm{dual}} \mathrm{lc}_{i,l}[Y]$ belongs to R. The same integer works for every i, Y and every such subring.

We check its numerical bound without suppressing factorials. The highest polynomial of $\kappa^\vee$ has total degree d_{add}, and its coefficient absolute sum is at most $\prod_{\tau,h} (h!)^{\kappa^\vee(\tau,h)} \le d_{\mathrm{add}}^{d_{\mathrm{add}}}$ when $d_{\mathrm{add}} \ge 1$. Every monomial factorial is at most $d_{\mathrm{add}}! \le d_{\mathrm{add}}^{d_{\mathrm{add}}}$. Thus its Fock self-pairing satisfies

$$0 < H_{\mathrm{dual}} \le d_{\mathrm{add}}^{d_{\mathrm{add}}} \left(d_{\mathrm{add}}^{d_{\mathrm{add}}} \right)^2 = d_{\mathrm{add}}^{3 d_{\mathrm{add}}}.$$

The self-pairing is a positive integer because the highest polynomial has integer coefficients and is nonzero. When $d_{\mathrm{add}} = 0$, it is the constant polynomial one and $H_{\mathrm{dual}} = 1$. Taking $d = d_{\mathrm{add}}$, $H = H_{\mathrm{dual}}$ proves (a), including $0^0 = 1$.

Products do not increase the product of the Gram norms. We record the precise tensor argument needed for (b). For two weights η, η', let K be the integer multiplication matrix $b_i^\eta b_j^{\eta'} = \sum_l K_{(i,j),l} b_l^{\eta+\eta'}$. Concatenating the column fillings, with only a permutation of tensor factors, gives

$$F_{\eta+\eta'} = (F_\eta \otimes F_{\eta'}) K, \qquad G_{\eta+\eta'} = K^{\mathsf{T}} (G_\eta \otimes G_{\eta'}) K. \tag{10}$$

Thus K is an isometric embedding for the indicated positive Gram forms. The forms are positive definite: each standard-basis product is one of the filling rows, so its filling matrix has full column rank. For vectors v, w, the polynomial product corresponds, by (WM4), to

$$u = G_{\eta+\eta'}^{-1} K^{\mathsf{T}} (G_\eta \otimes G_{\eta'})(v \otimes w).$$

This is the adjoint of the isometry K, and has norm at most $\|v\|_\eta \|w\|_{\eta'}$. Indeed $KK^\dagger$ is the orthogonal projection onto the image of K, so its adjoint is a contraction. Iterating proves the product assertion for any finite number of factors, with coefficient one. The empty product has norm one.

A single cleared determinant satisfies the stated bound. Apply the field endomorphism φ after specializing the added variables at z. It fixes the integer Gram matrices and their rational inverses, so (4) commutes with this operation. In the cleared determinant of height h, denote the matrix of remaining columns by Z_{rest}. It has $2m + n_{\mathrm{row}}$ rows and $2m + n_{\mathrm{row}} - h$ columns. Each entry is zero, one, an image of an entry of $\tau(Y)$, or an image of an added variable. Thus every entry has absolute value at most M^4.

Laplace expansion in the first h columns gives its coefficient vector in the one-column minor basis. The coordinates are, with their signs, complementary maximal minors of Z_{rest}, using all the constant rows and the complementary variable rows. In a one-column weight the filling matrix is the identity, so the squared coordinate norm is the sum of their squared absolute values. It is bounded by the sum over all maximal minors of Z_{rest}. Cauchy–Binet and Hadamard therefore give

$$\|\text{single-factor vector}\|^2 \le \det(Z_{\mathrm{rest}}^* Z_{\mathrm{rest}}) \le \prod_{\text{columns } c} \sum_a |(Z_{\mathrm{rest}})_{ac}|^2. \tag{11}$$

No division by a minor or assumption of full rank is needed; a rank-deficient matrix has the same nonnegative identity.

By Lemma 4.2.67, the admissible scales imply $r + 11m + 1 \le M$. Explicitly $r \le 3x^5$, $m \le 2\sqrt{x}$, $b \ge x^{10^{12}}$, and $M = p_0 p_1 \ge b^{20}$; these give $r + 11m + 1 \le 3x^5 + 22\sqrt{x} + 1 \le M$. The same inequalities ensure $M \ge 1$. Hence each column sum in (11) is at most M^9. By (1),

$$2m + n_{\mathrm{row}} - h \le 12m + 1.$$

Each determinant factor consequently has squared Gram norm at most $(M^9)^{12m+1}$. Apply (10) to the $\#D_j$ factors. Their product has weight κ by (1), and its coordinate vector is exactly $(\varphi(\mathrm{lc}_{i,l}[Y](z)))_l$ by (4). This proves

$$\big\|(\varphi(\mathrm{lc}_{i,l}[Y](z)))_l\big\|_\kappa^2 \le (M^9)^{(12m+1)\#D_j},$$

as in (b). The proof did not require φ to be surjective or continuous.

The two-sided substitution has exactly the displayed Schur factor. Write $\widetilde{B}_\tau = \mathrm{diag}(1_{r_+}, B_\tau)$ on $\mathcal{L}_j$. The hypothesis on Y, Y' and the explicit constant rows give

$$\mathsf{c}_{i,\tau,d}[Y'] = \mathsf{c}_{i,\tau,d}[Y]\,\widetilde{B}_\tau^{\mathsf{T}}. \tag{12}$$

For the unit constant rows this uses that the positive and $\mathcal{A}_j^+$ blocks are fixed. For the other rows it is precisely $\tau(Y') = \tau(Y)U_\tau^{\mathsf{T}}$; the carrier block has zero entries in every constant row. After substituting $x_\tau \mapsto A_\tau^{\mathsf{T}} x_\tau \widetilde{B}_\tau^{\mathsf{T}}$, the full stacked matrix for Y' is the original one multiplied on the left by $\mathrm{diag}(1_{2m}, A_\tau^{\mathsf{T}})$ and on the right by $\widetilde{B}_\tau^{\mathsf{T}}$. Multiplicativity of determinants proves the polynomial identity

$$\Pi_i[Y']^{A,\widetilde{B}} = s\,\Pi_i[Y], \qquad s = \prod_\tau (\det A_\tau \det B_\tau)^{\#D_j(\tau)}. \tag{13}$$

This holds for singular matrices as well.

Regard the polynomials as polynomials in the first columns with added-variable coefficients. Let $\mathcal{U}$ substitute $z_\tau \mapsto A_\tau^{\mathsf{T}} z_\tau B_\tau^{\mathsf{T}}$ on these coefficients. The full substitution in (13) acts on the first-column variables by $X_\tau \mapsto A_\tau^{\mathsf{T}} X_\tau$. The ordinary bilinear Fock pairing has the transpose-adjoint identity

$$\langle p(X), q(A^{\mathsf{T}}X)\rangle_{\mathrm{F}} = \langle p(AX), q(X)\rangle_{\mathrm{F}}. \tag{14}$$

The chain rule proves this for every matrix A: substitute the commuting constant-coefficient derivatives in $p(\partial)$ and evaluate at zero. Thus no inverse matrix or nonsingularity is required. Coefficient substitution commutes with this pairing, since the b_l have integer coefficients.

Pair (13) with b_l in the first columns, divide by the same nonzero h_κ, and use (14). By (WM2), $b_l(AX) = \sum_k S_\kappa(A)_{lk} b_k(X)$. The result is

$$\mathcal{U}\left(\sum_k S_\kappa(A)_{lk}\mathrm{lc}_{i,k}[Y']\right) = s\,\mathrm{lc}_{i,l}[Y].$$

The substitution $\mathcal{U}$ fixes the complex coefficients $S_\kappa(A)_{lk}$; on the remaining variables it is exactly the operation denoted $P^{A,B}$ in the statement. This is (c), with precisely its transpose convention and without any complex conjugation. □

Lemma 6.6.22. *Let $1 \le j \le m$, put $\#D_j = \sum_{\tau\in\Phi} \#D_j(\tau)$, and let d be an integer with $0 \le d \le (10m+1)\#D_j$. Then $d \le M$, $|\mathcal{B}_j| \le \Delta$, $12m + 1 \le \Delta$, $3m \le rt$, and*

$$N_{\mathrm{ch}}^4\Big(e^{2x^{30}+3x_1}\,\#\mathrm{GL}_{3m}(\mathcal{O}_E/\mathfrak{M}^2)\,d^{3d}\,M^{9(12m+1)\#D_j/2}\Big)^2 \le \exp\big(f\,m\,b\,(\log b)^2\big) \qquad (0^0 = 1).$$

Proof. By Lemma 4.2.67 we use: $x \geq e^{6.4\cdot 10^{15}}$ and $\log\log b \geq 6.4\cdot 10^{13}$ (item 1), $(\log b)^{100} \leq x$ and $x^{10^{12}} \leq b$ (item 2), $r \leq 3x^5$, $2 \leq m \leq 2\sqrt{x}$ (item 3, and $m = 2^{e+1}$), $f \leq x^{12}$ (item 4) and $\log M \leq 22\log b$ (item 5). By (AD1), $\log x \leq 10^6 \log x \leq \log x_1 \leq 10^6 \log x_1 \leq \log b$, so $x \leq x_1 \leq b$; by (AD2), $r \geq x^5$; by (AD5), $M \geq p_0 \geq b^{10}$.

Step 1: $\#D_j(\tau) \leq 2b$ for every $\tau \in \Phi$, hence $\#D_j \leq 2fb$. Let $\vartheta = 1$ be the trivial twist and $\alpha_e = \chi'_{j,1}\nu_j^\flat \upsilon^m = \chi_M^j \mu^\flat \upsilon^{m+e_j-j\Delta}$. If characters μ_1, μ_2 have weights e_1, e_2 and tame parts ψ_1, ψ_2, then $\mu_1\mu_2$ has weight e_1+e_2 and tame part $\psi_1\psi_2$ (multiply the defining formulas of Definition 3.1.1); so α_e has the weight $\tau \mapsto m + e_j - j\Delta - \kappa_0(\tau)$. By (b) of Lemma 6.6.23, α_e also has the weight $\tau \mapsto m - \#D_j(\tau)$. A weight is determined by the character: if μ has weight e, then for $v \in \Phi$ and $z \in \mathbb{C}$ with $|z| = 1$ the element $u \in \mathrm{U}(1)(\mathbb{A})$ with component z at v and 1 at all other places has integral finite components with reduction 1, so $\mu(u) = z^{e(v)}$, and $z \mapsto z^{e(v)}$ on the unit circle determines $e(v)$. Hence

$$\#D_j(\tau) = \kappa_0(\tau) + j\Delta - e_j = \kappa(\tau) + \tfrac{\Delta}{2} + j\Delta - e_j \leq \kappa(\tau) + (m+1)\Delta,$$

as $e_j \geq 0$ and $j \leq m$. Here $\kappa(\tau)$ is b or $a/x_1 = xb/x_1 \leq b$, and $(m+1)\Delta = 2(m+1)r^8 \leq 2\cdot 3\sqrt{x}\cdot 3^8 x^{40} \leq x^{41} \leq b$. So $\#D_j(\tau) \leq 2b$ and $\#D_j = \sum_{\tau\in\Phi} \#D_j(\tau) \leq 2fb$.

Step 2: the first four assertions. As $9m+1 \leq 19\sqrt{x} \leq x^5 \leq r$, we have $|\mathcal{B}_j| = r + 9m + 1 \leq 2r \leq 2r^8 = \Delta$, $12m+1 \leq r \leq \Delta$ and $3m \leq r \leq 5r^2 = rt$. By Step 1, $d \leq (10m+1)\#D_j \leq 11m\cdot 2fb \leq 44\sqrt{x}\, x^{12} b \leq x^{13} b \leq b^2 \leq M$.

Step 3: the logarithm of the left side. Write $G = \#\mathrm{GL}_{3m}(\mathcal{O}_E/\mathfrak{M}^2)$ and Λ for the left side of the inequality. All its factors are at least 1 ($N_{\mathrm{ch}} \geq 1$ by Lemma 6.7.10), and

$$\log\Lambda = 4\log N_{\mathrm{ch}} + 4x^{30} + 6x_1 + 2\log G + 6\,d\log d + 9(12m+1)\#D_j \log M,$$

with $d\log d = 0$ for $d = 0$ (the convention $0^0 = 1$). We bound the terms.

- $\log N_{\mathrm{ch}} \leq x^{33}$ by Lemma 6.7.10.
- $G \leq \#\mathrm{M}_{3m}(\mathcal{O}_E/\mathfrak{M}^2) = \#(\mathcal{O}_E/\mathfrak{M}^2)^{9m^2}$. Since $M = \pi_M\bar{\pi}_M \in \pi_M\mathcal{O}_E = \mathfrak{M}$, we have $M^2\mathcal{O}_E \subseteq \mathfrak{M}^2$, so $\#(\mathcal{O}_E/\mathfrak{M}^2) \leq \#(\mathcal{O}_E/M^2\mathcal{O}_E) = M^{2[E:\mathbb{Q}]} = M^{4f}$. Hence $\log G \leq 36fm^2\log M \leq 36\cdot x^{12}\cdot 4x\cdot 22\log b \leq 3168\, x^{13}\log b$.
- For $d \geq 1$, $\log d \leq \log M$ by Step 2, so $6\,d\log d \leq 6(10m+1)\#D_j\log M$.

The terms with $\#D_j$ add up to at most $(6(10m+1) + 9(12m+1))\#D_j\log M = (168m+15)\#D_j\log M \leq 183m\cdot 2fb\cdot 22\log b = 8052\, fmb\log b$, by Step 1, $m \geq 1$ and item 5. The remaining terms are at most $4x^{33} + 4x^{30} + 6x_1 + 6336\, x^{13}\log b \leq 6350\, b \leq 6350\, fmb\log b$, because $x^{33} \leq b$, $x_1 \leq b$ and $x^{13}\log b \leq x^{14} \leq b$ (as $\log b \leq x^{1/100}$), and $f, m, \log b \geq 1$. So

$$\log\Lambda \leq 14402\, fmb\log b \leq fmb(\log b)^2,$$

since $\log b \geq e^{6.4\cdot 10^{13}} \geq 14402$. Exponentiating gives the inequality. □

Lemma 6.6.23. *Let $1 \leq j \leq m$, $r_+ = k + j - 1$, ϑ a twist with modulus Q, $O = O_{j,\vartheta}$ and $\mathfrak{n} = \mathfrak{M}^2\prod_{w\in Q} w$. Let χ_ϑ be the multiplicative character of $R_\mathfrak{n}$ equal on units to $u \mapsto \prod_{w\in S_0\cup Q}\psi'_w(u \bmod w)$, $(\psi'_w)_w$ the tame part of $\chi'_{j,\vartheta}$, and to 0 on nonunits, and put $\alpha_e = \chi'_{j,\vartheta}\nu_j^\flat\upsilon^m$. Let $W = \mathrm{I}_{\mathcal{B}^{\mathrm{c}}} \oplus W'_j$, with index set $n = \mathcal{B}^{\mathrm{c}} \sqcup \mathcal{B}_j$; let $\pi_j\colon \mathcal{L}_j \to n$ send $c \in \{0,\dots,r_+-1\}$ to the basis vector of W_j of number c and be the inclusion on $\mathcal{A}_j^+$, $\mathcal{B}^\flat$ and $\mathcal{B}^{\mathrm{c}}$; let $\jmath_W\colon \mathcal{L}_j \sqcup \{1,\dots,m\} \to n$ be π_j on $\mathcal{L}_j$ and ng_j on $\{1,\dots,m\}$; and for $i \in \mathrm{Mem}_j$ let $\Pi_i^W \in \mathbb{C}[x]_{\mathcal{B}_j\times n}$ be Π_i with every variable $x_{\tau,b,c}$ renamed $x_{\tau,b,\pi_j(c)}$. Then:*

(a) $\mathfrak{n}$ *is a modulus with* $\Sigma(\mathfrak{n}) = S_0 \cup Q$*, and* $\chi_\vartheta = \psi_O^{\mathrm{res}}$*;*

(b) $\chi'_{j,\vartheta}$ *is tame of weight* 0*, and* α_e *is tame of weight* $\tau \mapsto m - \#D_j(\tau)$*, for* $(\mathfrak{n}, \chi_\vartheta)$*;* $\nu_j^\flat \upsilon^m$ *has trivial tame part;*

(c) $\jmath_W$ *is a bijection,* W *has the signs* $\mathrm{sgn}_{\jmath_W}$*, and* $\Pi_i^W = \Delta^{\jmath_W}(\epsilon_j; \mathsf{c}_i)$*, the product of stacked determinants with the index sets* $p = \{1, \dots, 2m\}$*,* $a = \mathcal{B}_j$*,* $m = \mathcal{L}_j$*,* n*,* $l = \{1, \dots, m\}$ *and* $\iota_\tau = D_j(\tau)$*;*

(d) for the pair $(W, \mathrm{I}_{\mathcal{B}_j})$*,* $\gamma(\tau) = m - \#D_j(\tau)$ *and every* $\gamma' \colon \Phi \to \mathbb{Z}$*,* $\Omega_{\gamma,\gamma'}(1, y)\, v_{\Pi_i^W} = v_{\Pi_i^W}$ *for all* $y \in G_\infty(1_{\mathcal{B}_j})$*.*

Proof. **(a)** The level system of O consists of the chosen places S_0 and the places of Q ((LF4)), all distinct and none conjugate to itself or another ((DP1)); so $\mathfrak{n} = \prod_{w \in S_0} w^2 \prod_{w \in Q} w$ is a modulus with $\Sigma(\mathfrak{n}) = S_0 \cup Q$. The character of O is $\mu_j^0 \vartheta$, whose tame part $\omega^j \psi_\vartheta$ (ψ_ϑ the tame part of ϑ) is that of $\chi'_{j,\vartheta} = \chi_M^j \vartheta$; hence χ_ϑ and ψ_O^{res} ((KN3), the product of the tame components of O over $M_O \cup Q_O = S_0 \cup Q$ on units, 0 on nonunits) coincide.

(b) $\chi'_{j,\vartheta}$ has weight 0 (χ_M and ϑ have weight 0) and tame part $\psi' = \omega^j \psi_\vartheta$. At a chosen place w, $\psi_{\vartheta,w} = 1$ (the places of Q are not chosen places) and $\omega_w^j \neq 1$, because ω_w has order $q_2 = (q_0 d)^{s+6} \geq 3^s > 2^{e+1} = m \geq j$ ($d \geq 3$ as $-d \equiv 1 \pmod 4$). At $w \in Q$, $\omega_w = 1$ and $\psi_{\vartheta,w} \neq 1$, ϑ being a twist. At all other places both are trivial. So $\psi'_w \neq 1$ exactly for $w \in \Sigma(\mathfrak{n})$, and $\chi'_{j,\vartheta}$ is tame of weight 0 for $(\mathfrak{n}, \chi_\vartheta)$. The characters $\mu^\flat$ and υ have trivial tame parts ((LF1), (LF2)), so $\nu_j^\flat \upsilon^m = \mu^\flat \upsilon^{m + e_j - j\Delta}$ has trivial tame part and weight $-\kappa_0 + m + e_j - j\Delta$. Hence α_e has the tame part ψ' and the weight $\tau \mapsto m + e_j - j\Delta - \kappa_0(\tau)$. It remains to show $\#D_j(\tau) = \kappa_0(\tau) + j\Delta - e_j$. By (LF4) and Definition 3.2.16, $\varsigma_\tau(c)$ is strictly decreasing in c and $\varsigma_\tau(r_+ - 1) = \frac{\Delta}{2} - \kappa_j(\tau)$ (the entry $k - 1 + (j-1)$ of the target parameter). As $\frac{\Delta}{2} = r^8 > \frac{t-1}{2}$, for $1 \leq h < r_+$ we have $\varsigma_\tau(h) \geq \varsigma_\tau(r_+ - 1) > \frac{t-1}{2} - \kappa_j(\tau)$, so the maximum in (LF4) is $\varsigma_\tau(h)$ and $\kappa_O^+(\tau, h) = \varsigma_\tau(h-1) - \varsigma_\tau(h) - 1 \geq 0$. Telescoping,

$\#D_j(\tau) = \sum_{1 \leq h < r_+} \kappa_O^+(\tau, h) + \Delta' = \kappa_0(\tau) + j\Delta - e_j$, so the weight of α_e is $m - \#D_j(\tau)$ and α_e is tame of that weight for $(\mathfrak{n}, \chi_\vartheta)$.

(c) The signs of W are $+1$ on $\mathcal{B}^{\mathrm{c}}$, $\mathcal{A}_j^+$ and $\mathcal{B}^\flat$, -1 on $\mathcal{A}_j^-$, and on $\mathcal{R}$ those of W_j: $+1$ on the basis vectors of numbers $0, \dots, r_+ - 1$ and -1 on those of numbers $r_+, \dots, r-1$ ((HP4)). The map π_j is injective and its image is the set of indices of sign $+1$; ng_j is injective ($\mathrm{ng}_j(i) = i \in \mathcal{A}_j^-$ for $i \leq j$, the basis vector of number $k + i - 2 \in \{r_+, \dots, r-1\}$ for $j < i \leq m$, as $r = k + m - 1$) and its image is the set of indices of sign -1. So $\jmath_W$ is a bijection and the sign of $\jmath_W(x)$ is $+1$ for $x \in \mathcal{L}_j$ and -1 for $x \in \{1, \dots, m\}$: W has the signs $\mathrm{sgn}_{\jmath_W}$. By (6.23), $\Delta^{\jmath_W}(\epsilon_j; \mathsf{c}_i)$ is the product over τ and $d \in D_j(\tau)$ of the determinants of the $\mathcal{L}_j \times \mathcal{L}_j$ matrices whose row $\epsilon_j(a)$ is the row a of $\mathsf{c}_{i,\tau,d}$ ($a \leq 2m$) and whose row $\epsilon_j(b)$ is $(x_{\tau,b,\jmath_W(k')})_{k' \in \mathcal{L}_j} = (x_{\tau,b,\pi_j(k')})_{k'}$ ($b \in \mathcal{B}_j$); $\Pi_i = \Delta^{\mathrm{id}}(\epsilon_j; \mathsf{c}_i)$ is the same product with $x_{\tau,b,k'}$ in place of $x_{\tau,b,\pi_j(k')}$. So $\Pi_i^W = \Delta^{\jmath_W}(\epsilon_j; \mathsf{c}_i)$.

(d) By (c), W has the signs $\mathrm{sgn}_{\jmath_W}$ and $\Pi_i^W = \Delta^{\jmath_W}(\epsilon_j; \mathsf{c}_i)$ with $\gamma(\tau) = \#l - \#\iota_\tau = m - \#D_j(\tau)$; (5) of Lemma 6.3.71 for the pair $(W, \mathrm{I}_{\mathcal{B}_j})$ gives the invariance. □

Lemma 6.6.24. *Let* O *be a descent pair for ranks* $r < n$*,* $\mathcal{V}$ *a divided splitting for finite index sets* N*,* m*,* a *and an embedding* $z \colon \{1, \dots, r\} \hookrightarrow m$*, and* s *an* $a \times N$ *matrix over* R_2*. Then there is a divided lattice* L *that is glued for* s*.*

Proof. Write $M = M_O$, $\hat{\mathcal{O}}_M = \prod_{w \in M} \mathcal{O}_{E,w}$, ϖ for the family of components of ϖ_O at M, $\phi = \phi_{\mathcal{V}}$, $d \colon a \hookrightarrow N$ for the divided embedding, and $\mathrm{red} \colon \hat{\mathcal{O}}_M \to R_2$ for the reduction; it is surjective with kernel $\varpi^2 \hat{\mathcal{O}}_M$, since $R_2 \cong \prod_{w \in M} \mathcal{O}_{E,w}/w^2$. Matrices over $\hat{\mathcal{O}}_M$ are reduced entrywise, written

$\bar{X}$. Two facts on R_2: an element y with $\bar{\varpi}y = 0$ is the reduction of an element of $\varpi\hat{\mathcal{O}}_M$, so the product of two such elements is 0; and $\bar{\varpi}^2 = 0$. We index the rows and columns of $(N \sqcup m)$-square matrices by $N \sqcup m$, write ι_z for the $(N \sqcup m) \times r$ matrix with entry 1 at $(z(i), i)$ in the block m and 0 elsewhere, and for an $n \times r$ matrix x write $x^\varepsilon = \left(\begin{smallmatrix} x_N \\ x_m \end{smallmatrix}\right)$ for its rows reordered by ε.

A Hermite form of the stacked matrix. Lift s to an $a \times N$ matrix t over $\hat{\mathcal{O}}_M$ and let $T = \left(\begin{smallmatrix} t \\ \varpi 1_N \end{smallmatrix}\right)$. At each $w \in M$, T_w has rank $\#N$ (its lower block is invertible over E_w), so by the elementary divisor theorem over the discrete valuation ring $\mathcal{O}_{E,w}$, $T_w = P\left(\begin{smallmatrix} \Lambda \\ 0 \end{smallmatrix}\right)Q$ with P, Q invertible and Λ diagonal; moving the rows of Λ to the bottom by a permutation, $T = U\left(\begin{smallmatrix} 0 \\ D \end{smallmatrix}\right)$ with $U \in \mathrm{GL}_{a\sqcup N}(\hat{\mathcal{O}}_M)$ and $D \in \mathrm{M}_N(\hat{\mathcal{O}}_M)$. Writing U in blocks U_{ij} along $a \sqcup N$, this says $t = U_{12}D$ and $\varpi 1_N = U_{22}D$; put $B = U_{22}$, so $BD = \varpi 1_N$. Moreover D is the block of the rows N of $U^{-1}T$. Reducing, $w := [s; \bar{\varpi}] = \bar{T} = \overline{U_N}\,\bar{D}$ and $\bar{D} = \overline{(U^{-1})_N}\,w$, where U_N are the columns N of U and $(U^{-1})_N$ the rows N of U^{-1}. Hence, for $N \times r$ matrices X, X' over R_2,

$$wX = wX' \iff \bar{D}X = \bar{D}X'. \tag{6.135}$$

The lattice. Let Δ' (resp. Δ) be the diagonal $m \times m$ matrix with entries ϖ (resp. 1) at the indices $z(i)$ and 1 (resp. ϖ) elsewhere, so $\Delta\Delta' = \varpi 1_m$ and $I_z^{\mathsf{T}}\Delta' = \varpi I_z^{\mathsf{T}}$. Put

$$G = \begin{pmatrix} D & -DI_\phi I_z^{\mathsf{T}} \\ 0 & \Delta' \end{pmatrix}, \qquad C = \begin{pmatrix} B & I_\phi I_z^{\mathsf{T}} \\ 0 & \Delta \end{pmatrix},$$

integral over $\hat{\mathcal{O}}_M$; then $CG = \varpi 1$, the upper right block being $-BDI_\phi I_z^{\mathsf{T}} + I_\phi I_z^{\mathsf{T}}\Delta' = -\varpi I_\phi I_z^{\mathsf{T}} + \varpi I_\phi I_z^{\mathsf{T}} = 0$. Choose a bijection $\varepsilon'\colon N \sqcup m \to \{1, \dots, n\}$ with $\varepsilon'(z(i)) = \mathrm{inc}_O(i)$ for all i (extend the injective partial map $z(i) \mapsto \mathrm{inc}_O(i)$ between sets of the same size n). Let $G^\star$, $C^\star$ be the $n \times n$ matrices with $G^\star_{\varepsilon'(p),\varepsilon(q)} = G_{pq}$ and $C^\star_{\varepsilon(p),\varepsilon'(q)} = C_{pq}$; then $C^\star G^\star = \varpi 1_n$. Let $c \in \mathrm{GL}_n(\mathbb{A}_{E,f})$ be $C^\star$ at the places of M (invertible over E_w as $C^\star G^\star = \varpi 1$) and 1 elsewhere, c^* its conjugate transpose (supported on $\bar{M}$, disjoint from M by (DP1), so c and c^* commute), and $\gamma = (c^*)^{-1}c$. Then $\gamma^*\gamma = c^*c^{-1}(c^*)^{-1}c = 1$, so $\gamma \in G_f(n)$. At $w \in M$, $\gamma_w = C^\star_w$ and $\varpi_O\gamma_w^{-1} = G^\star_w$; at $\bar{w}$, ϖ_O is 1 and $\gamma_{\bar{w}}^{-1}$ is the conjugate transpose of $C^\star_w$, integral; elsewhere $\gamma = 1$. So $L = \gamma$ is a divided lattice with $G_L = \overline{G^\star}$.

The congruence for L. For an $n \times r$ matrix x over R_2, the row $\varepsilon'(p)$ of $G_L x$ is the row p of $\bar{G}x^\varepsilon$, and the row $\varepsilon'(p)$ of $\bar{\varpi}\,\mathrm{Inc}_O$ is the row p of $\bar{\varpi}\iota_z$, as $\varepsilon'(p) = \mathrm{inc}_O(i)$ exactly when $p = z(i)$. So $G_L x = \bar{\varpi}\mathrm{Inc}_O$ if and only if $\bar{\Delta}'x_m = \bar{\varpi}I_z$ and $\bar{D}x_N = \bar{D}I_\phi I_z^{\mathsf{T}}x_m$. The first equation says that the rows of x_m outside the image of z vanish and that $Z = I_z^{\mathsf{T}}x_m$ (the rows $z(i)$) satisfies $\bar{\varpi}(1 - Z) = 0$; so

$$G_L x = \bar{\varpi}\,\mathrm{Inc}_O \iff x_m = I_z Z \text{ with } \bar{\varpi}(1 - Z) = 0, \text{ and } \bar{D}x_N = \bar{D}I_\phi Z. \tag{6.136}$$

For $A \in \mathrm{C}(\mathcal{V})$, by (6.135) the matrix xA is block normalised for s if and only if $x_m A = I_z$ and $\bar{D}x_N A = \bar{D}I_\phi$.

Condition (1). Let $G_L x = \bar{\varpi}\mathrm{Inc}_O$, with Z as in (6.136). Then $Y = 1 - Z$ has $\bar{\varpi}Y = 0$, so $Y^2 = 0$ by the first fact on R_2, Z is invertible with $Z^{-1} = 1 + Y$, and $\bar{\varpi}Z^{-1} = \bar{\varpi}$: $A_0 = Z^{-1} \in \mathrm{C}(\mathcal{V})$. Now $x_m A_0 = I_z$ and $\bar{D}x_N A_0 = \bar{D}I_\phi Z Z^{-1} = \bar{D}I_\phi$, so xA_0 is block normalised. If xA is block normalised for some $A \in \mathrm{C}(\mathcal{V})$, then $I_z Z A = I_z$, and multiplying by I_z^{T} on the left, $ZA = 1$, so $A = A_0$.

Condition (2). If xA is block normalised for some $A \in \mathrm{C}(\mathcal{V})$, put $Z = A^{-1}$; then $\bar{\varpi}Z = \bar{\varpi}$, $x_m = I_z Z$ and $\bar{D}x_N = \bar{D}I_\phi Z$, so $G_L x = \bar{\varpi}\mathrm{Inc}_O$ by (6.136).

Condition (3). The columns $\varepsilon(N)$ of G_L have the rows $\varepsilon'(N)$ equal to $\bar{D}$ and the rows $\varepsilon'(m)$ equal to 0. Reduce s modulo the chosen places to an $a \times N$ matrix over $\prod_{w\in M} k_w$; at each

w, column operations bring it to a matrix whose nonzero columns are among the a columns of $d(a)$ (its rank is at most $\#a$). Lift this invertible matrix to $J \in \mathrm{M}_N(R_2)$; J is invertible, its determinant reducing to a unit at each place. Then sJ has entries in the image of $\mathfrak{M}_O$ in the columns outside $d(a)$, so $\bar{\varpi} sJ$ vanishes there, and $\bar{\varpi} \cdot \bar{\varpi} J = 0$; hence $\bar{\varpi} wJ$ vanishes in those columns, and so does $\bar{\varpi} \bar{D} J = \overline{(U^{-1})_N}\, \bar{\varpi} wJ$. This is condition (3). □

Lemma 6.6.25. *Let $1 \le j \le m$, let Y and c'' be a short row family and a scale with (i) and (ii) of Lemma 6.6.17, let $L = (L_i)_{i \in \mathrm{Mem}_j}$ be divided lattices of $O_{j,1}$ with L_i glued for Λ_i, suppose that $\mathcal{V}_j$ is a divided splitting for $O_{j,\vartheta}$ for every twist ϑ, and let $\mathrm{gl}_\vartheta = \mathrm{gl}_{j,\vartheta}[L; c'']$, formed with Y. For $\zeta \in \mathrm{Tab}_j$ let $\bar{\zeta}_{i,\mathfrak{c}}$ have the conjugate coordinates of $\zeta_{i,\mathfrak{c}}$.*

(a) Let ϑ be a twist with modulus Q, $\ell \nmid \mathrm{N}Q$ a prime and $\iota \colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, and let $\zeta \in \mathrm{Tab}_j$ satisfy $\mathrm{gau}_{\iota \circ c}(x_\mathfrak{c}, \bar{\zeta}_{i,\mathfrak{c}}) \le 1$ for all $(i, \mathfrak{c})$, for the weight $(\kappa_O^-, 0)$ in rank $|\mathcal{B}^\circ|$ and $\iota \circ c$ the composite of ι with complex conjugation. Then $\mathrm{gl}_\vartheta \zeta$ is integral at ι.

(b) For every $\zeta \in \mathrm{Tab}_j$ and every automorphism σ of $\mathbb{C}$, $\|\mathrm{gl}_1 \zeta\|_\sigma^2 \le \exp(2fmb(\log b)^2) \|\zeta\|_\sigma^2$.

Proof. The weights, chosen modulus and conditions (GU2)–(GU4) do not depend on the twist, so the given L_i are also glued lattices for each $O_{j,\vartheta}$. All class sums at an open finite level are finite: definiteness and Theorem A.4.5 make the adelic quotient compact.

We first record the two elementary bounds for a point form. If v is a weight vector and z, g are finite points, then

$$\mathrm{gau}_\iota(g, \delta_z(v)(g)) \le \mathrm{gau}_\iota(z, v).$$

Indeed, in a nonzero summand of (GU5) write $z^{-1}\gamma g = u \in \mathbf{K}(O)$. In the gauge, rational covariance changes $g^{-1}\gamma^{-1}$ into $u^{-1}z^{-1}$. The Schur matrices of u and u^{-1} have integral entries and their determinant characters are units, so they preserve the coordinate maximum norm. The level character is a root of unity, hence has absolute value one under every ι. The ultrametric inequality proves the assertion after summing over γ.

For every automorphism σ of $\mathbb{C}$, the other bound is

$$\|\sigma(\delta_z(v)(g))\|_{\kappa_O} \le \#\Gamma_z \, \|\sigma(v)\|_{\kappa_O}, \qquad \Gamma_z = \mathrm{U}(\mathrm{I}_n)(E^+) \cap z\mathbf{K}(O)z^{-1}.$$

If the summation set is nonempty it is a coset of Γ_z. Each summand has the same Gram norm as $\sigma(v)$: the level character has absolute value one, and a rational unitary matrix remains unitary at every complex embedding after applying σ. This last assertion uses the actual CM field: complex conjugation commutes with every embedding of E, so the conjugate of its unitary equation is again the unitary equation. The Gram model (WM3) is the restriction of the ordinary exterior-tensor norm. Thus its representation preserves that norm. The ordinary triangle inequality gives the displayed bound.

We also have $\#\Gamma_z \le N_{\mathrm{ch}}$ for all the point forms used below. The group is finite by definiteness. After conjugating by z, reduce it at the chosen places. The kernel is trivial by Lemma 4.6.2(c), since it lies in the principal level at a chosen place. Hence it embeds in the product of $\mathrm{GL}_n(k_w)$. Here $n = r + t = 6r \le rt$ as $r \ge 3$, and block diagonal inclusion embeds every such finite group into $\mathrm{GL}_{rt}(k_w)$. Lagrange's theorem and (CX1) give the asserted bound.

We next prove the loss estimate for the Cartan product, retaining its conjugate embedding. Write $h_+ \in G_f(\mathcal{B}_j)$, $h_- \in G_f(\mathcal{B}^\circ)$, let L_i be one of the given glued lattices, and put

$$g = \mathrm{diag}_{\varepsilon_j}(h_+, h_-)\gamma_{L_i}.$$

For vectors y and η in the two block Weyl modules we claim

$$\mathrm{gau}_{\iota}(g, y \cdot \eta) \le |M|_{\ell}^{-\mathrm{loss}(\mathcal{V}_j)} \mathrm{gau}^{+}_{\iota}(h_{+}, y)\, \mathrm{gau}^{-}_{\iota \circ c}(h_{-}, \bar{\eta}). \tag{1}$$

Here is the matrix estimate underlying this claim. For a block of rows and a subset of its columns, suppose that after an invertible change of those columns the columns of $\gamma_{L_i}^{-1}$ outside that subset are integral, while multiplication by M makes every remaining column integral. Lift the invertible change modulo $\mathfrak{M}^2$ to an integral invertible finite matrix. This is possible locally at each chosen split place by lifting entries and a unit determinant; use its inverse conjugate transpose at the conjugate place and the identity elsewhere. Absorb that matrix into h_{+} or h_{-}. Such a change preserves the gauge, because its Schur matrix and inverse are integral. The relevant inverse columns then factor as

$$A_{\mathrm{int}}\ \mathrm{diag}(M^{-1} \text{ on the subset}, 1 \text{ elsewhere})\, h_{\pm}^{-1},$$

where A_{int} is integral. Schur matrices of integral rectangular matrices contract the coordinate maximum norm: this follows from Cauchy–Binet and the integral standard basis in (WM1)–(WM2). The middle diagonal matrix contributes at most

$$|M|_{\ell}^{-\sum_{\tau} (\#\ \mathrm{subset}) \sum_{h} \kappa_{O}^{\pm}(\tau, h)}.$$

To check the exponent, in a filling each column has distinct row entries, and so contains at most the size of the subset from that subset. Multiplication over all columns gives precisely this upper bound. The divided-splitting hypothesis excludes full-height determinant factors.

For the positive block use the subset $\mathrm{im}(d_j)$, of size $3m$. Condition (3) of (GU4) supplies the required change of columns; denote its invertible residue matrix by J. Indeed G_{L_i} is the reduction of $\varpi_O \gamma_{L_i}^{-1}$; outside the divided columns, $\bar{\varpi} G_{L_i} J = 0$ modulo $\mathfrak{M}^2$ says that $\varpi_O \gamma_{L_i}^{-1} J$ is divisible by ϖ_O, hence that $\gamma_{L_i}^{-1} J$ is integral there. On the divided columns use (GU2) and $M = \pi_M \bar{\pi}_M \in \mathfrak{M}$ to clear the denominator. Away from the chosen places (GU2) already gives integrality. For the negative block use the entire block as subset, and the same denominator clearing, without a change of columns.

Finally apply the mixed-action identity (d) of Lemma 3.2.20 to $C_O(y \cdot \eta)$, whose value is the tensor of the included vectors by Lemma 6.6.26(a). The positive part is evaluated on the indicated columns of g^{-1}. The negative part is evaluated on the columns of the inverse transpose of that matrix. Since g is unitary, these are the conjugates of the corresponding columns of g^{-1}. Thus that block is read at $\iota \circ c$ with $\bar{\eta}$, because $(\iota \circ c)(\bar{\eta}) = \iota(\eta)$. Applying the integral left inverse C'_O does not increase the maximum norm. The two block exponents add to exactly (GU1)'s $\mathrm{loss}(\mathcal{V}_j)$, proving (1).

We can now prove (a). The gluing level is contained in the principal level at every chosen place. In fact fixing the stacked matrix $[\Lambda_i; \bar{\varpi}]$ forces $\bar{\varpi} A = \bar{\varpi} I$ modulo $\mathfrak{M}^2$, hence $A = I$ modulo $\mathfrak{M}$. Its class stabilizers are therefore trivial by Lemma 4.6.2(c). Consequently the class sums in (TG6) are plain finite sums, with no stabilizer denominators. For their term indexed by $(i, \mathfrak{c}, h_{+})$, apply (1) with $h_{-} = x_{\mathfrak{c}}$, $y = \varphi''_{\vartheta, i}(h_{+})$ and $\eta = \zeta_{i, \mathfrak{c}}$. The first gauge is at most one by the assumed first-factor property (i), and the second is at most one by the hypothesis of (a). The point-form bound and multiplication by $M^{\mathrm{loss}(\mathcal{V}_j)}$ cancel the remaining factor exactly. Every term has gauge at most one at every point, including at primes dividing M. The ultrametric inequality for the finite sum proves integrality at ι.

For (b) we use the same finite expansion at the trivial twist. First,

$$\|\sigma(y \cdot \eta)\|_{\kappa_O}^2 = \|\sigma(y)\|_{\kappa_O^{+}}^2 \|\sigma(\eta)\|_{\kappa_O^{-}}^2. \tag{2}$$

Indeed the Cartan matrices and coordinate inclusions are integral, so commute with σ; by (a) of Lemma 6.6.26, their mixed image is the tensor of the included vectors. By (b) of Lemma 3.2.20 the mixed embedding is an isometry, and the exterior coordinate inclusions are isometries by (WM3). This proves (2). The assumed property (ii), the bound for Γ_z, and the fact that each squared table-entry norm is at most $\|\zeta\|_\sigma^2$ now show that the squared norm of every value of every point-form term is at most

$$N_{\mathrm{ch}}^2 \exp\bigl(fmb(\log b)^2\bigr)\|\zeta\|_\sigma^2. \tag{3}$$

It remains to bound explicitly the finite counts and the factor $M^{2\,\mathrm{loss}(\mathcal{V}_j)}$. We give the estimates, since a finiteness assertion alone would not imply the stated bound.

By Lemma 2.3.6 and (AD1),

$$x \ge 10^6, \qquad \log b \ge 319, \qquad \log b \le x, \qquad b \ge x^{10^{12}}. \tag{4}$$

For example $10^{14} q_0 \le \log x$ proves the first inequality, the two 10^6 inequalities in (AD1) give the last one, and $100 \log\log b \le \log x$ gives $\log b \le x$. Also $q_0 \le 10^{-14} \log x$. From the explicit tower formula, $l_0(s) \le 81 s$, $s \le 32 \log x$, and $2^s = m^{22} \le 2^{22} x^{11}$,

$$f \le q_1 = 3 q_0 l_0(s) 2^s \le (\log x)^2 x^{11} \le x^{13}. \tag{5}$$

The numerical coefficient used here is $3 \cdot 81 \cdot 32 \cdot 2^{22} \cdot 10^{-14} < 1$. Furthermore

$$n_m = r + 1 + 5mr \le 34 x^{11/2} \le x^6, \quad m \le x, \quad r \le x^6, \quad t \le x^7, \quad \Delta \le x^{49}, \quad \log M \le 22 \log b. \tag{6}$$

For every rank $1 \le n' \le 2n_m$, a level containing the principal level π_M^2 has at most e^b classes. To see this from the exact level in Lemma 4.6.4, let K_1 be the principal level $\pi_M \pi_N$ and K_2 the principal level π_M^2. Refining classes from K_1 to $\mathrm{K}_1 \cap \mathrm{K}_2$ increases their number by at most $[\mathrm{K}_1 : \mathrm{K}_1 \cap \mathrm{K}_2]$, and passing from the intersection to K_2 cannot increase it. Since K_1 is the identity modulo π_M, reduction of $u - I$ modulo π_M^2 embeds that quotient into the additive matrices over $\pi_M \mathcal{O}_E / \pi_M^2 \mathcal{O}_E$. Cross products vanish modulo π_M^2, so this reduction is a homomorphism with precisely that kernel. In particular its index is at most $M^{2f(n')^2}$ (in fact $M^{f(n')^2}$ suffices). Thus the class number is at most

$$\exp(x^{30}) M^{2f(n')^2} \le \exp(x^{30} + 176 x^{26}) \le \exp(x^{31}) \le e^b \tag{7}$$

by (4)–(6). This argument needs no coprimality assumption involving π_N.

The first-factor gluing levels at the trivial twist contain the principal level π_M^2 by (KN3); so does the output level by (DP4). The flat and second-factor class sets are defined at that principal level. All four ranks are at most $2n_m$: the first rank is $r + 9m + 1$, the second at most t, the flat rank $6m + 1$, and the output rank $6r$; (4), (AD2) and $m \ge 2$ give the claim. Therefore (7) bounds each of these class counts by e^b.

We now count tables. In the notation of (TG1)–(TG4), the residue ring has cardinality $\#R_2 = M^{2f} \le M^{4f}$, because the absolute norm of $\pi_M \mathcal{O}_E$ is M^f. Choosing Λ_i, the flat class, its row lists, and the second class gives

$$\#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) \le M^{\,4f(3m)(r+9m+1)} e^{2b} (6m+1)^{\,2mf\Delta'}. \tag{8}$$

Here $\Delta' \le \Delta/2$. The inequalities $r + 9m + 1 \le x^7$, $3m \le x^2$ and $6m + 1 \le x^2$ follow from (4)–(6). The logarithm of the first factor in (8) is at most $88 f x^9 \log b \le x^{24}$. The logarithm of its row-list factor is at most $4 f x^{50} \log x \le x^{65}$. Since $x^{24} + x^{65} \le b$ by (4), we obtain

$$\log \#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) \le 3b. \tag{9}$$

Every set being counted is nonempty.

The chosen group order has the equally explicit bound

$$\log N_{\mathrm{ch}} \le (rt)^2 \sum_{w \text{ chosen}} \log \mathrm{N}w \le f(rt)^2 \log M \le 22 f x^{26} \log b \le x^{42} \le b. \tag{10}$$

Indeed $\#\mathrm{GL}_{rt}(k_w) \le (\mathrm{N}w)^{(rt)^2}$, and the product of the chosen prime ideals divides $\pi_M \mathcal{O}_E$, which gives the second inequality.

For completeness the weight formulas give the required bound on the loss without estimating individual hooks or dimensions. At a fixed τ, the extended target sequence in (LF4) is decreasing: successive drops are 1 in its first block and Δ in its tail; the junction drop is positive because $\Delta \ge k$. The positive column counts are its successive drops clipped at $(t-1)/2 - \kappa_j(\tau)$, with one subtracted at each step. More explicitly, if $B_\tau = (t-1)/2 - \kappa_j(\tau)$, each positive count is at most $\max(\varsigma_\tau(h-1), B_\tau) - \max(\varsigma_\tau(h), B_\tau)$. Summing these nonnegative differences telescopes. Their sum is therefore at most

$$\big(\varsigma_\tau(0) - (t-1)/2 + \kappa_j(\tau)\big)^+ \le \kappa_j(\tau) \le b + (m+1)\Delta.$$

Here $\varsigma_\tau(0) = k/2 - 1$, $k \le t+1$, and $\kappa(\tau) \le b$ since $x_1 \ge x$. The negative column counts are at most Δ. In the first block their adjacent drop is 1; in the tail it is Δ. At the junction the minimum with $-\kappa_j(\tau) - (t-1)/2$ makes the count zero, since $j \ge 1$. When both arguments have been truncated to zero it is zero as well. This checks the endpoint convention in (LF4). Hence (GU1), $|\mathcal{B}^{\mathrm{c}}| = 3m$ and $|\mathcal{B}^{\circ}| \le t$ imply

$$\mathrm{loss}(\mathcal{V}_j) \le f\big[3m(b + xb/x_1 + (m+1)\Delta) + t^2\Delta\big] \le 7fmb. \tag{11}$$

For the last inequality $xb/x_1 \le b$, and (6) gives $3m(m+1)\Delta + t^2\Delta \le 6x^{51} + x^{63} \le x^{65} \le mb$.

Combining (9)–(11) gives exactly the remaining scalar budget:

$$\begin{aligned} &\log\Big[M^{2\,\mathrm{loss}(\mathcal{V}_j)} e^b \big(\#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) e^b N_{\mathrm{ch}}\big)^2\Big] \\ &\quad = 2\,\mathrm{loss}(\mathcal{V}_j)\log M + 3b + 2\log\#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) + 2\log N_{\mathrm{ch}} \\ &\quad \le 308 fmb \log b + 11b \le 319 fmb \log b \le fmb(\log b)^2. \end{aligned} \tag{12}$$

Finally apply the ordinary triangle inequality at a fixed output point to the expansion (TG6), using (3). There are $\#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ)$ outer indices and at most e^b first-factor classes for each. Thus the norm at that point is at most

$$M^{\mathrm{loss}(\mathcal{V}_j)} \#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) e^b N_{\mathrm{ch}} \exp\big(\tfrac{1}{2} fmb(\log b)^2\big) \|\zeta\|_\sigma.$$

The conjugate norm of a form is the class sum of the squared norms of these values. There are at most e^b output classes and each class weight $1/\#\Gamma$ is at most one. Squaring the last display, summing with those weights, and applying (12), we conclude

$$\|\mathrm{gl}_1\zeta\|_\sigma^2 \le \exp\big(2fmb(\log b)^2\big)\|\zeta\|_\sigma^2.$$

Every estimate holds for every σ, with the given Y, c'' and glued lattices unchanged. This proves (b). □

Lemma 6.6.26. *Let O be a descent pair for ranks $r < n$, let N, m be finite index sets and $\varepsilon\colon N \sqcup m \to \{1,\dots,n\}$ a bijection such that $\kappa_O^+(\tau,h) = 0$ for $|N| \le h < n$ and $\kappa_O^-(\tau,h) = 0$ for $|m| \le h < n$ ($\tau \in \Phi$). For a polynomial P in variables $X_{\tau,b,c}$ with b in N (or in m) let P^ε be P with every $X_{\tau,b,c}$ renamed $X_{\tau,\varepsilon(b),c}$; $\mathrm{Let}_{\pm 1}$ on polynomials in the variables $y_{\tau,b,a}$ with b in N (or m) is read with these rows. Then for all $y \in \mathbb{V}_{\kappa_O^+}$ (rows N) and $\eta \in \mathbb{V}_{\kappa_O^-}$ (rows m):*

(a) $C_O(y \cdot \eta) = S_{\kappa_O^+}(\iota_N)\, y \otimes S_{\kappa_O^-}(\iota_m)\, \eta$;

(b) $\overline{y \cdot \eta} = \bar{y} \cdot \bar{\eta}$, *the bars denoting the conjugate coordinates;*

(c) $\mathrm{Har}_O(y \cdot \eta) = \mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(y))^{\varepsilon} \cdot \mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}(\eta))^{\varepsilon}$.

Proof. Write $\kappa^{\pm} = \kappa_O^{\pm}$, $\kappa = \kappa_O$. By the hypothesis the rectangular Schur matrices $S_{\kappa^+}(z)$ for $z_\tau \in \mathrm{M}_{n\times|N|}$ and $S_{\kappa^-}(z)$ for $z_\tau \in \mathrm{M}_{n\times|m|}$ of (WM2) are defined with $d = 0$: $b'_i(zY) = \sum_j S(z)_{ij} b_j(Y)$, b'_i the standard basis in rank n; equivalently $S(z)\,\mathrm{ev}(Y) = \mathrm{ev}(zY)$ for every array Y, and likewise for square z. Every b_i for a weight λ is a product of minors $\Delta_{\tau,A}$ with $\lambda(\tau,|A|) \neq 0$, which reads only the columns $c < |A|$; for κ^+ these are columns $c < |N|$, for κ^- columns $c < |m|$.

Step 1: polynomials of rectangular Schur images. Let λ be κ^+ and $N' = |N|$, or $\lambda = \kappa^-$ and $N' = |m|$, and let $z_\tau \in \mathrm{M}_{n\times N'}(\mathbb{C})$. We show $\mathrm{Pol}_\lambda(S_\lambda(z)\xi)(Y) = \mathrm{Pol}_\lambda(\xi)(z^{\mathsf{T}}Y)$ for ξ in rank N' and arrays Y with n rows, the left side in rank n. As $G = F^{\mathsf{T}}F$ and $\Delta_T = \sum_i F_{Ti} b_i$,

$$\mathrm{Pol}_\lambda(\xi) = \sum_i (F^{\mathsf{T}}F\xi)_i b_i = \sum_{T\in\mathcal{C}_\lambda} (F\xi)_T\, \Delta_T$$

in either rank; the fillings in the two ranks have the same slots (τ,h,j), as $\lambda(\tau,h) = 0$ for $h \geq N'$. For fillings T (rank n) and T' (rank N') let $\Lambda(z)_{TT'} = \prod_{\tau,h,j} \det(z_\tau)_{T(\tau,h,j),T'(\tau,h,j)}$, the product of the minors of z_τ on the rows $T(\tau,h,j)$ and the columns $T'(\tau,h,j)$, both listed increasingly. By the Cauchy–Binet formula, $\Delta_{\tau,A}(zY') = \sum_{A'} \det(z_\tau)_{A,A'} \Delta_{\tau,A'}(Y')$ for arrays Y' with N' rows, the sum over the $|A|$-subsets A'; multiplying over the slots, $\Delta_T(zY') = \sum_{T'} \Lambda(z)_{TT'} \Delta_{T'}(Y')$. Expanding both sides in the $b_j(Y')$ (the left side by $\Delta_T = \sum_i F'_{Ti} b'_i$ and (WM2)) and using the linear independence of the b_j, $F'S_\lambda(z) = \Lambda(z)F$, F' the filling matrix in rank n. Hence

$$\mathrm{Pol}_\lambda(S_\lambda(z)\xi)(Y) = \sum_T (\Lambda(z)F\xi)_T \Delta_T(Y) = \sum_{T'} (F\xi)_{T'} \sum_T \Lambda(z)_{TT'} \Delta_T(Y) = \sum_{T'} (F\xi)_{T'} \Delta_{T'}(z^{\mathsf{T}}Y),$$

the last step by the Cauchy–Binet formula $\Delta_{\tau,A'}(z^{\mathsf{T}}Y) = \sum_A \det(z_\tau)_{A,A'} \Delta_{\tau,A}(Y)$, multiplied over the slots. This is the claim.

Step 2: (a). Let $U \subseteq \mathbb{V}_{\kappa^+} \otimes \mathbb{V}_{\kappa^-}$ (rank n) be the image of C_O. We show that $w(y,\eta) = S_{\kappa^+}(\iota_N)y \otimes S_{\kappa^-}(\iota_m)\eta$ lies in U. It is bilinear in (y,η), and the evaluation vectors span each Weyl module: a linear form (λ_i) vanishing on all $\mathrm{ev}(Y)$ gives the polynomial identity $\sum_i \lambda_i b_i = 0$, and the b_i, a $\mathbb{Z}$-basis of polynomials with integer coefficients, are linearly independent over $\mathbb{Q}$, hence over $\mathbb{C}$. So it suffices that $w(\mathrm{ev}(Y_1),\mathrm{ev}(Y_2)) = \mathrm{ev}_{\kappa^+}(\iota_N Y_1) \otimes \mathrm{ev}_{\kappa^-}(\iota_m Y_2)$ lies in U for all arrays Y_1 (rows N) and Y_2 (rows m). By the column remark we may take $Y_{1,\tau} \in \mathrm{M}_{N\times|N|}(\mathbb{C})$ (columns $0,\dots,|N|-1$) and $Y_{2,\tau} \in \mathrm{M}_{m\times|m|}(\mathbb{C})$. Membership in U is the vanishing of the linear forms that vanish on U, which are polynomials in the entries of (Y_1,Y_2); so it suffices to treat all $Y_{1,\tau}$, $Y_{2,\tau}$ invertible, a nonempty Zariski open subset of the affine space of these entries. Then for each τ let $g_\tau \in \mathrm{M}_n(\mathbb{C})$ have the column $c+1$ equal to $\iota_N Y_{1,\tau} e_c$ $(0 \leq c < |N|)$ and the column $n-c$ equal to $\iota_m (Y_{2,\tau}^{-1})^{\mathsf{T}} e_c$ $(0 \leq c < |m|)$; as $|N| + |m| = n$ these are all columns, and g_τ is invertible, its columns being bases of the two complementary coordinate subspaces $\iota_N\mathbb{C}^N$, $\iota_m\mathbb{C}^m$. Let h_τ have the column $c+1$ equal to $\iota_N (Y_{1,\tau}^{-1})^{\mathsf{T}} e_c$ and the column $n-c$ equal to $\iota_m Y_{2,\tau} e_c$. The entry (p,q) of $g_\tau^{\mathsf{T}} h_\tau$ is the dot product of the columns p of g_τ and q of h_τ: it is 0 if one lies in $\iota_N\mathbb{C}^N$ and the other in $\iota_m\mathbb{C}^m$, and it is $(Y_1^{\mathsf{T}}(Y_1^{-1})^{\mathsf{T}})_{cc'} = \delta_{cc'}$, respectively $((Y_2^{-1})Y_2)_{cc'} = \delta_{cc'}$, otherwise. So $h_\tau = (g_\tau^{-1})^{\mathsf{T}}$. With the arrays y_{id}, y_{w_0} of (c) of Lemma 3.2.20, the column c of

gy_{id} is $ge_{c+1} = \iota_N Y_1 e_c$ for $c < |N|$, and the column c of $(g^{-1})^{\mathsf{T}} y_{w_0}$ is $he_{n-c} = \iota_m Y_2 e_c$ for $c < |m|$. By the column remark,

$$\mathrm{ev}_{\kappa^+}(\iota_N Y_1) = \mathrm{ev}_{\kappa^+}(gy_{\mathrm{id}}) = S_{\kappa^+}(g)\,\mathrm{ev}_{\kappa^+}(y_{\mathrm{id}}), \qquad \mathrm{ev}_{\kappa^-}(\iota_m Y_2) = S_{\kappa^-}((g^{-1})^{\mathsf{T}})\,\mathrm{ev}_{\kappa^-}(y_{w_0}),$$

and by (d) and (c) of Lemma 3.2.20, with $e^-(\tau) = \sum_{1\le i<n} \kappa^-(\tau, i)$,

$$\begin{aligned} C_O\Big(\prod_\tau \det(g_\tau)^{-e^-(\tau)} S_\kappa(g)\,\mathrm{ev}_\kappa(y_{\mathrm{id}})\Big) &= \big(S_{\kappa^+}(g) \otimes S_{\kappa^-}((g^{-1})^{\mathsf{T}})\big)\big(\mathrm{ev}_{\kappa^+}(y_{\mathrm{id}}) \otimes \mathrm{ev}_{\kappa^-}(y_{w_0})\big) \\ &= \mathrm{ev}_{\kappa^+}(\iota_N Y_1) \otimes \mathrm{ev}_{\kappa^-}(\iota_m Y_2). \end{aligned}$$

So $w(y,\eta) \in U$ for all y, η: $w(y,\eta) = C_O x$ for some x, and as $C_O' C_O = 1$, $C_O(y \cdot \eta) = C_O C_O' C_O x = C_O x = w(y,\eta)$.

Step 3: (b). The entries of C_O' are integers, and those of $S_{\kappa^\pm}(\iota_N)$, $S_{\kappa^\pm}(\iota_m)$ are integers (by the Cauchy–Binet formula a minor of ιY is an integral combination of minors of Y, and the b_j form a $\mathbb{Z}$-basis). So complex conjugation of the coordinates commutes with $y \cdot \eta = C_O'(S_{\kappa^+}(\iota_N)y \otimes S_{\kappa^-}(\iota_m)\eta)$.

Step 4: (c). By (DP8), $\mathrm{Har}_O(\xi) = L(C_O\xi)$ for the linear map

$$L(\alpha \otimes \beta) = \mathrm{Let}_1(\mathrm{Pol}_{\kappa^+}\alpha)\,\mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa^-}\beta),$$

so by (a)

$$\mathrm{Har}_O(y \cdot \eta) = \mathrm{Let}_1(\mathrm{Pol}_{\kappa^+}(S_{\kappa^+}(\iota_N)y))\,\mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa^-}(S_{\kappa^-}(\iota_m)\eta)).$$

By Step 1, $\mathrm{Pol}_{\kappa^+}(S_{\kappa^+}(\iota_N)y)(Y) = \mathrm{Pol}_{\kappa^+}(y)(\iota_N^{\mathsf{T}} Y)$, and $(\iota_N^{\mathsf{T}} Y)_{\tau,b,a} = Y_{\tau,\varepsilon(b),a}$ ($b \in N$); so this polynomial is $\mathrm{Pol}_{\kappa^+}(y)$ with $y_{\tau,b,a}$ renamed $y_{\tau,\varepsilon(b),a}$. The letter substitution keeps the row index ($y_{\tau,i,a} \mapsto \sum_c X_{\tau,i,c}$), so Let_1 of it is $\mathrm{Let}_1(\mathrm{Pol}_{\kappa^+}(y))^\varepsilon$; likewise for η with ι_m and Let_{-1}. □

Lemma 6.6.27. *Let $1 \le j \le m$, $\kappa = \kappa^-_{O_{j,1}}$ in rank $|\mathcal{B}^\circ|$, $h = h_\kappa$, and $A = \mathrm{Mem}_j \times \mathrm{Cl}^\circ \times \mathcal{C}_\kappa$. For $\zeta \in \mathrm{Tab}_j$ let $\bar\zeta_{i,\mathfrak{c}}$ have the conjugate coordinates of $\zeta_{i,\mathfrak{c}}$.*

(a) For every prime ℓ there are tables $f_a \in \mathrm{Tab}_j$ ($a \in A$) with $\sum_{a\in A}\langle f_a, \zeta\rangle f_a = h^2\zeta$ for every $\zeta \in \mathrm{Tab}_j$, and with $\mathrm{gau}_{\iota\circ c}(x_{\mathfrak{c}}, \overline{(f_a)}_{i,\mathfrak{c}}) \le 1$ for the weight $(\kappa, 0)$, every ring homomorphism $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ and all a, i, $\mathfrak{c}$ ($\iota \circ c$ the composite with complex conjugation).

(b) There are tables $f_a \in \mathrm{Tab}_j$ ($a \in A$) with $\sum_{a\in A}\langle f_a, \zeta\rangle f_a = h^2\zeta$ for every ζ and $\|f_a\|_\sigma^2 \le h^2$ for every a and every automorphism σ of $\mathbb{C}$.

(c) $\#(\mathrm{Mem}_j \times \mathrm{Cl}^\circ) \cdot \big(\#A \cdot N_{\mathrm{ch}}\, h^2\big)^2 \le \exp\big(2fmb(\log b)^2\big)$.

Proof. Write $F = F_\kappa$, $G = F^{\mathsf{T}}F$, and let H be the integer matrix of the Fock pairing. Thus $GH = HG = hI$. All inner products below are conjugate linear in the first argument.

An integral frame. For each increasing-column filling T, let e_T be its coordinate vector in the row space of F, and put

$$\eta_T = HF^{\mathsf{T}} e_T = hG^{-1}F^{\mathsf{T}} e_T.$$

These vectors have integer coordinates. Since G, H are real symmetric,

$$\sum_T \eta_T \eta_T^* G = HF^{\mathsf{T}}FHG = HGHG = h^2 I.$$

This is exactly $\sum_T \langle \eta_T, \xi\rangle_\kappa \eta_T = h^2\xi$. Moreover

$$\|\eta_T\|_\kappa^2 = h^2 e_T^{\mathsf{T}} F G^{-1} F^{\mathsf{T}} e_T \le h^2.$$

Indeed $FG^{-1}F^{\mathsf{T}}$ is a real symmetric idempotent, hence an orthogonal projection. Every automorphism of $\mathbb{C}$ fixes η_T. Placing η_T in just the $(i,\mathfrak{c})$-slot and zero in the other slots proves (b), including its specified indexing set and the original Gram norm.

Integral frames at a finite prime. Fix ℓ. For each $\mathfrak{c}$, choose a rational unitary matrix $\delta_{\mathfrak{c}}$ such that $\delta_{\mathfrak{c}}x_{\mathfrak{c}}$ and its inverse are integral at every place above ℓ. For this choice apply Lemma 4.2.64 to the actual standard definite space underlying Cl°, with the finite set of all places of E above ℓ. The auxiliary finite factor in the dense products is 1 at these places, so the rational unitary components are dense in their product. At every prescribed place the inverse of $x_{\mathfrak{c}}$ belongs to the nonempty open set of movers δ for which $\delta x_{\mathfrak{c}}$ and its inverse are integral. Thus the lemma supplies the required $\delta_{\mathfrak{c}}$.

Let ρ be the rational unitary representation of weight $(\kappa,0)$, and put

$$v_{\mathfrak{c},T}=\overline{\rho(\delta_{\mathfrak{c}})^{-1}\eta_T}.$$

Because G is real and $\rho(\delta_{\mathfrak{c}})$ is unitary by Lemma 4.6.10, the map $\xi\mapsto\overline{\rho(\delta_{\mathfrak{c}})^{-1}\bar{\xi}}$ is a complex-linear unitary map. Consequently the vectors $v_{\mathfrak{c},T}$ have the same tight-frame identity. Define $f_{(i,\mathfrak{c},T)}$ to have value $v_{\mathfrak{c},T}$ in that slot and zero elsewhere.

We check the gauge with its stated conjugation. The identity $\rho(\delta_{\mathfrak{c}})\bar{v}_{\mathfrak{c},T}=\eta_T$ and multiplicativity of the Schur matrices give directly from (WM9)

$$\mathrm{gau}_{\iota oc}(x_{\mathfrak{c}},\bar{v}_{\mathfrak{c},T})=\mathrm{gau}_{\iota oc}(\delta_{\mathfrak{c}}x_{\mathfrak{c}},\rho(\delta_{\mathfrak{c}})\bar{v}_{\mathfrak{c},T})=\mathrm{gau}_{\iota oc}(\delta_{\mathfrak{c}}x_{\mathfrak{c}},\eta_T)\le 1.$$

For the last inequality, the inverse local matrix is integral, its Schur matrix is polynomial with integer coefficients, and η_T is an integer vector. There is no determinant factor since the determinant weight is zero. The approximation was made at every place above ℓ, so this argument applies to every ι, not merely a chosen embedding. Zero slots have gauge zero. The orthogonal-sum frame identity now proves (a).

Cardinalities in the prescribed scales. All estimates in this paragraph concern the fixed sets in the statement. Put $C=\#\mathcal{C}_{\kappa}$ and $P=\#(\mathrm{Mem}_j\times\mathrm{Cl}^{\circ})$. We give deliberately coarse polynomial bounds for their logarithms. By Lemma 4.2.67,

$$f\le x^{12},\quad t\le 15x^{5},\quad m\le 2\sqrt{x},\quad \Delta=2r^{8}\le 2\cdot 3^{8}x^{40},$$
$$\log M\le 22\log b,\quad \log b\le x^{1/100},\quad b\ge x^{10^{12}},$$

and $x\ge\exp(6.4\cdot 10^{15})$.

First, $0\le\kappa(\tau,h)\le\Delta$. To see the upper bound from (LF4), consecutive entries in the initial block of the target parameter differ by one, giving zero column count there. Consecutive entries in its tail differ by Δ, giving a count at most $\Delta-1$. At the interface with the first tail entry, the minimum with $-\kappa_j-(t-1)/2$ makes the positive part zero, since $\kappa_j\ge\kappa_1$. Truncated arguments equal to zero give a nonpositive difference. Taking the minimum in any remaining case can only decrease the difference. These cases exhaust the displayed formula in (LF4). Since the rank $n^{\circ}=|\mathcal{B}^{\circ}|$ is at most t, the total number of boxes is at most

$$L_0=ft^{2}\Delta\le 2\,952\,450x^{62}\le x^{63}.$$

A filling assigns a row to each box; forgetting the increasing-column condition bounds C by $(t+1)^{L_0}$. Thus

$$\log C\le L_0\log(t+1)\le x^{70}.$$

The hook estimate in Lemma 6.4.73, applied with the integer L_0, gives

$$\log h\le 3L_0\log L_0\le 3L_0^{2}\le x^{127}.$$

(The empty diagram has $C = h = 1$ and satisfies these bounds as well.)

Both standard definite ranks $|\mathcal{B}^\flat|$ and $|\mathcal{B}^\circ|$ lie between one and t, and hence are at most $2n_m$. The maximal integral level contains the principal level of $\pi_M\pi_N$. Therefore Lemma 4.6.4 bounds each maximal-level class set by $\exp(x^{30})$. To pass to the principal level $\mathfrak{M}^2$, use the rational integer M^2: its principal subgroup is contained in that of π_M^2, since $\pi_M\bar{\pi}_M = M$. Reduction modulo M^2 bounds the index by

$$\#\mathrm{M}_n(\mathcal{O}_E/M^2\mathcal{O}_E) = M^{4fn^2}.$$

Each maximal-level class splits into at most this many finer classes. For either of the two ranks, their logarithmic cardinality is consequently at most

$$x^{30} + 4ft^2 \log M \le x^{30} + 19\,800x^{22+1/100} \le x^{31}.$$

There are $3m|\mathcal{B}_j|$ matrix entries in a choice, and $\#(\mathcal{O}_E/\mathfrak{M}^2) \le M^{4f}$. Since $|\mathcal{B}_j| \le t$, their logarithmic contribution is at most

$$12fmt \log M \le 7\,920x^{17+1/2+1/100} \le x^{19}.$$

The lists of rows contribute exactly $f\Delta'(2m)\log(6m+1)$ to the logarithm. Here $0 \le \Delta' \le r^8$, so this is at most

$$x^{12} \cdot 3^8 x^{40} \cdot 4\sqrt{x}\log(12\sqrt{x}+1) \le x^{60}.$$

Including the two class sets proves

$$\log P \le x^{19} + 2x^{31} + x^{60} \le x^{61}.$$

All sets are nonempty: the identity gives a class, and zero matrices and constant lists give choices. The preceding logarithms are therefore legitimate. Also $\log N_{\mathrm{ch}} \le x^{33}$ by Lemma 6.7.10. Since $\#A = PC$, the logarithm of the left side of (c) equals

$$3\log P + 2\log C + 2\log N_{\mathrm{ch}} + 4\log h \le 3x^{61} + 2x^{70} + 2x^{33} + 4x^{127} \le x^{129}.$$

Finally $f, m, \log b \ge 1$ and $b \ge x^{10^{12}}$, so $x^{129} \le 2fmb(\log b)^2$. Exponentiating proves (c). □

Lemma 6.6.28. *Let $1 \le j \le m$, ϑ a twist, $O = O_{j,\vartheta}$, ℓ a prime and $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, and $\iota \circ c$ its composite with complex conjugation. If $\Xi \in \mathrm{Form}(O)$ is integral at $\iota \circ c$ and $\Xi' \in \mathrm{Form}(O)$ is integral at ι, then $|\iota(N_{\mathrm{ch}}\langle \Xi, \Xi'\rangle)|_\ell \le 1$.*

Proof. Put $n = r + t$, $\kappa = \kappa_O$, $e = e_O$, and $G = G_\kappa = F_\kappa^{\mathsf{T}} F_\kappa$. In particular G has integer entries. By admissibility $r \ge 3$ and $t = 5r$, so

$$1 \le n = 6r \le 5r^2 = rt.$$

The level $\mathbf{K}(O)$ is an open subgroup of $\mathbf{K}_0(n)$: it is the inverse image of a subgroup of a finite residue group under reduction. Thus Lemma 6.7.9 applies to each $h \in G_f(n)$ and gives

$$d_h = \#(\mathrm{U}(\mathrm{I}_n)(E) \cap h\mathbf{K}(O)h^{-1}) \mid N_{\mathrm{ch}}. \tag{1}$$

These stabilizers are the original ones in (DP5). There are finitely many double cosets. Indeed I_n is positive definite, so its adelic quotient is compact by Theorem A.4.5; passage to the quotient by the open subgroup $\mathbf{K}(O)$ gives a compact discrete space.

We first establish the exact bilinear identity for the two gauges. For a tuple of invertible matrices $A = (A_\tau)_\tau$ over $\mathbb{C}_\ell$, write

$$\mathscr{R}(A) = \left(\prod_\tau \det(A_\tau)^{e_\tau} \right) S_\kappa(A).$$

This denotes the matrix appearing in the gauge, without an additional conjugation. The substitution definition of the Schur matrices gives $\mathscr{R}(AB) = \mathscr{R}(A)\mathscr{R}(B)$ and $\mathscr{R}(1) = 1$.

The integer filling Gram satisfies

$$GS_\kappa(A) = S_\kappa(A^{\mathsf{T}})^{\mathsf{T}} G. \tag{2}$$

Here is a direct verification that fixes the transpose. For two arrays X, Y, let $\mathrm{ev}_\kappa(X)$ and $\mathrm{ev}_\kappa(Y)$ be their evaluation vectors. Then

$$\mathrm{ev}_\kappa(X)^{\mathsf{T}} G \, \mathrm{ev}_\kappa(Y) = \sum_T \Delta_T(X)\Delta_T(Y).$$

For each column of height h, Cauchy–Binet identifies its factor in this sum with $\det(X_h^{\mathsf{T}} Y_h)$, where X_h, Y_h are the first h columns of the appropriate arrays. Therefore replacing (X, Y) by (AX, Y) has the same effect as replacing it by $(X, A^{\mathsf{T}}Y)$. Since $\mathrm{ev}_\kappa(AX) = S_\kappa(A)\mathrm{ev}_\kappa(X)$, this gives

$$S_\kappa(A)^{\mathsf{T}} G = GS_\kappa(A^{\mathsf{T}}).$$

The evaluation vectors span: a linear functional vanishing on all of them is a polynomial relation among the independent standard polynomials b_i, hence is zero. Thus this is a matrix identity; replacing A by A^{T} proves (2). Determinants are unchanged by transpose, so (2) also gives

$$G\mathscr{R}(A) = \mathscr{R}(A^{\mathsf{T}})^{\mathsf{T}} G, \qquad \mathscr{R}(A^{\mathsf{T}})^{\mathsf{T}} G \mathscr{R}(A^{-1}) = G. \tag{3}$$

No inverse Gram matrix occurs.

Fix a double-coset representative h. For $\tau \in \Phi$, let $A_\tau = f_{\iota,\tau}(h)$, where $f_{\iota,\tau}$ is projection to the completion selected by $x \mapsto \iota(\tau(\bar{x}))$ followed by its continuous extension to $\mathbb{C}_\ell$, as in (WM9). The same notation applies to the arbitrary embedding $\iota : \mathbb{C} \to \mathbb{C}_\ell$, exactly as in the definition of integral forms. The standard finite unitary equation is $h^{-1} = \bar{h}^{\mathsf{T}}$. Consequently

$$f_{\iota\circ c,\tau}(h^{-1}) = A_\tau^{\mathsf{T}}. \tag{4}$$

To check the embedding in this equation, for $a \in E$ one has $\overline{\tau(\bar{a})} = \tau(a)$, since τ commutes with the CM involution. Thus the conjugate embedding in the left side, applied to the entry $\bar{h}_{ba}$ of h^{-1}, is the original embedding applied to h_{ba}. The corresponding identity on completions follows by continuity. Also $f_{\iota,\tau}(h^{-1}) = A_\tau^{-1}$.

Put

$$u = (\iota \circ c)(\Xi(h)), \qquad v = \iota(\Xi'(h)), \qquad x = \mathscr{R}(A^{\mathsf{T}})u, \qquad y = \mathscr{R}(A^{-1})v.$$

The two integrality hypotheses, at this very h, assert precisely that every coordinate of x and y belongs to the valuation ring of $\mathbb{C}_\ell$. By (3),

$$x^{\mathsf{T}} G y = u^{\mathsf{T}} G v = \iota(\overline{\Xi(h)}^{\mathsf{T}} G \Xi'(h)) = \iota(\langle \Xi(h), \Xi'(h) \rangle_\kappa). \tag{5}$$

The middle equality uses that G is integral and hence fixed by the embedding. The left side is integral because x, y and G have integral entries. This proves integrality of each actual pointwise

Gram pairing. It makes no assertion that either change-of-gauge matrix is integral, or that it individually preserves the Gram form over $\mathbb{C}_\ell$.

Finally the Petersson product is exactly

$$\langle \Xi, \Xi' \rangle = \sum_{[h]} \frac{1}{d_h} \langle \Xi(h), \Xi'(h) \rangle_\kappa .$$

Multiply by N_{ch}. By (1), every coefficient N_{ch}/d_h is an ordinary integer. By (5), each remaining pointwise factor is integral under ι. The finite sum is therefore integral by the ultrametric inequality, giving the stated bound. No class representative, level or stabilizer weight has been replaced. □

Lemma 6.6.29. *Let $1 \le j \le m$, let Y be a short row family, $c'' \in \mathbb{C}^\times$, and $L = (L_i)_{i \in \mathrm{Mem}_j}$ divided lattices of $O_{j,1}$ with L_i glued for Λ_i, and suppose that $\mathcal{V}_j$ is a divided splitting for $O_{j,\vartheta}$ for every twist ϑ. For a twist ϑ let $\mathrm{gl}_\vartheta = \mathrm{gl}_{j,\vartheta}[L; c'']$, formed with Y, and gl_ϑ^* its adjoint; let F_i be the choice functions for Y, and for $\zeta \in \mathrm{Tab}_j$ and $i \in \mathrm{Mem}_j$ let $\zeta_i \colon \mathrm{Cl}^\circ \to \mathbb{V}_j^-$ be $\mathfrak{c} \mapsto \zeta_{i,\mathfrak{c}}$. Then there are $C \in \mathbb{C}$, numbers $c'_\vartheta \in \mathbb{C}$ (one for each twist ϑ), nonzero numbers $c_i^\circ \in \mathbb{C}$ ($i \in \mathrm{Mem}_j$) and a linear map $\Theta^\circ \colon \mathcal{A}^{\mathrm{good}}(W_j) \to \mathrm{Tab}_j$ such that for every twist ϑ:*

(i) $\Gamma_j(\vartheta) \neq 0$ *and* $\Gamma_j(\vartheta)\,|c'_\vartheta|^2 = C$;

(ii) $c'_\vartheta\, \mathrm{gl}_\vartheta^* \circ \Theta_{j,\vartheta} = \Theta^\circ$;

(iii) for all $y \in \mathcal{A}^{\mathrm{good}}(W_j)$ and $\zeta \in \mathrm{Tab}_j$, the functions $y\,\mathsf{F}_i\,\mathrm{tt}_j(\zeta_i)$ are integrable on $[\mathrm{U}(W_j)]$ and

$$\langle \zeta, \Theta^\circ y \rangle = \sum_{i \in \mathrm{Mem}_j} c_i^\circ \int_{[\mathrm{U}(W_j)]} y(g)\, \mathsf{F}_i(g)\, \mathrm{tt}_j(\zeta_i)(g)\, dg .$$

Proof. Fix j, Y, c'' and L. Write $\mathcal{V} = \mathcal{V}_j$, $\mathrm{C} = \mathrm{C}(\mathcal{V})$, $\ell = \mathrm{loss}(\mathcal{V})$ and $\beta_i = \beta_{L_i}$. These do not depend on the twist: $\mathcal{V}$, R_2, $\bar\varpi$, C and the conditions (GU1)–(GU4) read of a descent pair only its chosen places, inc, its ranks and $\kappa_O^\pm$, which are those of $O_{j,1}$ for every $O_{j,\vartheta}$ ((LF4)); β_i reads $\chi_O = v^{r_-(O)}$, free of ϑ. So each L_i is a divided lattice of $O_{j,\vartheta}$ glued for Λ_i. For every $A \in \mathrm{C}$ fix $k_A \in \mathbf{K}_0(\mathcal{R})$ with $\mathrm{red}_{\mathfrak{M}^2}(k_A) = A$ and with component 1 at every finite place w such that neither w nor $\bar w$ is a chosen place; it exists because the chosen places are split and pairwise not conjugate, and at such a pair $(w, \bar w)$ an element of $G_f(\mathcal{R})$ is given by an arbitrary component in $\mathrm{GL}_{\mathcal{R}}(\mathcal{O}_{E,w})$ (the component at $\bar w$ being determined by $g^* g = 1$). Since $A\bar\varpi = \bar\varpi$ and $\bar\varpi$ generates $\mathfrak{M}/\mathfrak{M}^2$, $A \equiv 1$ modulo every chosen place, so k_A is integral and reduces to 1 at every chosen place: $k_A \in \mathrm{K}_M$ (the finite point of W_j is a diagonal matrix of units, so integrality and reductions are read in $G_f(\mathcal{R})$).

Step 1: adjointness. Let ϑ be a twist, $O = O_{j,\vartheta}$, $y \in \mathcal{A}^{\mathrm{good}}(W_j)$ and $\zeta \in \mathrm{Tab}_j$. By the definition of the adjoint and (a) of Lemma 6.6.30 ($y \in \mathcal{A}_M(W_j)$),

$$\langle \zeta, \mathrm{gl}_\vartheta^* \Theta_{j,\vartheta} y \rangle = \langle \mathrm{gl}_\vartheta \zeta, \Theta_{j,\vartheta} y \rangle = \int_{[\mathrm{U}(W_j)]} y(u)\, \overline{\mathrm{Th}_O(\mathrm{gl}_\vartheta \zeta)(u)}\, du .$$

Step 2: the descent of the comparison form. By (TG6) and linearity of Th_O, $\mathrm{Th}_O(\mathrm{gl}_\vartheta \zeta) = M^\ell \sum_{(i,\mathfrak{c})} \mathrm{Th}_O(\Xi_{i,\mathfrak{c}})$ with

$$\Xi_{i,\mathfrak{c}} = \sum_{x \bmod \mathbf{J}_\vartheta(\Lambda_i)}^{\mathrm{cl}} \mathrm{pr}_{\mathcal{V},L_i}((x, x_{\mathfrak{c}}); \varphi''_{\vartheta,i}(x))(\zeta_{i,\mathfrak{c}})$$

and $\mathbf{J}_\vartheta(\Lambda_i) = \mathbf{K}_O[[\Lambda_i;\bar{\varpi}],\phi_j]$ (TG5). We apply Lemma 6.6.32 to O, $(N,m,a,z) = (\mathcal{B}_j,\mathcal{B}^\circ,\mathcal{B}^{\mathrm{c}},z_j)$, $\mathcal{V}$, $s=\Lambda_i$, $L=L_i$, $b=\nu''_{j,\vartheta}$, $b'=\upsilon^{\lfloor m/2\rfloor-j}$, the elements k_A, $h^\circ = x_{\mathfrak{c}}$, $\varphi=\varphi''_{\vartheta,i}$ and $\eta=\zeta_{i,\mathfrak{c}}$. The characters satisfy $bb' = \chi'_O$:

As $\bar{\varphi}''_{\vartheta,i} = c''\Upsilon_{\vartheta,i}$ and, by (XE7), the sum over $\mathfrak{c}\in\mathrm{Cl}^\circ$ of the second kernels of Lemma 6.6.32 (characters $\chi_O=\chi_{O_{j,1}}$, $\upsilon^{\lfloor m/2\rfloor-j}$, modulus $\mathfrak{M}^2$, datum $\mathbf{1}_{z_j}$, polynomial $\mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}(\bar{\zeta}_{i,\mathfrak{c}}))$, point $x_{\mathfrak{c}}$) is $\mathrm{tt}_j(\zeta_i)$, we get for $u\in\mathrm{U}(W_j)(\mathbb{A}_F)$

$$\overline{\mathrm{Th}_O(\mathrm{gl}_\vartheta\zeta)(u)} = M^\ell \sum_{i\in\mathrm{Mem}_j}\beta_i\sum_{A\in\mathrm{C}}\mathrm{cks}_{O,\nu''_{j,\vartheta}}([\Lambda_i;\bar{\varpi}],\phi_j;c''\Upsilon_{\vartheta,i})(uk_A)\,\mathrm{tt}_j(\zeta_i)(uk_A). \tag{6.137}$$

Step 3: the first-factor pairing. The coset kernel sum is linear in its function (each kernel is linear in its polynomial, and $\mathrm{Pol}_{\kappa_O^+}$, Let_1 are linear), so the coset kernel sum in (6.137) is $c''\,\mathrm{cks}_{O,\nu''_{j,\vartheta}}([\Lambda_i;\bar{\varpi}],\phi_j;\Upsilon_{\vartheta,i})$. Apply Proposition 6.6.33 with $a=\mathcal{B}^{\mathrm{c}}\sqcup\mathcal{B}_j$, $w=[\Lambda_i;\bar{\varpi}]$ and $u_0=(1\,|\,0)\in\mathrm{M}_{\mathcal{B}^{\mathrm{c}}\times a}(R_2)$, for which $u_0w=\Lambda_i$: the coset kernel sum is the left side $L_{\vartheta,i}$ of the third exchange. By Proposition 6.6.36 (for the short row family Y) there are $C\in\mathbb{R}$ and numbers c_ϑ with $\Gamma_j(\vartheta)\,|c_\vartheta|^2=C$ and $c_\vartheta L_{\vartheta,i}=\mathsf{F}_i$ for all i; the function $L_{\vartheta,i}$ there is the one of Proposition 6.6.33. Hence

$$y(u)\,\overline{\mathrm{Th}_O(\mathrm{gl}_\vartheta\zeta)(u)} = \sum_{i\in\mathrm{Mem}_j}\sum_{A\in\mathrm{C}} a_i\,f_{\vartheta,i}(uk_A),\qquad a_i = c''M^\ell\beta_i,\quad f_{\vartheta,i}=y\,L_{\vartheta,i}\,\mathrm{tt}_j(\zeta_i),$$

using $y(uk_A)=y(u)$ ($k_A\in\mathrm{K}_M$ and y is right invariant under K_M).

Step 4: integrability and integration. $L_{\vartheta,i}=\mathrm{cks}_{O,\nu''}(\dots)$ is a finite combination of kernels $\theta^{W_j,V''_j}_{\chi_O,\nu''_{j,\vartheta};\mathfrak{M}^2\mathfrak{Q}_O}[\Phi,P](\cdot,h)$ and $\mathrm{tt}_j(\zeta_i)$ a finite combination of kernels $\theta^{W_j,V^\circ}_{\chi_O,\upsilon^{\lfloor m/2\rfloor-j};\mathfrak{M}^2}[\Phi',P'](\cdot,x_{\mathfrak{c}})$. The characters $\chi_O=\upsilon^{m-j}$ and $\upsilon^{\lfloor m/2\rfloor-j}$ have trivial tame parts, and $\nu''_{j,\vartheta}=\mu_j^0\vartheta\upsilon^{e_j}$ has the tame part $\omega^j\psi_\vartheta$, trivial off $S_0\cup Q=\Sigma(\mathfrak{M}^2\mathfrak{Q}_O)$. By Lemma 6.6.37, $f_{\vartheta,i}$ is a finite sum of continuous, left invariant functions integrable on $[\mathrm{U}(W_j)]$, hence integrable. The quotient measure of $[\mathrm{U}(W_j)]$ is invariant under right translation ($\mathrm{U}(W_j)(\mathbb{A}_F)$ is unimodular), so $u\mapsto f_{\vartheta,i}(uk_A)$ is integrable with the same integral. By Steps 1 and 3,

$$\langle\zeta,\mathrm{gl}^*_\vartheta\Theta_{j,\vartheta}y\rangle = \#\mathrm{C}\sum_{i\in\mathrm{Mem}_j}a_i\int_{[\mathrm{U}(W_j)]}y\,L_{\vartheta,i}\,\mathrm{tt}_j(\zeta_i)\,du. \tag{6.138}$$

Step 5: (ii) and (iii). Put $c'_\vartheta=c_\vartheta$ and $c_i^\circ=\#\mathrm{C}\,a_i=c''M^\ell\,\#\mathrm{C}\,\beta_i$, independent of ϑ. It is nonzero: $c''\neq0$, $M\geq1$, $\#\mathrm{C}\geq1$, and $\beta_i=\chi_O[r](\delta)/|\delta|^{r/2}$ is a value of a unitary character divided by a positive number. Since $c_\vartheta L_{\vartheta,i}=\mathsf{F}_i$, the function $y\mathsf{F}_i\mathrm{tt}_j(\zeta_i)=c_\vartheta f_{\vartheta,i}$ is integrable, and multiplying (6.138) by c_ϑ (the inner product is linear in its second argument)

$$\langle\zeta,c'_\vartheta\,\mathrm{gl}^*_\vartheta\Theta_{j,\vartheta}y\rangle = \sum_{i\in\mathrm{Mem}_j}c_i^\circ\int_{[\mathrm{U}(W_j)]}y(g)\,\mathsf{F}_i(g)\,\mathrm{tt}_j(\zeta_i)(g)\,dg =: R(\zeta,y),$$

for every twist ϑ, the right side not involving ϑ. Let $\Theta^\circ=c'_1\,\mathrm{gl}_1^*\circ\Theta_{j,1}$, a linear map $\mathcal{A}^{\mathrm{good}}(W_j)\to\mathrm{Tab}_j$. The case $\vartheta=1$ is (iii). For any ϑ, $\langle\zeta,c'_\vartheta\mathrm{gl}^*_\vartheta\Theta_{j,\vartheta}y\rangle=\langle\zeta,\Theta^\circ y\rangle$ for all ζ, so $c'_\vartheta\mathrm{gl}^*_\vartheta\Theta_{j,\vartheta}y=\Theta^\circ y$: this is (ii).

Step 6: (i). By Lemma 6.6.38, $\Gamma_j(\vartheta)>0$, and $\Gamma_j(\vartheta)\,|c'_\vartheta|^2=\Gamma_j(\vartheta)\,|c_\vartheta|^2=C$ by Proposition 6.6.36. This is (i). □

Lemma 6.6.30. *Let $1\leq j\leq m$, ϑ a twist, $O=O_{j,\vartheta}$ and $\Xi\in\mathrm{Form}(O)$. Then:*

(a) for every $y \in \mathcal{A}_M(W_j)$ the function $u \mapsto y(u)\,\overline{\mathrm{Th}_O(\Xi)(u)}$ is integrable on $[\mathrm{U}(W_j)]$ and

$$\langle \Xi, \Theta_{j,\vartheta}(y)\rangle = \int_{[\mathrm{U}(W_j)]} y(u)\,\overline{\mathrm{Th}_O(\Xi)(u)}\,du;$$

(b) $\mathrm{Th}_O(\Xi) \in \mathcal{A}_M(W_j)$.

Proof. Fix j, ϑ and put $O = O_{j,\vartheta}$. The rank r is positive and $n = r + t > r$. We first prove (b), then construct the vector-valued integral that gives (a).

The transposed lift gives the required archimedean type. By Lemma 6.5.11, O fits $l = 2\varsigma$. By Lemma 6.4.15(e), with

$$\gamma(\tau) = r_-(O), \qquad \gamma'(\tau) = \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau),$$

the vector $v_{\mathrm{Har}_O(\xi_O)}$ is an edge from e_ς to $e_{l_O/2}$ for these weights. They are exactly the weights of the actual pair characters $\chi_O = \upsilon^{r-(O)}$ and $\chi'_O = \mu_O \upsilon^{\lfloor n/2 \rfloor}$. The modulus is the product of the chosen and twist places. It is nonempty because the chosen places of D are nonempty; its places are pairwise nonconjugate. The actual datum is

$$\mathrm{J}_O(\xi_O) = \mathrm{mod}_{\mathfrak{m}}(\Psi_O, v_{\mathrm{Har}_O(\xi_O)}).$$

Here Ψ_O is (DP7)'s block function, so this is a datum of precisely the form required by Lemma 6.3.76; its Fock vector is a polynomial vector.

For $\Xi \in \mathrm{Form}(O)$ put $Y_\Xi = \overline{F_\Xi}$. By Lemma 6.6.83(1), Y_Ξ is a form of type $\overline{e_{l_O/2}}$ on I_n. Apply the reverse assertion of Lemma 6.3.76(1) to $S = W$, $T = \mathrm{I}_n$, characters (χ_O, χ'_O), the modulus and datum just specified, and $F' = Y_\Xi$. It proves absolute convergence, at every u, of

$$L^{\mathsf{t}} Y_\Xi(u) = \int_{[\mathrm{U}(\mathrm{I}_n)]} \theta_O(\omega_O(u,h)\mathrm{J}_O(\xi_O)) Y_\Xi(h)\,dh,$$

and proves that this function is a form of type $\overline{e_\varsigma}$ on W. Thus all hypotheses of this convergence assertion, including the conjugate target type and the edge in both directions, have been supplied.

By Lemma 6.6.83(2), $\mathrm{Th}_O(\Xi) = c_O \overline{L^{\mathsf{t}} Y_\Xi}$, with $c_O > 0$ depending only on O. Complex conjugation takes a form of type $\overline{e_\varsigma}$ to a form of type e_ς: it preserves continuity, boundedness, rational invariance and an open finite level, and $R(e_\varsigma)\overline{H} = \overline{R(\overline{e_\varsigma})H}$. Consequently $\mathrm{Th}_O(\Xi)$ has the required archimedean type.

The finite level is the prescribed principal level. Let $k \in \mathrm{K}_M$ in the actual finite frame of W_j. Then k is integral at every finite place and reduces to 1 at every chosen place. In the notation of Lemma 6.5.10, this says $k \in J_O$; it also supplies the integrality hypothesis away from $S_O \cup \bar{S}_O$ in its part (c). With $F = \Upsilon(O)$, that part gives

$$\langle F, \omega_O((1,k),1)F\rangle = \langle F, F\rangle.$$

The actual pair action preserves the positive inner product by Lemma 4.1.1(2). Therefore

$$\|\omega_O((1,k),1)F - F\|^2 = 2\|F\|^2 - 2\,\mathrm{Re}\langle F, \omega_O((1,k),1)F\rangle = 0,$$

and $\omega_O((1,k),1)F = F$. By the real/finite factorization Lemma 4.1.1(5), the same finite action fixes $\mathrm{J}_O(\xi) = v_{\mathrm{Har}_O(\xi)} \otimes F$ for every ξ. This uses the full pair action in Lemma 6.5.10, including its characters, so there is no omitted finite character factor at the twist places.

The representation law now gives $\mathcal{C}_O(u(1,k),h)(\xi) = \mathcal{C}_O(u,h)(\xi)$. Taking the finite class sum in (DP9) shows

$$\mathrm{Th}_O(\Xi)(u(1,k)) = \mathrm{Th}_O(\Xi)(u) \qquad (k \in \mathrm{K}_M).$$

Together with the preceding archimedean-type conclusion, this is exactly $\mathrm{Th}_O(\Xi) \in \mathcal{A}_M(W_j)$, proving (b).

The vector kernel and its pairing direction. For fixed u and finite h, define a vector $\mathsf{Kern}_O(u,h) \in \mathbb{V}_O$ by

$$\langle \xi, \mathsf{Kern}_O(u,h)\rangle_{\kappa_O} = \theta_O(\omega_O(u,(1,h))\mathrm{J}_O(\bar{\xi})) \qquad (\xi \in \mathbb{V}_O). \tag{1}$$

The right side is conjugate-linear in ξ. The positive Gram matrix is invertible by Lemma 4.6.10(b), so (1) defines a unique vector. Taking conjugates gives

$$\langle \mathsf{Kern}_O(u,h), \xi\rangle_{\kappa_O} = \mathcal{C}_O(u,h)(\xi). \tag{2}$$

We check that $h \mapsto \mathsf{Kern}_O(u,h)$ belongs to $\mathrm{Form}(O)$. For $k' \in \mathbf{K}(O)$, Lemma 6.6.31(b) and the representation law give, after pairing with every ξ,

$$\mathsf{Kern}_O(u,hk') = \tilde{\eta}_O(k')\,\mathsf{Kern}_O(u,h).$$

For a rational point δ of $\mathrm{U}(\mathrm{I}_n)$, rational theta invariance Lemma 6.2.5 first changes its finite component δ_f to the inverse real component. Part (a) of Lemma 6.6.31 therefore gives

$$\begin{aligned}\langle \xi, \mathsf{Kern}_O(u,\delta_f h)\rangle &= \theta_O(\omega_O(u,(1,h))\mathrm{J}_O(\overline{\rho_O(\delta_\infty^{-1})\xi}))\\ &= \langle \rho_O(\delta_\infty^{-1})\xi, \mathsf{Kern}_O(u,h)\rangle\\ &= \langle \xi, \rho_O(\delta_\infty)\mathsf{Kern}_O(u,h)\rangle,\end{aligned}$$

where the last equality is Lemma 4.6.10(c). These are precisely (DP5)'s transformation laws. Denote this form by $\mathsf{Kern}_O(u)$.

The space $\mathrm{Form}(O)$ is finite dimensional: Lemma 6.4.74(1), for the nonempty standard definite rank n and the open subgroup $\mathbf{K}(O) \subseteq \mathbf{K}_0(n)$, gives finitely many finite double cosets and finite stabilizers. A form is determined by its values on those representatives in the finite-dimensional space $\mathbb{V}_O$. Its class-sum pairing is positive definite, since its summands have positive weights and the Gram pairing is positive definite. Continuity of $u \mapsto \mathsf{Kern}_O(u)$ follows from (1), the continuous actual action and bounded theta functional, evaluated at those finitely many representatives.

Equations (2), (DP5) and (DP9) give the exact identity

$$\mathrm{Th}_O(\Xi)(u) = \langle \mathsf{Kern}_O(u), \Xi\rangle_{\mathrm{Form}(O)}. \tag{3}$$

The class weights are the SAME $1/\#\Gamma_h$ on both sides. No level index or real-dimension factor has been introduced.

Integrability in the finite-dimensional space of forms. Choose an orthonormal basis $(\Xi_a)_{a\in A}$ of $\mathrm{Form}(O)$, with A finite. By (3) and the conjugate symmetry of the inner product,

$$y(u)\mathsf{Kern}_O(u) = \sum_{a\in A} y(u)\,\overline{\mathrm{Th}_O(\Xi_a)(u)}\,\Xi_a. \tag{4}$$

Every descent on the right belongs to $\mathcal{A}_M(W_j)$ by (b), already proved. Both it and y are continuous bounded forms, left invariant under rational points. The quotient $[\mathrm{U}(W_j)]$ has finite

volume by Theorem 4.2.18: here E/E^+ is a CM quadratic extension, W_j is positive dimensional with nondegenerate hermitian form, and the measure in (XD1) is induced from its nonzero Haar measure by counting measure on rational points. These are exactly the hypotheses of that theorem, regardless of signature. Each scalar product in (4) is therefore absolutely integrable. The finite sum proves Bochner integrability of $y(u)\mathsf{Kern}_O(u)$ in $\mathrm{Form}(O)$. It also proves directly that $y\,\overline{\mathrm{Th}_O(\Xi)}$ is integrable for every Ξ, as asserted in (a).

Identification of the vector integral with the single lift. The highest vector ξ_O is real: it is the evaluation vector at the 0-1 array in (LF5), whose products of minors have integer values. For a real target point $x \in G_\infty(1_n)$, Lemma 6.6.31(a), (1) and unitarity give

$$\begin{aligned}\theta_O(\omega_O(u,(x,h))\mathrm{J}_O(\xi_O)) &= \langle \rho_O(x)\xi_O, \mathsf{Kern}_O(u,h)\rangle \\ &= \langle \xi_O, \rho_O(x)^{-1}\mathsf{Kern}_O(u,h)\rangle \\ &= F^{l_O}_{\mathsf{Kern}_O(u)}(x,h).\end{aligned} \tag{5}$$

Thus the actual full theta kernel of (LF5), with the actual pair characters, is the attached function of this vector kernel.

Put

$$I_y = \int_{[\mathrm{U}(W_j)]} y(u)\mathsf{Kern}_O(u)\,du \in \mathrm{Form}(O).$$

For fixed (x,h) the map $\eta \mapsto F^{l_O}_\eta(x,h)$ is a linear functional on a finite-dimensional space, hence is continuous. It commutes with the Bochner integral just proved to exist. By (5),

$$F^{l_O}_{I_y}(x,h) = \int_{[\mathrm{U}(W_j)]} \theta_O(\omega_O(u,(x,h))\mathrm{J}_O(\xi_O))y(u)\,du. \tag{6}$$

This equality also proves absolute convergence of each scalar integral in (6). By (LF5), $\Theta_{j,\vartheta}(y)$ is the algebraic form attached to its right side. By Lemma 6.4.72(b), applied to the algebraic form I_y of weight (κ_O, e_O) and its doubled parameter l_O, the algebraic form attached to $F^{l_O}_{I_y}$ is I_y itself. Consequently

$$\Theta_{j,\vartheta}(y) = I_y. \tag{7}$$

Only continuous linear functionals of an integrable finite-dimensional vector have been moved through integrals; there is no unproved interchange of two noncompact integrals.

Finally apply the continuous linear functional $\eta \mapsto \langle \Xi, \eta\rangle$ to (7). By (3),

$$\begin{aligned}\langle \Xi, \Theta_{j,\vartheta}(y)\rangle &= \int_{[\mathrm{U}(W_j)]} y(u)\langle \Xi, \mathsf{Kern}_O(u)\rangle\,du \\ &= \int_{[\mathrm{U}(W_j)]} y(u)\,\overline{\mathrm{Th}_O(\Xi)(u)}\,du.\end{aligned}$$

This is (a), with the stated conjugate order and the original quotient measure. If $\mathrm{Form}(O) = 0$, its orthonormal basis is empty, all vector kernels and descents vanish, and the same argument gives the identity with both sides zero. □

Lemma 6.6.31. *Let O be a descent pair for ranks $r < n$, $\rho = \rho_{\kappa_O, e_O}$, and $u \in \mathrm{G}(\varepsilon_O)$.*

(a) For $y \in G_\infty(1_n)$ and $\xi \in \mathbb{V}_O$, $\omega_O\big(1,(y,1)\big)\,\mathrm{J}_O(\bar\xi) = \mathrm{J}_O\big(\overline{\rho(y)\xi}\big)$.

(b) For $k \in \mathbf{K}(O)$ and $\xi \in \mathbb{V}_O$, $\omega_O\big(1,(1,k)\big)\,\mathrm{J}_O(\xi) = \tilde\eta_O(k)\,\mathrm{J}_O(\xi)$.

(c) For every rational point $\gamma = (\gamma_\infty, \gamma_f)$ of $\mathrm{U}(\mathrm{I}_n)$, $h \in G_f(n)$, $k \in \mathbf{K}(O)$ and $\xi \in \mathbb{V}_O$,

$$\mathcal{C}_O(u, \gamma_f h k)\big(\tilde\eta_O(k)\,\rho_O(\gamma)\xi\big) = \mathcal{C}_O(u,h)(\xi);$$

in particular, for $\Xi \in \mathrm{Form}(O)$ the function $h \mapsto \mathcal{C}_O(u,h)(\Xi(h))$ is constant on the double cosets $\mathrm{U}(\mathrm{I}_n)(E)\,h\,\mathbf{K}(O)$.

(d) For $x \in G_f(n)$ and $v \in \mathbb{V}_O$, $\mathrm{Th}_O\big(\delta_x(v)\big)(u) = \mathcal{C}_O(u,x)(v)$.

(e) For $x \in G_f(n)$, $v \in \mathbb{V}_O$ and $\Xi \in \mathrm{Form}(O)$, $\langle \delta_x(v), \Xi\rangle = \langle v, \Xi(x)\rangle_{\kappa_O}$, the inner product of (DP5) on the left.

Proof. Put $\kappa = \kappa_O$, $e = e_O$, and let $\gamma_0(\tau) = r_-(O)$, $\gamma_0'(\tau) = \lfloor n/2\rfloor + \mathrm{wt}_O(\tau)$; by (ii) of Lemma 3.2.11, υ has weight 1 at every $\tau \in \Phi$, so $\chi_O = \upsilon^{r_-(O)}$ and $\chi_O' = \mu_O \upsilon^{\lfloor n/2\rfloor}$ have the weights γ_0 and γ_0'. The matrices $S_\lambda(z)$ have entries in $\mathbb{Z}[z]$ for every weight λ (the minors of zY are integral combinations of those of Y by the Cauchy–Binet formula, and (b_j) is a $\mathbb{Z}$-basis of ∇_λ), so $S_\lambda(\bar z) = \overline{S_\lambda(z)}$. The map J_O is $\mathbb{C}$-linear (Har_O is linear, and so are $P \mapsto v_P$ and $v \mapsto v \otimes \Upsilon(O)$), and so is $\mathcal{C}_O(u,h)$ (two complex conjugations).

(a). By (5) of Lemma 4.1.1 for the pair $(W(O), \mathrm{I}_n)$, the characters χ_O, χ_O' and $x = 1$, $k = k' = 1$, $\omega_O(1,(y,1))(v \otimes \Upsilon(O)) = (\Omega_{\gamma_0,\gamma_0'}(1,y)v) \otimes \Upsilon(O)$ for every v in the Fock model of $\mathrm{Hom}(W(O), \mathrm{I}_n)$. Every y_τ is block diagonal for the signs of I_n (all $+1$), so the second part of (5) applies to $v = v_P$: the scalar is $\prod_\tau \det(y_\tau)^{\gamma_0(\tau)-r_-(O)} = 1$ (the block of sign -1 of y_τ is empty and $x = 1$), and P is replaced by $P'(X) = P(X')$ with

$$X'_{\tau,\cdot,c} = y_\tau^{\mathsf T} X_{\tau,\cdot,c} \ \text{ if } \varepsilon_O(c) = 1, \qquad X'_{\tau,\cdot,c} = y_\tau^{-1} X_{\tau,\cdot,c} \ \text{ if } \varepsilon_O(c) = -1,$$

$X_{\tau,\cdot,c}$ the column $(X_{\tau,i,c})_{1\le i\le n}$. For a sign σ let $Y^\sigma(X)$ be the array with entries $Y^\sigma(X)_{\tau,i,a} = \sum X_{\tau,i,c}$ over c with $\varepsilon_O(c) = \sigma$, $\mathrm{ord}_O(c) = a$, so that $\mathrm{Let}_\sigma(Q)(X) = Q(Y^\sigma(X))$. Then $Y^1(X') = y^{\mathsf T} Y^1(X)$ and $Y^{-1}(X') = y^{-1} Y^{-1}(X)$, the matrices acting on the rows at every τ as in (WM2). For a weight λ of rank n, $\alpha \in \mathbb{V}_\lambda$ and a family z of $n \times n$ matrices,

$$\mathrm{Pol}_\lambda(\alpha)(zY) = \sum_i (G_\lambda \alpha)_i \sum_j S_\lambda(z)_{ij} b_j(Y) = \sum_j \big(S_\lambda(z)^{\mathsf T} G_\lambda \alpha\big)_j b_j(Y) = \mathrm{Pol}_\lambda\big(S_\lambda(z^{\mathsf T})\alpha\big)(Y)$$

by (a) of Lemma 4.6.10. Applied with $z = y^{\mathsf T}$ for κ_O^+ and $z = y^{-1}$ for κ_O^-, this shows that the substitution $X \mapsto X'$ carries $\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}\alpha)\,\mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}\beta)$ to the polynomial of $S_{\kappa_O^+}(y)\alpha \otimes S_{\kappa_O^-}((y^{-1})^{\mathsf T})\beta$. Let L be the linear map $\alpha \otimes \beta \mapsto \mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}\alpha)\,\mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}\beta)$, so $\mathrm{Har}_O(w) = L(C_O w)$. By (d) of Lemma 3.2.20 with $g = y$ and $e^-(\tau) = \sum_{1\le i<n} \kappa_O^-(\tau,i) = -e(\tau)$ (DP3),

$$\begin{aligned}\mathrm{Har}_O(w)' &= L\big((S_{\kappa_O^+}(y) \otimes S_{\kappa_O^-}((y^{-1})^{\mathsf T}))C_O w\big) = L\Big(C_O \prod_\tau \det(y_\tau)^{e(\tau)} S_\kappa(y) w\Big)\\ &= \mathrm{Har}_O\Big(\prod_\tau \det(y_\tau)^{e(\tau)} S_\kappa(y) w\Big).\end{aligned}$$

For $w = \bar\xi$, by (WM2),

$$\prod_\tau \det(y_\tau)^{e(\tau)} S_\kappa(y)\bar\xi = \overline{\prod_\tau \det(\bar y_\tau)^{e(\tau)} S_\kappa(\bar y)\xi} = \overline{\rho(y)\xi}.$$

Hence $\Omega_{\gamma_0,\gamma_0'}(1,y) v_{\mathrm{Har}_O(\bar\xi)} = v_{\mathrm{Har}_O(\overline{\rho(y)\xi})}$, and (DP8) gives (a).

(b). If $S_O = \emptyset$, then $\Upsilon(O) = v^0$ ($\Phi_O = 1$), $\tilde\eta_O = 1$, and the last sentence of (6) of Lemma 4.1.1 gives $\omega_O(1,(1,k))(v \otimes v^0) = \chi_O(\det k)\, v \otimes v^0$; here $\chi_O(\det k) = \upsilon(\det k)^{r_-(O)} = 1$

by (ii) of Lemma 3.2.11, $\det k$ having unit finite components and infinite components 1. If $S_O \neq \emptyset$, let $\mathfrak{m} = \prod_{w\in S_O} w$, a modulus with $\Sigma(\mathfrak{m}) = S_O$ by (DP1), and identify $R_\mathfrak{m} = \prod_{w\in S_O} k_w$ by the Chinese remainder theorem; reduction modulo $\mathfrak{m}$ of $k \in \mathbf{K}_0(n)$ is then $(\mathrm{red}_w k)_w$. Reading Ψ_O of (DP7) as a function on $n \times r$ matrices over $R_\mathfrak{m}$, its function $\Psi_O^\natural$ of (6) is Φ_O, so $\mathrm{J}_O(\xi) = v \otimes (\Psi_O^\natural \otimes_{S_O} v^0)$ with $v = v_{\mathrm{Har}_O(\xi)}$, and (6) gives

$$\omega_O(1,(1,k))\mathrm{J}_O(\xi) = \chi_O(\det k)\, v\otimes(\Psi_k^\natural \otimes_{S_O} v^0), \qquad \Psi_k(X) = \Psi_O(j^{-1}X),\ j = (\mathrm{red}_w k)_w \in \mathbf{L}(O),$$

with $\chi_O(\det k) = 1$ as before. For $w \in M_O$, $j_w \mathrm{Inc}_O = \mathrm{Inc}_O$ gives $j_w^{-1}\mathrm{Inc}_O = \mathrm{Inc}_O$, so $j_w^{-1}X_w = \mathrm{Inc}_O$ if and only if $X_w = \mathrm{Inc}_O$. For $w \in Q_O$, ordering the indices as the image of inc_O followed by its complement, $j_w = \begin{pmatrix} A & 0 \\ B & D \end{pmatrix}$ with A its inc-block, so $j_w^{-1} = \begin{pmatrix} A^{-1} & 0 \\ * & D^{-1} \end{pmatrix}$ and the inc-rows of $j_w^{-1}X_w$ are A^{-1} times the inc-rows of X_w. Hence $\Psi_O(j^{-1}X) = \prod_{w\in Q_O} \psi_{O,w}(\det A_w)^{-1}\, \Psi_O(X) = \eta_O(j)\Psi_O(X)$, i.e. $\Psi_k = \tilde\eta_O(k)\Psi_O$, which gives (b) by linearity of $\Psi \mapsto \Psi^\natural \otimes_{S_O} v^0$.

(c). In $\mathrm{G}(\varepsilon_O) \times \mathrm{G}(1_n)$ we have $(u,(1,\gamma_f hk)) = (1,\gamma)\,(u,(1,h))\,(1,(\gamma_\infty^{-1},1))\,(1,(1,k))$, the second components multiplying to $(\gamma_\infty\gamma_\infty^{-1}, \gamma_f hk)$. Put $\zeta = \overline{\rho_O(\gamma)}\xi$, so $\tilde\eta_O(k)\rho_O(\gamma)\xi = \overline{\tilde\eta_O(k)}\,\zeta$. Since ω_O is a representation ((2) of Lemma 4.1.1) and J_O is linear,

$$\omega_O(u,(1,\gamma_f hk))\mathrm{J}_O(\overline{\tilde\eta_O(k)}\zeta) = \overline{\tilde\eta_O(k)}\,\tilde\eta_O(k)\,\omega_O(1,\gamma)\,\omega_O(u,(1,h))\,\omega_O(1,(\gamma_\infty^{-1},1))\mathrm{J}_O(\zeta)$$

by (b); here $\overline{\tilde\eta_O(k)}\tilde\eta_O(k) = 1$, as $\tilde\eta_O(k)$ is a value of characters of finite groups. By (a) with $y = \gamma_\infty^{-1}$ and (c) of Lemma 4.6.10 ($\gamma_\infty \in \prod_\tau \mathrm{U}(n)$, $\rho_O(\gamma) = \rho(\gamma_\infty)$ by (DP3)), $\omega_O(1,(\gamma_\infty^{-1},1))\mathrm{J}_O(\zeta) = \mathrm{J}_O(\overline{\rho(\gamma_\infty)^{-1}\rho(\gamma_\infty)\xi}) = \mathrm{J}_O(\bar\xi)$. Finally $\theta_O \circ \omega_O(1,\gamma) = \theta_O$ by Lemma 6.2.5 (1 and γ are rational points). Applying θ_O and complex conjugation gives the identity of (c). For $\Xi \in \mathrm{Form}(O)$, (DP5) gives $\Xi(\gamma_f hk) = \tilde\eta_O(k)\rho_O(\gamma)\Xi(h)$, so $\mathcal{C}_O(u,\gamma_f hk)(\Xi(\gamma_f hk)) = \mathcal{C}_O(u,h)(\Xi(h))$.

(d). For $y \in G_f(n)$ the set of $\gamma \in \Gamma$ with $x^{-1}\gamma y \in \mathbf{K}(O)$ is finite (Γ_f is discrete in $G_f(n)$, as I_n is definite, and $x\mathbf{K}(O)y^{-1}$ is compact), so $\delta_x(v)(y)$ is a finite sum, and $\delta_x(v)(y) = 0$ unless $y \in \Gamma_f x\mathbf{K}(O)$. By (c) and (DP9), only the double coset $D = \Gamma_f x\mathbf{K}(O)$ contributes to the class sum, with its representative $h_D = \gamma_1 x k_1$ ($\gamma_1 \in \Gamma$, $k_1 \in \mathbf{K}(O)$), and the summand is constant on D:

$$\mathrm{Th}_O(\delta_x(v))(u) = \frac{1}{\#\Gamma_{h_D}}\,\mathcal{C}_O(u,x)(\delta_x(v)(x)), \qquad \delta_x(v)(x) = \sum_{\gamma\in\Gamma_x} \tilde\eta_O(x^{-1}\gamma x)\,\rho_O(\gamma)^{-1}v,$$

where $\Gamma_x = \Gamma \cap x\mathbf{K}(O)x^{-1}$. For $\gamma \in \Gamma_x$ put $k = x^{-1}\gamma_f x \in \mathbf{K}(O)$; then $x = \gamma_f^{-1}xk$, and (c) for the rational point γ^{-1}, the point x and k gives

$$\mathcal{C}_O(u,x)(\tilde\eta_O(k)\rho_O(\gamma)^{-1}v) = \mathcal{C}_O(u,\gamma_f^{-1}xk)(\tilde\eta_O(k)\rho_O(\gamma^{-1})v) = \mathcal{C}_O(u,x)(v).$$

So, by linearity of $\mathcal{C}_O(u,x)$,

$$\mathcal{C}_O(u,x)(\delta_x(v)(x)) = \#\Gamma_x \cdot \mathcal{C}_O(u,x)(v).$$

Finally $\Gamma_{h_D} = \Gamma \cap h_D\mathbf{K}(O)h_D^{-1} = \gamma_1\Gamma_x\gamma_1^{-1}$, so $\#\Gamma_{h_D} = \#\Gamma_x$, and (d) follows.

(e). For $\Xi_1, \Xi_2 \in \mathrm{Form}(O)$ the summand $h \mapsto \langle \Xi_1(h), \Xi_2(h)\rangle_{\kappa_O}$ of the inner product (DP5) is constant on the double cosets: by (DP5), (c) of Lemma 4.6.10 and $|\tilde\eta_O(k)| = 1$, $\langle \Xi_1(\gamma_f hk), \Xi_2(\gamma_f hk)\rangle_{\kappa_O} = |\tilde\eta_O(k)|^2\langle \rho_O(\gamma)\Xi_1(h), \rho_O(\gamma)\Xi_2(h)\rangle_{\kappa_O} = \langle \Xi_1(h), \Xi_2(h)\rangle_{\kappa_O}$. As in (d), only the double coset D of x contributes, and $\langle \delta_x(v), \Xi\rangle = \#\Gamma_{h_D}^{-1}\langle \delta_x(v)(x), \Xi(x)\rangle_{\kappa_O}$. For $\gamma \in \Gamma_x$ with $k = x^{-1}\gamma_f x$, (DP5) gives $\rho_O(\gamma)\Xi(x) = \Xi(\gamma_f x) = \Xi(xk) = \tilde\eta_O(k)\Xi(x)$, so, the form being conjugate-linear in its first argument and $\rho_O(\gamma)$ unitary, $\langle \tilde\eta_O(k)\rho_O(\gamma)^{-1}v, \Xi(x)\rangle_{\kappa_O} = \overline{\tilde\eta_O(k)}\langle v, \rho_O(\gamma)\Xi(x)\rangle_{\kappa_O} = |\tilde\eta_O(k)|^2\langle v, \Xi(x)\rangle_{\kappa_O} = \langle v, \Xi(x)\rangle_{\kappa_O}$. Summing over the $\#\Gamma_x = \#\Gamma_{h_D}$ elements of Γ_x gives (e). □

Lemma 6.6.32. *Let O be a descent pair for ranks $r < n$ with $M_O \neq \emptyset$, let N, m, a be finite index sets, $z\colon \{1,\dots,r\} \hookrightarrow m$ an embedding, $\mathcal{V} = (\varepsilon, \phi_{\mathcal{V}}, d)$ a divided splitting for (N, m, a, z), $s \in \mathrm{M}_{a\times N}(R_2)$, L a divided lattice glued for s, and b, b' automorphic characters of $\mathrm{U}(1)$ with $bb' = \chi'_O$. For every $A \in \mathrm{C}(\mathcal{V})$ let $k_A \in \mathbf{K}_0(r)$ satisfy $\mathrm{red}_{\mathfrak{M}_O^2}(k_A) = A$ and have component 1 at every finite place w such that neither w nor $\bar{w}$ is a chosen place of O. Let $h^\circ \in G_f(m)$, let $\varphi\colon G_f(N) \to \mathbb{V}_{\kappa_O^+}$ (weight κ_O^+ in rank $|N|$, rows N) be any function, $\bar{\varphi}$ the function with the conjugate coordinates, and $\eta \in \mathbb{V}_{\kappa_O^-}$ (rank $|m|$, rows m). Let*

$$\Xi = \sum_{h \bmod \mathbf{K}_O[[s;\bar{\varpi}],\phi_{\mathcal{V}}]}^{\mathrm{cl}} \mathrm{pr}_{\mathcal{V},L}\big((h,h^\circ);\varphi(h)\big)(\eta) \ \in \mathrm{Form}(O),$$

the sum (6.22) *over the double cosets $\mathrm{U}(\mathrm{I}_N)(F)\backslash G_f(N)/\mathbf{K}_O[[s;\bar{\varpi}],\phi_{\mathcal{V}}]$ at their fixed representatives. Then for every $g \in \mathrm{U}(W(O))(\mathbb{A}_F)$*

$$\mathrm{Th}_O(\Xi)(g) = \overline{\beta_L \sum_{A\in\mathrm{C}(\mathcal{V})} \mathrm{cks}_{O,b}([s;\bar{\varpi}],\phi_{\mathcal{V}};\bar{\varphi})(gk_A)\cdot \theta^{W(O),\mathrm{I}_m}_{\chi_O,b';\mathfrak{M}_O^2}\Big[\mathbf{1}_{I_z}, \mathrm{Let}_{-1}\big(\mathrm{Pol}_{\kappa_O^-}(\bar{\eta})\big)\Big](gk_A,h^\circ)},$$

where $\mathbf{1}_{I_z}$ is the indicator function of the inclusion matrix of z over R_2, $\bar{\eta}$ has the conjugate coordinates, and Let_{-1} is read with the rows in m.

Proof. Write $\gamma = \gamma_L$, $\mathfrak{n} = \mathfrak{M}_O^2\mathfrak{Q}_O$ (a modulus with $\Sigma(\mathfrak{n}) = S_O$, (KN3)), $\bar{T} = \mathrm{red}_0(T)$ for matrices T over $R_{\mathfrak{n}}$, and $\mathrm{cd} = \mathrm{cd}_{\psi_O^{\mathrm{res}},\mathrm{red}_0,[s;\bar{\varpi}],\phi_{\mathcal{V}}}$. For $A \in \mathrm{C}(\mathcal{V})$ let $\bar{k}_A = \mathrm{red}_{\mathfrak{n}}(k_A) \in \mathrm{GL}_r(R_{\mathfrak{n}})$; its reduction modulo $\mathfrak{M}_O^2$ is A, and its components at the places of Q_O are 1, since such a place w is neither chosen nor the conjugate of a chosen place (DP1), so k_A has component 1 there.

Step 1: reduction to one product form. The class sum defining Ξ is a finite sum $\sum_c \omega_c \,\mathrm{pr}_{\mathcal{V},L}((h_c,h^\circ);\varphi(h_c))(\eta)$ at the fixed representatives h_c with rational weights ω_c, and the coset kernel sum $\mathrm{cks}_{O,b}([s;\bar{\varpi}],\phi_{\mathcal{V}};\bar{\varphi})$ of (KN5) is the class sum over the same double cosets $\mathrm{U}(\mathrm{I}_N)(F)\backslash G_f(N)/\mathbf{K}_O[[s;\bar{\varpi}],\phi_{\mathcal{V}}]$, at the same representatives with the same weights. Th_O is linear and complex conjugation fixes the ω_c. So it suffices to show, for every $h \in G_f(N)$, $y \in \mathbb{V}_{\kappa_O^+}$ (rows N) and $g \in \mathrm{U}(W(O))(\mathbb{A}_F)$,

$$\mathrm{Th}_O\big(\mathrm{pr}_{\mathcal{V},L}((h,h^\circ);y)(\eta)\big)(g) = \overline{\beta_L \sum_{A\in\mathrm{C}(\mathcal{V})} K_1(gk_A,h)\,K_2(gk_A,h^\circ)}, \tag{6.139}$$

with $K_1 = \theta^{W(O),\mathrm{I}_N}_{\chi_O,b;\mathfrak{n}}\big[\mathrm{cd},\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(\bar{y}))\big]$ and $K_2 = \theta^{W(O),\mathrm{I}_m}_{\chi_O,b';\mathfrak{M}_O^2}\big[\mathbf{1}_{I_z},\mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}(\bar{\eta}))\big]$; applied with $y = \varphi(h_c)$, $\bar{y} = \bar{\varphi}(h_c)$, this gives the claim. Fix h, y, g and put $x' = \mathrm{diag}_\varepsilon(h,h^\circ)$, $x = x'\gamma$.

Step 2: the descent of the delta form. By (GU6) and (d) of Lemma 6.6.31, the left side of (6.139) is $\mathcal{C}_O(g,x)(y\cdot\eta) = \overline{\theta_O\big(\omega_O(g,(1,x))\,\mathrm{J}_O(\overline{y\cdot\eta})\big)}$ (DP9). By (b) and (c) of Lemma 6.6.26 (its hypotheses are those of (GU1) on $\kappa_O^{\pm}$),

$$\mathrm{J}_O(\overline{y\cdot\eta}) = v_P \otimes \Upsilon(O), \qquad P = \mathrm{Har}_O(\bar{y}\cdot\bar{\eta}) = P_1^\varepsilon P_2^\varepsilon,$$
$$P_1 = \mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(\bar{y})), \qquad P_2 = \mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}(\bar{\eta})),$$

P_i^ε the polynomials with the row b of their variables renamed $\varepsilon(b)$.

Step 3: the point γ moves into the datum. As ω_O is a representation ((2) of Lemma 4.1.1), $\omega_O(g,(1,x)) = \omega_O(g,(1,x'))\,\omega_O(1,(1,\gamma))$. By (5) of Lemma 4.1.1 (real components 1), $\omega_O(1,(1,\gamma))(v_P\otimes f) = v_P \otimes \omega_O(1,(1,\gamma))f$, and by (4) there, for the set S_O (which contains the conjugate of none of its members, (DP1)), the function $\Phi_O \in \mathcal{T}_{S_O}$ (DP7) and the

point γ of $G_f(n)$ (its components are 1 outside the chosen places and their conjugates, (GU2)), with the pair $(W(O),\mathrm{I}_n)$ of index sets $\{1,\dots,r\}$ and $\{1,\dots,n\}$,

$$\omega_O(1,(1,\gamma))(\Phi_O\otimes_{S_O}v^0)=\frac{\chi_O[r](\det_{S_O}\gamma)}{|\det_{S_O}\gamma|^{r/2}}\,\Phi'\otimes_{S_O}v^0,\qquad \Phi'(X)=\Phi_O(\gamma^{-1}X).$$

Since γ has components 1 at the places of Q_O, $\det_{S_O}\gamma=\delta$, and the scalar is β_L (GU2).

Step 4: the moved datum. Let Ψ_L be the function on $\mathrm{M}_{n\times r}(R_\mathfrak{n})$ with $\Psi_L(T)=\prod_{w\in Q_O}\psi_{O,w}(\det(\text{inc-rows of } T \bmod w))$ if $G_L\bar{T}=\bar{\varpi}\,\mathrm{Inc}_O$ and $\Psi_L(T)=0$ otherwise. We show $\Phi'=\Psi_L^\natural$ ((XD5): $\Psi_L^\natural(X)=\Psi_L(X_{S_O}\bmod\mathfrak{n})$ if X is integral at S_O, 0 otherwise), so that $\omega_O(1,(1,\gamma))\mathrm{J}_O(\overline{y\cdot\eta})=\beta_L\,\mathrm{mod}_\mathfrak{n}(\Psi_L,v_P)$. Let X be a finite adelic $n\times r$ matrix. (i) If $\gamma^{-1}X$ is integral at S_O, so is X: the matrix $\varpi_O\gamma^{-1}$ is integral, hence so is $(\varpi_O\gamma^{-1})^*=\bar{\varpi}_O\gamma$ (using $(\gamma^{-1})^*=\gamma$); at $w\in S_O$ the component of $\bar{\varpi}_O$ is the conjugate of that of ϖ_O at $\bar{w}$, which is 1 because $\bar{w}$ is not a chosen place (DP1); so γ_w is integral and $X_w=\gamma_w(\gamma^{-1}X)_w$ is integral. (ii) Let X be integral at S_O. At $w\in Q_O$, $\gamma_w=1$. At a chosen place w, with ϖ_w the component of ϖ_O (a generator of $w\mathcal{O}_{E,w}$): if $\gamma_w^{-1}X_w=\mathrm{Inc}_O+\varpi_wZ$ with Z integral, then $\varpi_w\gamma_w^{-1}X_w\equiv\varpi_w\mathrm{Inc}_O\pmod{w^2}$, and the left side modulo w^2 is the component at w of $G_L\bar{X}$; conversely, if $G_L\bar{X}=\bar{\varpi}\mathrm{Inc}_O$, then $\varpi_w\gamma_w^{-1}X_w=\varpi_w\mathrm{Inc}_O+\varpi_w^2Z$ with Z integral, so $\gamma_w^{-1}X_w=\mathrm{Inc}_O+\varpi_wZ$. Hence, for X integral at S_O: $\gamma^{-1}X$ is integral at S_O with $(\gamma^{-1}X)_w\equiv\mathrm{Inc}_O\pmod w$ for all $w\in M_O$ if and only if $G_L\bar{X}=\bar{\varpi}\mathrm{Inc}_O$, and then $(\gamma^{-1}X)_w=X_w$ at $w\in Q_O$. Comparing with (DP7), $\Phi'(X)=\Phi_O(\gamma^{-1}X)=\Psi_L^\natural(X)$ when X is integral at S_O; when it is not, both vanish by (i).

Step 5: the glued decomposition. For $T\in\mathrm{M}_{n\times r}(R_\mathfrak{n})$ write T_N, T_m for the matrices of its rows $\varepsilon(N)$ and $\varepsilon(m)$, and put $\Psi^\times(T)=\mathrm{cd}(T_N)\,\mathbf{1}_{I_z}(\overline{T_m})$. We show

$$\Psi_L(T)=\sum_{A\in\mathrm{C}(\mathcal{V})}\Psi^\times(T\bar{k}_A).\tag{6.140}$$

The reduction of $T\bar{k}_A$ modulo $\mathfrak{M}_O^2$ is $\bar{T}A$. By (GU3), $\Psi^\times(T\bar{k}_A)\neq0$ forces $\bar{T}A$ to be block normalised for s. If $G_L\bar{T}\neq\bar{\varpi}\mathrm{Inc}_O$, no $\bar{T}A$ is block normalised by (2) of (GU4), and both sides vanish. Otherwise, by (1) of (GU4), there is exactly one A with $\bar{T}A$ block normalised, and it remains to see that $\Psi^\times(T\bar{k}_A)=\Psi_L(T)$ for it. Here $\mathbf{1}_{I_z}((\bar{T}A)_m)=1$ and $[s;\bar{\varpi}](\bar{T}A)_N=[s;\bar{\varpi}]I_{\phi_\mathcal{V}}$, so $\Psi^\times(T\bar{k}_A)=\psi_O^{\mathrm{res}}(\det\sigma)$ with σ the $r\times r$ matrix of the rows $\varepsilon(\phi_\mathcal{V}(c))=\mathrm{inc}_O(c)$ of $T\bar{k}_A$ ((GU1), (KN2)). The rows $\bar{\varpi}\cdot1$ of $[s;\bar{\varpi}]$ give $\bar{\varpi}(\bar{T}A)_N=\bar{\varpi}I_{\phi_\mathcal{V}}$, and as $\bar{\varpi}u=0$ in R_2 exactly for $u\in\mathfrak{M}_O/\mathfrak{M}_O^2$, $(\bar{T}A)_N\equiv I_{\phi_\mathcal{V}}$ modulo every chosen place; so $\det\sigma\equiv1$ modulo every $w\in M_O$, and $\psi_{O,w}(\det\sigma\bmod w)=1$ there. At $w\in Q_O$, $\bar{k}_A$ is 1, so σ mod w is the inc-rows of T mod w. Hence $\psi_O^{\mathrm{res}}(\det\sigma)=\prod_{w\in Q_O}\psi_{O,w}(\det(\text{inc-rows of } T\bmod w))=\Psi_L(T)$ (both sides 0 when some of these determinants vanish), proving (6.140).

Step 6: the translates move to the first variable. By (6) of Lemma 4.1.1 for the modulus $\mathfrak{n}$ and $k=k_A\in\mathbf{K}_0(r)$, $k'=1$,

$$\omega_O((1,k_A),1)\,\mathrm{mod}_\mathfrak{n}(\Psi^\times,v_P)=\chi_O'(\det k_A)^{-1}\,\mathrm{mod}_\mathfrak{n}(\Psi^\times(\cdot\,\bar{k}_A),v_P).$$

Here $\chi_O'(\det k_A)=1$: $\chi_O'=\mu_O\upsilon^{\lfloor n/2\rfloor}$, υ has trivial tame part ((ii) of Lemma 3.2.11), $\det k_A$ has unit finite components and infinite components 1, and the tame part of μ_O is trivial off S_O (DP2), while $\det k_A$ is 1 at the places of Q_O and $\equiv1$ modulo every chosen place ($A\bar{\varpi}=\bar{\varpi}$ gives $A\equiv1$ modulo $\mathfrak{M}_O$). By Steps 3–5, linearity of $\mathrm{mod}_\mathfrak{n}$ in the function, and (2) of Lemma 4.1.1,

$$\begin{aligned}\theta_O(\omega_O(g,(1,x))\mathrm{J}_O(\overline{y\cdot\eta}))&=\beta_L\sum_{A\in\mathrm{C}(\mathcal{V})}\theta_O(\omega_O(gk_A,(1,x'))\,\mathrm{mod}_\mathfrak{n}(\Psi^\times,v_P))\\&=\beta_L\sum_A\theta^{W(O),\mathrm{I}_n}_{\chi_O,\chi_O';\mathfrak{n}}[\Psi^\times,P_1^\varepsilon P_2^\varepsilon](gk_A,x').\end{aligned}$$

Step 7: the kernel factors over $\mathrm{I}_n = \mathrm{I}_N \oplus \mathrm{I}_m$. Apply (3) and (4) of Lemma 6.4.96 with $S = W(O)$, e_S the identity, $T = \mathrm{I}_n$ and $e_T = \varepsilon$: $\mathrm{I}_n^{\varepsilon}$ is the standard space of signs $+1$ on $N \sqcup m$, i.e. $\mathrm{I}_N \oplus \mathrm{I}_m$; $x'^{\varepsilon} = \mathrm{diag}(h, h^{\circ})$ by the definition of $\mathrm{diag}_{\varepsilon}$; the function $\Psi^{\times}(P_{\varepsilon}^{\mathsf{T}} X')$ is $X' \mapsto \mathrm{cd}(X'_N)\mathbf{1}_{I_z}(\overline{X'_m})$, X'_N, X'_m the rows N, m of X' (the row $\varepsilon(a)$ of $P_{\varepsilon}^{\mathsf{T}} X'$ is the row a of X'); and the renaming of (4) turns $P_1^{\varepsilon} P_2^{\varepsilon}$ into $P_1 P_2$, read in the rows N and m. By (a) of Lemma 6.3.80 for the modulus $\mathfrak{n}$ and Lemma 6.4.66 ($\mathfrak{n} \subseteq \mathfrak{M}_O^2$, the function $\mathbf{1}_{I_z} \circ \mathrm{red}_0$),

$$\mathrm{mod}_{\mathfrak{n}}(\mathrm{cd} \otimes (\mathbf{1}_{I_z} \circ \mathrm{red}_0), v_{P_1 P_2}) = \mathrm{mod}_{\mathfrak{n}}(\mathrm{cd}, v_{P_1}) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{M}_O^2}(\mathbf{1}_{I_z}, v_{P_2}),$$

and by (d) of Lemma 6.3.52 (target sums, $\alpha = \chi_O$, $\beta = b$, $\beta' = b'$, $bb' = \chi'_O$)

$$\theta^{W(O),\mathrm{I}_n}_{\chi_O,\chi'_O;\mathfrak{n}}\big[\Psi^{\times}, P_1^{\varepsilon} P_2^{\varepsilon}\big](g k_A, x') = K_1(g k_A, h)\, K_2(g k_A, h^{\circ}).$$

With Steps 2 and 6 this is (6.139). □

Proposition 6.6.33. *Let $1 \le j \le m$, ϑ a twist with modulus Q, $O = O_{j,\vartheta}$, $\chi' = \chi'_{j,\vartheta}$, $\nu'' = \nu''_{j,\vartheta}$, and let $\mathfrak{n}$, χ_ϑ, α_e, W and Π_i^W be as in Lemma 6.6.23. For $\Lambda \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times \mathcal{B}_j}(R_{\mathfrak{M}^2})$ and $y \in \mathrm{M}_{\mathcal{B}_j \times \mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{n}})$ put $\psi^{\mathrm{inv}}_{\Lambda}(y) = \sum_{\gamma \in \mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{M}^2})} \psi_{\Lambda}(\mathrm{red}_0(y)\,\gamma)$, and for $X = (X' \,|\, X'') \in \mathrm{M}_{\mathcal{B}_j \times n}(R_{\mathfrak{n}})$ (X' the columns $\mathcal{B}^{\mathrm{c}}$) put $\Phi_{\vartheta,i}(X) = \chi_\vartheta(\det X'')\, \psi^{\mathrm{inv}}_{\Lambda_i}(X''^{-1} X')$ if X'' is invertible and $\Phi_{\vartheta,i}(X) = 0$ otherwise. The **left side of the third exchange** is the function on $\mathrm{U}(W_j)(\mathbb{A}_F)$*

$$L_{\vartheta,i}(g) = \sum_{h' \bmod \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})}^{\mathrm{cl}} \mathsf{a}_{\chi'}(h') \sum_{h \bmod \mathbf{K}_0(\mathcal{B}_j)}^{\mathrm{cl}} \theta^{W,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}\big[\Phi_{\vartheta,i}, \Pi_i^W\big]\big(\mathrm{diag}(h', g, 1, x_{\mathfrak{c}_i}), h\big),$$

with the block diagonal point of components h' on $\mathcal{B}^{\mathrm{c}}$, g on $\mathcal{R}$, 1 on $\mathcal{A}_j^- \sqcup \mathcal{A}_j^+$ and $x_{\mathfrak{c}_i}$ on $\mathcal{B}^{\flat}$ (the function of the same name in Proposition 6.6.36). Let a be a finite index set, $w \in \mathrm{M}_{a \times \mathcal{B}_j}(R_{\mathfrak{M}^2})$ and $u \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times a}(R_{\mathfrak{M}^2})$ with $uw = \Lambda_i$, and let $\phi_j \colon \mathcal{R} \hookrightarrow \mathcal{B}_j$ be the inclusion. Then for every $g \in \mathrm{U}(W_j)(\mathbb{A}_F)$

$$L_{\vartheta,i}(g) = \mathrm{cks}_{O,\nu''}(w, \phi_j; \Upsilon_{\vartheta,i})(g).$$

Proof. Fix i, g, w and u. By (XE1), $\nu''/\chi' = \nu_j^{\flat}$, so $\alpha_e = \chi' \nu_j^{\flat} \upsilon^m = \nu'' \upsilon^m$. The level system of O has the chosen places S_0 and the places of Q ((LF4)), so $\mathfrak{M}_O^2 \mathfrak{Q}_O = \mathfrak{n}$ and $\mathrm{red}_0 \colon R_{\mathfrak{n}} \to R_{\mathfrak{M}^2}$ is the reduction of (KN3). Let $H = \mathrm{Stab}_{\mathrm{red}_0}(w, \phi_j) \subseteq \mathrm{GL}_{\mathcal{B}_j}(R_{\mathfrak{n}})$; by (KN3), $\mathbf{K}_{\mathfrak{n}}[H] = \mathbf{K}_O[w, \phi_j]$. For $h' \in G_f(\mathcal{B}^{\mathrm{c}})$ write $p(h') = \mathrm{diag}(h', g, 1, x_{\mathfrak{c}_i})$.

Step 1: the inner class sum at the row-fixing level. We apply Lemma 6.6.34 with the index sets $\mathcal{B}^{\mathrm{c}}$, $\mathcal{B}_j$, a, $\mathcal{R}$ in the roles of n, b, c, r, the space W, the modulus $\mathfrak{n}$, $\chi = \chi_\vartheta$, $\alpha = \alpha_e$, $\beta = \nu''$, $P = \Pi_i^W$, $\phi = \mathrm{red}_0$, $\Lambda = w$, $e = \phi_j$ and $F = \psi^{\mathrm{inv}}_{\Lambda_i}$. Its hypotheses: α_e is tame of weight $\gamma(\tau) = m - \#D_j(\tau)$ for $(\mathfrak{n}, \chi_\vartheta)$ by (b) of Lemma 6.6.23, and $\Omega_{\gamma,0}(1, y) v_{\Pi_i^W} = v_{\Pi_i^W}$ for $y \in G_\infty(1_{\mathcal{B}_j})$ by (d) there. For $A \in H$ we have $w\,\mathrm{red}_0(A) = w$, hence $\Lambda_i\,\mathrm{red}_0(A) = uw\,\mathrm{red}_0(A) = \Lambda_i$, and for $y \in \mathrm{M}_{\mathcal{B}_j \times \mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{n}})$ and $\gamma \in \mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{M}^2})$

$$\mathrm{tr}\big(\mathrm{red}_0(Ay)\,\gamma\,\Lambda_i\big) = \mathrm{tr}\big(\mathrm{red}_0(y)\,\gamma\,\Lambda_i\,\mathrm{red}_0(A)\big) = \mathrm{tr}\big(\mathrm{red}_0(y)\,\gamma\,\Lambda_i\big),$$

so $\psi_{\Lambda_i}(\mathrm{red}_0(Ay)\gamma) = \psi_{\Lambda_i}(\mathrm{red}_0(y)\gamma)$ and $F(Ay) = F(y)$. The function Φ of Lemma 6.6.34 is $\Phi_{\vartheta,i}$; let Φ_0 be its function Φ_0:

$$\Phi_0(X) = \mathrm{cd}_{\chi_\vartheta,\mathrm{red}_0,w,\phi_j}(X''_{\phi_j})\, \psi^{\mathrm{inv}}_{\Lambda_i}(X') \quad \text{if the columns of } X'' \text{ off } \mathcal{R} \text{ are those of } 1,$$
$$\Phi_0(X) = 0 \text{ otherwise.}$$

Lemma 6.6.34 gives, for every h',

$$\sum_{h \bmod \mathbf{K}_0(\mathcal{B}_j)}^{\mathrm{cl}} \theta^{W,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi_{\vartheta,i},\Pi_i^W](p(h'),h) = \sum_{h \bmod \mathbf{K}_O[w,\phi_j]}^{\mathrm{cl}} \theta^{W,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi_0,\Pi_i^W](p(h'),h), \qquad (6.141)$$

and the summands on the right are invariant under $\mathrm{U}(V_j'')(F)$ on the left and $\mathbf{K}_O[w,\phi_j]$ on the right.

Step 2: exchange of the two class sums. Multiply (6.141) by $\mathsf{a}_{\chi'}(h')$ and take the class sum over h' modulo $\mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$. Both class sums are finite sums at fixed representatives with fixed weights, so they may be interchanged:

$$L_{\vartheta,i}(g) = \sum_{h \bmod \mathbf{K}_O[w,\phi_j]}^{\mathrm{cl}} K(h), \qquad K(h) = \sum_{h' \bmod \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})}^{\mathrm{cl}} \mathsf{a}_{\chi'}(h')\, \theta^{W,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi_0,\Pi_i^W](p(h'),h).$$

Step 3: regrouping W. Let $n_1 = \mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{B}_j^{\mathrm{add}}$, $\mathcal{B}_j^{\mathrm{add}} = \mathcal{A}_j^+ \sqcup \mathcal{B}^\flat \sqcup \mathcal{B}^{\mathrm{c}}$, and let $e\colon n_1 \to n$ be the identity on each of the blocks $\mathcal{R}, \mathcal{A}_j^-, \mathcal{A}_j^+, \mathcal{B}^\flat$ (into $\mathcal{B}_j$) and $\mathcal{B}^{\mathrm{c}}$. Each summand of W is a standard space of signs (W_j by (HP4)), and an orthogonal sum of standard spaces of signs is the standard space of the concatenated signs (block diagonal J and point); so W is the standard space of its signs s on n; since J_W and the point of W are diagonal with entries that depend only on the sign, the space W^e of (1) of Lemma 6.4.96 is the standard space of signs $s \circ e$ on n_1, $W^e = W_j \oplus \mathrm{I}^-_{\mathcal{A}_j^-} \oplus W_j^{\mathrm{add}}$. For a matrix X with columns n_1 let $X^{(e)} = XP_e$, the matrix with columns n whose column $e(b)$ is the column b of X (P_e the permutation matrix of e, as in Lemma 6.4.96); for a function Φ on $\mathrm{M}_{\mathcal{B}_j \times n}(R_{\mathfrak{n}})$ put $\Phi^e(X) = \Phi(X^{(e)})$, and for $P \in \mathbb{C}[x]_{\mathcal{B}_j \times n}$ let P^e be P with $x_{\tau,b,c}$ substituted for $x_{\tau,b,e(c)}$ ($b \in \mathcal{B}_j$, $c \in n_1$). We apply (3) and (4) of Lemma 6.4.96 with $S = W$, $e_S = e$, $T = V_j''$ and e_T the identity of $\mathcal{B}_j$ (so $T^{e_T} = T$ and $h^{e_T} = h$). By (4), $\mathrm{mod}_{\mathfrak{n}}(\Phi_0, v_{\Pi_i^W})^{e_T \times e} = \mathrm{mod}_{\mathfrak{n}}(\Phi_0^e, v_{(\Pi_i^W)^e})$; and $p(h')^e = P_e\, p(h')\, P_e^{\mathsf{T}}$ is the block diagonal point $\mathrm{diag}(g, 1, (1, x_{\mathfrak{c}_i}, h'))$ on $\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{B}_j^{\mathrm{add}}$. So by (3), for every h',

$$\theta^{W,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi_0,\Pi_i^W](p(h'),h) = \theta^{W^e,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi_0^e,(\Pi_i^W)^e]\big(\mathrm{diag}(g,1,(1,x_{\mathfrak{c}_i},h')),h\big),$$

where $(1, x_{\mathfrak{c}_i}, h')$ is the block diagonal point on $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat \sqcup \mathcal{B}^{\mathrm{c}}$. For $X \in \mathrm{M}_{\mathcal{B}_j \times n_1}(R_{\mathfrak{n}})$ with the column blocks $X_{\mathcal{R}}$, X_- and X_{add}, the matrix $X^{(e)}$ has $X''_{\phi_j} = X_{\mathcal{R}}$, its columns $\mathcal{A}_j^-$ are X_-, its columns $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat$ are those of X_{add}, and X' is the block $X^{\mathrm{c}}_{\mathrm{add}}$ of X_{add} on $\mathcal{B}^{\mathrm{c}}$. The columns of X'' off $\mathcal{R}$ are those of 1 exactly when X_- is the inclusion matrix of $\mathcal{A}_j^-$ in $\mathcal{B}_j$ and the columns $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat$ of X_{add} are those of the inclusion matrix of $\mathcal{A}_j^+ \sqcup \mathcal{B}^\flat$ in $\mathcal{B}_j$; in that case $\psi^{\mathrm{inv}}_{\Lambda_i}(X') = \Psi^{\mathrm{add}}_{\Lambda_i}(X_{\mathrm{add}})$ by (XE6). As $\chi_\vartheta = \psi^{\mathrm{res}}_O$ ((a) of Lemma 6.6.23),

$$\Phi_0^e(X) = \mathrm{cd}(X_{\mathcal{R}}) \cdot \mathbf{1}_j^-(X_-) \cdot \Psi^{\mathrm{add}}_{\Lambda_i}(X_{\mathrm{add}}), \qquad \mathrm{cd} = \mathrm{cd}_{\psi^{\mathrm{res}}_O,\mathrm{red}_0,w,\phi_j}.$$

Step 4: the polynomial. $(\Pi_i^W)^e$ is Π_i with $x_{\tau,b,c}$ renamed $x_{\tau,b,e^{-1}\pi_j(c)}$; $e^{-1}\pi_j$ sends $c < r_+$ to the basis vector of W_j of number c in $\mathcal{R}$ and is the identity on $\mathcal{B}_j^{\mathrm{add}}$. For $l \in I_{\kappa_O^+}$ let P_l be as in Lemma 6.6.35 and $P_l^{\mathcal{R}}$ the polynomial P_l with $x_{\tau,b,c}$ renamed $x_{\tau,b,\pi_j(c)}$, in the columns $\mathcal{R}$. By Lemma 6.6.35,

$$(\Pi_i^W)^e = \sum_{l \in I_{\kappa_O^+}} P_l^{\mathcal{R}} \cdot \mathrm{lc}_{i,l},$$

with $\mathrm{lc}_{i,l}$ in the columns $\mathcal{B}_j^{\mathrm{add}}$. Moreover $P_l^{\mathcal{R}} = \mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(e_l))$, rows in $\mathcal{B}_j$: Let_1 substitutes for $y_{\tau,b,c}$ the sum of $x_{\tau,b,c'}$ over the basis vectors c' of W_j of sign $+1$ with $\mathrm{ord}(c') = c$; for these

$\mathrm{ord}(c')$ is the number of c' ((LF4)), and the numbers of the vectors of sign $+1$ are $0,\dots,r_+-1$ ((HP4)); so the sum is $x_{\tau,b,\pi_j(c)}$ for $c<r_+$ and empty for $c\ge r_+$, which is the substitution defining P_l, renamed by π_j.

Step 5: the kernel factors. The kernels are linear in the polynomial (the Fock vector, the datum modulo $\mathfrak{n}$ and the theta functional are linear). For each l, by (b) of Lemma 6.3.80 applied twice (to $W_j\oplus(\mathrm{I}^-_{\mathcal{A}_j^-}\oplus W_j^{\mathrm{add}})$ and to $\mathrm{I}^-_{\mathcal{A}_j^-}\oplus W_j^{\mathrm{add}}$; the second block carries the polynomial 1),

$$\mathrm{mod}_{\mathfrak{n}}(\Phi_0^e, v_{P_l^{\mathcal{R}}\mathrm{lc}_{i,l}}) = \mathrm{mod}_{\mathfrak{n}}(\mathrm{cd}, v_{P_l^{\mathcal{R}}})\boxtimes^{\mathrm{sc}}\Big(\mathrm{mod}_{\mathfrak{n}}(\mathbf{1}_j^-, v_1)\boxtimes^{\mathrm{sc}}\mathrm{mod}_{\mathfrak{n}}(\Psi^{\mathrm{add}}_{\Lambda_i}, v_{\mathrm{lc}_{i,l}})\Big).$$

The signs of W_j have $r_-(O)=r-r_+=m-j$ entries -1 ($r=k+m-1$), so $\chi_O=\upsilon^{m-j}$ and $\alpha_e=\nu''\upsilon^m=\chi_O\cdot\upsilon^j\cdot\nu''$. By (d) of Lemma 6.3.52 (source sums, applied twice, second character ν''),

$$\begin{aligned}&\theta^{W^e,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi_0^e, P_l^{\mathcal{R}}\mathrm{lc}_{i,l}]\,(\mathrm{diag}(g,1,(1,x_{\mathfrak{c}_i},h')),h)\\ &\quad=\theta^{W_j,V_j''}_{\chi_O,\nu'';\mathfrak{n}}[\mathrm{cd},P_l^{\mathcal{R}}](g,h)\;\theta^{\mathrm{I}^-_{\mathcal{A}_j^-},V_j''}_{\upsilon^j,\nu'';\mathfrak{n}}[\mathbf{1}_j^-,1](1,h)\;\theta^{W_j^{\mathrm{add}},V_j''}_{\nu'',\nu'';\mathfrak{n}}[\Psi^{\mathrm{add}}_{\Lambda_i},\mathrm{lc}_{i,l}]((1,x_{\mathfrak{c}_i},h'),h).\end{aligned}$$

Only the last factor depends on h'. Multiplying by $\mathsf{a}_{\chi'}(h')$ and taking the class sum over h', by Steps 3 and 4, linearity in the polynomial and the definition (XE6) of $\Upsilon_{\vartheta,i}(h)_l$ (with $\mathfrak{n}=\mathfrak{M}^2\mathfrak{Q}_O$),

$$K(h)=\sum_{l\in I_{\kappa_O^+}}\Upsilon_{\vartheta,i}(h)_l\,\theta^{W_j,V_j''}_{\chi_O,\nu'';\mathfrak{n}}[\mathrm{cd},P_l^{\mathcal{R}}](g,h)=\theta^{W_j,V_j''}_{\chi_O,\nu'';\mathfrak{n}}\Big[\mathrm{cd},\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(\Upsilon_{\vartheta,i}(h)))\Big](g,h),$$

since $\sum_l\Upsilon_{\vartheta,i}(h)_l\,\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(e_l))=\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(\Upsilon_{\vartheta,i}(h)))$ by linearity.

Step 6: conclusion. By Step 2 and Step 5, $L_{\vartheta,i}(g)$ is the class sum over h modulo $\mathbf{K}_O[w,\phi_j]$ of the kernels of $(W(O),\mathrm{I}_{\mathcal{B}_j})$ with characters χ_O, ν'', modulus $\mathfrak{M}_O^2\mathfrak{Q}_O$, datum $\mathrm{cd}_{\psi_O^{\mathrm{res}},\mathrm{red}_0,w,\phi_j}$ and polynomial $\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}(\Upsilon_{\vartheta,i}(h)))$ at (g,h), which is $\mathrm{cks}_{O,\nu''}(w,\phi_j;\Upsilon_{\vartheta,i})(g)$ by (KN5). □

Lemma 6.6.34. *Let n, b, c, r be finite index sets, W a space with index set $n\sqcup b$, and write the $b\times(n\sqcup b)$ matrices as $x=(x'\,|\,x'')$ with x' of size $b\times n$ and x'' of size $b\times b$. Let $\mathfrak{m}$ be a modulus, χ a multiplicative character of $R_{\mathfrak{m}}$, α an automorphic character of $\mathrm{U}(1)$ tame of weight γ for $(\mathfrak{m},\chi)$, and β an automorphic character of $\mathrm{U}(1)$. Let $P\in\mathbb{C}[x]_{b\times(n\sqcup b)}$ with $\Omega_{\gamma,0}(1,u)\,v_P=v_P$ for every $u\in G_\infty(1_b)$. Let $\phi\colon R_{\mathfrak{m}}\to S$ be a homomorphism of commutative rings, $\Lambda\in\mathrm{M}_{c\times b}(S)$, $e\colon r\hookrightarrow b$ an embedding, $H=\mathrm{Stab}_\phi(\Lambda,e)$, and F a function on $\mathrm{M}_{b\times n}(R_{\mathfrak{m}})$ with $F(Ay)=F(y)$ for all $A\in H$. Put*

$$\Phi(x)=\begin{cases}\chi(\det x'')\,F(x''^{-1}x') & x''\text{ invertible},\\ 0 & \text{otherwise},\end{cases}$$

$$\Phi_0(x)=\begin{cases}\mathrm{cd}_{\chi,\phi,\Lambda,e}(x''_e)\,F(x') & \text{the columns of } x''\text{ off } e(r)\text{ are those of } 1,\\ 0 & \text{otherwise},\end{cases}$$

x''_e the $b\times r$ matrix of the columns $e(r)$ of x''. Then for every $g\in\mathrm{U}(W)(\mathbb{A}_F)$ the functions $h\mapsto\theta^{W,\mathrm{I}_b}_{\alpha,\beta;\mathfrak{m}}[\Phi,P](g,h)$ and $h\mapsto\theta^{W,\mathrm{I}_b}_{\alpha,\beta;\mathfrak{m}}[\Phi_0,P](g,h)$ on $\mathrm{U}(\mathrm{I}_b)(\mathbb{A}_{F,f})$ are left invariant under $\mathrm{U}(\mathrm{I}_b)(F)$ and right invariant under $\mathbf{K}_b$ and under $\mathbf{K}_{\mathfrak{m}}[H]$ respectively, and

$$\sum_{h\bmod\mathbf{K}_{\mathfrak{m}}[H]}^{\mathrm{cl}}\theta^{W,\mathrm{I}_b}_{\alpha,\beta;\mathfrak{m}}[\Phi_0,P](g,h)=\sum_{h\bmod\mathbf{K}_b}^{\mathrm{cl}}\theta^{W,\mathrm{I}_b}_{\alpha,\beta;\mathfrak{m}}[\Phi,P](g,h).$$

Proof. Write $R = R_{\mathfrak{m}}$, $A = \Sigma(\mathfrak{m})$, $\Gamma = \mathrm{U}(\mathrm{I}_b)(F)$, $\mathrm{K} = \mathbf{K}_b$, $\mathrm{K}_H = \mathbf{K}_{\mathfrak{m}}[H]$, and, for g fixed and a function Ψ on $\mathrm{M}_{b\times(n\sqcup b)}(R)$, $\vartheta_\Psi(h) = \theta^{W,\mathrm{I}_b}_{\alpha,\beta;\mathfrak{m}}[\Psi, P](g,h)$; $\Psi \mapsto \vartheta_\Psi$ is linear, since $\Psi \mapsto \mathrm{mod}_{\mathfrak{m}}(\Psi, v_P)$ is ((XD5), (WR6)). For $B \in \mathrm{GL}_b(R)$ put $(\mathrm{tr}_B\Psi)(x) = \chi(\det B)\,\Psi(B^{-1}x)$.

Step 1: Φ_0 is Φ cut down to $x'' \in H$. Let $z \in \mathrm{M}_b(R)$ have the columns of 1 off $e(r)$, and $I_e \in \mathrm{M}_{b\times r}(R)$ the matrix of the columns $e(r)$ of 1. Then $z = 1 + uI_e^{\mathsf{T}}$ with $u = (z-1)I_e$, $z_e = I_e + u$, and the $r \times r$ matrix of the rows $e(r)$ of z_e is $1_r + I_e^{\mathsf{T}}u$, whose determinant is $\det(1_b + uI_e^{\mathsf{T}}) = \det z$ (Sylvester's identity). Moreover $\Lambda\phi(z_e) = \Lambda I_e$ iff $\Lambda\phi(u) = 0$ iff $\Lambda\phi(z) = \Lambda$ (as $\phi(I_e) = I_e$ and $I_e^{\mathsf{T}}I_e = 1_r$). Hence $\mathrm{cd}_{\chi,\phi,\Lambda,e}(z_e) = \chi(\det z)$ if $\Lambda\phi(z) = \Lambda$, and 0 otherwise. If z is invertible and $\Lambda\phi(z) = \Lambda$, then $z \in H$ and $F(z^{-1}y) = F(y)$; if z is not invertible, $\det z$ is not a unit and $\chi(\det z) = 0$. A z whose columns off $e(r)$ are not those of 1 is not in H. Therefore

$$\Phi_0(x) = \Phi(x) \ \text{ if } x'' \in H, \qquad \Phi_0(x) = 0 \ \text{ otherwise.} \tag{1}$$

Step 2: translates. For $B \in \mathrm{GL}_b(R)$, $\mathrm{tr}_B\Phi = \Phi$: if x'' is invertible,

$$\chi(\det B)\chi(\det B^{-1}x'')F((B^{-1}x'')^{-1}B^{-1}x') = \chi(\det x'')F(x''^{-1}x'),$$

and otherwise both sides vanish. By (1), $(\mathrm{tr}_B\Phi_0)(x) = (\mathrm{tr}_B\Phi)(x)$ if $B^{-1}x'' \in H$ and 0 otherwise, that is $\mathrm{tr}_B\Phi_0 = \Phi \cdot \mathbf{1}[x'' \in BH]$. If $\mathcal{B}$ is a set of representatives of $\mathrm{GL}_b(R)/H$, the cosets BH partition the invertible matrices, and Φ vanishes at the others; so

$$\Phi = \sum_{B\in\mathcal{B}} \mathrm{tr}_B\Phi_0, \qquad \mathrm{tr}_k\Phi_0 = \Phi_0 \ \ (k \in H). \tag{2}$$

Step 3: right translation of the kernels. Let $k \in \mathrm{K}$ and $\bar{k} = \mathrm{red}_{\mathfrak{m}}(k)$. By (6) of Lemma 4.1.1 (with the element 1 of the group of W and k of that of I_b), $\omega_{\alpha,\beta}(1,k)\,\mathrm{mod}_{\mathfrak{m}}(\Psi, v_P) = \alpha(\det k)\,\mathrm{mod}_{\mathfrak{m}}(\Psi(\bar{k}^{-1}\,\cdot\,), v_P)$. The finite components of $\det k$ are units and its infinite components are 1, so by the definition of the weight and tame part (Definition 3.1.2) and (XD4), $\alpha(\det k) = \prod_{w\in A}\psi_w(\det k_w \bmod w) = \chi(\det \bar{k})$. As $\omega_{\alpha,\beta}$ is a representation ((2) of Lemma 4.1.1),

$$\vartheta_\Psi(hk) = \vartheta_{\mathrm{tr}_{\bar{k}}\Psi}(h) \qquad (h \in \mathrm{U}(\mathrm{I}_b)(\mathbb{A}_{F,f}),\ k \in \mathrm{K}). \tag{3}$$

By (2) and (3), ϑ_Φ is right invariant under K and ϑ_{Φ_0} under K_H. The places of A satisfy $w \neq \bar{w}$, so the reduction $\mathrm{K} \to \mathrm{GL}_b(R)$ is onto (at each $w \in A$ the component of $\mathbf{K}_b$ above the place of F below w is $\mathrm{GL}_b(\mathcal{O}_{E,w})$ through ι_w); choose $k_B \in \mathrm{K}$ with $\mathrm{red}_{\mathfrak{m}}(k_B) = B$. By (2), linearity and (3),

$$\vartheta_\Phi(h) = \sum_{B\in\mathcal{B}} \vartheta_{\Phi_0}(hk_B). \tag{4}$$

Step 4: left invariance. Let $\delta \in \Gamma$, with archimedean and finite components δ_∞, δ_f. By Lemma 6.2.5, $\theta^{W,\mathrm{I}_b}_{\alpha,\beta}(\varphi)(g,(1,\delta_f h)) = \theta^{W,\mathrm{I}_b}_{\alpha,\beta}(\varphi)(g,(\delta_\infty^{-1},h))$ for every datum φ, and by (5) of Lemma 4.1.1, $\omega_{\alpha,\beta}(1,(\delta_\infty^{-1},1))\,\mathrm{mod}_{\mathfrak{m}}(\Psi, v_P) = \mathrm{mod}_{\mathfrak{m}}(\Psi, \Omega_{\gamma,0}(1,\delta_\infty^{-1})v_P) = \mathrm{mod}_{\mathfrak{m}}(\Psi, v_P)$ by the hypothesis on P (the second weight does not enter at the point 1 of the group of W). Hence $\vartheta_\Psi(\delta_f h) = \vartheta_\Psi(h)$ for every Ψ.

Step 5: the tower of class sums. Γ is discrete in $G = \mathrm{U}(\mathrm{I}_b)(\mathbb{A}_{F,f})$ (I_b is definite), and for an open compact K' and a function f left invariant under Γ and right invariant under K', with a Haar measure μ of G and the quotient measure on $\Gamma\backslash G$,

$$\int_{\Gamma\backslash G} f\,d\mu = \mu(K') \sum_{h \bmod K'}^{\mathrm{cl}} f(h) :$$

$\Gamma\backslash G$ is the finite disjoint union of the $\Gamma\backslash\Gamma h_{\mathfrak{c}}K'$, on which f is constant, and $\Gamma\backslash\Gamma h_{\mathfrak{c}}K'$ is the quotient of $h_{\mathfrak{c}}K'$ by the finite group $\Gamma\cap h_{\mathfrak{c}}K'h_{\mathfrak{c}}^{-1}$, of measure $\mu(K')/\#(\Gamma\cap h_{\mathfrak{c}}K'h_{\mathfrak{c}}^{-1})$. Apply this to $f=\vartheta_\Phi$, $K'=\mathrm{K}$ and to $f=\vartheta_{\Phi_0}$, $K'=\mathrm{K}_H$; K_H is open in K of index $\#\mathcal{B}$, as the preimage of H under the surjection onto $\mathrm{GL}_b(R)$. By (4) and the right invariance of μ,

$$\mu(\mathrm{K})\sum_{h\bmod \mathrm{K}}^{\mathrm{cl}}\vartheta_\Phi=\sum_{B\in\mathcal{B}}\int\vartheta_{\Phi_0}(hk_B)\,d\mu(h)=\#\mathcal{B}\,\mu(\mathrm{K}_H)\sum_{h\bmod \mathrm{K}_H}^{\mathrm{cl}}\vartheta_{\Phi_0},$$

and $\#\mathcal{B}\,\mu(\mathrm{K}_H)=\mu(\mathrm{K})$. □

Lemma 6.6.35. *Let $1\le j\le m$, let $i\in\mathrm{Mem}_j$, and write $\kappa=\kappa^+_{O_{j,1}}$. For $l\in I_\kappa$ let $e_l\in\mathbb{V}_j^+$ be the l-th unit vector and let $P_l\in\mathbb{C}[x]_{\mathcal{B}_j\times\{0,\dots,r_+-1\}}$ be the polynomial obtained from $\mathrm{Pol}_\kappa(e_l)$ by substituting $x_{\tau,b,c}$ for $y_{\tau,b,c}$ when $0\le c<r_+$ and 0 for $y_{\tau,b,c}$ when $c\ge r_+$ ($\tau\in\Phi$, $b\in\mathcal{B}_j$). Then, in $\mathbb{C}[x]_{\mathcal{B}_j\times\mathcal{L}_j}$,*

$$\Pi_i=\sum_{l\in I_\kappa}P_l\cdot\mathrm{lc}_{i,l},$$

both factors of each term read in $\mathbb{C}[x]_{\mathcal{B}_j\times\mathcal{L}_j}$ through the inclusions of $\{0,\dots,r_+-1\}$ and of $\mathcal{B}_j^{\mathrm{add}}$ in $\mathcal{L}_j$.

Proof. **The determinant indices have exactly the required heights.** Fix j and i, and put $\kappa=\kappa^+_{O_{j,1}}$. The formulas for the target parameter and (LF4) give

$$\kappa(\tau,h)=0\quad(1\le h<k-1\text{ or }h>r_+),\qquad\kappa(\tau,r_+)=\Delta',\quad r_+=k+j-1.\tag{1}$$

Here the weight is read in rank $|\mathcal{B}_j|$. We check the endpoints explicitly. Before position $k-1$, consecutive entries of the target parameter differ by one, so the positive part in (LF4) is zero. At $h=r_+$, the preceding entry is $\Delta/2-\kappa_j(\tau)$, and the maximum in (LF4) is $(t-1)/2-\kappa_j(\tau)$. Their difference minus one is $\Delta/2-(t+1)/2=\Delta'$. For $h>r_+$, the preceding entry has the form $\Delta/2-\kappa_{h+1-k}(\tau)$, with $h+1-k\ge j+1$. Since $\kappa_{j+1}=\kappa_j+\Delta$, it is at most $-\kappa_j-\Delta/2$, hence at most the threshold $(t-1)/2-\kappa_j$; the positive part is again zero. The gap inequalities used here follow from the admissible ranks and $\Delta=2r^8$, $t=5r$; in particular $\Delta>t+1$. Thus the index set $D_j(\tau)$ has one determinant of height h for each of the $\kappa(\tau,h)$ columns: the indices (h,c) provide those below r_+, and the Δ' extra indices provide those at r_+.

Clearing columns makes each factor a linear combination of minors. Let

$$R_{\mathrm{add}}=\mathbb{C}[x_{\tau,b,c}:\tau\in\Phi,\ b\in\mathcal{B}_j,\ c\in\mathcal{B}_j^{\mathrm{add}}].$$

The disjoint union defining $\mathcal{L}_j$ identifies the full polynomial ring with the polynomial ring over R_{add} in the first r_+ columns. This is a literal rearrangement of independent indeterminates.

Consider a determinant indexed by $d=(h,c)$. Its $2m$ constant rows are those of (XE6). In particular their entries in columns $0,\dots,h-1$ are zero. For each $0\le a<r_+-h$, constant row $a+1$ is exactly the unit row in column $h+a$. These rows exist: by (1), an occurring h satisfies $h\ge k-1$, and consequently

$$r_+-h\le j\le m\le 2m.$$

For each variable row b, subtract $x_{\tau,b,h+a}$ times constant row $a+1$, for all such a. These elementary row operations have determinant one. They leave the first h columns unchanged and set all variable entries in columns $h,\dots,r_+-1$ equal to zero. They leave the added columns unchanged, because each row used for clearing is a pure unit row in its indicated positive column.

Now expand along columns $0, \dots, h-1$. Only variable rows can occur there. For each set of h such rows, its contribution is the minor in those rows and the first h columns, times its complementary determinant and its Laplace sign. After clearing, that complementary determinant has entries in R_{add}. Hence this factor is an R_{add}-linear combination of the height-h minors of (WM1). For an extra index $d \in \{1, \dots, \Delta'\}$, all constant entries in the first r_+ columns vanish. The identical Laplace expansion, without a clearing operation, gives an R_{add}-linear combination of the height-r_+ minors. Both expansions use the original row and column orders and therefore retain every determinant sign, including the fixed bijection ϵ_j.

Multiplying over all determinants and using (1) proves that Π_i, as a polynomial over R_{add} in the first columns, is an R_{add}-linear combination of products of minors with exactly the column counts of κ. By (WM1), these products have the standard basis (b_l). Every such basis polynomial uses only columns $c < r_+$, since every occurring height is at most r_+. Write $\widehat{b_l}$ for its renaming to the first-column variables x. Extension of the standard basis from $\mathbb{C}$ to the polynomial coefficient ring therefore gives coefficients $a_{\mathrm{bas},l} \in R_{\mathrm{add}}$ with

$$\Pi_i = \sum_l a_{\mathrm{bas},l} \widehat{b_l}. \tag{2}$$

No evaluation of the added variables, choice of theta functional, or passage to a fraction field is involved.

The Fock pairing gives exactly the line coordinates. Let H_κ be the matrix with entries $(H_\kappa)_{ls} = \langle b_l, b_s \rangle_{\mathrm{F}}$. The pairing is bilinear, not hermitian, and extends R_{add}-bilinearly when only the first columns are differentiated. Explicitly,

$$\langle X^\alpha, X^\beta \rangle_{\mathrm{F}} = \mathbf{1}_{\alpha=\beta} \alpha!, \qquad \alpha! = \prod_{\tau,b,c} \alpha_{\tau,b,c}!. \tag{3}$$

Thus the coefficients in R_{add} are not differentiated. Renaming the first-column variables does not change (3). By Lemma 4.6.9,

$$G_\kappa H_\kappa = h_\kappa I. \tag{4}$$

Its hypotheses are precisely the products-of-minors basis, filling Gram matrix and ordinary Fock pairing of (WM1)–(WM5), in the same rank $|\mathcal{B}_j|$ used here. The scalar h_κ is nonzero: the highest polynomial is a nonzero polynomial with integer coefficients, so its self-pairing is the positive sum of its squared coefficients times the monomial factorials in (3).

Apply (3) to (2). The definition (XE6) then reads, as an equality of vectors over R_{add},

$$(\mathrm{lc}_{i,l})_l = h_\kappa^{-1} H_\kappa (a_{\mathrm{bas},l})_l. \tag{5}$$

This uses exactly the hook number of (WM5); no product of row or column factorials is cancelled or inserted.

The polynomial reconstruction is the claimed identity. By (WM4) and the definition of P_l,

$$P_l = \sum_s (G_\kappa)_{sl} \widehat{b_s}. \tag{6}$$

The substitution of zero for $c \geq r_+$ makes no further change to these basis polynomials, as their column support was checked above. Substituting (5) and (6), and then using (4), gives

$$\begin{aligned} \sum_l P_l \, \mathrm{lc}_{i,l} &= \sum_s \widehat{b_s} \big(G_\kappa h_\kappa^{-1} H_\kappa (a_{\mathrm{bas},l})_l \big)_s \\ &= \sum_s \widehat{b_s} \, a_{\mathrm{bas},s} = \Pi_i. \end{aligned}$$

Every equality is in $R_{\mathrm{add}}[x_{\tau,b,c} : c < r_+]$, and its canonical identification with the ring on $\mathcal{L}_j$ is the two inclusions in the statement. This proves the assertion for the fixed choice and hence for every j and i in the stated ranges. □

Proposition 6.6.36. *Let $1 \le j \le m$ and $r_+ = k + j - 1$. For a twist ϑ with modulus Q let $\mathfrak{n} = \mathfrak{M}^2 \prod_{w \in Q} w$, let χ_ϑ be the character of $R_\mathfrak{n}$ given on units by the tame part of $\chi'_{j,\vartheta}$, $u \mapsto \prod_{w \in S_0 \cup Q} \psi'_w(u \bmod w)$, and by 0 on nonunits, and for $\Lambda \in \mathrm{M}_{\mathcal{B}^{\mathrm{c}} \times \mathcal{B}_j}(\mathcal{O}_E/\mathfrak{M}^2)$ let $\psi^{\mathrm{inv}}_\Lambda(y) = \sum_{\gamma \in \mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(\mathcal{O}_E/\mathfrak{M}^2)} \psi_\Lambda(\bar{y}\gamma)$ for $y \in \mathrm{M}_{\mathcal{B}_j \times \mathcal{B}^{\mathrm{c}}}(R_\mathfrak{n})$, $\bar{y}$ its reduction modulo $\mathfrak{M}^2$. Let $W = \mathrm{I}_{\mathcal{B}^{\mathrm{c}}} \oplus W'_j$, with index set $\mathcal{B}^{\mathrm{c}} \sqcup \mathcal{B}_j$; for $X = (X' \mid X'') \in \mathrm{M}_{\mathcal{B}_j \times (\mathcal{B}^{\mathrm{c}} \sqcup \mathcal{B}_j)}(R_\mathfrak{n})$ put $\Phi_{\vartheta,i}(X) = \chi_\vartheta(\det X'')\, \psi^{\mathrm{inv}}_{\Lambda_i}(X''^{-1}X')$ if X'' is invertible and 0 otherwise. Let $\pi_j \colon \mathcal{L}_j \to \mathcal{B}^{\mathrm{c}} \sqcup \mathcal{B}_j$ send $c \in \{0, \dots, r_+ - 1\}$ to the basis vector of W_j of number c and be the inclusion on $\mathcal{A}^+_j$, $\mathcal{B}^\flat$ and $\mathcal{B}^{\mathrm{c}}$, and let Π^W_i be Π_i with every variable $x_{\tau,b,c}$ renamed $x_{\tau,b,\pi_j(c)}$. The **left side** of the third exchange is the function on $\mathrm{U}(W_j)(\mathbb{A}_F)$*

$$L_{\vartheta,i}(g) = \sum_{h' \bmod \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})}^{\mathrm{cl}} \mathsf{a}_{\chi'_{j,\vartheta}}(h') \sum_{h \bmod \mathbf{K}_0(\mathcal{B}_j)}^{\mathrm{cl}} \theta^{W,V''_j}_{\chi'_{j,\vartheta}\nu^\flat_j \upsilon^m,\, \nu''_{j,\vartheta};\,\mathfrak{n}}\big[\Phi_{\vartheta,i}, \Pi^W_i\big]\big(\mathrm{diag}(h', g, 1, x_{\mathfrak{c}_i}), h\big),$$

$\mathrm{diag}(h', g, 1, x_{\mathfrak{c}_i})$ the block diagonal point with components h' on $\mathcal{B}^{\mathrm{c}}$, g on $\mathcal{R}$, 1 on $\mathcal{A}^-_j \sqcup \mathcal{A}^+_j$ and $x_{\mathfrak{c}_i}$ on $\mathcal{B}^\flat$. Then there are $C \in \mathbb{R}$ and, for every twist ϑ, a number $c_\vartheta \in \mathbb{C}$ with

$$\Gamma_j(\vartheta)\, |c_\vartheta|^2 = C \qquad \text{and} \qquad c_\vartheta\, L_{\vartheta,i}(g) = \mathsf{F}_i(g) \quad \text{for all } i \in \mathrm{Mem}_j,\ g \in \mathrm{U}(W_j)(\mathbb{A}_F).$$

Proof. Fix ϑ and write $\chi' = \chi'_{j,\vartheta}$, $\nu'' = \nu''_{j,\vartheta}$, $\beta^{\mathrm{c}} = \nu^\flat_j \upsilon^m$ (the carrier character) and $\alpha_e = \chi'\beta^{\mathrm{c}}$; by the sidecalc of (XE1), $\nu'' = \chi'\nu^\flat_j$, so $\alpha_e = \nu''\upsilon^m$. Let $\mathbf{K}^{\mathrm{c}} = \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$ and $N = \#\mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(\mathcal{O}_E/\mathfrak{M}^2)$.

Step 0: characters. By (a) and (b) of Lemma 6.6.23 (whose $\mathfrak{n}$, χ_ϑ, α_e, W, π_j and Π^W_i are those of the statement): (i) $\mathfrak{n}$ is a modulus with $\Sigma(\mathfrak{n}) = S_0 \cup Q$; (ii) χ' is tame of weight 0 for $(\mathfrak{n}, \chi_\vartheta)$; (iv) α_e is tame of weight $\tau \mapsto m - \#D_j(\tau)$ for $(\mathfrak{n}, \chi_\vartheta)$; and β^{c} has trivial tame part. (iii) Hence $\beta^{\mathrm{c}}(\det k) = 1$ for $k \in \mathbf{K}_0(n)$, while $\chi'(\det k) = \nu''(\det k) = \alpha_e(\det k) = \chi_\vartheta(\det \bar{k})$, $\bar{k}$ the reduction modulo $\mathfrak{n}$ ((ii) of Lemma 3.2.11, Definition 3.1.1).

Step 1: the matched polynomial of the constant rows. Let $n = \mathcal{B}^{\mathrm{c}} \sqcup \mathcal{B}_j$ (index set of W), $l = \{1, \dots, m\}$, $p = \{1, \dots, 2m\}$, and let $\jmath_W \colon \mathcal{L}_j \sqcup l \to n$ be π_j on $\mathcal{L}_j$ and ng_j on l. By (c) of Lemma 6.6.23, $\jmath_W$ is a bijection, W has the signs $\mathrm{sgn}_{\jmath_W}$, and $\Delta^{\jmath_W}(\epsilon_j; \mathsf{c}_i) = \Pi^W_i$ (with $e = \epsilon_j$, $\iota_\tau = D_j(\tau)$ and $\eta = \mathsf{c}_i$). Let $f \colon p \sqcup l \to \mathcal{B}^{\mathrm{c}}$ be $a \mapsto (1, a)$, $i \mapsto (2, i)$; S^{c} has the signs sgn_f. In the matched polynomial $Q_{f,\jmath_W}(\mathsf{c}_i)$, the exponent of $\det y^{--}_\tau$ is $\#D_j(\tau) + |n| - 2m = \#D_j(\tau) + |\mathcal{B}_j| + m$, and $y^{--}_\tau = (x_{\tau,\mathrm{ng}_j(i),(2,i')})_{i,i'} = y^-_\tau$. For $d = (h, c) \in D_j(\tau)$, row a of $\mathsf{c}_{i,\tau,d}$ is the unit vector at the column $h + a - 1$ or at $a \in \mathcal{A}^+_j$, so row a of $\mathsf{c}_{i,\tau,d}\, y^{++}_\tau$ is $(x_{\tau,\mathrm{ps}_j(h,a),(1,a')})_{a'}$ and $\det(\mathsf{c}_{i,\tau,d} y^{++}_\tau) = \det y_{\tau,h}$; for $d \in \{1, \dots, \Delta'\}$, $\mathsf{c}_{i,\tau,d} y^{++}_\tau = \tau(Y_{\mathfrak{c}_i})[\lambda_{i,\tau}(d, \cdot)](x_{\tau,b,(1,a)})_{b \in \mathcal{B}^\flat, a}$, as the constant rows vanish in the columns $\mathcal{B}^{\mathrm{c}}$. Hence $Q_{f,\jmath_W}(\mathsf{c}_i) = P_j P^\flat_i$, read in the variables of the rows $\mathcal{B}_j$ of n.

Step 2: the exchange identity for $(W, V''_j, S^{\mathrm{c}})$. Fix i and g. For $h' \in G_f(\mathcal{B}^{\mathrm{c}})$ and a function Φ on $\mathrm{M}_{\mathcal{B}_j \times n}(R_\mathfrak{n})$ let $K_{h'}(\Phi)(h)$ be the mean over $k \in \mathbf{K}_0(\mathcal{B}_j)$ (Haar probability) of $\theta^{W,V''_j}_{\alpha_e,\nu'';\mathfrak{n}}[\Phi, \Pi^W_i](\mathrm{diag}(h', g, 1, x_{\mathfrak{c}_i}), hk)$; it is right $\mathbf{K}_0(\mathcal{B}_j)$-invariant and, by Lemma 6.2.5, left $\mathrm{U}(V''_j)(F)$-invariant. Let Φ, Ψ be matched for $(\mathrm{id}_n, \chi_\vartheta^{-1})$: Φ vanishes off the matrices $(k^{-1})_{\mathcal{B}_j}$ (rows $\mathcal{B}_j$ of k^{-1}, $k \in \mathrm{GL}_n(R_\mathfrak{n})$) and $\Phi((k^{-1})_{\mathcal{B}_j}) = \chi_\vartheta^{-1}(\det k)\Psi(k_{\mathcal{B}^{\mathrm{c}}})$. For $\kappa \in \mathbf{K}_0(\mathcal{B}_j)$ and $\kappa' = \mathrm{diag}(1_{\mathcal{B}^{\mathrm{c}}}, \bar{\kappa})$, $\bar{\kappa}^{-1}(k^{-1})_{\mathcal{B}_j} = ((k\kappa')^{-1})_{\mathcal{B}_j}$ and $(k\kappa')_{\mathcal{B}^{\mathrm{c}}} = k_{\mathcal{B}^{\mathrm{c}}}$, so $\Phi(\bar{\kappa}^{-1}X) = \chi_\vartheta(\det \bar{\kappa})^{-1}\Phi(X)$ for all X; the same law holds for $\Phi_{\vartheta,i}$ directly from its definition. Hence $\alpha_e(\det \kappa)\Phi(\bar{\kappa}^{-1}X) =$

$\Phi(X)$ (Step 0 (iii)); and $v_{\Pi_i^W}$ is fixed by $\Omega(1,y)$ for $y \in G_\infty(1_{\mathcal{B}_j})$ by (d) of Lemma 6.6.23 (for the weights of α_e, which is $m - \#D_j(\tau) = |l| - |\iota_\tau|$ by Step 0 (iv), and of ν''). By (4) of Lemma 6.3.71, $K_{h'}(\Phi)$ is the kernel itself, for these Φ and for $\Phi_{\vartheta,i}$. Now Proposition 6.3.67 applies with W, $V' = S^{\mathrm{c}}$ (index set $\mathcal{B}^{\mathrm{c}}$), $\mathrm{I}_a = V_j''$, the bijections $\jmath_W$, f, $e = \epsilon_j$ and $\sigma = \mathrm{id}_n$, $d = z_* = \frac{7m}{2} + \frac{k}{2}$ ($|\mathcal{B}_j| = r + 9m + 1 = 3m + 2z_*$, and $2|l| + 2 \le |n|$), $\iota_\tau = D_j(\tau)$, the modulus $\mathfrak{n}$, the character χ_ϑ, $\alpha = \alpha_e$ (Step 0 (iv)), $\beta = \nu''$ and $\eta = \mathsf{c}_i$, at the point $\mathrm{diag}(h', g, 1, x_{\mathsf{c}_i})$: there are $C_3 \in \mathbb{R}$, independent of ϑ (the index data do not involve ϑ), and $c_3 = c_3(\vartheta)$ with $L_*(\mathfrak{n}, \alpha_e^{-1}\upsilon^{3m+z_*}; z_*)\,|c_3|^2 = C_3$ and, by Step 1 and $\alpha_e/\nu'' = \upsilon^m$,

$$c_3 \sum_{h \bmod \mathbf{K}_0(\mathcal{B}_j)}^{\mathrm{cl}} K_{h'}(\Phi)(h) = \int_{[\mathrm{U}(S^{\mathrm{c}})]} \theta^{S^{\mathrm{c}},W}_{\upsilon^m,\alpha_e;\mathfrak{n}}\big[\Psi, \widetilde{P_j P_i^\flat}\big]\big(x, \mathrm{diag}(h', g, 1, x_{\mathsf{c}_i})\big)\,dx.$$

Here Ψ vanishes off the matrices $k_{\mathcal{B}^{\mathrm{c}}}$, which have left inverses, so the integrand is integrable by (2) of Lemma 6.3.71. This is the exchange identity of Lemma 6.6.63 for $V' = S^{\mathrm{c}}$, $b = \mathcal{B}^{\mathrm{c}}$, $W' = W_j'$, $a = \mathcal{B}_j$, the point $(g, 1, x_{\mathsf{c}_i})$ of $\mathrm{U}(W_j')$, $c = c_3$, $\alpha = \upsilon^m$, $\beta = \chi'$, $\beta' = \beta^{\mathrm{c}}$ and $Q = P_j P_i^\flat$.

Step 3: the one exchange against the carrier. By (a) of Lemma 6.6.62 for $\mathfrak{n}$, χ_ϑ and $c = \chi'$ (Step 0 (ii)) there is $\gamma = \gamma(\vartheta)$ with $L_*(\mathfrak{n}, \chi'^{-1}\upsilon^m; m)\,L_*(\mathfrak{n}, \chi'\upsilon^{m/2}; m/2)\,|\gamma|^2 = C_{12}$, C_{12} independent of ϑ, and $\gamma \sum_{h'} \omega_{h'}\kappa_{h'} = \varphi^\circ$, where h' runs over fixed representatives of the classes of $\mathrm{I}_{\mathcal{B}^{\mathrm{c}}}$ at the level $\mathbf{K}^{\mathrm{c}}$, $\omega_{h'} = \mathsf{a}_{\chi'}(h')/\#(\mathrm{U}(\mathrm{I}_{\mathcal{B}^{\mathrm{c}}})(F) \cap h'\mathbf{K}^{\mathrm{c}}h'^{-1})$ and $\kappa_{h'}(x) = \theta^{S^{\mathrm{c}},\mathrm{I}_{\mathcal{B}^{\mathrm{c}}}}_{\upsilon^m,\chi';\mathfrak{n}}[\chi_\vartheta \circ \det, 1](x, h')$, the function $\kappa_{h'}$ of Lemma 6.6.63. The function $\Psi' = \psi^{\mathrm{inv}}_{\Lambda_i}$ satisfies $\Psi'(y\gamma') = \Psi'(y)$ for $\gamma' \in \mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(R_{\mathfrak{n}})$ (substitute $\bar\gamma'\gamma$ for γ), and $\Phi_{\Psi'} = \Phi_{\vartheta,i}$. So (ii) of Lemma 6.6.63, with $c_0 = \gamma$ and $F = \varphi^\circ$, gives

$$\begin{aligned} &c_3\gamma \sum_{h'} \omega_{h'} \sum_{h}^{\mathrm{cl}} \theta^{W,V_j''}_{\alpha_e,\nu'';\mathfrak{n}}\big[\Phi_{\vartheta,i}, \Pi_i^W\big]\big(\mathrm{diag}(h', g, 1, x_{\mathsf{c}_i}), h\big) \\ &\qquad = \int_{[\mathrm{U}(S^{\mathrm{c}})]} \varphi^\circ(x)\,\theta^{S^{\mathrm{c}},W_j'}_{\upsilon^m,\beta^{\mathrm{c}};\mathfrak{n}}\big[\psi^{\mathrm{inv}}_{\Lambda_i}, P_j P_i^\flat\big]\big(x, (g, 1, x_{\mathsf{c}_i})\big)\,dx. \end{aligned} \tag{6.142}$$

The left side is $c_3\gamma\, L_{\vartheta,i}(g)$: the summand of the outer class sum of $L_{\vartheta,i}$ is constant on the classes, since for $k \in \mathbf{K}^{\mathrm{c}}$, (6) of Lemma 4.1.1 gives $\mathsf{a}_{\chi'}(h'k) = \chi'(\det k)\mathsf{a}_{\chi'}(h')$ (datum $v_1 \otimes v^0$, first character χ') and multiplies the inner kernel by $\nu''(\det k)^{-1}$ ($\Phi_{\vartheta,i}(X'\bar k \mid X'') = \Phi_{\vartheta,i}(X)$ by the invariance of ψ^{inv}), and $\chi'(\det k) = \nu''(\det k)$ (Step 0 (iii)).

Step 4: the right side is $N\,\mathsf{F}_i(g)$. By Lemma 6.4.66 the datum of $\psi^{\mathrm{inv}}_{\Lambda_i}$ modulo $\mathfrak{n}$ is that of $\sum_\gamma \psi_{\Lambda_i}(\cdot\,\gamma)$ modulo $\mathfrak{M}^2$, and the kernel is linear in the function. For $\gamma \in \mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(\mathcal{O}_E/\mathfrak{M}^2)$ choose $k_\gamma \in \mathbf{K}^{\mathrm{c}}$ reducing to γ: the chosen places are split ($w \ne \bar w$) and pairwise not conjugate, and at such a pair $(w, \bar w)$ an element of $G_f(\mathcal{B}^{\mathrm{c}})$ is given by an arbitrary component in $\mathrm{GL}_{\mathcal{B}^{\mathrm{c}}}(\mathcal{O}_{E,w})$, the component at $\bar w$ being determined by $g^*g = 1$; take the components at the chosen places lifting γ and 1 elsewhere. By (6) of Lemma 4.1.1 and Step 0 (iii), $\theta^{S^{\mathrm{c}},W_j'}_{\upsilon^m,\beta^{\mathrm{c}};\mathfrak{M}^2}[\psi_{\Lambda_i}(\cdot\,\gamma), P](x, \cdot) = \theta^{S^{\mathrm{c}},W_j'}_{\upsilon^m,\beta^{\mathrm{c}};\mathfrak{M}^2}[\psi_{\Lambda_i}, P](xk_\gamma, \cdot)$. The quotient measure of $[\mathrm{U}(S^{\mathrm{c}})]$ is right invariant, and $\varphi^\circ(xk_\gamma^{-1}) = \varphi^\circ(x)$ by (b) of Lemma 6.6.62 (χ' is tame of weight 0); so each of the N translates contributes $\mathsf{F}_i(g)$ (XE5), and the right side of (6.142) is $N\,\mathsf{F}_i(g)$.

Step 5: the constant. Put $c_\vartheta = c_3\gamma/N$; then $c_\vartheta L_{\vartheta,i}(g) = \mathsf{F}_i(g)$ for all i and g. Let $p_j^* = (\nu_*, z_*)$, $p_j^\pm = (\nu_\pm, z_\pm)$. The characters agree:

$\alpha_e^{-1}\upsilon^{3m+z_*} = (\nu_*\vartheta)^{-1}$, $\chi'^{-1}\upsilon^m = (\nu_+\vartheta)^{-1}$, $\chi'\upsilon^{m/2} = (\nu_-\vartheta^{-1})^{-1}$, and $\Sigma(\mathfrak{n}) = S_0 \cup Q$. Hence, by (6.129) and $|c_\vartheta|^2 = |c_3|^2|\gamma|^2N^{-2}$,

$$\begin{aligned} \Gamma_j(\vartheta)\,|c_\vartheta|^2 = &\Big(L_*(\mathfrak{n}, \alpha_e^{-1}\upsilon^{3m+z_*}; z_*)\,|c_3|^2\Big) \\ &\cdot \Big(L_*(\mathfrak{n}, \chi'^{-1}\upsilon^m; m)\,L_*(\mathfrak{n}, \chi'\upsilon^{m/2}; m/2)\,|\gamma|^2\Big)N^{-2} = C_3C_{12}N^{-2}, \end{aligned}$$

which is the claim with $C = C_3 C_{12} N^{-2}$. □

Lemma 6.6.37. *Let $1 \le j \le m$ and $y \in \mathcal{A}_M(W_j)$. For $k = 1, 2$ let a_k be a finite index set, $\mathfrak{m}_k$ a modulus, α_k, β_k automorphic characters of $\mathrm{U}(1)$ whose tame parts are trivial at every finite place outside $\Sigma(\mathfrak{m}_k)$, Φ_k a function on $\mathrm{M}_{a_k \times \mathcal{R}}(R_{\mathfrak{m}_k})$, $P_k \in \mathbb{C}[x]_{a_k \times \mathcal{R}}$ and $h_k \in G_f(a_k)$, and put $\kappa_k(u) = \theta^{W_j, \mathrm{I}_{a_k}}_{\alpha_k, \beta_k; \mathfrak{m}_k}[\Phi_k, P_k](u, h_k)$. Then the function $u \mapsto y(u)\,\kappa_1(u)\,\kappa_2(u)$ on $\mathrm{U}(W_j)(\mathbb{A}_F)$ is continuous, left invariant under the rational points and integrable on $[\mathrm{U}(W_j)]$.*

Proof. **The principal-level form has rapid decay.** The space W_j has rank r and the diagonal signs of (HP4). Its target parameter ς has gap Δ for these signs by Proposition 5.8.4(iii). We check that the type kernel is a cusp kernel of order zero. The rank r is odd and m is even by (AD2), so $k = r + 1 - m$ is even. The displayed formula for ς in Definition 3.2.16 therefore has integral entries. Consequently the entries of 2ς are congruent to $r - 1$ modulo 2. They are distinct, and entries belonging to opposite signs differ by at least 2Δ. By Lemma 4.2.67(i) and $r \ge x^5$ one has $r \ge 4$, whence

$$\Delta = 2r^8 \ge 500 r^3.$$

Thus 2ς has gap $500r^3$ in (DZ1) of Definition 5.6.3. Applying Lemma 5.6.21 with $B = 0$ shows that e_ς is a cusp kernel of order zero, for the same product of Cayley measures used here.

By the definition of $\mathcal{A}_M(W_j)$, the function y is continuous, bounded, invariant under the rational points, invariant under its principal open level, and reproduced by e_ς. It is therefore a form of this type in (ED2). By Lemma 6.3.75, for every integer $A \ge 0$ there is a finite constant $C_{y,A} \ge 0$ such that

$$|y(u)|\,\mathrm{ht}_{W_j}(u)^A \le C_{y,A} \qquad (u \in \mathrm{U}(W_j)(\mathbb{A}_F)).$$

This argument uses no projection onto good forms.

The two kernels have polynomial growth. For each $k \in \{1, 2\}$ put

$$\varphi_k = \mathrm{mod}_{\mathfrak{m}_k}(\Phi_k, v_{P_k}) \in \mathcal{M}_{W_j, \mathrm{I}_{a_k}}.$$

This is the datum specified by (XD5) and Definition 6.3.1; in particular its theta-model norm is finite. Read the finite point h_k as $(1, h_k)$ at the adelic places. By Lemma 6.2.28 there are $Y_k \ge 0$ and $A_k \in \mathbb{N}$ such that

$$|\kappa_k(u)| \le Y_k \|\varphi_k\|\,\mathrm{ht}_{W_j}(u)^{A_k} \mathrm{ht}_{\mathrm{I}_{a_k}}((1, h_k))^{A_k} = C_{\mathrm{ker},k}\,\mathrm{ht}_{W_j}(u)^{A_k},$$

where the last equality defines a finite nonnegative constant $C_{\mathrm{ker},k}$. The target point is fixed, so its height is a finite number. This also covers $a_k = \emptyset$: its target group is trivial and its height is 1.

The joint continuity of the Weil action in Lemma 4.1.1(2), continuity of the pair map and the automorphic characters, and boundedness of the canonical theta functional show that each κ_k is continuous. By Lemma 6.2.5 it is left invariant under the rational points of W_j. Hence the product with y is continuous and rationally left invariant, and descends to a continuous, therefore measurable, function on $[\mathrm{U}(W_j)]$.

A bounded majorant proves absolute integrability. Take $A = A_1 + A_2$ in the rapid-decay bound. For every u,

$$|y(u)\kappa_1(u)\kappa_2(u)| \le C_{y,A_1+A_2}\, C_{\mathrm{ker},1} C_{\mathrm{ker},2}.$$

The CM extension is E/F and W_j is a nondegenerate hermitian space of positive rank r. The adelic finite-volume theorem applies to this unitary group with the product Haar measure fixed

in (XD1), and to its quotient by counting measure on the rational points; see [37] and [233], Chapter 5. Thus this quotient has finite measure. Integrating the displayed constant majorant proves

$$\int_{[\mathrm{U}(W_j)]} |y(u)\kappa_1(u)\kappa_2(u)|\,du < \infty.$$

This is the asserted integrability, with the continuity and invariance already established. □

Lemma 6.6.38. *Let $1 \le j \le m$. Then $\Gamma_j(\vartheta) > 0$ for every twist ϑ.*

Proof. Fix a twist ϑ with modulus Q and tame part ψ_ϑ, fix $i \in \{*, +, -\}$, and put $\nu = (\nu_i \vartheta^{s_i})^{-1}$, $z = z_i$, $S = S_0 \cup Q$. It suffices to show $L_*(S, \nu; z) > 0$. Since p_j^i is a critical pair, z is an integer with $z \ge 1$, so by (XD7)

$$L_*(S, \nu; z) = \Big(\prod_{w \in S} \mathrm{N}w\Big)^{z^2} \prod_{z'=1}^{z} |L^S(z', \tilde{\nu})|^2,$$

and it suffices to show $L^S(z', \tilde{\nu}) \ne 0$ for every integer $z' \ge 1$.

The base change is a unitary Hecke character that is ramified at a chosen place. The map $x \mapsto x/\bar{x}$ is a continuous homomorphism $\mathbb{A}_E^\times \to \mathrm{U}(1)(\mathbb{A})$ carrying $E^\times$ into $\mathrm{U}(1)(E)$, so $\tilde{\nu}(x) = \nu(x/\bar{x})$ is a unitary Hecke character of E. If μ, μ' have weights e, e' and tame parts ψ, ψ', then $\mu\mu'$ has weight $e + e'$ and tame part $\psi\psi'$, and μ^{-1} has weight $-e$ and tame part ψ^{-1} (the defining identity is multiplicative). The tame parts of ν_*, ν_+, ν_- are $\omega^j, \omega^j, \omega^{-j}$, and that of ϑ^{s_i} is $\psi_\vartheta^{s_i}$; hence ν has the tame part $\psi = \omega^{-\epsilon j} \psi_\vartheta^{-s_i}$ with $\epsilon = 1$ for $i \in \{*, +\}$ and $\epsilon = -1$ for $i = -$. Since $M = \pi_M \bar{\pi}_M$ is not a unit, π_M lies in some prime ideal, so there is a chosen place w. By (a) of Lemma 4.6.2, $w \ne \bar{w}$, $\bar{w}$ is not a chosen place, and w lies above p_0 or p_1; so $\mathrm{N}w = \mathrm{N}\bar{w}$ is a power of a prime dividing M, and as $\mathrm{N}Q$ is prime to M, neither w nor $\bar{w}$ lies in Q. Therefore $\psi_{\vartheta,w} = \psi_{\vartheta,\bar{w}} = 1$, $\omega_{\bar{w}} = 1$, and $\psi_w = \omega_w^{-\epsilon j} \ne 1$ because ω_w has order q_2 and $1 \le j \le m < q_2$ ($q_2 = (q_0 d)^{s+6} \ge 3^s > 2^{e+1} = m$ with $s = 22(e+1)$ and $m = 2^{e+1}$ by (AD2) of Definition 2.3.4 and Definition 2.3.1, $d \ge 3$ as $-d \equiv 1 \pmod 4$). Choose $u \in \mathcal{O}_{E,w}^\times$ with $\psi_w(u \bmod w) \ne 1$, and let $x \in \mathbb{A}_E^\times$ have the component u at w and 1 at every other place. Conjugation maps E_w onto $E_{\bar{w}}$, so $\bar{x}$ has the component $\bar{u} \in \mathcal{O}_{E,\bar{w}}^\times$ at $\bar{w}$ and 1 elsewhere, and $x/\bar{x} \in \mathrm{U}(1)(\mathbb{A})$ has the components u at w, $\bar{u}^{-1}$ at $\bar{w}$ and 1 elsewhere; its finite components are integral and its infinite components are 1. By the defining identity of weight and tame part,

$$\tilde{\nu}(x) = \nu(x/\bar{x}) = \psi_w(u \bmod w)\, \psi_{\bar{w}}(\bar{u}^{-1} \bmod \bar{w}) = \psi_w(u \bmod w) \ne 1.$$

As $|x|_{\mathbb{A}} = 1$, $\tilde{\nu}$ is not of the form $|\cdot|_{\mathbb{A}}^{i\tau}$ for any $\tau \in \mathbb{R}$.

Nonvanishing. By (3) of Theorem A.1.12, applied to the number field E and the unitary Hecke character $\tilde{\nu}$ (Hecke [224], VII.8), the continuation of $L(s, \tilde{\nu})$ is holomorphic and has no zeros in $\mathrm{Re}\, s \ge 1$. For $\mathrm{Re}\, s > 1$,

$$L^S(s, \tilde{\nu}) = L(s, \tilde{\nu}) \prod_{w'} (1 - \tilde{\nu}(\varpi_{w'})\, \mathrm{N}w'^{-s}),$$

the product over the places $w' \in S \cup \bar{S}$ at which $\tilde{\nu}$ is unramified; the right side is holomorphic on $\mathrm{Re}\, s \ge 1$, so it is the continuation of $L^S(s, \tilde{\nu})$ there. At an integer $z' \ge 1$ each factor satisfies $|\tilde{\nu}(\varpi_{w'})\mathrm{N}w'^{-z'}| = \mathrm{N}w'^{-z'} < 1$, hence is nonzero, and $L(z', \tilde{\nu}) \ne 0$. So $L^S(z', \tilde{\nu}) \ne 0$, and $L_*(S, \nu; z) > 0$. The product of the three positive numbers is $\Gamma_j(\vartheta) > 0$. □

Lemma 6.6.39. *Let $1 \le j \le m$, Y a short row family, $c'' \in \mathbb{C}^\times$, and $L = (L_i)_{i \in \mathrm{Mem}_j}$ divided lattices of $O_{j,1}$ with L_i glued for Λ_i, and suppose that $\mathcal{V}_j$ is a divided splitting for $O_{j,\vartheta}$ for every twist ϑ. Let ϑ be a twist, $\mathrm{gl}_\vartheta = \mathrm{gl}_{j,\vartheta}[L; c'']$ (formed with Y), and w a finite place of E with $w \ne \bar{w}$ such that neither w nor $\bar{w}$ is a place of $O_{j,\vartheta}$. Then for every $\varphi \in \mathcal{F}_w(e_0, \mathcal{L}_{j,\vartheta}^\perp)$ and every $i \in \mathrm{Mem}_j$, the table $\zeta = \mathrm{gl}_\vartheta^* \varphi$ satisfies*

$$\mathrm{tt}_j(\zeta_i)(g) = 0 \qquad (g \in \mathrm{U}(W_j)(\mathbb{A})), \qquad \zeta_i(\mathfrak{c}) = \zeta_{i,\mathfrak{c}} \ (\mathfrak{c} \in \mathrm{Cl}^\circ).$$

Proof. Write $O = O_{j,\vartheta}$, $\mathcal{V} = \mathcal{V}_j$, $\ell = \mathrm{loss}(\mathcal{V})$, $b = \upsilon^{\lfloor m/2 \rfloor - j}$, and $\kappa^- = \kappa_O^-$ (free of ϑ). As in (TG6), each L_i is a divided lattice of O. Fix φ, i and g, and for $\mathfrak{c} \in \mathrm{Cl}^\circ$ let $\bar{k}_\mathfrak{c} \in \mathbb{V}_j^-$ have the conjugate coordinates of $\mathrm{kv}_\mathfrak{c} = \mathrm{kv}_{O,b;\mathfrak{M}^2}[\mathbf{1}_{z_j}; \kappa^-](g, x_\mathfrak{c})$; it does not depend on ϑ, since $W(O) = W_j$, $\chi_O = \upsilon^{m-j}$, Let_{-1} and κ^- do not.

Step 1: the theta kernel pairing as an inner product with a table. For $\xi \in \mathbb{V}_j^-$, $\mathrm{Pol}_{\kappa^-}(\bar{\xi}) = \sum_l (G_{\kappa^-}\bar{\xi})_l \, b_l$, and the kernels are linear in the polynomial; by (KN4),

$$\theta^{W_j, V^\circ}_{\chi_O, b; \mathfrak{M}^2}[\mathbf{1}_{z_j}, \mathrm{Let}_{-1}(b_l)](g, x_\mathfrak{c}) = \overline{(\mathrm{kv}_\mathfrak{c})_l}.$$

As G_{κ^-} is a real symmetric matrix,

$$\theta^{W_j, V^\circ}_{\chi_O, b; \mathfrak{M}^2}\big[\mathbf{1}_{z_j}, \mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa^-}(\bar{\xi}))\big](g, x_\mathfrak{c}) = \overline{\textstyle\sum_l (G_{\kappa^-}\xi)_l (\mathrm{kv}_\mathfrak{c})_l} = \overline{\langle \bar{k}_\mathfrak{c}, \xi \rangle_{\kappa^-}}.$$

Let $\eta \in \mathrm{Tab}_j$ have $\eta_{i,\mathfrak{c}} = \bar{k}_\mathfrak{c}$ and $\eta_{i',\mathfrak{c}} = 0$ for $i' \ne i$. Summing over $\mathfrak{c}$ ((XE7)) gives

$$\overline{\mathrm{tt}_j(\zeta_i)(g)} = \sum_{\mathfrak{c} \in \mathrm{Cl}^\circ} \langle \bar{k}_\mathfrak{c}, \zeta_{i,\mathfrak{c}} \rangle_{\kappa^-} = \langle \eta, \zeta \rangle = \langle \eta, \mathrm{gl}_\vartheta^* \varphi \rangle = \langle \mathrm{gl}_\vartheta \eta, \varphi \rangle.$$

Step 2: unfolding the comparison form. By (TG6), $\mathrm{gl}_\vartheta \eta$ is M^ℓ times a combination with positive real weights of the product forms $\mathrm{pr}_{\mathcal{V}, L_{i'}}((x, x_\mathfrak{c}); \varphi''_{\vartheta,i'}(x))(\eta_{i',\mathfrak{c}})$, which vanish for $i' \ne i$ (linearity in $\eta_{i',\mathfrak{c}}$). Exchanging the finite sums,

$$\langle \mathrm{gl}_\vartheta \eta, \varphi \rangle = M^\ell \sum_{x \bmod \mathbf{J}_\vartheta(\Lambda_i)}^{\mathrm{cl}} S(x), \qquad S(x) = \sum_{\mathfrak{c} \in \mathrm{Cl}^\circ} \langle \mathrm{pr}_{\mathcal{V}, L_i}((x, x_\mathfrak{c}); \varphi''_{\vartheta,i}(x))(\bar{k}_\mathfrak{c}), \ \varphi \rangle.$$

It suffices to show $S(x) = 0$ for every $x \in G_f(\mathcal{B}_j)$.

Step 3: the hypotheses of the period vanishing. We check the hypotheses of Proposition 6.6.40 for O and $\Xi = \varphi$. O has ranks $1 \le r < r + t$ and fits a parameter by Lemma 6.6.41; $M_O \ne \emptyset$. At $w \in Q_O = Q$ the tame part of the character of O is $\omega_w^j \psi_{\vartheta,w} = \psi_{\vartheta,w} \ne 1$ (ϑ is a twist, $\omega_w = 1$ off the chosen places). The hyperplane sums kill $\varphi \in [e_0]\mathrm{Form}(O)$ by Lemma 6.6.42. As $\varphi \in [e_0]\mathrm{Form}(O)$ is orthogonal to $\mathcal{L}_{j,\vartheta}$, $\mathrm{Th}_O(\varphi) = 0$ by Lemma 6.6.43. $H_w(X_*(w))\varphi = 0$ for the given w, with $w \ne \bar{w}$ and $w, \bar{w} \notin S_O$. For $N = \mathcal{B}_j$, $l = \mathcal{B}^\circ$ and $n = r + t = |\mathcal{B}_j| + |\mathcal{B}^\circ|$, the rank condition $2r + 2\#N + 3 < n$ reads $2r + |\mathcal{B}_j| + 3 < |\mathcal{B}^\circ|$, that is $18m + 5 < 2r$:

Step 4: conclusion. Let $\mathbf{K}^\circ = \mathbf{K}_{\mathfrak{M}^2}[\{1\}] \subseteq \mathbf{K}_0(\mathcal{B}^\circ)$, the level of the classes Cl° (TG3). Its elements act trivially on the reduction of the standard lattice of V° at every chosen place, so by (c) of Lemma 4.6.2 the stabilisers $\mathrm{U}(V^\circ)(F) \cap h\mathbf{K}^\circ h^{-1}$ are trivial, and the class sum modulo $\mathbf{K}^\circ$ at the representatives $x_\mathfrak{c}$ is the plain sum over $\mathfrak{c} \in \mathrm{Cl}^\circ$. Hence $S(x)$ is the class sum of Proposition 6.6.40 for $(N, l, a, z) = (\mathcal{B}_j, \mathcal{B}^\circ, \mathcal{B}^\mathrm{c}, z_j)$, the divided splitting $\mathcal{V}$, the divided lattice L_i, the point x, $y = \varphi''_{\vartheta,i}(x)$, the character b, $\Psi = \mathbf{1}_{z_j}$ and g, and it vanishes. By Steps 1 and 2, $\mathrm{tt}_j(\zeta_i)(g) = 0$; as g is arbitrary, the claim follows (the second display of the statement is the notation $\zeta_i(\mathfrak{c}) = \zeta_{i,\mathfrak{c}}$). □

Proposition 6.6.40. *Let O be a descent pair for ranks $1 \le r < n$ that fits a parameter, with $M_O \neq \emptyset$, and let $\Xi \in \mathrm{Form}(O)$ satisfy: $\psi_{O,w} \neq 1$ for every $w \in Q_O$; $\sum_{s \in H(\lambda)} \psi_{O,w}(\det s)^{-1}[s]_w \Xi = 0$ for every $w \in M_O$ and every nonzero row $\lambda \in k_w^r$; $\mathrm{Th}_O(\Xi) = 0$; and $H_w(X_*(w))\,\Xi = 0$ for some finite place w with $w \neq \bar{w}$ and $w, \bar{w} \notin S_O$. Let N, l, a be finite index sets with $2r + 2\#N + 3 < n$, $z\colon \{1, \dots, r\} \hookrightarrow l$ an embedding, $\mathcal{V}$ a divided splitting for (N, l, a, z), L a divided lattice, $x \in G_f(N)$, $y \in \mathbb{V}_{\kappa_O^+}$ (rank $\#N$, rows N), b an automorphic character of $\mathrm{U}(1)$, Ψ a function on $\mathrm{M}_{l\times r}(R_2)$ and $g \in \mathrm{U}(W(O))(\mathbb{A}_F)$. Let $\mathbf{K}^\circ = \mathbf{K}_{\mathfrak{M}_O^2}[\{1\}] \subseteq \mathbf{K}_0(l)$, and for $h \in G_f(l)$ let $\bar{k}(h) \in \mathbb{V}_{\kappa_O^-}$ (rank $\#l$, rows l) have the conjugate coordinates of $\mathrm{kv}_{O,b;\mathfrak{M}_O^2}[\Psi; \kappa_O^-](g, h)$. Then, the class sum being taken over the double cosets $\mathrm{U}(\mathrm{I}_l)(F)\backslash G_f(l)/\mathbf{K}^\circ$ at their fixed representatives,*

$$\sum_{h \bmod \mathbf{K}^\circ}^{\mathrm{cl}} \langle \mathrm{pr}_{\mathcal{V},L}((x,h);y)(\bar{k}(h)),\ \Xi\rangle = 0.$$

Proof. Write $W = W(O)$, $\kappa = \kappa_O$, $\kappa^\pm = \kappa_O^\pm$, $\rho = \rho_{\kappa,e_O}$, $\langle\,,\rangle = \langle\,,\rangle_\kappa$, and $\varepsilon\colon N \sqcup l \to \{1, \dots, n\}$ for the bijection of $\mathcal{V}$. For $h \in G_f(l)$ let $x'(h) = \mathrm{diag}_\varepsilon(x, h)\gamma_L$ and $\mathrm{kv}(h) = \mathrm{kv}_{O,b;\mathfrak{M}_O^2}[\Psi; \kappa^-](g, h)$, so that $\bar{k}(h) = \overline{\mathrm{kv}(h)}$; let $f(h)$ be the summand of the statement. For $u \in G_\infty(1_l)$ put $u^\varepsilon = \mathrm{diag}_\varepsilon(1, u) \in G_\infty(1_n)$. Let $C(\zeta) = y \cdot \bar{\zeta}$ for $\zeta \in \mathbb{V}_{\kappa^-}$ (rows l), a conjugate-linear map into $\mathbb{V}_O$. Let $(e_i)_{i \in I_{\kappa^-}}$ be the coordinate vectors of $\mathbb{V}_{\kappa^-}$ and $\varphi_i = \mathrm{mod}_{\mathfrak{M}_O^2}(\Psi, v_{\mathrm{Let}_{-1}(b_i)}) \in \mathcal{M}_{W,\mathrm{I}_l}$, so that $\mathrm{kv}(h)_i = \overline{\theta^{W,\mathrm{I}_l}_{\chi_O,b}(\varphi_i)(g, (1,h))}$ (KN4).

Step 1: the summand is a Gram pairing. By (GU6) and (e) of Lemma 6.6.31, $f(h) = \langle y \cdot \bar{k}(h), \Xi(x'(h))\rangle = \langle C(\mathrm{kv}(h)), \Xi(x'(h))\rangle$.

Step 2: C is equivariant for the real points of the second block. Let $u \in G_\infty(1_l)$ and $\zeta \in \mathbb{V}_{\kappa^-}$; we show $\rho(u^\varepsilon)C(\zeta) = C(\rho_{\kappa^-,0}(u)\zeta)$. For a square z and a rectangular z', $S(z)S(z') = S(zz')$ (apply the defining identity of (WM2) twice). By (WM2), $e_O = -e^-$ ((DP3), $e^-(\tau) = \sum_{1 \le i < n} \kappa^-(\tau, i)$), (d) of Lemma 3.2.20 for $g = \overline{u^\varepsilon}$ and (a) of Lemma 6.6.26 (its hypotheses are those of (GU1)),

$$C_O\,\rho(u^\varepsilon)(y \cdot \bar{\zeta}) = \big(S_{\kappa^+}(\overline{u^\varepsilon}) \otimes S_{\kappa^-}((\overline{u^\varepsilon})^{-\mathsf{T}})\big) C_O(y \cdot \bar{\zeta}) = S_{\kappa^+}(\overline{u^\varepsilon}\iota_N)\, y \otimes S_{\kappa^-}\big((\overline{u^\varepsilon})^{-\mathsf{T}}\iota_l\big)\bar{\zeta}.$$

Here $\overline{u^\varepsilon}\iota_N = \iota_N$, and u unitary gives $\bar{u}^{-\mathsf{T}} = u$, so $(\overline{u^\varepsilon})^{-\mathsf{T}}\iota_l = u^\varepsilon\iota_l = \iota_l u$. Hence the right side is $S_{\kappa^+}(\iota_N)y \otimes S_{\kappa^-}(\iota_l)(S_{\kappa^-}(u)\bar{\zeta}) = C_O(y \cdot S_{\kappa^-}(u)\bar{\zeta})$ by (a) of Lemma 6.6.26 again. As C_O has a left inverse, $\rho(u^\varepsilon)C(\zeta) = y \cdot S_{\kappa^-}(u)\bar{\zeta}$, and $S_{\kappa^-}(u)\bar{\zeta} = \overline{S_{\kappa^-}(\bar{u})\zeta} = \overline{\rho_{\kappa^-,0}(u)\zeta}$ (S has integral polynomial entries).

Step 3: real points act on the kernel vector. For $u \in G_\infty(1_l)$ and $h \in G_f(l)$ we show $(\rho_{\kappa^-,0}(u^{-1})\,\mathrm{kv}(h))_i = \overline{\theta^{W,\mathrm{I}_l}_{\chi_O,b}(\varphi_i)(g, (u,h))}$. By (1) of Lemma 6.3.71,

$$\theta(\varphi_i)(g, (u,h)) = \theta(\mathrm{mod}_{\mathfrak{M}_O^2}(\Psi, \Omega_{\gamma,\gamma'}(1,u)v_{\mathrm{Let}_{-1}(b_i)}))(g, (1,h)),$$

γ, γ' the weights of χ_O, b. By (5) of Lemma 4.1.1 for the pair (W, I_l) (u is block diagonal, I_l having only the sign $+1$): the scalar is $\prod_\tau \det(u_\tau)^{\gamma(\tau) - r_-(O)} = 1$, as υ has weight 1 ((ii) of Lemma 3.2.11) and $\chi_O = \upsilon^{r_-(O)}$; and the variables $X_{\tau,\cdot,c}$ of the columns c with $\varepsilon_O(c) = -1$, the only ones in $\mathrm{Let}_{-1}(b_i)$, are replaced by $u_\tau^{-1}X_{\tau,\cdot,c}$. So $\mathrm{Let}_{-1}(b_i)$ becomes $\mathrm{Let}_{-1}(b_i(u^{-1}\cdot)) = \sum_k S_{\kappa^-}(u^{-1})_{ik}\mathrm{Let}_{-1}(b_k)$ (WM2), and by linearity $\theta(\varphi_i)(g, (u,h)) = \sum_k S_{\kappa^-}(u^{-1})_{ik}\overline{\mathrm{kv}(h)_k}$. Conjugating, and using $\overline{S(z)} = S(\bar{z})$, gives the claim.

Step 4: the summand is the conjugate of a sum of period integrands. Let ι be the block diagonal embedding $\mathrm{G}(1_N) \times \mathrm{G}(1_l) \to \mathrm{G}(1_n)$ along ε, and for $h_2 \in \mathrm{G}(1_l)$ put

$$F(h_2) = \sum_{i \in I_{\kappa^-}} \theta^{W,\mathrm{I}_l}_{\chi_O,b}(\varphi_i)(g, h_2)\, Y_{C(e_i)}(\iota((1,x), h_2)\,(1, \gamma_L)).$$

Let $u \in G_\infty(1_l)$, $h \in G_f(l)$ and $z = \rho_{\kappa^-,0}(u^{-1})\mathrm{kv}(h)$. By Step 2, $C(z) = \rho((u^{-1})^\varepsilon)C(\mathrm{kv}(h))$, so by Step 1 and the unitarity of ρ ((c) of Lemma 4.6.10), $f(h) = \langle C(z), \rho(u^\varepsilon)^{-1}\Xi(x'(h))\rangle$. As $C(z) = \sum_i \bar{z}_i C(e_i)$ and the form is conjugate-linear in its first argument,

$$f(h) = \sum_i z_i \langle C(e_i), \rho(u^\varepsilon)^{-1}\Xi(x'(h))\rangle.$$

The point $\iota((1,x),(u,h))(1,\gamma_L)$ has infinite component u^ε and finite component $x'(h)$, so the last pairing is

$$\overline{Y_{C(e_i)}(\iota((1,x),(u,h))(1,\gamma_L))};$$

with Step 3,

$$f(h) = \overline{F(u,h)} \qquad (u \in G_\infty(1_l),\ h \in G_f(l)). \tag{6.143}$$

Step 5: invariance of the summand. (a) For a rational point δ of $\mathrm{U}(\mathrm{I}_l)$, $F(\delta h_2) = F(h_2)$: the kernels are left invariant by Lemma 6.2.5, $\iota((1,x),\delta h_2) = \iota(1,\delta)\,\iota((1,x),h_2)$ with $\iota(1,\delta)$ a rational point of $\mathrm{U}(\mathrm{I}_n)$, and $Y_\zeta(\delta' X) = Y_\zeta(X)$ for rational δ' by (DP5) and the multiplicativity of ρ. With (6.143) (taking $u = \delta_\infty u'$), $f(\delta_f h) = f(h)$. (b) For $k \in \mathbf{K}^\circ$, $f(hk) = f(h)$. First, $\mathrm{kv}(hk) = \mathrm{kv}(h)$: by (6) of Lemma 4.1.1 for the modulus $\mathfrak{M}_O^2$, $\omega_{\chi_O,b}((1,1),(1,k))\varphi_i = \chi_O(\det k)\,\mathrm{mod}_{\mathfrak{M}_O^2}(\Psi(\bar{k}^{-1}\,\cdot), v) = \varphi_i$, as $\bar{k} = 1$ and $\chi_O(\det k) = v(\det k)^{r-(O)} = 1$ ((ii) of Lemma 3.2.11; $\det k$ has unit finite and trivial infinite components). Second, $x'(hk) = x'(h)c$ with $c = \gamma_L^{-1} d \gamma_L$, $d = \mathrm{diag}_\varepsilon(1,k) \in \mathbf{K}_0(n)$, and $c \in \mathbf{K}(O)$ with $\tilde{\eta}_O(c) = 1$: outside the chosen places and their conjugates $\gamma_L = 1$ and $c = d$. At a chosen place w, $\varpi_w\gamma_w^{-1}$ is integral (GU2) and so is γ_w (the matrix $(\varpi_O\gamma_L^{-1})^* = \bar{\varpi}_O\gamma_L$ is integral, and the component of $\bar{\varpi}_O$ at w is 1, $\bar{w}$ not being chosen (DP1)); as $k \equiv 1$ modulo w^2, $d_w = 1 + \varpi_w^2 Z$ with Z integral, so $c_w = 1 + (\varpi_w\gamma_w^{-1})Z(\varpi_w\gamma_w)$ is integral and $\equiv 1 \pmod{w}$, hence in $\mathrm{GL}_n(\mathcal{O}_{E,w})$, and then $c_{\bar{w}}$, determined by $c^*c = 1$, is integral and invertible too. So $c \in \mathbf{K}_0(n)$, $\mathrm{red}_w c = 1$ for $w \in M_O$, and for $w \in Q_O$, $\mathrm{red}_w c = \mathrm{red}_w d$ has the rows $\mathrm{inc}_O(i) = \varepsilon(\phi_{\mathcal{V}}(i)) \in \varepsilon(N)$ ((GU1)) equal to those of the identity. By (DP4), $c \in \mathbf{K}(O)$ with inc-blocks 1 at Q_O, so $\tilde{\eta}_O(c) = 1$ and $\Xi(x'(hk)) = \Xi(x'(h))$ (DP5). With Step 1, $f(hk) = f(h)$.

Step 6: the class sum is a multiple of the period integral. By (6.143) and Step 5, $F(u,h) = \overline{f(h)}$ does not depend on u, is left invariant under the rational points of $\mathrm{U}(\mathrm{I}_l)$ and right invariant under the open subgroup $\mathbf{K}^\circ$ in h, hence continuous (locally constant in h). By (2) and then (1) of Lemma 6.4.74 with $\mathrm{K} = \mathrm{K}' = \mathbf{K}^\circ$ (the inner integral over $G_\infty(1_l)$ is $\overline{f(h)}$, the Haar measure there being a probability measure),

$$\int_{[\mathrm{U}(\mathrm{I}_l)]} F = \frac{c_l}{[\mathbf{K}_0(l) : \mathbf{K}^\circ]} \sum_{[h]} \frac{\overline{f(h)}}{\#(\mathrm{U}(\mathrm{I}_l)(F) \cap h\mathbf{K}^\circ h^{-1})} = \frac{c_l}{[\mathbf{K}_0(l) : \mathbf{K}^\circ]} \overline{\sum_{h \bmod \mathbf{K}^\circ}^{\mathrm{cl}} f(h)},$$

$c_l > 0$, the class sum (6.22) having rational weights.

Step 7: the periods vanish. Each summand of F is the integrand of Proposition 6.6.81 for O, Ξ, $\zeta = C(e_i)$, the character b, the datum φ_i, the points g, $h_1 = (1,x) \in \mathrm{G}(1_N)$ and $\gamma = \gamma_L$, and the partition $\{1,\dots,n\} = \varepsilon(N) \sqcup \varepsilon(l)$ (identified with $N \sqcup l$ through ε, so that $\mathrm{I}_n = \mathrm{I}_N \oplus \mathrm{I}_l$ and the block diagonal embedding is ι). Its hypotheses on O and Ξ and $2r + 2\#N + 3 < n$ are those of the statement. The components of γ_L outside the chosen places and their conjugates, hence outside Σ, are 1 (GU2). The datum $\varphi_i = v \otimes (\Psi^\natural \otimes_{M_O} v^0)$ ($v = v_{\mathrm{Let}_{-1}(b_i)}$, (XD5), $\Sigma(\mathfrak{M}_O^2) = M_O$) is the vacuum at the finite places outside Σ: for an integral finite adelic z with $z_w = 0$ at the places of $\Sigma \supseteq M_O \cup \bar{M}_O$, $\rho_f(z)$ is a scalar times $\rho(\mathrm{fv}(z))$ (WD8), which commutes with the operators $\rho(\mathrm{rv}(\cdot))$ of (WR6), the two vectors having no common nonzero component (WD7), so $\rho_f(z)(v \otimes f') = v \otimes \rho_f(z)f'$; and $\rho_f(z)(\Psi^\natural \otimes_{M_O} v^0) = \Psi^\natural \otimes_{M_O} v^0$ by (5) of Lemma 6.2.33. So $\int_{[\mathrm{U}(\mathrm{I}_l)]} F = 0$, and by Step 6 the class sum of the statement vanishes. □

Lemma 6.6.41. *Let $1 \le j \le m$ and ϑ a tame character with modulus Q. For $\tau \in \Phi$ and a basis index c of W_j put $l_\tau(c) = 2\varsigma_\tau(\mathrm{num}(c))$, $\varsigma_\tau(i)$ the entry of number i of $\varsigma(\tau)$. Then $O_{j,\vartheta}$ fits the parameter $l = (l_\tau)_{\tau\in\Phi}$.*

Proof. Fix $\tau \in \Phi$ and drop it from the notation: $\varsigma(i) = \varsigma_\tau(i)$ ($i \ge 0$, extended as in (LF4)), $w = \kappa_j(\tau)$, $l = l_\tau$, $\kappa^\pm(h) = \kappa^\pm_O(\tau, h)$ for $O = O_{j,\vartheta}$, $n = r + t$. Put $a = k + j - 1$, $b = m - j$ (so $a + b = r$), and $T = \frac{t-1}{2}$.

Step 0: arithmetic of the data. By Definition 2.3.3, $C_P \ge 6$, so (AD1) gives $\log\log b > 0$ and $\log x \ge 100 \log\log b > 0$; hence $x \ge 2$ and $r \ge x^5 \ge 32$ by (AD2). The integers r and $t = 5r$ are odd and $k = r+1-m$ is even. The extended target parameter is a strictly decreasing sequence of integers: $\varsigma(i) = \frac{k}{2} - 1 - i$ for $0 \le i \le k-2$, and $\varsigma(k-1+i) = \frac{\Delta}{2} - \kappa_{i+1} = -\kappa - (i+1)\Delta$ for $i \ge 0$, which is below $1 - \frac{k}{2}$. In particular

$$\varsigma(a-1) = \tfrac{\Delta}{2} - w, \qquad \varsigma(a) = -\tfrac{\Delta}{2} - w, \qquad \tfrac{\Delta}{2} = r^8 > T + 1, \qquad w \ge \tfrac{\Delta}{2} > k. \tag{6.144}$$

By (HP4) read in the numbering num, a basis vector c of W_j has sign $\varepsilon(c) = 1$ if and only if $\mathrm{num}(c) < a$; so $r_+(O) = a$, $r_-(O) = b$, and num is a bijection from the basis indices onto $\{0, \dots, r-1\}$.

Step 1: the weight of O. From (LF4) and (6.144), for $1 \le h < n$:

- if $h < a$, then $\varsigma(h) \ge \varsigma(a-1) > T - w$, so $\kappa^+(h) = \varsigma(h-1) - \varsigma(h) - 1 \ge 0$; $\kappa^+(a) = \varsigma(a-1) - (T-w) - 1 = \frac{\Delta}{2} - T - 1$, as $\varsigma(a) < -T - w < T - w$; and if $h > a$, then $\varsigma(h-1) \le \varsigma(a) < T - w$, so $\kappa^+(h) = 0$;
- if $h < b$, then $r - h - 1 \ge a$ and $\varsigma(r-h-1) \le \varsigma(a) < -w - T$, so $\kappa^-(h) = \varsigma(r-h-1) - \varsigma(r-h) - 1 \ge 0$; if $h = b$, then $r - h - 1 = a - 1$ and $\kappa^-(b) = -w - T - \varsigma(a) - 1 = \frac{\Delta}{2} - T - 1$; and if $h > b$, both arguments $r - h - 1$, $r - h$ (read as 0 when negative) are at most $a - 1$, so both values of ς exceed $-w - T$ and $\kappa^-(h) = 0$.

In particular $\kappa^+(h) = 0$ for $r_+(O) = a < h < n$ and $\kappa^-(h) = 0$ for $r_-(O) = b < h < n$, which is (iii) of (DP11).

Step 2: the parameter l_O. For $0 \le p < n$ the highest weight of $\kappa_O(h) = \kappa^+(h) + \kappa^-(n-h)$ is $\lambda_O(p) = \sum_{p<h<n} \kappa^+(h) + \sum_{0<h'<n-p} \kappa^-(h')$, and $e_O = -\sum_{0<h'<n} \kappa^-(h')$, so

$$e_O + \lambda_O(p) = A(p) - B(p), \qquad A(p) = \sum_{p<h<n} \kappa^+(h), \quad B(p) = \sum_{n-p\le h'<n} \kappa^-(h').$$

By Step 1, $A(p) = 0$ for $p \ge a$, and for $p < a$ the sum telescopes:

$$\begin{aligned} A(p) &= \sum_{h=p+1}^{a-1} \big(\varsigma(h-1) - \varsigma(h) - 1\big) + \tfrac{\Delta}{2} - T - 1 \\ &= \varsigma(p) - \varsigma(a-1) - (a - 1 - p) + \tfrac{\Delta}{2} - T - 1 = \varsigma(p) + w - T - (a - p). \end{aligned}$$

Likewise $B(p) = 0$ unless $n - p \le b$, i.e. $p \ge a + t$, and then, with $q = r - h'$,

$$\begin{aligned} B(p) &= \sum_{q=a+1}^{p-t} \big(\varsigma(q-1) - \varsigma(q) - 1\big) + \tfrac{\Delta}{2} - T - 1 \\ &= \varsigma(a) - \varsigma(p-t) - (p - t - a) + \tfrac{\Delta}{2} - T - 1 = -w - \varsigma(p-t) - p + t + a - T - 1. \end{aligned}$$

With $l_O(p+1) = 2(e_O + \lambda_O(p)) + n - 1 - 2p$ (DP11) and $2T = t - 1$ this gives

$$l_O(p+1) = \begin{cases} 2\varsigma(p) + 2w - 2a + r, & 0 \le p < a, \\ r + t - 1 - 2p, & a \le p < a + t, \\ 2\varsigma(p-t) + 2w - 2a + r, & a + t \le p < n. \end{cases}$$

Step 3: (i), the block rule. We check (WM8) for (l, l_O) with the index sets of W_j and $\{1, \dots, n\}$, $N = r \le N' = n$, the weights $\gamma = r_-(O) = b$ and $\gamma' = \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau) = \frac{r+t}{2} - w$ (the character $\mu_j^0 \vartheta$ has weight $-\kappa_j$, ϑ having weight 0), and the signs $(\varepsilon, \mathbf{1}_n)$.

(a) $l(c) = 2\varsigma(\mathrm{num}(c))$ is injective and even, and $N - 1 = r - 1$ is even. If $\varepsilon(c) \ne \varepsilon(c')$, say $\mathrm{num}(c) < a \le \mathrm{num}(c')$, then $|l(c) - l(c')| \ge 2(\varsigma(a-1) - \varsigma(a)) = 2\Delta = 4r^8 \ge 2 \cdot 500(7r)^3$, as $r^5 \ge 32^5 > 85750$. So l has gap $500(N + N')^3 = 500(7r)^3$ for ε. The map l_O is strictly decreasing by its definition in (DP11), and $l_O(p+1) \equiv n - 1 \pmod 2$; as all signs of $\mathbf{1}_n$ agree, it has the same gap for $\mathbf{1}_n$.

(b) The shifted entries are $\tilde{l}(c) = l(c) - 2\gamma' + n = 2\varsigma(\mathrm{num}(c)) + 2w$ and $\tilde{l}_O(p+1) = l_O(p+1) - 2b + r$. As $2a + 2b = 2r$, Step 2 gives $\tilde{l}_O(p+1) = 2\varsigma(p) + 2w$ for $p < a$, $t - 1 - 2(p-a)$ for $a \le p < a+t$, and $2\varsigma(p-t) + 2w$ for $p \ge a+t$. Since num is a bijection onto $\{0, \dots, r-1\}$, $\tilde{l}_O(\{1, \dots, n\}) = \tilde{l}(\{c\}) \cup [t] = \tilde{l}(\{c\}) \cup [N' - N]$.

(c) For $\mathrm{num}(c) < k - 1$, $\tilde{l}(c) \ge 2 - k + 2w > 0$ by (6.144); for $\mathrm{num}(c) = k - 1 + i$, $\tilde{l}(c) = \Delta - 2\kappa_{i+1} + 2\kappa_j = (2(j-i) - 1)\Delta$, positive exactly when $i < j$. So $\tilde{l}(c) > 0$ if and only if $\mathrm{num}(c) < a$, i.e. $\varepsilon(c) = 1$, and $\tilde{l}(c) < 0$ otherwise. As every sign of $\mathbf{1}_n$ is 1, (c) of (WM8) holds.

Step 4: (ii), the numbering. If $\varepsilon(c) = 1$, the c' of sign 1 with $l(c) < l(c')$ are those with $\mathrm{num}(c') < \mathrm{num}(c)$ (ς is strictly decreasing, and $\mathrm{num}(c') < \mathrm{num}(c) < a$ forces sign 1); there are $\mathrm{num}(c) = \mathrm{ord}_O(c)$ of them. If $\varepsilon(c) = -1$, the c' of sign -1 with $-l(c) < -l(c')$ are those with $\mathrm{num}(c) < \mathrm{num}(c') \le r - 1$; there are $r - 1 - \mathrm{num}(c) = \mathrm{ord}_O(c)$ of them (LF4).

Steps 3, 4 and 1 are (i), (ii) and (iii) of (DP11) at every $\tau \in \Phi$; so $O_{j,\vartheta}$ fits l. □

Lemma 6.6.42. *Let $1 \le j \le m$, ϑ a twist and $O = O_{j,\vartheta}$. Then for every chosen place w, every nonzero row $\lambda \in k_w^r$ and every $\Xi \in [e_0]\mathrm{Form}(O)$,*

$$\sum_{s \in H(\lambda)} \psi_{O,w}(\det s)^{-1} \, [s]_w \, \Xi = 0.$$

Proof. Fix a chosen place w, put $k_0 = k_w$, $G = \mathrm{GL}_r(k_0)$ and $\chi = \psi_{O,w}$. The tame component of a twist is trivial at every chosen place, since its modulus is prime to MN. Thus (LF2)–(LF4) give $\chi = \omega_w^j$, hence $\chi^{q_2} = 1$.

We first prove a finite-group assertion. Let c be a label allowed for q_2 and let $\lambda \ne 0$. Put $K_\lambda = \ker \lambda$. Choose $b \in k_0^r$ with $\lambda(b) = 1$. Relative to $k_0^r = K_\lambda \oplus k_0 b$, the elements of $H(\lambda)$ are precisely

$$\begin{pmatrix} 1 & u \\ 0 & a \end{pmatrix}, \qquad u \in K_\lambda, \quad a \in k_0^\times.$$

Indeed $1 + v\lambda$ has this matrix with $u = v - \lambda(v)b$ and $a = 1 + \lambda(v)$, and it is invertible exactly when $a \ne 0$. In particular its determinant is a. For $r > 1$, let P be the stabilizer of K_λ and

U its unipotent radical. Then $H(\lambda) = U \rtimes k_0^\times$, where the latter factor is the GL_1 factor of the Levi subgroup $\mathrm{GL}_{r-1}(k_0) \times \mathrm{GL}_1(k_0)$.

Let V_c be the irreducible representation with character $\pm\Xi_c$, which exists by Theorem A.5.27. Its central idempotent is e_c: in the usual irreducible-character idempotent formula, changing both factors $\Xi_c(1)$ and $\overline{\Xi_c(g)}$ by the same sign leaves their product unchanged. For $r > 1$, suppose that a nonzero vector in V_c transforms under $H(\lambda)$ by $\chi \circ \det$. It lies in V_c^U, and its GL_1 character is χ. Complete reducibility for the other Levi factor therefore gives an irreducible constituent $\tau \boxtimes \chi$ of the Harish-Chandra restriction V_c^U. We verify the required restriction by the label factorization in Theorem A.5.29. Factor $c = \prod_{i=1}^{t} f_i$ into its distinct monic irreducible factors, put $d_i = \deg f_i$, and let ρ_i be the irreducible cuspidal representation with character $\pm\Xi_{f_i}$, as supplied by Theorem A.5.28. Thus

$$V_c \simeq \mathrm{Ind}_Q^G(\rho_1 \boxtimes \cdots \boxtimes \rho_t),$$

where Q is the block parabolic of type $(d_1, \ldots, d_t)$ and the representation on its Levi subgroup is inflated across its unipotent radical.

Here is the specialization of finite-group Mackey decomposition that we need. The relative position of a hyperplane and a flag of type $(d_1, \ldots, d_t)$ is specified by the unique block i in which the one-dimensional quotient occurs. Indeed, intersecting the successive flag spaces with the hyperplane reduces the successive quotient dimensions by 1 in that block and by 0 in the others. Choosing bases in the successive quotients shows both that these are all the double cosets $P\backslash G/Q$ and that each such position is one double coset. In position i, the stabilizer on the i-th block is the parabolic of type $(d_i - 1, 1)$. Mackey decomposition, followed by averaging over U, consequently replaces ρ_i by its invariants under the unipotent radical of that parabolic; the other blocks remain unchanged, and induction on the hyperplane combines their dimensions d_h with $d_i - 1$. This averaging assertion also follows directly from the induced-function model: an invariant function is constant on the left U-orbits, while its values must be invariant under the image of U in the block stabilizer. To see the image explicitly, choose the one quotient vector in the i-th block and a basis for its intersection with the hyperplane. The maps in U from that quotient vector to the intersection basis project onto all matrices

$$\begin{pmatrix} 1 & u \\ 0 & 1 \end{pmatrix}, \qquad u \in k_0^{d_i - 1},$$

on that block. These are exactly the required unipotent radical; their parameters are unrestricted.

If $d_i > 1$, these invariants are zero by cuspidality of ρ_i. If $d_i = 1$, the radical is trivial, and the GL_1 factor acts by ρ_i. Consequently this Mackey decomposition gives

$$V_c^U \simeq \bigoplus_{\{i : d_i = 1\}} \left(\mathrm{Ind}_{Q_i}^{\mathrm{GL}_{r-1}(k_0)} \boxtimes_{h \neq i} \rho_h \right) \boxtimes \rho_i,$$

where Q_i is the block parabolic with the i-th block omitted and the factors are inflated to it. In particular every GL_1 character occurring in V_c^U is one of these ρ_i. If the character χ is the factor ρ_i corresponding to $f_i = X - a_i$, the degree-one clause of Theorem A.5.29 gives $\mathrm{ord}(\chi) = \mathrm{ord}(a_i)$. Since $\chi^{q_2} = 1$, it follows that $a_i^{q_2} = 1$. This contradicts the allowance condition on c, since $a_i \in k_0$ is a root of c. For $r = 1$ the representation V_c itself is ρ_{X-a} for the unique root a of c; the same order argument excludes a χ-isotypic vector directly.

In a complex representation of G, the element

$$T_{\chi,\lambda} = \sum_{s \in H(\lambda)} \chi(\det s)^{-1} s$$

acts as $|H(\lambda)|$ times the projector onto its $\chi \circ \det$ isotypic subspace. This follows directly by multiplying the sum on the left by an element of $H(\lambda)$ and by observing that the sum acts as $|H(\lambda)|$ on that subspace. The subspace just excluded is zero in V_c, so $T_{\chi,\lambda}$ acts as zero there. It follows that $T_{\chi,\lambda} e_c = 0$ in $\mathbb{C}[G]$: on the simple summand selected by e_c the first factor is zero, and on every other simple summand e_c is zero; the regular representation is faithful.

Embed $T_{\chi,\lambda}$ in the w factor of $\mathbb{C}[\bar{G}]$, with identity elements in every other factor. Every good family has its label c_w allowed for q_2, so multiplication of tensor factors gives

$$T_{\chi,\lambda} e_0 = \sum_{c \text{ good}} (T_{\chi,\lambda} e_{c_w}) \otimes \bigotimes_{u \neq w} e_{c_u} = 0.$$

Finally, write $\Xi = [e_0]Y$. The action in (DP5) extends to an algebra homomorphism, and hence

$$\sum_{s \in H(\lambda)} \psi_{O,w}(\det s)^{-1} [s]_w \Xi = [T_{\chi,\lambda}][e_0]Y = [T_{\chi,\lambda} e_0]Y = 0.$$

This is the required one-place assertion. □

Lemma 6.6.43. *Let $1 \leq j \leq m$, ϑ a twist and $O = O_{j,\vartheta}$. If $\varphi \in [e_0]\mathrm{Form}(O)$ is orthogonal to $\mathcal{L}_{j,\vartheta}$, then $\mathrm{Th}_O(\varphi) = 0$.*

Proof. Write $\Theta = \Theta_{j,\vartheta}$ and $\mathcal{L} = \mathcal{L}_{j,\vartheta} = \Theta(\mathcal{A}^{\mathrm{good}}(W_j))$. Let $y \in \mathcal{A}_M(W_j)$. By (i) of Lemma 6.6.10 and linearity of Θ, $\Theta(a \cdot y) = [a]\Theta(y)$ for every $a \in \mathbb{C}[\bar{G}]$; in particular $[e_0]\Theta(y) = \Theta(e_0 y) \in \mathcal{L}$, as $e_0 y$ is a good form. By (b) of Lemma 6.6.9 (for σ the identity, where $\langle\,,\rangle_\sigma$ is the inner product of $\mathrm{Form}(O)$), $[e_0]$ is an idempotent, so $[e_0]\varphi = \varphi$, and it is self-adjoint; hence

$$\langle \varphi, \Theta(y) \rangle = \langle [e_0]\varphi, \Theta(y) \rangle = \langle \varphi, [e_0]\Theta(y) \rangle = \langle \varphi, \Theta(e_0 y) \rangle = 0.$$

By (a) of Lemma 6.6.30, $\int_{[\mathrm{U}(W_j)]} y\, \overline{\mathrm{Th}_O(\varphi)} = \langle \varphi, \Theta(y) \rangle = 0$ for every $y \in \mathcal{A}_M(W_j)$. By (b) there, $y = \mathrm{Th}_O(\varphi)$ is admissible, so $\int_{[\mathrm{U}(W_j)]} |\mathrm{Th}_O(\varphi)|^2 = 0$. The function $\mathrm{Th}_O(\varphi)$ is continuous and left invariant under the rational points, and the quotient measure gives positive mass to every nonempty open subset of $[\mathrm{U}(W_j)]$ (the image of an open set of positive Haar measure); so $\mathrm{Th}_O(\varphi) = 0$. □

Proposition 6.6.44. *Let $1 \leq j \leq m$ and $y \in \mathcal{A}^{\mathrm{good}}(W_j)$. If*

$$\int_{[\mathrm{U}(W_j)]} y(g)\, \mathsf{F}_i(g)\, \mathrm{tt}_j(\zeta)(g)\, dg = 0$$

for every choice $i \in \mathrm{Mem}_j$ and every $\zeta \colon \mathrm{Cl}^\circ \to \mathbb{V}_j^-$, then $y = 0$.

Proof. Let s_j be the signs of W_j, $n_* = 2ft^3$, and let o, u, u° be as in Lemma 6.6.45. Suppose $y \neq 0$ and put $F = \bar{y}$ on $\mathrm{G}(s_j)$: it is continuous and bounded (y is a form of type e_ς, Definition 3.2.16), adelically holomorphic of weight u for o ((b) of Lemma 6.6.45), and $0 < \sup|F| < \infty$; by the definition of the supremum there is z with $|F(z)| > \frac{1}{2}\sup|F|$, a peak of F.

Let F_0 be as in Lemma 6.6.61, $C = \sup|F_0| < \infty$ and $\delta = 2b^{-19n_*}|F_0(1)|$. Let x be a peak of F. By Lemma 6.6.58, $\lambda_{W_j}(x) \geq (5b^{24})^{-1/2}$, so Lemma 6.6.61 gives (c_i) with $|K(h) - F_0(h)| \leq \delta |h|^{6n_*}$ for $K(h) = \sum_i c_i \mathsf{F}_i(x(h,1))$. Each $h \mapsto \mathsf{F}_i(x(h,1))$ is holomorphic of weight $u - u^\circ$ for o ((c) of Lemma 6.6.45), hence so is K (the sum of the extensions is an extension of the sum). As $\overline{F(x(h,1))} = y(x(h,1))$, (d) of Lemma 6.6.45 gives $\int_{G_\infty(s_j)} \overline{F(x(h,1))}\, K(h)\, m^{\mathrm{hol}}_{s_j,u^\circ}(h)\, dh = 0$.

These are the hypotheses of Lemma 6.6.80 for the index set of W_j (of size $r \le t$), s_j, o, the weights u, $u' = u^\circ$ ((a) of Lemma 6.6.45), F, z, $K_0 = F_0$, C and δ. Hence, with $B = b^{n_*}$,

$$|F_0(1)| \le (4B+1) \cdot 2B^{-19} \, |F_0(1)|.$$

By (AD1) and $C_P \ge 6$, $\log\log b \ge 6 \cdot 10^{12}$, so $b > 10$, and $n_* \ge 1$, so $B \ge b > 10$ and $(4B+1) \cdot 2 = 8B + 2 < B^2 \le B^{19}$; so $(4B+1) \cdot 2B^{-19} < 1$, which contradicts $F_0(1) \ne 0$. Therefore $y = 0$. □

Lemma 6.6.45. *Let $1 \le j \le m$ and $n_* = 2ft^3$. There are an order o on the basis of W_j, positive-first for s_j, and weights $u = (u_v)_{v \in \Phi}$, $u^\circ = (u_v^\circ)_{v \in \Phi}$ on that basis such that:*

(a) every u_v and every u_v° is K-dominant for (s_j, o) and has holomorphic gap $300n_*$ for s_j, and $|u_v(i)| \le 5b$ for all v and i;

(b) for every $y \in \mathcal{A}^{\mathrm{good}}(W_j)$, $\bar{y}$ is adelically holomorphic of weight u for o;

(c) for every choice $i \in \mathrm{Mem}_j$, F_i is adelically holomorphic of weight $u - u^\circ$ for o;

(d) if $y \in \mathcal{A}^{\mathrm{good}}(W_j)$ satisfies $\int_{[\mathrm{U}(W_j)]} y \, \mathsf{F}_i \, \mathrm{tt}_j(\zeta) = 0$ for all $i \in \mathrm{Mem}_j$ and all $\zeta \colon \mathrm{Cl}^\circ \to \mathbb{V}_j^-$, then for every $x \in \mathrm{G}(s_j)$ and all $(c_i)_{i \in \mathrm{Mem}_j}$ in $\mathbb{C}$ the function

$$h \mapsto y(x(h,1)) \sum_i c_i \mathsf{F}_i(x(h,1)) \, m^{\mathrm{hol}}_{s_j, u^\circ}(h)$$

is integrable on $G_\infty(s_j)$ with integral 0.

Proof. Write $\varsigma = \varsigma_\tau$, $\kappa_{j'} = \kappa_{j'}(\tau)$ where τ is fixed, $r_+ = k + j - 1$ and $q = \mathrm{num}(c)$, the number of a basis vector c; so $s_j(c) = 1$ if and only if $q < r_+$. By Lemma 4.2.67 and (AD2), $x \ge e^{6.4 \cdot 10^{15}}$, $x^{10^{12}} \le b$, $\sqrt{x} \le m \le 2\sqrt{x}$, $x^5 \le r \le 3x^5$, $t \le 15x^5$, $f \le x^{12}$; in particular $r > 9m + 1$, $\Delta > k$, and, as $t + k - 1$ is even, $e_j = j + \frac{t+k-1}{2}$. As $n_* = 2ft^3 \le 2x^{12}(15x^5)^3$, we have $300n_* + \frac{t+1}{2} \le 600x^{12}(15x^5)^3 + 8x^5 \le x^{40} \le r^8$, i.e. $300n_* \le \Delta'$; and $\kappa \le b$ (as $a/x_1 = xb/x_1 \le b$), so $\kappa_m \le b + (2m+1)r^8 \le 2b$.

Step 1: the target parameter and the order. By Definition 3.2.16, $\varsigma(i) = \frac{k}{2} - 1 - i$ for $0 \le i \le k-2$ and $\varsigma(k - 2 + j') = \frac{\Delta}{2} - \kappa_{j'}$ for $1 \le j' \le m$; these are integers, and the sequence is strictly decreasing, since $\varsigma(k-1) = -\kappa - \Delta < 1 - \frac{k}{2} = \varsigma(k-2)$ and $\kappa_{j'+1} - \kappa_{j'} = \Delta$. Put $l_\tau(c) = 2\varsigma(\mathrm{num}(c))$ and define the order

$$o(c) = -1 - \mathrm{num}(c) \ \ (s_j(c) = 1), \qquad o(c) = r - 1 - \mathrm{num}(c) \ \ (s_j(c) = -1).$$

It is injective, with values in $\{-r_+, \dots, -1\}$ on the positive and in $\{0, \dots, m - j - 1\}$ on the negative vectors, so it is positive-first for s_j. If $s_j(a) = s_j(b)$ and $o(a) < o(b)$, then $\mathrm{num}(a) > \mathrm{num}(b)$, hence $l_\tau(a) < l_\tau(b)$.

Step 2: the weight u. Let $u_\tau = \mu_{-l_\tau}$, the lowest K-type of $-l_\tau$ for s_j. As $-l_\tau(c) = -2\varsigma(q)$ is strictly increasing in q, $2\rho_{-l_\tau}(c) = q - (r - 1 - q)$, and $l_c^\rho = -\varsigma(q) + q - \frac{r-1}{2}$ (an integer, r being odd). Counting within the signs, $2\rho^{\mathrm{c}}(c) = q - (r_+ - 1 - q)$ for $s_j(c) = 1$ and $(q - r_+) - (r - 1 - q)$ for $s_j(c) = -1$. Hence

$$u_\tau(c) = -\varsigma(q) - q + r_+ - \tfrac{r+1}{2} \quad (s_j(c) = 1), \qquad u_\tau(c) = -\varsigma(q) - q + r_+ + \tfrac{r-1}{2} \quad (s_j(c) = -1).$$

Explicitly, with $k = r + 1 - m$: $u_\tau(c) = j - \frac{m}{2}$ for $q \le k - 2$, and $u_\tau(c) = \kappa_{j'} - \frac{\Delta}{2} + j - j' + 1 - \frac{r+1}{2}$ resp. $\kappa_{j'} - \frac{\Delta}{2} + j - j' + 1 + \frac{r-1}{2}$ for $q = k - 2 + j'$ of sign $+1$ resp. -1.

Step 3: the column counts. From (LF4) and Step 1 (with the extension $\varsigma(i) = \frac{\Delta}{2} - \kappa_{i+2-k}$ for $i \ge r$, and $\frac{\Delta}{2} > \frac{t-1}{2}$):

- for $1 \le h \le r_+ - 1$: $\varsigma(h) \ge \frac{\Delta}{2} - \kappa_j \ge \frac{t-1}{2} - \kappa_j$, so $\kappa_O^+(\tau, h) = \varsigma(h-1) - \varsigma(h) - 1 \ge 0$; $\kappa_O^+(\tau, r_+) = \frac{\Delta}{2} - \kappa_j - \frac{t-1}{2} + \kappa_j - 1 = \Delta'$ (as $\varsigma(r_+) = -\frac{\Delta}{2} - \kappa_j < \frac{t-1}{2} - \kappa_j$); $\kappa_O^+(\tau, h) = 0$ for $h > r_+$ (then $\varsigma(h-1) \le \varsigma(r_+)$);
- for $1 \le h < m - j$: $\kappa_O^-(\tau, h) = \Delta - 1$ (the minimum is $\varsigma(r-h-1) = \frac{\Delta}{2} - \kappa_{m-h}$, as $m - h > j$, and $\varsigma(r-h) = \frac{\Delta}{2} - \kappa_{m+1-h}$); $\kappa_O^-(\tau, m-j) = -\kappa_j - \frac{t-1}{2} - \frac{\Delta}{2} + \kappa_{j+1} - 1 = \Delta'$; $\kappa_O^-(\tau, h) = 0$ for $h > m - j$ (then $\varsigma(r-h) \ge \frac{\Delta}{2} - \kappa_j > -\kappa_j - \frac{t-1}{2}$).

For a positive c ($\mathrm{ord}_O(c) = q$), as $r_+ < |\mathcal{B}_j|$ the sum telescopes:

$$\sum_{q < p < |\mathcal{B}_j|} \kappa_O^+(\tau, p) = \varsigma(q) - \varsigma(r_+ - 1) - (r_+ - 1 - q) + \Delta'.$$

For a negative c with $q = k - 2 + j'$ ($j < j' \le m$), $\mathrm{ord}_O(c) = r - 1 - q = m - j'$, and as $m - j < |\mathcal{B}^\circ|$,

$$\sum_{m - j' < p < |\mathcal{B}^\circ|} \kappa_O^-(\tau, p) = (j' - j - 1)(\Delta - 1) + \Delta'.$$

Step 4: the weights u° and $u - u^\circ$. Let u° be the weights of Lemma 6.6.52 for o ($\lfloor m/2 \rfloor = \frac{m}{2}$): $u_\tau^\circ(c) = j - \frac{m}{2}$ for $s_j(c) = 1$ and, by Step 3, $u_\tau^\circ(c) = j - \frac{m}{2} + |\mathcal{B}^\circ| + (j' - j - 1)(\Delta - 1) + \Delta'$ for $q = k - 2 + j'$ negative. Let w be the weights of Lemma 6.6.49. For positive c, by Step 3 and $\varsigma(r_+ - 1) = \frac{\Delta}{2} - \kappa_j$, $\frac{\Delta}{2} - \Delta' = \frac{t+1}{2}$, $e_j = j + \frac{t+k-1}{2}$,

$$w_\tau(c) = \kappa_j - e_j - \varsigma(q) + \tfrac{\Delta}{2} - \kappa_j + (r_+ - 1 - q) - \Delta' = -\varsigma(q) - q + \tfrac{k}{2} - 1,$$

and $u_\tau(c) - u_\tau^\circ(c) = -\varsigma(q) - q + r_+ - \frac{r+1}{2} - j + \frac{m}{2} = -\varsigma(q) - q + \frac{k}{2} - 1$, as $r_+ - j = k - 1$ and $\frac{r+1-m}{2} = \frac{k}{2}$. For negative c with $q = k - 2 + j'$, $w_\tau(c) = \kappa_j - e_j + |\mathcal{B}_j|$, and with $-\varsigma(q) = \kappa_j + (j' - j)\Delta - \frac{\Delta}{2}$ and $-q + r_+ = j - j' + 1$,

$$u_\tau(c) - u_\tau^\circ(c) = \kappa_j + \tfrac{\Delta}{2} - \Delta' - j + \tfrac{r-1}{2} + \tfrac{m}{2} - |\mathcal{B}^\circ| = \kappa_j + \tfrac{t+1}{2} - j + \tfrac{r-1}{2} + \tfrac{m}{2} - |\mathcal{B}^\circ|;$$

its difference with $w_\tau(c)$ is $\frac{t+1}{2} + \frac{r-1}{2} + \frac{m}{2} + \frac{t+k-1}{2} - (|\mathcal{B}^\circ| + |\mathcal{B}_j|) = \frac{2t+r+m+k-1}{2} - (r+t) = 0$, as $|\mathcal{B}^\circ| + |\mathcal{B}_j| = r + t$ and $k = r + 1 - m$. So $u - u^\circ = w$.

Step 5: (a). *K-dominance.* Within each sign, $o(a) < o(b)$ means $\mathrm{num}(a) > \mathrm{num}(b)$, so K-dominance means that the weight does not decrease when q increases within a sign. For u_τ, by Step 2, the increment from q to $q+1$ (same sign) is $\varsigma(q) - \varsigma(q+1) - 1 \ge 0$, the $\varsigma(i)$ being strictly decreasing integers. For u_τ° it is 0 on the positive vectors and $\Delta - 1 \ge 0$ on the negative ones. *Holomorphic gap.* If $j = m$ there are no negative vectors and nothing is to be shown. Otherwise, u_τ being nondecreasing in q within each sign, its largest positive value is at $q = r_+ - 1$, namely $\kappa_j - \frac{\Delta}{2} + 1 - \frac{r+1}{2}$, and its smallest negative value at $q = r_+$, namely $\kappa_{j+1} - \frac{\Delta}{2} + \frac{r-1}{2}$; their difference is $\Delta + r - 1 \ge \Delta' \ge 300 n_*$. For u_τ° the smallest negative value minus the positive value is $|\mathcal{B}^\circ| + \Delta' \ge 300 n_*$. So both have holomorphic gap $300 n_*$ for s_j. *Size.* For $q \le k - 2$, $|u_\tau(c)| = |j - \frac{m}{2}| \le m$. Otherwise $\kappa_{j'} - \frac{\Delta}{2} = \kappa + j'\Delta$ lies in $[\kappa + \Delta, \kappa_m]$, so $u_\tau(c)$ lies between $\kappa + \Delta - m - r > 0$ and $\kappa_m + m + r \le 2b + 3m + 3x^5 \le 5b$. So $|u_\tau(c)| \le 5b$.

Step 6: (b), (c), (d). By Step 1, o satisfies the hypotheses of Lemma 6.6.46, Lemma 6.6.49 and Lemma 6.6.52. (b) is Lemma 6.6.46 (good forms lie in $\mathcal{A}_M(W_j)$). (c) is (b) of Lemma 6.6.49, as $w = u - u^\circ$ by Step 4. For (d): $\#\mathcal{R} = r \le t$, o is positive-first, and u, u° satisfy (a); so Lemma 6.6.68 (with $u' = u^\circ$) gives $\int_{G_\infty(s_j)} |m_{s_j,u^\circ}^{\mathrm{hol}}(h)|\,|h|^{6n_*}\,dh < \infty$ with $|h| \ge 1$, hence $m_{s_j,u^\circ}^{\mathrm{hol}}$ (a continuous function) is integrable, and the u_τ° are K-dominant by (a). Then (d) is Lemma 6.6.52 for $y \in \mathcal{A}^{\mathrm{good}}(W_j) \subseteq \mathcal{A}_M(W_j)$. □

Lemma 6.6.46. *Let $1 \le j \le m$, and for $\tau \in \Phi$ let $l_\tau \colon \mathcal{R} \to \mathbb{Z}$, $l_\tau(c) = 2\varsigma_\tau(\mathrm{num}(c))$, $\varsigma_\tau(i)$ the entry of number i of $\varsigma(\tau)$. Let o be an order on $\mathcal{R}$, positive-first for s_j, such that $l_\tau(a) < l_\tau(b)$ whenever $s_j(a) = s_j(b)$ and $o(a) < o(b)$, and let $u = (u_\tau)_{\tau\in\Phi}$ with $u_\tau = \mu_{-l_\tau}$ the lowest K-type of $-l_\tau$ for the signs s_j. Then for every $y \in \mathcal{A}_M(W_j)$, in particular for every good form y on W_j, the conjugate $\bar y$ is adelically holomorphic of weight u for o.*

Proof. **Step 1: every form of principal level is a normalised descent.** By Proposition 5.8.4 (with $V = V' = W_j$, for which ς has gap Δ by its (iii)), $\mathcal{A}_M(W_j)$ is finite-dimensional. Its Petersson product $(y_1, y_2) = \int_{[\mathrm{U}(W_j)]} y_1 \bar y_2$ is positive definite: a nonzero continuous function has $|y|^2 > 0$ on a nonempty open set, which has positive quotient measure. By (b) of Lemma 6.6.30, $U = \mathrm{Th}_O(\mathrm{Form}(O))$ is a subspace of $\mathcal{A}_M(W_j)$. Let $y \in \mathcal{A}_M(W_j)$ be orthogonal to U. By (a) of Lemma 6.6.30, $\langle \Xi, \Theta_{j,1}(y)\rangle = (y, \mathrm{Th}_O\Xi) = 0$ for every $\Xi \in \mathrm{Form}(O)$; for $\Xi = \Theta_{j,1}(y)$ this gives $\langle \Xi, \Xi\rangle = 0$. The inner product of $\mathrm{Form}(O)$ is positive definite: it is a class sum with positive weights of $\langle \Xi(h), \Xi(h)\rangle_{\kappa_O}$, the Gram form is positive definite ((b) of Lemma 4.6.10), and by (DP5) a form vanishing at the class representatives vanishes. So $\Theta_{j,1}(y) = 0$, and $y = 0$ by (1) of Proposition 6.5.9 (the lift $\Theta^{\mathrm{pr}}_{j,1}$ there is $\Theta_{j,1}$ on $\mathcal{A}_M(W_j)$). Hence $U^\perp = 0$ and, the dimension being finite, $U = \mathcal{A}_M(W_j)$: every $y \in \mathcal{A}_M(W_j)$ is $\mathrm{Th}_O(\Xi)$ for some $\Xi \in \mathrm{Form}(O)$.

Step 2: the theta datum of the highest vector is holomorphic. By Lemma 6.6.41, O fits l, and $1 \le r < n$. By Lemma 6.4.47, $\mathrm{Har}_O(\xi_O) = \prod_\tau P_\tau$ with P_τ in the variables of τ a joint harmonic for the signs $(s_j, \mathbf{1}_n)$, the weights $(r_-(O), \lfloor n/2\rfloor + \mathrm{wt}_O(\tau))$ and the parameters $(l_\tau, l_{O,\tau})$; by (b) of (HV7), P_τ is jointly highest of weights $(\mu_{l_{O,\tau}}, \mu_{-l_\tau})$ for $(l_{O,\tau}, -l_\tau)$ for the row and column units of $(s_j, \mathbf{1}_n)$ with the shifts $(r_-(O), -(\lfloor n/2\rfloor + \mathrm{wt}_O(\tau)))$. Put $\gamma = r_-(O)$ and $\gamma'(\tau) = \lfloor n/2\rfloor + \mathrm{wt}_O(\tau)$. By the hypothesis on o and Lemma 6.6.47 (with $l_v = l_\tau$, $l'_v = l_{O,\tau}$, $u_v = \mu_{-l_\tau}$, $e = \gamma'$), $\mathrm{Har}_O(\xi_O) \ne 0$ and $v = v_{\mathrm{Har}_O(\xi_O)}$ is holomorphic of weight u for the pair (γ, γ'). In particular $\xi_O \ne 0$. The characters $\chi_O = \upsilon^{r_-(O)}$ and $\chi'_O = \mu_O \upsilon^{\lfloor n/2\rfloor}$ of $\omega_O = \omega_{\chi_O,\chi'_O}$ (DP6) have the weights γ and γ', since υ has weight 1 ((ii) of Lemma 3.2.11) and μ_O has weight wt_O. By (3) of Lemma 6.6.48 with $S = W_j$, $T = \mathrm{I}_n$, $f = \Upsilon(O)$, for every $h' \in \mathrm{G}(1_n)$ the function

$$g \longmapsto \theta^{W_j,\mathrm{I}_n}_{\chi_O,\chi'_O}(\mathrm{J}_O(\xi_O))(g, h') = \theta_O\big(\omega_O(g, h')\,\mathrm{J}_O(\xi_O)\big)$$

is adelically holomorphic of weight u for o.

Step 3: all theta data. The highest vector has integer coordinates (y_{id} has entries 0 and 1 and the b_i have integer coefficients), so $\bar\xi_O = \xi_O$. The span of the $\rho(y)\xi_O$, $y \in G_\infty(1_n)$, is a nonzero ρ-invariant subspace of $\mathbb{V}_O$, hence $\mathbb{V}_O$ (the Weyl module is irreducible under $\rho(G_\infty(1_n))$: it is the irreducible polynomial representation of $\prod_\tau \mathrm{GL}_n(\mathbb{C})$ of its highest weight, read in the dual basis and twisted by a power of the determinant, and $\prod_\tau \mathrm{U}(n)$ is Zariski dense; classical). Conjugation of coordinates is a conjugate-linear bijection of $\mathbb{V}_O$, so the $\overline{\rho(y)\xi_O}$ span $\mathbb{V}_O$ as well: every $\zeta \in \mathbb{V}_O$ is $\sum_k c_k \overline{\rho(y_k)\xi_O}$ for finitely many $c_k \in \mathbb{C}$, $y_k \in G_\infty(1_n)$. As J_O is linear, (a) of Lemma 6.6.31 (with $\xi = \xi_O = \bar\xi_O$) gives

$$\mathrm{J}_O(\zeta) = \sum_k c_k\,\mathrm{J}_O\big(\overline{\rho(y_k)\xi_O}\big) = \sum_k c_k\,\omega_O(1, (y_k, 1))\mathrm{J}_O(\xi_O),$$

and for $h \in G_f(n)$, as ω_O is a representation ((2) of Lemma 4.1.1) and $(1, h)\cdot(y_k, 1) = (y_k, h)$ in $\mathrm{G}(1_n)$,

$$\theta_O\big(\omega_O(g, (1, h))\,\mathrm{J}_O(\zeta)\big) = \sum_k c_k\,\theta^{W_j,\mathrm{I}_n}_{\chi_O,\chi'_O}(\mathrm{J}_O(\xi_O))(g, (y_k, h)).$$

By Step 2 and (1) of Lemma 6.6.48, $g \mapsto \theta_O(\omega_O(g, (1, h))\mathrm{J}_O(\zeta))$ is adelically holomorphic of weight u for o, for every $\zeta \in \mathbb{V}_O$ and $h \in G_f(n)$.

Step 4: conclusion. Let $y \in \mathcal{A}_M(W_j)$ and Ξ as in Step 1. By (DP9), $\bar{y}(g) = \overline{\mathrm{Th}_O(\Xi)(g)} = \sum_{[h]} \frac{1}{\#\Gamma_h} \theta_O(\omega_O(g,(1,h))\, \mathrm{J}_O(\overline{\Xi(h)}))$, a finite sum over the classes at fixed representatives h, with $\zeta = \overline{\Xi(h)} \in \mathbb{V}_O$. By Step 3 and (1) of Lemma 6.6.48, $\bar{y}$ is adelically holomorphic of weight u for o. Good forms lie in $\mathcal{A}_M(W_j)$ (Definition 3.2.16). □

Lemma 6.6.47. *Let n be a nonempty finite index set with signs s, n' a finite index set, o an order on n that is positive-first for s, and $\gamma, e\colon \Phi \to \mathbb{Z}$. For every $v \in \Phi$ let $l_v\colon n \to \mathbb{Z}$ with $l_v(a) < l_v(b)$ whenever $s(a) = s(b)$ and $o(a) < o(b)$, let $l'_v\colon n' \to \mathbb{Z}$, $\nu_v\colon n' \to \mathbb{Z}$ and $u_v\colon n \to \mathbb{Z}$, and let $P_v \in \mathbb{C}[X_{ac} : a \in n', c \in n]$ be jointly highest of weights (ν_v, u_v) for $(l'_v, -l_v)$, for the row and column units of the signs $(s, \mathbf{1}_{n'})$ with the shifts $(\gamma(v), -e(v))$. Let $Q = \prod_{v\in\Phi} P_v(X_{v,\cdot,\cdot})$, the polynomial P_v being written in the variables $X_{v,a,c}$. Then $Q \neq 0$, and for all spaces with points S, T with signs s on n and $+1$ on n' and every bounded linear functional ℓ on $\mathcal{F}_{S,T}$, the function*

$$x \longmapsto \ell(\Omega_{\gamma,e}(x,1)\, v_Q) \qquad (x \in G_\infty(s))$$

is holomorphic of weight $u = (u_v)_{v\in\Phi}$ for o.

Proof. Fix S, T and ℓ, and write $f(x) = \ell(\Omega_{\gamma,e}(x,1)v_Q)$ $(x \in G)$, $G = G_\infty(s)$, $M = \mathrm{M}_n(\mathbb{C})^\Phi$, $\mathfrak{g} = \{X \in M : X_v^* \mathrm{diag}(s) + \mathrm{diag}(s) X_v = 0\ \forall v\}$ the Lie algebra of G, $\mathfrak{b} \subseteq M$ the families of matrices Z with $(Z_v)_{ij} = 0$ whenever $o(j) < o(i)$, and $B \subseteq \mathfrak{b}$ the families of o-triangular matrices (the invertible elements of $\mathfrak{b}$). For $Z \in M$ put $\lambda(Z) = \sum_{v\in\Phi}\sum_{c\in n} u_v(c)(Z_v)_{cc}$ and, for $b \in B$, $b^u = \prod_v \prod_c b_{v,cc}^{u_v(c)}$ as in (HV3). Products and inverses of elements of B lie in B, and the diagonal of a product of elements of $\mathfrak{b}$ is the product of the diagonals, o being injective; so $(bb')^u = b^u b'^u$ and $\lambda(bZb^{-1}) = \lambda(Z)$ for $b \in B$, $Z \in \mathfrak{b}$, and $(\exp Z)^u = e^{\lambda(Z)}$ for $Z \in \mathfrak{b}$.

Step 1: $Q \neq 0$, and the column action. Each P_v is nonzero by (HV7), and the P_v are written in disjoint sets of variables, so $Q \neq 0$. For $Z \in M$ let $\rho(Z)$ be the operator $\sum_{v\in\Phi}\sum_{c,c'\in n}(Z_v)_{cc'} E^{\mathrm{col}}_{v,cc'}$ on $\mathbb{C}[X_\iota]$, where $E^{\mathrm{col}}_{v,cc'}$ is the column unit of $(s, \mathbf{1}_{n'})$ with the shifts $(\gamma(v), -e(v))$ in the variables $X_{v,a,c}$; it is $\mathbb{C}$-linear in Z. We show

$$\rho(Z)Q = \lambda(Z)\, Q \qquad (Z \in \mathfrak{b}). \tag{6.145}$$

As $E^{\mathrm{col}}_{v,cc'}$ involves only the variables at v, $E^{\mathrm{col}}_{v,cc'}Q = (\prod_{w\neq v} P_w) E^{\mathrm{col}}_{v,cc'} P_v$, so it suffices that $E^{\mathrm{col}}_{v,cc} P_v = u_v(c) P_v$ and $E^{\mathrm{col}}_{v,cc'} P_v = 0$ whenever $o(c) < o(c')$. The first is the weight condition of P_v ((HV6) for the column units, order $-l_v$). Let $o(c) < o(c')$. If $s(c) = s(c')$, then $l_v(c) < l_v(c')$ by hypothesis, i.e. $-l_v(c') < -l_v(c)$, and $E^{\mathrm{col}}_{v,cc'} P_v = 0$ by (HV6). If $s(c) \neq s(c')$, then $s(c) = 1$ and $s(c') = -1$, o being positive-first; the variables $X_{v,a,c}$ and $X_{v,a,c'}$ have the signs 1 and -1, so by (HV5) $E^{\mathrm{col}}_{v,cc'} = -\sum_a \mathrm{lo}_{ac}\mathrm{ra}_{ac'} = \sum_{a\in n'} \partial^2/\partial X_{v,a,c}\partial X_{v,a,c'}$, and this kills P_v because P_v is termwise harmonic (two variables of one row from columns of opposite signs).

Step 2: derivatives along one-parameter subgroups. By Lemma 6.4.24 (signs $(s, \mathbf{1}_{n'})$, weights (γ, e)), for $X \in \mathfrak{g}$ and every polynomial P the map $t \mapsto \Omega_{\gamma,e}(\exp(tX), 1)v_P$ is differentiable at 0 with derivative $v_{\rho(X)P}$.

By (2) of Lemma 4.1.1, $\Omega_{\gamma,e}$ is a representation by bounded operators of $\mathcal{F}_\varepsilon$, and $x \mapsto \Omega_{\gamma,e}(x,1)w$ is continuous for every w (continuity of $(g,w) \mapsto \omega_\varepsilon^\infty(g)w$, of the pair map and of the determinants). Hence, writing $\Omega_{\gamma,e}(x\exp((t+h)X),1) = \Omega_{\gamma,e}(x\exp(tX),1)\Omega_{\gamma,e}(\exp(hX),1)$ and applying the bounded functional $\ell \circ \Omega_{\gamma,e}(x\exp(tX),1)$, for $x \in G$, $X \in \mathfrak{g}$ and $t \in \mathbb{R}$:

$$\frac{d}{dt} f(x\exp(tX)) = \Lambda_{x\exp(tX)}(X), \qquad \Lambda_x(Z) = \ell(\Omega_{\gamma,e}(x,1)v_{\rho(Z)Q}) \quad (Z \in M). \tag{6.146}$$

For fixed x, $Z \mapsto \Lambda_x(Z)$ is $\mathbb{C}$-linear, and for each Z the function $x \mapsto \Lambda_x(Z)$ is continuous. By (6.145), $\Lambda_x(Z) = \lambda(Z)f(x)$ for $Z \in \mathfrak{b}$.

Step 3: the torus. Let $d \in G \cap B$. Then $d_v^{-1} = \mathrm{diag}(s) d_v^* \mathrm{diag}(s)$ lies in $\mathfrak{b}$ and its (i,j) entry $s_i s_j \overline{(d_v)_{ji}}$ vanishes when $o(i) < o(j)$; so d_v^{-1}, hence d_v, is diagonal, and its entries have modulus 1. Write $d = \exp D$ with $D_v = \mathrm{diag}(i\theta_{v,c})_c$, $\theta_{v,c} \in \mathbb{R}$; then $D \in \mathfrak{g} \cap \mathfrak{b}$. By (6.146) and Step 2, $\phi(t) = e^{-t\lambda(D)} f(x \exp(tD))$ has derivative $e^{-t\lambda(D)}(-\lambda(D) f(x\exp(tD)) + \lambda(D) f(x \exp(tD))) = 0$, so $\phi(1) = \phi(0)$:

$$f(xd) = e^{\lambda(D)} f(x) = d^u f(x) \qquad (x \in G,\ d \in G \cap B). \tag{6.147}$$

Step 4: the extension. Let $\mathcal{U} = \{xb : x \in G,\ b \in B\} \subseteq M$ (products taken place by place). If $xb = x'b'$ with $x, x' \in G$, $b, b' \in B$, then $d = x'^{-1}x = b'b^{-1} \in G \cap B$, $b' = db$ and, by (6.147), $b'^u f(x') = b^u d^u f(x') = b^u f(x'd) = b^u f(x)$. So $\tilde{F}(xb) = b^u f(x)$ defines a function on $\mathcal{U}$; put $\tilde{F} = 0$ on $M \setminus \mathcal{U}$. It remains to show that every point of $\mathcal{U}$ has a neighbourhood in $\mathcal{U}$ on which $\tilde{F}$ is complex differentiable; then $\tilde{F}$ is holomorphic, hence complex analytic, near every point xb, which is the assertion.

Step 5: the strictly lower part. For $Z \in M$ let $N(Z) \in M$ keep the entries $(Z_v)_{ij}$ with $o(j) < o(i)$ and replace the others by 0, $J = \mathrm{diag}(s)$, and $\mathrm{v}(Z) = N(Z) - JN(Z)^*J$ (place by place); N is $\mathbb{C}$-linear and v is $\mathbb{R}$-linear. Then $\mathrm{v}(Z) \in \mathfrak{g}$ (as $\mathrm{v}^*J = N^*J - JN = -J\mathrm{v}$), $JN(Z)^*J \in \mathfrak{b}$ has zero diagonal, and $Z - \mathrm{v}(Z) = (Z - N(Z)) + JN(Z)^*J \in \mathfrak{b}$ has the diagonal of Z. By Step 2, $\Lambda_x(JN(Y)^*J) = \lambda(JN(Y)^*J) f(x) = 0$, so

$$\Lambda_x(\mathrm{v}(Y)) = \Lambda_x(N(Y)) \qquad (x \in G,\ Y \in M). \tag{6.148}$$

Step 6: complex differentiability at the identity of a chart. Fix $x_0 \in G$ and put $h(Z) = f(x_0 \exp \mathrm{v}(Z))$ for $Z \in M$. For $Y \in M$, $\mathrm{v}(tY) = t\mathrm{v}(Y)$, so by (6.146) and (6.148) the function $t \mapsto h(tY)$ is differentiable with derivative $D(tY)Y$, where $D(Z)Y = \Lambda_{x_0 \exp \mathrm{v}(Z)}(N(Y))$. Each $D(Z)$ is $\mathbb{C}$-linear, and $Z \mapsto D(Z)$ is continuous for the operator norm: in the basis of matrix units E_k of M, $D(Z)Y = \sum_k N(Y)_k \Lambda_{x_0 \exp \mathrm{v}(Z)}(E_k)$ with coefficients continuous in Z (Step 2). The derivative $t \mapsto D(tY)Y$ is continuous, so $h(Y) - h(0) = \int_0^1 D(tY)Y\, dt$ and

$$|h(Y) - h(0) - D(0)Y| \le \sup_{0 \le t \le 1} \|D(tY) - D(0)\|\, |Y| = o(|Y|) \qquad (Y \to 0).$$

Thus h is complex differentiable at 0 with derivative $D(0)$.

Step 7: complex differentiability on $\mathcal{U}$. Let $\Theta(Z) = \exp(\mathrm{v}(Z))\,(1 + Z - \mathrm{v}(Z))$, a smooth map $M \to M$ with $\Theta(0) = 1$ and real derivative the identity at 0. By the inverse function theorem there are open neighbourhoods W of 0 and V of 1, with $1 + Z - \mathrm{v}(Z)$ invertible for $Z \in W$, such that $\Theta\colon W \to V$ is a diffeomorphism; its inverse ψ has real derivative the identity at 1. Let $g_0 = x_0 b_0 \in \mathcal{U}$ and $V_0 = \{x_0 y b_0 : y \in V\}$, an open neighbourhood of g_0. For $g \in V_0$ put $Z = \psi(x_0^{-1} g b_0^{-1})$; then $g = (x_0 \exp \mathrm{v}(Z))\,((1 + Z - \mathrm{v}(Z)) b_0)$ with the first factor in G and the second in B, so $V_0 \subseteq \mathcal{U}$ and, as the diagonal of $1 + Z - \mathrm{v}(Z)$ is that of $1 + Z$,

$$\tilde{F}(g) = k(\psi(x_0^{-1} g b_0^{-1})), \qquad k(Z) = \prod_{v \in \Phi} \prod_{c \in n} (1 + Z_{v,cc})^{u_v(c)}\ b_0^u\ h(Z).$$

The product is holomorphic near $Z = 0$ and h is complex differentiable at 0 (Step 6), so k is complex differentiable at $0 = \psi(1)$. The map $g \mapsto x_0^{-1} g b_0^{-1}$ is $\mathbb{C}$-linear and ψ has the $\mathbb{C}$-linear derivative id at 1; by the chain rule $\tilde{F}$ is real differentiable at g_0 with $\mathbb{C}$-linear derivative, i.e. complex differentiable at g_0. As $g_0 \in \mathcal{U}$ was arbitrary and $V_0 \subseteq \mathcal{U}$, $\mathcal{U}$ is open and $\tilde{F}$ is complex differentiable at every point of $\mathcal{U}$; so $\tilde{F}$ is holomorphic on $\mathcal{U}$ (complex differentiable at every point of an open subset of $\mathbb{C}^N$, hence continuous and holomorphic in each variable, hence holomorphic by Osgood's lemma), and therefore complex analytic at every point of $\mathcal{U}$. By Step 4, $\tilde{F}(xb) = b^u f(x)$ for $x \in G$, $b \in B$: f is holomorphic of weight u for o. □

Lemma 6.6.48. *Let S, T be spaces with points with signs s on a nonempty index set n and s' on n', let α, β be automorphic characters of $\mathrm{U}(1)$ of weights γ, $\gamma' \colon \Phi \to \mathbb{Z}$, let o be an order on n and $u = (u_v)_{v\in\Phi}$ weights on n. Call $v \in \mathcal{F}_{S,T}$ **holomorphic of weight** u if for every bounded linear functional ℓ on $\mathcal{F}_{S,T}$ the function $x \mapsto \ell(\Omega_{\gamma,\gamma'}(x,1)v)$ on $G_\infty(s)$ is holomorphic of weight u for o. Then:*

(1) a finite linear combination of functions on $G_\infty(s)$ (resp. on $\mathrm{G}(s)$) that are holomorphic (resp. adelically holomorphic) of weight u for o is holomorphic (resp. adelically holomorphic) of weight u for o;

(2) the vectors holomorphic of weight u form a linear subspace of $\mathcal{F}_{S,T}$ that contains $\Omega_{\gamma,\gamma'}(1,y)v$ for every $y \in G_\infty(s')$ and every v in it;

(3) if v is holomorphic of weight u, then for every $f \in \mathcal{M}_{S,T}$ and every $h \in \mathrm{G}(s')$ the function $g \mapsto \theta^{S,T}_{\alpha,\beta}(v\otimes f)(g,h)$ on $\mathrm{G}(s)$ is adelically holomorphic of weight u for o; in particular, if v_P is holomorphic of weight u, so is $g \mapsto \theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Phi,P](g,h)$ for every modulus $\mathfrak{m}$ and every function Φ on $n' \times n$ matrices over $R_\mathfrak{m}$.

Proof. **(1).** Let $F_1,\dots,F_p$ be holomorphic of weight u for o on $G_\infty(s)$, with functions $\tilde F_k$ as in (HV3), and $c_1,\dots,c_p \in \mathbb{C}$. Then $\tilde F = \sum_k c_k\tilde F_k$ is complex analytic at every point xb ($x \in G_\infty(s)$, b a family of o-triangular matrices) at which all $\tilde F_k$ are, and $\tilde F(xb) = \bigl(\prod_v b_v^{u_v}\bigr)\sum_k c_kF_k(x)$; so $\sum_k c_kF_k$ is holomorphic of weight u for o. For functions on $\mathrm{G}(s)$ apply this, for each $g \in \mathrm{G}(s)$, to the functions $x \mapsto F_k(g(x,1))$.

(2). By (1), sums and scalar multiples of vectors holomorphic of weight u are holomorphic of weight u, and 0 is. Let v be holomorphic of weight u, $y \in G_\infty(s')$ and ℓ a bounded linear functional on $\mathcal{F}_{S,T}$. As $\Omega_{\gamma,\gamma'}$ is a representation of $G_\infty(s)\times G_\infty(s')$ ((2) of Lemma 4.1.1) and $(x,1)(1,y) = (1,y)(x,1)$,

$$\ell(\Omega_{\gamma,\gamma'}(x,1)\,\Omega_{\gamma,\gamma'}(1,y)v) = \ell'(\Omega_{\gamma,\gamma'}(x,1)v), \qquad \ell' = \ell\circ\Omega_{\gamma,\gamma'}(1,y),$$

and ℓ' is a bounded linear functional, $\Omega_{\gamma,\gamma'}(1,y)$ being a scalar times the bounded operator $\omega^\infty_\varepsilon$ of an element of the unitary group ((2) of Lemma 4.1.1). So $\Omega_{\gamma,\gamma'}(1,y)v$ is holomorphic of weight u.

(3). Fix f, h and $g \in \mathrm{G}(s)$, and let $\ell(w) = \theta_{\mathrm{Hom}(S,T)}(\omega_{\alpha,\beta}(g,h)(w\otimes f))$ for $w \in \mathcal{F}_{S,T}$. The map $w \mapsto w\otimes f$ is linear and $\|w\otimes f\| \le \|w\|\,\|f\|$ by (1) of Lemma 6.2.21; $\omega_{\alpha,\beta}(g,h)$ is a scalar of modulus 1 times a bounded operator ((2) of Lemma 4.1.1), and the theta functional is bounded. So ℓ is a bounded linear functional on $\mathcal{F}_{S,T}$. For $x \in G_\infty(s)$, $(g(x,1),h) = (g,h)\cdot((x,1),1)$, so by (2) and (5) of Lemma 4.1.1 (with $k=1$, $y=1$, $k'=1$; $\omega_{\alpha,\beta}(1,1)f = f$)

$$\theta^{S,T}_{\alpha,\beta}(v\otimes f)(g(x,1),h) = \theta_{\mathrm{Hom}(S,T)}\Bigl(\omega_{\alpha,\beta}(g,h)\bigl((\Omega_{\gamma,\gamma'}(x,1)v)\otimes f\bigr)\Bigr) = \ell(\Omega_{\gamma,\gamma'}(x,1)v),$$

which is holomorphic of weight u for o as a function of x. As g was arbitrary, $g \mapsto \theta^{S,T}_{\alpha,\beta}(v\otimes f)(g,h)$ is adelically holomorphic of weight u for o. The last assertion is the case $v = v_P$, $f = \Phi^\natural\otimes_{\Sigma(\mathfrak{m})}v^0$, since $\theta^{S,T}_{\alpha,\beta;\mathfrak{m}}[\Phi,P] = \theta^{S,T}_{\alpha,\beta}(\mathrm{mod}_\mathfrak{m}(\Phi,v_P))$ and $\mathrm{mod}_\mathfrak{m}(\Phi,v_P) = v_P\otimes(\Phi^\natural\otimes_{\Sigma(\mathfrak{m})}v^0)$ (Definition 6.3.1, (XD5)). □

Lemma 6.6.49. *Let $1 \le j \le m$, $O = O_{j,1}$, and for $\tau \in \Phi$ let $l_\tau(c) = 2\varsigma_\tau(\mathrm{num}(c))$ ($c \in \mathcal{R}$). Let o be an order on $\mathcal{R}$, positive-first for s_j, such that $l_\tau(a) < l_\tau(b)$ whenever $s_j(a) = s_j(b)$ and $o(a) < o(b)$. Let $w = (w_\tau)_{\tau\in\Phi}$ be the weights on $\mathcal{R}$*

$$w_\tau(c) = \kappa_j(\tau) - e_j + |\mathcal{B}_j|\,[s_j(c) = -1] - [s_j(c) = 1]\sum_{\mathrm{ord}_O(c)<p<|\mathcal{B}_j|}\kappa^+_O(\tau,p),$$

$[\cdot]$ *being* 1 *if the condition holds and* 0 *otherwise. Let* $\chi_O = \upsilon^{r_-(O)}$ *and* $\nu'' = \nu''_{j,1}$. *Then for every choice* $i \in \mathrm{Mem}_j$*:*

(a) there are finitely many $c_k \in \mathbb{C}$, $h_k \in G_f(\mathcal{B}_j)$, *functions* Φ_k *on* $\mathcal{B}_j \times \mathcal{R}$ *matrices over* $R_{\mathfrak{M}^2}$ *and vectors* ξ_k *of the Weyl module* $\mathbb{V}_j^+$ *of* κ_O^+ *in rank* $|\mathcal{B}_j|$ *with rows* $\mathcal{B}_j$ *such that, with the letter substitution* Let_1 *of* O *read with the rows in* $\mathcal{B}_j$,

$$\mathsf{F}_i(g) = \sum_k c_k\, \theta^{W_j,\mathrm{I}_{\mathcal{B}_j}}_{\chi_O,\nu'';\mathfrak{M}^2}\big[\Phi_k, \mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}\xi_k)\big](g,h_k) \qquad (g \in \mathrm{U}(W_j)(\mathbb{A}_F));$$

(b) the choice function F_i *is adelically holomorphic of weight* w *for* o.

Proof. **Step 1: the choice function is a multiple of a coset kernel sum.** By Proposition 6.6.36 for the trivial twist there is $c_1 \in \mathbb{C}$ with $\mathsf{F}_i = c_1 L_{1,i}$ for all $i \in \mathrm{Mem}_j$. By Proposition 6.6.33 for the trivial twist, with $a = \mathcal{B}^{\mathrm{c}}$, u the identity matrix and $w = \Lambda_i$ (so $uw = \Lambda_i$), $L_{1,i} = \mathrm{cks}_{O,\nu''}(\Lambda_i, \phi_j; \Upsilon_{1,i})$, $\nu'' = \nu''_{j,1}$. For the trivial twist $Q_O = \emptyset$, so $\mathfrak{Q}_O = \mathcal{O}_E$, and by (KN5)

$$\mathsf{F}_i(g) = c_1 \sum_{h \bmod \mathbf{K}_O[\Lambda_i,\phi_j]}^{\mathrm{cl}} \theta^{W_j,\mathrm{I}_{\mathcal{B}_j}}_{\chi_O,\nu'';\mathfrak{M}^2}\Big[\mathrm{cd},\ \mathrm{Let}_1\big(\mathrm{Pol}_{\kappa_O^+}(\Upsilon_{1,i}(h))\big)\Big](g,h),$$

a finite sum at fixed representatives $h \in G_f(\mathcal{B}_j)$, with $\mathrm{cd} = \mathrm{cd}^{\mathrm{res}}_{\psi_O,\mathrm{red}_0,\Lambda_i,\phi_j}$, a function on $\mathcal{B}_j \times \mathcal{R}$ matrices over $R_{\mathfrak{M}^2}$ (red_0 being the identity of $R_{\mathfrak{M}^2}$). This is (a), with $c_k = c_1/\#\Gamma_h$, $h_k = h$, $\Phi_k = \mathrm{cd}$ and $\xi_k = \Upsilon_{1,i}(h)$.

Step 2: the letter polynomials are holomorphic. Apply Lemma 6.6.50 with $S = W_j$, $T = \mathrm{I}_{\mathcal{B}_j}$ (rows $\mathcal{B}_j$, as for the Weyl module $\mathbb{V}_j^+$ of κ_O^+ in rank $|\mathcal{B}_j|$), $\sigma = 1$, $\mathrm{ord} = \mathrm{ord}_O$ on the positive basis vectors, $\kappa = \kappa_O^+$, the order o, the maps l_τ, $\gamma = r_-(O)$ and $e(\tau) = e_j - \kappa_j(\tau)$. Its hypotheses: by (LF4), $\mathrm{ord}_O(c) = \mathrm{num}(c)$ on the positive basis vectors, which are those of numbers $0, \dots, r_+ - 1$ with $r_+ = k + j - 1$ ((HP4) of Definition 3.2.13), so ord_O is a bijection of them onto $\{0, \dots, r_+ - 1\}$; by Lemma 6.6.41, O fits l, so (ii) of (DP11) is (ii) of Lemma 6.6.50 and (iii) of (DP11) gives $\kappa_O^+(\tau, p) = 0$ for $r_+ < p < n$, in particular for $r_+ < p < |\mathcal{B}_j|$; the l_τ are injective (by (i) of (DP11), (a) of the block rule); (i) is the hypothesis on o. With $N = |\mathcal{B}_j|$ the weight of Lemma 6.6.50 is w. So for every $\xi \in \mathbb{V}_j^+$ the vector $v_{\mathrm{Let}_1(\mathrm{Pol}_{\kappa_O^+}\xi)}$ is holomorphic of weight w for the pair $(r_-(O), e_j - \kappa_j)$.

Step 3: conclusion. The character $\chi_O = \upsilon^{r_-(O)}$ has weight $r_-(O)$ and $\nu'' = \mu_j^0 \upsilon^{e_j}$ has weight $-\kappa_j + e_j$, υ having weight 1 ((ii) of Lemma 3.2.11). By Step 2 and (3) of Lemma 6.6.48 (with $S = W_j$, $T = \mathrm{I}_{\mathcal{B}_j}$, $\alpha = \chi_O$, $\beta = \nu''$, the modulus $\mathfrak{M}^2$ and $\Phi = \mathrm{cd}$), every summand in Step 1 is adelically holomorphic of weight w for o as a function of g, and by (1) of Lemma 6.6.48 so is F_i, which is (b). □

Lemma 6.6.50. *Let* S *be a space with a point with signs* s *on a nonempty index set* n, T *a space with a point with signs* $+1$ *on a nonempty totally ordered index set* n', $N = \#n'$, σ *a sign,* $n_\sigma = \{c \in n : s(c) = \sigma\}$ *and* $\mathrm{ord}\colon n_\sigma \to \{0, \dots, \#n_\sigma - 1\}$ *a bijection; write* $\mathrm{Let}_\sigma = \mathrm{Let}^{\mathrm{ord}}_\sigma$. *Let* κ *be a weight in rank* N *with rows* n' *such that* $\kappa(\tau, p) = 0$ *for* $\#n_\sigma < p < N$ *and all* $\tau \in \Phi$. *Let* o *be an order on* n *that is positive-first for* s, *and* $l = (l_\tau)_{\tau\in\Phi}$ *injective maps* $l_\tau\colon n \to \mathbb{Z}$ *such that for every* τ*:*

(i) $l_\tau(a) < l_\tau(b)$ *whenever* $s(a) = s(b)$ *and* $o(a) < o(b)$*;*

(ii) $\mathrm{ord}(c) = \#\{d \in n_\sigma : \sigma\, l_\tau(c) < \sigma\, l_\tau(d)\}$ *for every* $c \in n_\sigma$.

Let $\gamma, e\colon \Phi \to \mathbb{Z}$ and let $w = (w_\tau)_{\tau\in\Phi}$ be the weights on n

$$w_\tau(c) = -e(\tau) + N\,[s(c) = -1] - \sigma\,[s(c) = \sigma] \sum_{\mathrm{ord}(c)<p<N} \kappa(\tau, p),$$

$[\cdot]$ being 1 if the condition holds and 0 otherwise. Then the linear map $\xi \mapsto \mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi)$ on $\mathbb{V}_\kappa$ is injective, and for every $\xi \in \mathbb{V}_\kappa$ and every bounded linear functional ℓ on $\mathcal{F}_{S,T}$ the function $x \mapsto \ell\big(\Omega_{\gamma,e}(x, 1)\, v_{\mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi)}\big)$ on $G_\infty(s)$ is holomorphic of weight w for o.

Proof. **Step 1: the highest vector.** Let $\pi\colon n' \to \{0, \dots, N-1\}$ be a bijection and y^π the array with $y^\pi_{\tau,a,c} = 1$ if $c = \pi(a)$ and 0 otherwise, and put $\xi_0 = \mathrm{ev}_\kappa(y^\pi)$. By Lemma 6.4.50 (with $\pi_\tau = \pi$ for all τ),

$$\mathrm{Pol}_\kappa(\xi_0) = \prod_{\tau\in\Phi} \prod_{1\le p<N} M_{\tau,p}^{\kappa(\tau,p)}, \qquad M_{\tau,p} = \det\big(y_{\tau,\pi^{-1}(i),j}\big)_{0\le i,j<p}.$$

Let $c_j = \mathrm{ord}^{-1}(j)$ for $0 \le j < \#n_\sigma$. By definition $\mathrm{Let}_\sigma(y_{\tau,a,j}) = X_{\tau,a,c_j}$ for $j < \#n_\sigma$ and $= 0$ for $j \ge \#n_\sigma$. For $p \le \#n_\sigma$, $\mathrm{Let}_\sigma(M_{\tau,p}) = \det(X_{\tau,\pi^{-1}(i),c_j})_{0\le i,j<p}$; for $p > \#n_\sigma$ the exponent $\kappa(\tau, p)$ is 0. As Let_σ is a homomorphism of algebras, $Q_0 = \mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi_0) = \prod_\tau P_\tau(X_{\tau,\cdot,\cdot})$ with

$$P_\tau = \prod_{1\le p\le \min(\#n_\sigma, N-1)} D_p^{\kappa(\tau,p)}, \qquad D_p = \det\big(X_{\pi^{-1}(i),c_j}\big)_{0\le i,j<p},$$

in the variables X_{ac} ($a \in n'$, $c \in n$).

Step 2: the staircase is jointly highest. Fix τ and apply Lemma 6.4.48 with $R = n'$, $C = n$, the signs s on C, the shifts $(\gamma_1, \gamma_2) = (\gamma(\tau), -e(\tau))$, $l'(a) = -\sigma\pi(a)$ and $l = l_\tau$ (both injective), $k(\sigma, p) = \kappa(\tau, p)$ and $k(-\sigma, p) = 0$ ($1 \le p < N$). Then $x_\sigma(a) = \#\{a' : -\pi(a') > -\pi(a)\} = \pi(a)$, so the row a_i of that lemma with $x_\sigma(a_i) = i$ is $\pi^{-1}(i)$; by (ii) the number $o(c)$ of that lemma is $\mathrm{ord}(c)$ for $c \in n_\sigma$, so its column of sign σ and number j is c_j; the condition $k(\eta, p) = 0$ for $p > \#\{c : s(c) = \eta\}$ holds by the hypothesis on κ for $\eta = \sigma$ and trivially for $\eta = -\sigma$; and since $k(-\sigma, \cdot) = 0$, $k(1, i) = 0$ or $k(-1, j) = 0$ for all i, j. Its polynomial is P_τ (the factors of sign $-\sigma$ have exponent 0), so P_τ is jointly highest of weights (ν_τ, w_τ) for $(l', -l_\tau)$ for the row and column units of the signs $(s, \mathbf{1}_{n'})$ with the shifts $(\gamma(\tau), -e(\tau))$, with some ν_τ and with the column weight of that lemma, which is

$$-e(\tau) + N\,[s(c) = -1] - s(c) \sum_{o(c)<p<N} k(s(c), p) = w_\tau(c),$$

the sum being 0 unless $s(c) = \sigma$.

Step 3: holomorphy of the highest vector. By (i), Step 2 and Lemma 6.6.47 (with $l_v = l_\tau$, $l'_v = l'$, $\nu_v = \nu_\tau$, $u_v = w_\tau$, $P_v = P_\tau$), $Q_0 \ne 0$ and v_{Q_0} is holomorphic of weight w: for every bounded linear functional ℓ on $\mathcal{F}_{S,T}$, $x \mapsto \ell(\Omega_{\gamma,e}(x, 1)v_{Q_0})$ is holomorphic of weight w for o. In particular $\xi_0 \ne 0$, as Pol_κ and Let_σ are linear.

Step 4: all vectors. Let H be the set of $\xi \in \mathbb{V}_\kappa$ for which $v_{\mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi)}$ is holomorphic of weight w. As $\xi \mapsto v_{\mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi)}$ is linear, H is a linear subspace by (2) of Lemma 6.6.48, and $\xi_0 \in H$ by Step 3. For $\xi \in H$ and $y \in G_\infty(1_{n'})$, Lemma 6.6.51 gives

$$v_{\mathrm{Let}_\sigma(\mathrm{Pol}_\kappa(S_\kappa(z_\sigma)\xi))} = \prod_v \det(y_v)^{r_- - \gamma(v)}\; \Omega_{\gamma,e}(1, y)\, v_{\mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi)},$$

with $z_{+1} = y$, $z_{-1} = \bar{y}$, which is holomorphic of weight w by (2) of Lemma 6.6.48. As y runs over $G_\infty(1_{n'}) = \prod_\tau \mathrm{U}(N)$, so does z_σ (complex conjugation is a bijection of $\mathrm{U}(N)$). Hence H

is a nonzero subspace invariant under the operators $S_\kappa(z)$, $z \in \prod_\tau \mathrm{U}(N)$, equivalently under $\rho_{\kappa,0}(h) = S_\kappa(\bar{h})$, $h \in \prod_\tau \mathrm{U}(N)$ ((WM2)). The Weyl module is irreducible under these operators (it is the irreducible polynomial representation of $\prod_\tau \mathrm{GL}_N(\mathbb{C})$ of highest weight $(\lambda_\tau)_\tau$, read in the dual basis, and $\prod_\tau \mathrm{U}(N)$ is Zariski dense; classical), so $H = \mathbb{V}_\kappa$, which is the second assertion.

Step 5: injectivity. Pol_κ is injective, as the b_i are linearly independent and G_κ is invertible ((b) of Lemma 4.6.10). Each b_i is a product of minors $\Delta_{\tau,A}$ with $\#A = h$ and $\kappa(\tau,h) \neq 0$ ((WM1)), which involve the columns $0,\dots,h-1$ only; by the hypothesis on κ, $h \leq \#n_\sigma$. So every $\mathrm{Pol}_\kappa\xi$ is a polynomial in the variables $y_{\tau,a,j}$ with $j < \#n_\sigma$, on which Let_σ is the injective renaming $y_{\tau,a,j} \mapsto X_{\tau,a,c_j}$ of variables. Hence $\xi \mapsto \mathrm{Let}_\sigma(\mathrm{Pol}_\kappa\xi)$ is injective. □

Lemma 6.6.51. *Let S be a space with a point with signs s on a nonempty index set n, T a space with a point with signs $+1$ on a nonempty totally ordered index set n', $r_- = \#\{c \in n : s(c) = -1\}$ and $\gamma,\gamma' \colon \Phi \to \mathbb{Z}$. For a sign σ and a map $\mathrm{ord} \colon \{c \in n : s(c) = \sigma\} \to \mathbb{N}$ let $\mathrm{Let}^{\mathrm{ord}}_\sigma$ be the homomorphism of algebras sending $y_{\tau,a,i}$ $(a \in n')$ to $\sum X_{\tau,a,c}$ over the $c \in n$ with $s(c) = \sigma$ and $\mathrm{ord}(c) = i$, the $X_{\tau,a,c}$ being the Fock variables of $\mathrm{Hom}(S,T)$. Then for every weight λ in rank $\#n'$ with rows n', every $\alpha \in \mathbb{V}_\lambda$ and every $y \in G_\infty(1_{n'})$,*

$$\Omega_{\gamma,\gamma'}(1,y)\, v_{\mathrm{Let}^{\mathrm{ord}}_\sigma(\mathrm{Pol}_\lambda\alpha)} = \prod_{v\in\Phi} \det(y_v)^{\gamma(v)-r_-}\; v_{\mathrm{Let}^{\mathrm{ord}}_\sigma(\mathrm{Pol}_\lambda(S_\lambda(z_\sigma)\alpha))}, \qquad z_{+1} = y, \quad z_{-1} = \bar{y},$$

$\bar{y}$ the entrywise complex conjugate.

Proof. As T has only the sign $+1$, y_v is block diagonal for the signs of T (its block of sign -1 is empty) and so is $1 \in G_\infty(s)$; so the second part of (5) of Lemma 4.1.1 applies to $(x,y) = (1,y)$: the scalar is $\prod_v \det(y_v)^{\gamma(v)-r_-}$ (the factors of the empty blocks and of $x = 1$ are 1), and v_P goes to $v_{P'}$ with $P'(X) = P(X')$, where, writing $X_{\tau,\cdot,c} = (X_{\tau,a,c})_{a\in n'}$ for the columns,

$$X'_{\tau,\cdot,c} = y_\tau^{\mathsf{T}} X_{\tau,\cdot,c} \;\text{ if } s(c) = 1, \qquad X'_{\tau,\cdot,c} = y_\tau^{-1} X_{\tau,\cdot,c} \;\text{ if } s(c) = -1.$$

Let $Y^\sigma(X)$ be the array with entries $Y^\sigma(X)_{\tau,a,i} = \sum X_{\tau,a,c}$ over c with $s(c) = \sigma$, $\mathrm{ord}(c) = i$, so that $\mathrm{Let}^{\mathrm{ord}}_\sigma(Q)(X) = Q(Y^\sigma(X))$. Then $Y^1(X') = y^{\mathsf{T}} Y^1(X)$ and $Y^{-1}(X') = y^{-1} Y^{-1}(X)$, the matrices acting on the rows at every τ as in (WM2). For a family z of $n' \times n'$ matrices, by (WM2) and (a) of Lemma 4.6.10,

$$\mathrm{Pol}_\lambda(\alpha)(zY) = \sum_i (G_\lambda\alpha)_i \sum_j S_\lambda(z)_{ij}\, b_j(Y) = \sum_j \big(S_\lambda(z)^{\mathsf{T}} G_\lambda\alpha\big)_j b_j(Y) = \mathrm{Pol}_\lambda(S_\lambda(z^{\mathsf{T}})\alpha)(Y).$$

With $z = y^{\mathsf{T}}$ for $\sigma = 1$ and $z = y^{-1}$ for $\sigma = -1$, and $(y^{-1})^{\mathsf{T}} = \bar{y}$ as y_v is unitary, $\mathrm{Let}^{\mathrm{ord}}_\sigma(\mathrm{Pol}_\lambda\alpha)' = \mathrm{Let}^{\mathrm{ord}}_\sigma(\mathrm{Pol}_\lambda(S_\lambda(z_\sigma)\alpha))$, which is the claim. □

Lemma 6.6.52. *Let $1 \leq j \leq m$, $O = O_{j,1}$, and for $\tau \in \Phi$ let $l_\tau(c) = 2\varsigma_\tau(\mathrm{num}(c))$ $(c \in \mathcal{R})$. Let o be an order on $\mathcal{R}$, positive-first for s_j, such that $l_\tau(a) < l_\tau(b)$ whenever $s_j(a) = s_j(b)$ and $o(a) < o(b)$, and let $u^\circ = (u^\circ_\tau)_{\tau\in\Phi}$ be the weights on $\mathcal{R}$*

$$u^\circ_\tau(c) = j - \lfloor m/2 \rfloor + [s_j(c) = -1]\Big(|\mathcal{B}^\circ| + \sum_{\mathrm{ord}_O(c)<p<|\mathcal{B}^\circ|} \kappa^-_O(\tau,p)\Big),$$

$[\cdot]$ being 1 if the condition holds and 0 otherwise. Suppose that every u°_τ is K-dominant for (s_j,o) and that $m^{\mathrm{hol}}_{s_j,u^\circ}$ is integrable on $G_\infty(s_j)$. Let $y \in \mathcal{A}_M(W_j)$ satisfy $\int_{[\mathrm{U}(W_j)]} y\, \mathsf{F}_i\, \mathrm{tt}_j(\zeta) = 0$ for all $i \in \mathrm{Mem}_j$ and all $\zeta \colon \mathrm{Cl}^\circ \to \mathbb{V}^-_j$. Then for every $x \in \mathrm{G}(s_j)$ and all $(c_i)_{i\in\mathrm{Mem}_j}$ in $\mathbb{C}$ the function $h \mapsto y(x(h,1)) \sum_i c_i \mathsf{F}_i(x(h,1))\, m^{\mathrm{hol}}_{s_j,u^\circ}(h)$ is integrable on $G_\infty(s_j)$ with integral 0.

Proof. Put $\mathfrak{m} = \mathfrak{M}^2 = \pi_M^2\mathcal{O}_E$, $\mathrm{I} = V^\circ = \mathrm{I}_{\mathcal{B}^\circ}$, $\alpha = \chi_O = \upsilon^{r_-(O)}$, $\beta = \upsilon^{\lfloor m/2\rfloor - j}$; they have trivial tame parts and the weights $\gamma' = r_-(O)$ and $\gamma = \lfloor m/2\rfloor - j$, so that $\mathrm{tt}_j(\zeta)(g) = \sum_{\mathfrak{c}} \theta^{W_j,\mathrm{I}}_{\alpha,\beta;\mathfrak{m}}[\mathbf{1}_{z_j}, \mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}\overline{\zeta(\mathfrak{c})})](g, x_{\mathfrak{c}})$.

Step 1: the kernel polynomials. Apply Lemma 6.6.50 with $S = W_j$, $T = \mathrm{I}$ (rows $\mathcal{B}^\circ$), $\sigma = -1$, $\mathrm{ord} = \mathrm{ord}_O$ on the negative basis vectors, $\kappa = \kappa_O^-$ in rank $|\mathcal{B}^\circ|$, the order o, the maps l_τ and the shifts (γ', γ) in the roles of (γ, e). Its hypotheses: by (LF4), $\mathrm{ord}_O(c) = r - 1 - \mathrm{num}(c)$ on the negative basis vectors, which are those of numbers $r_+, \dots, r-1$ ($r_+ = r - r_-(O)$; (HP4) of Definition 3.2.13), so ord_O is a bijection of them onto $\{0, \dots, r_-(O)-1\}$; by Lemma 6.6.41, O fits l, so (ii) of (DP11) gives (ii) of Lemma 6.6.50, (iii) of (DP11) gives $\kappa_O^-(\tau, p) = 0$ for $r_-(O) < p < |\mathcal{B}^\circ|$ (as $|\mathcal{B}^\circ| < r + t$), and (i) of (DP11) makes l_τ injective; (i) is the hypothesis on o. The weight of Lemma 6.6.50 is $-\gamma + |\mathcal{B}^\circ|[s_j(c) = -1] + [s_j(c) = -1]\sum_{\mathrm{ord}_O(c) < p < |\mathcal{B}^\circ|} \kappa_O^-(\tau, p) = u^\circ_\tau(c)$. Let $(e_l)_{l\in I}$ be the coordinate basis of $\mathbb{V}_j^-$, $Q_l = \mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-} e_l)$, and fix $\xi_0 \in \mathbb{V}_j^- \setminus \{0\}$ and $Q_0 = \mathrm{Let}_{-1}(\mathrm{Pol}_{\kappa_O^-}\xi_0)$. By Lemma 6.6.50, $Q_0 \neq 0$ and v_{Q_0} is holomorphic of weight u° for the pair (γ', γ) and the order o. By Lemma 6.6.51 ($\sigma = -1$), for $y' \in G_\infty(1_{\mathcal{B}^\circ})$,

$$\Omega_{\gamma',\gamma}(1, y')\, v_{Q_0} = \prod_v \det(y'_v)^{\gamma' - r_-(O)} \sum_{l\in I} \big(S_{\kappa_O^-}(\bar{y}')\xi_0\big)_l\, v_{Q_l} \in \mathrm{span}\{v_{Q_l} : l \in I\}.$$

Step 2: the reproducing formula. We apply Lemma 6.6.53 with $S = W_j$ (signs s_j on the nonempty $\mathcal{R}$), $n' = \mathcal{B}^\circ$, $\mathfrak{m} = \mathfrak{M}^2$ (so $N = \pi_M^2$), α, β as above, the order o, the weights u°, $e = z_j$ (so $\delta_e = \mathbf{1}_{z_j}$), Q_0, the representatives $h_{\mathfrak{c}} = x_{\mathfrak{c}}$, $\iota = I$ and $Q_{\mathfrak{c},l} = Q_l$. Its hypotheses: $2\#\mathcal{R} = 2r < t - 9m - 1 = |\mathcal{B}^\circ|$, as $3r > 9m + 1$ by Lemma 4.2.67 ($r \geq x^5$, $m \leq 2\sqrt{x}$); o is positive-first, the u°_τ are K-dominant and $m^{\mathrm{hol}}_{s_j,u^\circ}$ is integrable by hypothesis; Q_0 and the span condition are Step 1; the group $\mathbf{K}_{n'}(\mathfrak{m})$ of that lemma is $\mathbf{K}_{\mathfrak{M}^2}[\{1\}]$, so its classes are Cl° (TG3). Fix $x \in \mathrm{G}(s_j)$ and let $a_{\mathfrak{c},l}$ be the numbers it provides.

Step 3: $\psi_i = y\,\mathsf{F}_i$ is of level $\mathfrak{m}$. By (a) of Lemma 6.6.49, F_i is a finite combination of functions $\kappa(g) = \theta^{W_j,\mathrm{I}_{\mathcal{B}_j}}_{\chi_O,\nu'';\mathfrak{M}^2}[\Phi, P](g, h')$ with $\nu'' = \nu''_{j,1}$, $h' \in G_f(\mathcal{B}_j)$. Each such κ is continuous (joint continuity of the Weil representation, (2) of Lemma 4.1.1, continuity of the characters and of the pair map, boundedness of the theta functional), left invariant under Γ_{W_j} (Lemma 6.2.5) and bounded by $C\,\mathrm{ht}_{W_j}(g)^A$ for some C, A (Lemma 6.2.28, h' being fixed). It is right invariant under $\mathbf{K}_{\mathcal{R}}(\mathfrak{m})$: for k in that group, (6) of Lemma 4.1.1 (with $k' = 1$; the reduction of k modulo $\mathfrak{m}$ is 1, so $\Phi_{k,1} = \Phi$) gives $\omega_{\chi_O,\nu''}((1,k),1)\mathrm{mod}_{\mathfrak{m}}(\Phi, \upsilon_P) = \nu''(\det k)^{-1}\mathrm{mod}_{\mathfrak{m}}(\Phi, \upsilon_P)$, and $\nu''(\det k) = \prod_w \psi_w(\det k \bmod w) = 1$ by Definition 3.1.1, since the tame part ψ of ν'' is trivial off the chosen places and $\det k \equiv 1$ modulo every chosen place; then $\kappa(gk) = \kappa(g)$ by (2) of Lemma 4.1.1. The form y is continuous, left invariant under Γ_{W_j}, right invariant under $\mathrm{K}_M \supseteq \mathbf{K}_{\mathcal{R}}(\mathfrak{m})$ (Definition 3.2.16), and $|y|\,\mathrm{ht}^{M'}_{W_j}$ is bounded for every M' (Lemma 6.6.57). Hence ψ_i is continuous, invariant as required, and $|\psi_i|\,\mathrm{ht}^{M'}_{W_j} \leq C'|y|\,\mathrm{ht}^{M'+A}_{W_j}$ is bounded for every M': ψ_i is of level $\mathfrak{m}$.

Step 4: conclusion. By Step 2 for ψ_i,

$$h \mapsto \psi_i(x(h,1))m^{\mathrm{hol}}_{s_j,u^\circ}(h) \quad \text{and} \quad g \mapsto \psi_i(g)\theta^{W_j,\mathrm{I}}_{\alpha,\beta;\mathfrak{m}}[\mathbf{1}_{z_j}, Q_l](g, x_{\mathfrak{c}})$$

are integrable, and

$$\int_{G_\infty(s_j)} \psi_i(x(h,1))\, m^{\mathrm{hol}}_{s_j,u^\circ}(h)\, dh = \sum_{\mathfrak{c},l} a_{\mathfrak{c},l} \int_{[\mathrm{U}(W_j)]} y(g)\, \mathsf{F}_i(g)\, \theta^{W_j,\mathrm{I}}_{\alpha,\beta;\mathfrak{m}}[\mathbf{1}_{z_j}, Q_l](g, x_{\mathfrak{c}})\, dg.$$

Let $\zeta_{\mathfrak{c},l}\colon \mathrm{Cl}^\circ \to \mathbb{V}_j^-$ be e_l at $\mathfrak{c}$ and 0 elsewhere. As e_l has real coordinates and the kernels are linear in the polynomial ($v_0 = 0$ and data are linear in the Fock vector), $\mathrm{tt}_j(\zeta_{\mathfrak{c},l})(g) =$

$\theta^{W_j,\mathrm{I}}_{\alpha,\beta;\mathfrak{m}}[\mathbf{1}_{z_j},Q_l](g,x_{\mathfrak{c}})$, so each integral on the right is $\int y\,\mathsf{F}_i\,\mathrm{tt}_j(\zeta_{\mathfrak{c},l})=0$ by hypothesis. Hence the left side vanishes for every i; the integrand of the statement is $\sum_i c_i\psi_i(x(h,1))m^{\mathrm{hol}}_{s_j,u^\circ}(h)$, a finite combination of integrable functions with integral 0. □

Lemma 6.6.53. *Let S be a space with a point with signs s on a nonempty index set n, let n' be an index set with $2\#n<\#n'$ and $\mathrm{I}=\mathrm{I}_{n'}$. Let $\mathfrak{m}$ be a modulus with $\mathfrak{m}=N\mathcal{O}_E$ for some $N\in\mathcal{O}_E$, and for an index set m let*

$$\mathbf{K}_m(\mathfrak{m})=\{k\in\mathbf{K}_0(m):\ k_w\equiv 1\pmod{\mathfrak{m}\mathcal{O}_{E,w}}\ \text{for every } w\in\Sigma(\mathfrak{m})\}.$$

*A function $\psi\colon \mathrm{G}(s)\to\mathbb{C}$ is **of level** $\mathfrak{m}$ if it is continuous, left invariant under Γ_S, right invariant under $\mathbf{K}_n(\mathfrak{m})$, and $|\psi|\,\mathrm{ht}_S^M$ is bounded on $\mathrm{G}(s)$ for every $M\in\mathbb{N}$. Let α, β be automorphic characters of $\mathrm{U}(1)$ of weights γ', $\gamma\colon\Phi\to\mathbb{Z}$, both with trivial tame part. Let o be an order on n that is positive-first for s, and $u=(u_v)_{v\in\Phi}$ weights on n with every u_v K-dominant for (s,o) and $m^{\mathrm{hol}}_{s,u}$ integrable on $G_\infty(s)$. Let $e\colon n\to n'$ be injective, $\iota_e\in\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$ the inclusion matrix ($(\iota_e)_{a,k}=1$ if $a=e(k)$ and 0 otherwise) and δ_e the function on $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$ equal to 1 at ι_e and 0 elsewhere. Let $Q_0\neq 0$ be a polynomial in the variables $X_{v,a,k}$ ($v\in\Phi$, $a\in n'$, $k\in n$) such that for every bounded linear functional ℓ on $\mathcal{F}_{S,\mathrm{I}}$ the function $x\mapsto\ell(\Omega_{\gamma',\gamma}(x,1)v_{Q_0})$ on $G_\infty(s)$ is holomorphic of weight u for o. Let $(h_{\mathfrak{c}})_{\mathfrak{c}}$ be representatives of the classes of I modulo $\mathbf{K}_{n'}(\mathfrak{m})$, ι a finite set and $(Q_{\mathfrak{c},i})_{\mathfrak{c},i\in\iota}$ polynomials in the same variables such that*

$$\Omega_{\gamma',\gamma}(1,y)\,v_{Q_0}\in\mathrm{span}_{\mathbb{C}}\{v_{Q_{\mathfrak{c},i}}:i\in\iota\}\qquad\text{for every class }\mathfrak{c}\text{ and every }y\in G_\infty(1_{n'}).$$

Then for every $x\in\mathrm{G}(s)$ there are numbers $a_{\mathfrak{c},i}\in\mathbb{C}$ such that for every function ψ of level $\mathfrak{m}$ the functions $h\mapsto\psi(x(h,1))\,m^{\mathrm{hol}}_{s,u}(h)$ on $G_\infty(s)$ and $g\mapsto\psi(g)\,\theta^{S,\mathrm{I}}_{\alpha,\beta;\mathfrak{m}}[\delta_e,Q_{\mathfrak{c},i}](g,h_{\mathfrak{c}})$ on $[\mathrm{U}(S)]$ are integrable and

$$\int_{G_\infty(s)}\psi(x(h,1))\,m^{\mathrm{hol}}_{s,u}(h)\,dh=\sum_{\mathfrak{c}}\sum_{i\in\iota}a_{\mathfrak{c},i}\int_{[\mathrm{U}(S)]}\psi(g)\,\theta^{S,\mathrm{I}}_{\alpha,\beta;\mathfrak{m}}[\delta_e,Q_{\mathfrak{c},i}](g,h_{\mathfrak{c}})\,dg.$$

Proof. Fix $x\in\mathrm{G}(s)$ and let $\mathcal{V}$ be the complex vector space of functions of level $\mathfrak{m}$.

Step 0: the linear forms. Every $\psi\in\mathcal{V}$ is bounded, as $\mathrm{ht}_S\geq 1$. Since m is integrable and ψ is bounded and continuous, $h\mapsto\psi(x(h,1))m(h)$ is integrable, and $\ell(\psi)=\int_{G_\infty(s)}\psi(x(h,1))m(h)\,dh$ is a linear form on $\mathcal{V}$. For a polynomial P and $h'\in\mathrm{G}(1_{n'})$, Lemma 6.2.28 gives $Y\geq 0$ and $A\in\mathbb{N}$ with $|\theta_P(g,h')|\leq Y\|v_P\otimes F\|\,(\mathrm{ht}_S(g)\mathrm{ht}_{\mathrm{I}}(h'))^A$, and $|\psi|\,\mathrm{ht}_S^A$ is bounded; the function $g\mapsto\psi(g)\theta_P(g,h')$ is continuous ((2) of Lemma 4.1.1, the theta functional being bounded), left invariant under Γ_S (Lemma 6.2.5) and bounded, hence integrable on $[\mathrm{U}(S)]$, which has finite volume (Theorem 4.2.18). This is the integrability assertion of the lemma, and $L_{\mathfrak{c},i}(\psi)=\int_{[\mathrm{U}(S)]}\psi(g)\theta_{Q_{\mathfrak{c},i}}(g,h_{\mathfrak{c}})\,dg=\Theta_{v_{Q_{\mathfrak{c},i}}\otimes F}\psi(h_{\mathfrak{c}})$ is a linear form on $\mathcal{V}$; there are finitely many, the classes being finite in number.

Step 1: reduction by linear duality. If ℓ vanishes on the common kernel of the finitely many $L_{\mathfrak{c},i}$, then ℓ is a linear combination $\sum a_{\mathfrak{c},i}L_{\mathfrak{c},i}$ (the map $\mathcal{V}\to\mathbb{C}^r$, $\psi\mapsto(L_{\mathfrak{c},i}(\psi))$, has kernel inside $\ker\ell$, so ℓ factors through its image, and a linear form on a subspace of $\mathbb{C}^r$ extends to $\mathbb{C}^r$). The numbers $a_{\mathfrak{c},i}$ depend on x only, which is the assertion. So let $\psi\in\mathcal{V}$ with $L_{\mathfrak{c},i}(\psi)=0$ for all $\mathfrak{c}$ and i; we show $\ell(\psi)=0$.

Step 2: the lift by Q_0 vanishes. For a class $\mathfrak{c}$ let $\mathcal{S}_{\mathfrak{c}}=\mathrm{span}\{v_{Q_{\mathfrak{c},i}}:i\in\iota\}$ and, for $w\in\mathcal{S}_{\mathfrak{c}}$, $\Lambda_{\mathfrak{c}}(w)=\Theta_{w\otimes F}\psi(h_{\mathfrak{c}})$; as $w\mapsto w\otimes F$ is linear, $w\otimes F$ is a finite combination of the data $v_{Q_{\mathfrak{c},i}}\otimes F$, so the integral converges by Step 0, $\Lambda_{\mathfrak{c}}$ is linear, and it vanishes on the spanning vectors, hence on $\mathcal{S}_{\mathfrak{c}}$. Let $h'\in\mathrm{G}(1_{n'})$. Its finite component lies in a double coset: $h'_f=\gamma_f h_{\mathfrak{c}}k$ with $\gamma\in\Gamma_{\mathrm{I}}$

and $k \in \mathbf{K}_{n'}(\mathfrak{m})$; with $y = \gamma_\infty^{-1} h'_\infty \in G_\infty(1_{n'})$, $h' = \gamma\,(1,h_{\mathfrak{c}})\,(1,k)\,(y,1)$. By Lemma 6.2.5, $\theta(\varphi)(g,h') = \theta(\varphi)(g,(1,h_{\mathfrak{c}})(1,k)(y,1))$. By (5) of Lemma 4.1.1 (α of weight γ', β of weight γ), $\omega_{\alpha,\beta}(1,(y,1))(v_{Q_0}\otimes F) = (\Omega_{\gamma',\gamma}(1,y)v_{Q_0})\otimes F$, and by (5) there and (SH4) of Lemma 6.6.56 (α, β have trivial tame parts) $\omega_{\alpha,\beta}(1,(1,k))(w\otimes F) = w\otimes F$ for every Fock vector w. Hence

$$\Theta_{v_{Q_0}\otimes F}\psi(h') = \Lambda_{\mathfrak{c}}(\Omega_{\gamma',\gamma}(1,y)v_{Q_0}) = 0,$$

since $\Omega_{\gamma',\gamma}(1,y)v_{Q_0} \in \mathcal{S}_{\mathfrak{c}}$ by hypothesis. So $\Theta_{v_{Q_0}\otimes F}\psi = 0$.

Step 3: the matrix coefficient of v_{Q_0}. Put $v_0 = v_{Q_0}$ and $\kappa(h) = \langle v_0, \Omega_{\gamma',\gamma}(h,1)v_0\rangle$ for $h \in G_\infty(s)$. The functional $w \mapsto \langle v_0, w\rangle$ is bounded on $\mathcal{F}_{S,\mathrm{I}}$ (its norm is that of L^1, and v_0 is bounded), so κ is holomorphic of weight u for o by hypothesis. $\Omega_{\gamma',\gamma}(h,1)$ is a scalar of modulus 1 times an operator preserving the inner product ((2) of Lemma 4.1.1), and $\Omega_{\gamma',\gamma}$ is a representation, so $\kappa(h^{-1}) = \langle \Omega_{\gamma',\gamma}(h,1)v_0, v_0\rangle = \overline{\kappa(h)}$. By Lemma 6.6.54, $\kappa = \kappa(1)\,m = \langle v_0, v_0\rangle\, m$; in particular κ is integrable, and $\langle v_0, v_0\rangle > 0$ because $Q_0 \neq 0$ makes v_0 a nonzero continuous function.

Step 4: the convolution vanishes. Apply Lemma 6.6.55 to S, $T = \mathrm{I}$ ($2\#n < \#n'$), the characters α, β of weights γ', γ, the Schwartz vector v_0 (the Fock vector of a polynomial, (XD3) of Definition 3.2.22) with the integrable coefficient κ, the datum F, which is sharp for $J = \mathbf{K}_n(\mathfrak{m})$ off the places below $\Sigma(\mathfrak{m})$ for β (Lemma 6.6.56), and $y = \psi$, which is continuous, left invariant under Γ_S, right invariant under J and rapidly decreasing. By Step 2 its lift vanishes, so $\int \kappa(h)\psi(x(h,1))\,dh = 0$, that is $\langle v_0, v_0\rangle\,\ell(\psi) = 0$ by Step 3, and $\ell(\psi) = 0$. □

Lemma 6.6.54. *Let n be a nonempty finite index set, s signs on n, o an order that is positive-first for s, $u = (u_v)_{v\in\Phi}$ weights with every u_v K-dominant for (s,o), and $F\colon G_\infty(s) \to \mathbb{C}$ holomorphic of weight u for o with $F(g^{-1}) = \overline{F(g)}$ for every $g \in G_\infty(s)$. Then*

$$F(h) = m^{\mathrm{hol}}_{s,u}(h)\,F(1) \qquad (h \in G_\infty(s)).$$

Proof. Let $\tilde{F}$ be an extension of F as in (HV3). Call $t = (t_v)_{v\in\Phi}$ a *torus element* if every t_v is a diagonal matrix with entries of modulus 1; then $t \in G_\infty(s)$, every t_v is o-triangular, and $\overline{t^{\,u}} = (t^{-1})^u$, where $t^u = \prod_{v\in\Phi} t_v^{u_v}$.

Right translation by the torus. Let $x \in G_\infty(s)$ and t a torus element. By (HV3) at the point xt with the o-triangular family $b = 1$, $\tilde{F}(xt) = F(xt)$; at the point x with $b = t$, $\tilde{F}(xt) = t^u F(x)$. Hence $F(xt) = t^u F(x)$.

Left translation by the torus. Let $y \in G_\infty(s)$ and t a torus element. The hypothesis applied to $g = y^{-1}$ gives $F(y) = \overline{F(y^{-1})}$. Applying the hypothesis to $g = ty$ and then the right law to $x = y^{-1}$ and the torus element t^{-1},

$$F(ty) = \overline{F(y^{-1}t^{-1})} = \overline{(t^{-1})^u}\;\overline{F(y^{-1})} = t^u\,F(y).$$

Conclusion. Let $h \in G_\infty(s)$ and $d(\theta)$ ($\theta \in \mathbb{R}/\mathbb{Z}$) the torus element with component $\mathrm{diag}(e^{2\pi\mathrm{i}\theta o(i)})_{i\in n}$ at every v, so $d(\theta)^u = \prod_{v\in\Phi}\prod_{i\in n} e^{2\pi\mathrm{i}\theta o(i)u_v(i)}$. By the left law the integrand of the circle mean of Lemma 6.6.72 at the point h is

$$F(d(\theta)h)\prod_{v\in\Phi}\prod_{i\in n} e^{-2\pi\mathrm{i}\theta\,o(i)u_v(i)} = F(h)$$

for every θ, so the mean is $F(h)$ ($d\theta$ is a probability measure). By Lemma 6.6.72 the mean is $m^{\mathrm{hol}}_{s,u}(h)\,F(1)$. □

Lemma 6.6.55. *Let S, T be spaces with points with signs s on n and s' on n', $2\#n < \#n'$, let a, b be automorphic characters of $\mathrm{U}(1)$ of weights γ, $\gamma' \colon \Phi \to \mathbb{Z}$, and let $v \in \mathcal{F}_{S,T}$ be a Schwartz vector such that*

$$\kappa(x) = \langle v, \Omega_{\gamma,\gamma'}(x,1)\, v\rangle \qquad (x \in G_\infty(s))$$

is integrable on $G_\infty(s)$. Let S_0 be a finite set of finite places of F, $J \subseteq G_f(n)$ an open subgroup, $c \in \mathbb{C}$, and $F \in \mathcal{M}_{S,T}$ sharp for J off S_0 with mass c for the character b ((SH1)–(SH3)). Let $y \colon \mathrm{G}(s) \to \mathbb{C}$ be continuous, left invariant under Γ_S, right invariant under J, with $|y|\,\mathrm{ht}_S^M$ bounded for every $M \in \mathbb{N}$, and let $\Theta = \Theta_{v\otimes F}$ be the theta lift for the kernel $\theta_{a,b}^{S,T}$. If $\Theta y = 0$, then

$$\int_{G_\infty(s)} \kappa(x)\, y(g(x,1))\, dx = 0 \qquad \text{for every } g \in \mathrm{G}(s).$$

Proof. **Step 0: preliminaries.**

(i) φ is clean in the sense of Theorem 6.5.13: under the first alternative of (SH3) this is (DC1); under the second, $\varphi = v \otimes (\Psi \otimes_A v^0)$ is the datum of (v, Ψ) at A ((WR6)), and $\Psi \in \mathcal{T}_A$, a combination of the functions τ_y, is a Schwartz–Bruhat function of the components at A that vanishes unless x_w has a left inverse; this is (DC2). Its Fock vector v is a Schwartz vector.

(ii) For $x \in G_\infty(s)$ and $k \in G_f(n)$, $\langle \varphi, \omega((x,k),1)\varphi\rangle = \kappa(x)\,\langle F, \omega_{1,b}((1,k),1)F\rangle$: as $a(\det 1) = 1$, $\omega(g,1) = \omega_{1,b}(g,1)$; by (5) of Lemma 4.1.1, $\omega((x,k),1)\varphi = (\Omega_{\gamma,\gamma'}(x,1)v)\otimes(\omega_{1,b}((1,k),1)F)$; by (6) of Lemma 6.2.33 the inner product is $\kappa(x)\langle v_1 \otimes F, v_1 \otimes \omega_{1,b}((1,k),1)F\rangle$; and $v_1 \otimes \omega_{1,b}((1,k),1)F = \omega_{1,b}((1,k),1)(v_1 \otimes F) = \omega_{1,b}((1,k),1)F$ by (5) of Lemma 4.1.1 at the real point 1 and $v_1 \otimes F = F$ (SH1).

(iii) $K'_\Sigma \subseteq J$ and $b(\det k) = 1$ for $k \in K'_\Sigma$. Let $k \in K'_\Sigma$. By Lemma 6.5.6 for the vacuum F above Σ (SH1), $\gamma = k$ and $g = 1$, $\langle F, \omega_{1,b}((1,k),1)F\rangle = \mathrm{mc}(k)\langle F, F\rangle$. By (WR4), $\mathrm{mc}(k) = b(\det k)^{-1}\langle v^0, \omega_{1,1}((1,k),1)v^0\rangle$, and $\omega_{1,1}((1,k),1)v^0 = v^0$ by the last sentence of (6) of Lemma 4.1.1 with $v = v_1$ and $v_1 \otimes v^0 = v^0$ ((4) of Lemma 6.2.33); so $\mathrm{mc}(k) = b(\det k)^{-1}$, of modulus 1, as $\langle v^0, v^0\rangle = 1$. Thus the coefficient is not 0, and (SH2) gives $k \in J \cap \mathbf{K}_0(n)$ and $b(\det k)^{-1}\langle F, F\rangle = \langle F, F\rangle$, i.e. $b(\det k) = 1$. So the hypotheses of (2) and (3) of Proposition 6.5.4 hold for $\beta = b$, and every right J-invariant function is right K'_Σ-invariant.

Step 1: for every admissible y', $\int_{G_\infty(s)} \kappa(x)\langle y', z_0(\cdot\,(x,1))\rangle_S\, dx = 0$, where $z_0 = R_\Sigma y$. The function y is admissible. By Step 0 (i) and Theorem 6.5.13 with $\varphi' = \varphi$, the function $g \mapsto \langle \varphi, \omega(g,1)\varphi\rangle\langle y', R(g)y\rangle_S$ is integrable on $\mathrm{G}(s)$ and its integral times $\mathrm{vol}([\mathrm{U}(T)])$ is $\langle \Theta y', \Theta y\rangle_T = 0$; $\mathrm{vol}([\mathrm{U}(T)]) > 0$. The measure of $\mathrm{G}(s)$ is $dx\,dk$ ((VP1) of Definition 3.2.2), so by Fubini for almost every x the function $h_x(k) = \langle \varphi, \omega((x,k),1)\varphi\rangle\langle y', R((x,k))y\rangle_S$ is integrable on $G_f(n)$, and $\int\!\int h_x(k)\,dk\,dx = 0$. The group K_Σ is open, so $G_f(n) = \bigsqcup_q u_q K_\Sigma$ is a countable disjoint union of open cosets and, dk being left invariant, $\int h_x = \sum_q \int_{K_\Sigma} h_x(u_q\kappa')\,d\kappa'$, absolutely convergent. For $\kappa' \in K_\Sigma$, Step 0 (ii), Lemma 6.5.6 (with $\gamma = u_q$ and $g = (1,\kappa')$) and (SH2) give

$$\langle \varphi, \omega((x,u_q\kappa'),1)\varphi\rangle = \kappa(x)\,\mathrm{mc}(u_q)\,\langle F, F\rangle\,\mathbf{1}_{J\cap\mathbf{K}_0(n)}(\kappa'),$$

and for $\kappa' \in J$, $y(g(x,u_q\kappa')) = y(g(x,1)u_q)$ by the right J-invariance of y. As $dk(J\cap\mathbf{K}_0(n)) = [\mathbf{K}_0(n) : J\cap\mathbf{K}_0(n)]^{-1}$, $\int_{K_\Sigma} h_x(u_q\kappa')\,d\kappa' = c\,\kappa(x)\,\mathrm{mc}(u_q)\,\langle y', y(\cdot\,(x,1)u_q)\rangle_S$. Summing over q with (1) of Proposition 6.5.4 (y bounded, measurable and left invariant, y' integrable on $[\mathrm{U}(S)]$), $\int h_x = c\,\kappa(x)\,\langle y', z_0(\cdot\,(x,1))\rangle_S$ for almost every x. Since $c \neq 0$ (SH1), the claim follows; the

integrand is integrable, as $|\langle y', z_0(\cdot\,(x,1))\rangle_S| \le \|y'\|_{L^1} \sup|z_0|$ with $\sup|z_0| < \infty$ by (1) of Proposition 6.5.4.

Step 2: the convolution and its series. Put $y_1(g) = \int_{G_\infty(s)} \kappa(x)\, y(g(x,1))\, dx$. As y is bounded and continuous and κ integrable, y_1 is defined, $|y_1| \le \|\kappa\|_{L^1} \sup|y|$, and y_1 is continuous (dominated convergence); it is left invariant under Γ_S, and right invariant under J because $(1,k)$ commutes with $(x,1)$; hence also under K'_Σ (Step 0 (iii)). By (2) of Proposition 6.5.4 applied to y (bounded, continuous, left invariant, right invariant under K'_Σ and under the open group J), R_Σ commutes with this convolution: $z = R_\Sigma y_1$ satisfies $z(g) = \int \kappa(x)\, z_0(g(x,1))\, dx$. By Fubini ($y'$ integrable on $[\mathrm{U}(S)]$, z_0 bounded, κ integrable) and Step 1, $\langle y', z\rangle_S = \int \kappa(x)\langle y', z_0(\cdot\,(x,1))\rangle_S\, dx = 0$ for every admissible y'.

Step 3: $z = 0$. For $w \in \mathrm{G}(s)$ the translate $y_w = y(\cdot\, w)$ is admissible: it is continuous and left invariant; for $k \in w_f J w_f^{-1}$, $(1,k)w = w(1, w_f^{-1} k w_f)$, so $y_w(g(1,k)) = y_w(g)$, and $w_f J w_f^{-1}$ is open; and by (2) of Lemma 6.2.6 for the compact set $\{w^{-1}\}$ there is $c_w \ge 1$ with $\mathrm{ht}_S(g) \le c_w\, \mathrm{ht}_S(gw)$, so $|y_w|\,\mathrm{ht}_S^M \le c_w^M \sup|y|\,\mathrm{ht}_S^M$ is bounded. By Step 2, $\langle z, y_w\rangle_S = \overline{\langle y_w, z\rangle_S} = 0$ for every w. For $u \in G_f(n)$, Fubini as in Step 2 gives $\langle z, y_1(\cdot\,(1,u))\rangle_S = \int \kappa(x)\langle z, y_{(x,u)}\rangle_S\, dx = 0$, since $(1,u)(x,1) = (x,u)$. By (2) of Proposition 6.5.4 applied to y_1, z is bounded, continuous and left invariant, hence integrable on $[\mathrm{U}(S)]$, and (1) there for y_1 and $y' = z$ at the point 1 gives

$$\langle z, z\rangle_S = \langle z, R_\Sigma y_1\rangle_S = \sum_q \mathrm{mc}(u_q)\, \langle z, y_1(\cdot\, u_q)\rangle_S = 0.$$

So $\int_{[\mathrm{U}(S)]} |z|^2 = 0$; z is continuous and the quotient measure gives positive mass to the image of every nonempty open set, so $z = 0$.

Step 4: conclusion. y_1 is bounded and right invariant under K'_Σ, and $R_\Sigma y_1 = z = 0$; by (3) of Proposition 6.5.4 (hypothesis on b from Step 0 (iii)), $y_1 = 0$, which is the assertion. □

Lemma 6.6.56. *Let S, T be spaces with points with signs s on n and s' on n', $e\colon n \to n'$ injective, $\mathfrak{m}$ a modulus, $A = \Sigma(\mathfrak{m})$, S_0 the set of finite places of F below the places of A, and*

$$F = \delta_e^\natural \otimes_A v^0 \in \mathcal{M}_{S,T}.$$

Then $J = \mathbf{K}_n(\mathfrak{m})$ is an open subgroup of $\mathbf{K}_0(n)$ of finite index, $\langle F, F\rangle \ne 0$, and for every automorphic character b of $\mathrm{U}(1)$ with trivial tame part, F is sharp for J off S_0 with mass $c = \langle F, F\rangle/[\mathbf{K}_0(n) : J]$: (SH1)–(SH3) hold for b, and (SH4) holds for every pair a, b of automorphic characters of $\mathrm{U}(1)$ with trivial tame parts, with the open subgroups $\mathbf{K}_n(\mathfrak{m})$ and $\mathbf{K}_{n'}(\mathfrak{m})$.

Proof. **Step 0: the places.** A place $v \in S_0$ lies below some $w \in A$; the places of E above v are w and $\bar w$, and $w \ne \bar w$ because A contains the conjugate of none of its members. So the places of E above S_0 are exactly those of $A \cup \bar A$, and each $v \in S_0$ is split. For $k \in G_f(n)$ and $w \in A$, unitarity $k^* k = 1$ gives $k_{\bar w} = \left(\bar k_w^{\mathsf{T}}\right)^{-1}$ under the identification of $E_{\bar w}$ with E_w by conjugation; so k is integral at $\bar w$ if and only if $k_w \in \mathrm{GL}_n(\mathcal{O}_{E,w})$. Hence J is the set of $k \in \mathbf{K}_0(n)$ with $k_w \equiv 1$ modulo $\mathfrak{m}\mathcal{O}_{E,w}$ at the finitely many $w \in A$; it is an open subgroup of the compact group $\mathbf{K}_0(n)$, so its index is finite.

Step 1: left inverses. Let $w \in A$ and $x \in \mathrm{M}_{n'\times n}(\mathcal{O}_{E,w})$ with $x \equiv \iota_e$ modulo $\mathfrak{m}\mathcal{O}_{E,w}$. Read ι_e^{T} as the 0/1 matrix over $\mathcal{O}_{E,w}$; then $\iota_e^{\mathsf{T}} x \equiv \iota_e^{\mathsf{T}} \iota_e = 1_n$ modulo the maximal ideal, so $\det(\iota_e^{\mathsf{T}} x)$ is a unit and $L = (\iota_e^{\mathsf{T}} x)^{-1} \iota_e^{\mathsf{T}}$ is a left inverse of x over $\mathcal{O}_{E,w}$. Consequently: if $\delta_e^\natural(x) \ne 0$ then x_w has a left inverse over $\mathcal{O}_{E,w}$ for every $w \in A$.

Step 2: (SH1) and (SH3). By (1) and (2) of Lemma 6.2.33, $\langle F, F\rangle = \langle \delta_e^\natural, \delta_e^\natural\rangle_A \langle v^0, v^0\rangle$, and $\langle \delta_e^\natural, \delta_e^\natural\rangle_A$ is the measure of the set of $x \in X_A$ whose components at A are integral and reduce to ι_e; this set contains a nonempty open set, so $\langle F, F\rangle \ne 0$. Put $c = \langle F, F\rangle/[\mathbf{K}_0(n) : J]$. By (4)

of Lemma 6.2.33, $v_1 \otimes F = F$; by (5) there, $\rho_f(y)F = F$ for every $y \in \widehat{\mathcal{O}}_E^{n' \times n}$ with components 0 at $A \cup \bar{A}$, which by Step 0 are the y whose components at the places not above Σ vanish: F is a vacuum above Σ. This is (SH1). For (SH3), $A \neq \emptyset$ (a modulus has a nonempty set of places), $F = \Psi \otimes_A v^0$ with $\Psi = \delta_e^\natural \in \mathcal{T}_A$ ((6) of Lemma 4.1.1), and for any $w \in A$, $\Psi(x) \neq 0$ only if x_w has a left inverse (Step 1): the second alternative of (SH3) holds.

Step 3: (SH4). Let a, b have trivial tame parts, $k \in \mathbf{K}_n(\mathfrak{m})$, $k' \in \mathbf{K}_{n'}(\mathfrak{m})$. As $F = v_1 \otimes (\delta_e^\natural \otimes_A v^0)$ (Step 2), (6) of Lemma 4.1.1 with $v = v_1$ and then (4) of Lemma 6.2.33 give $\omega_{a,b}((1,k),(1,k'))F = a(\det k')\, b(\det k)^{-1}\, (\delta_e)^\natural_{k,k'} \otimes_A v^0$ with $(\delta_e)_{k,k'}(X) = \delta_e(\bar{k}'^{-1} X \bar{k}) = \delta_e(X)$, the reductions being 1. The determinants $\det k$, $\det k'$ lie in $\mathrm{U}(1)(\mathbb{A})$, have infinite components 1 and integral finite components, so by the definition of weight and tame part (Definition 3.1.1) $a(\det k') = b(\det k) = 1$, the tame parts being trivial. So $\omega_{a,b}((1,k),(1,k'))F = F$. Both groups are open (Step 0).

Step 4: (SH2) on J. Let b have trivial tame part. For $k \in J$, Step 3 with $a = 1$, $k' = 1$ gives $\omega_{1,b}((1,k),1)F = F$, so $\langle F, \omega_{1,b}((1,k),1)F\rangle = \langle F, F\rangle$.

Step 5: (SH2) off J. Let $k \in G_f(n)$ with $k_v \in K_v$ for all $v \in \Sigma$ and $k \notin J$. Write $k = k_2 k_1$, where k_1 has the components of k above S_0 and 1 elsewhere and k_2 the components above Σ and 1 elsewhere (components at different places commute). By Lemma 6.5.6 for the vacuum F above Σ (Step 2), $\gamma = k_2$ and $g = (1, k_1)$ (whose components at Σ are $1 \in K_v$),

$$\langle F, \omega_{1,b}((1,k),1)F\rangle = \mathrm{mc}_{b,\Sigma}(k_2)\, \langle F, \omega_{1,b}((1,k_1),1)F\rangle.$$

By (4) of Lemma 4.1.1 (k_1 has components 1 outside $A \cup \bar{A}$, $h = 1$), $\omega_{1,b}((1,k_1),1)F = \lambda\, \Psi' \otimes_A v^0$ for a scalar λ and $\Psi'(x) = \delta_e^\natural(xk_1)$, $\Psi' \in \mathcal{T}_A$. By (1), (2) of Lemma 6.2.33 the inner product on the right is $\lambda \langle \delta_e^\natural, \Psi'\rangle_A$, the integral over X_A of $\overline{\delta_e^\natural(x)}\, \delta_e^\natural(xk_1)$. Suppose this integrand is not 0 at some x. For $w \in A$, x_w and $x_w k_w$ are integral and congruent to ι_e modulo $\mathfrak{m}\mathcal{O}_{E,w}$; by Step 1 they have left inverses L, L' over $\mathcal{O}_{E,w}$, so $k_w = L(x_w k_w)$ and $k_w^{-1} = L' x_w$ are integral, $k_w \in \mathrm{GL}_n(\mathcal{O}_{E,w})$, and by Step 0 k is integral at $\bar{w}$ too. Then $\iota_e \bar{k}_w \equiv x_w k_w \equiv \iota_e$, and since the rows $e(n)$ of $\iota_e \bar{k}_w$ are the rows of $\bar{k}_w$, $\bar{k}_w = 1$. With $k_v \in K_v$ for $v \in \Sigma$ this gives $k \in J$, a contradiction. Hence the integrand vanishes identically and $\langle F, \omega_{1,b}((1,k),1)F\rangle = 0$. Together with Step 4 (and $J \subseteq \mathbf{K}_0(n)$) this is (SH2). □

Lemma 6.6.57. *Let $1 \leq j \leq m$ and $y \in \mathcal{A}_M(W_j)$. Then $\sup_{g \in \mathrm{G}(s_j)} |y(g)|\, \mathrm{ht}_{W_j}(g)^A < \infty$ for every $A \in \mathbb{N}$.*

Proof. **The type kernel is a cusp kernel.** As r is odd and m even, k is even and the entries of $\varsigma(v)$ in Definition 3.2.16 are integers; so the entries of $2\varsigma(v)$ are even, i.e. congruent to $r - 1$ modulo 2. They are distinct, and by (iii) of Proposition 5.8.4 ς has gap Δ for the signs of W_j, so entries attached to basis vectors of opposite signs differ by at least 2Δ. By Lemma 4.2.67, $r \geq x^5 \geq 4$, so $\Delta = 2r^8 \geq 500 r^3$. Hence $2\varsigma(v)$ has gap $500r^3$ for s_j at every $v \in \Phi$, and by Lemma 5.6.21 with $N = r$ and $B = 0$ the type kernel e_ς is a cusp kernel of order 0 on $G_\infty(s_j)$.

Rapid decay. By Definition 3.2.16, y is continuous, bounded, left invariant under the rational points, right invariant under the open subgroup K_M and reproduced by convolution with e_ς, i.e. it is a form of type e_ς in the sense of (ED2). By Lemma 6.3.75 for $V = W_j$, $B = 0$ and $e = e_\varsigma$, $\sup_g |y(g)|\, \mathrm{ht}_{W_j}(g)^A < \infty$ for every $A \in \mathbb{N}$. □

Lemma 6.6.58. *Let $1 \leq j \leq m$ and $y \in \mathcal{A}^{\mathrm{good}}(W_j)$. Every peak $g \in \mathrm{G}(s_j)$ of $\bar{y}$ satisfies $\lambda_{W_j}(g) \geq (5b^{24})^{-1/2}$.*

Proof. Let s_j be the signs of W_j (on the nonempty basis $\mathcal{R}$, $r \geq 1$), and let o, u be the order and the weight of Lemma 6.6.45. Put $F = \bar{y}$, $A = 5b$, $A' = b^{23}$ and $p = M\sqrt{-d} \in \mathcal{O}_E$. We check the hypotheses of Lemma 6.6.59 for $V = W_j$.

The weight. By (a) of Lemma 6.6.45 every u_v has holomorphic gap $300n_* \geq 1$ for s_j, hence gap 1 ($u_v(i)+1 \leq u_v(i)+300n_* \leq u_v(i')$ whenever $s_j(i) = +1$, $s_j(i') = -1$), and $|u_v(i)| \leq 5b = A$. By (AD1) and $C_P \geq 6$, $\log\log b \geq 6 \cdot 10^{12}$, so $b > 10$ and $A \geq 2$.

The level. $\bar{p} = M\overline{\sqrt{-d}} = -p$, and $p_v = \mathrm{i}M\sqrt{d}$ for every $v \in \Phi$, so $\operatorname{Im} p_v = M\sqrt{d} > 0$. As $10^{12}(2d+6) \leq 10^{12}C_P \leq \log\log b$, we have $d \leq b^2$, and $M \leq b^{22}$ by (AD5); so $\operatorname{Im} p_v \leq b^{23} = A'$, and $A' \geq 1$. Let $k \in \mathbf{K}_0(\mathcal{R})$ with $k-1 \in p\,\widehat{\mathcal{O}}_E$. Every chosen place w contains π_M, which divides M and hence p in $\mathcal{O}_E$; so k is integral and reduces to 1 at every chosen place, i.e. $k \in \mathrm{K}_M$. As y is a form of principal level (Definition 3.2.16), $y(xk) = y(x)$, hence $F(xk) = F(x)$.

Boundedness, automorphy, holomorphy. y is a form of type e_ς, so by (FT2) it is bounded and left invariant under Γ_{W_j}, and so is $F = \bar{y}$. By (b) of Lemma 6.6.45, F is adelically holomorphic of weight u for o, and o is positive-first for s_j.

Hence Lemma 6.6.59 applies: every peak g of $\bar{y}$ satisfies $\lambda_{W_j}(g) \geq (AA')^{-1/2} = (5b\cdot b^{23})^{-1/2} = (5b^{24})^{-1/2}$. □

Lemma 6.6.59. *Let V be a space with a point with signs s on a nonempty finite index set n, o an order on n that is positive-first for s, and $u = (u_v)_{v\in\Phi}$ weights such that every u_v has holomorphic gap 1 for s and $|u_v(i)| \leq A$ for all v and i, where $A \geq 2$. Let $p \in \mathcal{O}_E$ with $\bar{p} = -p$ and $0 < \operatorname{Im} p_v \leq A'$ for every $v \in \Phi$, where $A' \geq 1$. Let $F\colon \mathrm{G}(s) \to \mathbb{C}$ be bounded, left invariant under Γ_V, right invariant under every $k \in \mathbf{K}_0(n)$ whose entries satisfy $k - 1 \in p\,\widehat{\mathcal{O}}_E$, and adelically holomorphic of weight u for o. Then every peak g of F satisfies*

$$\lambda_V(g) \geq (AA')^{-1/2}.$$

Proof. Let $C = \sup|F|$. As g is a peak, $|F(g)| > \frac{C}{2}$, so $C > 0$. Suppose, to the contrary, that $\lambda_V(g) < (AA')^{-1/2}$. Since $(AA')^{-1/2} \leq 2^{-1/2} < 1$, there is a nonzero u in the lattice of V_g with $\|w_\infty\| < (AA')^{-1/2}$, where $w = (x_V g)^{-1}u$; w_f is integral.

Step 1: u is isotropic. As $g \in \mathrm{G}(s)$, $(x_V g)^* J_V (x_V g) = \varepsilon_s$, so $c = u^* J_V u = w^* \varepsilon_s w$. Here $c \in F$ (J_V is hermitian over E); its finite part is $w_f^* w_f$, integral, so $c \in \mathcal{O}_F$; at the real place of F below $v \in \Phi$, $|c_v| = |w_v^* \operatorname{diag}(s) w_v| \leq \|w_v\|^2 < 1$. Thus $|\mathrm{N}_{F/\mathbb{Q}}(c)| < 1$, and $c = 0$. In particular $w^*\varepsilon_s w = 0$ at every place, and $w_v \neq 0$ for every $v \in \Phi$ ($u \neq 0$ and $x_V g$ is invertible).

Step 2: the transvection. Let $m = 1 - p\,ww^*\varepsilon_s$ (adelic matrix, p read diagonally). By $\bar{p} = -p$ and $w^*\varepsilon_s w = 0$, $m^*\varepsilon_s m = \varepsilon_s - (\bar{p}+p)\varepsilon_s ww^*\varepsilon_s = \varepsilon_s$, so $m \in \mathrm{G}(s)$; and $(1 - p\,ww^*\varepsilon_s)(1 + p\,ww^*\varepsilon_s) = 1$. Since $(x_V g)^{-*}\varepsilon_s (x_V g)^{-1} = J_V$, $(x_V g) m (x_V g)^{-1} = 1 - p\,uu^* J_V \in \mathrm{U}(V)(F)$, so $gmg^{-1} \in \Gamma_V$. The finite part $m_f = 1 - p\,w_f w_f^*$ is integral with $m_f - 1 \in p\widehat{\mathcal{O}}_E$, and so is $m_f^{-1} = 1 + p\,w_f w_f^*$; hence $m_f^{-1} \in \mathbf{K}_0(n)$ fixes F from the right. Put $\phi(h) = F(g(h,1))$ for $h \in G_\infty(s)$. As $(m_\infty h, 1) = m(h,1)(1, m_f^{-1})$,

$$\phi(m_\infty h) = F\big(gmg^{-1} \cdot g(h,1)(1, m_f^{-1})\big) = F\big(g(h,1)\big) = \phi(h).$$

Step 3: the holomorphic function on the upper half plane. ϕ is holomorphic of weight u for o (adelic holomorphy at g); let $\tilde{\phi}$ be an extension as in (HV3). For $\zeta \in \mathbb{C}$ let $X(\zeta) \in \mathrm{M}_n(\mathbb{C})^\Phi$ have the components $1 - p_v(\zeta - \mathrm{i})w_v w_v^* \operatorname{diag}(s)$. Then $X(\mathrm{i}) = 1$, $X(1+\mathrm{i}) = m_\infty$, and, w_v being isotropic, $(1 - a\,w_v w_v^* \operatorname{diag}(s))(1 - a'\,w_v w_v^* \operatorname{diag}(s)) = 1 - (a+a')w_v w_v^* \operatorname{diag}(s)$, so $m_\infty X(\zeta) = X(\zeta+1)$. Let $\eta_v = \operatorname{Im}(p_v)\|w_v\|^2 > 0$; then $\sum_v \eta_v \leq A'\|w_\infty\|^2 < A^{-1} \leq \frac{1}{2}$. As $\operatorname{Re} p_v = 0$ ($\bar{p} = -p$), $p_v = \mathrm{i}\operatorname{Im} p_v$, and Lemma 6.6.60 (with $B = A \geq 1$, $y = w_v$, $\alpha = \operatorname{Im} p_v$) gives for every z with $\operatorname{Im} z > 0$ and every v a factorisation $X(z)_v = h_v(z)b_v(z)$, $h_v(z) \in \mathrm{U}(\operatorname{diag} s)$, $b_v(z)$ o-triangular, with $|b_v(z)^{u_v}| \leq e^{2A\eta_v}(1 + \eta_v \operatorname{Im} z)^{-1/2}$. Put $f(z) = \tilde{\phi}(X(z))$. By (HV3)

at the point $h(z)$ with $b(z)$, $\tilde\phi$ is complex analytic at $X(z)$ and $f(z) = \big(\prod_v b_v(z)^{u_v}\big)\phi(h(z))$; as $z \mapsto X(z)$ is affine, f is holomorphic on the upper half plane. Moreover:

(i) $f(\mathrm{i}) = \tilde\phi(1) = \phi(1) = F(g)$ ((HV3) at the point 1 with $b = 1$);

(ii) $|f(z)| \le C\prod_v e^{2A\eta_v}(1+\eta_v \operatorname{Im} z)^{-1/2} \le Ce^{2A\sum_v \eta_v} \le Ce^2$, and $f(z) \to 0$ as $\operatorname{Im} z \to \infty$;

(iii) $f(z+1) = \tilde\phi(m_\infty h(z)b(z)) = \big(\prod_v b_v(z)^{u_v}\big)\phi(m_\infty h(z)) = f(z)$, by (HV3) at the point $m_\infty h(z)$ and Step 2.

Step 4: Schwarz's lemma at the cusp. By (iii), $f(z) = \varphi(e^{2\pi \mathrm{i} z})$ for a holomorphic φ on the punctured unit disc, bounded by Ce^2 by (ii); its singularity at 0 is removable and $\varphi(0) = 0$ by (ii). Schwarz's lemma gives $|\varphi(q)| \le Ce^2|q|$ for $|q| < 1$, so by (i), at $q = e^{-2\pi}$, $|F(g)| \le Ce^{2-2\pi} < \frac{C}{2}$, as $2\pi - 2 > \log 2$. This contradicts $|F(g)| > \frac{C}{2}$. Hence $\lambda_V(g) \ge (AA')^{-1/2}$. □

Lemma 6.6.60. *Let n be a nonempty finite index set, s signs on n, $J = \operatorname{diag}(s)$, o an order on n that is positive-first for s, and w a weight on n with holomorphic gap 1 for s and $|w(i)| \le B$ for all i, where $B \ge 1$. Let $y \in \mathbb{C}^n$ with $y^*Jy = 0$, $\alpha > 0$, and $\eta = \alpha\, y^*y$ with $0 < \eta \le \frac12$. Then for every $z \in \mathbb{C}$ with $\operatorname{Im} z > 0$ there are $h \in \mathrm{U}(\operatorname{diag} s)$ and an o-triangular matrix b with*

$$1 - \mathrm{i}\alpha(z - \mathrm{i})\, yy^*J = h\, b, \qquad |b^w| \le \frac{e^{2B\eta}}{\sqrt{1+\eta \operatorname{Im} z}}.$$

Proof. Put $t = \mathrm{i}\alpha(z - \mathrm{i})$, so $\operatorname{Re} t = \alpha(1 - \operatorname{Im} z)$, and $M = 1 - t\, yy^*J$.

Step 1: the Gram matrix. As $J^* = J$ and $y^*Jy = 0$, $M^*JM = (1-\bar t\, Jyy^*)J(1-t\, yy^*J) = J - \tau\, Jyy^*J$ with $\tau = 2\operatorname{Re} t$, the term in $|t|^2$ containing y^*Jy. List n in increasing order of o, and for $a \in \mathbb{Z}$ let $T_a = \{l : o(l) < a\}$ and $x_l = s(l)|y_l|^2$. By the matrix determinant lemma, the principal minor of M^*JM on T_a is $\det(J_{T_a})\, p_a$ with

$$p_a = 1 - \tau \sum_{l \in T_a} x_l.$$

All p_a are positive. Since $\sum_l x_l = y^*Jy = 0$ and o lists the signs $+1$ first, the partial sums $S_a = \sum_{l\in T_a} x_l$ satisfy $0 \le S_a \le \frac12 y^*y$. If $\operatorname{Im} z \ge 1$ then $\tau \le 0$ and $p_a \ge 1$; otherwise $0 < \tau S_a \le \alpha y^*y = \eta \le \frac12$ and $p_a \ge \frac12$.

Step 2: the factorisation. A hermitian matrix whose leading principal minors (in the order o) are nonzero has a factorisation $U^*\Delta U$ with U unipotent and upper triangular for o and Δ real diagonal, Δ_{kk} the quotient of consecutive leading minors (Gaussian elimination). Here $\Delta_{kk} = s(k)\, p_{o(k)+1}/p_{o(k)}$, as $T_{o(k)+1} = T_{o(k)} \sqcup \{k\}$. Put $b = \operatorname{diag}\big(\sqrt{p_{o(k)+1}/p_{o(k)}}\big)_k U$; it is o-triangular, and $b^*Jb = U^*\Delta U = M^*JM$ (J and the diagonal factor commute). So $h = Mb^{-1}$ satisfies $h^*Jh = J$, i.e. $h \in \mathrm{U}(\operatorname{diag} s)$, and $M = hb$. With $L_k = \log p_{o(k)+1} - \log p_{o(k)}$, $|b^w| = \exp\big(\frac12 \sum_k L_k w(k)\big)$.

Step 3: the sums of the L_k. The L_k telescope along o: $\sum_k L_k = \log p_{\max} - \log p_{\min} = 0$ (both extreme values of p are 1), and $\sum_{s(k)=+1} L_k = \log p_*$ with $p_* = 1 - \tau\frac{y^*y}{2} = 1 - \eta(1 - \operatorname{Im} z) = Y - \eta$, $Y = 1 + \eta \operatorname{Im} z$. As $p_* \ge 1 - \eta \ge \frac12$, $Y/p_* = 1 + \eta/p_* \le 1 + 2\eta$, so $\log Y \le \log p_* + 2\eta$. Moreover $s(k)(p_{o(k)+1} - p_{o(k)}) = -\tau|y_k|^2$, so $s(k)L_k$ has the sign of $-\tau$ (or vanishes).

Step 4: the bound. As w has holomorphic gap 1, there is an integer c with $w(k) + 1 \le c$ for $s(k) = +1$ and $c \le w(k)$ for $s(k) = -1$ (take $c = 1 + \max_{s(k)=+1} w(k)$, or any integer at most $\min_{s(k)=-1} w(k)$ if there is no sign $+1$). If $\tau \le 0$, then $L_k \ge 0$ for $s(k) = +1$ and $L_k \le 0$

for $s(k)=-1$, and $\sum_k L_k w(k) = \sum_k L_k(w(k)-c) \le -\sum_{s(k)=+1} L_k = -\log p_*$. If $\tau>0$, the signs are reversed, and $\sum_k L_k w(k) = \sum_k L_k(w(k)+B) \le 2B\sum_{s(k)=-1} L_k = -2B\log p_*$. Use $-\log p_* \le -\log Y + 2\eta$, $\log Y \ge 0$ and $B \ge 1$. For $\tau \le 0$: $\frac12\sum_k L_k w(k) \le -\frac12 \log p_* \le \eta - \frac12 \log Y \le 2B\eta - \frac12 \log Y$. For $\tau > 0$: $\frac12 \sum_k L_k w(k) \le -B\log p_* \le -B\log Y + 2B\eta \le -\frac12 \log Y + 2B\eta$. So in both cases

$$\tfrac12 \sum_k L_k w(k) \le 2B\eta - \tfrac12 \log Y,$$

and exponentiating gives $|b^w| \le e^{2B\eta} Y^{-1/2}$. □

Lemma 6.6.61. *Let $1 \le j \le m$, $n_* = 2ft^3$, and $|h| = \max_{v\in\Phi} \|h_v\|$ for $h \in G_\infty(s_j)$. There are a bounded function $F_0 \colon G_\infty(s_j) \to \mathbb{C}$ with $F_0(1) \ne 0$ and, for every $g \in \mathrm{G}(s_j)$ with $\lambda_{W_j}(g) \ge (5b^{24})^{-1/2}$, numbers $(c_i)_{i\in \mathrm{Mem}_j}$ in $\mathbb{C}$ with*

$$\Big| \sum_{i\in \mathrm{Mem}_j} c_i\, \mathsf{F}_i(g(h,1)) - F_0(h) \Big| \le 2\, b^{-19n_*}\, |F_0(1)|\, |h|^{6n_*} \qquad (h \in G_\infty(s_j)).$$

Proof. Let $\tilde W_j$ be the padded space, with signs $\tilde s_j$ on $\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+$; let o be the order on $\mathcal{B}^{\mathrm{c}}$ of Lemma 6.6.64, u^{c} the weight $(0;3m)$ there; let γ_j', u_1, u_2, u_3 be as in Lemma 6.6.66, $c_P = c_m$ the coefficient there for $\gamma = m$, $m_i = m^{\mathrm{hol}}_{s^{\mathrm{c}},u_i}$, and $J = \int_{G_\infty(s^{\mathrm{c}})} |m_3|^2$. For $h \in G_\infty(s_j)$ let $\iota(h) \in G_\infty(\tilde s_j)$ be h on $\mathcal{R}$ and 1 on the padding; then $|\iota(h)| = \max(|h|,1) = |h|$, since every $x \in \mathrm{U}(\mathrm{diag}\, s)$ has $\|x\| \ge 1$ (its inverse $\mathrm{diag}(s)x^*\mathrm{diag}(s)$ has the same norm and $1 \le \|x\|\|x^{-1}\|$).

Step 0: numbers. By (AD1) and $C_P \ge 6$, $\log\log b \ge 6\cdot 10^{12}$, so $b > 5^4$; $10^{12}(2d+6) \le \log\log b$ gives $d \le b$; by (AD2), $m \le 2\sqrt{x} \le b$, $3m \le t$ and $r + 3m \le t$ ($r \ge x^5$). Both index sets are nonempty.

Step 1: the carrier and a peak off the cusp. χ_M is tame of weight 0 for $(\mathfrak{M},\chi)$, χ the character of $\mathcal{O}_E/\mathfrak{M}$ given by ω on units. So by (b) of Lemma 6.6.62 (with $B=0$) φ° is continuous, bounded, left $\Gamma_{S^{\mathrm{c}}}$-invariant and right $\mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$-invariant; by (i) of Lemma 6.6.64 it is adelically holomorphic of weight u^{c} for o; by (ii) there it is not 0. Hence $0 < \sup|\varphi^\circ| < \infty$ and φ° has a peak g_1. Apply Lemma 6.6.59 with $V = S^{\mathrm{c}}$, $u = u^{\mathrm{c}}$ (holomorphic gap $3m \ge 1$, entries at most $3m \le 5b = A$, $A \ge 2$), $p = \sqrt{-d}$ ($\bar p = -p$, $\mathrm{Im}\, p_v = \sqrt{d} \in (0,\sqrt{b}]$, $A' = \sqrt{b} \ge 1$); an element $k \in \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$ with $k \equiv 1$ modulo p fixes φ°. So $\lambda_{S^{\mathrm{c}}}(g_1) \ge (5b\sqrt{b})^{-1/2}$. As g_1 is a peak, $\varphi^\circ(g_1) \ne 0$ and $|\varphi^\circ(x)| \le 2|\varphi^\circ(g_1)|$ for all x.

Step 2: the coefficient. Let $v = v_{P_j}$. For $h \in G_\infty(s^{\mathrm{c}})$, $h' \in G_\infty(\tilde s_j)$, the determinants in $\Omega_{m,\gamma_j'}(h,h')$ have modulus 1 (from $g^*\mathrm{diag}(s)g = \mathrm{diag}(s)$), and ω^∞ preserves the inner product ((2) of Lemma 4.1.1); by Cauchy–Schwarz $|c_P(h,h')| \le c_P(1,1) = \langle v, v\rangle$, and c_P is continuous ((2) there). $P_j \ne 0$: it is a product of determinants of square matrices of distinct variables (the maps ng_j and $\mathrm{ps}_j(h,\cdot)$ of (XE3) are injective), so $\langle v,v\rangle > 0$.

Step 3: a bound for real integrals against the carrier. By (c) of Lemma 6.6.66, Lemma 6.6.68 applies with $n = \mathcal{B}^{\mathrm{c}}$ ($3m \le t$), $s = s^{\mathrm{c}}$, o, $u = u_3$ and $u' = u_1$: $0 < J < \infty$ and $\int |m_1(h')|\,|h'|^{6n_*} dh' \le b^{n_*} J$. Hence, if A is a measurable function on $G_\infty(s^{\mathrm{c}})$ with $|A(h')| \le c\,|h'|^{6n_*}$, then $h' \mapsto \varphi^\circ(g_1(h',1))A(h')m_1(h')$ is integrable and

$$\Big| \int_{G_\infty(s^{\mathrm{c}})} \varphi^\circ(g_1(h',1))A(h')\, m_1(h')\, dh' \Big| \le 2\,|\varphi^\circ(g_1)|\, c\, b^{n_*} J. \tag{6.149}$$

Step 4: the function F_0. Put

$$F_0(h) = \int_{G_\infty(s^{\mathrm{c}})} \varphi^\circ(g_1(h',1))\, c_P(h', \iota(h))\, m_1(h')\, dh' \qquad (h \in G_\infty(s_j)).$$

As $|c_P| \le c_P(1,1) \le c_P(1,1)|h'|^{6n_*}$ ($|h'| \ge 1$), (6.149) shows that the integral exists and $|F_0(h)| \le 2|\varphi^\circ(g_1)|c_P(1,1)b^{n_*}J$: F_0 is bounded. At $h=1$, (b) of Lemma 6.6.66 gives $c_P(h',1) = c_P(1,1)m_2(h')\overline{m_3(h')}$, so $F_0(1) = \int f\,\overline{m_3}$ with $f(h') = c_P(1,1)\,\varphi^\circ(g_1(h',1))\,m_1(h')\,m_2(h')$, and $f\,\overline{m_3}$ is integrable. The weights u_1, $u_2(\tau)$ are constant on each block, hence K-dominant for (s^{c}, o), so m_1, m_2 are holomorphic of weights u_1, u_2 for o with value 1 at 1 ((i) of Lemma 6.6.70); $h' \mapsto \varphi^\circ(g_1(h',1))$ is holomorphic of weight u^{c}; and a product of functions holomorphic of weights w, w' is holomorphic of weight $w+w'$ (the product of the extensions is analytic at xb with value $b^w b^{w'}$ times the product). Here

$$u^{\mathrm{c}} + u_1 + u_2(\tau) = \big(0 - \Delta' + \Delta';\ 3m+6m+1+d_j(\tau)+r+2m\big) = \big(0;\ d_j(\tau)+|\mathcal{B}_j|+2m\big) = u_3(\tau),$$

as $|\mathcal{B}_j| = r+9m+1$. So f is holomorphic of weight u_3, $u_3(\tau)$ is K-dominant, and Lemma 6.6.71 gives

$$F_0(1) = f(1)\,J = c_P(1,1)\,\varphi^\circ(g_1)\,J \neq 0, \qquad |F_0(1)| = J\,|\varphi^\circ(g_1)|\,c_P(1,1).$$

Step 5: approximation off the cusps. Let $g \in \mathrm{G}(s_j)$ with $\lambda_{W_j}(g) \ge (5b^{24})^{-1/2}$. The lattice of $\tilde{W}_j$ moved by $(g,1)$ is the product of that of W_j moved by g and those of the two definite summands; a nonzero vector of a definite standard summand has, by the trace and the arithmetic and geometric means as for a definite space ($\pm h(u,u)$ is a nonzero totally positive integer of F), euclidean length at least 1. So $\lambda_{\tilde{W}_j}((g,1)) \ge \min(\lambda_{W_j}(g),1) = \lambda_{W_j}(g)$, and

$$\lambda_{S^{\mathrm{c}}}(g_1)\,\lambda_{\tilde{W}_j}((g,1)) \ge (5b\sqrt{b})^{-1/2}(5b^{24})^{-1/2} = \tfrac{1}{5}\,b^{-51/4} \ge b^{-13}$$

($b^{1/4} \ge 5$). By (a) and (d) of Lemma 6.6.66, Lemma 6.6.73 applies to $V = S^{\mathrm{c}}$, $V' = \tilde{W}_j$, $\alpha = \upsilon^m$ (weight m), $\beta = \nu_j^\flat \upsilon^m$ (weight γ_j'), $Q = P_j$ and the points g_1, $(g,1)$: there is Ψ with

$$\big|\theta_\Psi(g_1(h',1), g(h,1)) - c_P(h', \iota(h))\big| \le b^{-20n_*}\big(|h'|\,|h|\big)^{6n_*} c_P(1,1)$$

for all h', h, where θ_Ψ is the kernel of Lemma 6.6.79 (note $(g,1)(\iota(h),1) = (g(h,1),1)$). By Lemma 6.6.79 for g_1 and Ψ there are (c_i) with

$$\sum_i c_i \mathsf{F}_i(g') = \int \varphi^\circ(g_1(h',1))\,\theta_\Psi(g_1(h',1), g')\,m_1(h')\,dh'$$

for all g', the integrand being integrable. Fix h and take $g' = g(h,1)$. Both this integral and $F_0(h)$ exist, so their difference is the integral of $\varphi^\circ(g_1(h',1))A(h')m_1(h')$ with $A(h') = \theta_\Psi(g_1(h',1), g(h,1)) - c_P(h', \iota(h))$, $|A(h')| \le \varepsilon|h'|^{6n_*}$, $\varepsilon = b^{-20n_*}|h|^{6n_*}c_P(1,1)$. By (6.149) and Step 4,

$$\Big|\sum_i c_i \mathsf{F}_i(g(h,1)) - F_0(h)\Big| \le 2|\varphi^\circ(g_1)|\,b^{-20n_*}|h|^{6n_*}c_P(1,1)\,b^{n_*}J = 2\,b^{-19n_*}\,|F_0(1)|\,|h|^{6n_*}.$$

□

Lemma 6.6.62. *Let s^{c} be the signs of S^{c} and $\mathrm{I} = \mathrm{I}_{\mathcal{B}^{\mathrm{c}}}$. For a character χ of $R_{\mathfrak{m}}$ (extended by 0 to the nonunits) write $\chi \circ \det$ for the function $y \mapsto \chi(\det y)$ on $\mathcal{B}^{\mathrm{c}} \times \mathcal{B}^{\mathrm{c}}$ matrices over $R_{\mathfrak{m}}$.*

(a) There is $C \in \mathbb{R}$ such that for every modulus $\mathfrak{m}$, every character χ of $R_{\mathfrak{m}}$ and every automorphic character c of $\mathrm{U}(1)$ tame of weight 0 for $(\mathfrak{m}, \chi)$ there is $\gamma \in \mathbb{C}$ with

$$L_*(\mathfrak{m}, c^{-1}\upsilon^m; m)\,L_*(\mathfrak{m}, c\,\upsilon^{m/2}; m/2)\,|\gamma|^2 = C$$

and, for every $x \in \mathrm{G}(s^{\mathrm{c}})$,

$$\gamma \sum_{h \bmod \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})}^{\mathrm{cl}} \mathsf{a}_c(h)\,\theta^{S^{\mathrm{c}},\mathrm{I}}_{\upsilon^m, c; \mathfrak{m}}[\chi \circ \det, 1](x,h) = \varphi^\circ(x).$$

(b) If some automorphic character of $\mathrm{U}(1)$ *of weight* 0 *is tame for some* $(\mathfrak{m},\chi)$*, then* φ° *is continuous, left invariant under* $\Gamma_{S^{\mathrm{c}}}$ *and right invariant under* $\mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$*, and*

$$\sup_x |\varphi^\circ(x)|\,\mathrm{ht}_{S^{\mathrm{c}}}(x)^B < \infty$$

for every $B \in \mathbb{N}$.

Proof. Write I_m, I_m^- for the standard spaces on $b = \{1,\dots,m\}$ with signs $+1$, -1, $\mathbf{K}_m = \mathbf{K}_0(b)$, $a = \mathcal{B}^{\mathrm{c}}$, $\mathbf{K}_a = \mathbf{K}_0(a)$, and $A = \Sigma(\mathfrak{m})$. Fix $\mathfrak{m}$, χ and c as in (a), with tame part ψ.

Step 0: three facts on characters. (i) For $k \in \mathbf{K}_0(n)$ (n any index set), $\det k \in \mathrm{U}(1)(\mathbb{A})$ has integral finite components and infinite components 1, so $c(\det k) = \prod_{w\in A}\psi_w(\det k \bmod w) = \chi(\det \bar{k})$, $\bar{k}$ the reduction modulo $\mathfrak{m}$, by Definition 3.1.1 and (XD4), and $\upsilon(\det k) = 1$ by (ii) of Lemma 3.2.11. (ii) υ has weight 1 and trivial tame part ((ii) of Lemma 3.2.11), so $c\upsilon^m$ is tame of weight m for $(\mathfrak{m},\chi)$, and c^{-1} is tame of weight 0 for $(\mathfrak{m},\chi^{-1})$, χ^{-1} being $u \mapsto \chi(u)^{-1}$ on units and 0 on nonunits. (iii) $\mathrm{mod}_{\mathfrak{m}}(1,v) = v \otimes v^0$ for every Fock vector v: $1^\natural = \mathbf{1}_A$, and $\mathbf{1}_A \otimes_A v^0 = P^A v^0 = v^0$ by Lemma 6.6.12 and (2) of Lemma 6.2.33.

Step 1: the first exchange. Apply Proposition 6.3.67 with $n = b$, $W = \mathrm{I}_m$, $l = p = \emptyset$, the identity maps j, e, σ, the zero space V' (index set $\emptyset$), $d = m/2$ ($|b| = 0+2d$, and $2|l|+2 = 2 \le m$), $\iota_\tau = \emptyset$, the character χ^{-1} and $\alpha = \beta = c^{-1}$ (tame of weight $0 = |l| - |\iota_\tau|$, Step 0 (ii)). Then $\Delta^j(e;\eta) = 1$ and $Q_{f,j}(\eta) = 1$ (empty products and the determinant of the empty matrix). Matched functions for (σ,χ) are a constant Ψ on the empty matrix and $\Phi(y) = \Psi\,\chi(\det y)^{-1}$ on invertible y, 0 elsewhere; take $\Psi = 1$, so $\Phi = \chi^{-1}\circ\det$. On the right side, $\mathrm{Hom}(V',\mathrm{I}_m)$ has the empty index set: its theta model is $\mathbb{C}$ with $v^0 = 1$, its canonical theta functional is the identity ($\mathrm{G}(\emptyset)$ is trivial, so the transporting element is 1), the Fock model on the empty index set is $\mathbb{C}$ with $v_1 = 1$ and $v \otimes f = vf$, and $\omega_{1,c^{-1}}$ is the identity; with Step 0 (iii) the kernel $\theta^{V',\mathrm{I}_m}_{1,c^{-1};\mathfrak{m}}[1,1]$ is the constant 1. By (VP1) of Definition 3.2.2 the measure of $G_\infty(\emptyset) = \{1\}$ is the unit point mass and $G_f(\emptyset) = \mathbf{K}_0(\emptyset) = \{1\}$ has mass 1, so $[\mathrm{U}(V')] = \mathrm{G}(\emptyset) = \{1\}$ has mass $v_0 = 1$. So there are $C_1 \in \mathbb{R}$, independent of $(\mathfrak{m},\chi,c)$, and γ_1 with $L_*(\mathfrak{m}, c\,\upsilon^{m/2}; m/2)\,|\gamma_1|^2 = C_1$ and

$$\gamma_1 \sum_{h \bmod \mathbf{K}_m}^{\mathrm{cl}} \theta^{\mathrm{I}_m,\mathrm{I}_m}_{c^{-1},c^{-1};\mathfrak{m}}[\chi^{-1}\circ\det,1](g,h) = v_0 \qquad (g \in \mathrm{G}(1_b)). \tag{6.150}$$

Step 2: conjugation to the negative space. By Lemma 6.4.55 for $S = T = \mathrm{I}_m$, $\alpha = \beta = c^{-1}$, $\Psi = \chi^{-1}\circ\det$, $P = 1$, there are $c_{\mathrm{I,I}}$ of modulus 1 and the unit $u \in R_{\mathfrak{m}}^\times$ (reduction of the unit of (1) of Lemma 4.1.1) with $\overline{\theta^{\mathrm{I}_m,\mathrm{I}_m}_{c^{-1},c^{-1};\mathfrak{m}}[\chi^{-1}\circ\det,1](g,h)} = c_{\mathrm{I,I}}\,\theta^{\mathrm{I}_m^-,\mathrm{I}_m}_{c\upsilon^m,c\upsilon^m;\mathfrak{m}}[\Psi',1](g,h)$, where $\Psi'(X) = \overline{\chi^{-1}(\det(u^{-1}X))} = \chi(u)^{-m}\chi(\det X)$ ($|\chi| = 1$ on units, both sides 0 on noninvertible X). Conjugating (6.150) (the class-sum weights are rational) gives, with $c_0 = \overline{\gamma_1}\,c_{\mathrm{I,I}}\,\chi(u)^{-m}/v_0$, the class representatives h_i' of $\mathrm{U}(\mathrm{I}_m)(F)\backslash G_f(b)/\mathbf{K}_m$ and their weights $\omega_i = 1/\#(\mathrm{U}(\mathrm{I}_m)(F) \cap h_i'\mathbf{K}_m h_i'^{-1})$,

$$c_0 \sum_i \omega_i\,\kappa_{h_i'}(y) = 1, \qquad \kappa_{h'}(y) = \theta^{\mathrm{I}_m^-,\mathrm{I}_m}_{c\upsilon^m,c\upsilon^m;\mathfrak{m}}[\chi\circ\det,1](y,h') \qquad (y \in \mathrm{G}(-1_b) = \mathrm{G}(1_b)). \tag{6.151}$$

Step 3: the second exchange as the hypothesis of the one exchange. Let $W' = S^{\mathrm{c}}$ (index set a) and $W = \mathrm{I}_m \oplus S^{\mathrm{c}}$ (index set $n = b \sqcup a$), so W has the signs sgn_j for j the identification of $m' \sqcup l$ with n, $m' = b \sqcup \{1,\dots,2m\}$, l the second block of a. Fix $x \in \mathrm{G}(s^{\mathrm{c}})$. For $h' \in G_f(b)$ and a function Φ on $\mathrm{M}_{a\times n}(R_{\mathfrak{m}})$ let $K_{h'}(\Phi)(h) = \int_{\mathbf{K}_a} \theta^{W,\mathrm{I}}_{c\upsilon^m,1;\mathfrak{m}}[\Phi,1](\mathrm{diag}(h',x),hk)\,dk$ (Haar probability measure; the kernel is continuous by (2) of Lemma 4.1.1); it is right $\mathbf{K}_a$-invariant, and left $\mathrm{U}(\mathrm{I})(F)$-invariant by Lemma 6.2.5. Let Φ, Ψ be matched for $(\mathrm{id}_{b\sqcup a},\chi^{-1})$.

Then Φ vanishes off the matrices $(k^{-1})_a$, $k \in \mathrm{GL}_n(R_\mathfrak{m})$, with $\Phi((k^{-1})_a) = \chi^{-1}(\det k)\Psi(k_b)$; for $\kappa \in \mathbf{K}_a$ and $\kappa' = \mathrm{diag}(1_b, \bar\kappa)$ we have $\bar\kappa^{-1}(k^{-1})_a = ((k\kappa')^{-1})_a$ and $(k\kappa')_b = k_b$, so $\Phi(\bar\kappa^{-1}X) = \chi(\det\bar\kappa)^{-1}\Phi(X)$ for all X, and $(c\upsilon^m)(\det\kappa)\Phi(\bar\kappa^{-1}X) = \Phi(X)$ by Step 0 (i). The vector v_1 is fixed by $\Omega_{m,0}(1,y)$, $y \in G_\infty(1_a)$ (m and 0 the weights of $c\upsilon^m$ and 1), by (5) of Lemma 4.1.1 (exponent $m - \#\{\text{signs } -1 \text{ of } W\} = 0$). So (4) of Lemma 6.3.71 makes $h \mapsto \theta^{W,\mathrm{I}}_{c\upsilon^m,1;\mathfrak{m}}[\Phi,1](\mathrm{diag}(h',x),h)$ right $\mathbf{K}_a$-invariant, hence equal to $K_{h'}(\Phi)$. Now apply Proposition 6.3.67 with W, $V' = \mathrm{I}_m^-$ (index set b, $f\colon l \to b$ the identification, $p = \emptyset$), $e\colon a \to m'$ any bijection, $\sigma = \mathrm{id}_{b\sqcup a}$, $d = m$ ($|a| = 3m = |b| + 2d$; $2|l| + 2 = 2m + 2 \le 4m$), $\iota_\tau = \emptyset$, the character χ, $\alpha = c\upsilon^m$ (tame of weight $m = |l|$, Step 0 (ii)) and $\beta = 1$, at the point $\mathrm{diag}(h',x)$. Here $\Delta^j(e;\eta) = 1$ and $Q_{f,j}(\eta) = \prod_\tau \det\big((x_{\tau,(2,i),i'})_{i,i'}\big)^{2m} = \tilde P^\circ$, the carrier polynomial P° in the variables of the rows a. So there are $C_2 \in \mathbb{R}$, independent of $(\mathfrak{m},\chi,c)$, and c_2 with $L_*(\mathfrak{m},(c\upsilon^m)^{-1}\upsilon^{m+m};m)\,|c_2|^2 = C_2$, where $(c\upsilon^m)^{-1}\upsilon^{m+m} = c^{-1}\upsilon^m$, and

$$c_2 \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} K_{h'}(\Phi)(h) = \int_{[\mathrm{U}(\mathrm{I}_m^-)]} \theta^{\mathrm{I}_m^-,W}_{c\upsilon^m,c\upsilon^m;\mathfrak{m}}\big[\Psi,\tilde P^\circ\big](y,\mathrm{diag}(h',x))\,dy;$$

the integrand is continuous ((2) of Lemma 4.1.1) on the compact $[\mathrm{U}(\mathrm{I}_m^-)]$, hence integrable. This is the exchange identity of Lemma 6.6.63 for $V' = \mathrm{I}_m^-$, $W' = S^{\mathrm{c}}$, $g = x$, $c = c_2$, $\alpha = \beta = c\upsilon^m$, $\beta' = 1$ and $Q = P^\circ$.

Step 4: the one exchange. By (ii) of Lemma 6.6.63 with $\Psi' = 1$, the family (h_i',ω_i) and c_0 of (6.151) (so $F = 1$),

$$c_2c_0\sum_i \omega_i \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} K_{h_i'}(\Phi_1)(h) = \int_{[\mathrm{U}(\mathrm{I}_m^-)]} \theta^{\mathrm{I}_m^-,S^{\mathrm{c}}}_{c\upsilon^m,1;\mathfrak{m}}\big[1,P^\circ\big](y,x)\,dy, \tag{6.152}$$

with $\Phi_1(X) = \chi(\det X'')$, X'' the columns a of X. On the right, $\omega_{c\upsilon^m,1}(y,x) = c(\det x)\,\omega_{\upsilon^m,1}(y,x)$ (WR4) and $\mathrm{mod}_\mathfrak{m}(1,v_{P^\circ}) = v_{P^\circ}\otimes v^0$ (Step 0 (iii)), so the right side is $c(\det x)\,\varphi^\circ(x)$ by (XE4).

Step 5: splitting the kernel on W. $\Phi_1 = 1\otimes(\chi\circ\det)$ on the columns b and a, and $v_1 = v_{1\cdot1}$, so by (b) of Lemma 6.3.80 and Step 0 (iii), $\mathrm{mod}_\mathfrak{m}(\Phi_1,v_1) = (v_1\otimes v^0)\boxtimes^{\mathrm{sc}}\mathrm{mod}_\mathfrak{m}(\chi\circ\det,v_1)$. By (d) of Lemma 6.3.52 with $\beta = c$, $\beta' = \upsilon^m$ and the second character 1, and by (WR4),

$$\begin{aligned} K_{h'}(\Phi_1)(h) &= \theta^{\mathrm{I}_m,\mathrm{I}}_{c,1}(v_1\otimes v^0)(h',h)\;\theta^{S^{\mathrm{c}},\mathrm{I}}_{\upsilon^m,1;\mathfrak{m}}[\chi\circ\det,1](x,h)\\ &= \theta^{\mathrm{I}_m,\mathrm{I}}_{c,1}(v_1\otimes v^0)(h',h)\;c(\det x)\,\theta^{S^{\mathrm{c}},\mathrm{I}}_{\upsilon^m,c;\mathfrak{m}}[\chi\circ\det,1](x,h).\end{aligned}$$

Summing over i with the weights ω_i gives $\mathsf{a}_c(h)$ (XE4) in the first factor; the class sums are finite, so they may be interchanged, and the left side of (6.152) is

$$c_2c_0\,c(\det x)\sum_h^{\mathrm{cl}} \mathsf{a}_c(h)\,\theta^{S^{\mathrm{c}},\mathrm{I}}_{\upsilon^m,c;\mathfrak{m}}[\chi\circ\det,1](x,h).$$

Dividing by $c(\det x)$, of modulus 1, gives (a) with $\gamma = c_2c_0$: as $|c_0| = |\gamma_1|/v_0$, $|\gamma|^2 = |c_2|^2|\gamma_1|^2v_0^{-2}$, and multiplying by the two L-value products gives

$$L_*(\mathfrak{m},c^{-1}\upsilon^m;m)\,L_*(\mathfrak{m},c\upsilon^{m/2};m/2)\,|\gamma|^2 = C_2C_1v_0^{-2} = C$$

for $C = C_1C_2v_0^{-2}$.

Step 6: (b). Let c be tame of weight 0 for $(\mathfrak{m},\chi)$. By (a), φ° is a finite linear combination of the functions $\kappa_h(x) = \theta^{S^{\mathrm{c}},\mathrm{I}}_{\upsilon^m,c;\mathfrak{m}}[\chi\circ\det,1](x,h)$. The function $\chi\circ\det$ vanishes at every matrix without a (left) inverse over $R_\mathfrak{m}$, so by (2) of Lemma 6.3.71 every κ_h is continuous,

left $\Gamma_{S^{\mathrm{c}}}$-invariant and satisfies $\sup_x |\kappa_h(x)|\,\mathrm{ht}_{S^{\mathrm{c}}}(x)^B < \infty$ for every B. For $k \in \mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$, (6) of Lemma 4.1.1 gives $\omega_{\mathcal{V}^m,c}((1,k),1)\,\mathrm{mod}_{\mathfrak{m}}(\chi\circ\det, v_1) = c(\det k)^{-1}\mathrm{mod}_{\mathfrak{m}}(\Phi_k, v_1)$ with $\Phi_k(X) = \chi(\det(X\bar{k})) = \chi(\det\bar{k})\chi(\det X)$, so by Step 0 (i) the datum is fixed and $\kappa_h(xk) = \kappa_h(x)$. Hence φ° has the properties of (b). □

Lemma 6.6.63. *Let V' be a space with index set b, W' a space with index set a, and $W = \mathrm{I}_b \oplus W'$, with index set $b \sqcup a$; write $\mathrm{diag}(h', g)$ for the point of $\mathrm{U}(W)(\mathbb{A}_F)$ with blocks $h' \in \mathrm{U}(\mathrm{I}_b)(\mathbb{A}_F)$ and $g \in \mathrm{U}(W')(\mathbb{A}_F)$. Let $\mathfrak{m}$ be a modulus, χ a multiplicative character of $R = R_{\mathfrak{m}}$, χ^{-1} the character $u \mapsto \chi(u)^{-1}$ on units and 0 on nonunits, α, β, β' automorphic characters of $\mathrm{U}(1)$, $Q \in \mathbb{C}[x]_{a\times b}$, and $\tilde{Q} \in \mathbb{C}[x]_{(b\sqcup a)\times b}$ the polynomial Q in the variables of the rows a. Let $g \in \mathrm{U}(W')(\mathbb{A}_F)$, $c \in \mathbb{C}$, and for every $h' \in \mathrm{U}(\mathrm{I}_b)(\mathbb{A}_{F,f})$ and every function Φ on $\mathrm{M}_{a\times(b\sqcup a)}(R)$ let $K_{h'}(\Phi)$ be a function on $\mathrm{U}(\mathrm{I}_a)(\mathbb{A}_{F,f})$, left invariant under $\mathrm{U}(\mathrm{I}_a)(F)$ and right invariant under $\mathbf{K}_a$. Assume the* exchange identity*: for every h' and all Φ, Ψ matched for $(\mathrm{id}_{b\sqcup a}, \chi^{-1})$ modulo $\mathfrak{m}$, the function $x \mapsto \theta^{V',W}_{\alpha,\beta\beta';\mathfrak{m}}[\Psi, \tilde{Q}](x, \mathrm{diag}(h', g))$ is integrable on $[\mathrm{U}(V')]$ and*

$$c \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} K_{h'}(\Phi)(h) = \int_{[\mathrm{U}(V')]} \theta^{V',W}_{\alpha,\beta\beta';\mathfrak{m}}[\Psi, \tilde{Q}](x, \mathrm{diag}(h', g))\, dx.$$

Let Ψ' be a function on $\mathrm{M}_{a\times b}(R)$ with $\Psi'(y\gamma) = \Psi'(y)$ for all $\gamma \in \mathrm{GL}_b(R)$, and for $x = (x' \,|\, x'') \in \mathrm{M}_{a\times(b\sqcup a)}(R)$ (x' the columns b, x'' the columns a) let $\Phi_{\Psi'}(x) = \chi(\det x'')\Psi'(x''^{-1}x')$ if x'' is invertible and $\Phi_{\Psi'}(x) = 0$ otherwise. Write $\kappa_{h'}(x) = \theta^{V',\mathrm{I}_b}_{\alpha,\beta;\mathfrak{m}}[\chi\circ\det, 1](x, h')$ and $\lambda(x) = \theta^{V',W'}_{\alpha,\beta';\mathfrak{m}}[\Psi', Q](x, g)$ for $x \in \mathrm{U}(V')(\mathbb{A}_F)$.

(i) For every h', $\kappa_{h'}\lambda$ is integrable on $[\mathrm{U}(V')]$ and

$$c \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} K_{h'}(\Phi_{\Psi'})(h) = \int_{[\mathrm{U}(V')]} \kappa_{h'}(x)\lambda(x)\, dx.$$

(ii) If $c_0 \in \mathbb{C}$, $(h'_j, \omega_j)_{j\in J}$ is a finite family of finite points and complex numbers and F is the function $F(x) = c_0 \sum_j \omega_j \kappa_{h'_j}(x)$, then $F\lambda$ is integrable and

$$c\, c_0 \sum_{j\in J} \omega_j \sum_{h \bmod \mathbf{K}_a}^{\mathrm{cl}} K_{h'_j}(\Phi_{\Psi'})(h) = \int_{[\mathrm{U}(V')]} F(x)\lambda(x)\, dx.$$

Proof. **Step 1: the matched partner of $\Phi_{\Psi'}$.** Put $\Psi(y) = \chi(\det y_1)\Psi'(y_2)$ for $y \in \mathrm{M}_{(b\sqcup a)\times b}(R)$, y_1 the rows b and y_2 the rows a (with $\chi(\det y_1) = 0$ unless y_1 is invertible). We show that $\Phi_{\Psi'}$ and Ψ are matched for (id, χ^{-1}). If $\Phi_{\Psi'}(x) \neq 0$, then x'' is invertible and x is the matrix of the rows a of the invertible matrix $\begin{pmatrix} 1_b & 0 \\ x' & x'' \end{pmatrix}$, which is k^{-1} for k its inverse. If $\Psi(y) \neq 0$, then $\det y_1$ is a unit and y is the matrix of the columns b of the invertible $\begin{pmatrix} y_1 & 0 \\ y_2 & 1_a \end{pmatrix}$. Now let $k \in \mathrm{GL}_{b\sqcup a}(R)$, in blocks $k = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$, $k^{-1} = \begin{pmatrix} A' & B' \\ C' & D' \end{pmatrix}$ (rows and columns b, a); the rows a of k^{-1} are $(C' \,|\, D')$ and the columns b of k are $\binom{A}{C}$. By Jacobi's theorem on complementary minors, $\det D' = \det A\,(\det k)^{-1}$, so D' is invertible iff A is; if they are not, both $\Phi_{\Psi'}(C' \,|\, D')$

and $\chi^{-1}(\det k)\Psi\binom{A}{C}$ vanish. If they are, the block (a,b) of $k^{-1}k=1$ gives $C'A+D'C=0$, so $D'^{-1}C'=C(-A^{-1})$ and $\Psi'(D'^{-1}C')=\Psi'(C)$ by the invariance of Ψ'; hence

$$\Phi_{\Psi'}(C'\mid D')=\chi(\det A)\chi(\det k)^{-1}\Psi'(C)=\chi^{-1}(\det k)\,\Psi\begin{pmatrix}A\\C\end{pmatrix}.$$

Step 2: the kernel of the partner factors. $\Psi=(\chi\circ\det)\otimes\Psi'$ and $\tilde{Q}=1\cdot Q$ in the notation of (a) of Lemma 6.3.80 (blocks $T_1=\mathrm{I}_b$, $T_2=W'$, source V'), so $\mathrm{mod}_{\mathfrak{m}}(\Psi,v_{\tilde{Q}})=\mathrm{mod}_{\mathfrak{m}}(\chi\circ\det,v_1)\boxtimes^{\mathrm{tg}}\mathrm{mod}_{\mathfrak{m}}(\Psi',v_Q)$. By the exact factorisation (d) of Lemma 6.3.52 (target sums, characters α and $\beta\beta'$),

$$\theta^{V',W}_{\alpha,\beta\beta';\mathfrak{m}}[\Psi,\tilde{Q}](x,\mathrm{diag}(h',g))=\kappa_{h'}(x)\,\lambda(x)\qquad(x\in\mathrm{U}(V')(\mathbb{A}_F)),$$

the finite point h' being read with infinite components 1.

Step 3: conclusion. (i) By Step 1 the exchange identity applies to $(\Phi_{\Psi'},\Psi)$: the left side of Step 2 is integrable on $[\mathrm{U}(V')]$ with integral $c\sum^{\mathrm{cl}}K_{h'}(\Phi_{\Psi'})$. So $\kappa_{h'}\lambda$ is integrable, and the identity follows. (ii) $F\lambda=c_0\sum_j\omega_j\kappa_{h'_j}\lambda$ is a finite combination of integrable functions; integrate term by term and use (i) for each h'_j. □

Lemma 6.6.64. *Let s^{c} be the signs of S^{c}, o the order on $\mathcal{B}^{\mathrm{c}}$ with $o((1,a))=-a$ $(1\le a\le 2m)$ and $o((2,a))=a-1$ $(1\le a\le m)$, and $u=(u_v)_{v\in\Phi}$ the weights with $u_v((1,a))=0$ and $u_v((2,a))=3m$.*

(i) If some automorphic character of $\mathrm{U}(1)$ *of weight* 0 *is tame for some* $(\mathfrak{m},\chi)$*, then φ° is adelically holomorphic of weight u for o.*

(ii) $\varphi^\circ\neq 0$.

Proof. **(i).** Fix $(\mathfrak{m},\chi)$ and an automorphic character c of $\mathrm{U}(1)$ of weight 0 tame for $(\mathfrak{m},\chi)$, and write $\mathrm{I}=\mathrm{I}_{\mathcal{B}^{\mathrm{c}}}$. By (a) of Lemma 6.6.62 and the definition of class sums there are finitely many $h_1,\dots,h_r\in G_f(\mathcal{B}^{\mathrm{c}})$ (read as adelic points with infinite components 1) and $a_1,\dots,a_r\in\mathbb{C}$ with $\varphi^\circ=\sum_k a_k\kappa_{h_k}$, where

$$\kappa_h(x)=\theta^{S^{\mathrm{c}},\mathrm{I}}_{\upsilon^m,c}(v_1\otimes f)(x,h),\qquad f=(\chi\circ\det)^\natural\otimes_{\Sigma(\mathfrak{m})}v^0\in\mathcal{M}_{S^{\mathrm{c}},\mathrm{I}},$$

since $\theta_{\upsilon^m,c;\mathfrak{m}}[\chi\circ\det,1]$ is the kernel of $\mathrm{mod}_{\mathfrak{m}}(\chi\circ\det,v_1)=v_1\otimes f$. A finite linear combination of functions holomorphic of weight u for o is holomorphic of weight u for o (the same combination of the extensions is an extension). So it suffices to show that each κ_h is adelically holomorphic of weight u for o.

Fix h and $g\in\mathrm{G}(s^{\mathrm{c}})$, and put $\ell(w)=\theta_{\mathrm{Hom}(S^{\mathrm{c}},\mathrm{I})}(\omega_{\upsilon^m,c}(g,h)(w\otimes f))$ for $w\in\mathcal{F}_{S^{\mathrm{c}},\mathrm{I}}$. The map $w\mapsto w\otimes f=\int w(y)\rho(\mathrm{rv}(y))f\,d\nu_\iota(y)$ is linear, and $\|w\otimes f\|\le\int|w(y)|\,\|\rho(\mathrm{rv}(y))f\|\,d\nu_\iota(y)=\|w\|\,\|f\|$, because each $\rho(z)$ is an isometry of $L^1(\mu_n)$ ($|\beta_s|=1$ and μ_n is translation invariant). As $\omega_{\upsilon^m,c}(g,h)$ is bounded ((2) of Lemma 4.1.1) and the theta functional is bounded, ℓ is a bounded linear functional on $\mathcal{F}_{S^{\mathrm{c}},\mathrm{I}}$. For $z\in G_\infty(s^{\mathrm{c}})$, $\omega_{\upsilon^m,c}(g(z,1),h)=\omega_{\upsilon^m,c}(g,h)\,\omega_{\upsilon^m,c}((z,1),1)$ ((2) of Lemma 4.1.1), and by (5) there (υ^m has weight m, c weight 0)

$$\omega_{\upsilon^m,c}((z,1),1)(v_1\otimes f)=\big(\Omega_{m,0}(z,1)v_1\big)\otimes f=\big(\Omega_{0,0}(z,1)v_1\big)\otimes f,$$

the factor $\det(1)^m$ of (WR5) being 1. Hence $\kappa_h(g(z,1))=\ell(\Omega_{0,0}(z,1)v_1)$. Apply Lemma 6.6.65 with p the first block, q the second block of $\mathcal{B}^{\mathrm{c}}$, $n'=\mathcal{B}^{\mathrm{c}}$, i the inclusion of the first block, $d=0$

(so $Q_0 = 1$ and $v_{Q_0} = v_1$), $S = S^{\mathrm{c}}$, $T = \mathrm{I}$ and the order o, which is injective and positive-first for s^{c} ($o((1,a)) = -a \le -1 < 0 \le a' - 1 = o((2,a'))$). Its weight u_0 is 0 on the first and $\#\mathcal{B}^{\mathrm{c}} = 3m$ on the second block, that is u. So $z \mapsto \kappa_h(g(z,1))$ is holomorphic of weight u for o for every g, which is (i).

(ii). Let $b = \{1,\dots,m\}$, $S = \mathrm{I}_b^-$ (signs -1), $T = S^{\mathrm{c}}$, $v = v_{P^\circ} \in \mathcal{F}_{S,T}$ (variables $X_{\tau,a,c}$, $a \in \mathcal{B}^{\mathrm{c}}$, $c \in b$) and $\varphi = v \otimes v^0$, the datum $v \otimes \Phi \otimes \Phi^\circ$ with $A = \emptyset$, $\Phi = 1$. By (XE4), $\varphi^\circ(x) = \int_{[\mathrm{U}(S)]} \theta^{S,T}_{v^m,1}(\varphi)(g,x)\,dg$ is the theta lift $\Theta_\varphi \mathbf{1}$ of the constant function $\mathbf{1}$ in the notation of Theorem 6.5.13.

Step 1: the hypotheses of Theorem 6.5.13. $2\,\mathrm{rk}\,S = 2m < 3m = \mathrm{rk}\,T$; v is a Schwartz vector; φ is clean by (DC1), all signs of S being -1. The function $\mathbf{1}$ is continuous and invariant on both sides, and $\mathrm{ht}_S \equiv 1$: let x_S be the point of S, $g \in \mathrm{G}(-1_b)$, $u \ne 0$ in the lattice of S_g and $w = (x_S g)^{-1}u$, so $w_f \in \widehat{\mathcal{O}}_E^m$. Since $(x_S g)^* J_S (x_S g) = \varepsilon_{-1_b}$, the number $a = -u^* J_S u \in F$ has the component $|w_v|^2 > 0$ at each $v \in \Phi$ (the infinite part of ε_{-1_b} is -1) and the finite part $-w_f^* w_f \in \widehat{\mathcal{O}}_F$ (its finite part is 1); so a is a nonzero totally positive integer of F and $\|w_\infty\|^2 = \mathrm{Tr}_{F/\mathbb{Q}}\, a \ge \#\Phi\, \mathrm{N}_{F/\mathbb{Q}}(a)^{1/\#\Phi} \ge 1$ (arithmetic and geometric means). Thus $\lambda_S \equiv 1$, and $\mathbf{1}\cdot \mathrm{ht}_S^N$ is bounded. Finally $V_S = \mathrm{vol}([\mathrm{U}(S)]) \in (0,\infty)$: $G_\infty(-1_b)$ is compact and $\Gamma_S \backslash G_f(b)/\mathbf{K}_0(b)$ is finite (finiteness of class numbers, Borel), so $[\mathrm{U}(S)]$ is compact. Hence $\langle \mathbf{1}, R(g)\mathbf{1}\rangle_S = V_S$ for every g.

Step 2: the coefficient of the datum. Let $g = (x,k)$, $x \in G_\infty(-1_b)$, $k \in G_f(b)$. By (5) of Lemma 4.1.1 (v^m of weight m, 1 of weight 0), $\omega_{v^m,1}(g,1)\varphi = (\Omega_{m,0}(x,1)v) \otimes f'_k$ with $f'_k = \omega_{v^m,1}((1,k),1)v^0 = \omega_{1,1}((1,k),1)v^0$ (WR4). The element x is block diagonal for the signs of b (one block) and so is $1 \in G_\infty(1_{\mathcal{B}^{\mathrm{c}}})$, so the second formula of (5) applies: the factor is $\prod_{v\in\Phi} \det(x_v)^{\#\{a : s^{\mathrm{c}}(a) = +1\}} = \prod_v \det(x_v)^{2m}$, and the substitution sends $X_{v,(2,i),c}$ (where $s^{\mathrm{c}}((2,i)) = -1 = s(c)$) to $\sum_{j\in b}(x_v^{-1})_{cj} X_{v,(2,i),j}$, so the matrix $(X_{v,(2,i),c})_{i,c}$ goes to itself times $(x_v^{-1})^{\mathsf{T}}$ and P° to $\prod_v \det(x_v)^{-2m} P^\circ$. Hence

$$\Omega_{m,0}(x,1)v = v \qquad (x \in G_\infty(-1_b)).$$

By (4) of Lemma 6.2.33 ($A = \emptyset$), $v_1 \otimes v^0 = v^0$, and by (5) of Lemma 4.1.1 for v_1, $f'_k = \omega_{1,1}((1,k),1)(v_1 \otimes v^0) = v_1 \otimes f'_k$. So (6) of Lemma 6.2.33 gives

$$\langle \varphi, \omega_{v^m,1}(g,1)\varphi\rangle = \langle v,v\rangle\, \langle v_1 \otimes v^0, v_1 \otimes f'_k\rangle = \langle v,v\rangle\, \mathrm{mc}(k), \qquad \mathrm{mc}(k) = \langle v^0, \omega_{1,1}((1,k),1)v^0\rangle.$$

mc is the vacuum coefficient $\mathrm{mc}_{1,\Sigma}$ for $\beta = 1$ and Σ the set of all finite places of F. It is right invariant under $\mathbf{K}_0(b)$: for $\kappa \in \mathbf{K}_0(b)$, $\omega_{1,1}((1,\kappa),1)v^0 = v^0$ by (6) of Lemma 4.1.1 (with $v_1 \otimes v^0 = v^0$).

Step 3: the Rallis inner product formula. By (1) of Theorem 6.5.13 for $y = y' = \mathbf{1}$, $(x,k) \mapsto V_S \langle v,v\rangle\, \mathrm{mc}(k)$ is integrable on $\mathrm{G}(-1_b)$ with the product of the measures of $G_\infty(-1_b)$ and $G_f(b)$. Here $\langle v,v\rangle > 0$ ($P^\circ \ne 0$, so v_{P° is a nonzero continuous function) and $V_S > 0$, so mc is integrable on $G_f(b)$ (Fubini, $0 < \mathrm{vol}(G_\infty(-1_b)) < \infty$), and (2) there gives

$$\langle \varphi^\circ, \varphi^\circ\rangle_T = \mathrm{vol}([\mathrm{U}(T)])\, V_S\, \langle v,v\rangle\, \mathrm{vol}(G_\infty(-1_b)) \int_{G_f(b)} \mathrm{mc}(k)\,dk.$$

Step 4: the finite integral is not zero. With Σ all finite places of F, the group K_Σ of Proposition 6.5.4 is $\mathbf{K}_0(b)$; let u_q be representatives of $G_f(b)/\mathbf{K}_0(b)$. By (1) there, $\sum_q |\mathrm{mc}(u_q)| < \infty$; as mc is right $\mathbf{K}_0(b)$-invariant and $\mathbf{K}_0(b)$ has mass 1, $\int_{G_f(b)} \mathrm{mc} = \sum_q \mathrm{mc}(u_q)$. The hypothesis of (2), (3) there holds for $\beta = 1$, and the Rallis series of $\mathbf{1}$ is the constant $\sum_q \mathrm{mc}(u_q)$. By (3), $R_\Sigma \mathbf{1} = 0$ would give $\mathbf{1} = 0$; so $\sum_q \mathrm{mc}(u_q) \ne 0$.

As $\mathrm{vol}([\mathrm{U}(T)]) > 0$, Steps 3 and 4 give $\langle \varphi^\circ, \varphi^\circ\rangle_T \ne 0$, so $\varphi^\circ \ne 0$. □

Lemma 6.6.65. *Let p, q and n' be finite index sets, $n = p \sqcup q$ with the signs $s = +1$ on p and $s = -1$ on q, $i\colon p \to n'$ an injective map and $d \in \mathbb{N}$. Let S, T be spaces with points with signs s on n and $+1$ on n', so that $\mathcal{F}_{S,T} = \mathcal{F}_\varepsilon$ with $\iota = \Phi \times n' \times n$ and $\varepsilon(v,a,b) = s(b)$, and put*

$$Q_d = \prod_{v\in\Phi} \det\bigl((X_{v,i(a),b})_{a,b\in p}\bigr)^d \in \mathbb{C}[X_\iota].$$

Then $Q_d \neq 0$, and for every order o on n that is positive-first for s and every bounded linear functional ℓ on $\mathcal{F}_{S,T}$ the function $x \mapsto \ell(\Omega_{0,0}(x,1)\, v_{Q_d})$ on $G_\infty(s)$ is holomorphic of weight u_d for o, where $u_d(v)(b) = -d$ for $b \in p$ and $u_d(v)(b) = \#n'$ for $b \in q$ ($v \in \Phi$).

Proof. Fix $v \in \Phi$ and write $X_{ac} = X_{v,a,c}$ ($a \in n'$, $c \in n$), $D = \det\bigl((X_{i(a),b})_{a,b\in p}\bigr)$ and $P = D^d$, so that $Q_d = \prod_v P(X_{v,\cdot,\cdot})$. The variable X_{ac} has the sign $s(c)$ for the signs $(s, \mathbf{1}_{n'})$ of (HV5); P involves only variables X_{ac} with $c \in p$ and $a \in i(p)$, all of sign $+1$.

$Q_d \neq 0$. As i is injective, the monomial $\prod_{a\in p} X_{i(a),a}$ occurs in D with coefficient 1, so $D \neq 0$ ($D = 1$ if $p = \emptyset$); the polynomial ring is an integral domain, so $Q_d \neq 0$.

P is termwise harmonic. The rows all have sign $+1$, so the first condition of (HV6) is empty; in the second, one of c, c' lies in q, and P does not involve the variables of that column, so the mixed derivative vanishes.

Column units, shifts $(0,0)$. By (HV5), $E^{\mathrm{col}}_{cc'} = -\sum_{a\in n'} \mathrm{lo}_{ac}\,\mathrm{ra}_{ac'} + \#n'\,\delta_{cc'}$. For $c, c' \in p$ the variables have sign $+1$, $\mathrm{lo}_{ac}\mathrm{ra}_{ac'} = \partial_{ac}X_{ac'} = X_{ac'}\partial_{ac} + \delta_{cc'}$, and so $E^{\mathrm{col}}_{cc'} = -\sum_a X_{ac'}\partial_{ac}$. By Laplace expansion along the column c, $\sum_a X_{ac'}\partial D/\partial X_{ac}$ is the determinant obtained from D by replacing the column c by the column c': it is D for $c' = c$ and 0 for $c' \neq c$ (two equal columns). Hence $E^{\mathrm{col}}_{cc}P = -dP$ and $E^{\mathrm{col}}_{cc'}P = dD^{d-1}\cdot 0 = 0$ for $c \neq c'$ in p. For $c, c' \in q$ the variables have sign -1, $\mathrm{lo}_{ac}\mathrm{ra}_{ac'} = -X_{ac}\partial_{ac'}$ and $\partial_{ac'}P = 0$, so $E^{\mathrm{col}}_{cc'}P = \#n'\,\delta_{cc'}P$. Thus P is K-highest of weight $u_d(v)$ (equal to $-d$ on p and $\#n'$ on q) for $-o$: every $E^{\mathrm{col}}_{cc'}$ with $c \neq c'$ of the same sign kills P.

Row units, shift 0. Let $l'\colon n' \to \mathbb{Z}$ be 1 on $i(p)$ and 0 elsewhere. By (HV5), $E^{\mathrm{row}}_{aa'} = \sum_{c\in p} X_{ac}\partial_{a'c} - \sum_{c\in q}\partial_{ac}X_{a'c}$. The second sum acts on P as $-\#q\,\delta_{aa'}$. By Laplace expansion along the row a', $\sum_{c\in p} X_{ac}\partial D/\partial X_{a'c}$ is 0 if $a' \notin i(p)$, and otherwise the determinant obtained by replacing the row a' by the row a: D for $a = a'$ and 0 for $a \neq a'$ in $i(p)$. Hence $E^{\mathrm{row}}_{aa}P = \nu(a)P$ with $\nu(a) = d\,[a \in i(p)] - \#q$, and $E^{\mathrm{row}}_{aa'}P \neq 0$ with $a \neq a'$ is possible only for $a' \in i(p)$, $a \notin i(p)$, where $l'(a') = 1 > 0 = l'(a)$. So $E^{\mathrm{row}}_{aa'}P = 0$ whenever $l'(a') < l'(a)$: P is K-highest of weight ν for l'.

Conclusion. P is jointly highest of weights $(\nu, u_d(v))$ for $(l', -o)$, for the row and column units of the signs $(s, \mathbf{1}_{n'})$ with the shifts $(0,0)$. With $l_v = o$ (so $l_v(a) < l_v(b)$ whenever $o(a) < o(b)$), $\gamma = e = 0$ and $P_v = P$ for every v, Lemma 6.6.47 shows that $x \mapsto \ell(\Omega_{0,0}(x,1)v_{Q_d})$ is holomorphic of weight u_d for o, for every bounded linear functional ℓ on $\mathcal{F}_{S,T}$. □

Lemma 6.6.66. *Let $1 \le j \le m$, $n_* = 2ft^3$, $\tilde{W}_j$ the padded space of the j-th lift, with signs $\tilde{s}_j$ on $\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+$, and for $\tau \in \Phi$ let $d_j(\tau) = \#D_j(\tau)$ and $\gamma'_j(\tau) = m - d_j(\tau)$. On $\mathcal{B}^{\mathrm{c}}$ let u_1, $u_2(\tau)$, $u_3(\tau)$ be the weights with the values, on the first and on the second block,*

$$u_1 = (-\Delta';\ 6m+1), \qquad u_2(\tau) = (\Delta';\ d_j(\tau) + r + 2m), \qquad u_3(\tau) = (0;\ d_j(\tau) + |\mathcal{B}_j| + 2m),$$

and write u_i also for the families $(u_i(\tau))_{\tau\in\Phi}$ ($u_1(\tau) = u_1$). For $\gamma\colon \Phi \to \mathbb{Z}$, $h \in G_\infty(s^{\mathrm{c}})$ and $h' \in G_\infty(\tilde{s}_j)$ put

$$c_\gamma(h,h') = \bigl\langle v_{P_j},\, \Omega_{\gamma,\gamma'_j}(h,h')\, v_{P_j}\bigr\rangle,$$

in the Fock model of $\mathrm{Hom}(S^{\mathrm{c}}, \tilde{W}_j)$. *Then:*

(a) the carrier character $\nu_j^\flat \upsilon^m$ has weight γ'_j and trivial tame part;

(b) for every γ and every $h \in G_\infty(s^{\mathrm{c}})$,

$$c_\gamma(h,1) = c_\gamma(1,1)\, m^{\mathrm{hol}}_{s^{\mathrm{c}},u_2}(h)\, \overline{m^{\mathrm{hol}}_{s^{\mathrm{c}},u_3}(h)};$$

(c) for every order o on $\mathcal{B}^{\mathrm{c}}$ and every $\tau \in \Phi$, the weights u_1 and $u_3(\tau)$ are K-dominant for (s^{c}, o) and have holomorphic gap $300n_*$ for s^{c}, and $|u_3(\tau)(b')| \le 5b$ for all $b' \in \mathcal{B}^{\mathrm{c}}$;

(d) P_j is homogeneous of a degree at most $b^{3/2}$.

Proof. Fix $\tau \in \Phi$ where it is not displayed and write $\varsigma = \varsigma_\tau$, $\kappa^+(h) = \kappa^+_O(\tau, h)$. By Lemma 4.2.67, $x \ge e^{6.4\cdot 10^{15}}$, $x^{10^{12}} \le b$, $m \le 2\sqrt{x}$, $x^5 \le r \le 3x^5$, $t \le 15x^5$, $r^8 \le 3^8 x^{40}$ and $f \le x^{12}$; in particular $k = r+1-m \ge 2$ and $r \ge 2(11m+2)$. As t is odd and k even, $e_j = j + \frac{t+k-1}{2}$ and $\Delta' = r^8 - \frac{t+1}{2}$ are integers, and $\Delta' \ge 0$.

Step 1: the determinant index. We show $d_j(\tau) = \kappa_j(\tau) - e_j$. By Definition 3.2.16, $\varsigma(i) = \frac{k}{2} - 1 - i$ for $0 \le i \le k-2$ and $\varsigma(k-2+j') = \frac{\Delta}{2} - \kappa_{j'}(\tau)$ for $1 \le j' \le m$; this sequence is strictly decreasing, since $\frac{\Delta}{2} - \kappa_1(\tau) = -\kappa(\tau) - \Delta < 1 - \frac{k}{2}$ and $\kappa_{j'}$ increases with j'. For $1 \le h \le r_+ - 1 = k + j - 2$ we have $\varsigma(h) \ge \varsigma(k+j-2) = \frac{\Delta}{2} - \kappa_j(\tau) \ge \frac{t-1}{2} - \kappa_j(\tau)$ (as $r^8 \ge \frac{t-1}{2}$), so by (LF4) $\kappa^+(h) = (\varsigma(h-1) - \varsigma(h) - 1)^+$. The difference $\varsigma(h-1) - \varsigma(h) - 1$ is 0 for $1 \le h \le k-2$, equals $\kappa_1(\tau) - \frac{\Delta}{2} - \frac{k}{2} = \kappa(\tau) + \Delta - \frac{k}{2} \ge 0$ for $h = k-1$, and equals $\kappa_{j'}(\tau) - \kappa_{j'-1}(\tau) - 1 = \Delta - 1 \ge 0$ for $h = k-2+j'$, $2 \le j' \le j$. So all terms are nonnegative and the sum telescopes:

$$\sum_{h=1}^{r_+-1} \kappa^+(h) = \varsigma(0) - \varsigma(k+j-2) - (k+j-2) = \kappa_j(\tau) - \tfrac{\Delta}{2} - \tfrac{k}{2} - j + 1.$$

As $D_j(\tau)$ is the disjoint union of these column sets and $\{1, \dots, \Delta'\}$, $d_j(\tau) = \kappa_j(\tau) - \frac{\Delta}{2} - \frac{k}{2} - j + 1 + \frac{\Delta}{2} - \frac{t+1}{2} = \kappa_j(\tau) - e_j$. In particular $d_j(\tau) \ge \Delta'$.

(a). By the defining formula of Definition 3.1.1, a product of characters with weights w, w' and tame parts ψ, ψ' has weight $w + w'$ and tame part $\psi\psi'$, and an integer power of a character with trivial tame part has trivial tame part. So $\nu_j^\flat \upsilon^m = \mu^\flat \upsilon^{m+e_j - j\Delta}$ has trivial tame part and weight $-\kappa_0(\tau) + m + e_j - j\Delta = m + e_j - \kappa_j(\tau) = m - d_j(\tau) = \gamma'_j(\tau)$, as $\kappa_j - \kappa_0 = j\Delta$.

(b). The rows $\mathrm{ng}_j(i)$ $(1 \le i \le m)$ are distinct and have sign -1 in the padded space (the elements of $\mathcal{A}_j^-$, and the basis vectors of W_j of numbers $k + i - 2 \ge k + j - 1$); the rows $\mathrm{ps}_j(h,a)$ $(1 \le a \le 2m)$ are distinct for fixed h and have sign $+1$ (basis vectors of numbers $h + a - 1 < r_+$, or elements of $\mathcal{A}_j^+$). The columns $(2, i')$ have sign -1 and $(1, a')$ sign $+1$. So every variable of P_j has sign $+1$, the padded space has $r_- = (m-j) + j = m$ negative indices, and $\#(\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+) = r + 3m$. For $u \in G_\infty(s^{\mathrm{c}})$ the substitution of Lemma 6.6.67 replaces y_τ^- by $y_\tau^-(u_\tau^-)^{\mathsf{T}}$, u_τ^- the block of u_τ on the second block (all m columns of sign -1 occur), and $y_{\tau,h}$ by $y_{\tau,h}(u_\tau^+)^{\mathsf{T}}$; so it multiplies P_j by $\prod_\tau \Delta_{n_+}(u_\tau)^{\nu(\tau)} \Delta_{n_-}(u_\tau)^{c(\tau)}$ with $\nu(\tau) = \sum_h \kappa^+(h)$ and $c(\tau) = d_j(\tau) + |\mathcal{B}_j| + m$. Lemma 6.6.67 with $e = \gamma'_j$ gives (b) with the weights $w_1(\tau) = (-\nu(\tau) + m - m + d_j(\tau);\ r + 3m - m + d_j(\tau)) = (\Delta';\ d_j(\tau) + r + 2m) = u_2(\tau)$ (Step 1: $d_j - \nu = \Delta'$) and $w_2(\tau) = (0;\ d_j(\tau) + |\mathcal{B}_j| + 2m) = u_3(\tau)$, and $\langle v_{P_j}, v_{P_j} \rangle = c_\gamma(1,1)$.

(c). u_1 and $u_3(\tau)$ are constant on each sign block, hence K-dominant for (s^{c}, o) for every order o. We have $300n_* + \frac{t+1}{2} \le 600x^{12}(15x^5)^3 + 8x^5 \le x^{40} \le r^8$, i.e. $300n_* \le \Delta'$. Hence u_1 has holomorphic gap $300n_*$ ($-\Delta' + 300n_* \le 0 < 6m+1$), and so has $u_3(\tau)$ ($300n_* \le \Delta' \le d_j(\tau)$). For the bound, $e_j \ge \frac{t-1}{2} \ge r + 11m + 1$, so by Step 1 $0 \le d_j(\tau) + |\mathcal{B}_j| + 2m = \kappa_j(\tau) - e_j + r + 11m + 1 \le \kappa_j(\tau)$; and $\kappa(\tau) \le b$ (as $a/x_1 = xb/x_1 \le b$), so $\kappa_j(\tau) \le b + (2m+1)r^8 \le b + 5\sqrt{x}\cdot 3^8 x^{40} \le 2b \le 5b$.

(d). $\det(y_\tau^-)$ and $\det(y_{\tau,h})$ are homogeneous of degrees m and $2m$, so P_j is homogeneous of degree $\sum_\tau (m\,c(\tau)+2m\,\nu(\tau)) \le \sum_\tau 3m(d_j(\tau)+|\mathcal{B}_j|+2m) \le 3fm\cdot 2b \le 12x^{25/2}b \le b^{3/2}$, using $\nu(\tau)\le d_j(\tau)$, (c) and $x^{25}\le b/144$. □

Lemma 6.6.67. *Let S, T be spaces with points with signs s on a nonempty index set n and s' on n', $n_\pm = \{i\in n : s(i)=\pm1\}$ and $r_- = \#\{a\in n' : s'(a)=-1\}$. Let P be a polynomial in the variables $X_{v,a,k}$ ($v\in\Phi$, $a\in n'$, $k\in n$) that involves only variables of sign $s'(a)s(k)=+1$. Let $\nu, c\colon \Phi\to\mathbb{N}$ and suppose that for every $u\in G_\infty(s)$ the substitution*

$$X_{v,a,k} \longmapsto \sum_{k'\in n:\ s(k')=s(k)} (u_v)_{k,k'}\, X_{v,a,k'} \qquad (s'(a)s(k)=+1)$$

multiplies P by $\prod_{v\in\Phi} \Delta_{n_+}(u_v)^{\nu(v)}\,\Delta_{n_-}(u_v)^{c(v)}$. Let $\gamma, e\colon \Phi\to\mathbb{Z}$ and let w_1, w_2 be the families of weights on n with

$$w_1(v)(i) = \begin{cases} -\nu(v)+r_- - e(v) & s(i)=+1,\\ \#n' - e(v) & s(i)=-1,\end{cases} \qquad w_2(v)(i) = \begin{cases} 0 & s(i)=+1,\\ c(v)+r_- & s(i)=-1.\end{cases}$$

Then for every $u\in G_\infty(s)$

$$\langle v_P, \Omega_{\gamma,e}(u,1)\,v_P\rangle = \langle v_P, v_P\rangle\; m^{\mathrm{hol}}_{s,w_1}(u)\,\overline{m^{\mathrm{hol}}_{s,w_2}(u)}.$$

Proof. For signs ε on a finite set ι put $\iota_\pm = \{i\in\iota : \varepsilon_i=\pm1\}$, write $x=(x_+,x_-)$ for $x\in\mathbb{C}^\iota$, $\mathrm{pr}_\pm = \frac12(1\pm\operatorname{diag}\varepsilon)$, and for a matrix g on ι let $g_{++},g_{+-},g_{-+},g_{--}$ be its blocks (rows first) and $\mathrm{bd}(g)$ the block-diagonal matrix with blocks g_{++},g_{--}. For a polynomial P in the variables X_i ($i\in\iota_+$) and an $\iota_+\times\iota_+$ matrix M let P^M be the polynomial $X\mapsto P(M^{\mathsf T}X)$, i.e. P after the substitution $X_i\mapsto\sum_{k\in\iota_+} M_{ki}X_k$; then $(P^M)^N = P^{NM}$. If P involves only these variables, $v_P(x) = P(\bar x_+)\,e^{-|x|^2/2}$.

Step 1: block identities in $\mathrm{U}(\operatorname{diag}\varepsilon)$. Let $g\in\mathrm{U}(\operatorname{diag}\varepsilon)$. From $g^*\operatorname{diag}(\varepsilon)g=\operatorname{diag}(\varepsilon)$ we get $g^{-1}=\operatorname{diag}(\varepsilon)g^*\operatorname{diag}(\varepsilon)$, hence $g\operatorname{diag}(\varepsilon)g^*=\operatorname{diag}(\varepsilon)$, $(g^{-1})_{++}=g^*_{++}$, $(g^{-1})_{--}=g^*_{--}$, and $|\det g|=1$. The blocks of $g^*\operatorname{diag}(\varepsilon)g=\operatorname{diag}(\varepsilon)$ on $\iota_-\times\iota_-$ and on $\iota_+\times\iota_+$ read

$$g^*_{--}g_{--} = 1+g^*_{+-}g_{+-}, \qquad g^*_{++}g_{++} = 1+g^*_{-+}g_{-+},$$

so g_{--} and g_{++} are invertible, and $Z=g_{+-}g_{--}^{-1}$ satisfies $Z^*Z = 1-(g_{--}g^*_{--})^{-1}$, so its operator norm is <1. Jacobi's theorem on complementary minors, $\det((g^{-1})_{--}) = \det(g_{++})/\det g$, gives

$$\overline{\det g_{--}} = \det(g_{++})/\det(g), \tag{6.153}$$

and the Schur complement formula, $(g^{-1})_{++} = (g_{++}-g_{+-}g_{--}^{-1}g_{-+})^{-1}$, gives $g_{++}-Zg_{-+}=M$ with $M=(g^*_{++})^{-1}$. Applied to $u_v\in\mathrm{U}(\operatorname{diag}s)$ (signs s on n), the same identities give $\Delta_{n_\pm}(u_v)\neq0$, $|\det u_v|=1$ and, from $(u_v^{-1})_{n_+n_+} = (u_v)^*_{n_+n_+}$ and Jacobi,

$$\overline{\Delta_{n_+}(u_v)} = \Delta_{n_-}(u_v)/\det(u_v). \tag{6.154}$$

Step 2: the Gaussian matrix. Let $H=\frac12(1+g^*g)$, a positive definite hermitian matrix. Since $(g\operatorname{diag}(\varepsilon)+\operatorname{diag}(\varepsilon)\,g)_{ij} = (\varepsilon_i+\varepsilon_j)g_{ij}$, we have $g\operatorname{diag}(\varepsilon)+\operatorname{diag}(\varepsilon)\,g = 2\operatorname{diag}(\varepsilon)\operatorname{bd}(g)$, and with $g^*=\operatorname{diag}(\varepsilon)g^{-1}\operatorname{diag}(\varepsilon)$,

$$1+g^*g = \operatorname{diag}(\varepsilon)g^{-1}\big(g\operatorname{diag}(\varepsilon)+\operatorname{diag}(\varepsilon)\,g\big) = 2\operatorname{diag}(\varepsilon)g^{-1}\operatorname{diag}(\varepsilon)\operatorname{bd}(g).$$

Hence $\det H = \det(g_{++})\det(g_{--})/\det g = |\det g_{--}|^2$ by (6.153), $H^{-1} = \mathrm{bd}(g)^{-1}\mathrm{diag}(\varepsilon)\, g\, \mathrm{diag}(\varepsilon)$, and, by $g\,\mathrm{diag}(\varepsilon)g^* = \mathrm{diag}(\varepsilon)$,

$$gH^{-1}g^* = g\,\mathrm{bd}(g)^{-1},$$

whose block on $\iota_+ \times \iota_-$ is Z. For $y = (y_+, 0)$ one computes $\mathrm{diag}(\varepsilon)y = y$, $\mathrm{diag}(\varepsilon)gy = (g_{++}y_+, -g_{-+}y_+)$, $\mathrm{bd}(g)^{-1}$ of this is $(y_+, -g_{--}^{-1}g_{-+}y_+)$, and g of this is $\big((g_{++} - Zg_{-+})y_+, 0\big) = (My_+, 0)$; so gH^{-1} maps $(y_+, 0)$ to $(My_+, 0)$.

Step 3: Gaussian integrals. Let H be positive definite hermitian on $\mathbb{C}^\iota$, $u, w \in \mathbb{C}^\iota$ and R a polynomial in the X_i, $i \in \iota_+$. Then

$$\int R(\bar y_+)\, \exp(-y^*Hy + u^{\mathsf T}y + y^*w)\, d\nu_\iota(y) = \det(H)^{-1}\, R(\lambda_+)\, \exp(u^{\mathsf T}H^{-1}w), \qquad \lambda^{\mathsf T} = u^{\mathsf T}H^{-1}. \tag{6.155}$$

Indeed, the integrand of $I(u,w) = \int \exp(-y^*Hy + u^{\mathsf T}y + y^*w)\, d\nu_\iota(y)$ is bounded by $\exp(-h|y|^2 + (|u|+|w|)|y|)$, $h > 0$ the least eigenvalue of H, so I is entire in (u,w) and may be differentiated under the integral sign. For $u = \bar w$ the substitution $y = z + H^{-1}w$ turns the exponent into $-z^*Hz + w^*H^{-1}w$, and $\int \exp(-z^*Hz)\, d\nu_\iota(z) = \det(H)^{-1}$ (diagonalise H by a unitary matrix, which preserves ν_ι, and use $\pi^{-1}\int_{\mathbb{C}} e^{-h|z|^2}\, dz = h^{-1}$); so $I(u,w) = \det(H)^{-1}\exp(u^{\mathsf T}H^{-1}w)$ on the totally real subspace $u = \bar w$ of maximal dimension, hence everywhere. As $\partial_{w_i}\exp(y^*w) = \bar y_i \exp(y^*w)$, the left side of (6.155) is $R(\partial_{w_+})I(u,w)$, and $R(\partial_{w_+})\exp(u^{\mathsf T}H^{-1}w) = R(\lambda_+)\exp(u^{\mathsf T}H^{-1}w)$.

Step 4: the Fock coefficient. Let $g \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$ and P a polynomial in the X_i, $i \in \iota_+$. We show

$$\langle v_P, \omega_\varepsilon^\infty(g)v_P\rangle = \det(g_{--})^{-1}\,\langle v_P, v_{P^M}\rangle, \qquad M = (g_{++}^*)^{-1}. \tag{6.156}$$

By the definitions of β_ε^∞ and e^∞,

$$-\tfrac12|y|^2 + \tfrac12(x^*\mathrm{diag}(\varepsilon)gy - y^*g^*\mathrm{diag}(\varepsilon)x) - \tfrac12|x - gy|^2 = -\tfrac12|x|^2 - y^*Hy + x^*\mathrm{pr}_+gy + y^*g^*\mathrm{pr}_-x,$$

so the integral defining $(\omega_\varepsilon^\infty(g)v_P)(x)$ is (6.155) with $R = P$, $u^{\mathsf T} = x^*\mathrm{pr}_+g$, $w = g^*\mathrm{pr}_-x$, times $\overline{\det g_{--}}\, e^{-|x|^2/2}$. By Step 2, $u^{\mathsf T}H^{-1}w = x^*\mathrm{pr}_+(gH^{-1}g^*)\mathrm{pr}_-x = \bar x_+^{\mathsf T}Zx_-$, and for $i \in \iota_+$, $\lambda_i = x^*\mathrm{pr}_+gH^{-1}e_i = \sum_{k\in\iota_+}\bar x_k M_{ki}$, so $P(\lambda_+) = P^M(\bar x_+)$. With $\overline{\det g_{--}}/\det H = \det(g_{--})^{-1}$ (Step 2):

$$(\omega_\varepsilon^\infty(g)v_P)(x) = \det(g_{--})^{-1}\, P^M(\bar x_+)\, \exp(\bar x_+^{\mathsf T}Zx_-)\, e^{-|x|^2/2}.$$

Multiply by $\overline{v_P(x)} = \overline{P(\bar x_+)}e^{-|x|^2/2}$. As $|\bar x_+^{\mathsf T}Zx_-| \le \|Z\||x_+||x_-| \le \frac12\|Z\||x|^2$ and $\|Z\| < 1$ (Step 1), the product is bounded by a polynomial times $\exp(-\frac12|x|^2)$, hence ν_ι-integrable, and Fubini over $\nu_\iota = \nu_{\iota_+}\otimes\nu_{\iota_-}$ applies. For fixed x_+, (6.155) on $\mathbb{C}^{\iota_-}$ with $H = 1$, $R = 1$, $u = Z^{\mathsf T}\bar x_+$, $w = 0$ gives $\int \exp(\bar x_+^{\mathsf T}Zx_-)e^{-|x_-|^2}\, d\nu_{\iota_-}(x_-) = 1$, and with $u = 0$ also $\int e^{-|x_-|^2}\, d\nu_{\iota_-} = 1$. So both sides of (6.156) equal $\det(g_{--})^{-1}\int \overline{P(\bar x_+)}\, P^M(\bar x_+)\, e^{-|x_+|^2}\, d\nu_{\iota_+}(x_+)$.

Step 5: the pair. Now $\iota = \Phi \times n' \times n$ and $\varepsilon(v,a,k) = s'(a)s(k)$. Fix $u \in G_\infty(s)$ and let $g = \bigoplus_{v\in\Phi} 1 \otimes (u_v^{-1})^{\mathsf T}$, the map $X \mapsto Xu_v^{-1}$ at each place; it lies in $\mathrm{U}(\mathrm{diag}\,\varepsilon)$ by (VP5) of Definition 3.2.2, and

$$g_{(v,a,k),(v',a',k')} = \delta_{vv'}\delta_{aa'}\,(u_v^{-1})_{k'k}.$$

By (WR5), $\Omega_{\gamma,e}(u,1) = \prod_{v\in\Phi}\det(u_v)^{-e(v)}\,\omega_\varepsilon^\infty(g)$. The block g_{++} lives on the (v,a,k) with $s(k) = s'(a)$; for such k,k' the relation $u_v^{-1} = \mathrm{diag}(s)u_v^*\mathrm{diag}(s)$ gives $\overline{(u_v^{-1})_{kk'}} = (u_v)_{k'k}$, so $(g_{++}^*)_{(v,a,k'),(v,a,k)} = (u_v)_{kk'}$ and the substitution $X \mapsto g_{++}^{\mathsf T}X$ is exactly the substitution of the statement. By hypothesis, $P^{g_{++}^*} = \chi(u)P$ with $\chi(u) = \prod_v \Delta_{n_+}(u_v)^{\nu(v)}\Delta_{n_-}(u_v)^{c(v)} \neq 0$ (Step 1). Applying $(\cdot)^M$ with $M = (g_{++}^*)^{-1}$ gives $P = (P^{g_{++}^*})^M = \chi(u)P^M$, so $P^M = \chi(u)^{-1}P$. The block g_{--} lives on the (v,a,k) with $s(k) = -s'(a)$ and is block diagonal over (v,a), the block

at (v,a) being the transpose of the principal block of u_v^{-1} on $n_{-s'(a)}$; by Jacobi's theorem its determinant is $\Delta_{n_{s'(a)}}(u_v)/\det(u_v)$. With $r_+ = \#n' - r_-$,

$$\det g_{--} = \prod_{v\in\Phi} \Big(\frac{\Delta_{n_+}(u_v)}{\det u_v}\Big)^{r_+} \Big(\frac{\Delta_{n_-}(u_v)}{\det u_v}\Big)^{r_-}.$$

By (6.156),

$$\langle v_P, \Omega_{\gamma,e}(u,1)v_P\rangle = \langle v_P, v_P\rangle \prod_{v\in\Phi} \det(u_v)^{\#n'-e(v)}\, \Delta_{n_+}(u_v)^{-\nu(v)-r_+}\, \Delta_{n_-}(u_v)^{-c(v)-r_-}. \quad (6.157)$$

Step 6: the model functions. Let w be a weight with the value a on n_+ and b on n_-, and $C = 2\sum_j |w(j)|$. If both n_+ and n_- are nonempty, $C \ge 2|a| + 2|b|$, so $a + C \ge b$, and (3.1) gives $m_{w+w^\sharp} = (\det)^b \Delta_{n_+}^{a+C-b}$ and $m_{w^\sharp} = \Delta_{n_+}^C$; if $n_- = \emptyset$, $m_{w+w^\sharp} = (\det)^{a+C}$ and $m_{w^\sharp} = (\det)^C$; if $n_+ = \emptyset$, $w^\sharp = 0$ and $m_w = (\det)^b$. In all cases, as $\Delta_{n_+} = \det$ if $n_- = \emptyset$ and $\Delta_\emptyset = 1$,

$$m^{\mathrm{hol}}_{s,w}(x) = \det(x)^b\, \Delta_{n_+}(x)^{a-b} \qquad (x \in \mathrm{U}(\mathrm{diag}\, s)).$$

For $w_1(v)$ ($a = -\nu(v) + r_- - e(v)$, $b = \#n' - e(v)$, $a - b = -\nu(v) - r_+$) this is

$$\det(u_v)^{\#n'-e(v)} \Delta_{n_+}(u_v)^{-\nu(v)-r_+}.$$

For $w_2(v)$ ($a = 0$, $b = c(v) + r_-$) it is

$$\det(u_v)^{c(v)+r_-} \Delta_{n_+}(u_v)^{-c(v)-r_-},$$

whose conjugate is $\Delta_{n_-}(u_v)^{-c(v)-r_-}$ by $\overline{\det u_v} = \det(u_v)^{-1}$ and (6.154). The product over $v \in \Phi$ of these two factors is the product in (6.157), which proves the lemma. □

Lemma 6.6.68. *Let D be admissible data and $n_* = 2ft^3$. Let n be a nonempty finite index set with $\#n \le t$, s signs on n, o a positive-first order for s, and $u = (u_v)_{v\in\Phi}$, $u' = (u'_v)_{v\in\Phi}$ weights such that every u_v and every u'_v is K-dominant for (s,o) and has holomorphic gap $300n_*$ for s, and $|u_v(i)| \le 5b$ for all v, i. For $h \in G_\infty(s)$ let $|h| = \max_{v\in\Phi} \|h_v\|$ (operator norms). Then $|h| \ge 1$ for every h, and*

$$0 < I := \int_{G_\infty(s)} |m^{\mathrm{hol}}_{s,u}|^2 < \infty, \qquad \int_{G_\infty(s)} |m^{\mathrm{hol}}_{s,u'}(h)|\, |h|^{6n_*}\, dh \le b^{n_*} I.$$

Proof. Write $N = \#n$.

Step 0: numbers. $f \ge 1$ and $N \le t$, so $n_* \ge 2N^3$. By Definition 2.3.3 and (AD1), $\log\log b \ge 6 \cdot 10^{12}$, so $b \ge 2^{40}$, and $\log b \ge 10^{12} \log x$; by (AD2) $t \le 15x^5$, so $2t + 1 \le 31x^5 \le b$; and $\log x \ge 100 \log\log b > 0$, so the integer x is at least 2, $r \ge x^5 \ge 32$ and $t = 5r \ge 160$. Put $L = 10b + N$ and $T = 8\big(2000(N + L + 1)^6\big)^{2N^2} 2^{10N^3}$. As $N + L + 1 \le 11b$ and $2000 \cdot 11^6 \le b$, $T \le 2^{3+10t^3} b^{14t^2}$, and

$$2^{6n_*} T^f \le 2^{12ft^3+3f+10ft^3} b^{14ft^2} \le 2^{25ft^3} b^{14ft^2} \le b^{ft^3} b^{ft^3} = b^{n_*} \quad (6.158)$$

($b \ge 2^{25}$, $t \ge 14$).

Step 1: the model functions as discrete series coefficients. Let w be one of the weights u_v, u'_v, and $l = 2w + 2\rho$ as in Lemma 6.6.69. As $300n_* > 500N^3 + 8n_* + N + 1$ (by $n_* \ge 2N^3$), Lemma 6.6.69 with $A = 8n_*$ and $\gamma = 300n_*$ gives: l has large gap $8n_*$, i.e. gap

$500N^3 + 8n_*$, and $c_{l/2} = m^{\mathrm{hol}}_{s,w}$ on $\mathrm{U}(\mathrm{diag}\, s)$. By (1) of Lemma 5.7.38, $|m^{\mathrm{hol}}_{s,w}(g)| \le (2/\|g\|)^c$ for $0 \le c \le 500N^3+8n_*$. For $w = u_v$, $|l_i| \le 10b+N = L$ ($|2\rho(i)| \le N-1$), and $10N^3 > 8N^2$, so (3) of Lemma 5.7.38 gives $d_v := d_{l/2} > 0$ and $\int d_v(2/\|g\|)^{10N^3} dg \le T$. Hence $|m^{\mathrm{hol}}_{s,u_v}|^2$ is integrable with integral d_v^{-1}, and by Tonelli over the factors of $G_\infty(s)$, $I = \prod_v d_v^{-1} \in (0,\infty)$.

Step 2: the second integral. For $h \in G_\infty(s)$ choose $a \in \Phi$ with $\|h_a\| = |h|$, and use $c = 10N^3+6n_*$ at a and $c = 10N^3$ at the other places for the factors of $m^{\mathrm{hol}}_{s,u'}$: $|m^{\mathrm{hol}}_{s,u'}(h)|\,|h|^{6n_*} \le 2^{6n_*}\prod_v (2/\|h_v\|)^{10N^3}$. So, by Tonelli and (6.158),

$$\int_{G_\infty(s)} |m^{\mathrm{hol}}_{s,u'}(h)|\,|h|^{6n_*} dh \le 2^{6n_*}\prod_v \Big(d_v^{-1}\int d_v(2/\|g\|)^{10N^3} dg\Big) \le 2^{6n_*}T^f I \le b^{n_*} I.$$

Finally every $h \in G_\infty(s)$ has $|h| \ge 1$: $h_v^{-1} = \mathrm{diag}(s) h_v^* \mathrm{diag}(s)$ has the norm of h_v, and $1 \le \|h_v\|\|h_v^{-1}\| = \|h_v\|^2$. □

Lemma 6.6.69. *Let n be a nonempty finite index set, $N = \#n$, s signs on n, o a positive-first order for s, $A \in \mathbb{N}$, and w a weight that is K-dominant for (s,o) and has holomorphic gap γ for s, where $\gamma > 500N^3 + A + N + 1$. Let $2\rho(a) = \#\{j : o(a) < o(j)\} - \#\{j : o(j) < o(a)\}$ and $l = 2w + 2\rho$. Then:*

(a) l has large gap A for s;

(b) $c_{l/2}(g) = m^{\mathrm{hol}}_{s,w}(g)$ for every $g \in \mathrm{U}(\mathrm{diag}\, s)$.

Proof. **(a).** $l(a) = 2w(a) + N - 1 - 2r(a) \equiv N-1$ modulo 2. If $s(a) = s(b)$ and $o(a) < o(b)$, then $w(b) \le w(a)$ (K-dominance) and $r(b) > r(a)$, so $l(b) \le l(a) - 2$: along o, l strictly decreases within each sign block. If $s(a) = +1$, $s(b) = -1$ (so $o(a) < o(b)$), then $w(a) + \gamma \le w(b)$ and $r(b) - r(a) \le N-1$, so $l(b) - l(a) \ge 2\gamma - 2(N-1) \ge 2(500N^3 + A)$, as $\gamma - N \ge 500N^3 + A + 2$. Hence l is injective and has gap $500N^3 + A$, i.e. large gap A; and $l(a) < l(b)$ whenever $s(a) = +1$, $s(b) = -1$.

Step 1: $\mu_l = w$. By (a), $l_j < l_i$ holds exactly when either $s(j) = s(i)$ and $o(j) > o(i)$, or $s(j) = +1$, $s(i) = -1$. Counting, with $P = \#n_+$, $Q = \#n_-$: for $s(i) = +1$, $2\rho_l(i) = 2\rho_l^{\mathrm{c}}(i) - Q$ and $2\rho(i) = 2\rho_l^{\mathrm{c}}(i) + Q$; for $s(i) = -1$, $2\rho_l(i) = 2\rho_l^{\mathrm{c}}(i) + P$ and $2\rho(i) = 2\rho_l^{\mathrm{c}}(i) - P$. As the entries of l have the parity of $N-1$, (3) of Lemma 5.6.27 gives $2l^\rho = l + 2\rho_l$, so $2\mu_l(i) = l_i + 2\rho_l(i) - 2\cdot 2\rho_l^{\mathrm{c}}(i) = 2w(i) + 2\rho(i) + 2\rho_l(i) - 2\cdot 2\rho_l^{\mathrm{c}}(i) = 2w(i)$ in both cases.

Step 2: both sides are analytic on G. By (ii) of Lemma 5.6.24 (l has gap 0), $c_{l/2}$ is the restriction to G of holomorphic functions on open neighbourhoods in $\mathrm{GL}_n(\mathbb{C})$ of the points of G; $m_{w+w^\sharp}$ and $m_{w^\sharp}$ are polynomials in the entries and the inverse determinant, and $m_{w^\sharp}$ does not vanish on G ((HV2)); so the same holds for $m^{\mathrm{hol}}_{s,w}$. Hence both restrictions are real analytic on the connected real Lie group G, and by the identity theorem it suffices to show that they agree on a neighbourhood of 1 in G.

Step 3: a factorisation near 1. Write matrices in blocks for $n = n_+ \sqcup n_-$. For $g = \begin{pmatrix} A & B \\ C & D \end{pmatrix}$ near 1, A and $S = D - CA^{-1}B$ are invertible and

$$g = x'\,a\,x, \qquad x' = \begin{pmatrix} 1 & 0 \\ CA^{-1} & 1 \end{pmatrix}, \quad a = \begin{pmatrix} A & 0 \\ 0 & S \end{pmatrix}, \quad x = \begin{pmatrix} 1 & A^{-1}B \\ 0 & 1 \end{pmatrix};$$

for g near 1, g and a are accretive and the leading principal minors of A and S in the order o are nonzero, so (Gaussian elimination in each block) $a = c^* b$ with c, b block-diagonal and upper triangular in the order o inside each block, c with unit diagonal.

Step 4: $c_{l/2}(g) = b^w$. By (1) of Lemma 5.6.26 with the block-diagonal factor 1, $c_{l/2}(g) = \mathrm{FJ}_l(1, g)$, whose integrand at $k \in K_s$ has the denominator $m_{-l^\rho}(k^*gk)$. Put $X = k^*xk$ and $X' = k^*x'k$; k is block-diagonal, so $X - 1$ has nonzero entries only in rows n_+ and columns n_-, $X' - 1$ only in rows n_- and columns n_+, and $(X-1)^2 = (X'-1)^2 = 0$. Let ε' be the constant sign $+1$ on n, and B'_l the set of invertible matrices y with $y_{ij} = 0$ unless $l_i \geq l_j$ (the set B_l of Lemma 5.6.27 for ε'). Since $l_i < l_j$ for $i \in n_+$, $j \in n_-$, the matrices $X^{-*} = (2-X)^*$ and $X'^{-1} = 2 - X'$ lie in B'_l, with unit diagonals. By (1) and then (2) of Lemma 5.6.27 (for ε', with the weight l^ρ, which satisfies $l_i^\rho \geq l_j^\rho$ whenever $l_i > l_j$ by (3) there), for $y = k^*ak$,

$$m_{-l^\rho}(X'yX) = m_{l^\rho}(X^{-1}y^{-1}X'^{-1}) = \overline{(X^{-*})^{l^\rho}}\,(X'^{-1})^{l^\rho}\, m_{l^\rho}(y^{-1}) = m_{-l^\rho}(y).$$

As $k^*gk = X'(k^*ak)X$ and a is accretive, $\mathrm{FJ}_l(1, g) = \mathrm{FJ}_l(1, a)$. Now $a = c^* \cdot 1 \cdot b$ with b, c block-diagonal and $b_{ij} = c_{ij} = 0$ whenever $l_i < l_j$ (inside a block, $l_i < l_j$ means $o(i) > o(j)$), and 1 and a are accretive; by (3) of Lemma 5.6.26 and Step 1, $\mathrm{FJ}_l(1, a) = \overline{c^w}\, b^w\, \mathrm{FJ}_l(1, 1) = b^w$, since c has unit diagonal and $\mathrm{FJ}_l(1, 1) = \|m_{\mu_l}\|^{-2} \int |m_{\mu_l}(k)|^2 dk = 1$ ($m_v(1) = 1$).

Step 5: $m^{\mathrm{hol}}_{s,w}(g) = b^w$. Let $C = 2\sum_j |w(j)|$. For ε' and the injective vector $-o$, the set B'_{-o} consists of the invertible matrices that are upper triangular in the order o; it contains x and x'^* (o lists n_+ first), both with unit diagonal. The weights $v = w + w^\sharp$ and $v = w^\sharp$ satisfy $v_i \geq v_j$ whenever $o(i) < o(j)$: within a block by K-dominance, and for $i \in n_+$, $j \in n_-$ because $w(j) - w(i) \leq C$. So (2) of Lemma 5.6.27 gives $m_v(x'ax) = m_v(a)$ for both, and $m^{\mathrm{hol}}_{s,w}(g) = m_{w+w^\sharp}(a)/m_{w^\sharp}(a)$. Next, for the signs s and l, b and c lie in B_l (block-diagonal, $b_{ij} \neq 0$ only if $o(i) \leq o(j)$, i.e. $l_i \geq l_j$), and $v = w + w^\sharp$, $v = w^\sharp$ satisfy $v_i \geq v_j$ whenever $s(i) = s(j)$ and $l_i > l_j$ ($w^\sharp$ is constant on each block); so (2) of Lemma 5.6.27 gives $m_v(a) = m_v(c^*b) = b^v$, and $m^{\mathrm{hol}}_{s,w}(g) = b^{w+w^\sharp}/b^{w^\sharp} = b^w$, the diagonal entries of b being nonzero. With Step 4, $c_{l/2} = m^{\mathrm{hol}}_{s,w}$ near 1 in G, and Step 2 concludes. □

Lemma 6.6.70. *Let n be a nonempty finite index set, s signs on n, o an order that is positive-first for s, and $u = (u_v)_{v\in\Phi}$ weights with u_v K-dominant for (s, o) for every v. Call a complex $n \times n$ matrix a o-*lower unipotent *if $a_{ii} = 1$ for all i and $a_{ij} = 0$ whenever $o(i) < o(j)$. Then:*

(i) $m^{\mathrm{hol}}_{s,u}$ is holomorphic of weight u for o, and $m^{\mathrm{hol}}_{s,u}(1) = 1$;

(ii) if $x \in G_\infty(s)$ and $x_v = a_v b_v$ for every v, with a_v o-lower unipotent and b_v o-triangular, then $m^{\mathrm{hol}}_{s,u}(x) = \prod_{v\in\Phi} b_v^{u_v}$;

(iii) if $d = (d_v)_{v\in\Phi}$ with every d_v diagonal with entries of modulus 1, then

$$m^{\mathrm{hol}}_{s,u}(dx) = \Big(\prod_v d_v^{u_v}\Big)\, m^{\mathrm{hol}}_{s,u}(x)$$

for every $x \in G_\infty(s)$.

Proof. Call a weight w *dominant for o* if $w(j) \leq w(i)$ whenever $o(i) < o(j)$, and a set $P \subseteq n$ an *initial segment* if $i \in P$ and $o(i') < o(i)$ imply $i' \in P$.

Step 1: minors of initial segments. Let P be an initial segment, y a complex $n \times n$ matrix, a o-lower unipotent, b o-triangular and d diagonal. For $i \in P$ and $k \notin P$ we have $o(i) < o(k)$, so $a_{ik} = 0$ and $b_{ki} = 0$. Hence $(ayb)_{P,P} = a_{P,P}\, y_{P,P}\, b_{P,P}$, where $a_{P,P}$ and $b_{P,P}$ are triangular for the order o on P, with diagonals 1 and $(b_{ii})_{i\in P}$, and

$$\Delta_P(ayb) = \Delta_P(y) \prod_{i\in P} b_{ii}, \qquad \Delta_P(dy) = \Delta_P(y) \prod_{i\in P} d_{ii}. \tag{6.159}$$

Step 2: the extension of m_w. Let w be dominant for o, $w_0 = \min w$, $w_1 = \max w$. For $w_0 < t \le w_1$ the set $P_t = \{i : w(i) \ge t\}$ is an initial segment (if $w(i) \ge t$ and $o(i') < o(i)$ then $w(i') \ge w(i)$). On the open set Ω_w of the $y \in \mathrm{GL}_n(\mathbb{C})$ put $\tilde m_w(y) = (\det y)^{w_0} \prod_{w_0 < t \le w_1} \Delta_{P_t}(y)$, a holomorphic function equal to m_w on $\mathrm{U}(\operatorname{diag} s)$ by (3.1). By (6.159) and $\det(ayb) = \det y \prod_i b_{ii}$, for $y \in \mathrm{GL}_n(\mathbb{C})$

$$\tilde m_w(ayb) = \tilde m_w(y) \prod_{i \in n} b_{ii}^{w_0 + \#\{t:\, w_0 < t \le w(i)\}} = \tilde m_w(y)\, b^w, \qquad \tilde m_w(dy) = d^w\, \tilde m_w(y) \ (d \text{ invertible}),$$

as $w_0 + \#\{t : w_0 < t \le w(i)\} = w(i)$.

Step 3: the weights $u_v + u_v^\sharp$ and $u_v^\sharp$ are dominant for o. Fix v, $w = u_v$ and $C = 2\sum_j |w(j)|$. Let $o(i) < o(j)$. If $s(i) = s(j)$, then $w(j) \le w(i)$ (K-dominance) and $w^\sharp(i) = w^\sharp(j)$. Otherwise $s(i) = +1$, $s(j) = -1$ (o is positive-first), so $w^\sharp(i) = C \ge 0 = w^\sharp(j)$ and $w(j) \le w(i) + C$. In both cases $w^\sharp(j) \le w^\sharp(i)$ and $(w + w^\sharp)(j) \le (w + w^\sharp)(i)$.

Step 4: (i). Put $\tilde F(y) = \prod_v \tilde m_{u_v + u_v^\sharp}(y_v) / \tilde m_{u_v^\sharp}(y_v)$ where all y_v are invertible and the denominators do not vanish, and $\tilde F = 0$ elsewhere on $\mathrm{M}_n(\mathbb{C})^\Phi$; it is holomorphic on the open set where the formula applies. Let $x \in G_\infty(s)$ and b a family of o-triangular matrices. By Step 2 (with $a = 1$), $\tilde m_{u_v^\sharp}(x_v b_v) = m_{u_v^\sharp}(x_v)\, b_v^{u_v^\sharp} \ne 0$ by (HV2) and $b_{v,ii} \ne 0$; so $\tilde F$ is complex analytic at xb and

$$\tilde F(xb) = \prod_v \frac{m_{u_v + u_v^\sharp}(x_v)\, b_v^{u_v + u_v^\sharp}}{m_{u_v^\sharp}(x_v)\, b_v^{u_v^\sharp}} = \Big(\prod_v b_v^{u_v}\Big) m_{s,u}^{\mathrm{hol}}(x).$$

So $m_{s,u}^{\mathrm{hol}}$ is holomorphic of weight u for o; and $m_w(1) = 1$ for every w by (3.1), so $m_{s,u}^{\mathrm{hol}}(1) = 1$.

Step 5: (ii) and (iii). In (ii), Step 2 with $y = 1$ gives $m_w(x_v) = \tilde m_w(a_v \cdot 1 \cdot b_v) = b_v^w$ for $w = u_v + u_v^\sharp$ and $w = u_v^\sharp$, hence $m_{s,u_v}^{\mathrm{hol}}(x_v) = b_v^{u_v + u_v^\sharp} / b_v^{u_v^\sharp} = b_v^{u_v}$. In (iii), $d_v x_v \in \mathrm{U}(\operatorname{diag} s)$ and Step 2 gives $m_w(d_v x_v) = d_v^w m_w(x_v)$, hence $m_{s,u_v}^{\mathrm{hol}}(d_v x_v) = d_v^{u_v} m_{s,u_v}^{\mathrm{hol}}(x_v)$; take the product over v. □

Lemma 6.6.71. *Let n be a nonempty finite index set, s signs on n, o a positive-first order for s, $u = (u_v)_{v \in \Phi}$ weights with every u_v K-dominant for (s, o), $m = m_{s,u}^{\mathrm{hol}}$, and let $F \colon G_\infty(s) \to \mathbb{C}$ be holomorphic of weight u for o with $F\,\overline{m}$ integrable on $G_\infty(s)$. Then $x \mapsto F(1)\,|m(x)|^2$ is integrable and*

$$\int_{G_\infty(s)} F(x)\, \overline{m(x)}\, dx = F(1) \int_{G_\infty(s)} |m(x)|^2\, dx.$$

Proof. Let $d(\theta)$ be as in Lemma 6.6.72 and $\chi(\theta) = \prod_{v,i} e^{2\pi \mathrm{i} \theta o(i) u_v(i)}$, of modulus 1. By (iii) of Lemma 6.6.70, $m(d(\theta)x) = \chi(\theta) m(x)$, so $\overline{m(d(\theta)x)} = \chi(\theta)^{-1} \overline{m(x)}$. The measure of $G_\infty(s)$ is invariant under left translation by $d(\theta) \in G_\infty(s)$ (Lemma 5.2.41 at every v). Let $f = F\overline{m}$ and $g(\theta, x) = f(d(\theta)x) = F(d(\theta)x)\chi(\theta)^{-1}\overline{m(x)}$, a continuous function on $\mathbb{R}/\mathbb{Z} \times G_\infty(s)$ (F is continuous, being the restriction of a function analytic at every point of $G_\infty(s)$, and m is continuous by (i) of Lemma 6.6.70). By the invariance, $\int |g(\theta, x)|\, dx = \int |f|$ for every θ, so g is integrable on the product (Tonelli) and, by Fubini and the invariance again,

$$\int_{G_\infty(s)} f\, dx = \int_{\mathbb{R}/\mathbb{Z}} \int_{G_\infty(s)} g(\theta, x)\, dx\, d\theta = \int_{G_\infty(s)} \overline{m(x)} \int_{\mathbb{R}/\mathbb{Z}} F(d(\theta)x) \chi(\theta)^{-1} d\theta\, dx.$$

By Lemma 6.6.72 the inner integral is $m(x)F(1)$; Fubini also shows that $x \mapsto \int g(\theta, x)\, d\theta = F(1)|m(x)|^2$ is integrable. This is the claim. □

Lemma 6.6.72. *Let n be a nonempty finite index set, s signs on n, o a positive-first order for s, $u = (u_v)_{v\in\Phi}$ weights with every u_v K-dominant for (s,o), and $F\colon G_\infty(s)\to\mathbb{C}$ holomorphic of weight u for o. For $\theta\in\mathbb{R}/\mathbb{Z}$ let $d(\theta)\in G_\infty(s)$ have the component $\operatorname{diag}(e^{2\pi\mathrm{i}\theta o(i)})_{i\in n}$ at every $v\in\Phi$. Then for every $x\in G_\infty(s)$*

$$\int_{\mathbb{R}/\mathbb{Z}} F\big(d(\theta)x\big)\prod_{v\in\Phi}\prod_{i\in n} e^{-2\pi\mathrm{i}\theta\, o(i)u_v(i)}\,d\theta = m^{\mathrm{hol}}_{s,u}(x)\,F(1),$$

$d\theta$ the invariant probability measure.

Proof. Let $\tilde F$ be an extension of F as in (HV3). For $x\in G_\infty(s)$ write $L(x)$ for the left side and $R(x) = m^{\mathrm{hol}}_{s,u}(x)F(1)$; for $s'\in\mathbb{C}^\times$ let $d(s')$ be the family with components $\operatorname{diag}(s'^{\,o(i)})_i$, so $d(\theta) = d(e^{2\pi\mathrm{i}\theta})$, and put $\chi(s') = \prod_{v,i} s'^{\,o(i)u_v(i)}$. Applying (HV3) at a point $y\in G_\infty(s)$ with the family $b = 1$ gives $\tilde F(y) = F(y)$; so $\tilde F$ is complex analytic at every point of $G_\infty(s)$, and $\tilde F(1) = F(1)$.

Step 1: near 1**.** Order n by o. A complex $n\times n$ matrix y whose leading principal minors (on the initial segments of o) do not vanish has a unique factorisation $y = ab$ with a o-lower unipotent and b o-triangular, the entries of a and b being rational functions of y regular on that set (Gaussian elimination); at $y = 1$, $a = b = 1$. Since $\tilde F$ is analytic at the family 1, there is $\epsilon > 0$ such that $\tilde F$ is holomorphic on the polydisc N of the families y with $|y_{v,ij} - \delta_{ij}| < \epsilon$ for all v, i, j. Let $K = \max o - \min o$, and let U_0 be the set of $x\in G_\infty(s)$ whose components have nonvanishing leading principal minors and whose factors a_v satisfy $|a_{v,ij}| < \epsilon\, 2^{-K}$ for $i\neq j$; it is an open neighbourhood of 1 in $G_\infty(s)$. Let $x\in U_0$, $x_v = a_v b_v$. For $s'\in\mathbb{C}$ let $A(s')$ be the family $d(s')\,a\,d(s')^{-1}$, with entries $s'^{\,o(i)-o(j)}a_{v,ij}$; these are zero unless $i = j$ (entry 1) or $o(i) > o(j)$, so A is a polynomial family in s' with $A(0) = 1$, and $A(s')\in N$ for $|s'| < 2$. Let $|s'| = 1$ and $y = d(s')x\in G_\infty(s)$. The family $\beta = (d(s')b)^{-1}$ is o-triangular (inverse of an o-triangular matrix) with diagonal entries $(s'^{\,o(i)}b_{v,ii})^{-1}$, and $y\beta = A(s')$. By (HV3) at y with β,

$$\tilde F\big(A(s')\big) = \beta^u F(y) = \chi(s')^{-1}\Big(\prod_v b_v^{u_v}\Big)^{-1} F\big(d(s')x\big).$$

The function $s'\mapsto \tilde F(A(s'))$ is holomorphic on $|s'| < 2$, so by the mean value property on the unit circle and $A(0) = 1$,

$$L(x) = \Big(\prod_v b_v^{u_v}\Big)\int_{\mathbb{R}/\mathbb{Z}} \tilde F\big(A(e^{2\pi\mathrm{i}\theta})\big)d\theta = \Big(\prod_v b_v^{u_v}\Big)\tilde F(1) = m^{\mathrm{hol}}_{s,u}(x)\,F(1)$$

by (ii) of Lemma 6.6.70. So $L = R$ on U_0.

Step 2: everywhere. $G_\infty(s) = \prod_{v\in\Phi}\mathrm{U}(\operatorname{diag} s)$ is a connected real Lie group (each $\mathrm{U}(p,q)$ is connected), a real-analytic submanifold of $\mathrm{M}_n(\mathbb{C})^\Phi$. R is the restriction of a function holomorphic near $G_\infty(s)$ ((i) of Lemma 6.6.70). For L, let $x_0\in G_\infty(s)$: the compact set $\{d(\theta)x_0\}$ lies in $G_\infty(s)$, where $\tilde F$ is analytic, so there is an open neighbourhood V of x_0 in $\mathrm{M}_n(\mathbb{C})^\Phi$ with $\tilde F$ holomorphic near $d(\theta)y$ for all θ and $y\in V$; then $(\theta,y)\mapsto\tilde F(d(\theta)y)$ is continuous on $\mathbb{R}/\mathbb{Z}\times V$ and holomorphic in y, so $y\mapsto\int\tilde F(d(\theta)y)\chi(e^{2\pi\mathrm{i}\theta})^{-1}d\theta$ is holomorphic on V (differentiation under the integral sign), and its restriction to $V\cap G_\infty(s)$ is L. So L and R are real analytic on $G_\infty(s)$, agree on the nonempty open set U_0, and therefore agree on the connected $G_\infty(s)$. □

Lemma 6.6.73. *Let $n_* = 2ft^3$. Let V, V' be spaces with points with signs s on a nonempty n and s' on a nonempty n', $\#n\le t$, $\#n'\le t$, and let α, β be automorphic characters of $\mathrm{U}(1)$ of weights γ, γ'. Let Q be a homogeneous polynomial of degree $d\le b^{3/2}$ in the variables indexed by $\Phi\times n'\times n$, and $c_Q(h,h') = \langle v_Q, \Omega_{\gamma,\gamma'}(h,h')v_Q\rangle$. For $h\in G_\infty(s)$ write $|h| = \max_{v\in\Phi}\|h_v\|$. Let $g\in$*

$\mathrm{G}(s)$ *and* $g' \in \mathrm{G}(s')$ *with* $\lambda_V(g)\,\lambda_{V'}(g') \geq b^{-13}$. *Then there is a function* Ψ *on* $\mathrm{M}_{n'\times n}(\mathcal{O}_E/\mathfrak{M}^2)$ *such that for all* $h \in G_\infty(s)$ *and* $h' \in G_\infty(s')$

$$\left|\theta^{V,V'}_{\alpha,\beta;\mathfrak{M}^2}[\Psi,Q](g(h,1),g'(h',1)) - c_Q(h,h')\right| \leq b^{-20n_*}\left(|h|\,|h'|\right)^{6n_*}|c_Q(1,1)|.$$

Proof. By Lemma 4.2.67, $x \geq e^{6.4\cdot 10^{15}}$, $x^{10^{12}} \leq b$, $t \leq 15x^5$, $f \leq q_1 \leq x^{12}$ and $q_1 d \leq x^{13}$. Note $\lambda_{V_g}(1) = \lambda_V(g)$ by (VP4) of Definition 3.2.2.

Step 1: an integer in the different. Put $N_{\mathfrak{D}} = q_1 d$; by Lemma 6.4.102, $N_{\mathfrak{D}} \in \mathfrak{D}_E$.

Step 2: the first minimum of Hom**.** By (VP3) of Definition 3.2.2 V_g is a framed hermitian space (a framed space of rank $\#n$ in the sense of (FT1)) and $\lambda_{V_g}(1) = \lambda_V(g)$ is the first minimum of (VP4) for both readings; its coordinate map is $c_{V_g}(u) = (x_V g)^{-1}u$, so L_1 is the lattice of V_g and $|u|_1 = \|((x_V g)^{-1}u)_\infty\|$. By Lemma 6.6.19 (at $g = 1$, with $N_{\mathfrak{D}}$ of Step 1) the lattice of V_g contains a basis of E^n of vectors of length at most $B = f\,\#n\,N_{\mathfrak{D}}\,\lambda_V(g)^{-1} \geq 1$. By (i) of Lemma 6.6.78 for $S = V_g$, $T = V'_{g'}$,

$$\lambda_{\mathrm{Hom}(V_g,V'_{g'})}(1) \geq \frac{\lambda_{V'}(g')}{B} = \frac{\lambda_V(g)\lambda_{V'}(g')}{f\,\#n\,q_1 d} \geq \frac{b^{-13}}{15x^{30}}.$$

Step 3: the scale c**.** Put $c = q_1/\pi_M^2 \in E^\times$. From $x^{q_1} - 1 = \mathrm{cyc}_{q_1}(x)h(x)$, $h \in \mathbb{Z}[x]$, $q_1\zeta^{q_1-1} = \mathrm{cyc}'_{q_1}(\zeta)h(\zeta)$, so $q_1\alpha_w$ is integral at every finite place w. If z is an integral finite adele whose components at the chosen places lie in $\mathfrak{M}^2 = \pi_M^2\mathcal{O}_E$, then $\pi_M^{-2}z_w$ is integral at the chosen places, and also at the other finite places, where π_M is a unit. So $c\,\alpha z = (q_1\alpha)(\pi_M^{-2}z)$ is integral. At every $v \in \Phi$, $|(\pi_M)_v|^2 = \pi_M\bar{\pi}_M = M \geq b^{20}$, so $|c_v| = q_1/M \leq x^{12}b^{-20}$.

Step 4: the separation and the conclusion. Let $r = b^6$ and $q = 2n_*$. Then $\delta = \#(\Phi \times n' \times n) \leq ft^2 < q$, and, with $\sqrt{2\pi\,\mathrm{Im}\,\jmath_v} = \sqrt{2\pi}\,d^{-1/4} \geq d^{-1}$ and Step 2,

$$r\,|c_v| \leq x^{12}b^{-14} \leq \frac{b^{-13}}{d\cdot 15x^{30}} \leq \sqrt{2\pi\,\mathrm{Im}\,\jmath_v}\;\lambda_{\mathrm{Hom}(V_g,V'_{g'})}(1),$$

since $15x^{42}d \leq 15x^{55} \leq b$. So Lemma 6.6.74 applies to $S = V$, $T = V'$, the points g, g', $\alpha' = \alpha$, $\beta' = \beta$, the modulus $\mathfrak{M}^2$, c, r, q and $P = Q$ of degree $d \leq b^{3/2}$, and gives Ψ with

$$\left|\theta^{V,V'}_{\alpha,\beta;\mathfrak{M}^2}[\Psi,Q](g(h,1),g'(h',1)) - c_Q(h,h')\right| \leq \Big(\frac{100(d+4n_*)}{b^{12}}\Big)^{2n_*}\left(|h|\,|h'|\right)^{6n_*}\langle v_Q, v_Q\rangle.$$

Here $n_* = 2ft^3 \leq 2x^{12}(15x^5)^3 \leq b^{3/2}$, so $100(d+4n_*) \leq 500\,b^{3/2} \leq b^2$ and the first factor is at most $(b^{-10})^{2n_*} = b^{-20n_*}$; and $\langle v_Q, v_Q\rangle = c_Q(1,1) = |c_Q(1,1)|$, as $\Omega_{\gamma,\gamma'}(1,1)$ is the identity. □

Lemma 6.6.74. *Let* S, T *be spaces with points with signs* s *on a nonempty* n *and* s' *on a nonempty* n', *let* $\delta = \#(\Phi \times n' \times n)$, *and let* α', β' *be automorphic characters of* $\mathrm{U}(1)$ *of weights* γ, γ'. *Let* $\mathfrak{m}$ *be a modulus,* $g \in \mathrm{G}(s)$, $h \in \mathrm{G}(s')$, *and* $\lambda = \lambda_{\mathrm{Hom}(S_g,T_h)}(1)$. *Let* $c \in E^\times$ *be such that* $c\,\alpha z$ *is integral for every integral finite adele* z *whose components at the places of* $\Sigma(\mathfrak{m})$ *lie in* $\mathfrak{m}$, *let* $r > 0$ *satisfy* $r\,|c_v| \leq \sqrt{2\pi\,\mathrm{Im}\,\jmath_v}\;\lambda$ *for every* $v \in \Phi$, *and let* $q > \delta$ *be an integer. Let* P *be a homogeneous polynomial of degree* d *in the variables indexed by* $\Phi \times n' \times n$. *For* $x \in G_\infty(s)$ *write* $\|x\| = \max_{v\in\Phi}\|x_v\|$, *the operator norm. Then there is a function* Ψ *on* $\mathrm{M}_{n'\times n}(R_{\mathfrak{m}})$ *such that for all* $x \in G_\infty(s)$ *and* $y \in G_\infty(s')$

$$\left|\theta^{S,T}_{\alpha',\beta'}(\mathrm{mod}_{\mathfrak{m}}(\Psi,v_P))(g(x,1),h(y,1)) - \langle v_P, \Omega_{\gamma,\gamma'}(x,y)\,v_P\rangle\right| \leq \Big(\frac{100(d+2q)}{r^2}\Big)^q\left(\|x\|\,\|y\|\right)^{3q}\langle v_P, v_P\rangle.$$

Proof. Write $v = v_P$, $H = \mathrm{Hom}(S,T)$ with point $x_H = x_T \otimes (x_S^{-1})^{\mathsf T}$, $p = h \otimes (g^{-1})^{\mathsf T} \in \mathrm{G}(s' \otimes s)$, $\omega = \omega_{s' \otimes s}$, $\chi = \alpha'(\det h)\,\beta'(\det g)^{-1}$ (of modulus 1), and for a function Φ on $\mathrm{M}_{n' \times n}(R_{\mathfrak m})$ and $f \in \mathcal{F}_{S,T}$ put $\varphi(\Phi, f) = \mathrm{mod}_{\mathfrak m}(\Phi, f)$, linear in Φ and in f. By (WR4) of Definition 3.2.18 and (WC4) of Definition 4.1.15, $\theta^{S,T}_{\alpha',\beta'}(\varphi)(g,h) = \chi\,\theta_H(\omega(p)\varphi)$. Since $x_H p = x_T h \otimes ((x_S g)^{-1})^{\mathsf T}$, the moved space H_p is $\mathrm{Hom}(S_g, T_h)$, so λ is the first minimum of the lattice $\Lambda = \{u \in \mathrm{M}_{n' \times n}(E) : ((x_H p)^{-1}u)_f \text{ integral}\}$ of H_p for the lengths $\|((x_H p)^{-1}u)_\infty\|$. For $u \in \mathrm{M}_{n' \times n}(E)$ put $z(u) = (x_H p)^{-1}u \in \mathbb{A}_E^{n' \times n}$ and $\xi(u) = (\kappa_v^{-1} z(u)_{v,a,b})_{v,a,b} \in \mathbb{C}^{\Phi \times n' \times n}$, with $\kappa_v^{-1} = \sqrt{2\pi\,\mathrm{Im}\,\jmath_v}$ as in (WD6); $u \mapsto \xi(u)$ is additive and injective.

The datum. For $X \in \mathrm{M}_{n' \times n}(R_{\mathfrak m})$ let $\mathbf{1}_X$ be the indicator of $\{X\}$ and $K_X = \theta^{S,T}_{\alpha',\beta'}(\varphi(\mathbf{1}_X, v))$. Put $\Psi = \sum_X \overline{K_X(g,h)}\,\mathbf{1}_X$. By linearity, $\theta^{S,T}_{\alpha',\beta'}(\varphi(\Psi, v)) = \sum_X \overline{K_X(g,h)}\,K_X$.

The kernel as a lattice sum. Fix $x \in G_\infty(s)$, $y \in G_\infty(s')$ and put $w = \Omega_{\gamma,\gamma'}(x,y)v$. By (5) of Lemma 4.1.1 (with finite components 1), $\omega_{\alpha',\beta'}((x,1),(y,1))\varphi(\mathbf{1}_X, v) = \varphi(\mathbf{1}_X, w)$, so by (2) of Lemma 4.1.1 $K_X(g(x,1), h(y,1)) = \chi\,\theta_H(\omega(p)\varphi(\mathbf{1}_X, w))$, while $K_X(g,h) = \chi\,\theta_H(\omega(p)\varphi(\mathbf{1}_X, v))$. As $|\chi| = 1$,

$$\overline{K_X(g,h)}\,K_X(g(x,1),h(y,1)) = \theta_H\big(\omega(p)\varphi(\mathbf{1}_X,w)\big)\,\overline{\theta_H\big(\omega(p)\varphi(\mathbf{1}_X,v)\big)}.$$

By Lemma 6.6.75 for H this is the absolutely convergent sum over $u \in \mathrm{M}_{n' \times n}(E)$ of

$$\langle \omega(p)\varphi(\mathbf{1}_X, v), \rho(x_H^{-1}u)\,\omega(p)\varphi(\mathbf{1}_X, w)\rangle.$$

Since $\omega(p)$ is unitary and $\omega(p)^{-1}\rho(z)\omega(p) = \rho(p^{-1}z)$ ((2) of Lemma 4.1.1), the term of u is $\langle \varphi(\mathbf{1}_X, v), \rho(z(u))\,\varphi(\mathbf{1}_X, w)\rangle$. Summing over the finitely many X and applying Lemma 6.6.76 to each u,

$$\theta^{S,T}_{\alpha',\beta'}(\varphi(\Psi,v))(g(x,1),h(y,1)) = \sum_u t(u), \qquad t(u) = c_{\mathfrak m}(z(u)_f)\,\langle v, \rho^\infty(\xi(u))\,w\rangle,$$

absolutely convergent. As $c_{\mathfrak m}(0) = 1$ and $\xi(0) = 0$, $t(0) = \langle v, w\rangle = \langle v, \Omega_{\gamma,\gamma'}(x,y)v\rangle$; so the left side of the assertion is at most $\sum_{u \neq 0} |t(u)|$.

Support and separation. Let $u \neq 0$ with $t(u) \neq 0$. Then $c_{\mathfrak m}(z(u)_f) \neq 0$, so by Lemma 6.6.76 $\alpha^{-1}z(u)_f$ is integral with components in $\mathfrak m$ at $\Sigma(\mathfrak m)$, and by the hypothesis on c the finite part $c\,z(u)_f = c\alpha \cdot \alpha^{-1}z(u)_f$ of $z(cu)$ is integral: cu is a nonzero vector of Λ. Let L be the set of $u \neq 0$ with $cu \in \Lambda$. For $u \in L$, by the definition of λ and the hypothesis on r,

$$r\lambda \le r\Big(\sum_{v,a,b} |c_v|^2 |z(u)_{v,a,b}|^2\Big)^{1/2} \le \lambda\Big(\sum_{v,a,b} \kappa_v^{-2} |z(u)_{v,a,b}|^2\Big)^{1/2} = \lambda\,\|\xi(u)\|,$$

so $\|\xi(u)\| \ge r$, as $\lambda > 0$. For distinct $u, u' \in L$, $u - u' \neq 0$ and $c(u-u') \in \Lambda$, so $\|\xi(u) - \xi(u')\| = \|\xi(u-u')\| \ge r$.

Packing. We show $\sum_{u \in L} \|\xi(u)\|^{-2q} \le (5/r)^{2q}$. The points $\xi(u)$, $u \in L$, lie in $\mathbb{C}^\delta = \mathbb{R}^{2\delta}$ and the open balls of radius $r/2$ around them are disjoint. For $j \ge 0$ let L_j be the set of $u \in L$ with $2^j r \le \|\xi(u)\| < 2^{j+1}r$; the balls of radius $r/2$ around $\xi(u)$, $u \in L_j$, lie in the ball of radius $(2^{j+1} + \frac12)r$ about 0, so comparing volumes, $\#L_j \le (2^{j+2}+1)^{2\delta} \le (5 \cdot 2^j)^{2\delta}$. As $L = \bigcup_j L_j$ and $2q \ge 2\delta + 2$,

$$\sum_{u \in L} \|\xi(u)\|^{-2q} \le \sum_{j \ge 0} (5 \cdot 2^j)^{2\delta} (2^j r)^{-2q} \le 5^{2\delta} r^{-2q} \sum_{j \ge 0} 2^{-2j} = \tfrac43\, 5^{2\delta} r^{-2q} \le (5/r)^{2q}.$$

Decay of each term. Let ε be the signs of $\mathcal{F}_{S,T}$ on $\iota = \Phi \times n' \times n$ and $\sigma = \bigoplus_{v \in \Phi} y_v \otimes (x_v^{-1})^{\mathsf T} \in \mathrm{U}(\mathrm{diag}\,\varepsilon)$. By (WR5), $w = \prod_v \det(y_v)^{\gamma(v)} \det(x_v)^{-\gamma'(v)}\,\omega_\varepsilon^\infty(\sigma)v$, and the determinants

have modulus 1 (from $x_v^*\mathrm{diag}(s)x_v = \mathrm{diag}(s)$ and likewise for y_v). For $u \in L$, $|c_{\mathfrak{m}}| \le 1$ and Lemma 6.6.77 (with $A = d+\delta$ and $n = q$) give

$$|t(u)| \le \big|\langle v, \rho^\infty(\xi(u))\,\omega_\varepsilon^\infty(\sigma)v\rangle\big| \le \big(4(d+\delta+q)\big)^q\,\|\sigma\|^{\delta+2q}\,\|\xi(u)\|^{-2q}\,\langle v,v\rangle.$$

The operator norm of a Kronecker product is the product of the norms, a transpose has the norm of the matrix, and $x_v^{-1} = \mathrm{diag}(s)x_v^*\mathrm{diag}(s)$ has the norm of x_v; hence $\|\sigma\| = \max_v \|y_v\|\|x_v\| \le \|x\|\|y\|$. Also $\|\sigma\| \ge 1$, since $\sigma^{-1} = \mathrm{diag}(\varepsilon)\sigma^*\mathrm{diag}(\varepsilon)$ has the norm of σ; with $\delta < q$ this gives $\|\sigma\|^{\delta+2q} \le (\|x\|\|y\|)^{3q}$ and $4(d+\delta+q) \le 4(d+2q)$.

Conclusion. Summing over L and using the packing bound,

$$\sum_{u\neq 0}|t(u)| \le \big(4(d+2q)\big)^q(\|x\|\|y\|)^{3q}\langle v,v\rangle\Big(\frac{5}{r}\Big)^{2q} = \Big(\frac{100(d+2q)}{r^2}\Big)^q(\|x\|\|y\|)^{3q}\langle v,v\rangle.$$

□

Lemma 6.6.75. *Let V be a space with a point with signs s on n, and θ_V its canonical theta functional. For all $f, f' \in \mathcal{M}_s$ the family $\big(\langle f', \rho(\gamma)f\rangle\big)_{\gamma\in V(E)}$ is absolutely summable, and*

$$\sum_{\gamma\in V(E)}\langle f', \rho(\gamma)f\rangle = \theta_V(f)\,\overline{\theta_V(f')}.$$

Proof. Write $W = \mathbb{A}_E^n$, $L = V(E)$, $K = W/L$ with its invariant probability measure dx, $\beta = \beta_s$, $\theta = \theta_V$; only the properties of a theta functional are used. Since $x_V^* J_V x_V = \varepsilon_s$, $\bar\gamma^{\mathsf T}\varepsilon_s\gamma' = u^* J_V u'$ for $\gamma = x_V^{-1}u$, $\gamma' = x_V^{-1}u'$; and $\psi_E(\bar a) = \psi_E(a)$ for $a \in \mathbb{A}_E$ by (WD4).

Step 1: a periodic function. For $\gamma \in L$, $\theta(\rho(x+\gamma)f) = \beta(\gamma,x)^{-1}\theta(\rho(\gamma)\rho(x)f) = \beta(\gamma,x)^{-1}\theta(\rho(x)f)$, and $|\beta| = 1$. So $F(x) = \theta(\rho(x)f)\,\overline{\theta(\rho(x)f')}$ is L-periodic, and it is continuous (θ bounded, ρ strongly continuous); we view it on K.

Step 2: its Fourier coefficients. For $\gamma \in L$ put $\chi_\gamma(x) = \beta(x,\gamma)\beta(\gamma,x)^{-1}$. By (WD6) and $\bar\jmath = -\jmath$, $\beta(\gamma,x)^{-1} = \psi_E(\bar a)$ with $a = \frac{\jmath}{2}\bar\gamma^{\mathsf T}\varepsilon_s x$, so $\chi_\gamma(x) = \psi_E(a)\psi_E(\bar a) = \psi_E(\jmath\,\bar\gamma^{\mathsf T}\varepsilon_s x)$, a continuous character of W; it is trivial on L, since $\bar\gamma^{\mathsf T}\varepsilon_s\gamma' \in E$ for $\gamma' \in L$ and ψ_E is trivial on E. From $\rho(x)\rho(\gamma) = \beta(x,\gamma)\rho(x+\gamma)$ and Step 1, $\theta(\rho(x)\rho(\gamma)f) = \chi_\gamma(x)\theta(\rho(x)f)$. By orthogonality of theta functions with $u = f'$, $v = \rho(\gamma)f$,

$$\int_K F(x)\,\chi_\gamma(x)\,dx = \int_K \overline{\theta(\rho(x)f')}\,\theta(\rho(x)\rho(\gamma)f)\,dx = \langle f', \rho(\gamma)f\rangle.$$

Step 3: these are all the characters of K. The map $y \mapsto x_V^{-1}y$ is an isomorphism of topological groups $\mathbb{A}_E^n \to W$ carrying E^n onto L, so it identifies $(\mathbb{A}_E/E)^n$ with K. For $\gamma = x_V^{-1}u$, $\chi_\gamma(x_V^{-1}y) = \psi_E(\jmath\,u^*J_V y) = \psi_E(\xi\cdot y)$ with $\xi = \jmath\,\overline{J_V u} \in E^n$ (J_V is hermitian). As u runs over E^n, ξ runs bijectively over E^n ($\jmath \neq 0$, J_V invertible). By (a) of Theorem A.5.2 and since the characters of a finite product are the products of characters of the factors, $\xi \mapsto (y \mapsto \psi_E(\xi\cdot y))$ is a bijection of E^n onto the characters of $(\mathbb{A}_E/E)^n$. Hence $\gamma \mapsto \chi_\gamma$ is a bijection of L onto the group of characters of K.

Step 4: absolute summability. By superposition and boundedness of $\langle\cdot,\cdot\rangle$ on Bochner integrals,

$$\langle f', \rho(\gamma)f\rangle = \iint \overline{f'(z')}\,f(z)\,\langle\rho(z')v^0, \rho(\gamma)\rho(z)v^0\rangle\,d\mu_n(z)\,d\mu_n(z').$$

Since the ρ preserve the inner product and compose up to phases of modulus 1,

$$|\langle\rho(z')v^0, \rho(\gamma)\rho(z)v^0\rangle| = |\langle v^0, \rho(\gamma+z-z')v^0\rangle| = |e_n(\gamma+z-z')|.$$

Let $K_0 = \sup_{y\in W}\sum_{\gamma\in L}|e_n(\gamma+y)|$. It is finite: the γ with $e_n(\gamma+y)\neq 0$ have $(\gamma+y)_f \in \alpha\widehat{\mathcal{O}}_E^n$ and so form (if any) a coset γ_0+L_0 of $L_0=\{x_V^{-1}u : u\in M\}$, $M=\{u\in E^n : (x_V^{-1}u)_f\in\alpha\widehat{\mathcal{O}}_E^n\}$ an $\mathcal{O}_E$-lattice of E^n, whose archimedean image Λ_0 is a lattice of $\mathbb{C}^{\Phi\times n}$; with $c=\pi\min_v \operatorname{Im}\jmath_v>0$ the sum is at most $\sup_t\sum_{\lambda\in\Lambda_0}\exp(-c\|\lambda+t\|^2)$, a continuous Λ_0-periodic function of t, hence bounded. By Tonelli, $\sum_{\gamma\in L}|\langle f', \rho(\gamma)f\rangle| \le K_0\,\|f\|\,\|f'\|<\infty$.

Step 5: Fourier inversion. F is continuous on the compact abelian group K and, by Steps 2–4, its Fourier coefficients $\int F\chi$ over all characters χ of K form the absolutely summable family $(\langle f', \rho(\gamma)f\rangle)_{\gamma\in L}$. By Fourier inversion on compact abelian groups (the continuous function $\sum_\chi(\int F\chi)\bar\chi$ has the same coefficients as F, so equals F), $F(0)=\sum_{\gamma\in L}\langle f', \rho(\gamma)f\rangle$, and $F(0)=\theta(f)\overline{\theta(f')}$. □

Lemma 6.6.76. *Let S, T be spaces with points with signs on n and n', and $\mathfrak{m}$ a modulus. For $X\in \mathrm{M}_{n'\times n}(R_\mathfrak{m})$ let $\mathbf{1}_X$ be the indicator function of $\{X\}$ on $\mathrm{M}_{n'\times n}(R_\mathfrak{m})$. For $z\in W$ let $\xi(z)\in\mathbb{C}^{\Phi\times n'\times n}$ have the components $\kappa_v^{-1}z_{v,a,b}$. There is a function $c_\mathfrak{m}$ on $\mathrm{M}_{n'\times n}(\mathbb{A}_{E,f})$ with $|c_\mathfrak{m}|\le 1$ and $c_\mathfrak{m}(0)=1$, vanishing at every z_f for which $\alpha^{-1}z_f$ is not integral or has an entry whose component at some $w\in\Sigma(\mathfrak{m})$ does not lie in $\mathfrak{m}\mathcal{O}_{E,w}$, such that for all $v,w\in\mathcal{F}_{S,T}$ and $z\in W$*

$$\sum_{X\in \mathrm{M}_{n'\times n}(R_\mathfrak{m})} \langle \mathrm{mod}_\mathfrak{m}(\mathbf{1}_X, v),\, \rho(z)\,\mathrm{mod}_\mathfrak{m}(\mathbf{1}_X, w)\rangle = c_\mathfrak{m}(z_f)\,\langle v, \rho^\infty(\xi(z))\,w\rangle.$$

Proof. Let $A=\Sigma(\mathfrak{m})$, $N=n'\times n$, $Q_A=\prod_{w\in A}E_w^N$ with $L_A=\prod_{w\in A}\mathcal{O}_{E,w}^N$ of volume 1, and $f_X=\mathbf{1}_X^\natural\otimes_A v^0$, so $\mathrm{mod}_\mathfrak{m}(\mathbf{1}_X,v)=v\otimes f_X$. As functions on Q_A, the $\mathbf{1}_X^\natural$ are the indicators of the cosets B_X of $\mathfrak{m}L_A$ in L_A, $X\in\mathrm{M}_{n'\times n}(R_\mathfrak{m})$, each of volume $(\#R_\mathfrak{m})^{-\#N}$. Write $z=z_\infty+z'+z''$, with z' the finite components at $A\cup\bar A$ and z'' the other finite components.

Step 1: separation of the archimedean part. By (WD6) $z_\infty=\mathrm{rv}(\xi(z))$, and z_∞, z', z'' have disjoint supports, so $\rho(z)=\rho(z_\infty)\rho(z')\rho(z'')$. By Lemma 6.2.21, $\rho(z)(w\otimes f_X)=(\rho^\infty(\xi(z))w)\otimes\rho(z'+z'')f_X$, and by (6), (4) of Lemma 6.2.33 and (3) of Lemma 6.2.21,

$$\langle v\otimes f_X, \rho(z)(w\otimes f_X)\rangle = \langle v, \rho^\infty(\xi(z))w\rangle\,\langle f_X, \rho(z'+z'')f_X\rangle.$$

So the claim holds with $c_\mathfrak{m}(z_f)=\sum_X\langle f_X,\rho(z'+z'')f_X\rangle$, which depends only on z_f; it remains to show the properties of $c_\mathfrak{m}$.

Step 2: the two finite parts. The operator $\rho(z'')$ commutes with P^A and with every $\rho(\mathrm{fv}(y))$, y supported on $A\cup\bar A$ (disjoint supports), so $\rho(z'')f_X=\mathbf{1}_X^\natural\otimes_A\rho(z'')v^0$. With $y=\alpha^{-1}z'$ (so $\mathrm{fv}(y)=z'$) and Lemma 4.1.3,

$$\langle f_X,\rho(z')\rho(z'')f_X\rangle = \langle\mathbf{1}_X^\natural, R_A(y)\mathbf{1}_X^\natural\rangle_{Q_A}\,\langle v^0, P^A\rho(z'')v^0\rangle = \langle\mathbf{1}_{B_X}, R_A(y)\mathbf{1}_{B_X}\rangle_{Q_A}\,\langle v^0,\rho(z'')v^0\rangle,$$

using $P^A\rho(z'')v^0=\rho(z'')P^Av^0=\rho(z'')v^0$. Here $\langle v^0,\rho(z'')v^0\rangle=\overline{e(z'')}$ (e the vacuum of (WD5)), of modulus at most 1, equal to 1 for $z''=0$, and 0 unless $z''\in\alpha\widehat{\mathcal{O}}_E^N$.

Step 3: the sum over the classes. Let

$$S(y)=\sum_X\langle\mathbf{1}_{B_X}, R_A(y)\mathbf{1}_{B_X}\rangle_{Q_A}=\sum_X\int_{B_X}\psi_0(\bar y^{\mathsf T}(2x+y)_A/2)\,\mathbf{1}_{B_X}(x+y_A)\,dx.$$

If $y_A\notin\mathfrak{m}L_A$, then $x+y_A\notin B_X$ for $x\in B_X$, and $S(y)=0$. If $y_A\in\mathfrak{m}L_A$, the cosets B_X partition L_A and

$$S(y)=\psi_0(\tfrac12\bar y^{\mathsf T}y_A)\int_{L_A}\psi_0(\bar y^{\mathsf T}x_A)\,dx;$$

the integrand is a character of the compact group L_A (the components of $\bar{y}$ at A are those of y at $\bar{A}$, conjugated), trivial exactly when these components are integral, by self-duality; so $S(y) = 0$ unless y is integral at $\bar{A}$, and $|S(y)| \le 1$, $S(0) = 1$.

Conclusion. $c_{\mathfrak{m}}(z_f) = S(\alpha^{-1}z')\,\overline{e(z'')}$, so $|c_{\mathfrak{m}}| \le 1$ and $c_{\mathfrak{m}}(0) = 1$. If $\alpha^{-1}z_f$ is not integral, it fails at a place outside $A \cup \bar{A}$ (then $e(z'') = 0$), at a place of $\bar{A}$ or at a place of A (then $S = 0$); if $\alpha^{-1}z_f$ has an entry whose component at some $w \in A$ is not in $\mathfrak{m}\mathcal{O}_{E,w}$, then $y_A \notin \mathfrak{m}L_A$ and $S = 0$. In all these cases $c_{\mathfrak{m}}(z_f) = 0$. □

Lemma 6.6.77. *Let ι be a nonempty finite index set, ε signs on ι, $P \in \mathbb{C}[X_i : i \in \iota]$ homogeneous of degree d, $v = v_P$, $\sigma \in \mathrm{U}(\operatorname{diag}\varepsilon)$, $y \in \mathbb{C}^\iota \setminus \{0\}$, and $A \ge d + \#\iota$, $n \ge 0$ integers. Write $|y|$ for the euclidean norm on $\mathbb{C}^\iota$, $\|\sigma\|$ for the operator norm of σ for it, and $(\varrho(y)c)(x) = \beta_\varepsilon^\infty(y,x)\,c(x-y)$ for functions c on $\mathbb{C}^\iota$. Then $\overline{v}\cdot\varrho(y)\omega_\varepsilon^\infty(\sigma)v$ is ν_ι-integrable, and*

$$\Big|\int \overline{v}\;\varrho(y)\,\omega_\varepsilon^\infty(\sigma)v\;d\nu_\iota\Big| \le (4(A+n))^n\,\|\sigma\|^{\#\iota+2n}\,|y|^{-2n}\,\langle v,v\rangle.$$

Proof. Write $\beta = \beta_\varepsilon^\infty$, $e = e^\infty$, $\nu = \nu_\iota$, $\mathrm{D} = \operatorname{diag}\varepsilon$ and $k = \#\iota$. Recall $\beta(a,x) = \exp((x^*\mathrm{D}a - a^*\mathrm{D}x)/2)$ and $e(x) = \exp(-|x|^2/2)$, and $v(x) = P(\zeta(x))e(x)$ with $\zeta_i(x) \in \{x_i, \bar{x}_i\}$, a Fock vector, so $v \in \mathcal{F}_\varepsilon$.

Elementary facts. The exponent of $\beta(a,x)$ is purely imaginary and real-linear in each argument, so $|\beta| = 1$, $\beta(a,x)\beta(b,x) = \beta(a+b,x)$, $\beta(a,x-y) = \beta(a,x)\beta(a,y)^{-1}$, and $\overline{\beta(t,z)} = \beta(z,t)$. As $\sigma^*\mathrm{D}\sigma = \mathrm{D}$, $|\det\sigma| = 1$, so $x \mapsto \sigma x + y$ preserves ν (its real Jacobian is $|\det\sigma|^2$); and $\|\sigma\| \ge 1$, since $\sigma^{-1} = \mathrm{D}\sigma^*\mathrm{D}$ has the same norm as σ. The block σ_- of σ on the indices of sign -1 is a compression of σ, so $|\det\sigma_-| \le \|\sigma\|^k$. Finally $|v(x)| \le C(1+|x|)^d\exp(-|x|^2/2)$ for some C, so v is bounded and integrable.

Pairing with a translated vacuum. For $w \in \mathcal{F}_\varepsilon$ and $z \in \mathbb{C}^\iota$, $\int \overline{w(t)}\,\beta(z,t)\,e(t-z)\,d\nu(t) = \overline{w(z)}$: this is the complex conjugate of the reproducing identity $w(z) = \int w(t)\beta(t,z)e(z-t)\,d\nu(t)$ of (WR5), as $\overline{\beta(t,z)} = \beta(z,t)$ and e is real and even.

Reduction to a convolution of $|v|$ with itself. By (WR5),

$$\omega_\varepsilon^\infty(\sigma)v(x) = \overline{\det\sigma_-}\int v(t)\beta(\sigma t,x)e(x-\sigma t)\,d\nu(t),$$

so

$$\overline{v(x)}\,(\varrho(y)\omega_\varepsilon^\infty(\sigma)v)(x) = \overline{\det\sigma_-}\int \overline{v(x)}\,v(t)\,\beta(y,x)\beta(\sigma t,x-y)\,e\big(x-(\sigma t+y)\big)\,d\nu(t).$$

The absolute value of the integrand is at most $\sup|v|\cdot|v(t)|\,e(x-\sigma t-y)$, integrable on $\mathbb{C}^\iota\times\mathbb{C}^\iota$ (integrate first in x); so the left side is integrable in x and Fubini's theorem applies. By the elementary facts, $\beta(y,x)\beta(\sigma t,x-y) = \beta(\sigma t,y)^{-1}\beta(\sigma t+y,x)$, and by the pairing identity with $w = v$, $z = \sigma t + y$,

$$\int \overline{v}\;\varrho(y)\omega_\varepsilon^\infty(\sigma)v\;d\nu = \overline{\det\sigma_-}\int v(t)\,\beta(\sigma t,y)^{-1}\,\overline{v(\sigma t+y)}\,d\nu(t),$$

whose absolute value is at most $\|\sigma\|^k\int|v(t)|\,|v(\sigma t+y)|\,d\nu(t)$.

A pointwise bound by dilation. Put $c = \sqrt{1+n/A} \ge 1$ and

$$G(x) = |P(\zeta(x))|^2\exp(-|x|^2/c^2).$$

Since $1-c^{-2}=n/(n+A)$,

$$|v(x)| = G(x)^{1/2}\exp\Big(-\frac{n\,|x|^2}{2(n+A)}\Big).$$

From $y=(\sigma t+y)-\sigma t$ and $\|\sigma\|\ge 1$, $|y|\le\|\sigma\|(|\sigma t+y|+|t|)$, so $|y|^2\le 2\|\sigma\|^2(|t|^2+|\sigma t+y|^2)$. Hence $u=(|t|^2+|\sigma t+y|^2)/(2(n+A))$ satisfies $u\ge u_0=|y|^2/(4\|\sigma\|^2(n+A))$, and $\exp(u)\ge\exp(1)\,u\ge\exp(1)\,u_0$ (as $\exp(u-1)\ge u$), so

$$\exp(-u)\le K_1=4(n+A)\|\sigma\|^2/(\exp(1)\,|y|^2).$$

With $\sqrt{ab}\le(a+b)/2$,

$$|v(t)|\,|v(\sigma t+y)| = \sqrt{G(t)G(\sigma t+y)}\;\exp(-nu)\le \tfrac12 K_1^n\big(G(t)+G(\sigma t+y)\big).$$

Integration. Substituting $x=cx'$ ($d\nu(x)=c^{2k}d\nu(x')$) and using $P(\zeta(cx'))=c^dP(\zeta(x'))$,

$$\int G\,d\nu = c^{2(k+d)}\int |P(\zeta(x'))|^2\exp(-|x'|^2)\,d\nu(x') = c^{2(k+d)}\langle v,v\rangle\le\exp(n)\,\langle v,v\rangle,$$

because $c^{2(k+d)}=(1+n/A)^{k+d}\le\exp(n(k+d)/A)\le\exp(n)$ by $k+d\le A$. By the invariance of ν, $\int G(\sigma t+y)\,d\nu(t)=\int G\,d\nu$. Therefore $\int|v(t)||v(\sigma t+y)|\,d\nu(t)\le K_1^n\exp(n)\langle v,v\rangle=\big(4(n+A)\big)^n\|\sigma\|^{2n}|y|^{-2n}\langle v,v\rangle$, and with the factor $\|\sigma\|^k$ this is the assertion. □

Lemma 6.6.78. *Let S be a space with a point with signs on n, T a space with a point with signs on n'. Let f be the number of infinite places of E^+ and d_E the discriminant of E.*

(i) If $B\ge 1$ and the lattice of S contains a basis $u_1,\dots,u_{\#n}$ of E^n over E with $\|(x_S^{-1}u_j)_\infty\|\le B$ for every j, then $\lambda_{\mathrm{Hom}(S,T)}(1)\ge\lambda_T(1)/B$.

(ii) $\lambda_{\mathrm{Hom}(S,T)}(1)\ge\lambda_S(1)\lambda_T(1)/(f\,\#n\,|d_E|)$.

Proof. **(i).** By (VP5) of Definition 3.2.2 the inverse of the point of $\mathrm{Hom}(S,T)$ is $Z\mapsto x_T^{-1}Zx_S$ on $n'\times n$ matrices. Let $Z\in\mathrm{M}_{n'\times n}(E)$ be a nonzero vector of the lattice of $\mathrm{Hom}(S,T)$, and $k=x_T^{-1}Zx_S\in\mathrm{M}_{n'\times n}(\mathbb{A}_E)$; so k_f is integral, and the length of Z is $\|k_\infty\|=\big(\sum_{v\in\Phi}\|k_v\|_{\mathrm F}^2\big)^{1/2}$, $\|\cdot\|_{\mathrm F}$ the Frobenius norm. As the u_j form a basis and $Z\ne0$, there is j with $Zu_j\ne0$. The vector $Zu_j\in E^{n'}$ satisfies $x_T^{-1}(Zu_j)=k\,y$ with $y=x_S^{-1}u_j$, whose finite part k_fy_f is integral because k_f and y_f are; so Zu_j is a nonzero vector of the lattice of T, and by (VP4) of Definition 3.2.2 $\lambda_T(1)\le\|(ky)_\infty\|$. By the Cauchy–Schwarz inequality $\|k_vy_v\|\le\|k_v\|_{\mathrm F}\|y_v\|$ at each $v\in\Phi$, hence

$$\|(ky)_\infty\|^2=\sum_{v\in\Phi}\|k_vy_v\|^2\le\Big(\max_{v\in\Phi}\|k_v\|_{\mathrm F}^2\Big)\sum_{v\in\Phi}\|y_v\|^2\le\|k_\infty\|^2\,\|y_\infty\|^2\le\|k_\infty\|^2B^2.$$

So every nonzero lattice vector of $\mathrm{Hom}(S,T)$ has length at least $\lambda_T(1)/B$, and $\lambda_{\mathrm{Hom}(S,T)}(1)\ge\min(1,\lambda_T(1)/B)=\lambda_T(1)/B$, since $\lambda_T(1)\le1\le B$.

(ii). Enumerate n. By (VP3) of Definition 3.2.2 S is a framed hermitian space (a framed space of rank $\#n$ in the sense of (FT1)) and $\lambda_S(1)$ is the first minimum of (VP4) for both readings; its coordinate map is $c_S(u)=x_S^{-1}u$, so at $g=1$ the set L_1 of Lemma 5.8.21 is the lattice of S and $|u|_1=\|(x_S^{-1}u)_\infty\|$. By Lemma 5.8.21 the lattice of S contains a basis of E^n of vectors of length at most $B=f\,\#n\,|d_E|\,\lambda_S(1)^{-1}$, and $B\ge1$ since $\lambda_S(1)\le1$. Part (i) gives $\lambda_{\mathrm{Hom}(S,T)}(1)\ge\lambda_T(1)/B=\lambda_S(1)\lambda_T(1)/(f\,\#n\,|d_E|)$. □

Lemma 6.6.79. *Let $1 \le j \le m$, $\tilde{W}_j$ the padded space (signs $\tilde{s}_j$ on $\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+$), and u_1 the weight on $\mathcal{B}^{\mathrm{c}}$ equal to $-\Delta'$ on the first and $6m+1$ on the second block, the same at every $\tau \in \Phi$. For $g \in \mathrm{G}(s_j)$ let $(g,1) \in \mathrm{G}(\tilde{s}_j)$ be the block diagonal point with g on $\mathcal{R}$ and 1 on $\mathcal{A}_j^- \sqcup \mathcal{A}_j^+$. Let $g_1 \in \mathrm{G}(s^{\mathrm{c}})$ and let Ψ be a function on $\mathrm{M}_{(\mathcal{R} \sqcup \mathcal{A}_j^- \sqcup \mathcal{A}_j^+) \times \mathcal{B}^{\mathrm{c}}}(\mathcal{O}_E/\mathfrak{M}^2)$, and put*

$$\theta_\Psi(x,g) = \theta^{S^{\mathrm{c}},\tilde{W}_j}_{\upsilon^m,\nu_j^\flat \upsilon^m;\mathfrak{M}^2}[\Psi, P_j](x,(g,1)) \qquad (x \in \mathrm{G}(s^{\mathrm{c}}),\ g \in \mathrm{G}(s_j)).$$

Then for every $g \in \mathrm{G}(s_j)$ the function $h \mapsto \varphi^\circ(g_1(h,1))\,\theta_\Psi(g_1(h,1),g)\,m^{\mathrm{hol}}_{s^{\mathrm{c}},u_1}(h)$ is integrable on $G_\infty(s^{\mathrm{c}})$, and there are numbers $(c_i)_{i \in \mathrm{Mem}_j}$, independent of g, with

$$\sum_{i \in \mathrm{Mem}_j} c_i\,\mathsf{F}_i(g) = \int_{G_\infty(s^{\mathrm{c}})} \varphi^\circ(g_1(h,1))\,\theta_\Psi(g_1(h,1),g)\,m^{\mathrm{hol}}_{s^{\mathrm{c}},u_1}(h)\,dh \qquad (g \in \mathrm{G}(s_j)).$$

Proof. Let o be the order on $\mathcal{B}^{\mathrm{c}}$ with $o((1,a)) = -a$, $o((2,a)) = a-1$; it is injective and positive-first for s.

Step 0: the carrier, the model function and the kernel. The character χ_M is tame of weight 0 for $(\mathfrak{M},\chi)$, χ the character of $\mathcal{O}_E/\mathfrak{M}$ given by its tame part on units. So by (b) of Lemma 6.6.62, φ° is continuous, left invariant under $\Gamma_{S^{\mathrm{c}}}$, right invariant under $\mathbf{K}_0(\mathcal{B}^{\mathrm{c}})$, and $|\varphi^\circ|\,\mathrm{ht}^B_{S^{\mathrm{c}}}$ is bounded for every B. The weights u_1 and $u_3(\tau)$ of Lemma 6.6.66 are K-dominant for (s,o) with holomorphic gap $300n_*$ and $|u_3(\tau)(b')| \le 5b$ ((c) there), and $3m \le t$ ((AD2) of Definition 2.3.4); so Lemma 6.6.68 with $u = u_3$, $u' = u_1$ gives $\int |m_1(h)|\,|h|^{6n_*}dh < \infty$, and since $|h| \ge 1$ there, m_1 is integrable. By (a) of Lemma 6.6.66, $\beta = \nu_j^\flat \upsilon^m$ has trivial tame part, and υ^m has weight m and trivial tame part. Fix $g \in \mathrm{G}(s_j)$ and put $\psi_g(x) = \varphi^\circ(x)\,\theta_\Psi(x,g)$ on $\mathrm{G}(s)$. Then ψ_g is of level $\mathfrak{n}$: it is continuous ((2) of Lemma 4.1.1, the theta functional being bounded) and left invariant under $\Gamma_{S^{\mathrm{c}}}$ (Lemma 6.2.5); for $k \in \mathbf{K}_{\mathcal{B}^{\mathrm{c}}}(\mathfrak{n})$, (6) of Lemma 4.1.1 gives $\omega((1,k),1)\mathrm{mod}_{\mathfrak{n}}(\Psi, v_{P_j}) = \beta(\det k)^{-1}\mathrm{mod}_{\mathfrak{n}}(\Psi_{k,1}, v_{P_j}) = \mathrm{mod}_{\mathfrak{n}}(\Psi, v_{P_j})$, as $\bar{k} = 1$ and $\beta(\det k) = 1$ (Definition 3.1.1), so $\theta_\Psi(x(1,k),g) = \theta_\Psi(x,g)$, and φ° is invariant too; and by Lemma 6.2.28 there are Y, A with $|\theta_\Psi(x,g)| \le Y'\,\mathrm{ht}_{S^{\mathrm{c}}}(x)^A$, Y' depending on g, so $|\psi_g|\,\mathrm{ht}^M_{S^{\mathrm{c}}} \le Y'|\varphi^\circ|\,\mathrm{ht}^{M+A}_{S^{\mathrm{c}}}$ is bounded.

Step 1: the reproducing formula on $(S^{\mathrm{c}}, W^\flat)$. Fix an injective $e\colon \mathcal{B}^{\mathrm{c}} \to \mathcal{B}^\flat$ ($3m \le 6m+1$) and let $p = \{(1,a) : 1 \le a \le 2m\}$, q the second block, $i = e|_p$, $d = \Delta'$, and

$$Q_0 = \prod_{\tau \in \Phi} \det\big((X_{\tau,e(1,a),(1,a')})_{1 \le a,a' \le 2m}\big)^{\Delta'}.$$

By Lemma 6.6.65 (signs $+1$ on p, -1 on q, $n' = \mathcal{B}^\flat$), $Q_0 \ne 0$ and for every bounded linear functional ℓ on $\mathcal{F}_{S^{\mathrm{c}},W^\flat}$ the function $x \mapsto \ell(\Omega_{0,0}(x,1)v_{Q_0})$ is holomorphic of weight $u_{\Delta'} = (-\Delta';\,6m+1) = u_1$ for o; as $\Omega_{m,0}(x,1) = \Omega_{0,0}(x,1)$ (the weight m multiplies by $\det 1$), the hypothesis of Lemma 6.6.53 on Q_0 holds for $(\gamma',\gamma) = (m,0)$. The weights u_1 are constant on each block, hence K-dominant. $\mathfrak{n} = \pi_M^2\mathcal{O}_E$ is a modulus with a generator, $2\#\mathcal{B}^{\mathrm{c}} = 6m < 6m+1$, and $\mathbf{K}_{\mathfrak{n}}[\{1\}] = \mathbf{K}_{\mathcal{B}^\flat}(\mathfrak{n})$, so the classes of Lemma 6.6.53 are $\mathrm{Cl}^\flat$ with the representatives $x_{\mathfrak{c}}$.

Step 2: the span. Let $\mathfrak{c} \in \mathrm{Cl}^\flat$, $Y_{\mathfrak{c}} \in \mathrm{GL}_{\mathcal{B}^\flat}(E)$ the matrix of the short row family, and $y \in G_\infty(1_{\mathcal{B}^\flat})$. By the second formula of (5) of Lemma 4.1.1 (the point 1 of $G_\infty(s)$ and y are block diagonal, all signs of $W^\flat$ being $+1$), $\Omega_{m,0}(1,y)v_{Q_0}$ is a scalar times $v_{Q_0'}$, where Q_0' is Q_0 after the substitution $X_{\tau,a,b} \mapsto \sum_{c \in \mathcal{B}^\flat}(y_\tau)_{ca}X_{\tau,c,b}$ of the variables with b in the positive block (the only ones in Q_0). So the matrix $(X_{\tau,e(1,a),(1,a')})_{a,a'}$ becomes $N_\tau X_\tau$, where $X_\tau = (X_{\tau,c,(1,a')})_{c \in \mathcal{B}^\flat,a'}$

and N_τ is the $2m \times \mathcal{B}^\flat$ matrix whose row a is the row $e(1,a)$ of y_τ^{T}. As $\tau(Y_{\mathfrak{c}})$ is invertible, $N_\tau = M_\tau\,\tau(Y_{\mathfrak{c}})$ with $M_\tau = N_\tau\tau(Y_{\mathfrak{c}})^{-1}$, and multilinearity of the determinant in the rows gives

$$\det(N_\tau X_\tau) = \sum_{r\colon \{1,\dots,2m\}\to\mathcal{B}^\flat} \Big(\prod_a (M_\tau)_{a,r(a)}\Big)\det\big(\tau(Y_{\mathfrak{c}})[r]\,X_\tau\big),$$

$\tau(Y_{\mathfrak{c}})[r]$ the matrix whose row a is the row $r(a)$ of $\tau(Y_{\mathfrak{c}})$. Expanding the product over τ and the Δ' factors, Q_0' is a linear combination of the polynomials $Q_{\mathfrak{c},\lambda} = \prod_\tau \prod_{k=1}^{\Delta'} \det(\tau(Y_{\mathfrak{c}})[\lambda_\tau(k,\cdot)]X_\tau)$, $\lambda = (\lambda_\tau)$ running over the families of maps $\lambda_\tau\colon \{1,\dots,\Delta'\}\times\{1,\dots,2m\}\to\mathcal{B}^\flat$. These form a finite set ι, and $Q_{\mathfrak{c},\lambda}$ is the flat determinant product $P_i^\flat$ of every choice $i=(\Lambda,\mathfrak{c},\lambda)$, read with the rows $\mathcal{B}^\flat$. So the span hypothesis of Lemma 6.6.53 holds, and with Step 1 that lemma gives numbers $a_{\mathfrak{c},\lambda}$, depending only on g_1, such that for every g the function $h\mapsto \psi_g(g_1(h,1))m_1(h)$ is integrable and

$$\int_{G_\infty(s)} \psi_g(g_1(h,1))\,m_1(h)\,dh = \sum_{\mathfrak{c},\lambda} a_{\mathfrak{c},\lambda}\int_{[\mathrm{U}(S^{\mathrm{c}})]} \psi_g(x)\,\theta_2^{\mathfrak{c},\lambda}(x)\,dx,$$

the right-hand integrands being integrable.

Step 3: the product of the kernels and the Fourier expansion. By (a) of Lemma 6.3.80 (target spaces $\tilde W_j$ and $W^\flat$, rows $\mathcal{R}\sqcup\mathcal{A}_j^-\sqcup\mathcal{A}_j^+$ and $\mathcal{B}^\flat$) and (d) of Lemma 6.3.52 ($\alpha=\upsilon^m$, $\beta=\nu_j^\flat\upsilon^m$, $\beta'=1$), for $x\in\mathrm{G}(s)$

$$\theta_\Psi(x,g)\,\theta_2^{\mathfrak{c},\lambda}(x) = \theta^{S^{\mathrm{c}},W_j'}_{\upsilon^m,\nu_j^\flat\upsilon^m;\mathfrak{n}}\big[\Psi\otimes\delta_e,\ P_jQ_{\mathfrak{c},\lambda}\big](x,(g,1,x_{\mathfrak{c}})).$$

The function $\Psi\otimes\delta_e$ lives on the finite abelian group $G=\mathrm{M}_{\mathcal{B}_j\times\mathcal{B}^{\mathrm{c}}}(R)$. The map $\Lambda\mapsto\psi_\Lambda$ from $\mathrm{M}_{\mathcal{B}^{\mathrm{c}}\times\mathcal{B}_j}(R)$ to the characters of G is a homomorphism; it is injective: if $\psi_\Lambda=1$, then taking y with the single entry t at (b,a) gives $\psi_{\mathfrak{n}}(t\Lambda_{ab})=1$ for all $t\in R$, and $\psi_{\mathfrak{n}}$ is primitive: if $a'\in\widehat{\mathcal{O}}_E$ and $\psi_{E,f}(\jmath\alpha\bar\alpha\varpi_{\mathfrak{n}}^{-1}a't)=1$ for all $t\in\widehat{\mathcal{O}}_E$, then $\overline{\varpi_{\mathfrak{n}}^{-1}a'}$ lies in the annihilator of $\widehat{\mathcal{O}}_E$ under $(u,v)\mapsto\psi_{E,f}(\jmath\alpha\bar\alpha\bar uv)$, which is $\widehat{\mathcal{O}}_E$ (Lemma 4.1.3), so $a'\in\varpi_{\mathfrak{n}}\widehat{\mathcal{O}}_E$, i.e. $a'\equiv 0$ modulo $\mathfrak{n}$. Both groups have the same order, so every character of G is some ψ_Λ, and the characters of a finite abelian group span the functions on it: $\Psi\otimes\delta_e=\sum_\Lambda f(\Lambda)\psi_\Lambda$ for some numbers $f(\Lambda)$. As the datum $\mathrm{mod}_{\mathfrak{n}}(\Phi,v)$ and the theta kernel are linear in Φ,

$$\theta_\Psi(x,g)\,\theta_2^{\mathfrak{c},\lambda}(x) = \sum_\Lambda f(\Lambda)\,\theta^{S^{\mathrm{c}},W_j'}_{\upsilon^m,\nu_j^\flat\upsilon^m;\mathfrak{n}}\big[\psi_\Lambda,P_jP^\flat_{(\Lambda,\mathfrak{c},\lambda)}\big](x,(g,1,x_{\mathfrak{c}})).$$

Each term times φ° is integrable on $[\mathrm{U}(S^{\mathrm{c}})]$ (bounded by Step 0's argument and Lemma 6.2.28; finite volume, Theorem 4.2.18), and by (XE5) its integral is $\mathsf{F}_{(\Lambda,\mathfrak{c},\lambda)}(g)$. Hence $\int\psi_g\,\theta_2^{\mathfrak{c},\lambda} = \sum_\Lambda f(\Lambda)\,\mathsf{F}_{(\Lambda,\mathfrak{c},\lambda)}(g)$.

Step 4: conclusion. Since $\psi_g(g_1(h,1))m_1(h)=\varphi^\circ(g_1(h,1))\theta_\Psi(g_1(h,1),g)m^{\mathrm{hol}}_{s^{\mathrm{c}},u_1}(h)$, Steps 2 and 3 give the integrability and the identity with $c_i=a_{\mathfrak{c}_i,\lambda_i}f(\Lambda_i)$ for $i=(\Lambda_i,\mathfrak{c}_i,\lambda_i)\in\mathrm{Mem}_j$; these depend on g_1 and Ψ but not on g. □

Lemma 6.6.80. *Let D be admissible data and $n_*=2ft^3$. Let n be a nonempty finite index set with $\#n\le t$, s signs on n, o a positive-first order for s, and $u=(u_v)_{v\in\Phi}$, $u'=(u'_v)_{v\in\Phi}$ weights such that every u_v and every u'_v is K-dominant for (s,o) and has holomorphic gap $300n_*$ for s, and $|u_v(i)|\le 5b$ for all v, i. For $h\in G_\infty(s)$ let $|h|=\max_{v\in\Phi}\|h_v\|$ (operator norms). Let $F\colon\mathrm{G}(s)\to\mathbb{C}$ be continuous, bounded and adelically holomorphic of weight u for o, let z be a peak of F, let $K_0\colon G_\infty(s)\to\mathbb{C}$ with $|K_0|\le C$ for some $C\ge 0$, and let $\delta\ge 0$. Assume that for*

every peak x of F there is a function $K\colon G_\infty(s)\to\mathbb{C}$, holomorphic of weight $u-u'$ for o, with $|K(h)-K_0(h)|\le\delta|h|^{6n_*}$ for all h and

$$\int_{G_\infty(s)}\overline{F(x\,(h,1))}\,K(h)\,m^{\mathrm{hol}}_{s,u'}(h)\,dh=0.$$

Then $|K_0(1)|\le(4b^{n_*}+1)\,\delta$.

Proof. Write $N=\#n$, $m_u=m^{\mathrm{hol}}_{s,u}$, $m_{u'}=m^{\mathrm{hol}}_{s,u'}$, and $\chi(\theta)=\prod_{v,i}e^{2\pi\mathrm{i}\theta o(i)u_v(i)}$.

Step 1: the integrals of the model functions. By Lemma 6.6.68, every $h\in G_\infty(s)$ has $|h|\ge1$, and

$$I:=\int_{G_\infty(s)}|m_u|^2\in(0,\infty),\qquad J:=\int_{G_\infty(s)}|m_{u'}(h)|\,|h|^{6n_*}dh\le b^{n_*}I<\infty.\tag{6.160}$$

Step 2: rotated peaks. For $g\in\mathrm{G}(s)$ the function $\varphi_g(h)=F(g(h,1))$ is holomorphic of weight u for o. For a family e of diagonal matrices with entries of modulus 1 and $h\in G_\infty(s)$, (HV3) at he with the family 1 and at h with the family e gives $\varphi_g(he)=\tilde\varphi_g(he)=e^u\varphi_g(h)$. So $F(z(d(\theta),1))=\chi(\theta)F(z)$ and $|F(z(d(\theta),1))|=|F(z)|$: every $z_\theta=z(d(\theta),1)$ is a peak. Since $|F(z)|>\frac12\sup|F|\ge0$, $F(z)\ne0$. For each $\theta\in\mathbb{R}/\mathbb{Z}$ let K_θ be a function given by the hypothesis for $x=z_\theta$, and put

$$W_\theta(h)=\overline{F(z(d(\theta)h,1))\chi(\theta)^{-1}},\qquad f=K_0'\,m_{u'},\quad K_0':=K_{\theta=0}.$$

Then $|W_\theta(h)|\le\sup|F|<2|F(z)|$; $(\theta,h)\mapsto W_\theta(h)$ is continuous; and since $z_\theta(h,1)=z(d(\theta)h,1)$, the hypothesis for z_θ gives $\int W_\theta K_\theta m_{u'}=\overline{\chi(\theta)^{-1}}\cdot0=0$.

Step 3: integrability. The functions K_θ, $m_{u'}$ are continuous (restrictions of functions analytic at every point of $G_\infty(s)$). As $|h|\ge1$, $|K_0'(h)|\le C+\delta|h|^{6n_*}\le(C+\delta)|h|^{6n_*}$, so f is integrable by (6.160), and $(\theta,h)\mapsto f(h)W_\theta(h)$ is integrable on $\mathbb{R}/\mathbb{Z}\times G_\infty(s)$, being dominated by $2|F(z)||f(h)|$. The function f is holomorphic of weight u for o: if $\tilde K$, $\tilde m$ are extensions of K_0', $m_{u'}$ as in (HV3) ((i) of Lemma 6.6.70), $\tilde K\tilde m$ is analytic at hb with value $b^{u-u'}K_0'(h)\,b^{u'}m_{u'}(h)=b^uf(h)$.

Step 4: each rotation is small. For every θ, by Step 2, $\int fW_\theta=\int(K_0'-K_\theta)\,m_{u'}\,W_\theta$, and $|K_0'-K_\theta|\le|K_0'-K_0|+|K_0-K_\theta|\le2\delta|h|^{6n_*}$; so by (6.160)

$$\Big|\int_{G_\infty(s)}f\,W_\theta\Big|\le2\delta\cdot2|F(z)|\cdot J\le4\delta\,|F(z)|\,b^{n_*}I.$$

Step 5: the mean over the rotations. By Lemma 6.6.72 for φ_z (with $\varphi_z(1)=F(z)$), $\int_{\mathbb{R}/\mathbb{Z}}W_\theta(h)\,d\theta=\overline{m_u(h)F(z)}$. By Fubini (Step 3), $h\mapsto f(h)\overline{m_u(h)}\,\overline{F(z)}$ is integrable, hence so is $f\overline{m_u}$ ($F(z)\ne0$), and

$$\int_{\mathbb{R}/\mathbb{Z}}\int_{G_\infty(s)}f\,W_\theta\,dh\,d\theta=\overline{F(z)}\int_{G_\infty(s)}f\,\overline{m_u}=\overline{F(z)}\,f(1)\,I$$

by Lemma 6.6.71. With Step 4, $|F(z)|\,|f(1)|\,I\le4\delta|F(z)|b^{n_*}I$, and as $|F(z)|I>0$ and $f(1)=K_0'(1)m_{u'}(1)=K_0'(1)$ ((i) of Lemma 6.6.70), $|K_0'(1)|\le4\delta b^{n_*}$.

Step 6: conclusion. $|1|=1$, so $|K_0(1)|\le|K_0'(1)|+|K_0'(1)-K_0(1)|\le4\delta b^{n_*}+\delta$. □

The last group proves that the periods of false lifts vanish (Proposition 6.6.81): a form of a descent pair that is killed by the hyperplane sums at the chosen places, by its normalised descent and by the Hecke polynomial at the lift root at one split place has vanishing theta

periods over a complementary definite block. The proof climbs a Witt tower. At the bottom, the vanishing of the normalised descent spreads to all data that are the vacuum off the level places (Lemma 6.6.84). The tower step (Lemma 6.6.86) passes vanishing to the space plus a hyperbolic plane: the descents there are bounded (Lemma 6.6.87) and killed by a transferred Hecke polynomial with a small root, and a bounded spherical function killed by such a polynomial vanishes (Lemma 6.6.89); in our reading this is the trivial bound for Satake parameters [248, 109], used in the contrapositive. At the top, vanishing descents kill the periods (Lemma 6.6.90). In our reading the argument is a vanishing counterpart of the tower property (Proposition 6.2.2); for Rallis's towers and the injectivity of theta liftings see [236, 237], and for the convergence of theta integrals over definite groups [323].

Proposition 6.6.81. *Let O be a descent pair with ranks $1 \le r < n$ that fits a parameter, $W = W(O)$, $\Sigma = S_O \cup \bar{S}_O$ and $\xi_O = v^+_{l_O}$. Let $\Xi \in \mathrm{Form}(O)$, and suppose that $\psi_{O,w} \neq 1$ for every $w \in Q_O$; that $\sum_{s \in H(\lambda)} \psi_{O,w}(\det s)^{-1}[s]_w \Xi = 0$ for every $w \in M_O$ and every nonzero row $\lambda \in k_w^r$; that $\mathrm{Th}_O(\Xi) = 0$; and that $\overline{H_w(X_*(w))}\,\Xi = 0$ for some finite place w with $w \neq \bar{w}$ and $w, \bar{w} \notin S_O$. For $\zeta \in \mathbb{V}_O$ put $Y_\zeta(h) = \overline{\langle \zeta, \rho_{\kappa_O,e_O}(h_\infty)^{-1}\Xi(h_f)\rangle_{\kappa_O}}$ on $\mathrm{G}(1_n)$. Let $\{1,\dots,n\} = N \sqcup l$ with $2r+2\#N+3 < n$, $\mathrm{I}_n = \mathrm{I}_N \oplus \mathrm{I}_l$, and $\iota\colon \mathrm{G}(1_N)\times\mathrm{G}(1_l) \to \mathrm{G}(1_n)$ the block-diagonal embedding. Then*

$$\int_{[\mathrm{U}(\mathrm{I}_l)]} \theta^{W,\mathrm{I}_l}_{\chi_O,b}(\varphi)(g,h_2)\, Y_\zeta\big(\iota(h_1,h_2)\,(1,\gamma)\big)\, dh_2 = 0$$

for every $\zeta \in \mathbb{V}_O$, every automorphic character b of $\mathrm{U}(1)$, every datum $\varphi \in \mathcal{M}_{W,\mathrm{I}_l}$ that is the vacuum at the finite places outside Σ, every $g \in \mathrm{G}(\varepsilon_O)$, every $h_1 \in \mathrm{G}(1_N)$ and every $\gamma \in G_f(n)$ whose components outside Σ are 1.

Proof. Write $\rho = \rho_{\kappa_O,e_O}$ and $\langle\,,\rangle = \langle\,,\rangle_{\kappa_O}$. Every Y_ζ is continuous, left invariant under the rational points of $\mathrm{U}(\mathrm{I}_n)$ (by (DP3) and (DP5), $\Xi(\gamma_f h_f) = \rho(\gamma_\infty)\Xi(h_f)$), and right invariant under every $k \in \mathbf{K}_0(n)$ whose components at Σ are 1: such a k has reductions 1 at S_O, so $k \in \mathbf{K}(O)$ with $\tilde{\eta}_O(k) = 1$ and $\Xi(h_f k) = \Xi(h_f)$. In particular Y_ζ is right invariant under an open subgroup of $G_f(n)$. Since $\langle\,,\rangle$ is conjugate-linear in its first argument, $\zeta \mapsto Y_\zeta(h)$ is linear.

Vanishing descents to W. Put $Y_0 = Y_{\xi_O}$. By Lemma 6.6.82 (O has rank $r \ge 1$ and fits a parameter), the descent D_{χ_O} of Y_0 to W vanishes on $v_P \otimes \Upsilon(O)$ for every polynomial P. This is (VT3) of Lemma 6.6.84 for the linear form $L = \langle \xi_O, \cdot\rangle$, for which the function Y there is Y_0; (VT1) and (VT2) are hypotheses. By Lemma 6.6.84, $D_{\chi_O}(\varphi) = 0$ for every datum φ on $\mathrm{Hom}(W, \mathrm{I}_n)$ that is the vacuum at the finite places outside Σ: the descents of Y_0 to W twisted by χ_O vanish off Σ.

The Hecke equation of Y_0. Let w be the place of the hypothesis, $q = \mathrm{N}w$ and $X = \overline{X_*(w)}$. For $\gamma' \in \mathrm{GL}_n(\mathcal{O}_{E,w})$ the element $\iota_w(\gamma')$ of $G_f(n)$ (component γ' at w, the forced component at $\bar{w}$, 1 elsewhere) lies in $\mathbf{K}_0(n)$ and has components 1 at Σ, as $w, \bar{w} \notin S_O$; so Y_0 is right invariant under $K_w = \iota_w(\mathrm{GL}_n(\mathcal{O}_{E,w}))$. The operators $T_{w,i}$ of (DP10) are the sums of right translates of Lemma 6.6.89; taking the coefficient $\langle \xi_O, \rho(h_\infty)^{-1}\cdot\rangle$ (linear, and it commutes with right translation by finite elements) and then complex conjugates (the coefficients $q^{i(i-1)/2}$ are real) turns $H_w(X_*(w))\Xi = 0$ into

$$\sum_{i=0}^{n} (-X)^i q^{\binom{i}{2}}\, T_{w,i} Y_0 = 0, \qquad \text{i.e.} \quad H^{\mathrm{I}_n}_w(X)\, Y_0 = 0.$$

By (DP10), $X_*(w) = (\chi_{O,w}\{r\}\, q^{n-r-1})^{-1}$ with $\chi_{O,w}\{r\} = \chi_O[r](\varpi_w)\, q^{r/2}$, and $|\chi_O[r](\varpi_w)| = 1$, so $|X| = (q^{r/2}q^{n-r-1})^{-1}$. The base change of υ is unramified at $\bar{w}$: for a unit u of $E_{\bar{w}}$, read as an idele with components 1 elsewhere, $u/\bar{u}$ has unit finite components and infinite components 1,

so $\upsilon(u/\bar{u}) = 1$ by (WD3); hence the base change of $\chi_O = \upsilon^{r_-(O)}$ is unramified at $\bar{w}$ too. Finally $w \notin \Sigma$, $w \neq \bar{w}$, and $2r + 2\#N + 3 < n$.

Vanishing descents to $W \oplus \mathbb{H}^{\#N}$. By Lemma 6.6.86, applied to W (of rank r), $c = \#N$, $V = \mathrm{I}_n$, $\nu = \chi_O$, $\Sigma_0 = S_O$, the function Y_0, the place w and the number X (its hypotheses were checked in the two previous paragraphs), the descents of Y_0 to $U = W \oplus \mathbb{H}^{\#N}$ twisted by $a = \chi_O \upsilon^{\#N}$ vanish off Σ.

Translations preserve vanishing descents. Let Y' be continuous on $\mathrm{G}(1_n)$, left invariant under the rational points and right invariant under an open subgroup, with descents to U twisted by a vanishing off Σ, and let $x \in \mathrm{G}(1_n)$ have finite components 1 outside Σ. Then the descents of $Y'_x = Y'(\cdot\, x)$ to U twisted by a vanish off Σ. Indeed, by the right invariance of the measure on $[\mathrm{U}(\mathrm{I}_n)]$ and since $\omega_{a,1}$ is a representation ((2) of Lemma 4.1.1), the descent of Y'_x by φ is the descent of Y' by $\varphi' = \omega_{a,1}(1, x^{-1})\varphi$. If φ is the vacuum at the finite places outside Σ, so is φ': for an integral finite adelic z with $z_v = 0$ for $v \in \Sigma$, $\rho_f(z)$ is a scalar times $\rho(\mathrm{fv}(z))$, $\mathrm{fv}(z)$ has infinite component 0 and finite components 0 at Σ, so the element $(1, x^{-1})$ of the pair, acting on $\mathrm{Hom}(U, \mathrm{I}_n)$ by left multiplication, fixes $\mathrm{fv}(z)$; by (2) of Lemma 4.1.1, $\omega_{a,1}(1, x^{-1})$ commutes with $\rho(\mathrm{fv}(z))$, hence $\rho_f(z)\varphi' = \omega_{a,1}(1, x^{-1})\rho_f(z)\varphi = \varphi'$.

Vanishing descents of every Y_ζ and of its translates. For $x \in G_\infty(1_n) = \prod_\tau \mathrm{U}(n)$ let $\pi(x)$ be the adjoint of $\rho(x)^{-1}$ for the positive definite form $\langle\,,\rangle$; then π is a representation of $G_\infty(1_n)$ on $\mathbb{V}_O$, and $Y_\zeta(h(x,1)) = \overline{\langle \rho(x)^{-1\,*}\zeta, \rho(h_\infty)^{-1}\Xi(h_f)\rangle}$ with $\rho(x)^{-1\,*} = \pi(x)$, i.e. $Y_0(\cdot\,(x,1)) = Y_{\pi(x)\xi_O}$. By the previous paragraph and linearity in ζ, the descents of Y_ζ to U twisted by a vanish off Σ for every ζ in the span of $\{\pi(x)\xi_O\}$. This span is $\mathbb{V}_O$: it is a nonzero π-invariant subspace ($\xi_O = \mathrm{ev}_{\kappa_O}(y^{l_O}) \neq 0$: y^{l_O} has in row a at τ a single entry 1, in the column $c_\tau(a) = \#\{a' : l_{O,\tau}(a') > l_{O,\tau}(a)\}$, and c_τ is a bijection onto $\{0, \dots, n-1\}$ as $l_{O,\tau}$ is injective; for the column filling with $T(\tau, h, j) = \{a : c_\tau(a) < h\}$ each factor of Δ_T at y^{l_O} is the determinant of a permutation matrix, so $\Delta_T(y^{l_O}) = \pm 1$, and Δ_T is an integral combination of the standard basis (b_i), so some $b_i(y^{l_O}) \neq 0$), its orthogonal complement is ρ-invariant, and $\mathbb{V}_O$ is irreducible under $\rho(G_\infty(1_n))$ (the Weyl module of weight κ_O is an irreducible polynomial representation of $\prod_\tau \mathrm{GL}_n(\mathbb{C})$, the twist by $\det^{e_O}$ and complex conjugation of the matrices do not change invariant subspaces, and $\prod_\tau \mathrm{U}(n)$ is Zariski dense in $\prod_\tau \mathrm{GL}_n(\mathbb{C})$). Applying the previous paragraph once more with $x = (1, \gamma)$, the descents of $Y_\zeta(\cdot\,(1,\gamma))$ to U twisted by a vanish off Σ, for every ζ and every $\gamma \in G_f(n)$ with components 1 outside Σ.

The periods. Fix ζ, γ and let $Y = Y_\zeta(\cdot\,(1,\gamma))$. It is continuous and left invariant under the rational points, and right invariant under every $k \in \mathbf{K}_0(n)$ with components 1 at Σ, because such k commutes with $(1,\gamma)$ (their nontrivial finite components lie at disjoint sets of places) and fixes Y_ζ. The character $a' = \chi_O = \upsilon^{r_-(O)}$ satisfies $a'(\det k) = 1$ for every $k \in \mathbf{K}_0(n)$: $\det k$ has unit finite components and infinite components 1, so $\upsilon(\det k) = 1$ by (WD3). By Lemma 6.6.90, applied to W, $N \sqcup l$, a' (so that $a'\upsilon^{\#N} = a$), $A = S_O$ and this Y, the integral of the statement vanishes for every b, φ, g and h_1 as there. □

Lemma 6.6.82. *Let O be a descent pair with ranks $1 \leq r < n$ that fits a parameter, $W = W(O)$ and $\xi_O = v^+_{l_O}$. Let $\Xi \in \mathrm{Form}(O)$ with $\mathrm{Th}_O(\Xi) = 0$, and let*

$$Y_0(h) = \overline{\langle \xi_O,\ \rho_{\kappa_O, e_O}(h_\infty)^{-1}\, \Xi(h_f)\rangle_{\kappa_O}} \qquad (h = (h_\infty, h_f) \in \mathrm{U}(\mathrm{I}_n)(\mathbb{A}_F)).$$

Then the descent D_{χ_O} of Y_0 to W vanishes on $v_P \otimes \Upsilon(O)$ for every polynomial P in the Fock variables of $\mathrm{Hom}(W, \mathrm{I}_n)$.

Proof. Let l be a parameter that fits O, $\Phi = v_{\mathrm{Har}_O(\xi_O)}$, $\Upsilon = \Upsilon(O)$, and $\gamma(\tau) = r_-(O)$, $\gamma'(\tau) = \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau)$ the weights of $\chi_O = \upsilon^{r_-(O)}$ and $\chi'_O = \mu_O \upsilon^{\lfloor n/2 \rfloor}$ (υ has weight 1).

The theta kernel. For $h \in \mathrm{G}(1_n)$ and $u \in \mathrm{G}(\varepsilon_O)$ put $\omega'(h,u) = \omega_O(u,h)$. Then (ω', θ_O) is a theta kernel for (I_n, W) on $\mathrm{Hom}(W, \mathrm{I}_n)$ in the sense of (ED3): ω' is a homomorphism with $(p,\varphi) \mapsto \omega'(p)\varphi$ continuous by (2) of Lemma 4.1.1, θ_O is a bounded linear functional, and $\theta_O(\omega'(\gamma h, \gamma' u)\varphi) = \theta_O(\omega'(h,u)\varphi)$ for rational points γ, γ' by Lemma 6.2.5. By (5) of Lemma 4.1.1 (with $\alpha = \chi_O$ of weight γ and $\beta = \chi'_O$ of weight γ'), $\omega'((y,1),(x,1))(v \otimes f) = (\Omega_{\gamma,\gamma'}(x,y)v) \otimes f$ for $y \in G_\infty(1_n)$, $x \in G_\infty(\varepsilon_O)$: the kernel has real part $(y,x) \mapsto \Omega_{\gamma,\gamma'}(x,y)$. Its lift (ED3) of a function F on $\mathrm{G}(1_n)$ with datum φ is

$$L_\varphi F(u) = \int_{[\mathrm{U}(\mathrm{I}_n)]} \theta^{W,\mathrm{I}_n}_{\chi_O,\chi'_O}(\varphi)(u,h)\, F(h)\, dh.$$

The harmonic descent vanishes. By (DP8), $\mathrm{J}_O(\xi_O) = \Phi \otimes \Upsilon$. By (2) of Lemma 6.6.83 (its function Y_Ξ is Y_0), $0 = \mathrm{Th}_O(\Xi)(u) = c_O \overline{L_{\Phi\otimes\Upsilon} Y_0(u)}$ with $c_O > 0$, so $L_{\Phi\otimes\Upsilon} Y_0 = 0$.

Polynomial data. By Lemma 6.4.15(e), Φ is an edge for the weights (γ,γ') from $e_{l/2}$ to $e_{l_O/2}$; by (ED4) it is in particular a half edge for $(y,x) \mapsto \Omega_{\gamma,\gamma'}(x,y)$ from $\overline{e_{l_O/2}}$ to $\overline{e_{l/2}}$. By (1) of Lemma 6.6.83, Y_0 is a form of type $\overline{e_{l_O/2}}$ on I_n. Let P be a polynomial in the Fock variables of $\mathrm{Hom}(W, \mathrm{I}_n)$. By (d) of (ED4), for the spaces $(\mathrm{I}_n, W, \mathrm{Hom}(W,\mathrm{I}_n))$, the theta kernel (ω', θ_O), the vector Υ and the form Y_0, there is a continuous compactly supported a on $G_\infty(\varepsilon_O)$ with

$$L_{v_P\otimes\Upsilon} Y_0 = R(a)\, L_{\Phi\otimes\Upsilon} Y_0 = 0.$$

The character. By (WR4) of Definition 3.2.18, $\omega_{\chi_O,1}(u,h) = \chi'_O(\det u)\, \omega_{\chi_O,\chi'_O}(u,h)$, so $\theta^{W,\mathrm{I}_n}_{\chi_O,1}(\varphi)(u,h) = \chi'_O(\det u)\, \theta^{W,\mathrm{I}_n}_{\chi_O,\chi'_O}(\varphi)(u,h)$ and

$$D_{\chi_O}(v_P \otimes \Upsilon)(u) = \chi'_O(\det u)\, L_{v_P\otimes\Upsilon} Y_0(u) = 0 \qquad (u \in \mathrm{G}(\varepsilon_O)).$$

□

Lemma 6.6.83. *Let O be a descent pair with ranks $r < n$, $W = W(O)$, $\xi_O = v^+_{l_O}$, $\rho = \rho_{\kappa_O, e_O}$ and $\langle\,,\rangle = \langle\,,\rangle_{\kappa_O}$. For $\Xi \in \mathrm{Form}(O)$ let*

$$Y_\Xi(h) = \overline{\langle \xi_O,\ \rho(h_\infty)^{-1}\, \Xi(h_f)\rangle} \qquad (h = (h_\infty, h_f) \in \mathrm{G}(1_n)).$$

Then:

(1) Y_Ξ is a form of type $\overline{e_{l_O/2}}$ on I_n;

(2) there is $c_O > 0$, depending only on O, such that for every $\Xi \in \mathrm{Form}(O)$ and every $u \in \mathrm{G}(\varepsilon_O)$

$$\mathrm{Th}_O(\Xi)(u) = c_O \cdot \overline{\int_{[\mathrm{U}(\mathrm{I}_n)]} \theta^{W,\mathrm{I}_n}_{\chi_O,\chi'_O}(\mathrm{J}_O(\xi_O))(u,h)\, Y_\Xi(h)\, dh}\,.$$

Proof. Put $\kappa = \kappa_O$, $e = e_O$, $d = \#I_\kappa = \dim \mathbb{V}_O$, $S_O = M_O \cup Q_O$, and let $\gamma(\tau) = r_-(O)$, $\gamma'(\tau) = \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau)$; by (ii) of Lemma 3.2.11, υ has weight 1 at every $\tau \in \Phi$, so $\chi_O = \upsilon^{r_-(O)}$ and $\chi'_O = \mu_O \upsilon^{\lfloor n/2 \rfloor}$ have the weights γ and γ'. The matrices $S_\kappa(z)$ have entries in $\mathbb{Z}[z]$ (the minors of zy are integral combinations of those of y by the Cauchy–Binet formula, and (b_j) is a $\mathbb{Z}$-basis of ∇_κ), so $S_\kappa(\bar z) = \overline{S_\kappa(z)}$, and the same holds for $\kappa^\pm_O$. The highest vector $\xi_O = \mathrm{ev}_\kappa(y^{l_O})$ has integer entries, as y^{l_O} has entries 0 and 1; so $\bar\xi_O = \xi_O$. By the sidecalc of (DP11), l_O is a doubled Harish-Chandra parameter of (κ, e) for the index set $\{1,\dots,n\}$.

Step 1: real points act on the theta datum through ρ. We show, for $y \in G_\infty(1_n)$ and $\xi \in \mathbb{V}_O$,

$$\omega_O(1,(y,1))\, \mathrm{J}_O(\bar\xi) = \mathrm{J}_O\big(\overline{\rho(y)\xi}\big). \tag{6.161}$$

This is (a) of Lemma 6.6.31.

Step 2: the level acts on the theta datum through $\tilde{\eta}_O$. We show $\omega_O(1,(1,k))\mathrm{J}_O(\xi) = \tilde{\eta}_O(k)\,\mathrm{J}_O(\xi)$ for $k \in \mathbf{K}(O)$, $\xi \in \mathbb{V}_O$. This is (b) of Lemma 6.6.31.

Step 3: the integrand. Fix $\Xi \in \mathrm{Form}(O)$ and $u \in \mathrm{G}(\varepsilon_O)$. By (DP5), $\Xi(\gamma_f g k) = \tilde{\eta}_O(k)\rho(\gamma_\infty)\Xi(g)$ for $\gamma \in \Gamma$, $g \in G_f(n)$, $k \in \mathbf{K}(O)$; the group K_1 of the $k \in \mathbf{K}_0(n)$ with $\mathrm{red}_w k = 1$ for $w \in S_O$ is open, lies in $\mathbf{K}(O)$ and has $\tilde{\eta}_O(K_1) = 1$. So Ξ is an algebraic form of weight (κ, e) on $\{1,\dots,n\}$, and by unitarity (Lemma 4.6.10(c)) $\overline{Y_\Xi(y,g)} = \langle \xi_O, \rho(y)^{-1}\Xi(g)\rangle = F_\Xi^{l_O}(y,g)$. Let

$$f(y,g) = \overline{\theta^{W,\mathrm{I}_n}_{\chi_O,\chi_O'}(\mathrm{J}_O(\xi_O))(u,(y,g))}\; F_\Xi^{l_O}(y,g) \qquad ((y,g) \in \mathrm{G}(1_n)).$$

As $(u,(y,g)) = (u,(1,g))\cdot(1,(y,1))$, ω_O is a representation ((2) of Lemma 4.1.1), $\xi_O = \bar{\xi}_O$, and by (6.161) and (DP9),

$$\overline{\theta_O(\omega_O(u,(y,g))\mathrm{J}_O(\xi_O))} = \overline{\theta_O(\omega_O(u,(1,g))\mathrm{J}_O(\overline{\rho(y)\xi_O}))} = \mathcal{C}_O(u,g)(\rho(y)\xi_O),$$

so $f(y,g) = \mathcal{C}_O(u,g)(\rho(y)\xi_O)\,F_\Xi^{l_O}(y,g)$. The function f is continuous (the kernel by (2) of Lemma 4.1.1, θ_O being a bounded linear functional; $F_\Xi^{l_O}$ by (b) of Lemma 6.4.72) and left Γ-invariant (Lemma 6.2.5; (b) of Lemma 6.4.72). It is right invariant under $\mathbf{K}(O)$ in g: by Step 2, $f(y,gk) = \overline{\tilde{\eta}_O(k)}\,\tilde{\eta}_O(k)\,f(y,g) = f(y,g)$, as $|\tilde{\eta}_O(k)| = 1$ (the $\psi_{O,w}$ are characters of finite groups).

Step 4: integration over the real points. The Cayley measure of $G_\infty(1_n)$ is a probability measure (Lemma 5.5.21, at every τ). The linear form $\mathcal{C}_O(u,g)$ on the finite-dimensional space $\mathbb{V}_O$ commutes with the integral of the continuous function $y \mapsto F_\Xi^{l_O}(y,g)\rho(y)\xi_O$, so by (WM7) and (b) of Lemma 6.4.72,

$$\begin{aligned} H(g) := \int_{G_\infty(1_n)} f(y,g)\,dy &= \mathcal{C}_O(u,g)\Big(\int F_\Xi^{l_O}(y,g)\,\rho(y)\xi_O\,dy\Big) \\ &= \mathcal{C}_O(u,g)(d^{-1}(F_\Xi^{l_O})^\flat_{l_O}(g)) = d^{-1}\,\mathcal{C}_O(u,g)(\Xi(g)). \end{aligned}$$

Step 5: unfolding. By (2) of Lemma 6.4.74 for $V = \mathbb{C}$, $\mathrm{K} = \mathrm{K}' = \mathbf{K}(O)$ and $c_n = 1$, and then (1) of Lemma 6.4.74 with $\mathrm{K} = \mathrm{K}' = \mathbf{K}(O)$ (where $\Gamma_h' = \Gamma_f \cap h\mathbf{K}(O)h^{-1}$ is the group Γ_h of the class sum),

$$\begin{aligned} \int_{[\mathrm{U}(\mathrm{I}_n)]} f &= \frac{1}{[\mathbf{K}_0(n):\mathbf{K}(O)]}\sum_{[h]}\frac{H(h)}{\#\Gamma_h} \\ &= \frac{1}{d\,[\mathbf{K}_0(n):\mathbf{K}(O)]}\sum_{[h]}\frac{1}{\#\Gamma_h}\,\mathcal{C}_O(u,h)(\Xi(h)) = \frac{\mathrm{Th}_O(\Xi)(u)}{d\,[\mathbf{K}_0(n):\mathbf{K}(O)]} \end{aligned}$$

by (DP9). Since $f = \overline{\theta^{W,\mathrm{I}_n}_{\chi_O,\chi_O'}(\mathrm{J}_O(\xi_O))(u,\cdot)\,Y_\Xi}$, this is (2) with $c_O = d\,[\mathbf{K}_0(n):\mathbf{K}(O)]$, a positive integer depending only on O.

Step 6: (1). By Step 3, $F_\Xi^{l_O}$ is the function of an algebraic form of weight (κ,e), so it is a form of type $e_{l_O/2}$ on I_n by Lemma 6.4.70. Complex conjugation preserves continuity, boundedness, left Γ-invariance and right invariance under an open subgroup, $\overline{e_{l_O/2}}$ is integrable exactly when $e_{l_O/2}$ is, and $R(\overline{e_{l_O/2}})\overline{F} = \overline{R(e_{l_O/2})F} = \overline{F}$ for $F = F_\Xi^{l_O}$ ((ED2) of Definition 3.2.29). So $Y_\Xi = \overline{F_\Xi^{l_O}}$ is a form of type $\overline{e_{l_O/2}}$ on I_n. □

Lemma 6.6.84. *Let O be a descent pair with ranks $r < n$, $W = W(O)$ and $\Sigma = S_O \cup \bar{S}_O$. Let $\Xi \in \mathrm{Form}(O)$, let L be a linear form on $\mathbb{V}_O$, and let Y be the function on $\mathrm{G}(1_n) = \mathrm{U}(\mathrm{I}_n)(\mathbb{A}_F)$ given by*

$$Y(h) = \overline{L(\rho_{\kappa_O,e_O}(h_\infty)^{-1}\,\Xi(h_f))} \qquad (h = (h_\infty,h_f)).$$

For a place $w \in M_O$ and a nonzero row $\lambda \in k_w^r$ let $H(\lambda)$ be the group of the invertible matrices $s \in \mathrm{GL}_r(k_w)$ of the form $s = 1 + v\lambda$ with a column $v \in k_w^r$, and for $s \in \mathrm{GL}_r(k_w)$ let $[s]_w$ be the action on $\mathrm{Form}(O)$ of the element of $\mathrm{GL}_r^{\mathrm{ch}}(O)$ with component s at w and 1 at the other chosen places. Suppose:

(VT1) *$\psi_{O,w} \neq 1$ for every $w \in Q_O$;*

(VT2) *$\sum_{s \in H(\lambda)} \psi_{O,w}(\det s)^{-1}\,[s]_w \Xi = 0$ for every $w \in M_O$ and every nonzero row $\lambda \in k_w^r$;*

(VT3) *the descent D_{χ_O} of Y to W vanishes on $v_P \otimes \Upsilon(O)$ for every polynomial P in the Fock variables of $\mathrm{Hom}(W, \mathrm{I}_n)$.*

Then $D_{\chi_O}(\varphi) = 0$ for every datum $\varphi \in \mathcal{M}_{W,\mathrm{I}_n}$ that is the vacuum at the finite places outside Σ.

Proof. Write $S = S_O$, ϖ_w for the fixed uniformisers ($w \in S$), $\mathrm{Box}_m = \prod_{w \in S} \varpi_w^m \mathrm{M}_{n\times r}(\mathcal{O}_{E,w})$, and $C_m(x) = x + \mathrm{Box}_m$ for an $n \times r$ matrix x over $\prod_{w\in S} E_w$. All functions Ψ of finite adelic $n \times r$ matrices below depend only on the components at S; for $g \in \prod_{w\in S} \mathrm{GL}_n(E_w)$ and $a \in \prod_{w\in S} \mathrm{GL}_r(E_w)$ put $(g \cdot \Psi)(X) = \Psi(g^{-1}X)$ and $(\Psi \cdot a)(X) = \Psi(Xa)$. For $k \in G_f(n)$ and a function Ξ' on $G_f(n)$, $R(k)\Xi'(h) = \Xi'(hk)$. An element $g \in \prod_{w\in S} \mathrm{GL}_n(\mathcal{O}_{E,w})$ has a *lift* $k_g \in \mathbf{K}_0(n)$: the element with component g_w at $w \in S$, the component at $\bar{w}$ forced by $k^*k = 1$ (the conjugate of the inverse transpose of g_w, integral and invertible), and 1 elsewhere; this is possible because no place of S is conjugate to itself or to another (DP1). In the same way an element of $\prod_{w\in S} \mathrm{GL}_r(E_w)$ is the family of components at S of an element of $G_f(r)$ supported on Σ.

The function Y satisfies the hypotheses of Lemma 6.6.85. Let $K_1 \subseteq \mathbf{K}_0(n)$ be the open subgroup of the elements whose reductions at the places of S are 1. It lies in $\mathbf{K}(O)$ and $\tilde{\eta}_O = 1$ on it, so Ξ is right invariant under K_1 by (DP5); hence Ξ is locally constant and Y is continuous and right invariant under K_1. For a rational point γ, $\Xi(\gamma_f h_f) = \rho_{\kappa_O,e_O}(\gamma_\infty)\Xi(h_f)$ by (DP3) and (DP5), so $Y(\gamma h) = Y(h)$. Thus Lemma 6.6.85 applies with $V = \mathrm{I}_n$, $a = \chi_O$ and $A = S$ ($S \cap \bar{S} = \emptyset$ by (DP1)).

Fix a polynomial P and $u \in \mathrm{G}(\varepsilon_O)$. For $\Psi \in \mathcal{T}_S$ and a function $\Xi'\colon G_f(n) \to \mathbb{V}_O$ with $\Xi'(\gamma_f h) = \rho_{\kappa_O,e_O}(\gamma_\infty)\Xi'(h)$ for rational γ and right invariant under an open subgroup, let $Y_{\Xi'}$ be formed from Ξ' as Y from Ξ and

$$B(\Psi, \Xi') = \int_{[\mathrm{U}(\mathrm{I}_n)]} \theta^{W,\mathrm{I}_n}_{\chi_O,1}(v_P \otimes (\Psi \otimes_S v^0))(u,h)\, Y_{\Xi'}(h)\, dh.$$

It is linear in Ψ (the map $\Psi \mapsto \Psi \otimes_S v^0$ is linear by (WR6)) and conjugate-linear in Ξ'. By (ii) of Lemma 6.6.85, applied for all P and u, it suffices to show: for every x there is m_0 with $B(\mathbf{1}_{x,m}, \Xi) = 0$ for all $m \geq m_0$.

Translation by the level. Let $k \in \mathbf{K}_0(n)$ and $\Psi \in \mathcal{T}_S$. Then $k \cdot \Psi \in \mathcal{T}_S$, where k acts through its components at S, and

$$B(k \cdot \Psi, R(k)\Xi) = B(\Psi, \Xi). \tag{6.162}$$

Let $k' \in \mathbf{K}_0(n)$ have the components of k at $S \cup \bar{S}$ and 1 elsewhere (it is unitary because the condition $k^*k = 1$ couples only the components at w and $\bar{w}$). By (4) of Lemma 4.1.1 with $g = 1$, $h = k'$, and by (5) there, $\omega_{\chi_O,1}((1,1),(1,k'))(v_P \otimes (\Psi \otimes_S v^0)) = c\, v_P \otimes ((k \cdot \Psi) \otimes_S v^0)$ with $k \cdot \Psi \in \mathcal{T}_S$ and $c = \chi_O[r](\det_S k')\,|\det_S k'|^{-r/2}$. The idele $\det_S k'$ has unit components at S and 1 elsewhere; so $|\det_S k'| = 1$, and υ, hence $\chi_O = \upsilon^{r-(O)}$ and $\chi_O[r] = \tilde{\chi}_O \upsilon^{-r}$, is 1 on it

and on its quotient by its conjugate, by (WD3): $c = 1$. Since $\omega_{\chi_O,1}$ is a representation ((2) of Lemma 4.1.1) and the quotient measure of $[\mathrm{U}(\mathrm{I}_n)]$ is right invariant,

$$B(k\cdot\Psi,\Xi') = \int \theta\big(\omega(u,h(1,k'))\,v_P\otimes(\Psi\otimes_S v^0)\big)Y_{\Xi'}(h)\,dh = B\big(\Psi,R(k'^{-1})\Xi'\big)$$

for every admissible Ξ'; with $\Xi' = R(k')\Xi$ this is $B(k\cdot\Psi,R(k')\Xi) = B(\Psi,\Xi)$. Finally $k'^{-1}k \in \mathbf{K}_0(n)$ has reductions 1 at S, so it lies in $\mathbf{K}(O)$ with $\tilde\eta_O(k'^{-1}k) = 1$, and $R(k)\Xi = R(k')R(k'^{-1}k)\Xi = R(k')\Xi$ by (DP5). This proves (6.162).

Translates of the block function pair to zero. Let Φ_O be the function of (DP7), so that $\Upsilon(O) = \Phi_O\otimes_S v^0$, and let $a\in G_f(r)$ be supported on Σ. Then $\Phi_O\cdot a\in\mathcal{T}_S$ and $B(\Phi_O\cdot a,\Xi) = 0$. Indeed, by (4) of Lemma 4.1.1 with $g = a$, $h = 1$ (the character of $\mathrm{U}(W)$ is trivial) and by (5), $\omega_{\chi_O,1}((1,a),(1,1))(v_P\otimes\Upsilon(O)) = c_a\,v_P\otimes((\Phi_O\cdot a)\otimes_S v^0)$ with $\Phi_O\cdot a\in\mathcal{T}_S$ and $c_a = |\det_S a|^{n/2}\upsilon(\det_S a)^n\neq 0$. Hence, $\omega_{\chi_O,1}$ being a representation,

$$c_a\,B(\Phi_O\cdot a,\Xi) = \int_{[\mathrm{U}(\mathrm{I}_n)]}\theta^{W,\mathrm{I}_n}_{\chi_O,1}\big(v_P\otimes\Upsilon(O)\big)(u(1,a),h)\,Y(h)\,dh = D_{\chi_O}\big(v_P\otimes\Upsilon(O)\big)(u(1,a)) = 0$$

by (VT3).

The level group and the block function. Let J be the group of $g\in\prod_{w\in S}\mathrm{GL}_n(\mathcal{O}_{E,w})$ whose family of reductions lies in $\mathbf{L}(O)$, and $\eta(g) = \eta_O((g_w \bmod w)_w)$, a character of J with values of modulus 1. The lift k_g of $g\in J$ lies in $\mathbf{K}(O)$ and $\tilde\eta_O(k_g) = \eta(g)$, so $R(k_g)\Xi = \eta(g)\Xi$, and $k_g\cdot\Psi = g\cdot\Psi$. We show: for a as above and $g\in J$,

$$g\cdot(\Phi_O\cdot a) = \eta(g)\,(\Phi_O\cdot a). \tag{6.163}$$

Put $Z = Xa$. As $g_w\in\mathrm{GL}_n(\mathcal{O}_{E,w})$, $g^{-1}Z$ is integral at S if and only if Z is; both sides vanish otherwise. Let Z be integral with reductions $\bar Z_w$, and $\bar g_w$ the reductions of g. At $w\in M_O$, $\bar g_w\mathrm{Inc}_O = \mathrm{Inc}_O$, so $\bar g_w^{-1}\bar Z_w = \mathrm{Inc}_O$ if and only if $\bar Z_w = \mathrm{Inc}_O$. At $w\in Q_O$, $\bar g_w$ maps the span of the basis vectors outside the image of inc_O into itself (its entries in the inc-rows and the other columns vanish), hence so does $\bar g_w^{-1}$; therefore the inc-rows of $\bar g_w^{-1}\bar Z_w$ are the inc-block of $\bar g_w^{-1}$ times the inc-rows of $\bar Z_w$, and the inc-block of $\bar g_w^{-1}$ is the inverse of that of $\bar g_w$. So $\psi_{O,w}(\det(\text{inc-rows of }\bar g_w^{-1}\bar Z_w)) = \psi_{O,w}(\det(\text{inc-block of }\bar g_w))^{-1}\psi_{O,w}(\det(\text{inc-rows of }\bar Z_w))$ (both sides 0 if the last determinant is 0). Taking the product over Q_O, $\Phi_O(g^{-1}Z) = \eta(g)\Phi_O(Z)$, which is (6.163).

Moreover J is transitive on the support of Φ_O: if Z is integral at S with $\Phi_O(Z)\neq 0$, then $Z = g\,\mathrm{Inc}_O$ for some $g\in J$. Take $g_w = 1 + (Z_w - \mathrm{Inc}_O)\mathrm{Inc}_O^{\mathsf{T}}$: it sends the basis vector of index $\mathrm{inc}_O(c)$ to the column c of Z_w and fixes the other basis vectors, so $g_w\mathrm{Inc}_O = Z_w$; its determinant is that of the inc-rows Z'_w of Z_w. At $w\in M_O$, $\bar Z_w = \mathrm{Inc}_O$, so $\bar g_w = 1$; at $w\in Q_O$, $\psi_{O,w}(\det\bar Z'_w)\neq 0$ forces $\det\bar Z'_w\neq 0$, and the entries of g_w in the inc-rows and the other columns vanish. In both cases $g_w\in\mathrm{GL}_n(\mathcal{O}_{E,w})$ and $(\bar g_w)_w\in\mathbf{L}(O)$.

Points with an integral block ratio at every place. Say that x has an *integral block ratio* at $w\in S$ if the inc-rows x'_w of x_w form an invertible matrix and the matrix $x''_wx'^{-1}_w$, x''_w the other rows, has entries in $\mathcal{O}_{E,w}$, and in $\varpi_w\mathcal{O}_{E,w}$ if $w\in M_O$. Suppose this holds at every $w\in S$. Let $a\in G_f(r)$ be supported on Σ with $a_w = x'^{-1}_w$ at $w\in S$, and $\Psi_0 = \Phi_O\cdot a$. The matrix x_wa_w has inc-rows 1_r and other rows $x''_wx'^{-1}_w$; so xa is integral at S, reduces to Inc_O at M_O and has inc-rows 1_r at Q_O, and $\Psi_0(x) = 1$. Since $\Phi_O(Z)$ depends only on Z modulo Box_1, and $\mathrm{Box}_ma\subseteq\mathrm{Box}_1$ for m at least some m_1 (the a_w are fixed matrices), Ψ_0 is constant on $C_m(x)$, equal to 1, for $m\geq m_1$.

Fix $m\geq m_1$ and choose $N\geq 1$ such that $(g-1)x\in\mathrm{Box}_m$ for every $g\in\prod_{w\in S}\mathrm{GL}_n(\mathcal{O}_{E,w})$ with $g\equiv 1$ modulo ϖ_w^N at every $w\in S$. Let J_N be the normal subgroup of these g in J; it has

finite index, $\eta = 1$ on it, and $g \cdot \mathbf{1}_{x,m} = \mathbf{1}_{x,m}$ for $g \in J_N$ (as $g^{-1}(x + \mathrm{Box}_m) = g^{-1}x + \mathrm{Box}_m$). Put

$$\Psi_1 = \frac{1}{[J : J_N]} \sum_{g \in J/J_N} \overline{\eta(g)}\, g \cdot \mathbf{1}_{x,m}.$$

Each $g \cdot \mathbf{1}_{x,m} = \mathbf{1}_{gx,m}$ lies in $\mathcal{T}_S$ by (i) of Lemma 6.6.85, and by (6.162) with $k = k_g$ and conjugate-linearity, $\overline{\eta(g)}\, B(g \cdot \mathbf{1}_{x,m}, \Xi) = B(g \cdot \mathbf{1}_{x,m}, \eta(g)\Xi) = B(\mathbf{1}_{x,m}, \Xi)$. Hence $B(\Psi_1, \Xi) = B(\mathbf{1}_{x,m}, \Xi)$. We show $\Psi_1 = \Psi_1(\mathrm{Inc}_O a^{-1})\, \Psi_0$. Re-indexing the sum gives $g \cdot \Psi_1 = \eta(g)\Psi_1$ for $g \in J$. If $\Psi_1(X) \neq 0$, then $g^{-1}X \in C_m(x)$ for some $g \in J$, so $1 = \Psi_0(g^{-1}X) = (g \cdot \Psi_0)(X) = \eta(g)\Psi_0(X)$ by (6.163), and $\Psi_0(X) \neq 0$. If $\Psi_0(X) \neq 0$, then $\Phi_O(Xa) \neq 0$, so $Xa = g\,\mathrm{Inc}_O$ with $g \in J$ by transitivity, i.e. $X = g(\mathrm{Inc}_O a^{-1})$ at S; then $\Psi_1(X) = \eta(g)^{-1}\Psi_1(\mathrm{Inc}_O a^{-1})$ and $\Psi_0(X) = \eta(g)^{-1}\Psi_0(\mathrm{Inc}_O a^{-1}) = \eta(g)^{-1}$, as $\Phi_O(\mathrm{Inc}_O) = 1$. So the two functions are proportional, and $B(\mathbf{1}_{x,m}, \Xi) = \Psi_1(\mathrm{Inc}_O a^{-1})\, B(\Psi_0, \Xi) = 0$ by the previous paragraph but one. So $m_0 = m_1$ works.

An annihilating row where the block ratio is not integral. Suppose x has no integral block ratio at some $w_0 \in S$, and write $\mathcal{O} = \mathcal{O}_{E,w_0}$. Then there is a row $l \in \mathcal{O}^n$ with $l x_{w_0} = 0$, whose inc-part $\tilde{\lambda} = (l_{\mathrm{inc}_O(c)})_c$ has nonzero reduction $\lambda \in k_{w_0}^r$, and whose other entries lie in $\varpi_{w_0}\mathcal{O}$ if $w_0 \in Q_O$. If x'_{w_0} is singular, take a nonzero row μ with $\mu x'_{w_0} = 0$, scaled so that its largest entry has absolute value 1, and let l be μ at the inc-indices and 0 elsewhere. Otherwise let z_j be the row of $x''_{w_0} x'^{-1}_{w_0}$ of a row index j outside the image of inc_O, and $l^{(j)}$ the row with entry 1 at j, $-z_j$ at the inc-indices and 0 elsewhere; then $l^{(j)} x_{w_0} = 0$, as the row j of x_{w_0} is $z_j x'_{w_0}$. If some z_j has an entry of absolute value > 1, let c be one of largest absolute value and $l = c^{-1} l^{(j)}$: its inc-part has largest entry of absolute value 1 and its entry at j lies in $\varpi_{w_0}\mathcal{O}$. If all z_j are integral, the failure forces $w_0 \in M_O$ and some $z_j \not\equiv 0$; take $l = l^{(j)}$.

Points without an integral block ratio pair to zero. Let w_0, l, λ be as just found and $H = H(\lambda)$, with $\psi = \psi_{O,w_0}$. For $s \in H$ write $s = 1 + v\lambda$, lift v to a column $\tilde{v} \in \mathcal{O}^r$ and put $h_s = 1_n + (\mathrm{Inc}_O \tilde{v})\, l$. Then $h_s x_{w_0} = x_{w_0}$; $\det h_s = 1 + l\,\mathrm{Inc}_O \tilde{v} = 1 + \tilde{\lambda}\tilde{v}$ reduces to $1 + \lambda v = \det s \neq 0$, so $h_s \in \mathrm{GL}_n(\mathcal{O})$; and in the decomposition of the indices into the image of inc_O and the rest the reduction of h_s is $\left(\begin{smallmatrix} s & v\bar{l}'' \\ 0 & 1 \end{smallmatrix}\right)$, $\bar{l}''$ the reduction of the other entries of l. Let g_s have component h_s at w_0 and 1 at the other places of S, and k_s its lift. As $g_s x = x$ and $g_s \mathrm{Box}_m = \mathrm{Box}_m$, $k_s \cdot \mathbf{1}_{x,m} = \mathbf{1}_{x,m}$, and (6.162) gives $B(\mathbf{1}_{x,m}, R(k_s)\Xi) = B(\mathbf{1}_{x,m}, \Xi)$ for every m. If $w_0 \in Q_O$, then $\bar{l}'' = 0$, the reduction of h_s is $\mathrm{diag}(s, 1)$, so $k_s \in \mathbf{K}(O)$ and $R(k_s)\Xi = \psi(\det s)^{-1}\Xi$. If $w_0 \in M_O$, let $d_s \in \mathbf{K}_0(n)$ have reduction $\mathrm{diag}(s, 1)$ at w_0 and 1 at the other places of S, so that $[s]_{w_0}\Xi = \psi(\det s) R(d_s)\Xi$ by (DP5); the reductions of $d_s^{-1}k_s$ are $\left(\begin{smallmatrix} 1 & s^{-1}v\bar{l}'' \\ 0 & 1 \end{smallmatrix}\right)$ at w_0, which fixes Inc_O, and 1 at the other places, so $d_s^{-1}k_s \in \mathbf{K}(O)$ with $\tilde{\eta}_O = 1$ (η_O reads only the places of Q_O), and $R(k_s)\Xi = R(d_s)\Xi = \psi(\det s)^{-1}[s]_{w_0}\Xi$. Summing over $s \in H$, by additivity in the second argument,

$$\#H \cdot B(\mathbf{1}_{x,m}, \Xi) = B\Big(\mathbf{1}_{x,m}, \sum_{s \in H} R(k_s)\Xi\Big).$$

For $w_0 \in M_O$ the sum is $\sum_s \psi(\det s)^{-1}[s]_{w_0}\Xi = 0$ by (VT2). For $w_0 \in Q_O$ it is $\big(\sum_{s \in H} \psi(\det s)^{-1}\big)\Xi$, and this coefficient is 0: as $\lambda \neq 0$, $v \mapsto 1 + v\lambda$ is a bijection from the columns with $1 + \lambda v \neq 0$ onto H (applying $1 + v\lambda$ to a vector e with $\lambda e = 1$ recovers v), $\det(1 + v\lambda) = 1 + \lambda v$, and $v \mapsto \lambda v$ is a surjective linear map $k_{w_0}^r \to k_{w_0}$ with fibres of $(\mathrm{N}w_0)^{r-1}$ elements, so the coefficient is $(\mathrm{N}w_0)^{r-1} \sum_{t \in k_{w_0}^\times} \psi(t)^{-1} = 0$ by (VT1). As $\#H \geq 1$, $B(\mathbf{1}_{x,m}, \Xi) = 0$ for every m, and $m_0 = 0$ works.

Every x falls under one of the two cases, which proves the claim and the lemma. □

Lemma 6.6.85. *Let W be a space with index set r_W, V a standard definite space with index set n, a an automorphic character of* U(1)*, A a finite set of finite places of E with $A \cap \bar{A} = \emptyset$, and*

$\Sigma = A \cup \bar{A}$. *Fix a uniformiser* ϖ_w *of* E_w *for* $w \in A$. *For an* $n \times r_W$ *matrix* $x = (x_w)_{w\in A}$ *over* $\prod_{w\in A} E_w$ *and an integer* $m \geq 0$ *let* $\mathbf{1}_{x,m}$ *be the function on finite adelic* $n \times r_W$ *matrices* X *equal to* 1 *if* $X_w - x_w \in \varpi_w^m \mathrm{M}_{n\times r_W}(\mathcal{O}_{E,w})$ *for every* $w \in A$, *and* 0 *otherwise. Proof. Put $\psi_0(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$, $Q_A = \prod_{w\in A} \mathrm{M}_{n\times r_W}(E_w)$ and $L_A = \prod_{w\in A} \mathrm{M}_{n\times r_W}(\mathcal{O}_{E,w})$.

(i). By (1) of Lemma 4.1.3, $\mathcal{T}_A$ is the space of locally constant compactly supported functions on Q_A; $\mathbf{1}_{x,m}$, the indicator of the compact open set $x + \varpi^m L_A$, is one of them.

Two Heisenberg facts. (h1) By (WD7), for vectors u, u' of the theta model,

$$(\rho(u)\rho(u')f)(x) = \beta(u,x)\beta(u',x)\beta(u',u)^{-1} f(x-u-u'),$$

so $\rho(u)\rho(u') = \beta(u,u')\beta(u',u)^{-1}\rho(u')\rho(u)$; if u and u' have no common nonzero component, $\beta(u,u') = \beta(u',u) = 1$ and they commute, and then also $\rho_f(x_1+x_2) = \rho_f(x_1)\rho_f(x_2)$ for finite x_1, x_2 with disjoint supports (the phases of (WD8) multiply). (h2) For finite z, y, $\rho_f(z)\rho_f(y) = c(z,y)\rho_f(y)\rho_f(z)$ with

$$c(z,y) = \psi_0((\bar{y}^{\mathsf{T}} z - \bar{z}^{\mathsf{T}} y)/2) = \psi_0(\bar{y}^{\mathsf{T}} z).$$

By Lemma 4.1.3, $(\jmath\alpha\bar{\alpha})\widehat{\mathcal{O}}_E = \mathfrak{D}_{E/\mathbb{Q}}^{-1}\widehat{\mathcal{O}}_E$, so at every finite place w the annihilator of $\mathcal{O}_{E,w}^N$ under $(u,v) \mapsto \psi_0(\bar{u}^{\mathsf{T}} v)$ (read at w) is $\mathcal{O}_{E,w}^N$.

(ii). Let Z be the compact group of the $z \in \widehat{\mathcal{O}}_E^N$ with $z_w = 0$ for $w \in \Sigma$, with its Haar probability measure dz, and $\mathcal{V} \subseteq \mathcal{M}_{W,V}$ the data that are the vacuum at the finite places outside Σ, i.e. fixed by every $\rho_f(z)$, $z \in Z$. Fix $g \in \mathrm{U}(W)(\mathbb{A}_F)$ and put $L(\varphi) = D_a(\varphi)(g)$.

L is a bounded linear form. By Theorem A.4.5, $[\mathrm{U}(V)]$ is compact of finite volume and Y is bounded; choose a compact K with $\mathrm{U}(V)(F)K = \mathrm{U}(V)(\mathbb{A}_F)$. By (2) of Lemma 4.1.1, $h \mapsto \omega_{a,1}(g,h)\varphi$ is continuous for each φ, so by the uniform boundedness principle $M_g = \sup_{h\in K} \|\omega_{a,1}(g,h)\| < \infty$; by Lemma 6.2.5, $|\theta_{a,1}^{W,V}(\varphi)(g,\gamma h)| = |\theta_{a,1}^{W,V}(\varphi)(g,h)|$ for rational γ, so $|\theta_{a,1}^{W,V}(\varphi)(g,h)| \leq \|\theta\| M_g \|\varphi\|$ for all h, θ the theta functional of $\mathrm{Hom}(W,V)$. Hence $|L(\varphi)| \leq \mathrm{vol}([\mathrm{U}(V)]) \sup|Y|\, \|\theta\| M_g \|\varphi\|$.

The averaged form. Each $\rho_f(z)$ is an isometry of $\mathcal{M}_{W,V}$ ($|\beta| = 1$ and μ is translation invariant), and $z \mapsto \rho_f(z)\varphi$ is continuous (continuity of translation in L^1, and dominated convergence for the factor β). So $L'(\varphi) = \int_Z L(\rho_f(z)\varphi)\, dz$ is a bounded linear form, and $L' = L$ on $\mathcal{V}$. It suffices to show $L' = 0$, and by Lemma 6.3.30 (for the theta model of $\mathrm{Hom}(W,V)$ and $Y = \mathbb{C}$) it suffices that $L'(v_P \otimes \rho_f(y)v^0) = 0$ for every polynomial P in the Fock variables and every $y \in \mathbb{A}_{E,f}^N$.

Evaluation on the test data. For $z \in Z$, $\mathrm{fv}(z)$ is finite and $\mathrm{rv}(\cdot)$ infinite, so by (h1) $\rho_f(z)$ commutes with every $\rho(\mathrm{rv}(\cdot))$ and hence with $v \otimes (\cdot)$ (a Bochner integral of these operators, (WR6)). By (h2) and (5) of Lemma 6.2.33 ($\rho_f(z)v^0 = v^0$),

$$L'(v_P \otimes \rho_f(y)v^0) = \Big(\int_Z c(z,y)\,dz\Big)\, L(v_P \otimes \rho_f(y)v^0).$$

Write $y = y_\Sigma + y'$ with y_Σ supported on Σ and y' off Σ. As $c(z,y) = \psi_0(\bar{y}'^{\mathsf{T}} z)$ for $z \in Z$, the integral of this character of Z is 0 unless it is trivial; it is trivial only if $y'_w \in \mathcal{O}_{E,w}^N$ for every finite $w \notin \Sigma$ (test with z supported at one place, and use the annihilator above). Then $y' \in \widehat{\mathcal{O}}_E^N$, and by (h1) and (5) of Lemma 6.2.33, $\rho_f(y)v^0 = \rho_f(y_\Sigma)\rho_f(y')v^0 = \rho_f(y_\Sigma)v^0$. By (WD8), (1) and (2) of Lemma 4.1.3 and (2) of Lemma 6.2.33 ($v^0 = P^A v^0 = \mathbf{1}_A \otimes_A v^0$),

$$\rho_f(y_\Sigma)v^0 = \mathrm{ph}\,\rho(\mathrm{fv}(y_\Sigma))(\mathbf{1}_A \otimes_A v^0) = \mathrm{ph}\,\big(R_A(y_\Sigma)\mathbf{1}_A\big) \otimes_A v^0, \qquad |\mathrm{ph}| = 1,$$

with $\Psi = R_A(y_\Sigma)\mathbf{1}_A \in \mathcal{T}_A$ (R_A the operator of Lemma 4.1.3). Being locally constant with compact support, Ψ is constant on the cosets of $\varpi^{m_1} L_A$ for some m_1 and vanishes off finitely many of them; for $m \geq m_1$ each such coset is the disjoint union of finitely many sets $x + \varpi^m L_A$, so $\Psi = \sum_k c_k \mathbf{1}_{x_k,m}$ with finitely many x_k independent of $m \geq m_1$. By linearity of $\Psi \mapsto v_P \otimes (\Psi \otimes_A v^0)$ and the hypothesis (taking $m \geq m_1$ and $m \geq m_0(P, x_k)$ for all k),

$$L(v_P \otimes \rho_f(y)v^0) = \mathrm{ph} \sum_k c_k\, D_a(v_P \otimes (\mathbf{1}_{x_k,m} \otimes_A v^0))(g) = 0.$$

Hence $L' = 0$, and $D_a(\varphi)(g) = L(\varphi) = L'(\varphi) = 0$ for every $\varphi \in \mathcal{V}$ and every g. □

Lemma 6.6.86. *For a space W and an integer $c \geq 0$ let $W \oplus \mathbb{H}^c$ be the iterated hyperbolic sum: $W \oplus \mathbb{H}^0 = W$ and $W \oplus \mathbb{H}^{i+1} = (W \oplus \mathbb{H}^i) \oplus \mathbb{H}$. For a finite set Σ of finite places, say that the descents of Y to a space U twisted by ν* vanish off Σ *if the descent of Y to $\mathrm{U}(U)$ twisted by ν is 0 for every datum on $\mathrm{Hom}(U,V)$ that is the vacuum at every finite place outside Σ.*

Let W be a space of rank r_W, $c \geq 0$ an integer, and V a standard definite space of rank n with $2r_W + 2c + 3 < n$. Let ν be an automorphic character of $\mathrm{U}(1)$, Σ_0 a finite set of finite places with $\Sigma_0 \cap \bar{\Sigma}_0 = \emptyset$, $\Sigma = \Sigma_0 \cup \bar{\Sigma}_0$, and Y a continuous function on $\mathrm{U}(V)(\mathbb{A}_F)$, left invariant under $\mathrm{U}(V)(F)$ and right invariant under an open subgroup of $\mathrm{U}(V)(\mathbb{A}_{F,f})$. Suppose that the descents of Y to W twisted by ν vanish off Σ. Suppose that there are a finite place $w \notin \Sigma$ with $w \neq \bar{w}$ and a number $X \in \mathbb{C}$ such that

- *the base changes $\tilde{\nu}$ and $\tilde{\upsilon}$ of ν and of υ are unramified at $\bar{w}$;*
- *Y is right invariant under K_w and $H_w^V(X)\,Y = 0$;*
- *$|X| = \big(q^{r_W/2}\, q^{n - r_W - 1}\big)^{-1}$, where $q = \mathrm{N}w$.*

Then the descents of Y to $W \oplus \mathbb{H}^c$ twisted by $\nu\upsilon^c$ vanish off Σ.

Proof. For $0 \leq i \leq c$ put $W_i = W \oplus \mathbb{H}^i$, a space of rank $r_W + 2i$, and $\nu_i = \nu\upsilon^i$. We prove by induction on $i \leq c$ the claim (V_i): the descents of Y to W_i twisted by ν_i vanish off Σ. Since $W_0 = W$ and $\nu_0 = \nu$, (V_0) is the hypothesis, and (V_c) is the assertion.

Let $0 \leq i < c$ and assume (V_i). Put $W' = W_{i+1} = W_i \oplus \mathbb{H}$, of rank $m' = r_W + 2i + 2$, and $k = n - m'$; then $k \geq 1$, because $m' \leq r_W + 2c < n$. By Lemma 6.6.85, applied to W', the character ν_{i+1} and the set Σ_0, it suffices to show that the descent

$$F(g) = \int_{[\mathrm{U}(V)]} \theta^{W',V}_{\nu_{i+1},1}(\varphi)(g,h)\, Y(h)\, dh$$

vanishes for every datum $\varphi = v_P \otimes \Phi \otimes \Phi^\circ$ with P a polynomial in the entries of $\mathrm{Hom}(W', V)$ at the infinite places and $\Phi = \mathbf{1}_{x,m}$ the indicator of a class at the places of Σ_0, as in (i) of Lemma 6.6.85; it lies in $\mathcal{T}_{\Sigma_0}$ and is a Schwartz–Bruhat function on $\mathrm{Hom}(W', V)\big(\prod_{u\in\Sigma_0} E_u\big)$. Fix such a φ.

F **is bounded.** Apply Lemma 6.6.87 to $U = W_i$ and the character ν_i: its hypothesis is (V_i), and $\nu_i \upsilon = \nu_{i+1}$; so F is a bounded function on $\mathrm{U}(W')(\mathbb{A}_F)$.

F **satisfies a Hecke equation.** As $w \notin \Sigma$ and Σ is stable under conjugation, neither w nor $\bar{w}$ lies in Σ_0, so φ is the vacuum at w and $\bar{w}$ in the sense of Lemma 6.6.11: for an integral finite adelic z with components 0 outside $\{w, \bar{w}\}$, $\rho_f(z)$ fixes $\Phi \otimes_{\Sigma_0} v^0$ by (5) of Lemma 6.2.33, and it commutes with the operators $\rho(\mathrm{rv}(y))$ of (WR6), whose vectors have finite components 0 (the bicharacter of (WD6) is 1 on a pair of vectors with disjoint supports), hence with the insertion $v_P \otimes (\cdot)$. Base change is multiplicative, $\tilde{\nu}_{i+1} = \tilde{\nu}\,\tilde{\upsilon}^{\,i+1}$, so $\tilde{\nu}_{i+1}$ is unramified at $\bar{w}$. Apply Lemma 6.6.11 with $S = W'$, $T = V$ (so $n_S = m'$, $n_T = n = m' + k$), $a = \nu_{i+1}$ and $y = Y$: the function $F = F_Y$ is right invariant under K_w, and there are α, β with $|\alpha| = q^{m'/2}$, $|\beta| = q^{n/2}$ such that, with $X' = q^k \alpha \beta^{-1} X$,

$$0 = F_{H_w^V(X)Y} = \prod_{j=0}^{k-1} (1 - q^j \alpha X) \cdot H_w^{W'}(X')\, F;$$

the left side vanishes because $H_w^V(X)Y = 0$ and the descent is linear in the function.

The sizes. By hypothesis $|X| = q^{-(2n - r_W - 2)/2}$. For $0 \le j \le k-1$,

$$|q^j \alpha X| \le q^{\,k-1+\frac{m'}{2}-\frac{2n-r_W-2}{2}} = q^{\frac{r_W-m'}{2}} = q^{-(i+1)} < 1,$$

so every factor $1 - q^j \alpha X$ is nonzero and $H_w^{W'}(X')F = 0$. Moreover $|X'| = q^{k+\frac{m'}{2}-\frac{n}{2}}|X| = q^{k/2}|X|$, and

$$q^{m'+1}|X'| = q^{\frac{m'+r_W+4-n}{2}} = q^{\frac{2r_W+2i+6-n}{2}} \le 1,$$

because $n \ge 2r_W + 2c + 4 \ge 2r_W + 2(i+1) + 4$, by the rank hypothesis and $i + 1 \le c$.

Conclusion of the step. The adelic unitary group of W' is $G_\infty \times G_f^{(m')}$ through its frames. The function F on it is bounded, right invariant under K_w, and killed by $H_w^{W'}(X') = \sum_{i'=0}^{m'} (-X')^{i'} q^{\binom{i'}{2}} T_{w,i'}$, with $q^{m'+1}|X'| \le 1$. By Lemma 6.6.89, $F = 0$. This proves (V_{i+1}) and the lemma. □

Lemma 6.6.87. *Let U be a space, $U \oplus \mathbb{H}$ its orthogonal sum with the hyperbolic plane, V a standard definite space, a an automorphic character of $\mathrm{U}(1)$, A a finite set of finite places with $A \cap \bar{A} = \emptyset$, $\Sigma = A \cup \bar{A}$, and Y a continuous function on $\mathrm{U}(V)(\mathbb{A}_F)$, left invariant under $\mathrm{U}(V)(F)$ and right invariant under an open subgroup of $\mathrm{U}(V)(\mathbb{A}_{F,f})$. Suppose that the descent of Y to $\mathrm{U}(U)$ twisted by a vanishes for every datum on $\mathrm{Hom}(U, V)$ that is the vacuum at every finite place outside Σ. Then for every polynomial P in the Fock variables of $\mathrm{Hom}(U \oplus \mathbb{H}, V)$ and every $\Phi \in \mathcal{T}_A$, the descent*

$$g \longmapsto \int_{[\mathrm{U}(V)]} \theta_{a\upsilon,1}^{U\oplus\mathbb{H},V}(v_P \otimes \Phi \otimes \Phi^\circ)(g,h)\, Y(h)\, dh$$

is a bounded function on $\mathrm{U}(U \oplus \mathbb{H})(\mathbb{A}_F)$.

Proof. Write $W' = U \oplus \mathbb{H}$, with signs s' on $n' = n_U \sqcup \{1, 2\}$ (the two indices of $\mathbb{H}$ last, of signs $+1$, -1), $V = \mathrm{I}_n$ (point 1, so $\mathrm{G}(1_n) = \{h : h^* h = 1\}$), $\varphi = v_P \otimes (\Phi \otimes_A v^0)$, $\omega = \omega_{a\upsilon,1}$ on $\mathcal{M}_{W',V}$

and $D(g)$ the descent of the statement. Call a datum *the vacuum off* Σ if it is the vacuum at the finite places outside Σ. By Theorem A.4.5, $[\mathrm{U}(V)]$ is compact of finite volume and Y is bounded.

Step 0: the splitting. Let $l = e_1$, $k = e_2$ (the basis vectors of $\mathbb{H}$) and i the inclusion of E^{n_U}. Then $k^*J_{W'}k = l^*J_{W'}l = 0$, $l^*J_{W'}k = 1$, $i^*J_{W'}i = J_U$, $i^*J_{W'}k = i^*J_{W'}l = 0$: (k, l, i) is a splitting of W' over U along a one-element set. It is base-adapted: $(l_{\mathbb{A}}\ k_{\mathbb{A}}\ i_{\mathbb{A}})$ is, up to the order of the columns, block diagonal with blocks $x_{\mathbb{H}}^{-1}$ and 1, $x_{\mathbb{H}}$ the point of $\mathbb{H}$ ((WR1) of Definition 3.2.18), whose real component is unitary and whose finite component is integral of unit determinant (the unit of (WD9) times $c_0 + \bar{c}_0 = 1$). Consider the induced splitting of $\mathrm{Hom}(W', V)$ over $\mathrm{Hom}(U, V)$ along $p_1 = n \times \{1\}$, with zero term Z and adelic frames $\kappa_{\mathbb{A}}, \lambda_{\mathbb{A}}, \iota_{\mathbb{A}}$ (the induced k, l, i). As $x_V = 1$, $J_V = 1$, they act on adelic matrices by $\kappa_{\mathbb{A}}b = b\,\mathrm{pr}_l$, $\lambda_{\mathbb{A}}b = b\,\mathrm{pr}_k$, $\iota_{\mathbb{A}}w = w\,\mathrm{pr}_i$. Hence the slices of the space $\mathrm{Hom}(W', V)$ along the induced splitting are the Hom slices, and the frame matrix of the induced splitting is $1_n \otimes M^{\mathsf{T}}$, where M has row blocks pr_k, pr_l, pr_i, i.e. $M = \mathrm{diag}(1, 1, \varepsilon_{s_U})(l_{\mathbb{A}}\ k_{\mathbb{A}}\ i_{\mathbb{A}})^*\varepsilon_{s'}$: unitary at the infinite places and integral at the finite places (where $\varepsilon = 1$); so the induced splitting is base-adapted, and at the finite places $\iota_{\mathbb{A}}$ is integral with $\iota_{\mathbb{A}}^*\iota_{\mathbb{A}} = 1$ (from $i^*J_{W'}i = J_U$).

Let $\theta' = \theta_{\mathrm{Hom}(W',V)}$, $\theta_0 = \theta_{\mathrm{Hom}(U,V)}$ and $\ell = \theta' - \theta_0 \circ Z$, a bounded linear form ((7) of Lemma 4.1.1). For $F \in \mathcal{M}_{W',V}$:

(z1) $\theta_0(Z(F)) = \int_{\mathbb{A}_E^{p_1}/E^{p_1}} \theta'(\rho(\kappa_{\mathbb{A}}b)F)\,db$, by (MX4) at $y = 0$;

(z2) $Z(\rho(\kappa_{\mathbb{A}}b)F) = Z(F)$ for adelic b, and $Z(\rho(\iota_{\mathbb{A}}w)F) = \rho(w)Z(F)$, by (1) of Lemma 6.2.44 at $x = 0$ for the induced splitting;

(z3) $\theta'(\rho(\kappa_{\mathbb{A}}b)F) = \theta'(F)$ for $b \in E^{p_1}$, since $\kappa_{\mathbb{A}}b$ is then a rational vector of $\mathrm{Hom}(W', V)$ read through its point (Lemma 4.1.17);

(z4) if F is the vacuum off Σ, so is $Z(F)$: for w integral with components 0 at Σ, $w' = \iota_{\mathbb{A},f}w$ is integral with components 0 at Σ and $\bar{w}'^{\mathsf{T}}w' = \bar{w}^{\mathsf{T}}w$, so $\rho_f(w)$ and $\rho_f(w')$ carry the same phase (WD8), and by (z2) $\rho_f(w)Z(F) = Z(\rho_f(w')F) = Z(F)$.

By (z2), (z3), $\ell(\rho(\kappa_{\mathbb{A}}b)F) = \ell(F)$ for $b \in E^{p_1}$, and by (z1), (z2), $\int_{\mathbb{A}_E^{p_1}/E^{p_1}} \ell(\rho(\kappa_{\mathbb{A}}b)F)\,db = 0$.

Step 1: the zero term contributes nothing. We show $\int_{[\mathrm{U}(V)]} \theta_0(Z(\omega(g, h)\varphi))Y(h)\,dh = 0$ for every $g \in \mathrm{G}(s')$. The integrand is continuous and left invariant under the rational points: by (2) of Lemma 6.2.45 with the element 1 of $\mathrm{G}(s')$, $Z(\omega(1, \gamma)F) = \omega_{a,1}(1, \gamma)Z(F)$, and θ_0 is invariant under rational points (Lemma 6.2.5). By Lemma 6.6.88, $g = q\kappa$ with $q = \mathrm{rad}(c_1, b_1)\,\mathrm{lev}(m, g_0)$, $g_0 \in \mathrm{G}(s_U)$, and κ unitary at the infinite places and in $\mathbf{K}_0(n')$ at the finite places. By (MX2), $qk_{\mathbb{A}} = k_{\mathbb{A}}m$ and $\mathrm{pr}_i q i_{\mathbb{A}} = g_0$ ($\mathrm{rad}(c_1, b_1)$ fixes $k_{\mathbb{A}}$, as $\mathrm{pr}_l k_{\mathbb{A}} = \mathrm{pr}_i k_{\mathbb{A}} = 0$, and $\mathrm{pr}_i\,\mathrm{rad}(c_1, b_1)\,i_{\mathbb{A}} = 1$, as $\mathrm{pr}_l k_{\mathbb{A}} = \mathrm{pr}_l i_{\mathbb{A}} = 0$, $\mathrm{pr}_i k_{\mathbb{A}} = 0$). Let $\varphi' = \omega(\kappa, 1)\varphi$. It is the vacuum off Σ: φ is ((5) of Lemma 6.2.33 for $\Phi \otimes_A v^0$, and $\rho_f(z)$ commutes with the real Heisenberg operators of (WR6), vectors with disjoint supports having bicharacter 1); by (2) of Lemma 4.1.1, $\rho(z)\omega(\kappa, 1) = \omega(\kappa, 1)\rho(z\kappa)$ for vectors z of $\mathrm{Hom}(W', V)$ ($X \mapsto X\kappa^{-1}$ being the pair map), and for z integral with components 0 at Σ so is $z\kappa_f$, with $\mathrm{tr}((z\kappa_f)^*z\kappa_f) = \mathrm{tr}(z^*z)$, so the phases of (WD8) agree and $\rho_f(z)\varphi' = \omega(\kappa, 1)\rho_f(z\kappa_f)\varphi = \varphi'$. By (2) of Lemma 6.2.45 at $x = 0$ (characters $(a, 1)$, so $av^{\#p} = av$),

$$Z(\omega(g, h)\varphi) = Z(\omega(q, h)\varphi') = c_m\,\omega_{a,1}(g_0, h)\,Z(\varphi'), \qquad c_m = v(\det m)^n|\det m|^{n/2}.$$

So the integral is $c_m\,D_a(Z(\varphi'))(g_0)$, the descent of Y to U by $Z(\varphi')$, which is the vacuum off Σ by (z4); it vanishes by hypothesis.

Step 2: a uniform bound for ℓ. Let $g \in \mathrm{G}(s')$ and $H = \mathrm{ht}_{W'}(g)$. If $H > 2$, Lemma 6.2.30 gives a nonzero u in the lattice of W'_g with $u^* J_{W'} u = 0$ and length at most $2/H$; as k is isotropic and nonzero, $Eu \to E^{n'}$, $u \mapsto k$, is an injective isometry, and Witt's theorem A.6.7 gives $\gamma \in \mathrm{U}(W')(F)$ with $\gamma u = k$. If $H \le 2$ put $\gamma = 1$. Let $\gamma_{\mathbb{A}} = x_{W'}^{-1} \gamma x_{W'}$ and $g' = \gamma_{\mathbb{A}} g$. As $x_{W'} g' = \gamma x_{W'} g$, $u \mapsto \gamma u$ carries the lattice of W'_g onto that of $W'_{g'}$ preserving lengths; so $\mathrm{ht}_{W'}(g') = H$, and if $H > 2$, k lies in the lattice of $W'_{g'}$ with length at most $2/H$.

The heights on V are 1: for $h \in \mathrm{G}(1_n)$ and a nonzero u in the lattice of V_h, $u^* u \in F$ is totally positive and, h being unitary, equal at the finite places to the integral value $(h^{-1}u)^*(h^{-1}u)$; so $u^*u \in \mathcal{O}_F \setminus \{0\}$ and the squared length is $\mathrm{Tr}_{F/\mathbb{Q}}(u^*u) \ge [F : \mathbb{Q}] \ge 1$. By (VP3) of Definition 3.2.2 V is a framed hermitian space (a framed space of rank $\#n$ in the sense of (FT1)) and $\lambda_V(h)$ is the first minimum of (VP4) for both readings; by what was just shown $\lambda_V(h) = 1$, and Lemma 5.8.21 at h gives $d \in \mathrm{GL}_n(E)$ whose columns lie in the lattice of V_h and have lengths at most $Z_0 = f\, n\, |d_E|$, $f = [F : \mathbb{Q}]$.

We apply (2) of Lemma 6.2.31 with $S = W'$, $T = V$, the characters $(av, 1)$, the set A, $\Psi = \Phi$ (so $f_0 = \Phi \otimes_A v^0$ and $v_P \otimes f_0 = \varphi$), the index sets n and $\{1\}$, $N = 0$, $r = 1$, the functional ℓ and the points (g', h). Its hypotheses: (a) by Lemma 6.2.28 for (W', V) there are Y_1, A_1 with $|\theta'(\omega(g', h)F)| \le Y_1 \|F\| H^{A_1}$ (as $\mathrm{ht}_V(h) = 1$); by (z1), $|\theta_0(Z\omega(g', h)F)| \le \sup_b |\theta'(\rho(\kappa_{\mathbb{A}} b)\omega(g', h)F)|$, and $\rho(\kappa_{\mathbb{A}} b)\omega(g', h) = \omega(g', h)\rho(z_b)$ for a vector z_b ((2) of Lemma 4.1.1), $\rho(z_b)$ an isometry; so $|\ell(\omega(g', h)F)| \le 2Y_1 \|F\| H^{A_1}$. (b) If $H > 2$, (d, k) is a short pair for $(g', h, \ell, Z_0, 2/H)$, and $Z_0 \cdot 2/H = 2Z_0 r/H$: (i) holds by the choices of d and γ; (ii) $k^* J_{W'} k = 0$; for (iii), (iv), the group $Z_{d,k}(R) = \{dYk^* J_{W'} x_{W'} : Y \in \mathrm{M}_{n\times 1}(R)\}$ is $\{\kappa_{\mathbb{A}}(dY)\}$, so (iii) is the invariance of ℓ under $\rho(\kappa_{\mathbb{A}} b)$, $b \in E^{p_1}$, and, $Y \mapsto dY$ inducing an automorphism of the compact group $\mathbb{A}_E^{p_1}/E^{p_1}$ that preserves its Haar probability measure, the mean in (iv) is $\int \ell(\rho(\kappa_{\mathbb{A}} b)F)\, db = 0$ (end of Step 0). As $\mathrm{mom}_{A_1}(v_P) < \infty$ (XD3), we obtain, with $K = C' \mathrm{mom}_{A_1}(v_P)$ independent of g and h,

$$\big|\ell(\omega(g', h)\varphi)\big| \le K.$$

Step 3: conclusion. By Lemma 6.2.5, $\theta^{W',V}_{av,1}(\varphi)(g', h) = \theta^{W',V}_{av,1}(\varphi)(g, h)$, so $D(g) = D(g')$. Writing $\theta' = \ell + \theta_0 \circ Z$ and using Step 1 at g',

$$D(g) = \int_{[\mathrm{U}(V)]} \ell(\omega(g', h)\varphi) Y(h)\, dh, \qquad |D(g)| \le K \sup|Y| \,\mathrm{vol}([\mathrm{U}(V)])$$

by Step 2, for every g. □

Lemma 6.6.88. *Let V, V_0 be spaces with points with signs s on n and s_0 on n_0, p a nonempty index set and (k, l, i) a base-adapted splitting of V over V_0 along p. Let $K_\infty(s)$ be the subgroup of $G_\infty(s)$ of the elements whose component at every infinite place is a unitary matrix. Then every $g \in \mathrm{G}(s)$ can be written*

$$g = \mathrm{rad}(c, b)\, \mathrm{lev}(m, g_0)\, \kappa$$

with an adelic $n_0 \times p$ matrix c, an adelic $p \times p$ matrix b, $m \in \mathrm{GL}_p(\mathbb{A}_E)$, $g_0 \in \mathrm{G}(s_0)$ and $\kappa \in K_\infty(s) \times \mathbf{K}_0(n)$.

Proof. Write $k_{\mathbb{A}}, l_{\mathbb{A}}, i_{\mathbb{A}}$ for the adelic frames and $M = (l_{\mathbb{A}} \mid k_{\mathbb{A}} \mid i_{\mathbb{A}})$. As $x_V^* J_V x_V = \varepsilon_s$, the relations of (MX1) give the Gram matrices

$$k_{\mathbb{A}}^* \varepsilon_s k_{\mathbb{A}} = 0, \quad l_{\mathbb{A}}^* \varepsilon_s l_{\mathbb{A}} = 0, \quad l_{\mathbb{A}}^* \varepsilon_s k_{\mathbb{A}} = 1, \quad i_{\mathbb{A}}^* \varepsilon_s i_{\mathbb{A}} = \varepsilon_{s_0}, \quad i_{\mathbb{A}}^* \varepsilon_s k_{\mathbb{A}} = 0, \quad i_{\mathbb{A}}^* \varepsilon_s l_{\mathbb{A}} = 0, \quad (6.164)$$

and every adelic vector is $x = l_{\mathbb{A}} \mathrm{pr}_l(x) + k_{\mathbb{A}} \mathrm{pr}_k(x) + i_{\mathbb{A}} \mathrm{pr}_i(x)$; so M is invertible, with inverse the matrix of rows $\mathrm{pr}_l = k_{\mathbb{A}}^* \varepsilon_s$, $\mathrm{pr}_k = l_{\mathbb{A}}^* \varepsilon_s$, $\mathrm{pr}_i = \varepsilon_{s_0} i_{\mathbb{A}}^* \varepsilon_s$, and pr_k is a left inverse of $k_{\mathbb{A}}$. Since

the splitting is base-adapted, M_f has entries in $\widehat{\mathcal{O}}_E$, and so has M_f^{-1}, whose rows are k_f^*, l_f^*, i_f^* ($\varepsilon_s = 1$ at the finite places); in particular k_f has the left inverse l_f^* over $\widehat{\mathcal{O}}_E$, and $k_f^* k_f = 0$.

Step 1: a compact element moves the frame into its own span. We show that there are $\kappa \in K_\infty(s) \times \mathbf{K}_0(n)$ and $m \in \mathrm{GL}_p(\mathbb{A}_E)$ with $g\kappa\, k_{\mathbb{A}} = k_{\mathbb{A}} m$.

Infinite places. Fix $v \in \Phi$, $D = \mathrm{diag}(s)$, $K_v = \mathrm{U}(D) \cap \mathrm{U}(n)$. For an $n \times p$ complex matrix X of rank p with $X^* D X = 0$ put $R_X = (X^*X)^{1/2} \in \mathrm{GL}_p(\mathbb{C})$ and $Q_X = X R_X^{-1}$; then $Q_X^* Q_X = 1$ and $Q_X^* D Q_X = 0$. Splitting the rows by sign, $Q_X^* Q_X = Q_{X,+}^* Q_{X,+} + Q_{X,-}^* Q_{X,-}$ and $Q_X^* D Q_X = Q_{X,+}^* Q_{X,+} - Q_{X,-}^* Q_{X,-}$, so $\sqrt{2}\, Q_{X,\pm}$ have orthonormal columns in $\mathbb{C}^{n_\pm}$, $n_\pm$ the number of indices of sign ± 1. Take $X_0 = (k_{\mathbb{A}})_v$ and $X = g_v^{-1}(k_{\mathbb{A}})_v$: both have rank p (pr_k is a left inverse of $k_{\mathbb{A}}$) and are isotropic for D by (6.164) and $g_v \in \mathrm{U}(D)$. Completing the orthonormal columns of $\sqrt{2}Q_{X_0,\pm}$ and $\sqrt{2}Q_{X,\pm}$ to orthonormal bases of $\mathbb{C}^{n_\pm}$ gives unitary $u_\pm$ with $u_\pm Q_{X_0,\pm} = Q_{X,\pm}$; the block diagonal matrix $\kappa_v = u_+ \oplus u_-$ (for the partition of the indices by sign) is unitary and commutes with D, so $\kappa_v \in K_v$, and $\kappa_v Q_{X_0} = Q_X$. Hence $g_v \kappa_v (k_{\mathbb{A}})_v = g_v \kappa_v Q_{X_0} R_{X_0} = g_v X R_X^{-1} R_{X_0} = (k_{\mathbb{A}})_v m_v$ with $m_v = R_X^{-1} R_{X_0} \in \mathrm{GL}_p(\mathbb{C})$.

Finite places. Let $Z = g_f^{-1} k_f$, an $n \times p$ matrix over $\mathbb{A}_{E,f}$ with the left inverse $\mathrm{pr}_{k,f}\, g_f$. For a finite place w of E, the ring $\mathcal{O}_{E,w}$ is a discrete valuation ring, so $L_w = Z_w E_w^p \cap \mathcal{O}_{E,w}^n$ is free of rank p and $\mathcal{O}_{E,w}^n / L_w$, being finitely generated and torsion free, is free; so L_w is a direct summand of $\mathcal{O}_{E,w}^n$ and $L_w = Z_w b'_w \mathcal{O}_{E,w}^p$ for some $b'_w \in \mathrm{GL}_p(E_w)$, whence $Z_w b'_w$ has a left inverse over $\mathcal{O}_{E,w}$. For all but finitely many w, $g_w \in \mathrm{GL}_n(\mathcal{O}_{E,w})$, so Z_w itself has a left inverse over $\mathcal{O}_{E,w}$ (as k_f has one) and we take $b'_w = 1$. Thus $b' = (b'_w)_w \in \mathrm{GL}_p(\mathbb{A}_{E,f})$ and $Y = Z b'$ has a left inverse over $\widehat{\mathcal{O}}_E$. As $g_f^* g_f = 1$, $Y^* Y = b'^* k_f^* k_f b' = 0 = k_f^* k_f$. By (2) of Lemma 3.2.6 for $X = k_f$ and Y there is $\kappa' \in \mathrm{GL}_n(\widehat{\mathcal{O}}_E)$ with $\kappa'^* \kappa' = 1$, i.e. $\kappa' \in \mathbf{K}_0(n)$, and $\kappa' k_f = g_f^{-1} k_f b'$; so $g_f \kappa' k_f = k_f b'$.

Put $\kappa = ((\kappa_v)_v, \kappa') \in K_\infty(s) \times \mathbf{K}_0(n)$ and $m = ((m_v)_v, b') \in \mathrm{GL}_p(\mathbb{A}_E)$; then $g\kappa k_{\mathbb{A}} = k_{\mathbb{A}} m$.

Step 2: an element stabilising the frame is a radical element times a Levi element. Let $h \in \mathrm{G}(s)$ and $m \in \mathrm{GL}_p(\mathbb{A}_E)$ with $h k_{\mathbb{A}} = k_{\mathbb{A}} m$. From $h^* \varepsilon_s = \varepsilon_s h^{-1}$ and $h^{-1} k_{\mathbb{A}} = k_{\mathbb{A}} m^{-1}$ we get $k_{\mathbb{A}}^* \varepsilon_s h = (m^{-1})^* k_{\mathbb{A}}^* \varepsilon_s$, so $\mathrm{pr}_l(h i_{\mathbb{A}}) = (m^{-1})^* k_{\mathbb{A}}^* \varepsilon_s i_{\mathbb{A}} = 0$ and

$$h i_{\mathbb{A}} = i_{\mathbb{A}} g_0 + k_{\mathbb{A}} B, \qquad g_0 = \mathrm{pr}_i(h i_{\mathbb{A}}),\ B = \mathrm{pr}_k(h i_{\mathbb{A}}).$$

By (6.164), $\varepsilon_{s_0} = (h i_{\mathbb{A}})^* \varepsilon_s (h i_{\mathbb{A}}) = g_0^* \varepsilon_{s_0} g_0$, so $g_0 \in \mathrm{G}(s_0)$. Write $h l_{\mathbb{A}} = l_{\mathbb{A}} X + i_{\mathbb{A}} Y + k_{\mathbb{A}} Z'$. Since h preserves the form, (6.164) gives

$$\begin{aligned} 1 &= (h l_{\mathbb{A}})^* \varepsilon_s (h k_{\mathbb{A}}) = X^* m, \\ 0 &= (h l_{\mathbb{A}})^* \varepsilon_s (h i_{\mathbb{A}}) = X^* B + Y^* \varepsilon_{s_0} g_0, \\ 0 &= (h l_{\mathbb{A}})^* \varepsilon_s (h l_{\mathbb{A}}) = X^* Z' + Z'^* X + Y^* \varepsilon_{s_0} Y. \end{aligned}$$

So $X = (m^{-1})^*$; with $c = \varepsilon_{s_0} (g_0^{-1})^* B^*$ (an adelic $n_0 \times p$ matrix, $\varepsilon_{s_0}^{-1} = \varepsilon_{s_0}$) the second relation reads $Y = -cX$; and with $Z = Z' X^{-1}$ the third reads $Z + Z^* = -c^* \varepsilon_{s_0} c$. Hence $Z_1 = Z + \frac{1}{2} c^* \varepsilon_{s_0} c$ satisfies $Z_1^* = -Z_1$. Let $b = -\jmath Z_1$; as $\bar{\jmath} = -\jmath$, $b + b^* = -2\jmath Z_1$, so $Z = -\frac{1}{2}(\jmath^{-1}(b + b^*) + c^* \varepsilon_{s_0} c)$. Now compare h with $q = \mathrm{rad}(c, b)\, \mathrm{lev}(m, g_0)$ on the columns of M, using pr_l, pr_k, pr_i on $l_{\mathbb{A}}, k_{\mathbb{A}}, i_{\mathbb{A}}$ ((MX1), (MX2)): $\mathrm{lev}(m, g_0)$ sends $k_{\mathbb{A}}, i_{\mathbb{A}}, l_{\mathbb{A}}$ to $k_{\mathbb{A}} m$, $i_{\mathbb{A}} g_0$, $l_{\mathbb{A}} X$, and $\mathrm{rad}(c, b)$ sends $k_{\mathbb{A}}$, $i_{\mathbb{A}}$, $l_{\mathbb{A}}$ to $k_{\mathbb{A}}$, $i_{\mathbb{A}} + k_{\mathbb{A}} c^* \varepsilon_{s_0}$, $l_{\mathbb{A}} - i_{\mathbb{A}} c + k_{\mathbb{A}} Z$. So

$$q k_{\mathbb{A}} = k_{\mathbb{A}} m, \qquad q i_{\mathbb{A}} = i_{\mathbb{A}} g_0 + k_{\mathbb{A}} c^* \varepsilon_{s_0} g_0 = i_{\mathbb{A}} g_0 + k_{\mathbb{A}} B, \qquad q l_{\mathbb{A}} = l_{\mathbb{A}} X - i_{\mathbb{A}} c X + k_{\mathbb{A}} Z X = h l_{\mathbb{A}},$$

as $c^* \varepsilon_{s_0} g_0 = B$. Since M is invertible, $h = q = \mathrm{rad}(c, b)\, \mathrm{lev}(m, g_0)$.

Conclusion. With κ, m of Step 1, Step 2 for $h = g\kappa$ gives $g\kappa = \mathrm{rad}(c, b)\, \mathrm{lev}(m, g_0)$, i.e. $g = \mathrm{rad}(c, b)\, \mathrm{lev}(m, g_0)\, \kappa^{-1}$ with $\kappa^{-1} \in K_\infty(s) \times \mathbf{K}_0(n)$. □

Lemma 6.6.89. *Let $n \geq 0$, let $G_f^{(n)} = \{g \in \mathrm{GL}_n(\mathbb{A}_{E,f}) : \bar{g}^{\mathsf{T}} g = 1\}$, let $s = (s_v)_{v\in\Phi}$ be signs $s_v \colon \{1,\dots,n\} \to \{\pm 1\}$, and let $G = G_\infty \times G_f^{(n)}$ with $G_\infty = \prod_{v\in\Phi} \mathrm{U}(\mathrm{diag}(s_v))$; the group $G_f^{(n)}$ acts on functions on G by right translation. Let w be a finite place of E with $w \neq \bar{w}$, $\mathcal{O}_w$ the integers of E_w and ϖ_w a uniformiser. For $\gamma \in \mathrm{GL}_n(E_w)$ let $\iota_w(\gamma) \in G_f^{(n)}$ be the element with component γ at w, $(\bar{\gamma}^{\mathsf{T}})^{-1}$ at $\bar{w}$ and 1 at the other finite places, and put $K_w = \iota_w(\mathrm{GL}_n(\mathcal{O}_w))$. For $0 \leq i \leq n$ let $R_i \subset \mathrm{GL}_n(E_w)$ be a set of representatives of the cosets $\mathrm{GL}_n(\mathcal{O}_w)\,\delta_i\,\mathrm{GL}_n(\mathcal{O}_w)/\mathrm{GL}_n(\mathcal{O}_w)$, where $\delta_i = \mathrm{diag}(\varpi_w 1_i, 1_{n-i})$, and for a function F on G that is right invariant under K_w let*

$$(T_{w,i}F)(g) = \sum_{\gamma\in R_i} F(g\,\iota_w(\gamma)) \qquad (g \in G).$$

Let $X \in \mathbb{C}$ with $(\mathrm{N}w)^{n+1}|X| \leq 1$, and let $F \colon G \to \mathbb{C}$ be a bounded function, right invariant under K_w, with

$$\sum_{i=0}^{n} (-X)^i\,(\mathrm{N}w)^{\binom{i}{2}}\,T_{w,i}F = 0.$$

Then $F = 0$.

Proof. Write $q = \mathrm{N}w$, so $q \geq 2$, and $K_0 = \mathrm{GL}_n(\mathcal{O}_w)$. The map ι_w is a homomorphism into $G_f^{(n)}$: complex conjugation exchanges the components at w and $\bar{w}$, and at w the product $\bar{h}^{\mathsf{T}} h$ for $h = \iota_w(\gamma)$ is $((\gamma^{\mathsf{T}})^{-1})^{\mathsf{T}}\gamma = 1$, and likewise at $\bar{w}$.

The operators and the number of their terms. If $\gamma \in \mathrm{GL}_n(E_w)$ and $k \in K_0$, then $F(g\,\iota_w(\gamma k)) = F(g\,\iota_w(\gamma)\,\iota_w(k)) = F(g\,\iota_w(\gamma))$ by the invariance of F, so $T_{w,i}F$ does not depend on the choice of R_i. Since $\delta_0 = 1$, we may take $R_0 = \{1\}$, so $T_{w,0}F = F$. We show that $\#R_i$ is the number $\binom{n}{i}_q$ of i-dimensional subspaces of k_w^n. The map $\gamma K_0 \mapsto L = \gamma\mathcal{O}_w^n$ is well defined and injective on cosets, since $\gamma\mathcal{O}_w^n = \gamma'\mathcal{O}_w^n$ exactly when $\gamma^{-1}\gamma' \in K_0$. If $\gamma = k\delta_i k'$ with $k, k' \in K_0$, then $L = k\delta_i\mathcal{O}_w^n$ satisfies $\varpi_w\mathcal{O}_w^n \subseteq L \subseteq \mathcal{O}_w^n$ with $\dim_{k_w} L/\varpi_w\mathcal{O}_w^n = n - i$, because $\delta_i\mathcal{O}_w^n$ does and k preserves $\mathcal{O}_w^n$ and $\varpi_w\mathcal{O}_w^n$. Conversely let L be an $\mathcal{O}_w$-module with these properties. It is free of rank n, being finitely generated and torsion free over the discrete valuation ring $\mathcal{O}_w$ and containing $\varpi_w\mathcal{O}_w^n$; so $L = \gamma\mathcal{O}_w^n$ for some $\gamma \in \mathrm{GL}_n(E_w)$. By the elementary divisor theorem over $\mathcal{O}_w$, $\gamma = k\,\mathrm{diag}(\varpi_w^{a_1},\dots,\varpi_w^{a_n})\,k'$ with $k, k' \in K_0$ and $a_l \in \mathbb{Z}$; then $L \subseteq \mathcal{O}_w^n$ gives $a_l \geq 0$, $\varpi_w\mathcal{O}_w^n \subseteq L$ gives $a_l \leq 1$, and $\dim L/\varpi_w\mathcal{O}_w^n = \#\{l : a_l = 0\} = n - i$ shows that exactly i of the a_l equal 1. Conjugating by a permutation matrix, which lies in K_0, puts γ in $K_0\delta_i K_0$. Hence the cosets of R_i correspond to the modules L, and these correspond, by $L \mapsto L/\varpi_w\mathcal{O}_w^n$, to the subspaces of dimension $n - i$ of $k_w^n = \mathcal{O}_w^n/\varpi_w\mathcal{O}_w^n$. Their number is $\binom{n}{n-i}_q = \binom{n}{i}_q$.

The total weight of the relation is below 2. By Gauss's q-binomial theorem,

$$\sum_{i=0}^{n} q^{\binom{i}{2}} \binom{n}{i}_q y^i = \prod_{j=0}^{n-1} (1 + q^j y)$$

for every y. At $y = |X|$, using $1 + u \leq e^u$,

$$\sum_{i=0}^{n} |X|^i q^{\binom{i}{2}} \#R_i = \prod_{j=0}^{n-1} (1 + q^j|X|) \leq \exp\Bigl(|X| \sum_{j=0}^{n-1} q^j\Bigr) \leq \exp(q^n|X|) \leq e^{1/2} < 2.$$

So $\theta = \sum_{i=1}^{n} |X|^i q^{\binom{i}{2}} \#R_i < 1$.

Conclusion. Let $S = \sup_{g\in G} |F(g)|$, finite since F is bounded. Evaluating the relation at $g \in G$ and using $T_{w,0}F = F$,

$$F(g) = -\sum_{i=1}^{n} (-X)^i q^{\binom{i}{2}} \sum_{\gamma\in R_i} F(g\,\iota_w(\gamma)), \qquad \text{so} \qquad |F(g)| \leq \theta S.$$

Taking the supremum over g gives $S \le \theta S$, hence $(1-\theta)S \le 0$ and $S = 0$, since $\theta < 1$ and $S \ge 0$. So $F = 0$. □

Lemma 6.6.90. *Let W be a space with signs ε_W, $n \ge 1$, and $\{1,\dots,n\} = N \sqcup l$ a decomposition of the index set of I_n, so that $\mathrm{I}_n = \mathrm{I}_N \oplus \mathrm{I}_l$ with the standard definite spaces on these index sets; let $\iota\colon \mathrm{G}(1_N) \times \mathrm{G}(1_l) \to \mathrm{G}(1_n)$ be the block-diagonal embedding. Let A be a finite set of finite places with $A \cap \bar{A} = \emptyset$, $\Sigma = A \cup \bar{A}$, and a an automorphic character of $\mathrm{U}(1)$ with $a(\det k) = 1$ for every $k \in \mathbf{K}_0(n)$ whose components at the places of Σ are 1. Let $Y\colon \mathrm{G}(1_n) \to \mathbb{C}$ be continuous, left invariant under the rational points, and right invariant under every $k \in \mathbf{K}_0(n)$ whose components at the places of Σ are 1. Suppose that the descents of Y to $W \oplus \mathbb{H}^{\#N}$ twisted by $a\upsilon^{\#N}$ vanish off Σ. Then for every automorphic character b of $\mathrm{U}(1)$, every datum $\varphi \in \mathcal{M}_{W,\mathrm{I}_l}$ that is the vacuum at the finite places outside Σ, every $g \in \mathrm{G}(\varepsilon_W)$ and every $h_1 \in \mathrm{G}(1_N)$,*

$$\int_{[\mathrm{U}(\mathrm{I}_l)]} \theta_{a,b}^{W,\mathrm{I}_l}(\varphi)(g,h_2)\, Y\big(\iota(h_1,h_2)\big)\, dh_2 = 0.$$

Proof. Write $c = \#N$, and call a datum *the vacuum off* Σ if it is the vacuum at the finite places outside Σ. By the associativity of orthogonal sums ((VP5) of Definition 3.2.2), $W \oplus \mathbb{H}^c$ is the orthogonal sum of W and $\mathbb{H}^c = 0 \oplus \mathbb{H}^c$, with the concatenated index sets. Fix b, φ, g and h_1 as in the statement. All integrals below are over the compact quotients $[\mathrm{U}(\mathrm{I}_m)]$ of continuous functions.

Step 1: a complementary datum. By (iii) of Lemma 6.6.91 (for the pair (W, I_N) and the characters a, b^{-1}) there is $\varphi'' \in \mathcal{M}_{W,\mathrm{I}_N}$, the vacuum off Σ, with $K'' = \theta_{a,b^{-1}}^{W,\mathrm{I}_N}(\varphi'')(g,h_1) \ne 0$. Let $\Phi = \varphi'' \boxtimes^{\mathrm{tg}} \varphi \in \mathcal{M}_{W,\mathrm{I}_n}$ (target product for $\mathrm{I}_n = \mathrm{I}_N \oplus \mathrm{I}_l$); by (ii) of Lemma 6.6.91 it is the vacuum off Σ.

Step 2: the function Y_2. Put $\vartheta(h) = \theta_{a,1}^{W,\mathrm{I}_n}(\Phi)(g,h)$ and $Y_2 = \vartheta\, Y$ on $\mathrm{G}(1_n)$. It is continuous ($\omega_{a,1}$ is continuous and θ bounded, (2) of Lemma 4.1.1). It is left invariant under Γ_{I_n}: ϑ by Lemma 6.2.5, Y by hypothesis. It is right invariant under every $k \in \mathbf{K}_0(n)$ with components 1 at Σ: by (i) of Lemma 6.6.91, $\vartheta(hk) = \theta(\omega_{a,1}(g,h)\,\omega_{a,1}((1,1),(1,k))\Phi) = a(\det k)\vartheta(h) = \vartheta(h)$ by the hypothesis on a, and $Y(hk) = Y(h)$. The descents of Y_2 to $\mathbb{H}^c$ twisted by υ^c vanish off Σ: let $\varphi' \in \mathcal{M}_{\mathbb{H}^c,\mathrm{I}_n}$ be the vacuum off Σ and $g' \in \mathrm{U}(\mathbb{H}^c)(\mathbb{A}_F)$. The source product $\Phi \boxtimes^{\mathrm{sc}} \varphi' \in \mathcal{M}_{W\oplus\mathbb{H}^c,\mathrm{I}_n}$ is the vacuum off Σ ((ii) of Lemma 6.6.91), and by the exact factorisation (d) of Lemma 6.3.52 for source sums (characters $a\upsilon^c$ on the target, 1 on the source)

$$\theta_{a\upsilon^c,1}^{W\oplus\mathbb{H}^c,\mathrm{I}_n}\big(\Phi \boxtimes^{\mathrm{sc}} \varphi'\big)\big(\mathrm{diag}(g,g'),h\big) = \vartheta(h)\,\theta_{\upsilon^c,1}^{\mathbb{H}^c,\mathrm{I}_n}(\varphi')(g',h).$$

Integrating against $Y(h)$, the descent of Y_2 to $\mathbb{H}^c$ by φ' at g' is the descent of Y to $W \oplus \mathbb{H}^c$ twisted by $a\upsilon^c$ by $\Phi \boxtimes^{\mathrm{sc}} \varphi'$ at $\mathrm{diag}(g,g')$, which is 0 by hypothesis.

Step 3: the period. By Lemma 6.6.92 for $n_1 = N$, $n_2 = l$ and Y_2, $\int_{[\mathrm{U}(\mathrm{I}_l)]} Y_2(\iota(h_1,h_2))\, dh_2 = 0$. By the exact factorisation (d) of Lemma 6.3.52 for target sums (character a on the target, $1 = b^{-1}b$ on the source),

$$\vartheta(\iota(h_1,h_2)) = \theta_{a,1}^{W,\mathrm{I}_N\oplus\mathrm{I}_l}(\varphi'' \boxtimes^{\mathrm{tg}} \varphi)\big(g,\mathrm{diag}(h_1,h_2)\big) = K''\,\theta_{a,b}^{W,\mathrm{I}_l}(\varphi)(g,h_2).$$

Hence $K'' \int \theta_{a,b}^{W,\mathrm{I}_l}(\varphi)(g,h_2)\, Y(\iota(h_1,h_2))\, dh_2 = 0$, and $K'' \ne 0$. □

Lemma 6.6.91. *Let A be a finite set of finite places of E with $A \cap \bar{A} = \emptyset$, $\Sigma = A \cup \bar{A}$, and call a datum* the vacuum off Σ *if it is the vacuum at the finite places outside Σ. Let S, T be spaces with points with signs on n and n', and α, β automorphic characters of $\mathrm{U}(1)$.*

(i) *If $\varphi \in \mathcal{M}_{S,T}$ is the vacuum off Σ, and $k \in \mathbf{K}_0(n)$, $k' \in \mathbf{K}_0(n')$ have components 1 at the places of Σ, then $\omega_{\alpha,\beta}((1,k),(1,k'))\varphi = \alpha(\det k')\,\beta(\det k)^{-1}\,\varphi$.*

(ii) *Source and target products of data that are the vacuum off Σ are the vacuum off Σ.*

(iii) *For every $(g,h) \in \mathrm{G}(s) \times \mathrm{G}(s')$ there is a datum $\varphi \in \mathcal{M}_{S,T}$ that is the vacuum off Σ with $\theta^{S,T}_{\alpha,\beta}(\varphi)(g,h) \neq 0$.*

Proof. Let $\eta = s' \otimes s$ on $m = n' \times n$, $\mathcal{M} = \mathcal{M}_{S,T} = \mathcal{M}_\eta$, Θ the theta functional of $\mathrm{Hom}(S,T)$, and let R be the set of finite places of F not below a place of Σ; as $\Sigma = \bar{\Sigma}$, the finite places of E above R are those outside Σ, so a datum is the vacuum off Σ exactly when it is a vacuum above R in the sense of (7) of Lemma 6.2.33.

(i). By (WR4), $\omega_{\alpha,\beta}((1,k),(1,k')) = \alpha(\det k')\beta(\det k)^{-1}\omega_\eta(\kappa)$ with κ the image of the pair under the pair map, $X \mapsto k'Xk^{-1}$. Its infinite components are 1, its finite components are integral unitary matrices, and its components at Σ are 1. (a) $c = \langle v^0, \omega_\eta(\kappa)v^0\rangle = \overline{\Delta_\eta(\kappa)}^{-1} = 1$: the archimedean factor of $\Delta_\eta(\kappa)$ is a determinant of an identity block, and $\widehat{\mathcal{O}}_E^m \cap \kappa_f^{-1}\widehat{\mathcal{O}}_E^m = \widehat{\mathcal{O}}_E^m$, so $u = 1$ in (WR3). (b) By (7) of Lemma 6.2.33 for vacua above R and $\gamma = \kappa$ (its components are 1 at the infinite places and at the finite places not above R, which are the places of Σ), $\langle\varphi, \omega_\eta(\kappa)\varphi\rangle = c\langle\varphi,\varphi\rangle = \langle\varphi,\varphi\rangle$; as $\omega_\eta(\kappa)$ preserves the inner product,

$$\langle\omega_\eta(\kappa)\varphi - \varphi, \omega_\eta(\kappa)\varphi - \varphi\rangle = \langle\varphi,\varphi\rangle - 2\,\mathrm{Re}\langle\varphi,\omega_\eta(\kappa)\varphi\rangle + \langle\varphi,\varphi\rangle = (2 - 2\,\mathrm{Re}\,c)\langle\varphi,\varphi\rangle = 0.$$

A vector g of $\mathcal{M}$ with $\int |g|^2 d\mu = 0$ vanishes μ-almost everywhere, hence is 0 (its continuous representative is given by the reproducing identity). So $\omega_\eta(\kappa)\varphi = \varphi$, which is (i).

(ii). Let $f = f_1 \boxtimes_e f_2$ be a product (WR6) of vacua off Σ, for a bijection $e\colon m_1 \sqcup m_2 \to m$, and z integral with components 0 at Σ, with blocks z_1, z_2 through e. The bicharacter (WD6) and the phase of (WD8) are products over the coordinates, so $(\rho_f(z)f)(x) = (\rho_f(z_1)f_1)(x_1)\,(\rho_f(z_2)f_2)(x_2) = f_1(x_1)f_2(x_2) = f(x)$, with x_1, x_2 the blocks of x. Source and target products are products of this kind.

(iii). Let k be the image of (g,h) under the pair map and $u = \omega_{\alpha,\beta}(g,h)v^0$; $\langle u,u\rangle = \langle v^0, v^0\rangle = 1$. By orthogonality of theta functions for the theta functional Θ, $\int_{\mathbb{A}_E^m/L} |\Theta(\rho(x)u)|^2 dx = 1$, L the rational vectors of $\mathrm{Hom}(S,T)$; so the continuous L-periodic function $G(x) = |\Theta(\rho(x)u)|$ is not identically 0. Let W_Σ be the set of $x \in \mathbb{A}_E^m$ whose components at the finite places outside Σ are 0. By strong approximation for the additive group (E is dense in the adeles of E away from the infinite places), L is dense in the product of the components at the finite places outside Σ (the point of $\mathrm{Hom}(S,T)$ is a homeomorphism there), so $L + W_\Sigma$ is dense; as G is continuous and L-periodic, $G(x) \neq 0$ for some $x \in W_\Sigma$. Put $\varphi = \rho(k^{-1}x)v^0$. Since k^{-1} acts place by place, $k^{-1}x \in W_\Sigma$, so for z integral with components 0 at Σ the vectors $\mathrm{fv}(z)$ and $k^{-1}x$ have disjoint supports, $\rho_f(z)$ commutes with $\rho(k^{-1}x)$, and $\rho_f(z)\varphi = \rho(k^{-1}x)\rho_f(z)v^0 = \varphi$: φ is the vacuum off Σ. Finally $\omega_{\alpha,\beta}(g,h)\varphi = \rho(x)\omega_{\alpha,\beta}(g,h)v^0 = \rho(x)u$ (the scalar characters cancel in $\omega\rho(k^{-1}x)\omega^{-1} = \rho(x)$), so $|\theta^{S,T}_{\alpha,\beta}(\varphi)(g,h)| = |\Theta(\rho(x)u)| = G(x) \neq 0$. □

Lemma 6.6.92. *Let $n = n_1 \sqcup n_2$ be finite index sets, $\mathrm{I}_n = \mathrm{I}_{n_1} \oplus \mathrm{I}_{n_2}$, $\iota\colon \mathrm{G}(1_{n_1}) \times \mathrm{G}(1_{n_2}) \to \mathrm{G}(1_n)$ the block-diagonal embedding, and $\mathbb{H}^c = 0 \oplus \mathbb{H}^c$ with $c = \#n_1$, 0 the zero space. Let A be a finite set of finite places with $A \cap \bar{A} = \emptyset$ and $\Sigma = A \cup \bar{A}$. Let $Y\colon \mathrm{G}(1_n) \to \mathbb{C}$ be continuous, left invariant under Γ_{I_n}, and right invariant under every $k \in \mathbf{K}_0(n)$ whose components at the places of Σ are 1. If the descents of Y to $\mathbb{H}^c$ twisted by v^c vanish off Σ, then*

$$\int_{[\mathrm{U}(\mathrm{I}_{n_2})]} Y\big(\iota(h_1,h_2)\big)\,dh_2 = 0 \qquad \text{for every } h_1 \in \mathrm{G}(1_{n_1}).$$

Proof. Write $c = \#n_1$, $\Gamma = \Gamma_{\mathrm{I}_n}$, and let $x_0 \in \mathrm{M}_{n\times n_1}(E)$ have entries δ_{ij} ($i \in n$, $j \in n_1$). The point of I_m is 1, so $\Gamma_{\mathrm{I}_m} = \mathrm{U}(\mathrm{I}_m)(F)$ and $\mathrm{G}(1_m) = \{g \in \mathrm{GL}_m(\mathbb{A}_E) : g^*g = 1\} = G_\infty(1_m)\times G_f(m)$, with $G_\infty(1_m)$ compact. By Theorem A.4.5, $[\mathrm{U}(\mathrm{I}_m)]$ is compact of finite measure for $m \neq \emptyset$, and Y is bounded; for $m = \emptyset$ the group is trivial of mass 1. The groups $\mathrm{G}(1_m)$ are unimodular (a compact group times the finite adelic points of a reductive group), so their quotient measures are invariant under right translations. For $\gamma \in \Gamma_{\mathrm{I}_{n_2}}$, $\iota(1,\gamma) \in \Gamma$, so functions $a \mapsto Y(\iota(h_1,a)q)$ are read on $[\mathrm{U}(\mathrm{I}_{n_2})]$.

Step 0: $c = 0$. Then $n_2 = n$, ι is the identity, $\mathrm{Hom}(0,\mathrm{I}_n)$ has rank 0, its theta model is $\mathbb{C}$ with $v^0 = 1$, its theta functional and all its Weil and Heisenberg operators are the identity (the rank-0 conventions of Definition 3.2.12). The datum 1 is the vacuum off Σ, and its descent is the constant $\int_{[\mathrm{U}(\mathrm{I}_n)]} Y$, which therefore vanishes. From now on $c \geq 1$.

Step 1: the splitting. Index the c planes of $S = 0 \oplus \mathbb{H}^c$ by n_1 (a fixed bijection), so that S has index set $n_1 \times \{1,2\}$, signs $s(j,1) = 1$, $s(j,2) = -1$, and J_S and the point x_S are block diagonal with the blocks $\left(\begin{smallmatrix}0&1\\1&0\end{smallmatrix}\right)$ and the point of $\mathbb{H}$ on $\{(j,1),(j,2)\}$. Let l, k be the $(n_1 \times \{1,2\}) \times n_1$ matrices with columns $e_{(j,1)}$, $e_{(j,2)}$. Then $k^*J_Sk = l^*J_Sl = 0$ and $l^*J_Sk = 1$: $(k, l, \emptyset)$ is the tautological splitting of S over the zero space along n_1. It is base-adapted: $(l_{\mathbb{A}}\ k_{\mathbb{A}}) = x_S^{-1}(l\ k)$ with $(l\ k)$ a permutation matrix; the real component $2^{-1/2}\left(\begin{smallmatrix}1&-1\\1&1\end{smallmatrix}\right)$ of the point of $\mathbb{H}$ is unitary, and its finite component (WR1) has entries in $\widehat{\mathcal{O}}_E$ and determinant equal to the unit of (WD9) (as $c_0 + \bar{c}_0 = 1$ by (WD1)), so its inverse is integral. Consider the induced splitting of the space $\mathrm{Hom}(S,\mathrm{I}_n)$ over the zero space $\mathrm{Hom}(0,\mathrm{I}_n)$ along $n \times n_1$ (MX4). As $x_{\mathrm{I}_n} = 1$ and $J_{\mathrm{I}_n} = 1$, its adelic frames act on adelic $n \times n_1$ matrices by

$$k_{\mathbb{A}}^{\mathrm{Hom}} b = b\,\mathrm{pr}_l, \qquad l_{\mathbb{A}}^{\mathrm{Hom}} b = b\,\mathrm{pr}_k.$$

Hence (i) the slices of the space $\mathrm{Hom}(S,\mathrm{I}_n)$ along the induced splitting are the Hom slices $f[x]$ of (MX4); (ii) the induced splitting is base-adapted: its frame matrix is $1_n \otimes M^{\mathsf{T}}$ with M the square matrix with row blocks pr_k, pr_l, that is $M = (l_{\mathbb{A}}\ k_{\mathbb{A}})^*\varepsilon_s$, unitary at the infinite places and integral at the finite places, where $\varepsilon_s = 1$.

Step 2: test data. Let b be an adelic $n \times n_1$ matrix with $b_w = 0$ at every finite place $w \notin \Sigma$, and $f_b = \rho(y_b)v^0 \in \mathcal{M}_{S,\mathrm{I}_n}$ with $y_b = k_{\mathbb{A}}^{\mathrm{Hom}} b$; the components of y_b at the finite places outside Σ vanish. By (WD7), $\rho(u)\rho(y) = \beta(u,y)\beta(y,u)^{-1}\rho(y)\rho(u)$ for vectors u, y of the theta model (β its bicharacter). If z is an integral finite adelic vector of $\mathrm{Hom}(S,\mathrm{I}_n)$ with $z_w = 0$ for $w \in \Sigma$, then $\mathrm{fv}(z)$ and y_b have no common nonzero component, so $\beta(\mathrm{fv}(z), y_b) = \beta(y_b, \mathrm{fv}(z)) = 1$ and $\rho_f(z)f_b = \rho(y_b)\rho_f(z)v^0 = f_b$ by (5) of Lemma 6.2.33. So f_b is the vacuum off Σ, and by hypothesis

$$\Theta_b(g') = \int_{[\mathrm{U}(\mathrm{I}_n)]} \theta^{S,\mathrm{I}_n}_{\upsilon^c,1}(f_b)(g',h)\,Y(h)\,dh = 0 \qquad (g' \in \mathrm{G}(s)).$$

Step 3: the terms at a Levi element. Let $m = \alpha h_1 \in \mathrm{GL}_{n_1}(\mathbb{A}_E)$, α the Weil idele read with components 1 at the infinite places, and $g_0 = \mathrm{lev}(m,1) = k_{\mathbb{A}} m\,\mathrm{pr}_k + l_{\mathbb{A}}(m^{-1})^*\mathrm{pr}_l \in \mathrm{G}(s)$ (MX2). As $\mathrm{pr}_k k_{\mathbb{A}} = \mathrm{pr}_l l_{\mathbb{A}} = 1$ and $\mathrm{pr}_l k_{\mathbb{A}} = \mathrm{pr}_k l_{\mathbb{A}} = 0$, $g_0 k_{\mathbb{A}} = k_{\mathbb{A}} m$ and $g_0^{-1} l_{\mathbb{A}} = l_{\mathbb{A}} m^*$. Apply (2) of Lemma 6.2.45 to $(V, V_0, T) = (S, 0, \mathrm{I}_n)$ and the characters $(1,1)$ (so that $1 \cdot \upsilon^{\#n_1} = \upsilon^c$): here $B = \mathrm{pr}_k g_0^{-1} l_{\mathbb{A}} = 0$, W is empty, and $\omega_{1,1}(1,h)$ and $\rho(0)$ on the rank-0 model are the identity. The theta term (MX6) for the splitting, I_n and $(\upsilon^c, 1)$ is $\mathrm{term}_x(f)(g,h) = (\omega_{\upsilon^c,1}(g,h)f)[x]$, the theta functional of the zero space being the identity. Hence, for $x \in \mathrm{M}_{n\times n_1}(E)$ and $h \in \mathrm{G}(1_n)$,

$$\mathrm{term}_x(f)(g_0,h) = \upsilon(\det m)^{\#n}\,|\det m|^{\#n/2}\,f[h^{-1}xm], \tag{6.165}$$

and likewise, with $g = 1$ and $h = \gamma \in \Gamma$, $\mathrm{term}_x(f)(g_0,\gamma h) = \mathrm{term}_{\gamma^{-1}x}(f)(g_0,h)$, using $\omega(g_0,\gamma h) = \omega(1,\gamma)\omega(g_0,h)$ ((2) of Lemma 4.1.1).

Step 4: integrable terms. By Step 1 (i) and (2) of Lemma 6.2.44 for the induced splitting, $T(h) = \sum_x |\mathrm{term}_x(f_b)(g_0,h)\,Y(h)| \le M \sup|Y|\,\|\omega_{v^c,1}(g_0,h)f_b\|$, the norm of the rank-0 model being $|\cdot|$; the right side is continuous in h by (2) of Lemma 4.1.1. By Step 3, T is left Γ-invariant (γ^{-1} permutes $\mathrm{M}_{n\times n_1}(E)$), so its integral over any Borel set of representatives of $\Gamma\backslash\mathrm{G}(1_n)$ equals $\int_{\Gamma\backslash\mathrm{G}(1_n)} T$. As the quotient is compact and the quotient map open, there is a compact K with $\Gamma K = \mathrm{G}(1_n)$; cover K by finitely many Vg_i, V an open neighbourhood of 1 with $VV^{-1}\cap\Gamma = \{1\}$; then $\bigcup_i (Vg_i\cap K)\setminus\Gamma\big(\bigcup_{j<i} Vg_j\cap K\big)$ is a Borel set of representatives inside K, over which $\int T \le \mathrm{vol}(K)\,M\sup|Y|\sup_K\|\omega(g_0,\cdot)f_b\| < \infty$. So f_b has integrable terms at g_0 with weight Y.

Step 5: the Fourier coefficient. For $h\in\mathrm{G}(1_n)$ put $q(h) = \iota(h_1,1)^{-1}h$ and $\mathrm{fr}(h) = h^{-1}x_0h_1 = q(h)^{-1}x_0$ (as $\iota(h_1,1)x_0 = x_0h_1$); $\mathrm{fr}(h)^*\mathrm{fr}(h) = 1$ at every place. Let $\mathbf{1}_{\mathrm{int}}(h)$ be 1 if the finite components of $\mathrm{fr}(h)$ are integral and 0 otherwise; it is locally constant. By (6.165) at $x = x_0$, $h^{-1}x_0m = \alpha\,\mathrm{fr}(h)$. By Step 1 (i) and (1) of Lemma 6.2.44 (with $a=0$, $w=0$), $f_b[y] = \psi_E(\jmath\, b^*y)\,v^0[y]$, where $b^*y = \sum_{i,j}\bar b_{ij}y_{ij}$; by Step 1 (ii) and Lemma 6.2.11 (at $g=1$, in the basis 1), $v^0[y] = C_1|e_{n\times n_1}(y)|^2$ with $C_1\neq 0$ independent of b and y (the rank-0 vacuum vector is 1). By (WD5), as α is 1 at the infinite places, $\mathrm{Im}\,\jmath_v = 1/\sqrt{d}$ and $\mathrm{tr}(\mathrm{fr}(h)_v^*\mathrm{fr}(h)_v) = c$ for $v\in\Phi$, and $\alpha\,\mathrm{fr}(h)_f \in \alpha\widehat{\mathcal{O}}_E^{n\times n_1}$ exactly when $\mathrm{fr}(h)_f$ is integral, $|e_{n\times n_1}(\alpha\,\mathrm{fr}(h))|^2 = e^{-2\pi c\#\Phi/\sqrt{d}}\,\mathbf{1}_{\mathrm{int}}(h)$. Hence

$$\mathrm{term}_{x_0}(f_b)(g_0,h) = c_*\,\mathrm{ch}_b(\mathrm{fr}(h))\,\mathbf{1}_{\mathrm{int}}(h),$$
$$\mathrm{ch}_b(y) = \psi_E(\jmath\, b^*\alpha y),\quad c_* = C_1\upsilon(\det m)^{\#n}|\det m|^{\#n/2}e^{-2\pi c\#\Phi/\sqrt{d}} \neq 0.$$

The Gram matrix $x_0^*x_0 = 1$ is invertible, and $\Gamma_{x_0} = \{\gamma\in\Gamma : \gamma x_0 = x_0\} = \iota(1,\Gamma_{\mathrm{I}_{n_2}})$. By (2) of Lemma 6.3.25 (for $W=S$, $W_0=0$, $V=\mathrm{I}_n$, the characters $(\upsilon^c,1)$, the datum f_b, the weight Y and $g=g_0$; Step 4), the centre coefficient at $\jmath\cdot 1$ of $\Theta_b = 0$ at g_0, which is 0, is the integral of $\mathrm{term}_{x_0}(f_b)(g_0,h)Y(h)$ over $\Gamma_{x_0}\backslash\mathrm{G}(1_n)$. Dividing by c_*: for every b as in Step 2,

$$h\mapsto \mathrm{ch}_b(\mathrm{fr}(h))\,\mathbf{1}_{\mathrm{int}}(h)\,Y(h) \text{ is integrable on } \Gamma_{x_0}\backslash\mathrm{G}(1_n) \text{ with integral 0.} \tag{6.166}$$

Step 6: the period. For $q\in\mathrm{G}(1_n)$ let $\mathrm{per}(q) = \int_{[\mathrm{U}(\mathrm{I}_{n_2})]} Y(\iota(h_1,a)q)\,da$; the claim is $\mathrm{per}(1) = 0$.

(a) per is continuous, by dominated convergence (Y continuous and bounded, the quotient of finite measure).

(b) $\mathrm{per}(\iota(1,v)q) = \mathrm{per}(q)$ for $v\in\mathrm{G}(1_{n_2})$, since $\iota(h_1,a)\iota(1,v) = \iota(h_1,av)$ and the quotient measure is right invariant; and $\mathrm{per}(qk) = \mathrm{per}(q)$ for $k\in\mathbf{K}_0(n)$ with components 1 at Σ, by the invariance of Y.

(c) If $q^{-1}x_0 = q'^{-1}x_0$, then $q'q^{-1}$ fixes x_0, so $q'q^{-1} = \iota(1,v)$ (sidecalc of Step 5) and $\mathrm{per}(q') = \mathrm{per}(q)$ by (b).

(d) Let $q,q'\in G_\infty(1_n)\times\mathbf{K}_0(n)$ with $(q^{-1}x_0)_v = (q'^{-1}x_0)_v$ for $v\in\Phi\cup\Sigma$. Let $\kappa\in\mathbf{K}_0(n)$ have components $(q_f^{-1}q'_f)_w$ at the finite places $w\notin\Sigma$ and 1 at Σ, and $k = (1,\kappa)$. Then $(qk)^{-1}x_0$ has the components of $q'^{-1}x_0$ at every place, so $\mathrm{per}(q') = \mathrm{per}(qk) = \mathrm{per}(q)$ by (c) and (b).

(e) If $\mathbf{1}_{\mathrm{int}}(h) = 1$, there is $q'\in G_\infty(1_n)\times\mathbf{K}_0(n)$ with $q'^{-1}x_0 = \mathrm{fr}(h)$: x_0 and $\mathrm{fr}(h)_f$ are integral with left inverses x_0^*, $\mathrm{fr}(h)_f^*$ and equal Gram matrices 1, so (2) of Lemma 3.2.6 gives $d\in\mathrm{GL}_n(\widehat{\mathcal{O}}_E)$ with $d^*d = 1$ and $dx_0 = \mathrm{fr}(h)_f$; then $d\in\mathbf{K}_0(n)$ and $q' = (q(h)_\infty, d^{-1})$.

Step 7: Stone–Weierstrass. Let $\pi(q) = ((q^{-1}x_0)_v)_{v\in\Phi\cup\Sigma} \in \prod_{v\in\Phi\cup\Sigma} \mathrm{M}_{n\times n_1}(E_v)$ and $K_{\mathrm{fr}} = \pi(G_\infty(1_n)\times \mathbf{K}_0(n))$, a compact Hausdorff space. As π is a continuous surjection of a compact space onto K_{fr}, hence a quotient map, (d) and (a) give a continuous $J\colon K_{\mathrm{fr}}\to\mathbb{C}$ with $J\circ\pi = \overline{\mathrm{per}}$. For b as in Step 2, $\mathrm{ch}_b(y)$ depends only on $(y_v)_{v\in\Phi\cup\Sigma}$ and so defines a function on K_{fr}; $\mathrm{ch}_b\mathrm{ch}_{b'} = \mathrm{ch}_{b+b'}$, $\overline{\mathrm{ch}_b} = \mathrm{ch}_{-b}$, $\mathrm{ch}_0 = 1$. They separate points: ψ_E is nontrivial on each completion E_v (for $v\in\Phi$ by (WD4); for finite v because otherwise it would be trivial on the dense subgroup $E+E_v$ of $\mathbb{A}_E$, by strong approximation for the additive group, contradicting (a) of Theorem A.5.2); if $y, y'\in K_{\mathrm{fr}}$ differ in the entry (i,j) at v, the b with the single entry $t\in E_v$ there gives $\mathrm{ch}_b(y)/\mathrm{ch}_b(y') = \psi_E(\bar{t}\jmath\alpha_v\delta)$ with $\delta\neq 0$, which is $\neq 1$ for some t. By the Stone–Weierstrass theorem their span is uniformly dense in the continuous functions on K_{fr}.

Let $F(h) = \overline{\mathrm{per}(q(h))}\,\mathbf{1}_{\mathrm{int}}(h)\,Y(h)$. It is continuous, and left Γ_{x_0}-invariant: $q(\iota(1,\gamma)h) = \iota(1,\gamma)q(h)$, $\mathrm{fr}(\iota(1,\gamma)h) = \mathrm{fr}(h)$, and (b). If $\mathbf{1}_{\mathrm{int}}(h) = 1$, then by (e) and (c), $(\mathrm{fr}(h)_v)_{v\in\Phi\cup\Sigma} = \pi(q')\in K_{\mathrm{fr}}$ and $J(\pi(q')) = \overline{\mathrm{per}(q(h))}$. Given $\epsilon>0$ choose $Q = \sum_k c_k\mathrm{ch}_{b_k}$ with $|J-Q|\le\epsilon$ on K_{fr}; then $|F(h) - Q(\mathrm{fr}(h))\mathbf{1}_{\mathrm{int}}(h)Y(h)| \le \epsilon\,\mathbf{1}_{\mathrm{int}}(h)|Y(h)|$. By (6.166) ($b=0$ for integrability, $b=b_k$ for the integrals), F is integrable on $\Gamma_{x_0}\backslash\mathrm{G}(1_n)$ and $|\int F| \le \epsilon\int \mathbf{1}_{\mathrm{int}}|Y|$. Hence $\int_{\Gamma_{x_0}\backslash\mathrm{G}(1_n)} F = 0$.

Step 8: positivity. Let $\varsigma(h) = \mathbf{1}_{\mathrm{int}}(h)\,|\mathrm{per}(q(h))|^2 \ge 0$, continuous by (a). For every h, as $\mathrm{fr}(\iota(1,a)h) = \mathrm{fr}(h)$, $\mathrm{per}(q(\iota(1,a)h)) = \mathrm{per}(\iota(1,a)q(h)) = \mathrm{per}(q(h))$ and $\iota(1,a)h = \iota(h_1,a)q(h)$,

$$\int_{[\mathrm{U}(\mathrm{I}_{n_2})]} F(\iota(1,a)h)\,da = \overline{\mathrm{per}(q(h))}\,\mathbf{1}_{\mathrm{int}}(h)\int_{[\mathrm{U}(\mathrm{I}_{n_2})]} Y(\iota(h_1,a)q(h))\,da = \varsigma(h),$$

the integral converging absolutely. Suppose $\mathrm{per}(1)\neq 0$. At $h^\dagger = \iota(h_1,1)$, $q(h^\dagger) = 1$ and $\mathrm{fr}(h^\dagger) = x_0$ is integral, so $\varsigma(h^\dagger) = |\mathrm{per}(1)|^2 > 0$, and $\varsigma>0$ near $h^\dagger$. Apply Lemma 6.2.47 to $\mathrm{G}(1_n)$, the trivial group as first factor, $\mathrm{G}(1_{n_2})$ with the embedding $a\mapsto\iota(1,a)$ (a continuous injective homomorphism and a homeomorphism onto its closed image, the stabiliser of x_0), the discrete subgroup $\Gamma_{\mathrm{I}_{n_2}}$ (with image Γ_{x_0}, discrete), the function ς, the constant 1 and, at every h, the element 1: it gives $\int_{\Gamma_{x_0}\backslash\mathrm{G}(1_n)} F = R$ with $R\neq 0$, contradicting Step 7. So $\mathrm{per}(1) = \int_{[\mathrm{U}(\mathrm{I}_{n_2})]} Y(\iota(h_1,h_2))\,dh_2 = 0$. □

6.7 Hecke values and test forms

This section bounds the Hecke ratios ρ_j of the comparison along a regular family (Proposition 6.7.1), as the cost of one lift requires. The Hecke value product factors into ratios of main and of ramified critical pairs (Lemma 6.7.2). The ramified ratios are small along a regular family by definition, and the work is in the main ratios, whose inverses have height at most $6\beta_{\mathrm{den}} - h_{\mathrm{dir}}$.

The key step realises Hecke L-values as squared norms of theta lifts from U(1) (Proposition 6.7.13): for a critical pair $p = (\nu, z)$ with $z\ge 2$, the algebraic part of the lift of Definition 4.2.5 is a positive constant, independent of the twist, times the partial L-value, so that a main ratio is a ratio of squared norms. The proof writes the norm, by the Rallis formula for sharp data, as a series of vacuum coefficients, whose sum in rank one is the partial L-value times an Euler product. For theta series attached to Hecke characters see [128], and for theta functions with complex multiplication [272, 274]; the unramified computation is that of the doubling method [231, 187], and for theta lifts from U(1) see [121].

The inverse main ratio is then a product of four numbers whose heights add: the squared norm of the untwisted lift, bounded through its conjugates and denominators (Lemma 6.7.4); the pairing of two test forms projected to the line of the lift, bounded by the denominator condition of the regular family; the inverse square of a flat ramified ratio, which is small; and a term bounded at each prime ℓ by $\ell^{2F(\ell)}$ through the choice of the test forms. So the finite prime sums enter through the test forms and the archimedean sizes through the untwisted norm, and

their difference is the direction amount (Definition 2.4.2). For the algebraicity of critical Hecke L-values of CM fields see [274, 159]. The architecture follows [259].

Proposition 6.7.1. *Let θ be a regular family of m-fold twists and $1 \le j \le m$.*

(a) For every main pair p for j, the family $\iota \mapsto r_p(\theta(\iota)^j)^{-1}$ has height at most $6\beta_{\mathrm{den}} - h_{\mathrm{dir}}$.

(b) There are $e \in \mathbb{Z}$, main pairs $p_1, \dots, p_{k/2}$ for j, ramified pairs $q_1, \dots, q_{5m}$ and signs $s_1, \dots, s_{5m} \in \{\pm 1\}$, independent of the twist, with

$$\Gamma_j(\vartheta) = \Gamma_j(1)\,\mathrm{N}Q^e\Big(\prod_{a=1}^{k/2} r_{p_a}(\vartheta)\prod_{b=1}^{5m} r_{q_b}(\vartheta, s_b)\Big)^2 \qquad \text{for every twist } \vartheta.$$

(c) The family $\iota \mapsto \rho_j(\theta(\iota)^j)^{-1}$ has height at most $10\,m\,x_1 + k\,(6\beta_{\mathrm{den}} - h_{\mathrm{dir}})$.

Proof. Part (a). Let $p = (\nu, z)$ be a main pair for j; by (RH1), $z \ge 10$. For a prime identification $\iota \mid \ell$ put $\vartheta_\iota = \theta(\iota)^j$, a twist with the modulus Q_ι of $\theta(\iota)$, so $\ell \nmid \mathrm{N}Q_\iota$ by (SR1). Write $\varphi_\iota = \varphi_{p,\vartheta_\iota}$, the lift of p at ϑ_ι (the vector paired in Proposition 6.7.17), a scalar multiple of $\lambda_{p,\vartheta_\iota}$ by (OL4), and $\beta = \beta_{\mathrm{den}}$.

Step 1: a flat ramified pair. Let $\nu_{\mathrm{fl}} = \chi_M \upsilon^{-2}$. Weights and tame parts multiply, so ν_{fl} has weight -2 at every infinite place and tame part ω, which is trivial off the chosen places and, at a chosen place w, equal to $\eta_w^{q_2}$ of order $q_2 > 1$. As $1 \le 2 \le t$ and $2 \le 4b$, $p_{\mathrm{fl}} = (\nu_{\mathrm{fl}}, 2)$ is a critical pair; it is flat and ramified. For every tame character ϑ, $r_{p_{\mathrm{fl}}}(\vartheta) > 0$: numerator and denominator are absolute values of absolutely convergent Euler products at $z = 2$ with factors $(1 - \tilde{\mu}(x_w)\mathrm{N}w^{-2})^{-1} \ne 0$, $|\tilde{\mu}| = 1$, hence not 0. Write $r_\iota = r_{p_{\mathrm{fl}}}(\vartheta_\iota)$.

Step 2: test forms at ι and $\bar{\iota}$. Let $c = c_{\mathrm{tf}} \ne 0$ be the number of Proposition 6.7.17 for j, p and p_{fl}. Apply Proposition 6.7.17 to ϑ_ι with the embeddings ι and $\bar{\iota}$ (both over ℓ, and $\ell \nmid \mathrm{N}Q_\iota$): there are test forms Ξ_ι, Ξ'_ι for ℓ of O_{p,ϑ_ι} with $\|\overline{\iota(c\,r_\iota)}\|\ell^{-F(\ell)} \le \|\iota\langle \Xi_\iota, \varphi_\iota\rangle\|$ and $\|\bar{\iota}(c\,r_\iota)\|\ell^{-F(\ell)} \le \|\bar{\iota}\langle \Xi'_\iota, \varphi_\iota\rangle\|$. Since $\bar{\iota}(u) = \iota(\bar{u})$, r_ι is real and $\overline{\langle \Xi', \varphi\rangle} = \langle \varphi, \Xi'\rangle$, the product of the two inequalities is

$$\|\iota(c\bar{c}\,r_\iota^2)\|\,\ell^{-2F(\ell)} \le \|\iota(P_\iota)\|, \qquad P_\iota = \langle \Xi_\iota, \varphi_\iota\rangle\langle \varphi_\iota, \Xi'_\iota\rangle. \tag{6.167}$$

The left side is positive, so $P_\iota \ne 0$ and $\varphi_\iota \ne 0$; hence $c_s \ne 0$, and $\eta_P \ne 0$ or $j_p = 0$, so the scale factor $c_s^{2z}(\pi_M \eta_P)^{j_p}$ of (OL4) is not 0 (as $\pi_M \ne 0$), and Proposition 6.7.13 applies to p.

Step 3: the inverse ratio as a product of four factors. By Proposition 6.7.13, $r_p(\vartheta_\iota) = \mathrm{alg}_p(\vartheta_\iota)/\mathrm{alg}_p(1) > 0$; by (OL4), with $\mathrm{N}Q = 1$ for the trivial twist,

$$r_p(\vartheta_\iota)^{-1} = \mathrm{N}Q_\iota^{2z-1}\|\varphi_{p,1}\|^2/\|\varphi_\iota\|^2.$$

Let $\mathrm{pr} = \mathrm{pr}_{p,\vartheta_\iota}$, the orthogonal projection to $\mathbb{C}\lambda_{p,\vartheta_\iota} = \mathbb{C}\varphi_\iota$. For a nonzero vector φ of an inner product space and vectors Ξ, Ξ',

$$\langle \mathrm{pr}\,\Xi, \mathrm{pr}\,\Xi'\rangle = \langle \Xi, \varphi\rangle\langle \varphi, \Xi'\rangle/\|\varphi\|^2$$

(expand $\mathrm{pr}\,\Xi$ along $\varphi/\|\varphi\|$); we apply it to $\varphi = \varphi_\iota$. Hence, P_ι and r_ι being nonzero,

$$r_p(\vartheta_\iota)^{-1} = \mathrm{N}Q_\iota^{2z-1} \cdot y_\iota^{(1)}\,y_\iota^{(2)}\,y_\iota^{(3)}\,y_\iota^{(4)},$$
$$y_\iota^{(1)} = \|\varphi_{p,1}\|^2,\ y_\iota^{(2)} = \langle \mathrm{pr}\,\Xi_\iota, \mathrm{pr}\,\Xi'_\iota\rangle,\ y_\iota^{(3)} = r_\iota^{-2},\ y_\iota^{(4)} = \frac{r_\iota^2}{P_\iota}.$$

Step 4: the heights of the factors. (i) By Lemma 6.7.4, $y^{(1)}$ has height at most $\beta - \sum_\sigma s_\infty(\kappa(\sigma))$. (ii) By (RW) there is a denominator bound (γ_ℓ) for (θ, j); by (DB2) and (DL2), applied to the main pair p and the test forms Ξ_ι, Ξ'_ι for ℓ, $\|\iota(y_\iota^{(2)})\| \le e^{\gamma_\ell}$, and by (DB1) $\sum_{\ell\in T}\gamma_\ell \le \beta$ for every finite set T; so $y^{(2)}$ has height at most β by Lemma 3.1.8 (c). (iii) p_{fl} is a ramified critical pair, so by (SR2) with $s=1$ the family $\iota \mapsto r_\iota^{-1}$ has height at most x_1, and $y^{(3)}$ at most $2x_1$ by Lemma 3.1.8 (e). (iv) For $y^{(4)}$ take $H = c\bar c \ne 0$ in the definition of height: for every automorphism σ, $|\sigma(H)| = |\sigma(c)|\,|\sigma(\bar c)| \le e^\alpha$ ($\sigma(\bar c)$ is the value at c of the automorphism $u \mapsto \sigma(\bar u)$) with $\alpha = 2(fmb/k + 3x^{34})$ by Proposition 6.7.17; by (6.167), $\|\iota(Hy_\iota^{(4)})\| \le \ell^{2F(\ell)}$, with $2F(\ell) \ge 0$ (a sum of nonnegative terms); and for every finite set S of primes, by Lemma 6.7.12 and Lemma 6.7.11,

$$\alpha + \sum_{\ell\in S} 2F(\ell)\log\ell \le 2\beta + \sum_{\sigma\in\Phi} s_{\mathrm{fin}}(\kappa(\sigma),\sigma).$$

So $y^{(4)}$ has height at most $2\beta + \sum_\sigma s_{\mathrm{fin}}(\kappa(\sigma),\sigma)$.

Step 5: conclusion. By Lemma 3.1.8 (e) the product $y^{(1)}y^{(2)}y^{(3)}y^{(4)}$ has height at most $4\beta + 2x_1 - h_{\mathrm{dir}}$, and by Lemma 3.1.8 (b) (the positive integers $\mathrm{N}Q_\iota$ are prime to ℓ by (SR1), exponent $2z-1$) so does $\iota \mapsto r_p(\vartheta_\iota)^{-1}$. As $x_1 \le \beta$ by Lemma 6.7.11, Lemma 3.1.8 (a) gives the height bound $6\beta - h_{\mathrm{dir}}$.

Part (b). By Lemma 6.7.2 (c), for every twist ϑ, $\Gamma_j(\vartheta) = \Gamma_j(1)\,\mathrm{N}Q^e(\cdots)^2$ with $e = z_*^2 + z_+^2 + z_-^2$ and, inside the square, the ratios at ϑ of the $k/2$ lower points (ν_*, z), $7\lfloor m/2\rfloor < z \le z_*$, which are main pairs for j by Lemma 6.7.2 (a), and the ratios with signs of the $5m$ lower points listed in Lemma 6.7.2 (b), which are ramified pairs. Numbering the former $p_1,\dots,p_{k/2}$ and the latter $q_1,\dots,q_{5m}$ with their signs s_b gives (b); e, the pairs and the signs depend only on j.

Part (c) from (a), (b). By (b) with $\vartheta = \theta(\iota)^j$, the number $\rho_j(\vartheta)^{-1}$ is $\mathrm{N}Q^{-e}$ times the squares of $k/2$ inverse ratios of main pairs and $5m$ inverse ratios of ramified pairs. By (a) each squared main inverse ratio has height at most $2(6\beta_{\mathrm{den}} - h_{\mathrm{dir}})$; by the small-ratio condition (SR2) each ramified inverse ratio $r_{q_b}(\theta(\iota)^j, s_b)^{-1}$ has height at most x_1, so its square at most $2x_1$; and the factor $\mathrm{N}Q^{-e}$, prime to $\ell(\iota)$, costs nothing (height calculus, Lemma 3.1.8). Heights add over products, so the height is at most $k(6\beta_{\mathrm{den}} - h_{\mathrm{dir}}) + 5m\cdot 2x_1$. □

Lemma 6.7.2. *Let $1 \le j \le m$ and put $e = z_*^2 + z_+^2 + z_-^2$.*

(a) For $7\lfloor m/2\rfloor < z \le z_*$ the lower point (ν_*, z) of p_j^* is a main pair for j; there are $k/2$ such z.

(b) The $5m$ lower points (ν_*, z) with $1 \le z \le 7\lfloor m/2\rfloor$, (ν_+, z) with $1 \le z \le m$ and (ν_-, z) with $1 \le z \le \lfloor m/2\rfloor$ are ramified pairs; attach to them the signs s_*, s_+, s_- respectively.

(c) For every twist ϑ, $\Gamma_j(\vartheta) > 0$ and

$$\Gamma_j(\vartheta) = \Gamma_j(1)\,\mathrm{N}Q^e\Big(\prod_{z=7\lfloor m/2\rfloor+1}^{z_*} r_{(\nu_*,z)}(\vartheta)\prod_{z=1}^{7\lfloor m/2\rfloor} r_{(\nu_*,z)}(\vartheta,s_*)\prod_{z=1}^{m} r_{(\nu_+,z)}(\vartheta,s_+)\prod_{z=1}^{\lfloor m/2\rfloor} r_{(\nu_-,z)}(\vartheta,s_-)\Big)^2.$$

Proof. Numerical facts. By (AD2), $m = 2^{e_1+1}$ is even and $r = 3^{e'+1}$ is odd, so $t = 5r$ is odd, $k = r + 1 - m$ is even and $\lfloor m/2\rfloor = m/2$. By (AD1), $\log x \ge 100\log\log b \ge 100\cdot 10^{12} C_P$ with $C_P \ge q_0 \ge 1$, so $x \ge 4$; by (AD2), $m \ge \sqrt{x} \ge 2$ and in fact $m \ge 10$ (as $x \ge e^{10^{14}}$), and

$r \ge x^5 \ge 12\sqrt{x}+1 \ge 6m+1$. Hence $n_* = j + (t-11m-1)/2$ is an integer ($t-11m-1$ is even) with $n_* \ge 0$ (as $t = 5r > 11m+1$) and $n_* \le m + (5r-1)/2 \le 4r = t - r$ (as $2m - 1 \le 3r$).

(a). The character $\nu_* = \mu_j^0 \upsilon^{n_*}$ has weight $-\kappa_j + n_*$ (weights add under products; μ_j^0 has weight $-\kappa_j$ and υ weight 1) and tame part ω^j (υ has trivial tame part). So it is of weight $-c$ with $c = \kappa_j - n_*$, and every lower point (ν_*, z) is a critical pair. Let $7m/2 < z \le z_*$. (Mp1): $z > 7m/2 \ge m$ and $z > 7m/2 \ge 35 \ge 10$; $z \le z_* = 7m/2 + k/2 = (r+1+6m)/2 \le r$, since $6m+1 \le r$. (Mp2): the tame part is ω^j. (Mp3): $\kappa_j(v) + r - t \le \kappa_j(v) - n_* \le \kappa_j(v)$ is $0 \le n_* \le t - r$, shown above. The number of such z is $z_* - 7m/2 = k/2$.

(b). The tame parts of ν_*, ν_+, ν_- are ω^j, ω^j, ω^{-j} (Definition 6.6.1). By Lemma 6.7.3, for $1 \le |n| \le 8m$, $\omega_w^n \ne 1$ exactly at the chosen places w; as $1 \le j \le m$, the tame part $\omega^{\pm j}$ is nontrivial exactly at the chosen places, so each of these critical pairs is ramified. Their number is $7m/2 + m + m/2 = 5m$.

(c). Fix a twist ϑ with modulus Q. Its places are prime to MN (Definition 3.1.2), and the chosen places lie above $p_0 p_1 = M$, so $S_0 \cap Q = \emptyset$ and $\prod_{w \in S_0 \cup Q} \mathrm{N}w = \mathrm{N}S_0 \cdot \mathrm{N}Q$ with $\mathrm{N}S_0 = \prod_{w \in S_0} \mathrm{N}w$.

Nonvanishing. Let λ be one of the characters ν_i^{-1}, $(\nu_i \vartheta^{s_i})^{-1}$ and $T \in \{S_0, S_0 \cup Q\}$. It has weight c_i, where ν_i has weight $-c_i$ with $c_i(v) \ge z_i \ge 1$ (ϑ has weight 0). The base change $\tilde{\lambda}(x) = \lambda(x/\bar{x})$ is a unitary Hecke character of E whose restriction to the circle $\{x_v \in \mathbb{C} : |x_v| = 1\}$ at an infinite place v is $x_v \mapsto x_v^{2c_i(v)} \ne 1$; so $\tilde{\lambda}$ is not of the form $|\cdot|_{\mathbb{A}}^{i\tau}$, and by Theorem A.1.12 (3) its L-function is holomorphic and has no zeros in $\mathrm{Re}\, s \ge 1$. The partial L-function $L^T(s, \lambda)$ differs from it by finitely many factors $1 - \tilde{\lambda}(x_w)\mathrm{N}w^{-s}$ at unramified places, which do not vanish for $\mathrm{Re}\, s \ge 1$ since $|\tilde{\lambda}(x_w)\mathrm{N}w^{-s}| \le \mathrm{N}w^{-1} < 1$. Hence $L^T(z, \lambda) \ne 0$ for every integer $z \ge 1$. In particular every factor of $\Gamma_j(\vartheta)$ in (6.129) is a positive real number, so $\Gamma_j(\vartheta) > 0$, and the ratios below have nonzero denominators.

Factorisation. For $i \in \{*, +, -\}$ and $1 \le z \le z_i$, the definition of the ratio of the lower point (ν_i, z) gives

$$\left|L^{S_0 \cup Q}(z, (\nu_i \vartheta^{s_i})^{-1})\right|^2 = \left|L^{S_0}(z, \nu_i^{-1})\right|^2 r_{(\nu_i, z)}(\vartheta, s_i)^2,$$

as the denominator $|L^{S_0}(z, \nu_i^{-1})|$ is nonzero. Inserting this in (XD7) of Definition 3.2.22,

$$\begin{aligned} L_*(S_0 \cup Q, (\nu_i \vartheta^{s_i})^{-1}; z_i) &= \mathrm{N}Q^{z_i^2}\ \mathrm{N}S_0^{z_i^2} \prod_{z=1}^{z_i} \left|L^{S_0}(z, \nu_i^{-1})\right|^2 \prod_{z=1}^{z_i} r_{(\nu_i, z)}(\vartheta, s_i)^2 \\ &= \mathrm{N}Q^{z_i^2}\, L_*(S_0, \nu_i^{-1}; z_i) \prod_{z=1}^{z_i} r_{(\nu_i, z)}(\vartheta, s_i)^2. \end{aligned}$$

For the trivial twist ($Q = \emptyset$, $\vartheta^{s_i} = 1$) the left side is $L_*(S_0, \nu_i^{-1}; z_i)$, so $\Gamma_j(1) = \prod_i L_*(S_0, \nu_i^{-1}; z_i)$. Multiplying over $i \in \{*, +, -\}$ gives $\Gamma_j(\vartheta) = \Gamma_j(1)\, \mathrm{N}Q^e \big(\prod_i \prod_{z=1}^{z_i} r_{(\nu_i, z)}(\vartheta, s_i)\big)^2$. Splitting the range $1 \le z \le z_*$ at $7m/2$ and using $s_* = 1$, so that $r_{(\nu_*, z)}(\vartheta, s_*) = r_{(\nu_*, z)}(\vartheta)$, gives the displayed formula. □

Lemma 6.7.3. *Let D be admissible data. For every finite place w of E and every integer n with $1 \le |n| \le 8m$, $\omega_w^n \ne 1$ if and only if w is a chosen place.*

Proof. Put s for the exponent of the admissible datum. By (AD2) of Definition 2.3.4, there is an integer $e \ge 0$ with

$$m = 2^{e+1} \ge 2, \qquad s = 22(e+1), \qquad 2^s = m^{22}.$$

The parameter integers q_0, d are positive and $q_0 d \ge 2$. Consequently their defining formula gives

$$q_2 = (q_0 d)^{s+6} \ge 2^{s+6} = 64 m^{22} > 8m. \tag{1}$$

This comparison already suffices; it requires no divisibility assertion involving q_1. The related size inequality also holds directly:

$$q_1 d = 3q_0 d\, l_0(s)\, 2^s = 3q_0 d\, l_0(s) m^{22} \geq m^{22} > 8m,$$

since $l_0(s) \geq 1$ and $m^{21} \geq 2^{21} > 8$.

Fix w and n as in the statement. If w is not chosen, the definition in Definition 3.2.26 gives $\omega_w = 1$, so $\omega_w^n = 1$.

If w is chosen, the same definition fixes η_w of exact order q_2^2 and sets $\omega_w = \eta_w^{q_2}$. For every positive integer a,

$$\omega_w^a = 1 \quad \Longleftrightarrow \quad \eta_w^{q_2 a} = 1 \quad \Longleftrightarrow \quad q_2^2 \mid q_2 a \quad \Longleftrightarrow \quad q_2 \mid a.$$

Thus ω_w has exact order q_2. Take $a = |n|$. The assumptions and (1) give $0 < a \leq 8m < q_2$, so $q_2 \nmid a$ and $\omega_w^a \neq 1$. If $n > 0$ this is the desired assertion. If $n < 0$, then $\omega_w^n = (\omega_w^{|n|})^{-1}$, and an inverse equals the identity exactly when the original element does. Hence $\omega_w^n \neq 1$ also in this case. The two cases for w prove the equivalence. □

Lemma 6.7.4. *Let $1 \leq j \leq m$ and let p be a main pair for j. Then the constant family $\iota \mapsto \|\varphi_{p,1}\|^2$ has height at most $\beta_{\mathrm{den}} - \sum_{\sigma\in\Phi} s_\infty(\kappa(\sigma))$.*

Proof. Let $p = (\nu, z)$, ν of weight $-c$; by (RH1), $10 \leq z \leq r$.

Step 1: a flat pair of the same rank. The character υ^{-z} of $\mathrm{U}(1)$ has weight $-z$ at every infinite place and trivial tame part. As $1 \leq z \leq r \leq t$ and $z \leq r \leq 3x^5 \leq b \leq 4b$ (items 2 and 3 of Lemma 4.2.67), $q = (\upsilon^{-z}, z)$ is a critical pair with $c_q(\tau) = z$ for every τ, and $z \geq 2$. Its row lengths $c_q(\tau) - z$ vanish, so $j_q = 0$ and $n_q := n_{\upsilon^{-z}} = M^{4fz}$. Put $y_q = N_{\mathrm{ch}}\, n_q^2\, \mathrm{alg}_q(1) = N_{\mathrm{ch}} n_q^2 \|\varphi_{q,1}\|^2$.

Step 2: y_q is integral at every prime identification. Let O be the descent pair of $X(q,1)$, of rank $2z$. Its weight is 0, so $\mathbb{V}_O = \mathbb{C}$ with $\langle a, b\rangle_0 = \bar{a}b$, and by (DP5)

$$y_q = \sum_{[h]} \frac{N_{\mathrm{ch}}}{\#\Gamma_h}\, \overline{n_q \varphi_{q,1}(h)}\; n_q \varphi_{q,1}(h),$$

the sum over $\mathrm{U}(\mathrm{I}_{2z})(E)\backslash G_f(2z)/\mathbf{K}(O)$. Each $N_{\mathrm{ch}}/\#\Gamma_h$ is an integer by Lemma 6.7.9 ($2z \leq 2r \leq rt$, $\mathbf{K}(O) \subseteq \mathbf{K}_0(2z)$ open). Let $\iota \mid \ell$ be a prime identification and $\bar{\iota}$ its conjugate; both are embeddings $\mathbb{C} \to \overline{\mathbb{Q}}_\ell \subset \mathbb{C}_\ell$, and $\ell \nmid \mathrm{N}Q = 1$. By Lemma 6.7.7 for q and the trivial twist, the weight-0 form $n_q\varphi_{q,1}$ is integral at ι and at $\bar{\iota}$: $\|\iota(n_q\varphi_{q,1}(h))\| \leq 1$ and $\|\iota(\overline{n_q\varphi_{q,1}(h)})\| = \|\bar{\iota}(n_q\varphi_{q,1}(h))\| \leq 1$. By the ultrametric inequality $\|\iota(y_q)\| \leq 1$.

Step 3: the size of the integer factor. By Lemma 6.7.10, $N_{\mathrm{ch}} \geq 1$ and $\log N_{\mathrm{ch}} \leq x^{33}$. By items 2–5 of Lemma 4.2.67 ($f \leq x^{12}$, $z \leq r \leq 3x^5$, $\log M \leq 22 \log b$, $\log b \leq x^{1/100}$), $\log n_q^2 = 8fz \log M \leq 8 \cdot x^{12} \cdot 3x^5 \cdot 22\, x^{1/100} \leq x^{19}$ and $8f \leq 8x^{12}$. By Lemma 6.7.11, $3x^{34} \leq \frac{fmb}{k} + 3x^{34} \leq \beta_{\mathrm{den}}$. Hence

$$\log(N_{\mathrm{ch}} n_q^2) + 8f \leq x^{33} + x^{19} + 8x^{12} \leq 3x^{34} \leq \beta_{\mathrm{den}}. \tag{6.168}$$

Step 4: the jet sizes. For $\tau \in \Phi$, (RH3) and $z \leq r$ give $c(\tau) - z \geq \kappa_j(\tau) + r - t - r = \kappa(\tau) + (2j+1)r^8 - 5r \geq \kappa(\tau)$. The function s_∞ is nondecreasing on $\mathbb{Z}_{\geq 0}$: $s_\infty(i+1) - s_\infty(i) = \log(i+1) + \log(M/\Omega)$, and $M \geq \Omega$, because $\mathrm{rd}_E \geq 1$ gives $\Omega \leq 2\pi e^{|c_{\mathrm{CS}}(\overline{d})|} \leq e^{C_P+2} \leq e^{\log\log b} = \log b \leq b^{20} \leq M$ (by (AD1), $10^{12} C_P \leq \log\log b$, and $C_P \geq 64$ by item 1 of Lemma 4.2.67). Hence

$$\sum_{\tau\in\Phi} s_\infty(\kappa(\tau)) \leq \sum_{\tau\in\Phi} s_\infty(c(\tau) - z). \tag{6.169}$$

Step 5: the multiplier. By Lemma 6.7.5 (for this z and $\sigma = 1$), $\|\varphi_{p,1}\|^2 \neq 0$ and $\|\varphi_{q,1}\|^2 \neq 0$. Put $H = y_q/\|\varphi_{p,1}\|^2$, which is nonzero, $\alpha = \beta_{\mathrm{den}} - \sum_\tau s_\infty(\kappa(\tau))$ and $h_\ell = 0$ for every prime ℓ. (HG2): $H\,\|\varphi_{p,1}\|^2 = y_q$ is integral at every ι by Step 2. (HG3): $\alpha + 0 \leq \alpha$. (HG1): let σ be an automorphism of $\mathbb{C}$. It maps K to itself; if it does not fix K, then σ', $\sigma'(w) = \overline{\sigma(w)}$, fixes K and $|\sigma'(H)| = |\sigma(H)|$, so we may assume that σ fixes K. Let C be the constant of Lemma 6.7.5 for z and σ. Applied to q ($c_q(\tau) - z = 0$ and $s_\infty(0) = 0$) and to p, it gives $\log|\sigma(\|\varphi_{q,1}\|^2)| = C + r_q$ with $r_q \leq 4f$ and $\log|\sigma(\|\varphi_{p,1}\|^2)| = C + r_p + \sum_\tau s_\infty(c(\tau) - z)$ with $r_p \geq -4f$. As $N_{\mathrm{ch}} n_q^2$ is a positive integer, σ fixes it, and by (6.169) and (6.168)

$$\log|\sigma(H)| = \log(N_{\mathrm{ch}} n_q^2) + r_q - r_p - \sum_\tau s_\infty(c(\tau) - z) \leq \log(N_{\mathrm{ch}} n_q^2) + 8f - \sum_\tau s_\infty(\kappa(\tau)) \leq \alpha.$$

So the constant family $\iota \mapsto \|\varphi_{p,1}\|^2$ has height at most $\alpha = \beta_{\mathrm{den}} - \sum_{\sigma\in\Phi} s_\infty(\kappa(\sigma))$. □

Lemma 6.7.5. *Let $z \geq 2$ and let σ be an automorphism of $\mathbb{C}$ fixing K. There is $C \in \mathbb{R}$ such that for every critical pair $p = (\nu, z)$, with ν of weight $-c$, we have $\|\varphi_{p,1}\|^2 \neq 0$ and*

$$\log|\sigma(\|\varphi_{p,1}\|^2)| = C + r + \sum_{\tau\in\Phi} s_\infty(c(\tau) - z)$$

for some real $r \geq -4f$, with moreover $r \leq 4f$ if $c(\tau) = z$ for every $\tau \in \Phi$.

Proof. Fix $z \geq 2$ and σ, put $n = 2z$, and let $a > 0$ be the number of Lemma 6.7.6 and $B_z > 0$ the number of Proposition 6.7.13, both for this z (and σ). Put

$$C = \log|\sigma(|c_s|^{4z})| + \log a + \log B_z,$$

which is a real number ($c_s \neq 0$ by (OL4), so $\sigma(|c_s|^{4z}) \neq 0$) depending only on D, z and σ. Let $p = (\nu, z)$ be a critical pair, ν of weight $-c$, $X = X(p, 1)$ and $J = j_p = \sum_\tau(c(\tau) - z)$.

Step 1: the scale factor. By (OL4), $\varphi_{p,1} = c_s^{2z}(\pi_M \eta_P)^J \lambda_X$, so, the inner product being sesquilinear and $|\pi_M|^2 = M$,

$$\|\varphi_{p,1}\|^2 = |c_s|^{4z}\, M^J\, |\eta_P|^{2J} \|\lambda_X\|^2.$$

At the trivial twist ($Q = \emptyset$, $\mathrm{N}Q = 1$), $\mathrm{alg}_p(1) = \|\varphi_{p,1}\|^2$, which is positive by Proposition 6.7.13; in particular $\|\varphi_{p,1}\|^2 \neq 0$. As $M^J \in \mathbb{Q}$ is fixed by σ,

$$|\sigma(\|\varphi_{p,1}\|^2)| = |\sigma(|c_s|^{4z})|\, M^J\, |\sigma(|\eta_P|^{2J}\|\lambda_X\|^2)|. \tag{6.170}$$

Step 2: the conjugate pair. By Lemma 6.7.6 there is a critical pair $p' = (\nu', z)$, ν' of weight $-c'$ with $c'(\sigma\tau) = c(\tau)$ for all $\tau \in \Phi$, such that, with $X' = X(p', 1)$,

$$|\sigma(|\eta_P|^{2J}\|\lambda_X\|^2)| = a\,\Omega^{-J}\,\|\lambda_{X'}\|^2.$$

As $\tau \mapsto \sigma\tau$ is a permutation of Φ, $j_{p'} = \sum_\tau(c'(\sigma\tau) - z) = J$ and $\prod_\tau(c'(\tau) - z)! = \prod_\tau(c(\tau) - z)!$.

Step 3: the norm of the conjugate lift. By Step 1 for p' and by Proposition 6.7.13 for p' at the trivial twist,

$$\begin{aligned}|c_s^{2z}(\pi_M\eta_P)^J|^2\|\lambda_{X'}\|^2 &= \mathrm{alg}_{p'}(1)\\ &= |c_s^{2z}(\pi_M\eta_P)^J|^2 B_z \prod_\tau (c'(\tau) - z)! \cdot d' \cdot L^{S_M}(z, \nu'), \qquad d' = \dim \mathbb{V}_{O_{X'}},\end{aligned}$$

and the scale factor is nonzero ($c_s \neq 0$, $\pi_M \neq 0$, $\eta_P \neq 0$ by (OL4)). Hence, by Step 2,

$$\|\lambda_{X'}\|^2 = B_z \prod_\tau (c(\tau) - z)! \cdot d' \cdot L^{S_M}(z, \nu') > 0.$$

Step 4: the L-value at $z \geq 2$. The character ν' takes values in the unit circle (a continuous character of the compact group $\mathrm{U}(1)(E)\backslash\mathrm{U}(1)(\mathbb{A})$), hence so does $\tilde{\nu}'$, and $L^{S_M}(z, \nu') = \prod_w (1 - a_w q_w^{-z})^{-1}$ over the finite places w of E outside $S_M \cup \bar{S}_M$, $q_w = \mathrm{N}w$, with $a_w = \tilde{\nu}'(\varpi_w)$ of modulus 1 if $\tilde{\nu}'$ is unramified at w and $a_w = 0$ otherwise. For real $0 \leq x < 1$ and $|u| \leq x$, $1 - x \leq |1 - u| \leq 1 + x$, so $|\log|1 - u|| \leq -\log(1 - x)$. With $x = q_w^{-z} \leq q_w^{-2}$, and since above each rational prime ℓ there are at most $[E : \mathbb{Q}] = 2f$ places, each with $q_w \geq \ell$,

$$\left|\log |L^{S_M}(z, \nu')|\right| \leq \sum_w -\log(1 - q_w^{-2}) \leq 2f \sum_\ell -\log(1 - \ell^{-2}) = 2f \log \zeta(2) = 2f \log \frac{\pi^2}{6} < f.$$

Step 5: assembling. By (6.170) and Steps 2 and 3,

$$\log|\sigma(\|\varphi_{p,1}\|^2)| = C + J \log M - J \log \Omega + \sum_\tau \log(c(\tau) - z)! + r, \qquad r = \log d' + \log|L^{S_M}(z, \nu')|.$$

By the definition of the jet size, $\sum_\tau s_\infty(c(\tau) - z) = \sum_\tau \log(c(\tau) - z)! + J \log(M/\Omega)$, which is the claimed formula. As $\mathbb{V}_{O_{X'}} = \mathbb{C}^{I_\kappa}$ is nonzero, $d' \geq 1$, and Step 4 gives $r > -f \geq -4f$. If $c(\tau) = z$ for every τ, then $c'(\tau) = z$ for every τ, the weight $\kappa_{O_{X'}}$ is zero, its only column filling is the empty one with $\Delta_\emptyset = 1$, so I_κ has one element, $d' = 1$ and $r = \log|L^{S_M}(z, \nu')| < f \leq 4f$. □

Lemma 6.7.6. *For an automorphism σ of $\mathbb{C}$ fixing K and $\tau \in \Phi$, let $\sigma\tau \in \Phi$ be the place induced by $\sigma \circ \iota_\tau$, where ι_τ is the embedding of E over K inducing τ; so $\tau \mapsto \sigma\tau$ is a permutation of Φ. Let $z \geq 2$ be an integer and σ an automorphism of $\mathbb{C}$ fixing K. There is a real number $a > 0$ such that for every critical pair $p = (\nu, z)$, with ν of weight $-c$, there is a critical pair $p' = (\nu', z)$, with ν' of weight $-c'$, such that $c'(\sigma\tau) = c(\tau)$ for every $\tau \in \Phi$ and*

$$\left|\sigma\left(|\eta_P|^{2j_p} \|\lambda_{X(p,1)}\|^2\right)\right| = a\, \Omega_s^{-j_p} \|\lambda_{X(p',1)}\|^2.$$

Proof. **The common transport is fixed before the critical pair.** Fix $z \geq 2$ and $\sigma \in \mathrm{Aut}(\mathbb{C}/K)$, put $n = 2z$, and let $\mathcal{A}$ be the chosen places. Apply Lemma 4.2.14 in the standard positive rank-n model, identified with $\mathrm{Hom}(\mathrm{I}_1, \mathrm{I}_n)$ in column coordinates. Both have Gram matrix and adelic point equal to the identity; the sign-preserving coordinate bijection identifies their canonical functionals exactly by Lemma 4.1.17, with the same fixed line factors. Write $L_\sigma, t_\sigma, u_\sigma, C_\sigma$ for its transport, scale, chosen-place norm-one idele and nonzero vacuum scalar. Its Taylor, unitary-action and chosen-place assertions apply in this exact model. They give $|t_\sigma|^2 = \Omega_s^{-1}$ and fix these witnesses independently of all row lengths and critical characters. Write $e(\tau) = \sigma\tau$ and $m_\sigma(g) = \sigma(\Delta_n(g))/\Delta_n(g)$ for a rank-n finite unitary g.

Use the same assertions for $\sigma^\dagger = \mathrm{conj} \circ \sigma \circ \mathrm{conj}$, with its own fixed witnesses. Every embedding of a CM field commutes with complex conjugation, so $\sigma^\dagger|_E = \sigma|_E$ and both induce e. The character-conjugation assertion of Lemma 4.2.14 gives, for every critical pair $p = (\nu, z)$, one automorphic character ν' obtained from either automorphism. It has finite character $\sigma \circ \nu_f$, archimedean weight $-c'$ with $c'(e\tau) = c(\tau)$, and the same triviality conditions at finite subgroups. Thus $z \leq c' \leq 4b$, its tame part is trivial off the same chosen places, and $1 \leq z \leq t$ is unchanged. Therefore $p' = (\nu', z)$ is critical. Put

$$X = X(p, 1), \quad Y = X(p', 1), \quad \ell_\tau = c(\tau) - z, \quad J = \sum_\tau \ell_\tau.$$

The row lengths of Y are $\ell'_{e\tau} = \ell_\tau$, so $j_p = j_{p'} = J$.

The untwisted finite datum has one transport scalar. There are no twist places in either X or Y. By (DP7) their position function is the same rational-valued indicator: it is 1 on integral position vectors whose reduction at every chosen place is the fixed incidence column, and 0 otherwise. Denote its Schrödinger vector by $B_{\mathcal{A}}$. The chosen-place assertion (CT5) of Lemma 4.2.14, applied to this indicator, gives

$$L_\sigma B_{\mathcal{A}} = C_\sigma \omega(u_\sigma) B_{\mathcal{A}}. \tag{1}$$

Here and below $\omega(u_\sigma)$ means the scalar unitary action on the rank-n column space. In particular C_σ does not depend on p.

The character and multiplier factors match the same pair action. Write $\chi_X = \nu \upsilon^z$ and $\chi_Y = \nu' \upsilon^z$. For finite points $g \in G_f(1)$ and $h \in G_f(n)$, let g' be scalar multiplication by g^{-1} on the rank-n column and let h' be multiplication by h. Then

$$\omega_X(g,h) = \chi_X(g)^{-1} \omega(g') \omega(h').$$

The representation and commuting-action identities here are those of Lemma 4.1.1(2).

We check the scalar multiplier without commuting a field automorphism with complex conjugation. The hypotheses of Lemma 4.1.13 hold for the fixed finite model: c_0 is integral by (WD1), its lattice is self-dual by Lemma 4.1.3, and (WD3) makes the finite splitting character unitary, trivial on finite integral units and inverse under conjugation. Its normalized lattice measure and multiplier are the ones in (CT6). For a rank-one finite unitary v, put $\delta = \Delta_1(v)$. That lemma gives

$$\bar{\delta} = \upsilon(v)\delta, \qquad \delta\bar{\delta} = I(v) \in \mathbb{Z}_{>0}.$$

Applying σ to their algebraic product gives

$$\left(\frac{\sigma\delta}{\delta}\right)^2 = \frac{\upsilon(v)}{\sigma(\upsilon(v))}.$$

The direct-sum identity of the same lemma, with $v = g^{-1}$ and $n = 2z$, consequently gives

$$m_\sigma(g') = \left(\frac{\sigma(\upsilon(g))}{\upsilon(g)}\right)^z, \qquad \sigma(\chi_X(g)) = \chi_Y(g) m_\sigma(g'). \tag{2}$$

Apply (CT6) of Lemma 4.2.14 successively to the two finite unitary factors, and then use (1) and (2). The scalar u_σ commutes with g' and h', so

$$L_\sigma\big(\omega_X(g,h) B_{\mathcal{A}}\big) = C_\sigma \chi_Y(u_\sigma^{-1}) m_\sigma(h')\, \omega_Y(g u_\sigma^{-1}, h) B_{\mathcal{A}}. \tag{3}$$

Indeed the argument of the last underlying unitary is $hZ(gu_\sigma^{-1})^{-1} = u_\sigma h Z g^{-1}$, and its pair character is $\chi_Y(g)^{-1}\chi_Y(u_\sigma)$. This gives exactly the inverse character factor in (3).

The kernel coordinates are ordinary derivatives with the stated Gram normalization. For a one-row weight the standard basis of (WM1) is indexed by multi-indices $\mathbf{r} = (r_{\tau,i})$ with $\sum_i r_{\tau,i} = \ell_\tau$ and consists of the distinct monomials $\prod_{\tau,i} y_{\tau,i,0}^{r_{\tau,i}}$. Every such monomial occurs among the products of height-one minors, and these monomials are linearly independent; hence any basis consisting of products of minors is this basis, up to its indexing. The filling matrix has a row containing 1 precisely in the coordinate of its monomial. There are $\ell_\tau! / \prod_i r_{\tau,i}!$ labelled fillings at each place with those multiplicities. Therefore the Gram matrix is diagonal, with

$$G_{\mathbf{r},\mathbf{r}} = \prod_\tau \frac{\ell_\tau!}{\prod_i r_{\tau,i}!}, \qquad \mathrm{Pol}_\kappa(\xi) = \sum_{\mathbf{r}} G_{\mathbf{r},\mathbf{r}} \xi_{\mathbf{r}} X^{\mathbf{r}}. \tag{4}$$

The fixed mixed Cartan matrix in (DP8) is the identity after the zero-weight factor is removed. To prove this for the actual fixed choice, (c) and (d) of Lemma 3.2.20 show that it commutes with every Schur matrix and fixes the highest evaluation vector. Its orbit spans: if a linear form vanishes on that orbit, its homogeneous polynomial vanishes on every tuple of nonzero first columns of invertible matrices. These tuples form a dense open set, so the polynomial is zero; independence of the monomials makes the linear form zero. Thus the matrix is the identity. The positive letter substitution sends $y_{\tau,i,0}$ to the unique column variable $X_{\tau,i}$, and the zero-weight negative factor is 1. Consequently $\mathrm{Har}_X(\xi) = \mathrm{Pol}_\kappa(\xi)$.

For $F_X(g,h) = \omega_X(g,h)B_{\mathcal{A}}$ let $\mathcal{E}_F$ be the entire germ of the common transport lemma. By Lemma 4.1.5, the finite pair operator commutes with the real datum operation. By Lemma 4.2.2, the theta value of $v_{X^{\mathbf{r}}} \otimes F$ is exactly $\partial^{\mathbf{r}}\mathcal{E}_F(0)$. Substitute (4) in (DP8) and (OL2), and compare the coefficient of each arbitrary $\xi_{\mathbf{r}}$. The same nonzero integer $G_{\mathbf{r},\mathbf{r}}$ occurs on both sides and cancels. Hence

$$k_X(g)(h)_{\mathbf{r}} = \partial^{\mathbf{r}}\mathcal{E}_{F_X(g,h)}(Z)\Big|_{Z=0}. \tag{5}$$

This includes zero row lengths, and inserts no factorial divisor.

Taylor transport passes through the rank-one class sum. All class sums used here are finite. Indeed apply Lemma 6.4.74(1) to the zero scalar function, with maximal integral level $\mathbf{K}_0$ and with $\mathbf{K}'$ equal to the rank-one chosen level or the target level (DP4). These are open residue-defined subgroups, so the lemma gives finite class sets and finite stabilizers in both ranks. For a multi-index $\mathbf{r}$ of the weight of X, put $\mathbf{r}^e_{e\tau,i} = r_{\tau,i}$. Define the coordinate pullback from the weight of Y to that of X by $(R_e w)_{\mathbf{r}} = w_{\mathbf{r}^e}$. It is a bijection of coordinate spaces. Every multi-index in (5) has total degree J. Apply (CT1)–(CT2) to $F_X(g,h)$ and then (3). The ordinary chain rule and the explicit permutation convention of (CT1) give

$$\sigma\big(\eta_P^J k_X(g)(h)\big) = t_\sigma^J C_\sigma \chi_Y(u_\sigma^{-1}) m_\sigma(h')\, R_e k_Y(g u_\sigma^{-1})(h). \tag{6}$$

Right multiplication by u_σ^{-1} permutes the double cosets of the rank-one class sum (OL3). This group is abelian, so its stabilizer $\mathrm{U}(1)(E) \cap g\mathbf{K}_X^{\mathrm{ch}} g^{-1}$ is unchanged under this translation. The two critical pairs have the same chosen places and the same rank-one level. Thus their class sums have identical rational weights $1/\#\Gamma_g$, fixed by σ. Sum (6) to obtain

$$\sigma\big(\eta_P^J \lambda_X(h)\big) = t_\sigma^J C_\sigma \chi_Y(u_\sigma^{-1}) m_\sigma(h')\, R_e \lambda_Y(h). \tag{7}$$

All witnesses preceding p remain independent of it.

Polarization uses the conjugate automorphism, rather than commuting it with conjugation. Write $A_X = \eta_P^J \lambda_X$ and $B_Y = \lambda_Y$. Apply (7) both to σ and to $\sigma^\dagger$; the critical pair p' and the permutation e are the same, as established above. Formula (4) shows that the two Gram matrices are carried to one another by R_e, since the row lengths are merely permuted. Both target levels are the same: in (DP4) the chosen-place level depends on the fixed incidence column, and there are no twist places or level characters. Their norm sums therefore have the same rational stabilizer weights.

For any complex number w one has $\sigma(\bar{w}) = \overline{\sigma^\dagger(w)}$ by definition. Expand the finite class sum $\langle A_X, A_X\rangle = \sum_{[h]} (\#\Gamma_h)^{-1} \overline{A_X(h)}^{\mathsf{T}} G_X A_X(h)$, apply this identity coordinatewise and use (7) for its two factors. By (CT7), the point-dependent multiplier cancels: $m_\sigma(h')\overline{m_{\sigma^\dagger}(h')} = 1$. The result is

$$\sigma\langle A_X, A_X\rangle = \overline{t_{\sigma^\dagger}^J C_{\sigma^\dagger} \chi_Y(u_{\sigma^\dagger}^{-1})}\, t_\sigma^J C_\sigma \chi_Y(u_\sigma^{-1}) \langle B_Y, B_Y\rangle. \tag{8}$$

Every character value displayed here has modulus one because χ_Y is unitary. Both scales have squared modulus Ω_s^{-1}. Set $a = |C_\sigma|\,|C_{\sigma^\dagger}| > 0$. It is fixed before p, because both common

transport scalars were fixed before its character and row lengths. Taking absolute values in (8) gives

$$\left|\sigma\left(|\eta_P|^{2j_p}\|\lambda_{X(p,1)}\|^2\right)\right| = a\,\Omega_s^{-j_p}\|\lambda_{X(p',1)}\|^2.$$

The identities also hold for a zero lift and for $J = 0$, without division by either lift. This proves the frozen assertion. □

Lemma 6.7.7. *Let $q = (\nu_q, z_q)$ be a flat critical pair (Definition 4.2.4) with $z_q \geq 2$, let ϑ be a tame character with modulus Q, ℓ a prime with $\ell \nmid \mathrm{N}Q$ and $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism. Then the form $n_{\nu_q}\varphi_{q,\vartheta}$ is integral at j.*

Proof. Let $X = X(q,\vartheta)$ and $N = 2z_q$. The row lengths $c_q(\tau) - z_q$ vanish, so $j_q = 0$, the weight of O_X is 0, $\varphi_{q,\vartheta} = c_s^N\lambda_X$ and $n_{\nu_q} = M^{4fz_q} = M^{2fN}$. For a weight-0 form ($e_O = 0$, $S_0 = 1$) integrality at j means $\|j(\Xi(h))\| \leq 1$ for every $h \in G_f(N)$. The group $\mathbf{K}_X^{\mathrm{ch}}$ is an open subgroup of the stabiliser of $\widehat{\mathcal{O}}_E$ in $G_f(1)$ whose elements reduce to 1 at every chosen place, and a chosen place exists ($M > 1$); so by (c) of Lemma 4.6.2, for the definite line I_1 with the lattice $\mathcal{O}_E$, every $\Gamma_g = \mathrm{U}(1)(E) \cap g\mathbf{K}_X^{\mathrm{ch}}g^{-1}$ is trivial. Hence

$$n_{\nu_q}\varphi_{q,\vartheta}(h) = \sum_{[g]} M^{2fN} c_s^N\, k_X(g)(h),$$

a finite sum (the class set is finite, [33]). By (a) of Lemma 6.7.8 ($\ell \nmid \mathrm{N}Q$) each term has $\|j(\cdot)\| \leq 1$, and by the ultrametric inequality so has the sum. So $n_{\nu_q}\varphi_{q,\vartheta}$ is integral at j. □

Lemma 6.7.8. *Let $q = (\nu_q, z_q)$ be a flat critical pair (Definition 4.2.4) with $z_q \geq 2$, and put $N = 2z_q$. Let $g \in G_f(1)$ and $h \in G_f(N)$.*

(a) If ϑ is a tame character with modulus Q, ℓ a prime with $\ell \nmid \mathrm{N}Q$ and $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism, then $\|j(M^{2fN}c_s^N\, k_{X(q,\vartheta)}(g)(h))\| \leq 1$.

(b) For every automorphism σ of $\mathbb{C}$,

$$|\sigma(c_s^N\, k_{X(q,1)}(g)(h))| \leq M^{fN}\exp\bigl(C_P\,(q_1N+1)^2 + fN\log 4\bigr).$$

Proof. Let $X = X(q,\vartheta)$ and $O = O_X$. By (OL4), X has rank N, row lengths $c(\tau) - z_q = 0$ (the weight of ν_q is $-z_q$ at every τ), character $\nu_q\vartheta$, chosen places M_O the chosen places of D and twist places Q_O the places of Q. By (OL1), O has ranks $1 < N$, $W(O)$ is the standard definite line, $\kappa_O = 0$, $e_O = 0$, $\chi_O = 1$ and $\chi'_O = \nu_q\vartheta\upsilon^{z_q}$; the tame part $(\psi_{O,w})_w$ of $\mu_O = \nu_q\vartheta$ is trivial off $M_O \cup Q_O$.

Step 1: the kernel form is a theta value of the block datum. The weight 0 has exactly one column filling, the empty one, whose product of minors is 1; so the standard basis of $\nabla_0 = \mathbb{Z}$ is (1), $\mathbb{V}_O = \mathbb{C}$, $F_0 = G_0 = (1)$, $\mathrm{Pol}_0(\xi) = \xi$ and $\mathrm{ev}_0(y) = (1)$. For $\kappa^+ = \kappa^- = 0$, (c) of Lemma 3.2.20 reads $C_O \cdot 1 = 1$, so $C_O = (1)$, and since the letter substitutions fix constants, $\mathrm{Har}_O(\xi)$ is the constant polynomial ξ. As v_P is linear in P and data are linear in the Fock vector, $\mathrm{J}_O(\xi) = \xi\, v_1 \otimes \Upsilon(O) = \xi\,\Upsilon(O)$, by (4) of Lemma 6.2.33 for $A = S_O$ and $\Psi = \Phi_O$. Taking $\xi = 1$ in (OL2), with $G_0 = (1)$,

$$k_X(g)(h) = \theta_O(\omega_O((1,g),(1,h))\,\Upsilon(O)). \tag{6.171}$$

By (VP5), $\mathrm{Hom}(W(O), \mathrm{I}_N)$ has index set $N \times \{1\}$, identified with $\{1,\dots,N\}$, all signs $+1$, matrix 1 and point 1: it is the standard space V_s of the signs $s = (+1,\dots,+1)$, that is I_N. Since $k_{V_s} = 1$ in (WC2), (WC3) gives $\theta_O = \theta_{\mathrm{I}_N}$, the canonical functional used in Lemma 6.4.83.

Step 2: the pair action is a root of unity times a finite unitary operator. The pair map of (VP5) sends $((1,g),(1,h))$ to $X \mapsto hXg^{-1}$, i.e. to the element of $\mathrm{G}(s)$ with infinite component 1 and finite component $k_f = g^{-1}h \in G_f(N)$. By (DP6) and (WR4), with $\chi_O = 1$,

$$\omega_O((1,g),(1,h)) = \chi'_O((1,g))^{-1}\,\omega_s((1,k_f)).$$

We show that $\chi'_O((1,g))$ is a root of unity. The weights of ν_q, ϑ, υ are $-z_q$, 0, 1, and each has a tame part ((OL1), Definition 3.1.2, (WD3)); multiplying the defining identities of Definition 3.1.1, χ'_O has weight 0 and a tame part ψ'. Let h_E be the class number of E. The ideal of the finite idele g to the power h_E is principal, so $g^{h_E} = \gamma_0 u_0$ with $\gamma_0 \in E^\times$ and $u_0 \in \widehat{\mathcal{O}}_E^\times$. As $\bar{g}g = 1$, conjugation gives $g^{-h_E} = \bar{\gamma}_0\bar{u}_0$, hence $g^{2h_E} = \gamma u$ with $\gamma = \gamma_0/\bar{\gamma}_0 \in \mathrm{U}(1)(E)$ and $u = u_0/\bar{u}_0 \in \widehat{\mathcal{O}}_E^\times$, $u\bar{u} = 1$. In $\mathrm{U}(1)(\mathbb{A})$ this reads $(1,g)^{2h_E} = \gamma\cdot(\gamma_\infty^{-1},u)$, γ_∞ the infinite components of γ. Since χ'_O is trivial on $\mathrm{U}(1)(E)$ and has weight 0, and (γ_∞^{-1},u) has integral finite components,

$$\chi'_O((1,g))^{2h_E} = \prod_w \psi'_w(u \bmod w),$$

a finite product of values of characters of the finite groups $k_w^\times$, hence a root of unity; so $\chi'_O((1,g))$ is a root of unity.

Step 3: finite Fourier expansion of the block datum. Let $A = S_O = M_O \cup Q_O$; by (DP1) it contains the conjugate of none of its members, so $A \cap \bar{A} = \emptyset$. Fix a uniformiser at each $w \in A$ and let $\varpi \in \mathbb{A}_{E,f}^\times$ have these components at A and 1 elsewhere. Let $L_A = \prod_{w\in A}\mathcal{O}_{E,w}^N$, $R_A = \prod_{w\in A} k_w$ and $d_A = \#R_A = \prod_{w\in A}\mathrm{N}w$; reduction identifies $L_A/\varpi L_A$ with R_A^N, and vectors supported at A are written as elements of $\prod_{w\in A} E_w^N$. Put $\psi_0(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$; by Lemma 4.1.3, $\widehat{\mathcal{O}}_E^N$ is its own annihilator under $(u,v)\mapsto\psi_0(\bar{u}^{\mathsf{T}}v)$, and in particular $\psi_0(\widehat{\mathcal{O}}_E) = 1$. Let $Y_A = \varpi^{-1}L_A$. For $z \in Y_A$ the character $x \mapsto \psi_0(z^{\mathsf{T}}x)$ of L_A is trivial on ϖL_A and depends only on z mod L_A. If it is trivial on L_A, then $\psi_0(z^{\mathsf{T}}v) = 1$ for every $v \in \widehat{\mathcal{O}}_E^N$ (as z is supported at A), so $\bar{z}$, hence z, is integral, i.e. $z \in L_A$. Thus $z \mapsto \psi_0(z^{\mathsf{T}}\cdot)$ is an injective homomorphism from Y_A/L_A, of order d_A^N, into the character group of R_A^N, of the same order, hence a bijection. Orthogonality of characters of the finite group R_A^N gives, for x integral at A and $u \in R_A^N$ with a lift $\tilde{u} \in L_A$, that $d_A^{-N}\sum_{z\in Y_A/L_A}\psi_0(z^{\mathsf{T}}(x_A - \tilde{u}))$ is 1 if x_A mod $\varpi = u$ and 0 otherwise. Summing against Ψ_O, for every finite adelic vector x,

$$\Phi_O(x) = \sum_{z\in Y_A/L_A}\widehat{\Phi}(z)\,\psi_0(z^{\mathsf{T}}x_A)\,\mathbf{1}_A(x), \qquad \widehat{\Phi}(z) = d_A^{-N}\sum_{u\in R_A^N}\Psi_O(u)\,\psi_0(-z^{\mathsf{T}}\tilde{u}),$$

the sum over a fixed set of representatives z. For such z let $y(z)$ be the finite adelic vector supported at $\bar{A}$ with $\overline{y(z)} = z$. Then $y(z)_A = 0$, and (WR6) gives $\tau_{y(z)}(x) = \psi_0(z^{\mathsf{T}}x_A)\mathbf{1}_A(x)$; so $\Phi_O = \sum_z \widehat{\Phi}(z)\tau_{y(z)}$. For y supported at $A\cup\bar{A}$, (2) of Lemma 4.1.3 applied to $\mathbf{1}_A$ gives $\tau_y \otimes_A f = \rho(\mathrm{fv}(y))(\mathbf{1}_A\otimes_A f)$, and $\mathbf{1}_A\otimes_A v^0 = P^A v^0 = v^0$ by (1) of Lemma 4.1.3 and (2) of Lemma 6.2.33. By linearity of $\Psi\mapsto\Psi\otimes_A v^0$,

$$\Upsilon(O) = \sum_z \widehat{\Phi}(z)\,\rho(\mathrm{fv}(y(z)))v^0. \tag{6.172}$$

Step 4: the kernel value as a combination of moved-vacuum theta values. By (2) of Lemma 4.1.1, $\omega_s((1,k_f))\rho(\mathrm{fv}(y)) = \rho((1,k_f)\mathrm{fv}(y))\omega_s((1,k_f))$, and $(1,k_f)\mathrm{fv}(y) = (0,k_f\alpha y) = \mathrm{fv}(k_f y)$, α being a scalar. With $\mathcal{V}_N(x,k) = \theta_{\mathrm{I}_N}(\rho(\mathrm{fv}(x))\omega_s((1,k))(c_s^N v^0))$ as in Lemma 6.4.83, (6.171), Step 2 and (6.172) give

$$c_s^N k_X(g)(h) = \chi'_O((1,g))^{-1}\sum_z \widehat{\Phi}(z)\,\mathcal{V}_N(k_f y(z),k_f). \tag{6.173}$$

Step 5: (a). Every value of Ψ_O is 0 or a product of values of characters of the groups $k_w^\times$, and every value of ψ_0 is $\exp(2\pi i \operatorname{Tr}_{E/\mathbb{Q}}(a))$ for some $a \in E$; all are 0 or roots of unity, so $d_A^N \widehat{\Phi}(z)$ is integral over $\mathbb{Z}$. Every $w \in A$ contains $M\,\mathrm{N}Q$: a chosen place contains π_M, hence $M = \pi_M \bar{\pi}_M$, and a place w of Q contains the rational prime below it, which divides $\mathrm{N}w$ and so $\mathrm{N}Q$. By the Chinese remainder theorem $R_A = \mathcal{O}_E/\prod_{w\in A} w$ is a quotient of $\mathcal{O}_E/M\mathrm{N}Q\,\mathcal{O}_E$, of order $(M\mathrm{N}Q)^{2f}$ as $[E:\mathbb{Q}] = 2f$. So $t = (M\mathrm{N}Q)^{2fN}/d_A^N$ is an integer and $M^{2fN}\widehat{\Phi}(z) = t\,\mathrm{N}Q^{-2fN}\, d_A^N \widehat{\Phi}(z)$. As $\ell \nmid \mathrm{N}Q$, $\|j(M^{2fN}\widehat{\Phi}(z))\| \le 1$. Further $\|j(\chi'_O((1,g))^{-1})\| = 1$ by Step 2, and $\|j(\mathcal{V}_N(k_f y(z), k_f))\| \le 1$ by (1) of Lemma 6.4.83. Multiplying (6.173) by M^{2fN}, applying j and the ultrametric inequality to the finite sum gives (a).

Step 6: (b). Now $\vartheta = 1$, so $Q = \emptyset$, $A = M_O$, and the product over Q_O in (DP7) is empty: Ψ_O is the indicator of the single point $u_0 = (\mathrm{Inc}_O)_{w\in M_O}$ of R_A^N. Hence $\widehat{\Phi}(z) = d_A^{-N}\psi_0(-z^{\mathsf{T}}\tilde{u}_0)$, and $|\sigma(\widehat{\Phi}(z))| = d_A^{-N}$ for every automorphism σ of $\mathbb{C}$, since σ maps roots of unity to roots of unity. Also $|\sigma(\chi'_O((1,g))^{-1})| = 1$, and $|\sigma(\mathcal{V}_N(k_f y(z), k_f))| \le \exp(C_P(q_1 N+1)^2)$ by (2) of Lemma 6.4.83. Applying σ to (6.173), a sum of d_A^N terms,

$$|\sigma(c_s^N k_{X(q,1)}(g)(h))| \le d_A^N \cdot d_A^{-N} \exp(C_P(q_1N+1)^2) \le M^{fN} \exp\bigl(C_P(q_1N+1)^2 + fN\log 4\bigr),$$

the last step as $M \ge 1$ and $fN\log 4 \ge 0$. This is (b). □

Lemma 6.7.9. *Let D be admissible data, $1 \le n \le rt$, $K' \subseteq \mathbf{K}_0(n)$ an open subgroup and $h \in G_f(n)$. Then $\Gamma_h = \mathrm{U}(\mathrm{I}_n)(E) \cap hK'h^{-1}$ is a finite group whose order divides N_{ch}.*

Proof. The group $\mathrm{U}(\mathrm{I}_n)(E)$ is discrete in $G_\infty(1)\times G_f(n)$ and $G_\infty(1)\times hK'h^{-1}$ is compact, so Γ_h is finite. As $M = p_0p_1 > 1$, π_M is not a unit of $\mathcal{O}_E$, so there is a chosen place w. For $\gamma \in \Gamma_h$ the element $h^{-1}\gamma h$ lies in $K' \subseteq \mathbf{K}_0(n)$, so its component at w lies in $\mathrm{GL}_n(\mathcal{O}_{E,w})$, and $\gamma \mapsto \mathrm{red}_w(h^{-1}\gamma h)$ is a homomorphism $\Gamma_h \to \mathrm{GL}_n(k_w)$. If γ is in its kernel, then $(h^{-1}\gamma h)_w$ has finite order and is $\equiv 1 \pmod{w}$, so it is 1 by (b) of Lemma 4.6.2; hence $\gamma_w = 1$, and $\gamma = 1$, a rational point being determined by its component at w. So $\#\Gamma_h$ divides $\#\mathrm{GL}_n(k_w)$. As $n \le rt$, $\mathrm{GL}_n(k_w)$ is a subgroup of $\mathrm{GL}_{rt}(k_w)$ (block diagonal with the identity of rank $rt-n$), so $\#\mathrm{GL}_n(k_w)$ divides $\#\mathrm{GL}_{rt}(k_w)$, which divides N_{ch} by (CX1). □

Lemma 6.7.10. *For admissible data D, $1 \le N_{\mathrm{ch}}$ and $\log N_{\mathrm{ch}} \le x^{33}$.*

Proof. Each factor $\#\mathrm{GL}_{rt}(k_w)$ is a positive integer at most $(\mathrm{N}w)^{(rt)^2}$. By Lemma 4.2.66, item 3, and Lemma 4.2.67, items 3–5,

$$\log N_{\mathrm{ch}} \le (rt)^2 \sum_{w \text{ chosen}} \log \mathrm{N}w = (rt)^2 f \log M \le (45x^{10})^2 \cdot x^{12} \cdot 22 \log b \le x^{33},$$

using $rt = 5r^2 \le 45x^{10}$, $f \le x^{12}$ and $\log b \le x^{1/100}$. □

Lemma 6.7.11. *For admissible data D,*

$$x_1 \le \beta_{\mathrm{den}} \qquad \textit{and} \qquad \frac{f\,m\,b}{k} + 3x^{34} \le \beta_{\mathrm{den}}.$$

Proof. By Lemma 2.3.6, $\log x \ge 10^{14} C_P \ge 10^{14}$ (as $C_P \ge q_0 \ge 18480$), $\log x_1 \ge 10^6 \log x$ and $\log b \ge 10^6 \log x_1$; so $x \ge e^{10^{14}}$, $\log b \ge 10^{12}\log x$, that is $b \ge x^{10^{12}}$, and $\log b \ge 2$. By (AD2), $m \le 2\sqrt{x}$ and $x^5 \le r \le 3x^5$, so $k = r + 1 - m$ satisfies $1 \le x^5 + 1 - 2\sqrt{x} \le k \le r \le 3x^5$; and $f \ge 1$. Hence

$$\beta_{\mathrm{den}} = \frac{f\,x\,b\,(\log b)^3}{m\,k} \ge \frac{x\,b}{2\sqrt{x}\cdot 3x^5} = \frac{b}{6x^{9/2}} \ge \frac{b}{x^5} \ge x^{10^{12}-5},$$

using $6 \le x^{1/2}$.

First inequality. $\log x_1 \le 10^{-6}\log b$ gives $x_1 \le b^{10^{-6}}$, and $b^{1-10^{-6}} \ge x^{(1-10^{-6})10^{12}} \ge x^5$, so $x_1 \le b^{10^{-6}} \le b/x^5 \le \beta_{\mathrm{den}}$.

Second inequality. $\beta_{\mathrm{den}}/\frac{fmb}{k} = \frac{x(\log b)^3}{m^2} \ge \frac{x\cdot 8}{4x} = 2$, so $\frac{fmb}{k} \le \frac{1}{2}\beta_{\mathrm{den}}$; and $3x^{34} \le \frac{1}{2}x^{10^{12}-5} \le \frac{1}{2}\beta_{\mathrm{den}}$. Adding, $\frac{fmb}{k} + 3x^{34} \le \beta_{\mathrm{den}}$. □

Lemma 6.7.12. *For every finite set T of primes,*

$$\sum_{\ell\in T} 2F(\ell)\log\ell \;\le\; \sum_{\sigma\in\Phi} s_{\mathrm{fin}}(\kappa(\sigma),\sigma).$$

Proof. Fix $\sigma\in\Phi$ and put $y=\kappa(\sigma)$ and $g(\nu)=\Lambda_K(\nu)\big(y/\nu-\kappa(-\nu\sigma)\big)_+$ for integers $\nu\ge 1$. Each $g(\nu)\ge 0$, since $\Lambda\ge 0$ and $1-\chi_K(\nu)\in\{0,1,2\}$. If $g(\nu)\ne 0$ then $y/\nu>\kappa(-\nu\sigma)\ge 1$, so $\nu<y=\kappa(\sigma)\le a$ (both values b and a/x_1 of κ are at most $a=xb$). Hence $s_{\mathrm{fin}}(y,\sigma)=\sum_{\nu\ge1} g(\nu)$, a finite sum; as Λ_K vanishes off prime powers and distinct pairs (p,e) give distinct p^e,

$$s_{\mathrm{fin}}(y,\sigma)=\sum_p\sum_{e\ge1} g(p^e) \;\ge\; \sum_{p\in T}\sum_{e\ge1} g(p^e).$$

For a prime p and $e\ge1$, $\Lambda_K(p^e)=\log p\,(1-\chi_K(p)^e)$, which is 0 if $\chi_K(p)=1$; $2\log p$ for odd e and 0 for even e if $\chi_K(p)=-1$; and $\log p$ if $p=d$ ($\chi_K(d)=0$). In all cases $\Lambda_K(p^e)=2\log p\cdot v(\pi_p)\,\mathbf{1}_{I_p}(e)$, so $\sum_{e\ge1} g(p^e)=2\log p\cdot s_p(\kappa(\sigma),\sigma)$. Summing over $\sigma\in\Phi$,

$$\sum_{\sigma\in\Phi} s_{\mathrm{fin}}(\kappa(\sigma),\sigma) \;\ge\; \sum_{p\in T} 2\log p\sum_{\sigma\in\Phi} s_p(\kappa(\sigma),\sigma) = \sum_{p\in T} 2F(p)\log p.$$

□

Proposition 6.7.13. *Let $z\ge 2$. There is a real number $B_z>0$, depending only on D and z, with the following property. Let $p=(\nu,z)$ be a critical pair, ν of weight $-c$, and put*

$$A=\big|c_s^{2z}(\pi_M\eta_P)^{j_p}\big|^2\,B_z\prod_{\tau\in\Phi}(c(\tau)-z)!\cdot\dim\mathbb{V}_{O_{X(p,1)}}.$$

Then for every tame character ϑ with modulus Q

$$\mathrm{alg}_p(\vartheta)=A\cdot L^{S_M\cup Q}(z,\nu\vartheta)\qquad\text{and}\qquad \mathrm{alg}_p(\vartheta)>0.$$

In particular $A\ne0$, $L^{S_M\cup Q}(z,\nu\vartheta)\ne0$, and $r_p(\vartheta)=\mathrm{alg}_p(\vartheta)/\mathrm{alg}_p(1)$.

Proof. Fix p and a tame character ϑ with modulus Q. Put $n=2z$, $X=X(p,\vartheta)$, $O=O_X$, $S=S_M\cup Q$ (the places of the level system of X), and $q_w=\mathrm{N}w$. By (DP1) the places of S are distinct, and none is the conjugate of itself or of another one; the character of X is $\nu_X=\nu\vartheta$, with tame part trivial off S, and its row lengths $\ell_X(\tau)=c(\tau)-z$ depend only on p.

Step 1: two indices. Let w be a finite place with $w\ne\bar w$. The relation $g^*g=1$ determines the component of $g\in G_f(m)$ at $\bar w$ from the one at w, which is an arbitrary element of $\mathrm{GL}_m(E_w)$; integral points correspond to $\mathrm{GL}_m(\mathcal{O}_{E,w})$. As the places of S are pairwise distinct and not conjugate to one another, reduction $\mathbf{K}_0(m)\to\prod_{w\in S}\mathrm{GL}_m(k_w)$ is surjective (prescribe the components at $w\in S$, the forced ones at $\bar w$, and 1 elsewhere; $\mathrm{GL}_m(\mathcal{O}_{E,w})\to\mathrm{GL}_m(k_w)$ is onto). Hence $[\mathbf{K}_0(1):\mathbf{K}_X^{\mathrm{ch}}]=\prod_{w\in S_M}\#k_w^\times=\prod_{w\in S_M}(q_w-1)$, and $[\mathbf{K}_0(n):\mathbf{K}(O)]=[\prod_{w\in S}\mathrm{GL}_n(k_w):\mathbf{L}(O)]$, where $\mathbf{L}(O)$ is the product of its local conditions (DP4) for the one index $i_0=\mathrm{inc}_O(1)$: at

$w \in S_M$, j_w fixes the basis vector e_{i_0}; at $w \in Q$, row i_0 of j_w vanishes outside column i_0, i.e. j_w^{T} preserves the line $k_w e_{i_0}$. Since $\mathrm{GL}_n(k_w)$ acts transitively on the $q_w^n - 1$ nonzero vectors and (through $j \mapsto j^{\mathsf{T}}$) on the $(q_w^n - 1)/(q_w - 1)$ lines,

$$[\mathbf{K}_0(n) : \mathbf{K}(O)] = \prod_{w \in S_M} (q_w^n - 1) \prod_{w \in Q} \frac{q_w^n - 1}{q_w - 1}.$$

Step 2: the norm of λ_X as a Petersson norm. By Lemma 6.7.14 (a), (b),

$$\|\lambda_X\|^2 = [\mathbf{K}_0(1) : \mathbf{K}_X^{\mathrm{ch}}]^2 \, [\mathbf{K}_0(n) : \mathbf{K}(O)] \, \dim \mathbb{V}_O \, \langle f_X, f_X \rangle_{\mathrm{I}_n},$$

with f_X the lift of the constant function $\mathbf{1}$ of Lemma 6.7.14 (c).

Step 3: the inner product formula. We apply Lemma 6.5.12 with $(S, T) = (\mathrm{I}_1, \mathrm{I}_n)$, so $2 \operatorname{rk} S = 2 < n = \operatorname{rk} T$; the characters $a = \chi_O = v^0 = 1$ (all signs of I_1 are $+1$) and $b = \chi_O' = \nu_X v^z$, of weights $\gamma = 0$ and $\gamma' = -(\ell_X + z) + z = -\ell_X$; the Fock vector $v = v_{\mathrm{Har}_O(\xi_X)}$, an edge for the weights $(0, -\ell_X)$ from the type $\mathbf{1}$ to e_X' by Lemma 6.7.14 (c); S_0 the set of places of the maximal totally real subfield E^+ (the base field of Lemma 6.5.12) below the places of S (so its complement Σ consists of the finite places of E^+ below no place of S, and $k_v \in K_v$ for $v \in \Sigma$ means that k is integral at the places of E outside $S \cup \bar{S}$), $J = J_O = \mathbf{K}_X^{\mathrm{ch}}$ and $F = \Upsilon(O) = \Phi_O \otimes_S v^0$. The vector v is a Schwartz vector, being the Fock vector of a polynomial (XD3). The hypotheses on F: by Lemma 6.5.10 (a), $\langle F, F \rangle \neq 0$ and $\langle F, F \rangle / [\mathbf{K}_0(1) : J] = c_O$; by Lemma 6.2.33 (4), $v_1 \otimes F = F$; by Lemma 6.5.10 (b′), F is a vacuum above Σ; this is (SH1). By Lemma 6.5.10 (c), for $k \in G_f(1)$ integral off $S \cup \bar{S}$, $\langle F, \omega_{1,b}((1,k),1)F \rangle = \langle F, \omega_O((1,k),1)F \rangle$ is $\langle F, F \rangle$ for $k \in J$ and 0 otherwise (SH2); all signs of I_1 agree (SH3); and by Lemma 6.5.10 (e), with $\omega_{a,b} = \omega_O$, F is fixed by $\omega_{a,b}((1,k),(1,k'))$ for k, k' in open subgroups of $G_f(1)$, $G_f(n)$ (SH4). So F is sharp for J off S_0 with mass c_O, where, O having ranks $1 < n$,

$$c_O = \prod_{w \in S_M} \frac{1}{q_w^n (q_w - 1)} \prod_{w \in Q} \frac{(q_w - 1)\, q_w^{n-1}}{q_w^n}.$$

By Lemma 6.7.14 (c) the lift by $v \otimes F = \mathrm{J}_O(\xi_X)$ of the constant function $\mathbf{1}$, a J-invariant form of type $\mathbf{1}$, is f_X. With $y = y' = \mathbf{1}$, and $\langle \mathbf{1}, \rho(q)\mathbf{1} \rangle_{\mathrm{I}_1} = V_1$, the volume of $[\mathrm{U}(\mathrm{I}_1)]$ (finite and positive, the quotient being compact), Lemma 6.5.12 gives, with its constant $A_v \neq 0$ depending only on I_1, I_n and v,

$$\langle f_X, f_X \rangle_{\mathrm{I}_n} = A_v \, c_O \, V_1 \sum_q \mathrm{mc}(q),$$

the sum running over $G_f(1)$ modulo the points integral outside $S \cup \bar{S}$, represented by points with component 1 at $S \cup \bar{S}$; the matrix coefficient of the unramified vector for b and $\operatorname{rk} T = 2z$ is the normalised vacuum coefficient mc of Lemma 6.7.16 for ν_X and $k = z$.

Step 4: the vacuum sum. By Lemma 6.7.15, for ν_X, the set S, $D = S \cup \bar{S}$ and $k = z \geq 2$ (its hypothesis $\psi_w = 1$ off S holds), mc is constant on each coset at representatives with component 1 at D, and the sum is $L^S(z, \nu_X) \prod_v e_v(z)$ over the places v of F below no place of D. The places of F below D are those below the $w \in S$; each such v splits as $w\bar{w}$, and $w \mapsto v$ is injective on S. With $P_z = \prod_v e_v(z)$ over all finite places of F (absolutely convergent and positive by (c) of Lemma 6.7.15),

$$\sum_q \mathrm{mc}(q) = L^S(z, \nu\vartheta)\, P_z \prod_{w \in S} (1 - q_w^{-n})^{-1}.$$

Step 5: collecting the factors. By (OL4), $\mathrm{alg}_p(\vartheta) = \left| c_s^{2z} (\pi_M \eta_P)^{j_P} \right|^2 \|\lambda_X\|^2 / \mathrm{N}Q^{2z-1}$. Insert Steps 1–4. At $w \in S_M$ the place contributes $(q_w - 1)^2 \cdot (q_w^n - 1) \cdot \frac{1}{q_w^n (q_w - 1)} \cdot \frac{q_w^n}{q_w^n - 1} = q_w - 1$, and at

$w \in Q$ it contributes $\frac{q_w^n-1}{q_w-1}\cdot\frac{(q_w-1)q_w^{n-1}}{q_w^n}\cdot\frac{q_w^n}{q_w^n-1} = q_w^{n-1}$; the product of the latter is $\mathrm{N}Q^{2z-1}$. Hence

$$\mathrm{alg}_p(\vartheta) = \left|c_s^{2z}(\pi_M\eta_P)^{j_p}\right|^2 \prod_{w\in S_M}(q_w-1)\cdot\dim\mathbb{V}_O\cdot A_v\,V_1\,P_z\cdot L^{S_M\cup Q}(z,\nu\vartheta). \tag{6.174}$$

The constant A_v. The type on I_1 is $e=\mathbf{1}$, so $\overline{e(x)}/e(1)=1$ and, by its definition in Lemma 6.5.12, $A_v = \mathrm{vol}([\mathrm{U}(\mathrm{I}_n)])\,\lambda_{\mathrm{I}_1}\int_{G_\infty(+)}\langle v,\Omega_{0,-\ell_X}(x,1)v\rangle\,dx$, with $\lambda_{\mathrm{I}_1}>0$ the constant of Lemma 6.5.12 for $S=\mathrm{I}_1$ and $G_\infty(+)=\mathrm{U}(1)^\Phi$. By Lemma 6.7.14 (d), $\Omega_{0,-\ell_X}(x,1)v=v$, and $G_\infty(+)$ has mass 1 (Lemma 5.5.21 for $N=1$), so the integral is $\|v\|^2$. Again by Lemma 6.7.14 (d), $v=v_{P_0}$ with $P_0=\prod_\tau X_{\tau,1,1}^{\ell_X(\tau)}$. All signs of $\mathrm{Hom}(\mathrm{I}_1,\mathrm{I}_n)$ are $+1$, so by (WR5) $v_{P_0}(x)=P_0(\bar{x})\,e^{-x^*x/2}$ on $\mathbb{C}^{\Phi\times n\times 1}$, and by Fubini over the coordinates

$$\|v\|^2=\int|P_0(\bar{x})|^2e^{-x^*x}\,d\nu_\iota(x)=\prod_{\tau\in\Phi}\Big(\frac{1}{\pi}\int_{\mathbb{C}}|y|^{2\ell_X(\tau)}e^{-|y|^2}dy\Big)\cdot\Big(\frac{1}{\pi}\int_{\mathbb{C}}e^{-|y|^2}dy\Big)^{f(n-1)}=\prod_{\tau\in\Phi}\ell_X(\tau)!,$$

since $\frac{1}{\pi}\int_{\mathbb{C}}|y|^{2m}e^{-|y|^2}dy=\int_0^\infty u^me^{-u}\,du=m!$ (polar coordinates, $u=|y|^2$). Hence $A_v=\mathrm{vol}([\mathrm{U}(\mathrm{I}_n)])\,\lambda_{\mathrm{I}_1}\prod_\tau(c(\tau)-z)!$. *The constant A.* Put

$$B_z=\prod_{w\in S_M}(q_w-1)\cdot\mathrm{vol}([\mathrm{U}(\mathrm{I}_{2z})])\,\lambda_{\mathrm{I}_1}\,V_1\,P_z.$$

It depends only on D (through E and S_M) and z, and it is positive: $q_w\ge 2$, the quotients $[\mathrm{U}(\mathrm{I}_m)]$ ($m=1,2z$) are compact and carry the quotient of a Haar measure, so V_1 and $\mathrm{vol}([\mathrm{U}(\mathrm{I}_{2z})])$ are finite and positive, $\lambda_{\mathrm{I}_1}>0$ and $P_z>0$. As $X(p,\vartheta)$ and $X(p,1)$ have the same row lengths and rank, $O=O_{X(p,\vartheta)}$ and $O_{X(p,1)}$ have the same weight κ_O (one row of length $c(\tau)-z$ at τ), so $\dim\mathbb{V}_O=\dim\mathbb{V}_{O_{X(p,1)}}$. Now (6.174) reads $\mathrm{alg}_p(\vartheta)=A\,L^{S_M\cup Q}(z,\nu\vartheta)$ with A as in the statement, which does not depend on ϑ or Q. Finally $A>0$: $c_s\neq 0$ by (OL4), $\pi_M\neq 0$ as $|\pi_M|^2=M$, $\eta_P\neq 0$ as s_0, u_{CS} and Ω_{CM} are nonzero (OL4), $\dim\mathbb{V}_O\ge 1$, and $B_z>0$.

Step 6: positivity and the ratio. $L^S(z,\nu\vartheta)\neq 0$ by (c) of Lemma 6.7.15 (for $\nu_X=\nu\vartheta$, S and $k=z\ge 2$). So $\mathrm{alg}_p(\vartheta)\neq 0$; as a squared norm divided by $\mathrm{N}Q^{2z-1}>0$ it is ≥ 0, hence >0. For an automorphic character μ of $\mathrm{U}(1)$, $\widetilde{\mu^{-1}}(x)=\mu(\bar{x}/x)=\tilde{\mu}(\bar{x})$, and conjugation permutes the places off $S\cup\bar{S}$ preserving norms, so $L^S(z,\mu^{-1})=L^S(z,\mu)$. Therefore, by the definition of the ratio and the identity just proved for ϑ and for the trivial twist ($Q=\emptyset$),

$$r_p(\vartheta)=\frac{|L^{S_M\cup Q}(z,\nu\vartheta)|}{|L^{S_M}(z,\nu)|}=\frac{|\mathrm{alg}_p(\vartheta)/A|}{|\mathrm{alg}_p(1)/A|}=\frac{\mathrm{alg}_p(\vartheta)}{\mathrm{alg}_p(1)}.$$

□

Lemma 6.7.14. *Let X be L-value data of rank n, $O=O_X$, $\xi_X=\xi_O$, let*

$$f_X(h)=\int_{[\mathrm{U}(\mathrm{I}_1)]}\theta_O(\omega_O(u,h)\,\mathrm{J}_O(\xi_X))\,du\qquad(h\in\mathrm{U}(\mathrm{I}_n)(\mathbb{A})),$$

and let $\Theta_X\in\mathrm{Form}(O)$ be the algebraic form attached to f_X. Then:

(a) $\lambda_X=[\mathbf{K}_0(1):\mathbf{K}_X^{\mathrm{ch}}]\,\Theta_X$;

(b) $\langle\Theta_X,\Theta_X\rangle=[\mathbf{K}_0(n):\mathbf{K}(O)]\cdot\dim\mathbb{V}_O\cdot\langle f_X,f_X\rangle_{\mathrm{I}_n}$;

(c) the pair (ω_O, θ_O) is a theta kernel for $(\mathrm{I}_1, \mathrm{I}_n)$ on $\mathrm{Hom}(\mathrm{I}_1, \mathrm{I}_n)$ with real part $\Omega_{0,-\ell_X}$, and $f_X = L_{\mathrm{J}_O(\xi_X)}\mathbf{1}$ is its lift of the constant function $\mathbf{1}$ on $\mathrm{U}(\mathrm{I}_1)(\mathbb{A})$ with the datum $\mathrm{J}_O(\xi_X) = v_{\mathrm{Har}_O(\xi_X)} \otimes \Upsilon(O)$; the constant function $\mathbf{1}$ is a form of the type $\mathbf{1}$ (the constant function 1 on the real points of $\mathrm{U}(\mathrm{I}_1)$) on I_1; and there is a type e'_X on the spaces with the signs of I_n, depending only on n and ℓ_X, such that $v_{\mathrm{Har}_O(\xi_X)}$ is an edge for the weights $(0, -\ell_X)$ from $\mathbf{1}$ to e'_X;

(d) in the Fock variables $X_{\tau,i,1}$ of $\mathrm{Hom}(\mathrm{I}_1, \mathrm{I}_n)$ of (DP8), $\mathrm{Har}_O(\xi_X) = \prod_{\tau\in\Phi} X_{\tau,1,1}^{\ell_X(\tau)}$, and $\Omega_{0,-\ell_X}(x,1)\, v_{\mathrm{Har}_O(\xi_X)} = v_{\mathrm{Har}_O(\xi_X)}$ for every $x \in G_\infty(+) = \mathrm{U}(1)^\Phi$.

Proof. Throughout, $O = O_X$, $\kappa = \kappa_O$, $\ell = \ell_X$, $\xi = \xi_X$, $d = \dim \mathbb{V}_O = \#I_\kappa$, $G = G_\kappa$, $\langle\,,\rangle = \langle\,,\rangle_\kappa$ on $\mathbb{V}_O$, and $K = \mathbf{K}_X^{\mathrm{ch}}$. By (OL1), $\kappa_O^- = 0$, so $e_O = 0$, $\kappa(\tau,1) = \ell(\tau)$ and $\kappa(\tau,h) = 0$ for $h \geq 2$; we write $\rho = \rho_{\kappa,0}$ on $G_\infty(1) = \prod_{\tau\in\Phi} \mathrm{U}(n)$, so that $\rho_O(\gamma) = \rho(\gamma_\infty)$ for rational points γ of $\mathrm{U}(\mathrm{I}_n)$. Also $\chi_O = \upsilon^0 = 1$ has weight 0, and $\chi'_O = \nu_X \upsilon^{\lfloor n/2\rfloor}$ has weight $-(\ell + \lfloor n/2\rfloor) + \lfloor n/2\rfloor = -\ell$. For definite signs the measure of $G_\infty(s)$ is a probability measure (Lemma 5.5.21), invariant under left and right translations and hence under inversion (Lemma 5.2.41); an open subgroup $K' \subseteq \mathbf{K}_0(m)$ has measure $[\mathbf{K}_0(m) : K']^{-1}$.

Step 1: four facts on $\mathbb{V}_O$. By (a) of Lemma 4.6.10, S_κ is multiplicative and, for all families $z = (z_\tau)$ of complex $n \times n$ matrices,

$$S_\kappa(z)^{\mathsf{T}} G = G\, S_\kappa(z^{\mathsf{T}}). \tag{6.175}$$

(1a) *Unitarity.* By (b) and (c) of Lemma 4.6.10 with $e = 0$, ρ is a unitary representation of $G_\infty(1)$ for $\langle\,,\rangle$, $\rho(h^{-1}) = S_\kappa(h^{\mathsf{T}})$, and G is positive definite. In particular $w \in \mathbb{V}_O$ is determined by the numbers $\eta^{\mathsf{T}} G w$, $\eta \in \mathbb{V}_O$. (1b) *Substitution.* For $\eta \in \mathbb{V}_O$, $\mathrm{Pol}_\kappa(\eta)(zy) = \sum_{i,j} (G\eta)_i S_\kappa(z)_{ij} b_j(y) = \mathrm{Pol}_\kappa(S_\kappa(z^{\mathsf{T}})\eta)(y)$, by (6.175) and the symmetry of G. (1c) *Irreducibility.* As κ has one row of length $\ell(\tau)$ at τ, $\nabla_\kappa \otimes \mathbb{C}$ is the space of polynomials homogeneous of degree $\ell(\tau)$ in $y_{\tau,1,0}, \ldots, y_{\tau,n,0}$ for every τ, on which $\prod_\tau \mathrm{GL}_n(\mathbb{C})$ acts by $P \mapsto P(z\,\cdot)$ through the matrices $S_\kappa(z)^{\mathsf{T}}$; this is the tensor product over τ of symmetric powers of the dual of the standard representation, which is irreducible [92]. A subspace of $\mathbb{V}_O$ invariant under all $S_\kappa(z)$ has an invariant annihilator in $\nabla_\kappa \otimes \mathbb{C}$, so S_κ is irreducible; as $\prod_\tau \mathrm{U}(n)$ is Zariski dense in $\prod_\tau \mathrm{GL}_n(\mathbb{C})$ and $h \mapsto \bar{h}$ is an automorphism of it, ρ is irreducible. (1d) *The highest vector.* $\xi = \mathrm{ev}_\kappa(y_{\mathrm{id}})$ has integral entries, and $F_\kappa \xi = (\Delta_T(y_{\mathrm{id}}))_{T\in\mathcal{C}_\kappa}$. Here $\Delta_T(y) = \prod_{\tau,j} y_{\tau,a(\tau,j),0}$ with $T(\tau,1,j) = \{a(\tau,j)\}$, and in column 0 the array y_{id} has entry 1 in row 1 only; so $\Delta_T(y_{\mathrm{id}})$ is 1 for the filling with all rows equal to 1 and 0 otherwise. Hence $\|\xi\|^2 = |F_\kappa\xi|^2 = 1$ and $\mathrm{Pol}_\kappa(\xi)(y) = \xi^{\mathsf{T}} G\, \mathrm{ev}_\kappa(y) = (F_\kappa\xi)\cdot(F_\kappa \mathrm{ev}_\kappa(y)) = \prod_\tau y_{\tau,1,0}^{\ell(\tau)}$. We use Schur's orthogonality in the following form: if π is a continuous irreducible unitary representation of a compact group C with Haar probability measure on a Hilbert space of finite dimension d_π, then for all vectors a, b, c

$$\int_C \langle \pi(y)a, b\rangle\, \pi(y)c\, dy = d_\pi^{-1} \langle a, c\rangle\, b. \tag{6.176}$$

Indeed the operator $b \mapsto \int \langle \pi(y)a, b\rangle \pi(y)c\, dy$ commutes with every $\pi(z)$ (substitute $y \mapsto zy$), so it is a scalar by Schur's lemma, and its trace is $\int \langle \pi(y)a, \pi(y)c\rangle\, dy = \langle a, c\rangle$.

Step 2: the theta datum under the real points. By (d) of Lemma 3.2.20 for $(\kappa_O^+, \kappa_O^-) = (\kappa, 0)$ (so I_{κ^-} is a point, $S_{\kappa^-} = 1$, $G_{\kappa^-} = 1$, Pol_{κ^-} is the identity of $\mathbb{C}$ and $e^- = 0$), the matrix $C_O \in \mathrm{M}_{I_\kappa}(\mathbb{Z})$ commutes with every $S_\kappa(z)$, and by (DP8) $\mathrm{Har}_O(\eta) = \mathrm{Let}_1(\mathrm{Pol}_\kappa(C_O\eta))$, where Let_1 renames $y_{\tau,a,0}$ as $X_{\tau,a,1}$ (no variable of column $c \geq 1$ occurs). By (1b) with $z = y^{\mathsf{T}}$, for $y \in G_\infty(1)$,

$$\mathrm{Har}_O(\eta)((y_\tau^{\mathsf{T}} X_\tau)_\tau) = \mathrm{Har}_O(S_\kappa(y)\eta)(X), \qquad X_\tau = (X_{\tau,a,1})_a, \tag{6.177}$$

and every $\mathrm{Har}_O(\eta)$ is homogeneous of degree $\ell(\tau)$ in the variables at τ. By (c) of Lemma 3.2.20, $C_O\xi = \xi$, so $\mathrm{Har}_O(\xi) = P_0 := \prod_\tau X_{\tau,1,1}^{\ell(\tau)}$ by (1d). By Lemma 6.3.77, (ω_O, θ_O) is a theta kernel for $(\mathrm{I}_1, \mathrm{I}_n)$ on $\mathrm{Hom}(\mathrm{I}_1, \mathrm{I}_n)$ with real part $\Omega := \Omega_{0,-\ell}$. All signs are $+1$, so (5) of Lemma 4.1.1 applies to all $x \in G_\infty(+) = \mathrm{U}(1)^\Phi$ and $y \in G_\infty(1)$, with the factor $\prod_\tau x_\tau^{\ell(\tau)}$ and the substitution $X_{\tau,a,1} \mapsto x_\tau^{-1} \sum_i (y_\tau)_{ia} X_{\tau,i,1}$: for P homogeneous of degree $m(\tau)$ in the variables at τ,

$$\Omega(x,y)\, v_P = \prod_\tau x_\tau^{\ell(\tau)-m(\tau)}\, v_{P\circ y^{\mathsf{T}}}, \qquad (P\circ y^{\mathsf{T}})(X) = P((y_\tau^{\mathsf{T}} X_\tau)_\tau). \tag{6.178}$$

With (6.177), $\Omega(x,y) v_{\mathrm{Har}_O(\eta)} = v_{\mathrm{Har}_O(S_\kappa(y)\eta)}$, and the first formula of (5) of Lemma 4.1.1 gives $\omega_O((x,g),(y,h))\mathrm{J}_O(\eta) = \omega_O((1,g),(1,h))\mathrm{J}_O(S_\kappa(y)\eta)$. By (OL2), (6.175) and (1a), for $x \in G_\infty(+)$, $g \in G_f(1)$, $y \in G_\infty(1)$, $h \in G_f(n)$, $\eta \in \mathbb{V}_O$,

$$\theta_O(\omega_O((x,g),(y,h))\,\mathrm{J}_O(\eta)) = (S_\kappa(y)\eta)^{\mathsf{T}} G\, k_X(g)(h) = \eta^{\mathsf{T}} G\, \rho(y^{-1})\, k_X(g)(h); \tag{6.179}$$

it does not depend on x.

Step 3: the kernel is constant on the classes. The rational points of I_1 are $\mathrm{U}(1)(E)$, embedded diagonally; we identify γ with its finite component, as (OL3) does. For $\gamma \in \mathrm{U}(1)(E)$ the theta-kernel invariance (ED3) gives $\theta_O(\omega_O((\gamma_\infty,\gamma g),(1,h))\varphi) = \theta_O(\omega_O((1,g),(1,h))\varphi)$; by (6.179) at $x = \gamma_\infty$ and at $x = 1$ (both with $y = 1$), $\eta^{\mathsf{T}} G k_X(\gamma g)(h) = \eta^{\mathsf{T}} G k_X(g)(h)$ for all η, so $k_X(\gamma g) = k_X(g)$ by (1a). Let $k \in K$. By (2) of Lemma 4.1.1, $\omega_O((1,gk),(1,h)) = \omega_O((1,g),(1,h))\,\omega_O((1,k),(1,1))$. If $S_O \neq \emptyset$, then by (DP7) $\Upsilon(O) = \Phi_O \otimes_{S_O} v^0$ with $\Phi_O = \Psi_O^\natural$ for the modulus $\mathfrak{m} = \prod_{w\in S_O} w$, and (6) of Lemma 4.1.1 (with $\alpha = \chi_O = 1$, $\beta = \chi_O'$, $k' = 1$) gives

$$\omega_O((1,k),(1,1))(v\otimes\Upsilon(O)) = \chi_O'(k)^{-1}\, v \otimes (\Psi_O(\,\cdot\,\bar{k})^\natural \otimes_{S_O} v^0),$$

$\bar{k} = (k \bmod w)_{w\in S_O}$. As $\bar{k}_w = 1$ at the chosen places and $r = 1$, (DP7) gives $\Psi_O(X\bar{k}) = \prod_{w\in Q_X} \psi_{X,w}(\bar{k}_w)\,\Psi_O(X)$, ψ_X the tame part of $\mu_O = \nu_X$. The finite components of k are integral and its infinite components are 1, so by Definition 3.1.2, (OL1) and the trivial tame part of υ, $\chi_O'(k) = \nu_X(k)\upsilon(k)^{\lfloor n/2\rfloor} = \prod_{w\in M_X\cup Q_X} \psi_{X,w}(\bar{k}_w) = \prod_{w\in Q_X} \psi_{X,w}(\bar{k}_w)$. The two factors cancel, so $\omega_O((1,k),(1,1))\mathrm{J}_O(\eta) = \mathrm{J}_O(\eta)$. If $S_O = \emptyset$, then $\Upsilon(O) = v^0$, ν_X has trivial tame part, and the last formula of (6) gives the same. By (OL2), $k_X(gk) = k_X(g)$. So $g \mapsto k_X(g)$ is constant on the double cosets $\mathrm{U}(1)(E)\, g\, K$, and by (6.179), for fixed (y,h), the function $(x,g) \mapsto \theta_O(\omega_O((x,g),(y,h))\mathrm{J}_O(\xi))$ depends only on g and is left $\mathrm{U}(1)(E)$- and right K-invariant.

Step 4: unfolding, and (a). Let $m \in \{1,n\}$, $V = \mathrm{I}_m$ with rational points Γ_V, and $K' \subseteq \mathbf{K}_0(m)$ open. As V is definite (for $m = 1$, a hermitian line), $\mathrm{U}(V)$ is anisotropic over F, $[\mathrm{U}(V)]$ is compact [37] and $\Gamma_V\backslash G_f(m)/K'$ is finite [33]. For a representative h, the finite group $\Gamma_h = \Gamma_V \cap hK'h^{-1}$ (discrete and compact) acts freely on $G_\infty(1_m)\times hK'$ by left multiplication, the quotient maps bijectively onto the classes of $\Gamma_V hK'$ in $[\mathrm{U}(V)]$, and these sets partition $[\mathrm{U}(V)]$. Hence for Ψ bounded measurable on $\mathrm{G}(1_m)$, left Γ_V-invariant and with $\Psi(y,hk) = \Psi(y,h)$ for $k \in K'$,

$$\int_{[\mathrm{U}(V)]} \Psi = [\mathbf{K}_0(m) : K']^{-1} \sum_{[h]} \frac{1}{\#\Gamma_h} \int_{G_\infty(1_m)} \Psi(y,h)\, dy. \tag{6.180}$$

For $m = 1$, $K' = K$ ($G_f(1)$ is abelian, so Γ_g is that of (OL3)) and

$$\Psi(x,g) = \theta_O(\omega_O((x,g),(y,h))\mathrm{J}_O(\xi)),$$

Step 3, (6.179) and the mass 1 of $G_\infty(+)$ give, with (OL3), ξ real and (1a),

$$f_X(y,h) = [\mathbf{K}_0(1) : K]^{-1}\, \xi^{\mathsf{T}} G \rho(y^{-1}) \lambda_X(h) = [\mathbf{K}_0(1) : K]^{-1}\, \langle \rho(y)\xi, \lambda_X(h)\rangle. \tag{6.181}$$

By (LF5) and (6.176) for ρ (irreducible by (1c)) with $a = c = \xi$, $b = \lambda_X(h)$, and $\|\xi\| = 1$ (1d),

$$\Theta_X(h) = d\,[\mathbf{K}_0(1) : K]^{-1} \int_{G_\infty(1)} \langle \rho(y)\xi, \lambda_X(h)\rangle\, \rho(y)\xi\, dy = [\mathbf{K}_0(1) : K]^{-1} \lambda_X(h).$$

As $\lambda_X \in \mathrm{Form}(O)$ (OL2, OL3), $\Theta_X \in \mathrm{Form}(O)$, and (a) holds.

Step 5: (b). By (6.181) and (a), $f_X(y,h) = \langle \rho(y)\xi, \Theta_X(h)\rangle$. The function $\Psi = |f_X|^2$ on $\mathrm{G}(1_n)$ is left invariant under the rational points γ ($\Theta_X(\gamma_f h) = \rho(\gamma_\infty)\Theta_X(h)$ by (DP5), and (1a)) and right invariant under $\mathbf{K}(O)$ ($|\tilde{\eta}_O| = 1$, the $\psi_{O,w}$ being characters of finite groups). By (6.180) with $m = n$, $K' = \mathbf{K}(O)$, and by (6.176) paired with $w = \Theta_X(h)$, which gives $\int |\langle \rho(y)\xi, w\rangle|^2 dy = \langle w, d^{-1}\|\xi\|^2 w\rangle = d^{-1}\|w\|^2$,

$$\langle f_X, f_X\rangle_{\mathrm{I}_n} = [\mathbf{K}_0(n) : \mathbf{K}(O)]^{-1} \sum_{[h]} \frac{1}{\#\Gamma_h}\, d^{-1}\|\Theta_X(h)\|^2 = [\mathbf{K}_0(n) : \mathbf{K}(O)]^{-1} d^{-1} \langle \Theta_X, \Theta_X\rangle,$$

the last sum being the class sum of (DP5). This is (b).

Step 6: (c). The first assertion is Step 2. By (ED3),

$$L_{\mathrm{J}_O(\xi)}\mathbf{1}(h) = \int_{[\mathrm{U}(\mathrm{I}_1)]} \theta_O(\omega_O(u,h)\mathrm{J}_O(\xi))\, du = f_X(h).$$

The constant $\mathbf{1}$ is continuous, bounded, invariant on both sides, and $R(\mathbf{1})\mathbf{1} = \mathbf{1}$ (mass 1), so it is a form of type $\mathbf{1}$ on I_1. Let $\Phi = v_{P_0}$ ($P_0 \neq 0$, so $\Phi \neq 0$), let $H \subset \mathcal{F}_\varepsilon$ be the span of the v_P with P homogeneous of degree $\ell(\tau)$ in the variables at every τ, and $\pi(y) = \Omega(1,y)|_H$ for $y \in G_\infty(1)$. By (6.178), $\pi(y)v_P = v_{P\circ y^{\mathsf{T}}}$, so H is invariant and $\pi(yy') = \pi(y)\pi(y')$; π is unitary ((2) of Lemma 4.1.1: $\omega_\varepsilon^\infty$ preserves the inner product) and continuous (its matrix entries are polynomials in y), and it is irreducible, being the action $P \mapsto P\circ y^{\mathsf{T}}$ on polynomials homogeneous of degree $\ell(\tau)$ at τ, irreducible as in (1c). Put $d_H = \dim H$, $c_H = d_H/\|\Phi\|^2$ and

$$e'_X(y) = c_H\, \langle \pi(y)\Phi, \Phi\rangle \qquad (y \in G_\infty(1)),$$

a type on the spaces with the signs of I_n; it depends only on n and ℓ. By (6.176) for π: (i) $\int e'_X(y)\pi(y)\Phi\, dy = \Phi$; (ii) $w = c_H \int \langle \pi(y)\Phi, w\rangle \pi(y)\Phi\, dy$ for $w \in H$; (iii) $\int e'_X(y)\pi(y)w\, dy = \|\Phi\|^{-2}\langle \Phi, w\rangle\Phi$ for $w \in H$. Also $\Omega(x,1)\Phi = \Phi$ for $x \in G_\infty(+)$, by (6.178) with $m = \ell$, and $\Omega(1,z)v_P = \zeta^m v_P$ for P of degree m and central $z = (\zeta_\tau 1_n)_\tau$, $\zeta^m = \prod_\tau \zeta_\tau^{m(\tau)}$. *Half edge for Ω from $\mathbf{1}$ to e'_X.* (a) $\mathbf{1}$ is continuous and integrable, $\mathbf{1}(x^{-1}) = \overline{\mathbf{1}(x)}$, $\mathbf{1}(1) \neq 0$, $\int \mathbf{1}\, dz = 1 = \mathbf{1}(x^{-1})\mathbf{1}(y)/\mathbf{1}(1)$; on the compact group $G_\infty(+)$ all operator norms are 1, and $a = \mathbf{1}$ is continuous with compact support with $\int a(x)\mathbf{1}(x^{-1}y)dx = \mathbf{1}(y)$: a cusp kernel of order 0. (b) The zeta integral is $\int \langle \Phi, \Omega(x,1)\Phi\rangle\, dx = \|\Phi\|^2 \neq 0$. For (c) and (d) fix spaces with points S, T, V with the signs $+1$ on $\{1\}$, on n and on $n \times \{1\}$, a theta kernel (ω, θ) for (S,T) on V with real part Ω, $f \in \mathcal{M}_\eta$ and a form F of type $\mathbf{1}$ on S, and put $\Lambda_h(v) = L_{v\otimes f}F(h)$ for $v \in \mathcal{F}_\varepsilon$, $h \in \mathrm{G}(s')$. This is defined and linear in v: $[\mathrm{U}(S)]$ is compact (S is a hermitian line), $g \mapsto \theta(\omega(g,h)(v \otimes f))$ is continuous and left Γ_S-invariant, hence bounded, and F is bounded. Since ω is a homomorphism with real part Ω, $\Lambda_{h(y,1)}(v) = \Lambda_h(\Omega(1,y)v)$. Since $R(\mathbf{1})F = F$ and the measure of $G_\infty(s)$ is invariant, $F(g(x,1)) = F(g)$; substituting $g \mapsto g(x,1)$ in $[\mathrm{U}(S)]$ (the quotient measure is right invariant) gives $\Lambda_h(\Omega(x,1)v) = \Lambda_h(v)$. (d) Let $P = \sum_m P_m$ be a polynomial, P_m homogeneous of multidegree m. By (6.178) and the last identity, $\Lambda_h(v_P) = \sum_m \prod_\tau x_\tau^{\ell(\tau)-m(\tau)} \Lambda_h(v_{P_m})$ for every x; integrating over $G_\infty(+)$ gives $\Lambda_h(v_P) = \Lambda_h(v_{P_\ell})$. Put $a_P(y) = c_H\langle \pi(y)\Phi, v_{P_\ell}\rangle$, continuous on the compact group $G_\infty(1)$. By (ii), and since Λ_h is linear on the finite-dimensional space H, $\Lambda_h(v_{P_\ell}) = \int a_P(y)\Lambda_h(\pi(y)\Phi)\, dy = \int a_P(y) L_{\Phi\otimes f}F(h(y,1))\, dy = R(a_P)L_{\Phi\otimes f}F(h)$. (c) Let $L = L_{\Phi\otimes f}F$ have a level K''. It is left Γ_T-invariant by (ED3). It is continuous: on $C \times N$, C the

closure of a relatively compact Borel fundamental domain of Γ_S and N a compact neighbourhood of h_0, the function $(g,h)\mapsto\theta(\omega(g,h)(\Phi\otimes f))$ is uniformly continuous. It is bounded: T is definite, so $\Gamma_T\backslash G_f(n)/K''$ is finite and $G_\infty(s')$ is compact. Finally $R(e'_X)L(h)=\int e'_X(y)\Lambda_h(\pi(y)\Phi)\,dy=\Lambda_h(\Phi)=L(h)$ by (i). So L is a form of type e'_X. *Half edge for* $(y,x)\mapsto\Omega(x,y)$ *from* $\bar e'_X$ *to* $\bar{\mathbf{1}}=\mathbf{1}$. (a) $\bar e'_X(y)=c_H\langle\Phi,\pi(y)\Phi\rangle$ is continuous, $\bar e'_X(y^{-1})=\overline{\bar e'_X(y)}$ (unitarity), $\bar e'_X(1)=d_H\neq0$, and with (6.176) for $a=\pi(x)\Phi$, $b=\pi(y)\Phi$, $c=\Phi$, paired with Φ,

$$\int\bar e'_X(z)\,\bar e'_X((zx)^{-1}y)\,dz=c_H^2\int\langle\Phi,\pi(z)\Phi\rangle\langle\pi(z)\pi(x)\Phi,\pi(y)\Phi\rangle\,dz$$
$$=\frac{c_H^2}{d_H}\langle\pi(x)\Phi,\Phi\rangle\langle\Phi,\pi(y)\Phi\rangle=\frac{\bar e'_X(x^{-1})\,\bar e'_X(y)}{\bar e'_X(1)};$$

operator norms on $G_\infty(1)$ are 1, and $a=\bar e'_X$ reproduces $\bar e'_X$ (the identity at $x=1$): a cusp kernel of order 0. (b) The zeta integral $\int\langle\Phi,\pi(y)\Phi\rangle\,e'_X(y)\,d_H^{-1}dy=c_Hd_H^{-1}\int|\langle\Phi,\pi(y)\Phi\rangle|^2dy$ is positive (continuous, nonnegative, equal to $\|\Phi\|^4$ at $y=1$). For (c), (d) fix S', T', V' with the signs $+1$ on n, on $\{1\}$ and on $n\times\{1\}$, a theta kernel (ω,θ) for (S',T') on V' with $\omega((y,1),(x,1))(v\otimes f)=(\Omega(x,y)v)\otimes f$, f, and a form F of type $\bar e'_X$ on S'; put $\Lambda'_g(v)=L_{v\otimes f}F(g)$, defined and linear as before ($[\mathrm{U}(S')]$ is compact). As before $\Lambda'_{g(x,1)}(v)=\Lambda'_g(\Omega(x,1)v)$, and substituting $h\mapsto h(y^{-1},1)$ gives $\int\theta(\omega(h,g)(v\otimes f))F(h(y,1))\,dh=\Lambda'_g(\Omega(1,y^{-1})v)$. (c) If $L'=L_{\Phi\otimes f}F$ has a level, it is continuous, left $\Gamma_{T'}$-invariant and bounded as in (c) above (T' is a hermitian line), and $L'(g(x,1))=\Lambda'_g(\Omega(x,1)\Phi)=L'(g)$, so $R(\mathbf{1})L'=L'$: it is a form of type $\mathbf{1}$. (d) Let $P=\sum_m P_m$ as before. Inserting $F=R(\bar e'_X)F$, applying Fubini's theorem (bounded integrand, finite measures), the last identity and $y\mapsto y^{-1}$ (with $\bar e'_X(y^{-1})=e'_X(y)$), $\Lambda'_g(v_P)=\sum_m J_m$ with $J_m=\int e'_X(y)\Lambda'_g(\pi_m(y)v_{P_m})\,dy$, $\pi_m(y)v_{P_m}=\Omega(1,y)v_{P_m}=v_{P_m\circ y^{\mathsf T}}$. For $m\neq\ell$ choose a central z with $\zeta^{m-\ell}\neq1$; as $e'_X(zy)=\overline{\zeta^\ell}e'_X(y)$ and $\Omega(1,zy)v_{P_m}=\zeta^m\Omega(1,y)v_{P_m}$, the substitution $y\mapsto zy$ gives $J_m=\zeta^{m-\ell}J_m$, so $J_m=0$. For $m=\ell$, (iii) and the linearity of Λ'_g on H give $J_\ell=\|\Phi\|^{-2}\langle\Phi,v_{P_\ell}\rangle L'(g)$. With the constant $a=\|\Phi\|^{-2}\langle\Phi,v_{P_\ell}\rangle$ on the compact group $G_\infty(+)$ and $R(\mathbf{1})L'=L'$, $L_{v_P\otimes f}F=R(a)L'$. So $v_{\mathrm{Har}_O(\xi_X)}=\Phi$ is an edge for the weights $(0,-\ell_X)$ from $\mathbf{1}$ to e'_X.

Step 7: (d). Step 2 gives $\mathrm{Har}_O(\xi)=P_0=\prod_\tau X_{\tau,1,1}^{\ell(\tau)}$, and (6.178) with $y=1$ and $m=\ell$ gives $\Omega(x,1)v_{P_0}=v_{P_0}$ for $x\in G_\infty(+)$. □

Lemma 6.7.15. *Let ν be an automorphic character of* U(1) *with a weight and a tame part ψ, let S be a finite set of finite places of E with $\psi_w=1$ for every finite place $w\notin S$, put $D=S\cup\bar S$, let $k\geq2$ be an integer, T a space of rank $2k$, and* mc *the normalised vacuum coefficient for $b=\nu v^k$. Let $K^D\subseteq\mathrm{U}(1)(\mathbb{A}_f)$ be the subgroup of the points that are integral at every finite place not in D.*

(a) Every coset c of K^D in $\mathrm{U}(1)(\mathbb{A}_f)$ contains points whose component is 1 at every place of D, and mc *takes one value* $\mathrm{mc}(c)$ *at all of them.*

(b) The family $(\mathrm{mc}(c))_c$, indexed by the cosets $c\in\mathrm{U}(1)(\mathbb{A}_f)/K^D$, is absolutely summable, and

$$\sum_{c\in\mathrm{U}(1)(\mathbb{A}_f)/K^D}\mathrm{mc}(c)=L^S(k,\nu)\prod_v e_v(k),$$

where v runs over the finite places of the totally real subfield F of E that lie below no place of D, the product converges absolutely, and $e_v(k)=1-\mathrm{N}w^{-2k}$ if v splits in E as $w\bar w$ with $w\neq\bar w$, and $e_v(k)=1-\mathrm{N}w^{-k}$ if w is the only place of E above v.

(c) *Define $e_v(k)$ by the same formula for every finite place v of F. For every set V' of finite places of F the product $\prod_{v\in V'} e_v(k)$ converges absolutely and is a positive real number. The partial L-function is the absolutely convergent Euler product $L^S(k,\nu)=\prod_{u\notin D}\bigl(1-\tilde\nu(x_u)\mathrm{N}u^{-k}\bigr)^{-1}$ over the finite places u of E not in D, x_u an idele with a uniformiser at u and 1 elsewhere, with nonzero factors; in particular $L^S(k,\nu)\neq 0$.*

Proof. Write $\mathrm{U}(1)(F_v)=\{u\in(E\otimes_F F_v)^\times : u\bar u=1\}$ for the component of $\mathrm{U}(1)(\mathbb{A}_f)$ above a finite place v of F. Since $\bar D=D$, a place v of F lies below a place of D exactly when all places of E above v lie in D. For a finite place u of E let x_u be the idele with a uniformiser ϖ_u of E_u at u and 1 elsewhere, as in Lemma 6.7.16 (c).

Step 1: the local groups. If w is the only place of E above v, then $E\otimes_F F_v=E_w$ is a field on which conjugation is the nontrivial automorphism over F_v; it preserves $|\cdot|_w$, so $|u|_w^2=|u\bar u|_w=1$ for $u\in\mathrm{U}(1)(F_v)$, and every such u is a unit: every point of $\mathrm{U}(1)(\mathbb{A}_f)$ is integral at w. If v splits as $w\bar w$, then $E\otimes_F F_v=E_w\times E_{\bar w}$, conjugation exchanges the factors, and $u\bar u=1$ says $u_{\bar w}=\overline{u_w}^{-1}$. So $u\mapsto u_w$ is an isomorphism $\mathrm{U}(1)(F_v)\to E_w^\times$, and $|u_{\bar w}|_{\bar w}=|u_w|_w^{-1}$; hence u is integral at w and at $\bar w$ if and only if $\mathrm{ord}_w(u_w)=0$.

Step 2: $\tilde\nu$ off D. Let $u\notin D$ be a finite place, $t\in\mathcal{O}_{E,u}^\times$ and y the idele with component t at u and 1 elsewhere. Then $y/\bar y\in\mathrm{U}(1)(\mathbb{A})$ has archimedean components 1, unit components at u and $\bar u$ (namely t and $\bar t^{-1}$ if $\bar u\neq u$, and $t/\bar t$ if $\bar u=u$) and components 1 elsewhere. By the defining formula of weight and tame part, $\tilde\nu(y)=\nu(y/\bar y)$ is a product of values of ψ_u and $\psi_{\bar u}$, which are trivial because $u,\bar u\notin D\supseteq S$; so $\tilde\nu(y)=1$. Thus $\tilde\nu$ is unramified at every $u\notin D$; its value $\tilde\nu(x_u)$ does not depend on the uniformiser and has absolute value 1. Two consequences.

(i) If v splits as $w\bar w$ below no place of D, then $\bar x_w$ is an idele $x_{\bar w}$ (component $\bar\varpi_w$, a uniformiser of $E_{\bar w}$) and $\tilde\nu(\bar x_w)=\nu(\bar x_w/x_w)=\nu(x_w/\bar x_w)^{-1}=\tilde\nu(x_w)^{-1}$.

(ii) If $w\notin D$ is the only place above v, then $\tilde\nu(x_w)=1$: if w is unramified over v, take $\varpi_w\in F_v$, so $x_w=\bar x_w$; if w is ramified over v, then $x_w/\bar x_w$ has component $\varpi_w/\bar\varpi_w$ at w, a unit of norm one, and 1 elsewhere, so $\nu(x_w/\bar x_w)=\psi_w(\varpi_w/\bar\varpi_w \bmod w)=1$.

Hence $L^S(s,\nu)=\prod_{u\notin D}(1-\tilde\nu(x_u)\mathrm{N}u^{-s})^{-1}$, absolutely convergent for $\mathrm{Re}\,s>1$; grouping the factors by the places v of F below no place of D, $L^S(k,\nu)=\prod_v L_v(k)$, absolutely convergent, with

$$\begin{aligned} L_v(k)&=\bigl(1-\tilde\nu(x_w)\mathrm{N}w^{-k}\bigr)^{-1}\bigl(1-\tilde\nu(x_w)^{-1}\mathrm{N}w^{-k}\bigr)^{-1} && (v=w\bar w \text{ split}),\\ L_v(k)&=\bigl(1-\mathrm{N}w^{-k}\bigr)^{-1} && (\text{otherwise}). \end{aligned} \tag{6.182}$$

Step 3: the cosets; proof of (a). Let V be the set of places of F that split in E and lie below no place of D. For $v\in V$ fix a place w_v above v and a uniformiser of E_{w_v}, write $\mathrm{N}_v=\mathrm{N}w_v$ and $\gamma_{v,z}=\gamma_{w_v,z}$ ($z\in\mathbb{Z}$) for the points of Lemma 6.7.16 (c). Let $\mathbb{Z}^{(V)}$ be the group of finitely supported maps $V\to\mathbb{Z}$, and define $\mathrm{ord}\colon\mathrm{U}(1)(\mathbb{A}_f)\to\mathbb{Z}^{(V)}$ by $q\mapsto(\mathrm{ord}_{w_v}(q_{w_v}))_{v\in V}$; the image is finitely supported because a finite adelic point is integral at almost all places, and ord is a homomorphism. Its kernel is K^D: by Step 1 every point is integral at the places above a nonsplit v, and at the two places above $v\in V$ it is integral exactly when its coordinate at v vanishes; the places above the remaining v lie in D, where K^D imposes nothing. It is surjective: for $z\in\mathbb{Z}^{(V)}$ the point $\gamma_z=\prod_{v\in\mathrm{supp}\,z}\gamma_{v,z_v}$ has $\mathrm{ord}(\gamma_z)=z$. So the cosets of K^D correspond to $\mathbb{Z}^{(V)}$, and the coset of z contains γ_z, whose component is 1 at every place of D. If q,q' lie in one coset and both have component 1 at every place of D, then $\kappa=q^{-1}q'\in K^D$ has component 1 at the places of D, hence is integral at every finite place, and Lemma 6.7.16 (b) (with the left factor 1; its hypothesis on D holds because $\psi_w=1$ for $w\notin S$ and $D\supseteq S$) gives $\mathrm{mc}(q')=\mathrm{mc}(q\kappa)=\mathrm{mc}(q)$. This proves (a), and $\mathrm{mc}(c)=\mathrm{mc}(\gamma_z)$ for the coset c of z.

Step 4: the values. The factors γ_{v,z_v} of γ_z have pairwise disjoint supports ($\gamma_{v,z}$ has components different from 1 only at w_v, $\bar{w}_v$), and if two points q, q' have, at every finite place, one of their two components equal to 1, and u, u' are finite ideles as in Lemma 6.7.16 (a) for q and q', then uu' is one for qq' (the condition $uu'\widehat{\mathcal{O}}_E = \widehat{\mathcal{O}}_E \cap qq'\widehat{\mathcal{O}}_E$ is checked place by place), so the formula Lemma 6.7.16 (a) and the multiplicativity of b, υ and $|\cdot|$ give $\mathrm{mc}(qq') = \mathrm{mc}(q)\,\mathrm{mc}(q')$; induction on $\#\operatorname{supp} z$ gives $\mathrm{mc}(\gamma_z) = \prod_{v\in\operatorname{supp} z} \mathrm{mc}(\gamma_{v,z_v})$. Put $c_v = \tilde{\nu}(\bar{x}_{w_v})$, so $\tilde{\nu}(x_{w_v}) = c_v^{-1}$ by Step 2 (i) and $|c_v| = 1$. By Lemma 6.7.16 (c),

$$\mathrm{mc}(\gamma_{v,z}) = a_v(z) := c_v^z\,\mathrm{N}_v^{-k|z|} \qquad (z \in \mathbb{Z}),$$

since $(c_v^{-1}\mathrm{N}_v^{-k})^{-z} = c_v^z\mathrm{N}_v^{kz}$ for $z < 0$. In particular $a_v(0) = 1$ and $|a_v(z)| = \mathrm{N}_v^{-k|z|}$.

Step 5: absolute summability. Put $B_v = \sum_{z\in\mathbb{Z}} |a_v(z)| = 1 + \beta_v$ with $\beta_v = 2\mathrm{N}_v^{-k}/(1-\mathrm{N}_v^{-k}) \le 4\mathrm{N}_v^{-k}$. Above each rational prime p there are at most $[F:\mathbb{Q}]$ places of F, each of norm at least p, and for $v \in V$ the number N_v is the norm of v; so $\sum_{v\in V}\beta_v \le 4[F:\mathbb{Q}]\sum_p p^{-k} < \infty$ as $k \ge 2$. For a finite set $V' \subseteq V$, distributivity gives

$$\sum_{\operatorname{supp} z\subseteq V'}\ \prod_{v\in V'} |a_v(z_v)| = \prod_{v\in V'} B_v \le \exp\Bigl(\sum_{v\in V}\beta_v\Bigr), \qquad \sum_{\operatorname{supp} z\subseteq V'}\ \prod_{v\in V'} a_v(z_v) = \prod_{v\in V'} A_v,$$

where $A_v = \sum_{z\in\mathbb{Z}} a_v(z)$. Every finite subset of $\mathbb{Z}^{(V)}$ consists of maps supported in some finite V', so $(\mathrm{mc}(\gamma_z))_z$ is absolutely summable with sum of moduli $B = \prod_{v\in V} B_v$ (a convergent product of numbers ≥ 1). Enumerate $V = \{v_1, v_2, \dots\}$ and put $V_n = \{v_1, \dots, v_n\}$; then

$$\Bigl|\sum_{z\in\mathbb{Z}^{(V)}} \mathrm{mc}(\gamma_z) - \prod_{i\le n} A_{v_i}\Bigr| \le \sum_{\operatorname{supp} z\not\subseteq V_n} |\mathrm{mc}(\gamma_z)| = B - \prod_{i\le n} B_{v_i} \longrightarrow 0,$$

so the sum in (b) is $\lim_n \prod_{i\le n} A_{v_i}$ (if V is finite the limit is reached).

Step 6: the local sums. With $\xi = c_v\mathrm{N}_v^{-k}$ and $\xi' = c_v^{-1}\mathrm{N}_v^{-k}$, both of modulus $\mathrm{N}_v^{-k} < 1$, the two geometric series give

$$\begin{aligned} A_v &= \sum_{z\ge 0}\xi^z + \sum_{z\ge 1}\xi'^z = \frac{1}{1-\xi} + \frac{\xi'}{1-\xi'} = \frac{1-\xi\xi'}{(1-\xi)(1-\xi')} \\ &= \frac{1-\mathrm{N}_v^{-2k}}{(1-c_v\mathrm{N}_v^{-k})(1-c_v^{-1}\mathrm{N}_v^{-k})} = e_v(k)\,L_v(k), \end{aligned}$$

by (6.182) with $\tilde{\nu}(x_{w_v})^{\pm 1} = c_v^{\mp 1}$.

Step 7: conclusion. For a place v of F below no place of D that does not split, (6.182) gives $e_v(k)L_v(k) = 1$. The products $\prod_v e_v(k)$ and $\prod_v L_v(k) = L^S(k,\nu)$ over the places v of F below no place of D converge absolutely, as $|1-e_v(k)| \le \mathrm{N}w^{-k}$ and $|1-L_v(k)^{-1}| \le 3\mathrm{N}w^{-k}$ with $\sum_v \mathrm{N}w^{-k} < \infty$ as in Step 5; so their product is the absolutely convergent product $\prod_v e_v(k)L_v(k)$, whose limit does not depend on the order of the factors. Its factors are 1 off V and A_v on V, so it equals $\lim_n \prod_{i\le n} A_{v_i}$, which by Step 5 is the sum in (b). This proves (b).

Step 8: proof of (c). For every finite place v of F and a place w above it, $0 < e_v(k) < 1$ and $1 - e_v(k) \le \mathrm{N}w^{-k} \le \mathrm{N}v^{-k}$ (as $\mathrm{N}w \ge \mathrm{N}v$). Above each rational prime p there are at most $[F:\mathbb{Q}]$ places of F, each of norm at least p, so $\sum_v \mathrm{N}v^{-k} \le [F:\mathbb{Q}]\sum_p p^{-k} < \infty$ as $k \ge 2$. Since $-\log(1-t) \le 2t$ for $0 \le t \le \frac{1}{2}$ and $1 - e_v(k) \le 2^{-k} \le \frac{1}{4}$, the series $\sum_{v\in V'} \log e_v(k)$ converges absolutely, and $\prod_{v\in V'} e_v(k) = \exp\sum_{v\in V'}\log e_v(k)$ is an absolutely convergent product with value in $(0,1]$. For the Euler product: by Step 2 the factor at $u \notin D$ is $(1-\xi_u)^{-1}$ with $|\xi_u| = \mathrm{N}u^{-k} \le 2^{-k}$, so it is defined and nonzero, and $\sum_{u\notin D}|\xi_u| \le 2[F:\mathbb{Q}]\sum_p p^{-k} < \infty$ (at most two places of E above each place of F); the identity with $L^S(k,\nu)$ is Step 2. With the principal branch, $|\log(1-\xi_u)| \le 2|\xi_u|$, so $\prod_u(1-\xi_u)^{-1} = \exp(-\sum_u \log(1-\xi_u))$ converges absolutely and is not 0. □

Lemma 6.7.16. *Let $S = \mathrm{I}_1$, so that $\mathrm{G}(s) = \mathrm{U}(1)(\mathbb{A})$ and the finite points form $G_f(1) = \{q \in \mathbb{A}_{E,f}^{\times} : q\bar{q} = 1\}$. Let $k \geq 1$ be an integer, T a space of rank $2k$, ν an automorphic character of $\mathrm{U}(1)$ with a weight and a tame part $\psi = (\psi_w)_w$, and $b = \nu\upsilon^k$. For $q \in G_f(1)$ let*

$$\mathrm{mc}(q) = \frac{\langle v^0, \omega_{1,b}(q,1)\, v^0\rangle}{\langle v^0, v^0\rangle}$$

be the ***normalised vacuum coefficient****, formed in $\mathcal{M}_{S,T}$. A point $q \in G_f(1)$ is* integral at *a finite place w if $q_w \in \mathcal{O}_{E,w}$.*

(a) For $q \in G_f(1)$ and every finite idele u with $u\widehat{\mathcal{O}}_E = \widehat{\mathcal{O}}_E \cap q\widehat{\mathcal{O}}_E$,

$$\mathrm{mc}(q) = b(q)^{-1}\, \upsilon(u)^{2k}\, |u|^k.$$

(b) Let D be a set of finite places of E with $\psi_w = 1$ for every finite place $w \notin D$. Then $\mathrm{mc}(\kappa q \kappa') = \mathrm{mc}(q)$ for every $q \in G_f(1)$ and all $\kappa, \kappa' \in G_f(1)$ that are integral at every finite place and have component 1 at every place of D.

(c) Let w be a finite place with $\bar{w} \neq w$, ϖ_w a uniformiser of E_w, $x_w \in \mathbb{A}_{E,f}^{\times}$ the idele with component ϖ_w at w and 1 elsewhere, and $\bar{x}_w$ its conjugate (component $\bar{\varpi}_w$ at $\bar{w}$, 1 elsewhere). For $z \in \mathbb{Z}$ the point $\gamma_{w,z} = (x_w/\bar{x}_w)^z$ lies in $G_f(1)$ (component ϖ_w^z at w, $\bar{\varpi}_w^{-z}$ at $\bar{w}$, 1 elsewhere), and

$$\mathrm{mc}(\gamma_{w,z}) = \begin{cases} \big(\tilde{\nu}(\bar{x}_w)\, \mathrm{N}w^{-k}\big)^z, & z \geq 0, \\ \big(\tilde{\nu}(x_w)\, \mathrm{N}w^{-k}\big)^{-z}, & z < 0. \end{cases}$$

Proof. Throughout, $L_1 = \widehat{\mathcal{O}}_E$. Two facts from (WD3) are used: $\upsilon(\bar{x}) = \upsilon(x)^{-1}$ for every idele x, and $\upsilon(x) = 1$ for every idele x whose finite components are units and whose infinite components are 1. Conjugation maps E_w isometrically onto $E_{\bar{w}}$ and $\mathrm{N}\bar{w} = \mathrm{N}w$, so $|\bar{x}| = |x|$.

Step 1: the ideles u. Let $q \in G_f(1)$. At a finite place w, $\mathcal{O}_{E,w} \cap q_w\mathcal{O}_{E,w} = \varpi_w^{m_w}\mathcal{O}_{E,w}$ with $m_w = \max(0, \mathrm{ord}_w\, q_w)$, and $m_w = 0$ for almost all w because q_w is a unit for almost all w. Hence finite ideles u with $uL_1 = L_1 \cap qL_1$ exist, and two of them differ by a factor whose finite components are units; that factor has υ-value 1 and norm 1. So the right side of (a) does not depend on the choice of u. Moreover $q^{-1} = \bar{q}$, so $L_1 \cap q^{-1}L_1 = L_1 \cap \bar{q}L_1$ is the conjugate of $L_1 \cap qL_1$, that is $\bar{u}L_1$.

Step 2: proof of (a). By (WR4) with $\alpha = 1$, $\beta = b$, the point $q \in \mathrm{G}(s)$ and $h = 1 \in \mathrm{G}(s')$, s' the signs of T on its index set n' with $\#n' = 2k$,

$$\omega_{1,b}(q,1) = b(q)^{-1}\, \omega_{s'}(h_q), \qquad h_q = 1_{2k} \otimes (q^{-1})^{\mathsf{T}} = q^{-1} \cdot 1_{2k}.$$

The point h_q has infinite components 1. By Lemma 6.2.13(1),(2),

$$\langle v^0, v^0\rangle = 1, \qquad \langle v^0, \omega_{s'}(h_q)v^0\rangle = \overline{\Delta_{s'}(h_q)}^{-1}.$$

For the idele u of (a), the matrix $u' = u \cdot 1_{2k}$ satisfies

$$u'L_1^{2k} = L_1^{2k} \cap h_q^{-1}L_1^{2k} = (L_1 \cap qL_1)^{2k}.$$

Thus (WR3), whose infinite factor is 1 here, gives $\Delta_{s'}(h_q) = \upsilon(u)^{2k}|u|^{-k}$. Since $|\upsilon(u)| = 1$ and $|u| > 0$, its inverse conjugate is $\upsilon(u)^{2k}|u|^k$. Multiplying by $b(q)^{-1}$ and using the denominator 1 proves (a).

Step 3: proof of (b). Let κ be as in (b). At a finite place w with $\bar{w} \neq w$, $(\kappa\bar{\kappa})_w = \kappa_w \overline{\kappa_{\bar{w}}} = 1$ with both factors integral, so κ_w is a unit; at $w = \bar{w}$, $|\kappa_w|_w^2 = |\kappa_w \bar{\kappa}_w|_w = 1$. So all finite components of κ, and likewise of κ', are units, $\kappa q \kappa' L_1 = qL_1$, and the same u serves for q and $\kappa q \kappa'$ in (a). Further $b(\kappa) = \nu(\kappa)\upsilon(\kappa)^k$ with $\upsilon(\kappa) = 1$ by the second fact above, and, κ having integral finite components and infinite components 1, the defining formula of weight and tame part gives $\nu(\kappa) = \prod_w \psi_w(\kappa_w \bmod w) = 1$, because $\kappa_w = 1$ for $w \in D$ and $\psi_w = 1$ for $w \notin D$. Likewise $b(\kappa') = 1$. So $b(\kappa q \kappa') = b(q)$, and (a) gives $\mathrm{mc}(\kappa q \kappa') = \mathrm{mc}(q)$.

Step 4: proof of (c). Since $\bar{w} \neq w$, $\gamma = \gamma_{w,z}$ has the components stated and $\gamma\bar{\gamma} = 1$, so $\gamma \in G_f(1)$. Its value under b is

$$b(\gamma) = \nu\big((x_w/\bar{x}_w)^z\big)\,\big(\upsilon(x_w)\upsilon(\bar{x}_w)^{-1}\big)^{kz} = \tilde{\nu}(x_w)^z\,\upsilon(x_w)^{2kz}.$$

If $z \geq 0$, then $L_1 \cap \gamma L_1$ has component $\varpi_w^z \mathcal{O}_{E,w}$ at w and $\mathcal{O}_{E,w'}$ at every other finite place w' (at $\bar{w}$ the component $\bar{\varpi}_w^{-z}$ of γ has order $-z \leq 0$); so $u = x_w^z$, $|u| = \mathrm{N}w^{-z}$ and $\upsilon(u)^{2k} = \upsilon(x_w)^{2kz}$. By (a), $\mathrm{mc}(\gamma) = \tilde{\nu}(x_w)^{-z}\mathrm{N}w^{-kz}$, and $\tilde{\nu}(x_w)^{-1} = \nu(\bar{x}_w/x_w) = \tilde{\nu}(\bar{x}_w)$. If $z < 0$, the component of $L_1 \cap \gamma L_1$ is $\bar{\varpi}_w^{-z}\mathcal{O}_{E,\bar{w}}$ at $\bar{w}$ and integral elsewhere, so $u = \bar{x}_w^{-z}$, $|u| = \mathrm{N}w^z$ and $\upsilon(u)^{2k} = \upsilon(\bar{x}_w)^{-2kz} = \upsilon(x_w)^{2kz}$; by (a), $\mathrm{mc}(\gamma) = \tilde{\nu}(x_w)^{-z}\mathrm{N}w^{kz} = \big(\tilde{\nu}(x_w)\mathrm{N}w^{-k}\big)^{-z}$. □

The test forms (Proposition 6.7.17) are the finite half of the bound: for every prime $\ell \nmid \mathrm{N}Q$ they pair with the scaled lift of a main pair to a number divisible by at most $\ell^{F(\ell)}$, up to one number $c_{\mathrm{tf}} \neq 0$ with small conjugates, chosen before the prime. They are built on four blocks of the definite space from point forms, which are integral and orthogonal to the false lifts by the vanishing of their periods (Proposition 6.6.81), and their pairing with every kernel form is a theta kernel on twelve blocks times three values of flat pairs (Lemma 6.7.18). The twelve-block kernel is handled by the sharpness of the jet valuation bound (Proposition 6.7.24), and a multiplicative pigeonhole over the class characters of U(1) keeps the product large (Lemma 6.7.22). The jet pair and the vacuum scales are those fixed in Section 4. For the ℓ-adic integrality of Hecke L-values of CM fields, the background of the construction, see [159, 272].

Proposition 6.7.17. *Let $1 \leq j \leq m$, let $p = (\nu, z)$ be a main pair for j, and let $p_{\mathrm{fl}} = (\nu_{\mathrm{fl}}, 2)$ be a flat critical pair. There is $c_{\mathrm{tf}} \in \mathbb{C} \setminus \{0\}$ with $|\sigma(c_{\mathrm{tf}})| \leq \exp(fmb/k + 3x^{34})$ for every automorphism σ of $\mathbb{C}$, such that for every prime ℓ, every embedding $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ and every twist ϑ with $\ell \nmid \mathrm{N}Q$ there is a test form Ξ for ℓ of $O_{p,\vartheta}$ with*

$$\big\|\iota\big(c_{\mathrm{tf}}\, r_{p_{\mathrm{fl}}}(\vartheta)\big)\big\| \cdot \ell^{-F(\ell)} \;\leq\; \big\|\iota\langle \Xi, \varphi_{p,\vartheta}\rangle\big\|,$$

where $\varphi_{p,\vartheta}$ is the lift of p at ϑ.

Proof. Let $p = (\nu, z)$, ν of weight $-c$, and $l(\tau) = c(\tau) - z$, so $\sum_\tau l(\tau) = j_p$.

Step 1: the jet degrees, the vacuum scale and nonvanishing. By (RH1), (RH3) and $z \leq r$, for every $\tau \in \Phi$: $l(\tau) \geq \kappa_j(\tau) + r - t - r = \kappa(\tau) + (2j+1)r^8 - 5r \geq \kappa(\tau)$, and $l(\tau) \leq \kappa_j(\tau) - z \leq \kappa(\tau) + (2m+1)r^8 \leq \kappa(\tau) + x^{42}$, since $m \leq 2\sqrt{x}$, $r \leq 3x^5$ by (AD2) and $(4\sqrt{x}+1)3^8x^{40} \leq x^{42}$ as $x \geq e^{10^{14}}$ by Lemma 2.3.6. So Proposition 6.7.24 applies to l; let $t_{\mathrm{shp}} \neq 0$ be its number, $|\sigma(t_{\mathrm{shp}})| \leq \exp(fmb/k)$. Applied at any prime p' and any ring homomorphism $\mathbb{C} \to \mathbb{C}_{p'}$ (one exists: both fields are algebraically closed of characteristic 0 and of the cardinality of the continuum), its conclusion is a positive lower bound for the norm of a multiple of c_s^{12}, so $c_s \neq 0$. Hence for every flat critical pair q with $z_q \geq 2$ the scale factor $c_s^{2z_q}$ of $\varphi_{q,\vartheta'}$ is nonzero (row lengths 0), and Proposition 6.7.13 gives $\mathrm{alg}_q(\vartheta') > 0$ and $r_q(\vartheta') = \mathrm{alg}_q(\vartheta')/\mathrm{alg}_q(1)$; as $N_{\mathrm{ch}}, n_{\nu_q} \geq 1$,

$$I_q^{N_{\mathrm{ch}}}(\vartheta') > 0, \qquad I_q^{N_{\mathrm{ch}}}(\vartheta') = r_q(\vartheta')\, I_q^{N_{\mathrm{ch}}}(1). \tag{6.183}$$

Step 2: the group G and the flat pairs over it. Let G be the set of automorphic characters of $\mathrm{U}(1)$ of weight 0 whose tame part is trivial off the chosen places; it is a group under multiplication. Let $\mathbf{K}^{\mathrm{ch}} \subseteq G_f(1)$ be the points integral at every finite place and congruent to 1 modulo every chosen place, and $C = \mathrm{U}(1)(E)\backslash G_f(1)/\mathbf{K}^{\mathrm{ch}}$, a finite abelian group (Lemma 6.7.22 (a); $G_f(1)$ is commutative). Every $\chi \in G$ is trivial on $\mathrm{U}(1)(\mathbb{R})$ (weight 0), on $\mathrm{U}(1)(E)$ and on $\mathbf{K}^{\mathrm{ch}}$ (its tame part is trivial off the chosen places and the residues at the chosen places are 1), so $g \mapsto \chi(g)$ is a character of C that determines χ, as $\mathrm{U}(1)(\mathbb{A}) = \mathrm{U}(1)(\mathbb{R}) \times G_f(1)$; hence G is finite. By (AD2) and Lemma 2.3.6, $m \geq \sqrt{x} \geq 12$, so $z \geq m+1 \geq 12$ by (RH1). For $\chi \in G$ put

$$q_1(\chi) = (\chi \upsilon^{-(z-10)},\, z-10), \qquad q_3(\chi) = (\chi \upsilon^{-2},\, 2).$$

These are flat critical pairs: $\chi\upsilon^{-z'}$ has weight $-z'$ and the tame part of χ, and $1 \leq z' \leq z \leq t$, $z' \leq z \leq c(\tau) \leq 4b$ because p is critical. As $\mathbb{C}$ is algebraically closed, choose $V \in \mathbb{C}$ with

$$V^{\#G} = \prod_{\chi \in G} I^{N_{\mathrm{ch}}}_{q_3(\chi)}(1)\, I^{N_{\mathrm{ch}}}_{q_1(\chi)}(1);$$

$V \neq 0$ by (6.183). Put $c_{\mathrm{tf}} = t_{\mathrm{shp}}\, I^{N_{\mathrm{ch}}}_{p_{\mathrm{fl}}}(1)\, V \neq 0$.

Step 3: the conjugates of c_{tf}. Let σ be an automorphism of $\mathbb{C}$. By Lemma 6.7.22 (b) for $\iota = \sigma$, $a(\chi) = I^{N_{\mathrm{ch}}}_{q_3(\chi)}(1)$, $b(\chi) = I^{N_{\mathrm{ch}}}_{q_1(\chi)}(1)$ and $\psi = 1$, there are $\varphi', \chi' \in G$ with $|\sigma(V)| \leq |\sigma(I^{N_{\mathrm{ch}}}_{q_3(\varphi')}(1))|\,|\sigma(I^{N_{\mathrm{ch}}}_{q_1(\chi')}(1))| \leq \exp(x^{34})^2$ by Lemma 6.7.23. With $|\sigma(t_{\mathrm{shp}})| \leq \exp(fmb/k)$ and $|\sigma(I^{N_{\mathrm{ch}}}_{p_{\mathrm{fl}}}(1))| \leq \exp(x^{34})$ (Lemma 6.7.23), $|\sigma(c_{\mathrm{tf}})| \leq \exp(fmb/k + 3x^{34})$.

Step 4: the choices at (ℓ, ι, ϑ). Fix a prime ℓ, a ring homomorphism $\iota\colon \mathbb{C} \to \mathbb{C}_\ell$ and a twist ϑ with modulus Q, $\ell \nmid \mathrm{N}Q$, and let $X = X(p, \vartheta)$; then $\ell_X = l$ and $\mathbf{K}^{\mathrm{ch}}_X = \mathbf{K}^{\mathrm{ch}}$ (the chosen places of X are those of D). Let $\mathfrak{m} = \pi_M \mathcal{O}_E$ and $F_{\mathfrak{m},y_0}$ the indicator datum of Proposition 6.7.24. By Proposition 6.7.24 at (ℓ, ι) there are γ with $\sum_i \gamma(\tau, i) = l(\tau)$ and $x_0 \in R^{12}_{\mathfrak{m}}$ with

$$\ell^{-F(\ell)} \leq \Big\| \iota\Big(\frac{c_s^{12}}{t_{\mathrm{shp}}} \prod_\tau l(\tau)!\, [Z^\gamma] T(F_{\mathfrak{m},x_0}) \Big) \Big\|. \tag{6.184}$$

Let $\chi_0 = \nu \upsilon^{z-2} \nu_{\mathrm{fl}}^{-1}$ and, for $g \in G_f(1)$, $s_0(g) = \theta^{\mathrm{I}_1,\mathrm{I}_{12}}_{1,\chi_0}(v_{X^\gamma} \otimes F_{\mathfrak{m},x_0})((1,g),(1,1))$. The germ θ_F of Proposition 6.7.24 is $\mathscr{E}_{V_{12},F}$ of Lemma 4.2.2, defined for $F = F_{\mathfrak{m},x_0}$ in the finite span $\mathcal{M}_{\mathrm{fin},V_{12}}$ there: by (4) and (2) of Lemma 6.2.33 and (WR6), $F_{\mathfrak{m},x_0} = v_1 \otimes (\Psi_{\mathfrak{m},x_0} \otimes_{\Sigma(\mathfrak{m})} v^0) = \Psi_{\mathfrak{m},x_0} \otimes_{\Sigma(\mathfrak{m})} v^0 = \sum_y c_y(\Psi_{\mathfrak{m},x_0})\, \rho(\mathrm{fv}(y))\, v^0$, a finite combination of finite Heisenberg translates of the vacuum, and the datum $v_{X^\gamma} \otimes F_{\mathfrak{m},x_0}$ of (WR6) is $v_{X^\gamma} \otimes (\Psi_{\mathfrak{m},x_0} \otimes_{\Sigma(\mathfrak{m})} v^0)$. By Lemma 4.2.2 (with $Q = X^\gamma$, the constant $\pi_M \eta_P$, $F_0 = F_{\mathfrak{m},x_0}$, and v_P linear in P), the Taylor coefficient is $[Z^\gamma]T(F_{\mathfrak{m},x_0}) = (\pi_M \eta_P)^{j_p}\, \theta_{\mathrm{Hom}(\mathrm{I}_1,\mathrm{I}_{12})}(v_{X^\gamma} \otimes F_{\mathfrak{m},x_0})/\gamma!$, $\gamma! = \prod_{\tau,i} \gamma(\tau,i)!$. At $g = 1$ the pair map gives the identity of G, $\chi_0(1) = 1$, $\Delta(1) = 1$, and the Weil operator at 1 is the identity on the theta model by its defining reproducing identity (WD7); so $s_0(1) = \theta_{\mathrm{Hom}(\mathrm{I}_1,\mathrm{I}_{12})}(v_{X^\gamma} \otimes F_{\mathfrak{m},x_0})$. With $T_\gamma = \prod_\tau l(\tau)!/\gamma!$, (6.184) becomes

$$\|\iota(t_{\mathrm{shp}})\|\, \ell^{-F(\ell)} \leq \big\|\iota\big(c_s^{12}(\pi_M \eta_P)^{j_p} T_\gamma\big)\big\|\, \|\iota(s_0(1))\|. \tag{6.185}$$

By Lemma 6.7.22 (a), with the chosen places as S, $K = \mathbf{K}^{\mathrm{ch}}$, a set R of representatives of C and $s = s_0$, there are $z_0 \in G_f(1)$ and $\psi \in G$ with $\|\iota(s_0(1))\| \leq \|\iota(A)\|$, $A = \frac{1}{\#C} \sum_{g \in R} \psi(gz_0) s_0(gz_0)$. By Lemma 6.7.22 (b) for ι, a, b, V as in Step 3 and this ψ, there are $\psi_3, \psi_1 \in G$ with $\psi_3\psi_1 = \psi$ and $\|\iota(V)\| \leq \|\iota(W)\|$, $W = I^{N_{\mathrm{ch}}}_{q_3(\psi_3)}(1)\, I^{N_{\mathrm{ch}}}_{q_1(\psi_1)}(1)$.

Step 5: the test form and its pairing with the lift. Apply Lemma 6.7.18 to j, p, ℓ, ϑ, the flat pairs $q = q_1(\psi_1)$, $q_2 = p_{\mathrm{fl}}$, $q_3 = q_3(\psi_3)$, x_0, $\alpha = \gamma$ and $\chi = \chi_0\psi^{-1}$; the character condition

holds since $\chi\cdot\nu_{\mathrm{fl}}\vartheta\upsilon^2\cdot\psi_3\cdot\psi_1=\chi_0\nu_{\mathrm{fl}}\vartheta\upsilon^2=\nu\vartheta\upsilon^z$. It gives a test form Ξ for ℓ of $O_{p,\vartheta}$ with, for all $g\in G_f(1)$,

$$\langle\Xi,k_X(g)\rangle\,h_{\mathrm{U}}^3c_s^{2z-12}=T_\gamma\,W\,I_{p_{\mathrm{fl}}}^{N_{\mathrm{ch}}}(\vartheta)\,s_\chi(g),$$

where s_χ is s_0 with χ in place of χ_0. By (WR4), $\omega_{1,\chi}((1,g),(1,1))=\chi(g)^{-1}\omega_{1,1}((1,g),(1,1))$, so $s_\chi(g)=\psi(g)s_0(g)$. By Lemma 4.6.2 (c) (the definite line I_1 with its standard lattice, a chosen place w, and $\mathbf{K}^{\mathrm{ch}}$ acting trivially modulo w) all stabilisers Γ_g are trivial, so $h_{\mathrm{U}}=\#C$ and, by (OL3), $\lambda_{p,\vartheta}=\sum_{g\in R}k_X(g)$. As C is a group, $g\mapsto gz_0$ permutes the classes, and k_X is constant on classes, so $\lambda_{p,\vartheta}=\sum_{g\in R}k_X(gz_0)$. Pairing with Ξ (linear in the second argument), multiplying by $c_s^{12}(\pi_M\eta_P)^{j_p}$ and using (6.183) for p_{fl}, with $r=r_{p_{\mathrm{fl}}}(\vartheta)$:

$$(\#C)^2\,\langle\Xi,\varphi_{p,\vartheta}\rangle=r\,I_{p_{\mathrm{fl}}}^{N_{\mathrm{ch}}}(1)\,W\,c_s^{12}(\pi_M\eta_P)^{j_p}\,T_\gamma\,A. \tag{6.186}$$

Step 6: the inequality. By the choices of Step 4 and (6.185),

$$\begin{aligned}\|\iota(c_{\mathrm{tf}}\,r)\|\,\ell^{-F(\ell)}&=\|\iota(r\,I_{p_{\mathrm{fl}}}^{N_{\mathrm{ch}}}(1))\|\,\|\iota(V)\|\,\|\iota(t_{\mathrm{shp}})\|\,\ell^{-F(\ell)}\\&\le\|\iota(r\,I_{p_{\mathrm{fl}}}^{N_{\mathrm{ch}}}(1))\|\,\|\iota(W)\|\,\|\iota(c_s^{12}(\pi_M\eta_P)^{j_p}T_\gamma)\|\,\|\iota(A)\|,\end{aligned}$$

which is $\|\iota((\#C)^2\langle\Xi,\varphi_{p,\vartheta}\rangle)\|$ by (6.186). Since $\#C$ is a positive integer, $\|\iota(\#C)\|\le1$, and the claim $\|\iota(c_{\mathrm{tf}}r_{p_{\mathrm{fl}}}(\vartheta))\|\,\ell^{-F(\ell)}\le\|\iota\langle\Xi,\varphi_{p,\vartheta}\rangle\|$ follows. □

Lemma 6.7.18. *Let $1\le j\le m$, let $p=(\nu,z)$ be a main pair for j, let ℓ be a prime and ϑ a twist with modulus Q and $\ell\nmid\mathrm{N}Q$; let $X=X(p,\vartheta)$, so that $\ell_X(\tau)=c(\tau)-z$ for the weight $-c$ of ν. Let $q=(\nu_1,z-10)$, $q_2=(\nu_2,2)$ and $q_3=(\nu_3,2)$ be flat critical pairs. Let $\mathfrak{m}=\pi_M\mathcal{O}_E$, $x_0\in R_{\mathfrak{m}}^{12}$, let $\alpha\colon\Phi\times\{1,\dots,12\}\to\mathbb{Z}_{\ge0}$ satisfy $\sum_{i=1}^{12}\alpha(\tau,i)=\ell_X(\tau)$ for every $\tau\in\Phi$, and let χ be an automorphic character of* $\mathrm{U}(1)$ *with*

$$\chi\cdot\nu_2\vartheta\upsilon^2\cdot\nu_3\upsilon^2\cdot\nu_1\upsilon^{z-10}=\nu\vartheta\upsilon^z.$$

For $g\in G_f(1)$ put

$$s(g)=\theta_{1,\chi}^{\mathrm{I}_1,\mathrm{I}_{12}}\big(v_{X^\alpha}\otimes F_{\mathfrak{m},x_0}\big)\big((1,g),(1,1)\big),$$

$X^\alpha=\prod_{\tau,i}X_{\tau,i}^{\alpha(\tau,i)}$ in the Fock variables of $\mathrm{Hom}(\mathrm{I}_1,\mathrm{I}_{12})$*, and let $h_{\mathrm{U}}=\sum_{[g]}1/\#\Gamma_g$, the class sum of* 1 *over* $\mathrm{U}(1)(E)\backslash G_f(1)/\mathbf{K}_X^{\mathrm{ch}}$*. Then there is a test form Ξ for ℓ of $O_{p,\vartheta}$ such that for every $g\in G_f(1)$*

$$\langle\Xi,k_X(g)\rangle\,h_{\mathrm{U}}^3\,c_s^{2z-12}=\frac{\prod_{\tau\in\Phi}\ell_X(\tau)!}{\prod_{\tau,i}\alpha(\tau,i)!}\,I_q^{N_{\mathrm{ch}}}(1)\,I_{q_3}^{N_{\mathrm{ch}}}(1)\,I_{q_2}^{N_{\mathrm{ch}}}(\vartheta)\,s(g).$$

Proof. Let $O=O_{p,\vartheta}$, $X_1=X(q,1)$, $X_2=X(q_2,\vartheta)$, $X_3=X(q_3,1)$, and let $F(h_1,h_2,h_3)\in\mathrm{Form}(O)$ be the forms of Lemma 6.7.19 for these data. For a flat pair $q'\in\{q,q_2,q_3\}$ and the tame character ϑ' attached to it (1, ϑ, 1), let $\mathrm{xs}_{q',\vartheta'}$ be the map of Lemma 6.7.21, formed with a fixed set of representatives and with values in $\mathrm{Form}(O)$. Put

$$G(h_2,h_3)=\mathrm{xs}_{q,1}\big(h_1\mapsto F(h_1,h_2,h_3)\big),\qquad H(h_2)=\mathrm{xs}_{q_3,1}\big(h_3\mapsto G(h_2,h_3)\big),\qquad\Xi=\mathrm{xs}_{q_2,\vartheta}(H).$$

The number h_{U} of Lemma 6.7.21 is the same for X_1, X_2, X_3 and X, the group $\mathbf{K}^{\mathrm{ch}}$ depending only on the chosen places.

Step 1: Ξ is integral above ℓ. Let $j\colon\mathbb{C}\to\mathbb{C}_\ell$ be a ring homomorphism. Each $F(h_1,h_2,h_3)$ is integral at j by Lemma 6.7.19 (ii). By Lemma 6.7.21 (a), applied to q and q_3 at the trivial character (modulus 1, prime to ℓ) and to q_2 at ϑ ($\ell\nmid\mathrm{N}Q$), the forms $G(h_2,h_3)$, $H(h_2)$ and Ξ are integral at j.

Step 2: Ξ is orthogonal to the false lifts. The forms orthogonal to the false lifts for $(e_{X-1}, \ker \mathrm{Th}_O)$ form a linear subspace, an intersection of orthogonal complements. By definition $G(h_2,h_3)$ is $N_{\mathrm{ch}} n_{\nu_1}^2$ times the form of Lemma 6.7.19 (iii), hence lies in it; $H(h_2)$ and Ξ are linear combinations of such forms.

Step 3: the pairing. Fix $g \in G_f(1)$ and let $L = \langle \cdot\,, k_X(g)\rangle$, conjugate-linear on $\mathrm{Form}(O)$. By Lemma 6.7.19 (i), $L(F(h_1,h_2,h_3)) = B_1 \cdot 1 \cdot k_{X_1}(g)(h_1)$ with $B_1 = T_\alpha\, s(g)\, k_{X_2}(g)(h_2)\, k_{X_3}(g)(h_3)$, so Lemma 6.7.21 (b) for q ($N = 2z-20$) gives $L_1(G(h_2,h_3)) = T_\alpha\, s(g)\, k_{X_2}(g)(h_2)\, I_q^{N_{\mathrm{ch}}}(1) \cdot k_{X_3}(g)(h_3)$ for the conjugate-linear form $L_1 = h_{\mathrm{U}} c_s^{2z-20} L$. Applying Lemma 6.7.21 (b) to L_1 and q_3 ($N=4$), $L_2 = h_{\mathrm{U}} c_s^4 L_1$ satisfies $L_2(H(h_2)) = T_\alpha\, s(g)\, I_q^{N_{\mathrm{ch}}}(1)\, I_{q_3}^{N_{\mathrm{ch}}}(1) \cdot k_{X_2}(g)(h_2)$; applying it to L_2 and q_2 at ϑ,

$$h_{\mathrm{U}} c_s^4 L_2(\Xi) = h_{\mathrm{U}}^3 c_s^{2z-12} \langle \Xi, k_X(g)\rangle = T_\alpha\, I_q^{N_{\mathrm{ch}}}(1)\, I_{q_3}^{N_{\mathrm{ch}}}(1)\, I_{q_2}^{N_{\mathrm{ch}}}(\vartheta)\, s(g).$$

With Steps 1 and 2, Ξ is a test form for ℓ of $O_{p,\vartheta}$ with the asserted pairing. □

Lemma 6.7.19. *Let $1 \le j \le m$, let $p = (\nu, z)$ be a main pair for j, ϑ a twist, $X = X(p,\vartheta)$ and $O = O_{p,\vartheta}$. Let $q = (\nu_1, z-10)$, $q_2 = (\nu_2, 2)$, $q_3 = (\nu_3, 2)$ be flat critical pairs, and put $X_1 = X(q,1)$, $X_2 = X(q_2,\vartheta)$, $X_3 = X(q_3,1)$. Let $x_0 \in R_{\mathfrak{m}}^{12}$, let $\alpha\colon \Phi \times \{1,\dots,12\} \to \mathbb{Z}_{\ge 0}$ with $\sum_i \alpha(\tau,i) = \ell_X(\tau)$ for every τ, and let χ be an automorphic character of $\mathrm{U}(1)$ with $\chi \cdot \nu_2\vartheta\upsilon^2 \cdot \nu_3\upsilon^2 \cdot \nu_1\upsilon^{z-10} = \nu\vartheta\upsilon^z$. For $g \in G_f(1)$ let $s(g) = \theta_{1,\chi}^{\mathrm{I}_1,\mathrm{I}_{12}}(v_{X^\alpha} \otimes F_{\mathfrak{m},x_0})((1,g),(1,1))$ and $T_\alpha = \prod_\tau \ell_X(\tau)! / \prod_{\tau,i} \alpha(\tau,i)!$. Then there are forms $F(h_1,h_2,h_3) \in \mathrm{Form}(O)$, for $h_1 \in G_f(2z-20)$ and $h_2, h_3 \in G_f(4)$, such that:*

(i) for all $g \in G_f(1)$ and all h_1, h_2, h_3,

$$\langle F(h_1,h_2,h_3), k_X(g)\rangle = T_\alpha\, s(g)\, k_{X_2}(g)(h_2)\, k_{X_3}(g)(h_3)\, k_{X_1}(g)(h_1);$$

(ii) every $F(h_1,h_2,h_3)$ is integral at every ring homomorphism $\mathbb{C} \to \mathbb{C}_\ell$, for every prime ℓ;

(iii) for every set R_1 of representatives of $\mathrm{U}(\mathrm{I}_{2z-20})(E)\backslash G_f(2z-20)/\mathbf{K}(O_{X_1})$ and all h_2, h_3, the form $\sum_{h_1 \in R_1} \frac{1}{\#\Gamma_{h_1}} \varphi_{q,1}(h_1)\, F(h_1,h_2,h_3)$, with $\Gamma_{h_1} = \mathrm{U}(\mathrm{I}_{2z-20})(E) \cap h_1 \mathbf{K}(O_{X_1}) h_1^{-1}$, is orthogonal to the false lifts for $(e_{X-1}, \ker \mathrm{Th}_O)$.

Proof. Put $n = 2z$ and split $\{1,\dots,n\}$ into the consecutive blocks B_1, B_2, B_3, B_4 of sizes $12, 4, 4, 2z-20$ (the data $X_1 = X(q,1)$ require $z - 10 \ge 2$), so that $\mathrm{I}_n = \mathrm{I}_{12} \oplus \mathrm{I}_4 \oplus \mathrm{I}_4 \oplus \mathrm{I}_{2z-20}$ with B_2, B_3, B_4 carrying the index sets of X_2, X_3, X_1. Let M be the chosen places, Q the modulus of ϑ, $S_O = M \cup Q$, $\mathfrak{m}' = \prod_{w \in S_O} w$ and $\mathfrak{m} = \pi_M \mathcal{O}_E = \prod_{w \in M} w$ (the chosen places are unramified and distinct, Lemma 4.6.2 (a)), so that $R_{\mathfrak{m}'} = \prod_{w \in S_O} k_w$ and, by (DP7) and (XD5), $\mathrm{J}_O(\xi) = \mathrm{mod}_{\mathfrak{m}'}(\Psi_O, v_{\mathrm{Har}_O(\xi)})$. For $h_1 \in G_f(2z-20)$, $h_2, h_3 \in G_f(4)$ put $d = \mathrm{diag}(1, h_2, h_3, h_1) \in G_f(n)$.

Step 1: the vector. By (OL1), (OL4) the weight $\kappa = \kappa_O$ has one row of length $\ell = \ell_X$ at each τ, so the products of minors are the monomials $y^\beta = \prod_{\tau,a} y_{\tau,a,0}^{\beta(\tau,a)}$ with $\sum_a \beta(\tau,a) = \ell(\tau)$, and the standard basis consists of all of them. A filling $T \in \mathcal{C}_\kappa$ chooses one row for each of the $\ell(\tau)$ columns at every τ and Δ_T is the monomial of these rows; so F_κ has entries $0,1$ with one 1 in each row, G_κ is diagonal, and $(G_\kappa)_{\beta\beta} = \prod_\tau \ell(\tau)! / \prod_{\tau,a} \beta(\tau,a)!$, the number of fillings with monomial y^β. Extend α by 0 to $\Phi \times \{1,\dots,n\}$ and let $e_\alpha \in \mathbb{V}_O(\mathbb{Z})$ be the coordinate vector of y^α; then $\mathrm{Pol}_\kappa(e_\alpha) = T_\alpha y^\alpha$. By Lemma 3.2.20 for $(\kappa, 0)$, C_O is a square integral matrix (I_{κ^-} is a point) with an integral left inverse, hence in $\mathrm{GL}_{I_\kappa}(\mathbb{Z})$, commuting with every $S_\kappa(z)$ by (d). Put $c = C_O^{-1} e_\alpha \in \mathbb{V}_O(\mathbb{Z})$. By (DP8), $\mathrm{Har}_O(c) = \mathrm{Let}_1(\mathrm{Pol}_\kappa(e_\alpha)) = T_\alpha X^\alpha$, $X^\alpha = \prod_{\tau, i \in B_1} X_{\tau,i,1}^{\alpha(\tau,i)}$. If $z' = (z'_\tau)$ is block diagonal with the identity on B_1, then $S_\kappa(z') e_\alpha = e_\alpha$: the column α of $S_\kappa(z')$

lists the coefficients of y^α in the $b_i(z'y)$, and $b_i(z'y) = b_i(y)$ if b_i involves only rows of B_1, while otherwise every monomial of $b_i(z'y)$ contains a variable of a row outside B_1. Hence $S_\kappa(z')c = c$. For the flat pairs q_i the weight is 0: $\mathbb{V} = \mathbb{C}$, $G = 1$, and by (c) of Lemma 3.2.20 the 1×1 matrix C is 1, so the theta datum of 1 is $\mathrm{mod}(\Psi, v_1)$ for the block datum Ψ of the pair.

Step 2: the point. Let i_2, i_3, i_1 be the indices $\mathrm{inc}(1)$ of $O_{X_2}, O_{X_3}, O_{X_1}$, placed in B_2, B_3, B_4, and $\iota_0 = \mathrm{inc}_O(1)$. For $w \in M$ let $Y_w \in k_w^n$ be the column with $x_0 \bmod w$ on B_1 and the unit vectors at i_2, i_3, i_1 on B_2, B_3, B_4; as $Y_w \neq 0$, choose $\bar{A}_w \in \mathrm{GL}_n(k_w)$ whose column ι_0 is Y_w. For $w \in Q$ let $\bar{A}_w$ be the permutation matrix of the transposition of ι_0 and i_2 (the identity if they agree); its row i_2 is $e_{\iota_0}^\mathsf{T}$, so the row ι_0 of $\bar{A}_w^{-1}$ is $e_{i_2}^\mathsf{T}$. Every $w \in S_O$ satisfies $w \neq \bar{w}$, and no member of S_O is conjugate to another (DP1). Let $A \in G_f(n)$ have at each $w \in S_O$ a component $A_w \in \mathrm{GL}_n(\mathcal{O}_{E,w})$ reducing to $\bar{A}_w$, at $\bar{w}$ the component $(\overline{A_w}^\mathsf{T})^{-1}$ forced by $A^*A = 1$, and 1 elsewhere; then $A \in \mathbf{K}_0(n)$. For $X = (X_w)_{w \in S_O}$, $X_w \in k_w^n$, write $X^{(i)}$ for the rows in B_i. Then $\bar{A}_w^{-1} X_w = \mathrm{Inc}_O$ iff $X_w = Y_w$ ($w \in M$), and the inc-row of $\bar{A}_w^{-1} X_w$ is the entry i_2 of X_w ($w \in Q$). The tame part of $\mu_O = \nu\vartheta$ at $w \in Q$ is that of ϑ, which is also that of $\mu_{O_{X_2}} = \nu_2\vartheta$, the tame parts of ν, ν_2 being trivial off M. Hence, by (DP7) for the four pairs,

$$\Psi_O(\bar{A}^{-1}X) = \Psi_0(X^{(1)})\, \Psi_{O_{X_2}}(X^{(2)})\, \Psi_{O_{X_3}}(X^{(3)} \bmod \mathfrak{m})\, \Psi_{O_{X_1}}(X^{(4)} \bmod \mathfrak{m}), \tag{6.187}$$

where Ψ_0 is the indicator of x_0 on $\mathrm{M}_{12\times 1}(R_\mathfrak{m})$, read on $R_{\mathfrak{m}'}$ through the reduction, and $S_{O_{X_2}} = S_O$, $S_{O_{X_3}} = S_{O_{X_1}} = M$.

Step 3: point forms. For $y \in G_f(n)$ and $v \in \mathbb{V}_O$ let

$$\delta_y(v)(x) = \sum_\gamma \tilde{\eta}_O(y^{-1}\gamma x)\, \rho_O(\gamma)^{-1} v \qquad (x \in G_f(n)),$$

the sum over the rational points γ of $\mathrm{U}(\mathrm{I}_n)$ with $y^{-1}\gamma x \in \mathbf{K}(O)$, a finite set (discrete and compact). Substituting $\gamma\gamma'$ for γ shows $\delta_y(v)(\gamma' x k) = \tilde{\eta}_O(k)\rho_O(\gamma')\delta_y(v)(x)$ for rational γ' and $k \in \mathbf{K}(O)$, so $\delta_y(v) \in \mathrm{Form}(O)$, supported on $\mathrm{U}(\mathrm{I}_n)(E)\, y\, \mathbf{K}(O)$. For $\varphi \in \mathrm{Form}(O)$ only the class of y contributes to the class sum (DP5), and for $\gamma \in \Gamma_y = \mathrm{U}(\mathrm{I}_n)(E) \cap y\mathbf{K}(O)y^{-1}$, with $k_\gamma = y^{-1}\gamma y$, $\rho_O(\gamma)\varphi(y) = \varphi(\gamma y) = \varphi(y k_\gamma) = \tilde{\eta}_O(k_\gamma)\varphi(y)$; as ρ_O is unitary for $\langle\,,\rangle_\kappa$ ((c) of Lemma 4.6.10) and $|\tilde{\eta}_O| = 1$, each term of $\langle \delta_y(v)(y), \varphi(y)\rangle_\kappa$ is $\langle v, \varphi(y)\rangle_\kappa$, whence

$$\langle \delta_y(v), \varphi\rangle = \frac{1}{\#\Gamma_y}\, \#\Gamma_y\, \langle v, \varphi(y)\rangle_\kappa = \langle v, \varphi(y)\rangle_\kappa. \tag{6.188}$$

Define $F(h_1, h_2, h_3) = \delta_{dA}(c)$.

Step 4: proof of (i). By (6.188), c real, and (OL2) with $\xi = \bar{c} = c$, $\langle F(h_1, h_2, h_3), k_X(g)\rangle = c^\mathsf{T} G_\kappa k_X(g)(dA) = \theta_O(\omega_O((1, g), (1, dA))\mathrm{J}_O(c))$. By (2) of Lemma 4.1.1, $\omega_O((1, g), (1, dA)) = \omega_O((1, g), (1, d))\, \omega_O((1, 1), (1, A))$, and by (6) there (with $k = 1$, $k' = A$, $\chi_O = 1$) and (6.187),

$$\omega_O((1, 1), (1, A))\mathrm{J}_O(c) = \mathrm{mod}_{\mathfrak{m}'}(\Psi_0 \otimes \Psi_{O_{X_2}} \otimes \Psi'_{O_{X_3}} \otimes \Psi'_{O_{X_1}},\ v_{T_\alpha X^\alpha \cdot 1 \cdot 1 \cdot 1}),$$

Ψ' denoting the function read modulo $\mathfrak{m}$. By (a) of Lemma 6.3.80, applied three times, this is the target product $T_\alpha \,\mathrm{mod}_{\mathfrak{m}'}(\Psi_0, v_{X^\alpha}) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{m}'}(\Psi_{O_{X_2}}, v_1) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{m}'}(\Psi'_{O_{X_3}}, v_1) \boxtimes^{\mathrm{tg}} \mathrm{mod}_{\mathfrak{m}'}(\Psi'_{O_{X_1}}, v_1)$ for $\mathrm{I}_n = \mathrm{I}_{12} \oplus \mathrm{I}_4 \oplus \mathrm{I}_4 \oplus \mathrm{I}_{2z-20}$. By Lemma 6.4.66, $\mathrm{mod}_{\mathfrak{m}'}(\Psi_0, v_{X^\alpha}) = \mathrm{mod}_\mathfrak{m}(\mathbf{1}_{x_0}, v_{X^\alpha}) = v_{X^\alpha} \otimes (\Psi_{\mathfrak{m},x_0} \otimes_M v^0)$, which is the datum $v_{X^\alpha} \otimes F_{\mathfrak{m},x_0}$ of $s(g)$, because $F_{\mathfrak{m},x_0} = v_1 \otimes (\Psi_{\mathfrak{m},x_0} \otimes_M v^0) = \Psi_{\mathfrak{m},x_0} \otimes_M v^0$ by (4) of Lemma 6.2.33 ($\Sigma(\mathfrak{m}) = M$), and $\mathrm{mod}_{\mathfrak{m}'}(\Psi'_{O_{X_i}}, v_1) = \mathrm{J}_{O_{X_i}}(1)$ ($i = 3, 1$), while $\mathrm{mod}_{\mathfrak{m}'}(\Psi_{O_{X_2}}, v_1) = \mathrm{J}_{O_{X_2}}(1)$ (Step 1). The characters: $\omega_O = \omega_{1,\chi'_O}$ by (DP6), with $\chi'_O = \nu\vartheta v^z = \chi \cdot \nu_2\vartheta v^2 \cdot \nu_3 v^2 \cdot \nu_1 v^{z-10}$ by hypothesis, the last three being $\chi'_{O_{X_2}}, \chi'_{O_{X_3}}, \chi'_{O_{X_1}}$, and

$\chi_{O_{X_i}} = 1$. So the exact factorisation (d) of Lemma 6.3.52 (target sums), applied three times at the source point $(1, g)$ and the block diagonal target point $(1, d)$, gives

$$\langle F(h_1,h_2,h_3), k_X(g)\rangle = T_\alpha\, s(g)\, \theta_{O_{X_2}}(\omega_{O_{X_2}}((1,g),(1,h_2))\mathrm{J}_{O_{X_2}}(1)) \cdot \theta_{O_{X_3}}(\cdots h_3 \cdots)\, \theta_{O_{X_1}}(\cdots h_1 \cdots),$$

where the last three factors are $k_{X_2}(g)(h_2)$, $k_{X_3}(g)(h_3)$, $k_{X_1}(g)(h_1)$ by (OL2) in weight 0. This is (i).

Step 5: proof of (ii). Let $j\colon \mathbb{C} \to \mathbb{C}_\ell$ be a ring homomorphism and, for $x \in G_f(n)$, $x_\ell = (x_{\ell,\tau})_\tau$ its ℓ-adic gauge at j (Definition 6.1.3); $e_O = 0$, so we must show that $S_\kappa(x_\ell^{-1})\, j(F(x))$ has integral coordinates. For a rational point γ, $j(\rho_O(\gamma)v) = S_\kappa(j(\overline{\gamma_\infty}))\, j(v) = S_\kappa(\gamma_\ell)\, j(v)$, as S_κ has integral polynomial entries and $j(\tau(\bar\gamma))$ is the image of γ at the place defining the gauge. Put $y = dA$. On the support, $x = \gamma' y k$ with $k \in \mathbf{K}(O)$ and $F(x) = \tilde\eta_O(k)\rho_O(\gamma')F(y)$, so, S_κ being multiplicative ((a) of Lemma 4.6.10), $S_\kappa(x_\ell^{-1})j(F(x)) = j(\tilde\eta_O(k))\, S_\kappa(k_\ell^{-1})\, S_\kappa(y_\ell^{-1})\, j(F(y))$, and $F(y) = \sum_{\gamma\in\Gamma_y} \tilde\eta_O(k_\gamma)\rho_O(\gamma)^{-1}c$ with $\gamma y = y k_\gamma$. Hence

$$S_\kappa(y_\ell^{-1})\, j(F(y)) = \sum_{\gamma\in\Gamma_y} j(\tilde\eta_O(k_\gamma))\, S_\kappa((k_\gamma)_\ell^{-1})\, S_\kappa(A_\ell^{-1})\, S_\kappa(d_\ell^{-1})\, c,$$

and $S_\kappa(d_\ell^{-1})c = c$ by Step 1, d_ℓ being block diagonal with the identity on B_1. The values of $\tilde\eta_O$ are roots of unity, so $\|j(\tilde\eta_O(\cdot))\| = 1$; $k, k_\gamma, A \in \mathbf{K}_0(n)$ have integral invertible components, so the matrices $S_\kappa(k_\ell^{\pm1})$, $S_\kappa((k_\gamma)_\ell^{-1})$, $S_\kappa(A_\ell^{-1})$ have integral entries; and c is integral. By the ultrametric inequality all coordinates have absolute value at most 1; off the support $F = 0$. So $F(h_1,h_2,h_3)$ is integral at j.

Step 6: proof of (iii). Let $N = B_1 \cup B_2 \cup B_3$ ($\#N = 20$) and $l = B_4$, so $\mathrm{I}_n = \mathrm{I}_N \oplus \mathrm{I}_l$, and let $\iota\colon \mathrm{G}(1_N) \times \mathrm{G}(1_l) \to \mathrm{G}(1_n)$ be the block diagonal embedding. Put $K_1 = \mathbf{K}(O_{X_1})$, $d_0 = \mathrm{diag}(1, h_2, h_3) \in G_f(20)$, so that $(1, d(h_1)A) = \iota((1,d_0),(1,h_1))\,(1,A)$ with $d(h_1) = \mathrm{diag}(1,h_2,h_3,h_1)$, and for $\zeta \in \mathbb{V}_O$ let $Y_\zeta(h) = \overline{\langle \zeta, \rho_O(h_\infty)^{-1}\Xi(h_f)\rangle_\kappa}$ on $\mathrm{G}(1_n)$, as in Proposition 6.6.81 ($e_O = 0$). Fix a finite place w with $w \neq \bar w$ and $w, \bar w \notin S_O$, and $\Xi \in e_{X^{-1}}\mathrm{Form}(O) \cap \ker H_w(X_*(w)) \cap \ker \mathrm{Th}_O$. Let $y = \sum_{h_1\in R_1} \frac{1}{\#\Gamma_{h_1}} \varphi_{q,1}(h_1) F(h_1,h_2,h_3)$; we show $\langle \Xi, y\rangle = 0$.

(1) *The pairing as a sum of periods.* The inner product of (DP5) is hermitian (G_κ is real symmetric), so by (6.188) $\langle \Xi, F(h_1,h_2,h_3)\rangle = \overline{\langle c, \Xi(d(h_1)A)\rangle_\kappa} = Y_c(\iota((1,d_0),(1,h_1))(1,A))$. The pair q is flat ($j_q = 0$), so by (OL4), (OL3) $\varphi_{q,1} = c_s^{2(z-10)} \sum_{[g]} \frac{1}{\#\Gamma_g} k_{X_1}(g)$ over $\mathrm{U}(1)(E)\backslash G_f(1)/\mathbf{K}^{\mathrm{ch}}_{X_1}$, and in weight 0 (OL2) gives $k_{X_1}(g)(h) = \theta_{1,b}^{\mathrm{I}_1,\mathrm{I}_l}(\varphi_1)((1,g),(1,h))$ with $\varphi_1 = \mathrm{J}_{O_{X_1}}(1)$ and $b = \chi'_{O_{X_1}}$ ((DP6), (XD2); $\chi_{O_{X_1}} = 1$). The inner product being linear in the second argument,

$$\langle \Xi, y\rangle = c_s^{2(z-10)} \sum_{[g]} \frac{1}{\#\Gamma_g} \sum_{h_1\in R_1} \frac{1}{\#\Gamma_{h_1}} f_g(1,h_1),$$

$$f_g(h') = \theta_{1,b}^{\mathrm{I}_1,\mathrm{I}_l}(\varphi_1)((1,g),h')\, Y_c(\iota((1,d_0),h')(1,A))$$

for $h' \in \mathrm{G}(1_l)$.

(2) *Invariance of f_g.* (a) Real points: $\varphi_1 = v_1 \otimes \Upsilon(O_{X_1})$ by (DP8) (Har = 1 in weight 0), so by (5) of Lemma 4.1.1 (all signs +1, the source character 1 of weight 0, $P = 1$) $\omega_{1,b}((1,g),(y,k))\varphi_1 = \omega_{1,b}((1,g),(1,k))\varphi_1$ for $y \in G_\infty(1_l)$; and $\rho_O(\iota(1,y))c = S_\kappa(\overline{\iota(1,y)})c = c$ by Step 1 ($\iota(1,y)$ is block diagonal with the identity on B_1), so by the unitarity of ρ_O ((c) of Lemma 4.6.10) $Y_c(x\,\iota(1,(y,1))) = Y_c(x)$ whenever $x_\infty = 1$. Hence $f_g(y,k) = f_g(1,k)$. (b) Rational points: by Lemma 6.3.77 the pair $(\omega_{O_{X_1}}, \theta_{O_{X_1}})$ is a theta kernel for $(\mathrm{I}_1, \mathrm{I}_l)$, hence invariant under the rational points of $\mathrm{U}(\mathrm{I}_l)$ ((ED2), (ED3) of Definition 3.2.29); and for a rational point γ' of $\mathrm{U}(\mathrm{I}_l)$,

$\iota((1,d_0),\gamma'h') = \iota(1,\gamma')\iota((1,d_0),h')$ with $\iota(1,\gamma')$ a rational point of $\mathrm{U}(\mathrm{I}_n)$, and $Y_c(\gamma x) = Y_c(x)$ for rational γ by (DP5) and the multiplicativity of ρ_O. So $f_g(\gamma'h') = f_g(h')$. (c) The level K_1: for $k \in K_1$, $k_{X_1}(g)(h'k) = \tilde{\eta}_{O_{X_1}}(k)k_{X_1}(g)(h') = k_{X_1}(g)(h')$ ($Q_{O_{X_1}} = \emptyset$), and $\iota((1,d_0),(1,h'k))(1,A) = \iota((1,d_0),(1,h'))(1,A)(1,k'')$ with $k'' = A^{-1}d_kA \in \mathbf{K}_0(n)$, $d_k = \mathrm{diag}(1_{20},k)$. At $w' \in M$, $\bar{k}_{w'}$ fixes the unit vector e_{i_1} of B_4 ((DP4) for O_{X_1}), so $\bar{d}_{k,w'}Y_{w'} = Y_{w'}$ and $\bar{k}''_{w'}e_{\iota_0} = \bar{A}_{w'}^{-1}\bar{d}_{k,w'}Y_{w'} = e_{\iota_0}$. At $w' \in Q$, $\bar{A}_{w'}$ is the transposition matrix P of ι_0 and $i_2 \in B_2$, and row i_2 of $\bar{d}_{k,w'}$ is $e_{i_2}^{\mathsf{T}}$, so row ι_0 of $\bar{k}''_{w'} = P\bar{d}_{k,w'}P$ is $e_{\iota_0}^{\mathsf{T}}$: it vanishes outside column ι_0 and its inc-block is 1. So $k'' \in \mathbf{K}(O)$ with $\tilde{\eta}_O(k'') = 1$ (DP4), whence $\Xi(xk'') = \Xi(x)$ and $f_g(h'k) = f_g(h')$.

(3) *Unfolding.* The space I_l is definite, so $[\mathrm{U}(\mathrm{I}_l)]$ is compact [37] and $\Gamma_l\backslash G_f(l)/K_1$ is finite [33], Γ_l the rational points. For $h \in R_1$ the sets $\Gamma_l(G_\infty(1_l) \times hK_1)$ partition $\mathrm{G}(1_l)$, an element $\gamma \in \Gamma_l$ maps $G_\infty(1_l) \times hK_1$ to a set meeting it iff $\gamma \in \Gamma_h$, and Γ_h (finite) acts freely (its real components determine it). With the measure of (VP1) of Definition 3.2.2, in which $G_\infty(1_l)$ has mass 1 (Lemma 5.5.21) and hK_1 has mass $[\mathbf{K}_0(l) : K_1]^{-1}$, (2) gives

$$\int_{[\mathrm{U}(\mathrm{I}_l)]} f_g(h')\,dh' = [\mathbf{K}_0(l) : K_1]^{-1} \sum_{h_1 \in R_1} \frac{1}{\#\Gamma_{h_1}} f_g(1,h_1).$$

(4) *The periods vanish.* We apply Proposition 6.6.81 to $O = O_{p,\vartheta}$ (ranks $1 < n$; it fits a parameter by Lemma 6.7.20), Ξ, $\zeta = c$, the partition $\{1,\dots,n\} = N \sqcup l$, the character b, the datum φ_1, the points $(1,g) \in \mathrm{G}(\varepsilon_O)$, $(1,d_0) \in \mathrm{G}(1_N)$ and $\gamma = A$. Its hypotheses: $2 \cdot 1 + 2 \cdot 20 + 3 = 45 < 2z$, since $z > m \geq \sqrt{x} \geq 23$ by (RH1), (AD2) and Lemma 2.3.6. The tame part of $\mu_O = \nu\vartheta$ is $\omega^j\psi_\vartheta$ ((RH2); tame parts multiply, Definition 3.1.2); as $\mathrm{N}Q$ is prime to M, ω is trivial on Q and ψ_ϑ is trivial at the chosen places. So for $w' \in Q_O = Q$, $\psi_{O,w'} = \psi_{\vartheta,w'} \neq 1$ (ϑ a twist); for $w' \in M_O = M$ and a nonzero $\lambda \in k_{w'}$, $H(\lambda) = k_{w'}^\times$ ($r = 1$), Ξ is fixed by every $[s]_{w'}$ ($\Xi \in e_{X-1}\mathrm{Form}(O)$, Definition 6.1.3), and $\psi_{O,w'} = \omega_{w'}^j \neq 1$ by Lemma 6.7.3 ($1 \leq j \leq m$), so $\sum_{s \in H(\lambda)} \psi_{O,w'}(\det s)^{-1}[s]_{w'}\Xi = (\sum_{s \in k_{w'}^\times} \psi_{O,w'}(s)^{-1})\Xi = 0$; $\mathrm{Th}_O(\Xi) = 0$; and $H_w(X_*(w))\Xi = 0$ with $w \neq \bar{w}$, $w, \bar{w} \notin S_O$. The datum φ_1 is the vacuum at the finite places outside $\Sigma = S_O \cup \bar{S}_O$: by (4) and (5) of Lemma 6.2.33, $\varphi_1 = \Phi_{O_{X_1}} \otimes_M v^0$ is fixed by $\rho_f(y')$ for every integral y' vanishing at $M \cup \bar{M} \subseteq \Sigma$. The components of A outside Σ are 1 (Step 2). As $\chi_O = v^{r_-(O)} = 1$, the conclusion of Proposition 6.6.81 is $\int_{[\mathrm{U}(\mathrm{I}_l)]} f_g = 0$. By (3) and (1), $\langle \Xi, y\rangle = 0$. So y is orthogonal to $\mathcal{F}_w(e_{X-1}, \ker \mathrm{Th}_O)$ for every such w, which is (iii). □

Lemma 6.7.20. *Let X be L-value data of rank $n \geq 2$. Then O_X fits the parameter $l = (l_\tau)_{\tau\in\Phi}$ with $l_\tau(1) = 0$ for every $\tau \in \Phi$.*

Proof. Write $O = O_X$ and $\ell = \ell_X$. By (OL1), O has ranks $1 < n$, $\varepsilon_O(1) = +1$ (so $r_+(O) = 1$, $r_-(O) = 0$), $\mathrm{ord}_O(1) = 0$, $\kappa_O^+(\tau,1) = \ell(\tau)$, $\kappa_O^+(\tau,i) = 0$ for $i \geq 2$, $\kappa_O^- = 0$, and $\mu_O = \nu_X$ has weight $\mathrm{wt}_O(\tau) = -(\ell(\tau) + \lfloor n/2 \rfloor)$. Hence (DP3) gives $\kappa_O(\tau,1) = \ell(\tau)$, $\kappa_O(\tau,i) = 0$ for $2 \leq i < n$ and $e_O = 0$, so the highest weight is $\lambda_{O,\tau}(0) = \ell(\tau)$ and $\lambda_{O,\tau}(i) = 0$ for $1 \leq i < n$, and by (DP11)

$$l_{O,\tau}(1) = 2\ell(\tau) + n - 1, \qquad l_{O,\tau}(a) = n + 1 - 2a \quad (2 \leq a \leq n).$$

(i). The weights of (DP11)(i) are $\gamma(\tau) = r_-(O) = 0$ and $\gamma'(\tau) = \lfloor n/2 \rfloor + \mathrm{wt}_O(\tau) = -\ell(\tau)$, the signs are $s = \varepsilon_O$ on $\{1\}$ and $t = \mathbf{1}_n$, and $N = 1 \leq N' = n$. Fix τ; we check the block rule for $(l_\tau, l_{O,\tau})$. (a) l_τ is injective, $l_\tau(1) = 0 \equiv N - 1 \pmod 2$, and $\{1\}$ carries one sign, so l_τ has every gap for s. As $\ell(\tau) \geq 0$, $l_{O,\tau}(1) \geq n - 1 > n - 3 = l_{O,\tau}(2)$, so $l_{O,\tau}$ is strictly decreasing, hence injective; all its values are $\equiv n - 1 \pmod 2$; and t is constant. So both have gap $500(N + N')^3$. (b) The shifted entries are $\tilde{l}_\tau(1) = l_\tau(1) - 2\gamma'(\tau) + N' = 2\ell(\tau) + n$ and $\tilde{l}'_\tau(b) = l_{O,\tau}(b) - 2\gamma(\tau) + N = l_{O,\tau}(b) + 1$, that is $\tilde{l}'_\tau(1) = 2\ell(\tau) + n$ and $\tilde{l}'_\tau(b) = n + 2 - 2b$ for

$2 \le b \le n$. The latter values are $\{n-2-2\beta : 0 \le \beta < n-1\} = [n-1]$, so $\tilde{l}'_\tau(\{1,\dots,n\}) = \tilde{l}_\tau(\{1\}) \cup [N'-N]$. (c) All signs of s and t are $+1$, and the only value of $\tilde{l}_\tau$ is $2\ell(\tau)+n > 0$; so whenever $\tilde{l}_\tau(1) = \tilde{l}'_\tau(b)$ we have $s(1) = t(b)$, as required.

(ii). The only index of sign $+1$ is $c = 1$, so the right side of (DP11)(ii) is $\#\{c' \in \{1\} : l_\tau(1) < l_\tau(c')\} = 0 = \mathrm{ord}_O(1)$.

(iii). $\kappa^+_O(\tau, i) = 0$ for $r_+(O) = 1 < i < n$, and $\kappa^-_O = 0$. □

Lemma 6.7.21. *Let $q = (\nu_q, z_q)$ be a flat critical pair with $z_q \ge 2$; put $N = 2z_q$. Let ϑ' be a tame character with modulus Q', $X' = X(q,\vartheta')$, $O' = O_{X'}$, $\varphi = \varphi_{q,\vartheta'}$ and $n = n_{\nu_q}$. Fix a set R of representatives of $\mathrm{U}(\mathrm{I}_N)(E)\backslash G_f(N)/\mathbf{K}(O')$, and for $h \in R$ let $\Gamma_h = \mathrm{U}(\mathrm{I}_N)(E) \cap h\mathbf{K}(O')h^{-1}$. Let O be a descent pair, and for a map $F\colon G_f(N) \to \mathrm{Form}(O)$ put*

$$\mathrm{xs}(F) = N_{\mathrm{ch}} \sum_{h \in R} \frac{1}{\#\Gamma_h} \frac{n^2}{\mathrm{N}Q'^{N-1}} \varphi(h)\, F(h) \ \in \mathrm{Form}(O).$$

Then:

(a) if ℓ is a prime with $\ell \nmid \mathrm{N}Q'$, $j\colon \mathbb{C} \to \mathbb{C}_\ell$ a ring homomorphism and $F(h)$ is integral at j for every h, then $\mathrm{xs}(F)$ is integral at j;

(b) if $g \in G_f(1)$, $A, B \in \mathbb{C}$ and $L\colon \mathrm{Form}(O) \to \mathbb{C}$ is conjugate-linear with $L(F(h)) = B\,A\,k_{X'}(g)(h)$ for every h, then

$$h_{\mathrm{U}}\, c_s^N\, L(\mathrm{xs}(F)) = B\, I_q^{N_{\mathrm{ch}}}(\vartheta')\, A,$$

where $h_{\mathrm{U}} = \sum_{[u]} 1/\#\Gamma_u$ is the class sum of 1 over $\mathrm{U}(1)(E)\backslash G_f(1)/\mathbf{K}^{\mathrm{ch}}_{X'}$.

Proof. A class sum of a function constant on the double cosets may be computed at the representatives R; this applies below to the inner products of (DP5).

Step 1: the stabilisers divide N_{ch}. Let $h \in G_f(N)$. As $N = 2z_q \le 2t \le rt$ and $\mathbf{K}(O') \subseteq \mathbf{K}_0(N)$ is open, $\Gamma_h = \mathrm{U}(\mathrm{I}_N)(E) \cap h\mathbf{K}(O')h^{-1}$ is finite and $\#\Gamma_h$ divides N_{ch} by Lemma 6.7.9.

Step 2: proof of (a). The forms integral at j form a set closed under sums (ultrametric inequality) and under multiplication by scalars c with $\|j(c)\| \le 1$ (the coordinates in the definition are linear in the form). The scalar of the summand at h is $\frac{N_{\mathrm{ch}}}{\#\Gamma_h} \cdot \frac{n}{\mathrm{N}Q'^{N-1}} \cdot n\varphi(h)$: the first factor is an integer by Step 1; $\|j(\mathrm{N}Q')\| = 1$ as $\ell \nmid \mathrm{N}Q'$; and $\|j(n\varphi(h))\| \le 1$ because $n\varphi$ is integral at j by Lemma 6.7.7 (for weight 0 integrality at j is this inequality at every point). So each summand, hence $\mathrm{xs}(F)$, is integral at j.

Step 3: central translation of kernel forms. Let $z, g \in G_f(1)$ and $h \in G_f(N)$, and write $z^{-1}h$ for $(z^{-1}1_N)h \in G_f(N)$. In rank one the pair points of $((1,zg),(1,h))$ and $((1,g),(1,z^{-1}h))$ coincide, $hX(zg)^{-1} = (z^{-1}h)Xg^{-1}$; comparing the characters of (DP6), $\omega_{O'}((1,zg),(1,h)) = \chi'_{O'}(z)^{-1}\omega_{O'}((1,g),(1,z^{-1}h))$, so

$$k_{X'}(zg)(h) = \chi'_{O'}(z)^{-1}\, k_{X'}(g)(z^{-1}h).$$

As $G_f(1)$ is commutative, $u \mapsto z^{-1}u$ permutes $\mathrm{U}(1)(E)\backslash G_f(1)/\mathbf{K}^{\mathrm{ch}}_{X'}$ and $\Gamma_u = \mathrm{U}(1)(E) \cap \mathbf{K}^{\mathrm{ch}}_{X'}$ does not depend on u; with the display (applied to $z^{-1}u$) this gives $\lambda_{X'}(zh) = \chi'_{O'}(z)^{-1}\lambda_{X'}(h)$.

Step 4: $\langle \lambda_{X'}, k_{X'}(g)\rangle$ does not depend on g. The scalar matrix $z1_N$ is central in $G_f(N)$ and commutes with the rational points, so $h \mapsto zh$ permutes the double cosets for $\mathbf{K}(O')$ and

preserves $\#\Gamma_h$. Hence, by Step 3 and $|\chi'_{O'}(z)| = 1$ (an automorphic character of $\mathrm{U}(1)$ takes values in the unit circle, $\mathrm{U}(1)(E)\backslash\mathrm{U}(1)(\mathbb{A})$ being compact),

$$\begin{aligned}\langle \lambda_{X'}, k_{X'}(zg)\rangle &= \chi'_{O'}(z)^{-1}\sum_{[h]}\frac{\overline{\lambda_{X'}(zh)}\,k_{X'}(g)(h)}{\#\Gamma_h}\\ &= \chi'_{O'}(z)^{-1}\overline{\chi'_{O'}(z)^{-1}}\,\langle \lambda_{X'}, k_{X'}(g)\rangle = \langle \lambda_{X'}, k_{X'}(g)\rangle.\end{aligned}$$

By (OL3) and linearity in the second argument,

$$\langle \lambda_{X'}, \lambda_{X'}\rangle = \sum_{[u]}\langle \lambda_{X'}, k_{X'}(u)\rangle/\#\Gamma_u = h_{\mathrm{U}}\langle \lambda_{X'}, k_{X'}(g)\rangle$$

for every g. Multiplying by $|c_s^N|^2$,

$$h_{\mathrm{U}}\, c_s^N\,\langle \varphi, k_{X'}(g)\rangle = \|\varphi\|^2. \tag{6.189}$$

Step 5: proof of (b). L is additive and $L(cx) = \bar{c}\,L(x)$; the weights $N_{\mathrm{ch}}/\#\Gamma_h$ and $n^2/\mathrm{N}Q'^{N-1}$ are real. So

$$L(\mathrm{xs}(F)) = \frac{N_{\mathrm{ch}}n^2}{\mathrm{N}Q'^{N-1}}\sum_{h\in R}\frac{\overline{\varphi(h)}\,B\,A\,k_{X'}(g)(h)}{\#\Gamma_h} = \frac{N_{\mathrm{ch}}n^2}{\mathrm{N}Q'^{N-1}}\,B\,A\,\langle \varphi, k_{X'}(g)\rangle,$$

and by (6.189), $h_{\mathrm{U}}c_s^N L(\mathrm{xs}(F)) = N_{\mathrm{ch}}n^2\,\|\varphi\|^2\,\mathrm{N}Q'^{-(2z_q-1)}\,B\,A = B\,I_q^{N_{\mathrm{ch}}}(\vartheta')\,A$ by (OL4). □

Lemma 6.7.22. *(a) Let S be a finite set of finite places of E, and $K \subseteq \mathrm{U}(1)(\mathbb{A}_f)$ the subgroup of the points that are integral at every finite place and congruent to 1 modulo every place of S. The set $C = \mathrm{U}(1)(E)\backslash\mathrm{U}(1)(\mathbb{A}_f)/K$ is finite. Let $R \subseteq \mathrm{U}(1)(\mathbb{A}_f)$ be a set of representatives of C, ℓ a prime, $\iota\colon \mathbb{C}\to\mathbb{C}_\ell$ a ring homomorphism and $s\colon \mathrm{U}(1)(\mathbb{A}_f)\to\mathbb{C}$ a function. Then there are $z \in \mathrm{U}(1)(\mathbb{A}_f)$ and an automorphic character χ of $\mathrm{U}(1)$ of weight 0 with a tame part trivial at every finite place outside S such that*

$$\|\iota(s(1))\| \le \Big\|\iota\Big(\frac{1}{\#C}\sum_{g\in R}\chi(gz)\,s(gz)\Big)\Big\|.$$

(b) Let G be a finite group, $\iota\colon \mathbb{C}\to\mathbb{F}$ a ring homomorphism into a normed field, $a, b\colon G\to\mathbb{C}$ functions and $V \in \mathbb{C}$ with $V^{\#G} = \prod_{\chi\in G} a(\chi)\,b(\chi)$. Then for every $\psi \in G$ there are $\varphi, \chi \in G$ with $\varphi\chi = \psi$ and $\|\iota(V)\| \le \|\iota(a(\varphi)\,b(\chi))\|$.

Proof. Proof of (a). The group $\mathrm{U}(1)(\mathbb{A}_f)$ is commutative, so C is the quotient group $A = \mathrm{U}(1)(\mathbb{A}_f)/\mathrm{U}(1)(E)K$; it is finite by the finiteness of class numbers [33] (K is an open subgroup of the integral points). Write $[g]$ for the class of g and $\widehat{A}$ for the group of characters of A; $\#\widehat{A} = \#A = \#C$.

Step 1: every character of A is an automorphic character of weight 0 with tame part trivial off S. Let $\lambda \in \widehat{A}$ and define $\chi_\lambda(u) = \lambda([u_f])$ for $u \in \mathrm{U}(1)(\mathbb{A})$ with finite part u_f. It is a homomorphism, trivial on $\mathrm{U}(1)(E)$, with values roots of unity (so of modulus 1), and continuous, being constant on the cosets of the open subgroup $\mathrm{U}(1)(\mathbb{A}_\infty)\times K$. Let $\mathrm{red}\colon \mathrm{U}(1)(\widehat{\mathcal{O}}) \to H = \prod_{w\in S} k_w^\times$ be reduction modulo the places of S on the points integral at every finite place; its kernel is K. So λ restricted to the integral points is $\theta\circ\mathrm{red}$ for a character θ of the subgroup $\mathrm{red}(\mathrm{U}(1)(\widehat{\mathcal{O}}))$ of the finite abelian group H. A character of a subgroup of a finite abelian group extends to the whole group, and a character of H is a product $\prod_{w\in S}\psi_w$ of characters ψ_w of

$k_w^\times$; put $\psi_w = 1$ for $w \notin S$. Then for every $u \in \mathrm{U}(1)(\mathbb{A})$ with integral finite components, $\chi_\lambda(u) = \prod_w \psi_w(u \bmod w) = \prod_{v\in\Phi} u_v^0 \prod_w \psi_w(u \bmod w)$: χ_λ has weight 0 and tame part ψ, trivial outside S.

Step 2: orthogonality. Let $r_1 \in R$ be the representative of the class of 1 and $z = r_1^{-1}$. For $\lambda \in \widehat{A}$ put

$$t(\lambda) = \frac{1}{\#C} \sum_{g\in R} \chi_\lambda(gz)\, s(gz) = \frac{1}{\#C} \sum_{g\in R} \lambda([g]\,[z])\, s(gz).$$

For $g \in R$ the class $[g][z] = [g][r_1]^{-1}$ is trivial exactly when $g = r_1$, as R contains one point of each class. By the orthogonality relation $\sum_{\lambda\in\widehat{A}} \lambda(x) = \#A$ for $x = 1$ and 0 for $x \neq 1$,

$$\sum_{\lambda\in\widehat{A}} t(\lambda) = \frac{1}{\#C} \sum_{g\in R} s(gz) \sum_{\lambda\in\widehat{A}} \lambda([g][z]) = \frac{\#A}{\#C}\, s(r_1 z) = s(1).$$

Step 3: the ultrametric inequality. Since ι is a ring homomorphism and the norm of $\mathbb{C}_\ell$ is ultrametric, $\|\iota(s(1))\| = \|\sum_\lambda \iota(t(\lambda))\| \le \max_\lambda \|\iota(t(\lambda))\|$. Take λ attaining the maximum and $\chi = \chi_\lambda$; with z as in Step 2 this is (a).

Proof of (b). Fix ψ. For $\chi \in G$ put $N(\chi) = \|\iota(a(\psi\chi^{-1})\, b(\chi))\|$ and choose χ_0 with $N(\chi_0)$ maximal (G is finite and nonempty). The map $\chi \mapsto \psi\chi^{-1}$ is a bijection of G, so, ι and the norm being multiplicative,

$$\|\iota(V)\|^{\#G} = \prod_{\chi\in G} \|\iota(a(\chi))\|\, \|\iota(b(\chi))\| = \prod_{\chi\in G} \|\iota(a(\psi\chi^{-1}))\|\, \|\iota(b(\chi))\| = \prod_{\chi\in G} N(\chi) \le N(\chi_0)^{\#G}.$$

Taking $\#G$-th roots of these non-negative numbers gives $\|\iota(V)\| \le N(\chi_0)$, and $\varphi = \psi\chi_0^{-1}$, $\chi = \chi_0$ satisfy $\varphi\chi = \psi$. □

Lemma 6.7.23. *Let $q = (\nu_q, z_q)$ be a flat critical pair with $z_q \ge 2$. Then for every automorphism σ of $\mathbb{C}$*

$$|\sigma(I_q^{N_{\mathrm{ch}}}(1))| \le \exp(x^{34}).$$

Proof. Let $X = X(q,1)$, $O = O_X$, $N = 2z_q$, $\varphi = \varphi_{q,1} = c_s^N \lambda_X$ and $y = I_q^{N_{\mathrm{ch}}}(1) = N_{\mathrm{ch}} n_{\nu_q}^2 \mathrm{alg}_q(1)$ ((OL4)). Put $B = M^{fN} \exp(C_P(q_1 N + 1)^2 + fN \log 4)$.

Step 1: class counts. The principal congruence subgroup of level $\pi_M \pi_N$ in $\mathbf{K}_0(1)$ lies in $\mathbf{K}_X^{\mathrm{ch}}$, and that in $\mathbf{K}_0(N)$ lies in $\mathbf{K}(O)$ (its elements reduce to 1 at the chosen places, and $Q = \emptyset$, (DP4)). As $1 \le N \le 2t \le n_m$ ($m \ge 2$), Lemma 4.6.4 gives at most $\exp(x^{30})$ classes in $\mathrm{U}(1)(E)\backslash G_f(1)/\mathbf{K}_X^{\mathrm{ch}}$ and in $\mathrm{U}(\mathrm{I}_N)(E)\backslash G_f(N)/\mathbf{K}(O)$.

Step 2: the conjugates of a value. Let τ be an automorphism of $\mathbb{C}$ and $h \in G_f(N)$. By (OL3), $\varphi(h) = \sum_{[g]} \frac{1}{\#\Gamma_g} c_s^N k_X(g)(h)$; as τ fixes rational numbers and $\#\Gamma_g \ge 1$, (b) of Lemma 6.7.8 and Step 1 give $|\tau(\varphi(h))| \le \exp(x^{30})\, B$.

Step 3: the conjugates of y. The weight of O is 0, so by (DP5) $\|\varphi\|^2 = \sum_{[h]} \frac{1}{\#\Gamma_h} \overline{\varphi(h)}\varphi(h)$. Let σ be an automorphism of $\mathbb{C}$ and $\sigma'(w) = \overline{\sigma(\bar{w})}$, also an automorphism; then $|\sigma(\bar{w})| = |\sigma'(w)|$. As $N_{\mathrm{ch}} n_{\nu_q}^2$ is a positive integer, Steps 1 and 2 (for $\tau = \sigma, \sigma'$) give

$$|\sigma(y)| \le N_{\mathrm{ch}} n_{\nu_q}^2 \sum_{[h]} |\sigma'(\varphi(h))|\, |\sigma(\varphi(h))| \le N_{\mathrm{ch}}\, n_{\nu_q}^2 \exp(3x^{30})\, B^2.$$

Step 4: sizes. By Lemma 6.7.10, $\log N_{\mathrm{ch}} \le x^{33}$. By Lemma 4.2.67 (items 2–5: $f \le x^{12}$, $z_q \le t \le 15x^5$, $\log M \le 22 \log b$, $\log b \le x^{1/100}$), $\log n_{\nu_q}^2 = 8 f z_q \log M \le x^{19}$, and $2fN \log M \le$

x^{19}, $2fN\log 4 \le x^{19}$. For the remaining term, by (AD2) $2^s = m^{22} \le 2^{22}x^{11}$ and $s \le 32\log x$, so $l_0(s) \le 81\max(s,1) \le 2592\log x$, and $q_0 \le C_P \le \log x$ (item 1 of Lemma 4.2.67 and (AD1)); hence $q_1 \le 3\cdot 2592\cdot 2^{22}(\log x)^2 x^{11}$, $q_1N+1 \le 10^{13}(\log x)^2x^{16}$ (as $N \le 30x^5$), and $2C_P(q_1N+1)^2 \le 2\cdot 10^{26}(\log x)^5x^{32} \le x^{33}$, since $x \ge e^{6.4\cdot 10^{15}}$ (item 1). So

$$\log|\sigma(y)| \le x^{33} + x^{19} + 3x^{30} + 2\log B \le x^{33} + x^{19} + 3x^{30} + x^{19} + x^{33} + x^{19} \le x^{34}.$$

□

The test forms need pairings that, at each prime p, are divisible by no more than $p^{F(p)}$. Such a pairing is a Taylor coefficient of a theta function at a CM point, and its divisibility is governed by the derivatives of theta functions of CM elliptic curves; in our reading $F(p)$ is the valuation that these derivatives force, so the requirement is that this divisibility is attained and not exceeded. The last group proves it (Proposition 6.7.24): for every degree l in the relevant range there is one number $t_{\mathrm{shp}} \neq 0$, with all conjugates at most $\exp(fmb/k)$ and chosen before the prime, such that at every prime some suitably normalised Taylor coefficient of degree l of the theta germ at an indicator datum has p-adic norm at least $p^{-F(p)}$.

The method has its origins in the p-adic theory of theta functions and Eisenstein series on CM elliptic curves [159, 272, 219, 13]. The curves enter through potentially good reduction [266, 281], the integrality of singular moduli, the extension of homomorphisms of semiabelian schemes [77, 178] and formal logarithms [124]. The proof has three steps. An arithmetic tight frame with a common unit row realises products of theta functions along its rows as theta germs (Lemma 6.7.35). The valuation budget is attained at each prime separately, from the derivative rate of one curve through six and then twelve copies (Lemma 6.7.25). Finite theta averaging passes to one indicator datum (Lemma 6.7.36), and the losses are absorbed into t_{shp}.

Proposition 6.7.24. *Let $V_{12} = \mathrm{Hom}(\mathrm{I}_1, \mathrm{I}_{12})$ for the standard definite spaces I_1, I_{12} of ranks 1 and 12, with coordinates $Z = (Z_{\tau,j})_{\tau\in\Phi,\,1\le j\le 12}$. For a modulus $\mathfrak{m}$ put $A = \Sigma(\mathfrak{m})$. For $y_0 \in R_{\mathfrak{m}}^{12}$ let $\Psi_{\mathfrak{m},y_0}$ be the function on finite adelic vectors that is the indicator of the class y_0 among vectors integral at A, with no restriction away from A. The **indicator datum** is*

$$F_{\mathfrak{m},y_0} = v_1 \otimes (\Psi_{\mathfrak{m},y_0} \otimes_A v^0)$$

in the polarized datum construction (WR6), where v_1 is the positive real vacuum of (WR5). It is a vector of the theta model; its theta values are those of (WC3) of Definition 4.1.15. The class indicator is used as the polarized Schrödinger input in (WR6). Let $T(F) = \sum_\gamma [Z^\gamma]T(F)\,Z^\gamma$ be the Taylor series at 0 of $Z \mapsto \theta_F(\pi_M\eta_P Z)$. Let $l\colon \Phi \to \mathbb{Z}_{\ge 0}$ satisfy $\kappa(\tau) \le l(\tau) \le \kappa(\tau) + x^{42}$ for every $\tau \in \Phi$. Then there is $t_{\mathrm{shp}} \in \mathbb{C}\setminus\{0\}$ with $|\sigma(t_{\mathrm{shp}})| \le \exp(fmb/k)$ for every automorphism σ of $\mathbb{C}$ such that, for the modulus $\mathfrak{m} = \pi_M\mathcal{O}_E$, every prime p and every ring homomorphism $\iota\colon \mathbb{C} \to \mathbb{C}_p$, there are a multi-index γ on $\Phi \times \{1,\dots,12\}$ with $\sum_{j=1}^{12}\gamma(\tau,j) = l(\tau)$ for every τ, and $y_0 \in R_{\mathfrak{m}}^{12}$, with

$$p^{-F(p)} \;\le\; \Big\|\iota\Big(\frac{c_s^{12}}{t_{\mathrm{shp}}}\prod_{\tau\in\Phi} l(\tau)!\;\,[Z^\gamma]\,T(F_{\mathfrak{m},y_0})\Big)\Big\|.$$

Proof. **A fixed scalar before all prime embeddings.** Write v^0 for the rank-twelve vacuum in the prescribed positive model. Its finite theta function is not identically zero. Indeed Lemma 4.2.2 makes its entire theta function nonzero, because the map is injective and the vacuum has norm one by Lemma 4.1.10. Rational vectors are dense in its real coordinate space. The

exact rational finite-translation formula therefore gives a rational finite translate with nonzero theta value. Choose one finite x_*, once for all primes and embeddings, such that

$$\theta_{x_*}(v^0) \neq 0, \qquad \theta_x(F) = \theta(\rho(\mathrm{fv}(x))F).$$

Put

$$c_* = c_s^{12}\theta_{x_*}(v^0), \qquad B_* = \prod_{\tau\in\Phi} B(l(\tau)), \qquad t_{\mathrm{shp}} = M^{12f}c_*B_*^2, \tag{1}$$

where B is the positive integer product of Lemma 6.7.28. The fixed tensor normalization (WC1) of Definition 4.1.15 and the rank-one bounds of Proposition 4.2.1, for the simultaneous choice supplied by Lemma 4.2.3 and fixed as the common jet-pair and vacuum-scale choice, with C_P and its vacuum-constant summand as defined in Definition 2.3.3, give

$$|\sigma(c_*)| \leq \exp(12C_Pq_1^2) \qquad (\sigma \in \mathrm{Aut}(\mathbb{C}/K)).$$

The same bound holds for every automorphism of $\mathbb{C}$. Its restriction to the imaginary quadratic field is either the identity or conjugation; composing with ordinary complex conjugation in the latter case gives an automorphism over K and preserves the absolute value in question. Thus Lemma 6.7.28(2) gives

$$t_{\mathrm{shp}} \neq 0, \qquad |\sigma(t_{\mathrm{shp}})| \leq \exp(fmb/k) \quad (\sigma \in \mathrm{Aut}\,\mathbb{C}). \tag{2}$$

Everything in (1) has been chosen before p, ι.

An attained twelve-copy product. Choose the single frame (I, w_i, c_i) of Lemma 6.7.35. It too is fixed before every prime identification. Now fix p, ι, put

$$u_i = w_i/\bar{\pi}_M, \qquad v_{\mathrm{loc}} = \iota(\pi_M\beta), \qquad \beta = s_0/u_{\mathrm{CS}}.$$

The same lemma gives the full two-index Gram resolution for u_i, the simultaneous unit row, and, at nonsplit primes, integrality of every u_i at every place above p and $|v_{\mathrm{loc}}|_p = 1$. Moreover its normalized forms are exactly

$$L_i(Z) = \sum_\tau \iota(\beta\overline{\tau(w_i)})Z_\tau = \sum_\tau v_{\mathrm{loc}}\iota(\overline{\tau(u_i)})Z_\tau.$$

Consequently every hypothesis of Lemma 6.7.25 holds. That lemma supplies twelve multi-indices α_c, and nonnegative integer exponents $e_{i,c}$, with

$$\sum_{c=1}^{12}\alpha_c = l, \qquad |e_c| \leq |l|,$$

whose product coefficient norm is at least p^{-R_p}, where

$$R_p = F(p) + 2v_p(B_*) - \sum_\tau v_p(l(\tau)!). \tag{3}$$

The scale bounds Lemma 2.3.6 give $\kappa(\tau) \leq b$ and $x^{42} \leq b$, so $|l| \leq 2fb$. Since $c_i \geq 6fb$, one has $3e_{i,c} \leq 3|l| \leq c_i$.

Realization in the prescribed model. Apply Lemma 4.2.36 with its finite coordinate set $\{1, \ldots, 12\}$, $\delta = \bar{\pi}_M$, and these integer exponents. It gives an actual finite-part vector F_0, with no additional scalar, whose Taylor series at $\pi_M\eta_PZ$ is the complex monomial theta product with forms $\sum_\tau \beta\overline{\tau(w_i)}Z_{\tau,c}$. After applying ι, its coefficients are precisely those used in (3). No continuity of ι is needed: each coefficient of a composition with a zero-constant linear form

is a finite algebraic sum of coefficients. Define $\gamma(\tau,c)=(\alpha_c)_\tau$. Distinct copies have distinct variables, so coefficient extraction factors and gives

$$\sum_{c=1}^{12}\gamma(\tau,c)=l(\tau),\qquad |\iota[Z^\gamma]T(F_0)|_p\ge p^{-R_p}. \tag{4}$$

The realization lemma also proves

$$|\iota\theta_x(F_0)|_p\le 1\quad\text{for every finite } x,\qquad \rho_f(\alpha^{-1}\pi_M\lambda_f)F_0=F_0\quad(\lambda\in\mathfrak{a}^{12}). \tag{5}$$

Here the period is $\pi_M\mathfrak{a}^{12}$, because $\bar\delta=\pi_M$; the dual translation denominator is $\bar\pi_M$. Thus (5) is exactly the period hypothesis of Lemma 6.7.36.

Indicator selection and cancellation. The map $\mathscr{L}(F)=[Z^\gamma]T(F)$ is complex-linear on the actual finite part. Apply Lemma 6.7.36 to F_0, this functional and x_*. It produces $y_0\in R_{\mathfrak{m}}^{12}$ satisfying

$$|\iota[Z^\gamma]T(F_{\mathfrak{m},y_0})|_p\ge\left|\iota\Big(M^{12f}[Z^\gamma]T(F_0)\theta_{x_*}(v^0)\Big)\right|_p.$$

Multiply this inequality by $\left|\iota(c_s^{12}\prod_\tau l(\tau)!/t_{\mathrm{shp}})\right|_p$. The fixed nonzero vacuum value and the level factor cancel by (1), giving, with (3)–(4),

$$\left|\iota\left(\frac{c_s^{12}}{t_{\mathrm{shp}}}\prod_\tau l(\tau)!\,[Z^\gamma]T(F_{\mathfrak{m},y_0})\right)\right|_p\ge p^{-R_p-\sum_\tau v_p(l(\tau)!)+2v_p(B_*)}=p^{-F(p)}.$$

This is the required estimate for the scalar of (1), whose conjugate bound is (2). The local choices γ,y_0,F_0 may depend on p,ι; the scalar does not. □

Lemma 6.7.25. *Fix a prime embedding $\iota:\mathbb{C}\hookrightarrow\mathbb{C}_p$. Let I be finite, $u_i\in E$, and $c_i\ge 0$ integers, such that for all $\tau,\sigma\in\Phi$,*

$$\sum_i c_i\,\tau(u_i)\overline{\sigma(u_i)}=\mathbf{1}_{\tau=\sigma}.$$

Take $v_{\mathrm{loc}}\in\mathbb{C}_p$, put

$$L_i(Z)=\sum_{\tau\in\Phi}v_{\mathrm{loc}}\,\iota(\overline{\tau(u_i)})Z_\tau,\quad f_i=y(L_i),\quad \Theta=\prod_i\theta(L_i)^{c_i},$$

and suppose some i_0 has $\left|v_{\mathrm{loc}}\iota(\overline{\tau(u_{i_0})})\right|_p=1$ for every τ. If p is nonsplit, also suppose that every u_i is integral at every place above p and $|v_{\mathrm{loc}}|_p=1$. For every $\kappa(\tau)\le l_\tau\le\kappa(\tau)+x^{42}$, there are twelve multi-indices $\alpha_c\in\mathbb{N}^\Phi$ and $e_c\in\mathbb{N}^I$ satisfying

$$\sum_{c=1}^{12}\alpha_c=l,\qquad |e_c|\le|l|,$$

and

$$\prod_{c=1}^{12}\left|[Z^{\alpha_c}]\left(\prod_i f_i^{e_{c,i}}\Theta\right)\right|_p\ge p^{-\left(F(p)+2\sum_\tau v_p(B(l_\tau))-\sum_\tau v_p(l_\tau!)\right)}.$$

Proof. **The supplied resolution has the exact inert normal form.** First suppose p is inert. It is odd by Lemma 4.2.45. Write $L_i^0=\sum_\tau\iota(\overline{\tau(u_i)})Z_\tau$, so $L_i=v_{\mathrm{loc}}L_i^0$. All their coefficients are integral. For every positive odd e, Lemma 4.2.45 gives

$$\iota(\overline{\tau(u_i)})^{p^e}\equiv\iota((u(-p^e)\tau)(u_i))\pmod{pO}.$$

The quotient O/pO has characteristic p, so the power of a sum distributes in this quotient. Multiply by the coefficients of L_i^0, sum with multiplicities c_i, and apply the stated resolution identity, including its two embedding indices. The result is

$$\sum_i c_i (L_i^0)^{p^e} L_i^0 \equiv \sum_\tau Z_\tau^{p^e} Z_{u(-p^e)\tau} = \Gamma_e \pmod{pO[[Z]]}.$$

No one-embedding norm identity would suffice here.

Use the one-curve factorization Lemma 4.2.39 and its scale ϖ, of valuation $\rho = 1/(p^2-1)$. Since $v_p(p\varpi^{p+1}/p) = 1/(p-1)$, Lemma 4.2.46 applies to the displayed congruences with multiplier one. It gives

$$\prod_i \theta(\varpi L_i^0)^{c_i} = W_0(Z) \exp\left(\frac{\varpi^{p+1}}{p} \sum_{e \text{ odd}, h \geq 0} \lambda_{eh} \Gamma_e^{p^h} \right), \qquad W_0 \in O[[Z]].$$

The constant coefficient is one, so $W_0(0) = 1$ and W_0 is a unit. The coefficients λ_{e0} are units by the inert assertion of Lemma 4.2.39. Substitute $v_{\mathrm{loc}} Z$. It preserves integrality and changes λ_{eh} to $\lambda_{eh} v_{\mathrm{loc}}^{(p^e+1)p^h}$, still integral and still unit for $h = 0$. Thus Θ has exactly the normal form and all hypotheses required in Lemma 6.7.33 for its partner maps.

At every nonsplit prime the resolution also supplies an integral span for the forms. Indeed put $a_{\tau i} = c_i \iota(\tau(u_i)) \in O$. Then

$$\sum_i a_{\tau i} v_{\mathrm{loc}} \iota(\overline{\sigma(u_i)}) = v_{\mathrm{loc}} \mathbf{1}_{\tau=\sigma}.$$

The last assertion of Lemma 6.7.29 therefore supplies, in any residual degree, a six-copy monomial witness of product norm at least one.

Split primes. Here $F(p) = 0$ and $\gamma_p = 0$. The unit form and Lemma 6.7.29 give six copies in degree l, with product norm at least

$$|\prod_\tau l_\tau!|_p^{-1} = p^{\sum_\tau v_p(l_\tau!)}.$$

Append six zero-degree copies with monomial factor one. Their coefficients are $\Theta(0) = 1$. Since the loss valuations are nonnegative, this proves the required, possibly weaker, bound. No integrality of the other forms is used in this case.

Small nonsplit primes. Suppose $p \leq k$. Apply Lemma 6.7.26, obtaining $S, e, j, \nu', \nu'', \eta, J$ and $l = \nu' + \nu'' + \eta$. If S is empty, take six zero-degree copies as the coupling witness. If S is nonempty, the packing says p is inert; the normal form already proved and Lemma 6.7.33 give a six-copy monomial witness in degree $\nu' + \nu''$, with valuation budget

$$\gamma_p |\nu' + \nu''| - J - V_p(\nu') - V_p(\nu'').$$

This same displayed budget is zero in the empty case. Here $V_p(\omega) = \sum_\tau v_p(\omega_\tau!)$.

The unit form and Lemma 6.7.29 supply another six copies in degree η, with budget $\gamma_p|\eta| - V_p(\eta)$. Concatenate the witnesses. Their aggregate degree is l and their product norm is at least p^{-R}, where

$$R = \gamma_p |l| - J - V_p(\nu') - V_p(\nu'') - V_p(\eta).$$

The factorial-splitting inequality and the small-prime budget (1) in Lemma 6.7.26 imply

$$R \leq \gamma_p |l| - J + 3f(\log b + 2) - V_p(l) \leq F(p) + \sum_\tau v_p(B(l_\tau)) - V_p(l).$$

Adding the nonnegative extra loss sum gives the asserted bound. This covers the ramified prime: its coupling set is empty, and its residual rate is exactly the ramified one-curve rate.

Large nonsplit primes. Now $p > k$. The packing lemma says it is inert, and chooses all exponents equal to one. The negative-budget assertion of Lemma 6.7.33 supplies six copies of degree $\nu' + \nu''$ with product norm at least p^J. The integral-span assertion established above supplies six copies in degree η with norm at least one. Their concatenation has budget $-J$. By the large-prime budget (2) of Lemma 6.7.26,

$$-J \le F(p) + 2\sum_{\tau} v_p(B(l_\tau)) - V_p(l),$$

as required.

Each use of the six-copy lemmas bounds every monomial-factor degree by the degree of that witness. Its aggregate degree is coordinatewise at most l, so every such degree is at most $|l|$. The appended zero-degree copies have this property as well. This proves all conclusions. □

Lemma 6.7.26. *Let p be nonsplit in K and let $\kappa(\tau) \le l_\tau \le \kappa(\tau) + x^{42}$ be integers. Put $r_e(\tau) = u(-p^e)\tau$ and*

$$\gamma_p = \begin{cases} p/(p^2-1), & p \text{ inert}, \\ 1/(2(p-1)), & p = d, \end{cases} \qquad V_p(\nu) = \sum_{\tau\in\Phi} v_p(\nu_\tau!).$$

There exist $S \subseteq \Phi$, odd positive integers e_τ and integers $j_\tau \ge 0$ for $\tau \in S$, and multi-indices

$$\nu' = \sum_{\tau\in S} p^{e_\tau} j_\tau \mathbf{1}_\tau, \quad \nu'' = \sum_{\tau\in S} j_\tau \mathbf{1}_{r_{e_\tau}(\tau)}, \quad \eta \ge 0, \qquad l = \nu' + \nu'' + \eta,$$

with $J = \sum_{\tau\in S} j_\tau$, such that the unique-lowest coupling condition of Lemma 6.7.34 holds for the maps r_e and this S, e. If $S \ne \varnothing$, p is inert. In addition,

$$V_p(l) \le V_p(\nu') + V_p(\nu'') + V_p(\eta) + 3f(\log b + 2).$$

If $p \le k$, the choices satisfy

$$\gamma_p|l| - J + 3f(\log b + 2) \le F(p) + \sum_{\tau} v_p(B(l_\tau)). \tag{1}$$

If $p > k$, then p is inert, $S = \Phi$, $e_\tau = 1$, and the choices satisfy

$$V_p(l) - J \le F(p) + 2\sum_{\tau} v_p(B(l_\tau)). \tag{2}$$

Proof. **Elementary preliminary bounds and partners.** The scale bounds Lemma 2.3.6 imply $x \ge 10^6$. As $r \ge x^5$, $m \le 2\sqrt{x}$, one has $k = r+1-m \ge x$, while $d \le C_P \le 10^{-14}\log x < x$. Thus $d \le k$. Also $k \le 4x^5$, whereas $2^s = m^{22} \ge x^{11}$, so $k \le 2^s$. Put $H = l_0(s)$ and $L = \log b$.

The primes $2, 3, 5, 7, 11$ split in K. For two use $d \equiv 7 \pmod 8$. Each odd prime in this list divides q_0 and hence $d+1$; the discriminant $-d$ is then a nonzero square modulo that prime, so it splits. Every prime dividing $q_1 = 3q_0H2^s$ similarly splits, since H is a power of three. Thus nonsplit $p \ge 13$ and $p \nmid q_1$. In particular each r_e is a permutation, and for odd e it equals g^e, with g the permutation $\tau \mapsto u(-p)\tau$.

There are no pairs of b-places $\tau, r_e\tau$ at $p = d$, for any $e \ge 1$. They would have the same class modulo q_0, hence $-d^e \equiv 1 \pmod{q_0}$. But $d \equiv q_0/2 - 1$, q_0 is divisible by four, and therefore $d^2 \equiv 1 \pmod{q_0}$. Its powers are 1 or d, neither congruent to -1, a contradiction.

Small primes: choose all short pairs. Suppose $p \le k$. Call (τ, e) short when $e \in I_p$, $2e < H$, and $\tau, r_e\tau \in \Phi_b$. Ramified short pairs do not exist by the preceding paragraph; otherwise the prime is inert and e is positive odd. The sparsity in the datum implies the forbidden-triple hypothesis of Lemma 6.7.27 for Φ_b, g, H: a triple at times $0 < i < j < H$ would have ratios $(-p)^i, (-p)^j$, which are of the permitted signs times p^i, p^j modulo the prime-to-p part of q_1. The prime is at most $k \le kt$, so sparsity applies.

Let S be all short-pair starts, choose their unique exponents e_τ, and put $j_\tau = \lfloor l_\tau / p^{e_\tau} \rfloor$. At ramified p, take S empty. We have $l_\tau \le 2b$, by Lemma 6.7.28; on Φ_b, $l_\tau \ge b$. The matching and capacity assertions of Lemma 6.7.27 give the unique-lowest condition and $\nu' + \nu'' \le l$. Put $\eta = l - \nu' - \nu''$.

We prove its quantitative budget. Extend $j_\tau = 0$ off S, and define

$$R_\tau = \sum_{e \in I_p} \min(\kappa(\tau)/p^e, \kappa(r_e\tau)).$$

All these positive series converge by comparison with $b \sum_{e \ge 1} p^{-e}$. The elementary identity $v - (v - w)_+ = \min(v, w)$, and the geometric sums over I_p, give

$$\gamma_p \sum_\tau \kappa(\tau) - F(p) = v_p(\pi_p) \sum_\tau R_\tau \le \sum_\tau R_\tau. \tag{3}$$

Here the geometric sum is $p/(p^2 - 1)$ in the inert case, and $1/(p - 1)$ in the ramified case, multiplied by $v_p(\pi_p) = 1/2$ in the latter.

Put $n_0 = \lceil H/2 \rceil$. For $e < n_0$, any nonshort term of R_τ is at most a/x_1: either its start or its end is not a b-place and has weight a/x_1. If a short term exists, it is unique and bounded by

$$\kappa(\tau)/p^{e_\tau} \le l_\tau / p^{e_\tau} < j_\tau + 1.$$

For the tail, $H > 27s$ implies $n_0 - 1 \ge s$, hence $p^{n_0 - 1} \ge 2^s \ge k$. Therefore

$$\sum_{e \ge n_0} b/p^e = \frac{bp^{-n_0}}{1 - p^{-1}} \le \frac{2b}{kp}.$$

Since $n_0 \le H$, both cases, including absence of a short term, give

$$R_\tau \le j_\tau + 1 + H\, a/x_1 + 2b/(kp).$$

Also $0 \le \gamma_p \le 1$, so $\gamma_p |l| \le \gamma_p \sum_\tau \kappa(\tau) + f x^{42}$. Combine this inequality with (3), subtract J, and add $3f(L + 2)$. Apply the small-prime bound of Lemma 6.7.28 at each l_τ. This proves (1).

Large primes: couple every place once in exponent. Suppose $p > k$. Since $d \le k$, this nonsplit prime is inert. Take $S = \Phi$, $e_\tau = 1$, and

$$i_\tau = \left\lfloor \frac{\max(l_\tau - n_*, 0)}{p} \right\rfloor, \qquad j_\tau = \min(i_\tau, l_{r_1\tau}).$$

As $l_\tau \le 2b$ and $p > k$, $i_\tau \le 2b/k \le n_*$. The unique-lowest condition follows because the only positive odd exponent at most one is one and r_1 is a permutation. At a point $\sigma = r_1\tau$, the contributions are $pj_\sigma + j_\tau$. They are bounded by

$$\max(l_\sigma - n_*, 0) + \min(n_*, l_\sigma) = l_\sigma.$$

Thus the capacity and residual η again exist.

For a single τ, the consecutive-product divisibilities of Lemma 6.7.28 and one step of Legendre's formula give

$$v_p(l_\tau!) \le i_\tau + v_p(i_\tau!) + v_p(B(l_\tau)) \le i_\tau + 2v_p(B(l_\tau)).$$

The second step uses $i_\tau \le n_*$, so $i_\tau! \mid n_*! \mid B(l_\tau)$. Since $n_* \ge x^{42}$, the truncated numerator defining i_τ is at most $\kappa(\tau)$. Hence

$$i_\tau - j_\tau \le (\kappa(\tau)/p - \kappa(r_1\tau))_+ \le s_p(\kappa(\tau), \tau).$$

The last term is the first nonnegative summand of the inert local prime sum. Sum over τ to obtain (2).

Bound the factorial cost of splitting three degrees. For $0 \le v \le 2b$ and $p \ge 3$, choose $h_0 = \lceil L \rceil + 1$. Then $v \le 2e^L < e^{L+1} \le p^{h_0}$. Writing $\mathrm{dig}_p(v)$ for the sum of the base-p digits, Legendre's formula gives

$$v_p(v!) = (v - \mathrm{dig}_p(v))/(p-1), \qquad 0 \le \mathrm{dig}_p(v)/(p-1) \le h_0 \le L + 2.$$

Thus $v/(p-1) - (L+2) \le v_p(v!) \le v/(p-1)$. At each τ, apply the upper bound to $l_\tau!$ and the lower bound to the three factorials of $\nu'_\tau, \nu''_\tau, \eta_\tau$. Their linear terms cancel, giving error at most $3(L+2)$. All arguments are at most $l_\tau \le 2b$. Summing over the f places proves the remaining assertion. □

Lemma 6.7.27. *Let Q be a finite set, $g : Q \to Q$ a permutation, $B \subseteq Q$, and $H \ge 3$ an integer. Suppose there do not exist $\tau \in B$ and integers $0 < i < j < H$ for which $g^i\tau, g^j\tau \in B$. Consider all pairs (τ, e) with $\tau \in B$, e positive odd, $2e < H$, and $g^e\tau \in B$. Then each start belongs to at most one such pair, each end belongs to at most one such pair, and no end is a start.*

Let S be any subset of their starts and e_τ the corresponding exponent. For $\tau, \sigma \in S$ and positive odd $a \le e_\tau$,

$$g^a\sigma = g^{e_\tau}\tau \quad \Longrightarrow \quad (\sigma, a) = (\tau, e_\tau).$$

Furthermore, let $p \ge 2$, let $b_0 > 0$, and let l_τ be nonnegative integers for $\tau \in Q$, with $l_\tau \le 2b_0$ for all τ and $l_\tau \ge b_0$ for $\tau \in B$. Put

$$j_\tau = \lfloor l_\tau / p^{e_\tau} \rfloor, \qquad \nu' = \sum_{\tau \in S} p^{e_\tau} j_\tau \mathbf{1}_\tau, \quad \nu'' = \sum_{\tau \in S} j_\tau \mathbf{1}_{g^{e_\tau}\tau}.$$

Then $\nu' + \nu'' \le l$ coordinatewise.

Proof. Suppose two pairs have the same start, with exponents $e < e'$. The three points at times $0, e, e'$, all in B, contradict the hypothesis, since $0 < e < e' < H$. Thus the exponent at a start is unique.

Suppose two pairs $(\tau, e), (\sigma, e')$ have the same end. If $e = e'$, injectivity of g^e gives $\tau = \sigma$. If, say, $e < e'$, then $\tau = g^{e'-e}\sigma$. The three points starting at σ, at times $0, e' - e, e'$, lie in B; these times satisfy $0 < e' - e < e' < H$. This again contradicts sparsity. Thus ends also determine their pairs uniquely.

If an end $g^e\tau$ were a start σ of a pair of exponent e', then the times $0, e, e + e'$ from τ would all lie in B. They are strictly increasing, and $e + e' < H$ follows by adding $2e < H$ and $2e' < H$. This is impossible.

For the claimed unique-lowest condition, the pair (σ, a) itself belongs to the considered collection: its start lies in B, its end equals the end of (τ, e_τ) and lies in B, it is positive odd, and $2a \le 2e_\tau < H$. Uniqueness at an end therefore identifies the two pairs.

Finally a start cannot receive an end contribution, so at a start τ the sum $\nu' + \nu''$ equals $p^{e_\tau}\lfloor l_\tau / p^{e_\tau} \rfloor \le l_\tau$. At an end it receives exactly one contribution, namely j_τ from its unique pair. Since $e_\tau \ge 1$ and $p \ge 2$,

$$j_\tau \le l_\tau / p^{e_\tau} \le 2b_0/2 = b_0.$$

The degree at that end is therefore at most its prescribed l, because the end lies in B. At a point which is neither a start nor an end the degree is zero. These cases prove the coordinatewise bound. □

Lemma 6.7.28. *Put $L = \log b$, $H = l_0(s)$, $n_* = \lceil 6b/k \rceil$, and, for an integer $v \ge 0$, put*

$$v^- = \max(v - n_*, 0), \qquad B(v) = \prod_{i=1}^{n_*} (v^- + i).$$

Then $n_* \ge x^{42}$, $B(v) > 0$, and, for every prime p,

$$v_p(n_*!) \le v_p(B(v)), \qquad v_p(v!) \le v_p(v^-!) + v_p(B(v)).$$

For $p \le k$, one has

$$3(L+2) + x^{42} + 1 + H\, a/x_1 + 2b/(kp) \le v_p(B(v)). \tag{1}$$

If $\kappa(\tau) \le l_\tau \le \kappa(\tau) + x^{42}$ for all $\tau \in \Phi$, and a nonzero scalar $c_0 \in \mathbb{C}$ satisfies

$$|\sigma(c_0)| \le \exp(12 C_P q_1^2) \quad (\sigma \in \operatorname{Aut} \mathbb{C}),$$

then

$$t = M^{12f} c_0 \prod_{\tau \in \Phi} B(l_\tau)^2 \ne 0, \qquad |\sigma(t)| \le \exp(fmb/k) \quad (\sigma \in \operatorname{Aut} \mathbb{C}). \tag{2}$$

Proof. **Record quantitative scale consequences.** Write $w = \log x$. Those bounds and the defining scale inequalities give

$$x \ge 10^6, \quad L \ge 100, \quad \log x_1 \ge 10^6 w, \quad L \ge 10^6 \log x_1 \ge 10^{12} w, \quad L \le x^{1/100}. \tag{3}$$

The last inequality is the exponential of $100 \log L \le w$. In particular $b \ge x^{10^{12}}$ and $x_1 \le b^{10^{-6}}$. The rank formulas give $k = r + 1 - m \le 3x^5 + 1 \le 4x^5 \le x^6$, and $m \ge \sqrt{x}$. Since $s \ge 1$, $H \le 81 s \le 2592 w$. Thus $H + 1 \le x^2$ for $x \ge 10^6$: use $w \le \sqrt{x}$, followed by $2592\sqrt{x} + 1 \le x^2$.

For later use the explicit tower formula gives

$$q_1 = 3 q_0 H 2^s \le 7776\, 2^{22} q_0 w x^{11} \le w^2 x^{11} \le x^{13}. \tag{4}$$

Here $2^s = m^{22} \le 2^{22} x^{11}$, $q_0 \le C_P \le 10^{-14} w$, and $7776\, 2^{22} < 10^{14}$. Also $C_P \le x$, $f \ge 1$, $2 \le k \le b$, and $\log M \le 22L$.

Put $\varepsilon = a/x_1 = xb/x_1$. The inequalities just proved imply

$$3(L+2) + x^{42} + 1 \le \varepsilon, \qquad (H+1)\varepsilon \le b/k^2, \qquad \varepsilon \ge 1. \tag{5}$$

Here are direct estimates for both nontrivial assertions. First $\varepsilon \ge b^{1-10^{-6}}$, $x^{42} \le b^{1/4}$, and $3(L+2) + 1 \le b^{1/4}$. For the latter, $e^{L/4} \ge L^3/384 \ge 3L + 7$ for $L \ge 100$. Since $2b^{1/4} \le b^{1/2} \le b^{1-10^{-6}}$, the first assertion follows. For the second,

$$(H+1) x k^2 \le x^2 x x^{12} = x^{15} \le x_1,$$

by $\log x_1 \ge 10^6 \log x$; cancel x_1 and multiply by b.

Consecutive products supply the loss. The product $B(v)$ consists of n_* positive consecutive integers, so it is positive and divisible by $n_*!$, since $B(v) = n_*!\binom{v^- + n_*}{n_*}$. Furthermore $v \le v^- + n_*$, whence $v! \mid (v^- + n_*)! = v^-!B(v)$. Taking valuations gives the first two assertions. From (3) and $k \le x^6$ we have $6b/k \ge x^{42}$, so $n_* \ge x^{42}$.

Legendre's formula gives $v_p(n_*!) \ge \lfloor n_*/p \rfloor \ge n_*/p - 1$. For $p \le k$, put $D_p = b/(kp)$. By (5), $D_p \ge b/k^2 \ge (H+1)\varepsilon \ge 1$. Also $n_*/p \ge 6D_p$. Consequently

$$v_p(B(v)) \ge n_*/p - 1 \ge 3D_p.$$

The expression on the left of (1) is at most

$$\varepsilon + H\varepsilon + 2D_p \le D_p + 2D_p = 3D_p$$

by (5). This proves (1), uniformly for all v.

The same loss has a small archimedean cost. Since $x_1 \ge x$, every $\kappa(\tau) \le b$. Thus $l_\tau \le b + x^{42} \le 2b$. Also

$$n_* \le 6b/k + 1 \le 7b/k, \qquad 2b + n_* \le 6b, \qquad \log(2b + n_*) \le 2L.$$

The middle estimate uses $k \ge 2$, and the last uses $b \ge 6$. Each factor of $B(l_\tau)$ is at most $2b + n_*$, so

$$\log B(l_\tau) \le 14bL/k.$$

For any automorphism σ, it fixes the positive integer factors of t, and the assumed bound on c_0 therefore yields

$$\log|\sigma(t)| \le 264fL + 28fbL/k + 12C_P q_1^2.$$

If a logarithm is not taken, the same inequality follows by multiplying the corresponding positive exponential bounds. Divide the displayed upper bound by $fb/k > 0$. Its three terms are bounded as follows, using (3)–(4):

$$264Lk/b \le 264x^7/x^{10^{12}} \le 1, \quad 28L \le 28x^{1/100} \le \sqrt{x}/2, \quad 12C_P q_1^2 k/(fb) \le 12x^{33}/x^{10^{12}} \le 1.$$

The middle inequality holds for $x \ge 10^6$, since $56 \le x^{49/100}$. The sum is at most $2 + \sqrt{x}/2 \le \sqrt{x} \le m$. This proves (2). Every factor in its defining product is nonzero, so $t \ne 0$, completing the proof. □

Lemma 6.7.29. *Use the exact normalized theta function θ, translated curve parameter y, prime embedding and ring $O = \mathcal{O}_{\mathbb{C}_p}$ of Lemma 4.2.37, and the number γ_p of Lemma 6.7.30. Let X, I be finite sets, let $L_i(Z) = \sum_{x \in X} \mu_{ix} Z_x$ with $\mu_{ix} \in \mathbb{C}_p$, and let $m_i \ge 0$. Put*

$$f_i = y(L_i(Z)), \quad R_\mu = \{A((f_i)_i) : A \in O[[U_i : i \in I]]\}, \quad \Theta(Z) = \prod_i \theta(L_i(Z))^{m_i}.$$

There exist $\delta_0, \dots, \delta_5 \in \mathbb{Z}_p$, with $\delta_0 = 1$ and $\sum_c \delta_c^2 = 0$, such that

$$U(Z) = \prod_{c=0}^{5} \Theta(\delta_c Z) \in R_\mu, \qquad U^{-1} \in R_\mu, \qquad U(0) = 1.$$

If some $i_0 \in I$ satisfies $|\mu_{i_0 x}|_p = 1$ for every $x \in X$, then for every $\nu \in \mathbb{N}^X$ there are $\alpha_c \in \mathbb{N}^X$ and $e_c \in \mathbb{N}^I$, $0 \le c \le 5$, with

$$\sum_c \alpha_c = \nu, \quad |e_c| \le |\nu|, \qquad \prod_{c=0}^{5} \left| [Z^{\alpha_c}] \left(\prod_i f_i^{e_{c,i}} \Theta \right) \right|_p \ge p^{-\gamma_p |\nu|} \left| \prod_x \nu_x! \right|_p^{-1}. \tag{1}$$

If instead there are $a_{xi} \in O$ and $u \in O^\times$ with

$$\sum_i a_{xi}\mu_{ix'} = u\,\mathbf{1}_{x=x'},$$

then the same existence assertion holds with the right side of (1) replaced by 1.

Proof. **Choose integral scalars whose squares cancel.** For odd p, the sets of squares and of minus one minus a square in $\mathbb{F}_p$ both have cardinality $(p+1)/2$, and therefore intersect. This gives $a^2+b^2=-1$ modulo p, with at least one coordinate nonzero. Holding the other coordinate fixed, successive lifting with the unit derivative $2a$ or $2b$ gives a solution in $\mathbb{Z}_p$. Thus minus one is a sum of four squares in $\mathbb{Z}_p$, adding two zeros if needed. For $p=2$, minus seven has a square root in $\mathbb{Z}_2$. Explicitly start with an odd solution modulo eight. If $v^2 \equiv -7 \pmod{2^h}$, $h \geq 3$, adding either zero or 2^{h-1} changes its square by either zero or 2^h modulo 2^{h+1}, since v is odd. Choose the correction giving a solution modulo 2^{h+1}. These compatible corrections converge to the required root. Then

$$-1 = 1^2 + 1^2 + 2^2 + (\sqrt{-7})^2.$$

In either case choose $a_1, \ldots, a_4 \in \mathbb{Z}_p$ with sum of squares minus one and take $(\delta_0, \ldots, \delta_5) = (1, a_1, a_2, a_3, a_4, 0)$.

Cancel the quadratic exponential in the same parameter. Put $g = -\log\theta$, so $\theta = \exp(-g)$ as formal series and $g(0)=0$. The last assertion of Lemma 4.2.37 gives $\exp(\delta_c^2 g(z) - g(\delta_c z)) \in O[[y]]$. Their product, because $\sum_c \delta_c^2 = 0$, equals $\prod_c \theta(\delta_c z)$. It has constant coefficient one. Thus it and its reciprocal belong to $O[[y]]$: in an outer representation $A(y)$, the constant coefficient of A is one, so its formal reciprocal lies in $O[[U]]$. Substitute $L_i(Z)$, raise to m_i, and multiply over i. This gives $U, U^{-1} \in R_\mu$ and $U(0)=1$, with exactly the stated six scalars. No integrality of the μ_{ix} is needed for these formal substitutions.

Use the attained one-variable derivative. Let $d_0 = |\nu|$. By Lemma 6.7.30, there is a power $A(z) = y(z)^j \in O[[y]]$ for which

$$|d_0![z^{d_0}]A|_p \geq p^{-\gamma_p d_0}.$$

Put $B(Z) = A(L_{i_0}(Z)) \in R_\mu$. The multinomial formula gives

$$[Z^\nu]B = \frac{d_0!}{\prod_x \nu_x!}[z^{d_0}]A \prod_x \mu_{i_0 x}^{\nu_x}.$$

All factors in the last product are units in norm. Hence this coefficient has norm at least the right side of (1). Take $H_0 = BU^{-1} \in R_\mu$, and $H_c = 1$ for $c > 0$. Then, since $\delta_0 = 1$,

$$\prod_{c=0}^{5} (H_c\Theta)(\delta_c Z) = B(Z).$$

Apply Lemma 6.7.32 with one new copy of X, coefficient matrix (δ_c), and target ν. It yields the required aggregate exponents and monomial factors. Its coefficient inequality transfers the displayed lower bound and proves (1).

An integral span supplies a unit coefficient directly. Under the last hypothesis, put

$$B_x(Z) = \sum_i a_{xi} y(L_i(Z)) \in R_\mu.$$

Since $y(z) = z+$ higher-degree terms, $B_x = uZ_x+$ terms of total degree at least two. Thus $\prod_x B_x^{\nu_x}$ has unique lowest total-degree term $u^{|\nu|}Z^\nu$. Multiplication by Θ, whose constant coefficient is one, leaves this coefficient unchanged. It has norm one. Apply Lemma 6.7.31 to this

integral formal factor and multiplier Θ at degree ν. It gives one monomial factor of degree at most $|\nu|$ with coefficient norm at least one. Use that factor and degree ν in the first copy, and use factor one and degree zero in the remaining five copies. Their coefficients are $\Theta(0) = 1$, proving the final assertion. □

Lemma 6.7.30. *Let $d \equiv 7 \pmod 8$ be prime, let $K = \mathbb{Q}(\sqrt{-d}) \subset \mathbb{C}$, and let $M \subset \mathbb{C}$ be an $\mathcal{O}_K$-stable lattice with marked point t satisfying the hypotheses of Lemma 4.2.6. Use its normalized equation $Y^2 + aXY = X^3 + X$ and invariant differential dz. Fix an embedding $\iota : \mathbb{C} \hookrightarrow \mathbb{C}_p$, and let $y(z) \in \mathbb{C}_p[[z]]$ be the coefficientwise image of*

$$\frac{\wp_M'(z+t) - a(\wp_M(z+t) - \wp_M(t))}{2}.$$

Put $O = \mathcal{O}_{\mathbb{C}_p}$ and $R = \{A(y(z)) : A \in O[[U]]\}$. Set

$$\gamma_p = \begin{cases} 0, & p \text{ split in } K, \\ p/(p^2-1), & p \text{ inert in } K, \\ 1/(2(p-1)), & p = d. \end{cases}$$

For every integer $n \geq 0$, there is an integer j, $0 \leq j \leq n$, such that

$$p^{-n\gamma_p} \leq |n![z^n]y(z)^j|_p = \max_{A \in O[[U]]} |n![z^n]A(y(z))|_p \leq 1.$$

Proof. **The normalized local ring has integral differentiation and addition.** The all-prime good model is Lemma 4.2.6. At its marked section $Q = (0,0)$, the derivative with respect to X of $Y^2 + aXY - X^3 - X$ is -1. Formal coefficient comparison therefore solves uniquely $X = X_0(Y) \in Y^2 O[[Y]]$. The analytic differential normalization identifies the completion at Q with R, and gives $y(0) = 0$, $y'(0) = 1$. Differentiating the equation in its invariant coordinate gives

$$x' = 2y + ax, \qquad y' = 1 + 3x^2 - ay, \qquad x = X_0(y).$$

Thus $y' \in O[[y]]$, and the formal chain rule shows that R is stable under differentiation. This calculation involves no division by two and holds also at $p = 2$.

Translate the elliptic group law so that Q is its identity. Translation by an integral section is defined over O; hence the completed group law has coefficients in O. The invariant differential is still dz, so in the analytic coordinate its addition is $z + w$. Consequently

$$y(z+w) \in O[[y(z), y(w)]].$$

The normalized formal logarithm of this law is the compositional inverse of $y(z)$.

Construct a scaled parameter at split primes. For odd nonsplit primes, Lemma 4.2.41 supplies a generator T of R, numbers q, ρ, and a scalar ϖ with

$$T(\varpi z) = \varpi Y_0(z), \quad v_p(\varpi) = \rho, \quad Y_0 \in O[[z]], \quad Y_0 \equiv \sum_{h \geq 0} z^{q^h} \pmod{\pi O[[z]]}, \tag{1}$$

where $(q, \rho) = (p^2, 1/(p^2-1))$ in the inert case, and $(q, \rho) = (p, 1/(2(p-1)))$ if $p = d$. We establish the corresponding assertion with $q = p, \rho = 1/(p-1), \pi = p$ at split primes, including two.

Over a finite local extension the full CM action is defined and extends to the same good elliptic scheme by Theorem A.2.19: the base is a noetherian normal discrete valuation ring, its generic point is open dense, and the scheme is abelian. Uniqueness preserves the ring action. The two idempotents in $\mathcal{O}_K \otimes \mathbb{Z}_p = \mathbb{Z}_p \times \mathbb{Z}_p$ split its p-divisible group into factors of height one. Their heights are one on the generic Tate module and remain one since the corresponding finite flat kernels have constant rank. Their dimensions sum to one, so over the algebraically closed residue field exactly one is connected of dimension one and the other is etale. The formal group is the connected factor. Its multiplication-by-p kernel has rank p and is supported at its identity in the special fibre. Therefore multiplication by p on the one-dimensional special-fibre formal group has order exactly p: its kernel algebra is the quotient by its defining series, whose length is that order.

For $u \in \mathbb{Z}_p$, the formal multiplication series $[u]$ is integral. Indeed for integers $u_m \to u$, the coefficients of $y(u_m y^{-1}(U))$ lie in O; in each degree they are polynomials in u_m over $\mathbb{C}_p$, so converge to those of $y(uy^{-1}(U))$, and O is closed. In particular $y(\zeta z) \in R$ for every $(p-1)$st root of unity $\zeta \in \mathbb{Z}_p$. Put

$$T(z) = \frac{1}{p-1} \sum_{\zeta^{p-1}=1} \zeta^{-1} y(\zeta z).$$

It belongs to R, has linear term z, and has only degrees congruent to one modulo $p-1$. Its inverse change from the parameter y is integral, by recursive coefficient comparison; thus $O[[T]] = R$. The multiplication series in this parameter is

$$T(pz) = g(T(z)), \qquad g(U) = pU + b_1 U^p + \sum_{i \geq 2} b_i U^{1+i(p-1)}, \qquad b_i \in O.$$

The support follows by commuting with all the displayed roots of unity. The special-fibre order just proved makes b_1 a unit. These assertions also apply for $p = 2$, when the averaging group is trivial.

Choose $\varpi^{p-1} = -p/b_1$, so $v_p(\varpi) = 1/(p-1)$. Direct scaling gives

$$g(\varpi U) = p\varpi(U - U^p + pE(U)), \qquad E \in U^2 O[[U]].$$

For $Y_0 = T(\varpi z)/\varpi$, the resulting equation is

$$Y_0(pz) = p(Y_0 - Y_0^p + pE(Y_0)).$$

For $n \geq 2$, the coefficient multiplying $[z^n]Y_0$ is $p^{n-1} - 1$, a unit, while the remaining coefficient uses only lower degrees. Induction makes Y_0 integral. Reduction modulo pO gives $Y_0 - Y_0^p \equiv z$, hence (1) with $q = p$, by iteration in each fixed degree. This proves the required split-prime assertion without changing the differential scale.

Derivative maxima are attained and submultiplicative. For every n, apply Lemma 6.7.31 to the one series y, the multiplier one, and degree n. It gives $0 \leq j \leq n$ maximizing the norm of $[z^n]A(y)$ over all integral A. Denote the attained maximum after multiplication by $n!$ by c_n. Differentiation stability and integral constant terms give

$$0 \leq c_n \leq 1, \qquad c_0 = 1.$$

We claim $c_{m+n} \leq c_m c_n$. Choose a maximizing power y^j in degree $m+n$. Its value at $z+w$ is an integral series in $y(z), y(w)$. Apply Lemma 6.7.31 to these two zero-constant series and the coefficient at $z^m w^n$. Some product $y(z)^u y(w)^v$ bounds that coefficient. Multiplying by $m!n!$, and using

$$m!n![z^m w^n] y(z+w)^j = (m+n)![z^{m+n}] y(z)^j,$$

bounds it by $c_m c_n$, as required.

Prime-power coefficients force the rate in every degree. In (1), if $N = q^h$ and $r = N - 1$, the coefficient $[z^N]Y_0$ is congruent to one modulo πO, and therefore has norm one. Thus

$$|[z^N]T|_p = p^{r\rho}.$$

Legendre's formula gives $v_p(N!) \leq (N-1)/(p-1)$. In all three cases, $\gamma_p = 1/(p-1) - \rho \geq 0$, so, since $T \in R$,

$$c_N \geq |N![z^N]T|_p \geq p^{-r\gamma_p} \geq p^{-N\gamma_p}. \tag{2}$$

These N are arbitrarily large.

For completeness, put $\eta = p^{-\gamma_p} \in (0,1]$. Suppose that for some $n > 0$ one had $c_n < \eta^n$. Write $N = hn + r$, $0 \leq r < n$. Submultiplicativity and $c_r \leq 1$ imply $c_N \leq c_n^h$. At the arbitrarily large N in (2) this gives

$$\eta^n(\eta^n)^h \leq \eta^N \leq c_n^h, \qquad \eta^n \leq (c_n/\eta^n)^h.$$

The last right-hand side tends to zero, a contradiction. Hence $c_n \geq \eta^n$ for every positive n; for zero it is equality. Combining this with the attained maximum proves the assertion. □

Lemma 6.7.31. *Let L be a field with a nonarchimedean absolute value and valuation ring $O = \{a \in L : |a| \leq 1\}$. Let I, X be finite sets, let $f_i \in L[[Z_x : x \in X]]$ have zero constant term for every $i \in I$, and let $s \in L[[Z_x : x \in X]]$. For every $\alpha \in \mathbb{N}^X$, there exists $m \in \mathbb{N}^I$, with $|m| \leq |\alpha|$, such that simultaneously for all $G \in O[[U_i : i \in I]]$,*

$$|[Z^\alpha](G((f_i)_i)s)| \leq \left|[Z^\alpha]\left(\prod_{i\in I} f_i^{m_i} s\right)\right|.$$

Proof. Put $d = |\alpha|$. For every multi-index $b \in \mathbb{N}^I$ with $|b| \leq d$, put

$$a_b = [Z^\alpha]\left(\prod_i f_i^{b_i} s\right).$$

The set of these b is finite and nonempty, since it contains zero. Choose m on this set maximizing $|a_b|$. Each f_i has zero constant term, so every monomial of $\prod_i f_i^{b_i}$ has total degree at least $|b|$; this remains true if a factor is zero. Multiplication by s, which has no negative degrees, cannot lower that degree. Consequently terms of G of degree greater than d make no contribution to the coefficient at α. Formal substitution therefore gives the finite identity

$$[Z^\alpha](G((f_i)_i)s) = \sum_{|b|\leq d} [U^b]G\, a_b.$$

All coefficients $[U^b]G$ have absolute value at most one. The ultrametric inequality bounds the absolute value of this finite sum by $\max_{|b|\leq d}|a_b| = |a_m|$. The chosen m depends only on the f_i, s, α, so the bound holds for every G at once. □

Lemma 6.7.32. *Let L be a nonarchimedean valued field with valuation ring O. Let X, I, K be finite sets and let $n \geq 1$. Let $f_i \in L[[Z_x : x \in X]]$ have zero constant term, let $\Theta \in L[[Z_x : x \in X]]$, and let $H_c = G_c((f_i)_i)$ with $G_c \in O[[U_i : i \in I]]$, for $1 \leq c \leq n$. Take $A_{ck} \in O$ and set*

$$P(W) = \prod_{c=1}^{n} (H_c\Theta)\left(\left(\sum_{k\in K} A_{ck}W_{xk}\right)_{x\in X}\right).$$

For every $\beta \in \mathbb{N}^{X\times K}$, put $\nu_x = \sum_k \beta_{xk}$. There exist $\alpha_c \in \mathbb{N}^X$ and $e_c \in \mathbb{N}^I$ such that

$$\sum_c \alpha_c = \nu, \qquad |e_c| \le |\alpha_c| \le |\nu|,$$

and

$$|[W^\beta]P| \le \prod_{c=1}^{n} \left| [Z^{\alpha_c}] \left(\prod_i f_i^{e_{c,i}} \Theta \right) \right|.$$

Proof. Write $B_c = H_c\Theta$. The coefficient of the finite product defining P is the finite sum over all tuples $(\gamma_c)_{c=1}^n$ of nonnegative multi-indices on $X \times K$ with $\sum_c \gamma_c = \beta$, of

$$\prod_c [W^{\gamma_c}] B_c \left(\left(\sum_k A_{ck} W_{xk} \right)_x \right).$$

The indexing set is nonempty, since one may place β in the first copy and zero in the others. Choose a tuple whose summand has largest absolute value. The ultrametric inequality bounds $|[W^\beta]P|$ by that summand's absolute value. Put $\alpha_{c,x} = \sum_k \gamma_{c,xk}$. Then $\sum_c \alpha_c = \nu$.

Linear substitution gives the exact formula

$$[W^{\gamma_c}] B_c \left(\left(\sum_k A_{ck} W_{xk} \right)_x \right) = [Z^{\alpha_c}] B_c \prod_{x\in X} \left(\binom{\alpha_{c,x}}{(\gamma_{c,xk})_{k\in K}} \prod_{k\in K} A_{ck}^{\gamma_{c,xk}} \right).$$

Every multinomial coefficient is an integer and has absolute value at most one in a nonarchimedean valued field, by repeated use of the triangle inequality on sums of ones. The entries of A also have absolute value at most one. Hence

$$|[W^\beta]P| \le \prod_c |[Z^{\alpha_c}](H_c\Theta)|.$$

For each c, apply Lemma 6.7.31 with $s = \Theta$ and target α_c. It supplies e_c of degree at most $|\alpha_c|$ for which the corresponding monomial coefficient dominates that of $G_c((f_i)_i)\Theta$. Multiply these finitely many inequalities. Finally $\alpha_c \le \sum_d \alpha_d = \nu$ coordinatewise, so $|\alpha_c| \le |\nu|$. The argument also covers an empty variable set or an empty set K, since all coefficient expansions above remain finite and the zero multi-index is available. □

Lemma 6.7.33. *Use the normalized CM theta setting and the series $f_i = y(L_i(Z))$, R_μ, $\Theta = \prod_i \theta(L_i)^{m_i}$ of Lemma 6.7.29, with variable set Q. Let $p > 2$ be inert in K, put $\rho = 1/(p^2-1)$, $\gamma = p/(p^2-1)$, and assume $\mu_{i\tau} \in O$. Take exactly the maps r_a, coefficients λ_{ab}, subset S, odd exponents e_τ, multiplicities j_τ, series Ξ and degrees ν', ν'' satisfying the coupling hypotheses of Lemma 6.7.34; put $\nu = \nu' + \nu''$ and $J = \sum_{\tau\in S} j_\tau$. Suppose*

$$v_p(\varpi) = \rho, \qquad \Theta(\varpi Z) = W(Z) \exp\left(\frac{\varpi^{p+1}}{p} \Xi(Z) \right), \qquad W \in O[[Z]]^\times.$$

Then there are six multi-indices $\alpha_c \in \mathbb{N}^Q$ and six $e_c \in \mathbb{N}^I$, with $\sum_c \alpha_c = \nu$ and $|e_c| \le |\nu|$, such that

$$\prod_{c=0}^{5} \left| [Z^{\alpha_c}] \left(\prod_i f_i^{e_{c,i}} \Theta \right) \right|_p \ge p^{-r_0}, \qquad r_0 = \frac{J}{p-1} - J - \rho|\nu| - v_p(\nu''!).$$

Here $\nu''! = \prod_\tau \nu_\tau''!$. Moreover

$$r_0 \le -J, \qquad r_0 \le \gamma|\nu| - J - v_p(\nu'!) - v_p(\nu''!).$$

Proof. Choose the six scalars δ_c and the cancelling product

$$U = \prod_c \Theta(\delta_c Z)$$

supplied by Lemma 6.7.29. Its coefficients belong to R_μ, and $U(0) = 1$. We first check integrality after scaling. The parameter assertion Lemma 4.2.41 implies $y(\varpi z) \in O[[z]]$, with zero constant coefficient, since $v_p(\varpi) = \rho$. This assertion holds at any scalar of valuation at least ρ, not just the particular root chosen in that lemma. As the coefficients of each L_i are integral, $f_i(\varpi Z) = y(\varpi L_i(Z))$ is integral. An integral formal series in these zero-constant series remains integral. Therefore

$$U(\varpi Z) \in O[[Z]], \qquad U(\varpi Z)(0) = 1.$$

Put $F(Z) = \Theta(\varpi Z)$ and $\kappa = \varpi^{p+1}/p$. Then

$$|\kappa|_p = p^{1-(p+1)\rho} = p^{1-1/(p-1)} > 1,$$

because $p > 2$. All hypotheses of Lemma 6.7.34 hold for F, W, and the product $\prod_c F(\delta_c Z) = U(\varpi Z)$. Consequently, with

$$G(Z', Z'') = \Theta(Z' + Z'') \prod_{c=1}^{5} \Theta(\delta_c Z'),$$

that result gives

$$|\nu''!|_p \, |\varpi|_p^{|\nu|} |[(Z')^{\nu'}(Z'')^{\nu''}]G|_p = |\kappa|_p^J.$$

The scaling factor is exactly $\varpi^{|\nu'|+|\nu''|}$, since substitution of $\varpi Z', \varpi Z''$ multiplies each homogeneous coefficient by that power. Rearranging the displayed norm identity yields

$$|[(Z')^{\nu'}(Z'')^{\nu''}]G|_p = p^{(1-1/(p-1))J + \rho|\nu| + v_p(\nu''!)} = p^{-r_0}.$$

Apply Lemma 6.7.32 to six copies with all integral formal multipliers equal to one, and to the integral two-copy coefficient matrix

$$A_{c,0} = \delta_c, \qquad A_{c,1} = \mathbf{1}_{c=0}.$$

Its substituted product is precisely G, because $\delta_0 = 1$. The target is (ν', ν''), whose aggregate is ν. This gives the stated monomial witnesses and norm bound.

For the two final inequalities, each $e_\tau \geq 1$, hence

$$|\nu'| = \sum_{\tau \in S} p^{e_\tau} j_\tau \geq pJ, \qquad |\nu''| = J.$$

Since $\rho(p+1) = 1/(p-1)$, one has $\rho|\nu| \geq J/(p-1)$. Also $v_p(\nu''!) \geq 0$. Substitution in r_0 gives $r_0 \leq -J$. Finally Legendre's formula gives $v_p(\nu'!) \leq |\nu'|/(p-1)$. Using $\gamma = 1/(p-1) - \rho$ and $|\nu| = |\nu'| + J$, subtract the proposed second upper bound from r_0. The difference is exactly

$$v_p(\nu'!) - |\nu'|/(p-1) \leq 0.$$

This proves both inequalities, including the empty-coupling case. □

Lemma 6.7.34. *Let p be prime, $O = \mathcal{O}_{\mathbb{C}_p}$, and let Q be a finite set. For each odd positive integer a, let $r_a : Q \to Q$ be a map, and take $\lambda_{ab} \in O$ for $b \geq 0$, with $\lambda_{a0} \in O^\times$. Put*

$$\Gamma_a(Z) = \sum_{\tau \in Q} Z_\tau^{p^a} Z_{r_a(\tau)}, \qquad \Xi(Z) = \sum_{\substack{a \geq 1 \text{ odd} \\ b \geq 0}} \lambda_{ab} \Gamma_a(Z)^{p^b}.$$

Let $S \subseteq Q$, and choose odd positive integers e_τ for $\tau \in S$, such that

$$\tau, \sigma \in S, \quad a \leq e_\tau, \quad a \text{ odd}, \quad r_a(\sigma) = r_{e_\tau}(\tau) \implies (\sigma, a) = (\tau, e_\tau).$$

Let $j_\tau \geq 0$ for $\tau \in S$, and put

$$J = \sum_{\tau \in S} j_\tau, \quad \nu' = \sum_{\tau \in S} p^{e_\tau} j_\tau \, \mathbf{1}_\tau, \quad \nu'' = \sum_{\tau \in S} j_\tau \, \mathbf{1}_{r_{e_\tau}(\tau)}.$$

Suppose $W \in O[[Z]]^\times$, $\kappa \in \mathbb{C}_p$ with $|\kappa|_p > 1$, and $F = W \exp(\kappa \Xi)$. Let $n \geq 1$, let $\delta_0, \ldots, \delta_{n-1} \in \mathbb{C}_p$ with $\delta_0 = 1$, and suppose

$$U(Z) = \prod_{c=0}^{n-1} F(\delta_c Z) \in O[[Z]], \qquad U(0) = 1.$$

Then, for

$$G(Z', Z'') = F(Z' + Z'') \prod_{c=1}^{n-1} F(\delta_c Z'),$$

one has the exact attained coefficient norm

$$\left| \prod_{\tau \in Q} \nu''_\tau! \right|_p \left| [(Z')^{\nu'} (Z'')^{\nu''}] G \right|_p = |\kappa|_p^J.$$

Proof. **Repeated derivatives retain their leading reduction.** The sum defining Ξ is well-defined coefficientwise: a term with indices a, b has degree $(p^a + 1)p^b$, and only finitely many pairs have bounded degree. Put $V_\tau = \partial \Xi / \partial Z_{r_{e_\tau}(\tau)}$. Since W is an integral unit, $B_x = W^{-1} \partial_x W$ is integral for every x. Formal differentiation gives

$$\partial_x F = (\kappa \partial_x \Xi + B_x) F.$$

Only the first factor of G involves Z'', so its logarithmic derivative in Z''_x is $\kappa(\partial_x \Xi)(Z' + Z'') + B_x(Z' + Z'')$. All series in this expression except κ have integral coefficients. If $q \in O[[Z', Z'']]$, then

$$\partial_{Z''_x}(qG) = \kappa q_{\text{new}} G, \qquad q_{\text{new}} = q(\partial_x \Xi)(Z' + Z'') + \kappa^{-1}\big(\partial_{Z''_x} q + q B_x(Z' + Z'')\big).$$

The series q_{new} is integral, and its reduction modulo the maximal ideal is the product of the reductions of q and $(\partial_x \Xi)(Z' + Z'')$, because $|\kappa^{-1}|_p < 1$. Starting with $q = 1$, differentiate j_τ times in $Z''_{r_{e_\tau}(\tau)}$, for every $\tau \in S$. This gives an integral q such that

$$\partial_{Z''}^{\nu''} G = \kappa^J q G, \qquad \overline{q(Z', 0)} = \prod_{\tau \in S} \overline{V_\tau(Z')}^{j_\tau}.$$

The selected coefficient is a unit. In the residue field of characteristic p, differentiation annihilates the terms of Ξ with $b > 0$, and also annihilates the derivative of $Z_\sigma^{p^a}$. Hence

$$\overline{V_\tau} = \sum_{\substack{a \geq 1 \text{ odd} \\ \sigma \in Q \\ r_a(\sigma) = r_{e_\tau}(\tau)}} \overline{\lambda_{a0}} Z_\sigma^{p^a}.$$

Set $Z_\sigma = 0$ for $\sigma \notin S$. The uniqueness hypothesis says that among all terms of this series of total degree at most p^{e_τ}, exactly one remains: $\overline{\lambda_{e_\tau,0}} Z_\tau^{p^{e_\tau}}$. Its coefficient is nonzero. Products of series each having a unique nonzero term of smallest total degree have the product of those terms as their unique term of smallest total degree: expanding the product, any use of a higher-degree term raises the total degree. The same assertion holds for powers. Since $\overline{U}(0) = 1$, it follows that the coefficient at ν' of $q(Z', 0)U(Z')$ reduces to

$$\prod_{\tau \in S} \overline{\lambda_{e_\tau,0}}^{j_\tau} \neq 0.$$

Setting the variables outside S to zero does not change this coefficient, because ν' is supported on S. Its coefficient before reduction is integral and has norm one.

Pass from derivatives to the coefficient. By the product hypothesis, $G(Z', 0) = U(Z')$. Extract the coefficient at $(Z')^{\nu'}$ after setting $Z'' = 0$ in the derivative identity. The elementary coefficient formula for ordinary derivatives gives

$$\left(\prod_{\tau \in Q} \nu_\tau''! \right) [(Z')^{\nu'} (Z'')^{\nu''}] G = \kappa^J [Z^{\nu'}](q(Z, 0)U(Z)).$$

Taking norms and using the unit coefficient just proved yields the asserted equality. This argument includes $S = \varnothing$ or $J = 0$; the empty product of leading coefficients is one. □

Lemma 6.7.35. *Put $\omega = (1 + \sqrt{-d})/2$, let ζ be the fixed primitive q_1-th root, and put $D_{\mathrm{rel}} = \mathrm{cyc}'_{q_1}(\zeta)$, where cyc_{q_1} is the cyclotomic polynomial. Use the prescribed finite idele*

$$\alpha_w = \begin{cases} D_{\mathrm{rel}}^{-1}, & \omega \in w, \\ 1, & \omega \notin w, \end{cases} \qquad \mathfrak{a} = E \cap \alpha \widehat{\mathcal{O}}_E.$$

Let $\chi_{\mathrm{fin}} = \upsilon_f |\cdot|^{-1/2}$ be the fixed algebraic finite splitting character: its exponents are zero on the chosen CM type and minus one on the conjugate type. Use the same fixed vacuum root and period factor as the arithmetic theta normalization:

$$s_0^f = \chi_{\mathrm{fin}}(\alpha)^{-1}, \qquad \beta = s_0 / u_{\mathrm{CS}}, \qquad |\iota u_{\mathrm{CS}}|_p = 1 \quad \text{for every } p, \iota.$$

For $\phi_\tau(z) = \iota(\overline{\tau(z)})$, let α_{ϕ_τ} denote the image of the component of α at the prime induced by ϕ_τ. Then, for every prime p, every prime identification $\iota : \mathbb{C} \to \mathbb{C}_p$, and every $\tau \in \Phi$,

$$|\iota\beta|_p = |\alpha_{\phi_\tau}|_p^{-1}, \qquad |\iota(\beta\overline{\tau(w)})|_p \leq 1 \quad (w \in \mathfrak{a}).$$

In particular β is a unit at every nonsplit prime of K.

There exist a finite set I, vectors $w_i \in \mathfrak{a}$, and integers $c_i \geq 6fb$, chosen before all p, ι, such that

$$\sum_{i \in I} c_i \, \tau(w_i) \overline{\sigma(w_i)} = M \mathbf{1}_{\tau = \sigma} \qquad (\tau, \sigma \in \Phi).$$

For every p, ι there exists $i_0 \in I$, allowed to depend on p, ι, such that

$$|\iota(\beta\overline{\tau(w_{i_0})})|_p = 1 \qquad \textit{simultaneously for every } \tau \in \Phi.$$

Put $u_i = w_i/\bar{\pi}_M$ and $v_{\mathrm{loc}} = \iota(\pi_M\beta)$. Then

$$\sum_i c_i\tau(u_i)\overline{\sigma(u_i)} = \mathbf{1}_{\tau=\sigma}, \qquad v_{\mathrm{loc}}\iota(\overline{\tau(u_i)}) = \iota(\beta\overline{\tau(w_i)}).$$

At every nonsplit prime p, every u_i is integral at every place above p, and $|v_{\mathrm{loc}}|_p = 1$. No new vacuum scalar or theta functional is chosen.

Proof. **1. The exact finite-character valuation and period factor.** The infinity type of χ_{fin} means that on principal finite ideles $z \in E^\times$ its value is $\prod_{\tau\in\Phi}\overline{\tau(z)}$. On finite idele units its image is finite. Indeed the unit group is compact and profinite, and a continuous character into the circle has finite image, since the circle has no small subgroups. For any finite idele x, finiteness of the ideal class group gives a positive power whose ideal is principal, say the ideal of z. Raising to a further power kills the character of the remaining finite unit. Consequently for some integer $n > 0$,

$$\chi_{\mathrm{fin}}(x)^n = \prod_{\tau\in\Phi}\overline{\tau(z)}, \qquad x^n \text{ and } z \text{ have the same finite valuations.}$$

Applying ι, taking absolute values and then the positive n-th root gives

$$|\iota\chi_{\mathrm{fin}}(x)|_p = \prod_{\tau\in\Phi}|x_{\phi_\tau}|_p. \tag{1}$$

The absolute value of α_{ϕ_τ} is independent of τ. The condition $\omega \in w_{\phi_\tau}$ reads $|\iota\bar{\omega}|_p < 1$, independent of τ, because these embeddings fix K. Also all conjugates of D_{rel} have equal valuations at any fixed finite prime. This can be seen without a different comparison: write the derivative as the product of $\zeta - \zeta^a$ over the other primitive conjugates. For v prime to q_1, each quotient $(1-\zeta^{v(a-1)})/(1-\zeta^{a-1})$ is an algebraic integer, by a finite geometric sum; its reciprocal is also an algebraic integer by choosing the inverse of v modulo q_1. It is a unit. The remaining root-of-unity factors are units as well. Thus a Galois conjugate of D_{rel} differs from it by a unit.

Write the common absolute value as A_p. Equation (1) yields $|\iota\chi_{\mathrm{fin}}(\alpha)|_p = A_p^f$; the specified f-th-root equation gives $|\iota s_0|_p = A_p^{-1}$. For the specified common jet-pair and vacuum-scale choice, the all-prime unit assertion of Lemma 4.2.3 gives $|\iota u_{\mathrm{CS}}|_p = 1$. Hence

$$|\iota\beta|_p = A_p^{-1}, \qquad |\iota(\beta\overline{\tau(w)})|_p = |(\alpha^{-1}w)_{\phi_\tau}|_p \le 1 \quad (w \in \mathfrak{a}). \tag{2}$$

This proves the period assertions apart from the nonsplit specialization below.

2. A fixed cyclotomic fractional frame. Abbreviate $q = q_1$ and $U_0 = (d+1)/4$. Every prime dividing q divides U_0. For odd primes this follows from $q_0 \mid 2(d+1)$ and the tower primes $2, 3$; at 2, $d \equiv 7 \pmod 8$ makes U_0 even. Choose z_0, $0 \le z_0 < q$, such that

$$U_0 z_0^2 + z_0 + 1 = qe_0 \tag{3}$$

for an integer $e_0 > 0$. Such a residue exists because $z \mapsto U_0 z^2 + z$ is a permutation modulo q: a difference factors as $(z - z')(1 + U_0(z + z'))$, whose second factor is a unit modulo q. Put $t_0 = \bar{\omega} + U_0 z_0$. Then

$$t_0 + \bar{t}_0 = 1 + 2U_0 z_0, \quad t_0\bar{t}_0 = U_0 q e_0, \quad (\omega + U_0 z_0)t_0 = U_0 q e_0. \tag{4}$$

For each rational prime $\ell \mid q$, write $q = \ell^{a_\ell+1}Q_\ell$, with $\ell \nmid Q_\ell$, and put $r_\ell = q/\ell$, $a_\ell^* = \zeta^{r_\ell}$. There is $V_\ell \in \mathcal{O}_E$, dividing Q_ℓ, such that

$$D_{\mathrm{rel}}(a_\ell^* - 1)Q_\ell = qV_\ell. \tag{5}$$

Here is an elementary verification. The cyclotomic identity $\mathrm{cyc}_{Q_\ell}(T^{\ell^{a_\ell+1}}) = \mathrm{cyc}_q(T)\mathrm{cyc}_{Q_\ell}(T^{\ell^{a_\ell}})$, differentiated at ζ, shows that $\ell^{a_\ell+1}$ divides $D_{\mathrm{rel}}\mathrm{cyc}_{Q_\ell}(\zeta^{\ell^{a_\ell}})$. Since $\mathrm{cyc}_{Q_\ell}(T) \mid T^{Q_\ell} - 1$, this latter cyclotomic value divides $a_\ell^* - 1$. Thus q divides the left side of (5). On the other hand $T^q - 1 = (T^{r_\ell} - 1)\mathrm{cyc}_q(T)R(T)$ for an integral polynomial R. Differentiating and multiplying by ζ gives $q = D_{\mathrm{rel}}(a_\ell^* - 1)R(\zeta)\zeta$. Together with (5), cancellation of q gives $Q_\ell = V_\ell R(\zeta)\zeta$, proving the divisibility assertion.

Put $\gamma_\ell = t_0 Q_\ell/q$, and form the finite family

$$v_{\ell,h,k,i} = \zeta^h \left(\mathbf{1}_{k=0}(a_\ell^*)^i + \gamma_\ell((a_\ell^*)^i - (a_\ell^*)^k)\right), \quad 0 \le h < r_\ell, \quad 0 \le k, i < \ell. \tag{6}$$

Every vector in (6) lies in $\mathfrak{a}$. If $\omega \in w$, (5) shows that $D_{\mathrm{rel}}\gamma_\ell(a_\ell^* - 1) = t_0 V_\ell$ is integral, so the required $D_{\mathrm{rel}}v$ is integral at w. If $\omega \notin w$, and $w \nmid q$, integrality is immediate. If $w \mid q$ while ω is a unit, then $\bar\omega \in w$, because every prime divisor of q divides $U_0 = \omega\bar\omega$. Hence $\omega + U_0 z_0$ is a unit at w, and the last equation in (4) shows that t_0/q is integral there. Thus γ_ℓ, and hence v, is integral at w. This verifies membership at every finite place.

The Gram sum of the ℓ-family is $C_\ell \mathbf{1}_{\tau=\sigma}$, where

$$C_\ell = q + Q_\ell(1 + 2U_0(z_0 + \ell Q_\ell e_0)). \tag{7}$$

For clarity, expand the two bracketed factors in (6). The sums of the powers of either primitive ℓ-th root are zero. If $G = \sum_{i<\ell} \tau(a_\ell^*)^i\overline{\sigma(a_\ell^*)^i}$, the sum over k, i is $G(1 + \gamma_\ell + \bar\gamma_\ell + 2\ell\gamma_\ell\bar\gamma_\ell)$. Multiplication by the sum over $h < r_\ell$ turns G into the complete root-of-unity sum $q\mathbf{1}_{\tau=\sigma}$. Substituting (4) in the diagonal expression gives exactly (7).

Let $C = \sum_{\ell\mid q} C_\ell$. This positive integer is prime to q. Modulo a prime $\ell_0 \mid q$, every summand with $\ell \ne \ell_0$ vanishes, since Q_ℓ is divisible by ℓ_0. The remaining summand is $Q_{\ell_0} \not\equiv 0$, since q and U_0 vanish modulo ℓ_0.

We retain a crude explicit bound. From (3), $e_0 \le 2U_0 q$, while $z_0 < q$, $Q_\ell \le q$, and $\ell Q_\ell \le q$. Equation (7) gives $C_\ell \le 2q + 2U_0 q^2 + 4U_0^2 q^3 \le 8U_0^2 q^3$. There are at most q prime factors, so in particular

$$C \le 8U_0^2 q^5. \tag{8}$$

All this data was chosen without any prime identification.

3. The common unit row. The powers ζ^i, $0 \le i < q$, form a frame of length q, by root-of-unity orthogonality. Their union with (6) contains a vector that has a unit normalized coefficient at all CM embeddings simultaneously, for every prime identification. If $|\iota\beta|_p = 1$, use $1 = \zeta^0$.

Otherwise (2) and the definition of α imply that $p \mid q$, and that ω belongs to every prime induced by ϕ_τ. Use the one vector

$$v_{p,0,1,0} = \gamma_p(1 - a_p^*).$$

Equation (5) says $D_{\mathrm{rel}}v_{p,0,1,0} = -t_0 V_p$. At each of those primes, $t_0 \equiv 1$: ω and U_0 vanish there. Also V_p is a unit there, since it divides Q_p, which is prime to p. Formula (2) therefore gives

$$|\iota(\beta\overline{\tau(v_{p,0,1,0})})|_p = |\phi_\tau(t_0 V_p)|_p = 1 \quad \text{for every } \tau. \tag{9}$$

The selected index depends on p, ι, but the finite family does not.

4. The exact length M and large multiplicities. Put $R = 6fb$, an integer. The admissible-data inequalities give $d \le b$, $q \le b$, $f \le q \le b$, and $b \ge 7$. Indeed $q \mid b$; $f = \varphi(q) \le q$; and $\log\log b \ge 10^{12} C_P \ge 2d$ implies $b \ge e^d$. Thus

$$(dq)^6(R+1) \le 7b^{14} \le b^{20} \le M. \tag{10}$$

As $U_0 \le d$ and $d \ge 7$, $9U_0^2 \le d^6$. Using (8),

$$R(C+q) + qC \le 9U_0^2 q^6 (R+1) \le (dq)^6(R+1) \le M. \tag{11}$$

Because $\gcd(q, C) = 1$, every integer at least $(q-1)(C-1)$ is a nonnegative combination of q and C. One short proof is to choose $B \in \{0, \dots, q-1\}$ with BC congruent to the given integer modulo q; its difference from BC is a multiple of q greater than $-q$, hence nonnegative. Apply this to $M - R(C+q)$, which is at least qC by (11). Obtain $A, B \ge 0$ with $Aq + BC = M - R(C+q)$. Give each root-of-unity vector multiplicity $A + R$, and every vector of (6) multiplicity $B + R$. Their full two-index Gram sum is

$$((A+R)q + (B+R)C)\mathbf{1}_{\tau=\sigma} = M\mathbf{1}_{\tau=\sigma}.$$

Every multiplicity is at least R, and the unit row of Section 3 is retained with positive multiplicity. This is the required single fixed family.

5. Nonsplit primes and the resolution at scale $\bar\pi_M$. Every rational prime dividing q splits in K. For odd primes, $-d \equiv 1 \pmod p$, so the defining quadratic has two distinct roots. At 2, the polynomial of ω reduces to $T(T-1)$, again with distinct roots. Thus a nonsplit prime does not divide q. Since $D_{\mathrm{rel}} \mid q$ (differentiate $T^q - 1 = \mathrm{cyc}_q(T)R(T)$ at ζ), the idele α is a unit at all its primes. Equation (2) proves that β is a unit, and membership in $\mathfrak{a}$ proves that all w_i are integral there.

The primes p_0, p_1 are also split in K: they are congruent to one modulo d, so $\chi_K(p_i) = 1$; neither equals d. Therefore π_M and $\bar\pi_M$ are units at every nonsplit prime. Dividing the Gram identity by $\tau(\bar\pi_M)\overline{\sigma(\bar\pi_M)} = \bar\pi_M \pi_M = M$ gives the claimed resolution. Finally $\pi_M \beta\, \overline{\tau(w_i/\bar\pi_M)} = \beta\overline{\tau(w_i)}$, which proves the exact linear-form identity and the remaining unit assertion. □

Lemma 6.7.36. *Write $\theta_x(F) = \theta(\rho(\mathrm{fv}(x))F)$. Let F belong to the finite part and satisfy*

$$\rho_f(\alpha^{-1}\pi_M \lambda_f)F = F \qquad (\lambda \in \mathfrak{a}^{12}).$$

Fix a prime embedding $\iota : \mathbb{C} \hookrightarrow \mathbb{C}_p$, and suppose $|\iota\theta_x(F)|_p \le 1$ for every finite x. Then for every complex-linear functional $\mathscr{L}$ on the finite part and every finite x, there exists $a_0 \in (\mathcal{O}_E/\mathfrak{m})^{12}$ with

$$\Big|\iota\Big(M^{12f}\mathscr{L}(F)\theta_x(v^0)\Big)\Big|_p \le |\iota\mathscr{L}(F_{\mathfrak{m},a_0})|_p\,.$$

No restriction on $p \mid M$ is imposed.

Proof. **The exact lattice and finite pairing.** Put $A_1 = \sqrt{2\pi/\sqrt{d}}$ and $\Gamma = \{A_1(\tau\lambda_c)_{\tau,c} : \lambda \in \mathfrak{a}^{12}\}$. This lattice is self-dual for $E_1(z,w) = \pi^{-1}\operatorname{Im}\sum z_{\tau,c}\bar w_{\tau,c}$. Indeed (WD2) gives $\mathfrak{a}\bar{\mathfrak{a}} = \mathfrak{D}_{E/K}^{-1}$. The different tower formula gives $\jmath\mathfrak{a}\bar{\mathfrak{a}} = \mathfrak{D}_{E/\mathbb{Q}}^{-1}$. The trace-dual ideal of $\mathfrak{a}$, for the alternating trace form $\mathrm{Tr}_{E/\mathbb{Q}}(\jmath\lambda\bar\mu)$, is therefore $\jmath^{-1}\mathfrak{D}_{E/\mathbb{Q}}^{-1}\bar{\mathfrak{a}}^{-1} = \mathfrak{a}$. This trace form is $-E_1$ in the coordinates above, which has the same integral dual. The different and annihilator normalizations are also checked explicitly in Lemma 4.1.10 and Lemma 4.1.3.

Write

$$G = \Gamma/\pi_M\Gamma, \qquad Y = \bar{\pi}_M^{-1}\Gamma/\Gamma, \qquad D_1 = M^{12f}.$$

Both finite groups have cardinal D_1: multiplication by π_M on the underlying rational space has determinant of absolute value $\mathrm{Norm}_{E/\mathbb{Q}}(\pi_M)^{12} = M^{12f}$. The pairing

$$\chi_y(\lambda) = \exp\left(2i\,\mathrm{Im}\sum_{\tau,c}\lambda_{\tau,c}\bar{y}_{\tau,c}\right) \tag{1}$$

is well-defined on $G \times Y$ and perfect. Well-definedness uses the adjoint of multiplication by π_M, which is multiplication by $\bar{\pi}_M$. If one argument pairs trivially with every other, self-duality puts it in the indicated denominator lattice; cardinal equality then proves perfection. Choose rational representatives for both quotients, identifying their coordinates with vectors in $\mathfrak{a}^{12}$ and $\bar{\pi}_M^{-1}\mathfrak{a}^{12}$, respectively.

Averaging with no denominator. For a rational vector u, let $T_u = \rho(0, u_f)$, and for $\lambda \in \mathfrak{a}^{12}$ let $S_\lambda = \rho_f(\alpha^{-1}\lambda_f)$. The signed operators S_λ are a representation of the additive integral lattice: expand (WD8), use $c_0 + \bar{c}_0 = 1$, and use the integral annihilator for $\psi_{E,f}(\jmath\alpha\bar{\alpha}\,\cdot)$. They fix the vacuum. The exact raw translation formula of Lemma 4.2.2 identifies their signed real lattice action. Thus the fixed space of all S_λ in the finite part has dimension one: its entire image belongs to the principal theta line for Γ, of dimension one by Theorem A.2.16, with Hermitian form $\pi^{-1}\sum z\bar{w}$. The entire map is injective and the vacuum is a nonzero vector in that line, by Lemma 4.2.2 and Lemma 4.1.10. Hence that fixed space is exactly $\mathbb{C}v^0$.

For $y \in Y$, the vector $T_{-y}F$ still has the specified $\pi_M\Gamma$ signed periods: its commutator with each such period is one by (1). Consequently the finite average

$$\mathcal{A}T_{-y}F := \sum_{\lambda\in G} S_\lambda T_{-y}F = b_y v^0 \tag{2}$$

is defined independently of the representatives and is fixed by every S_λ. No division by $|G|$ occurs. The raw projective law and rational invariance, with their signs as in Lemma 4.2.2, give

$$T_y S_\lambda T_{-y} = \chi_y(\lambda) S_\lambda.$$

Character orthogonality on the perfect pairing (1) now gives the exact vector identity

$$\sum_{y\in Y} b_y T_y v^0 = \sum_{y\in Y} T_y \mathcal{A} T_{-y} F = D_1 F. \tag{3}$$

Indeed the coefficient of $S_\lambda F$ is zero for nonzero $\lambda \in G$ and D_1 at zero.

Applying a finite translate and the theta functional to (2) gives

$$|\iota(b_y\theta_x(v^0))|_p \le 1. \tag{4}$$

Every summand is a finite theta value of F times a root of unity: this follows by composing the raw and signed operators (WD7)–(WD8). The assumed integrality and the ultrametric triangle inequality prove (4), also when $p \mid M$.

Each representative y has $\bar{\pi}_M y \in \mathfrak{a}^{12}$. Thus Lemma 6.7.37 gives $T_y v^0 = \sum_{a_0} \xi_{y,a_0} F_{\mathfrak{m},a_0}$ with roots of unity ξ_{y,a_0}. Apply $\mathscr{L}$ to (3), multiply by $\theta_x(v^0)$, and substitute these expansions:

$$D_1 \mathscr{L}(F)\theta_x(v^0) = \sum_{y,a_0} \xi_{y,a_0}(b_y\theta_x(v^0))\mathscr{L}(F_{\mathfrak{m},a_0}).$$

All coefficients on the right have prime-adic norm at most one by (4). The norm of this finite sum is at most the largest norm of an indicator value. Choose a residue class attaining that finite maximum. This is the required inequality. □

Lemma 6.7.37. *Put $\mathfrak{a} = E \cap \alpha\widehat{\mathcal{O}}_E$, $\mathfrak{m} = (\pi_M)$ and $A = \Sigma(\mathfrak{m})$. For $a_0 \in (\mathcal{O}_E/\mathfrak{m})^{12}$, let Ψ_{a_0} be its class indicator in the integral position coordinates at A, and put*

$$F_{\mathfrak{m},a_0} = v_1 \otimes (\Psi_{a_0} \otimes_A v^0).$$

For every $u \in E^{12}$ satisfying $\bar{\pi}_M u \in \mathfrak{a}^{12}$, there are roots of unity $\xi_{a_0} \in \mathbb{C}$ such that, as vectors of the prescribed model,

$$\rho(0, u_f)v^0 = \sum_{a_0 \in (\mathcal{O}_E/\mathfrak{m})^{12}} \xi_{a_0} F_{\mathfrak{m},a_0}.$$

Consequently these coefficients have norm one under every prime embedding.

Proof. Set $y = \alpha^{-1}u_f$. The hypothesis is precisely $\bar{\pi}_M y \in \widehat{\mathcal{O}}_E^{12}$. At a place in A, $\bar{\pi}_M$ is a unit, so y_A is integral. Outside $A \cup \bar{A}$, both π_M and $\bar{\pi}_M$ are units, so y is integral. At the places of A, the conjugate vector satisfies

$$\pi_M \bar{y} \in \mathcal{O}_A^{12}. \tag{1}$$

Here the selected places and their conjugates are disjoint because the principal level primes are split and (π_M) selects exactly one member of each pair.

First remove the coordinates outside $A \cup \bar{A}$. A raw integral finite translation acts on their vacuum by a root of unity. Indeed its vacuum coefficient has modulus one and is a finite additive-character value, by (WD5); the evaluation identity and invariant norm in Lemma 4.1.10(1), or the equality case of Cauchy–Schwarz, show that the translated unit vacuum is a scalar multiple of itself. That scalar is the conjugate of its vacuum coefficient and hence a root of unity. The vacuum and Heisenberg operators factor over the selected and remaining coordinates. Disjoint finite supports have trivial cross bicharacter. Thus it remains to expand the selected translate, with one overall root of unity retained.

Use $\psi_0(t) = \psi_{E,f}(\jmath\alpha\bar{\alpha}t)$ and the exact raw operator of Lemma 4.1.3(2). Its action on the position box $B = \mathbf{1}_{\mathcal{O}_A^{12}}$ is

$$(R_A(y)B)(x) = \psi_0\Big(\bar{y}^{\mathsf{T}}(2x + y)_A/2\Big)\, B(x + y_A) = \psi_0\Big(\bar{y}^{\mathsf{T}} y_A/2\Big)\, \psi_0(\bar{y}^{\mathsf{T}} x_A) B(x). \tag{2}$$

The second equality uses the already proved integrality of y_A. The arithmetic normalization in Lemma 4.1.3 says that the integral lattice is its own annihilator for $\psi_0(\bar{z}^{\mathsf{T}}x)$. Equation (1) therefore implies that the last character in (2) is trivial on $\pi_M\mathcal{O}_A^{12}$. It is constant on every class modulo $\mathfrak{m}$.

Choose any integral representative z_0 of a_0. The scalar

$$\xi'_{a_0} = \psi_0\Big(\bar{y}^{\mathsf{T}} y_A/2 + \bar{y}^{\mathsf{T}}(z_0)_A\Big)$$

is independent of the representative by (1), and is a root of unity because a finite adelic additive character has finite order at each point. Thus the equality of position functions is exactly

$$R_A(y)B = \sum_{a_0} \xi'_{a_0} \Psi_{a_0}. \tag{3}$$

This is an expansion of a character on residue classes, not an average over characters, and has no denominator.

By Lemma 4.1.3(2)–(4), the fixed map $\Psi \mapsto \Psi \otimes_A v^0$ takes (3) to the equality of the actual selected coherent vectors. Its image of B is the same vacuum, and its raw intertwining has exactly the phase used in (2). Inserting v_1 leaves the positive real vacuum fixed, again by clause (4), and leaves all finite factors unchanged. Restoring the overall root of unity from the remaining finite coordinates gives the asserted coefficients ξ_{a_0}. Every root of unity has prime-adic norm one under every embedding, which proves the last assertion. □

7 Regular twist families: congruences and local loss

This section proves that every datum has a regular family of twists (Theorem 7.3.1), the arithmetic input of Theorem C. A regular family (Definition 6.1.3) consists of one m-fold twist θ_ι for each prime identification $\iota \mid \ell$, with modulus prime to ℓ, such that the inverse ratios of Hecke L-values at the ramified critical pairs form a family of height at most x_1 and the denominators of the projections to the spaces of lifts are bounded by numbers whose sum over all primes is at most β_{den}.

The twist is chosen one prime at a time, and nothing ties the choices at different primes together. The price of the choice at ℓ consists of multiples of the ℓ-adic valuations of a few integers fixed by the datum and a local loss at the places above ℓ. Weighted with $\log \ell$, the valuations of a fixed integer sum over all primes to at most its logarithm, and this is why the prices add up to an amount that the denominator budget absorbs (Proposition 7.3.3). At one prime three inputs are needed: a twist that makes the Selmer groups of finitely many Galois representations small and the ratios of L-values ℓ-adically close to units, for all its powers τ^j, $1 \le j \le m$, at once, which is the twisting theorem (Theorem 7.4.3); the Galois representations to which it is applied, the main summands attached to the Hecke eigensystems of the good forms (Proposition 7.5.1); and a passage from Selmer groups to denominators. A denominator at ℓ measures congruences between lifts and the forms orthogonal to them, and such congruences produce Galois cohomology classes, after Ribet and Mazur–Wiles [241, 197, 327] and, for unitary groups, Bellaïche–Chenevier [20, 21, 19]. Here the classes are controlled through a common Ribet element, whose leading coefficient is bounded by a Selmer length, a ramification term, the local loss above ℓ and the odd classes of the Tate twists of a CM field (Theorem 7.6.6).

Section 7.1 comes first: it fixes the conventions of the section on class field theory, p-adic Hodge theory, Galois cohomology and ℓ-adic coefficients, and derives from published theorems what is used about the Galois representations attached to eigenforms on definite unitary groups. Section 7.2 sets up the local and global vocabulary and proves the bound for the odd classes (Theorem 7.2.8). Section 7.3 proves the existence of regular families from a twist with few congruences at one prime (Proposition 7.3.2) and the sum of the prices. The three inputs at one prime follow: the twisting theorem (Section 7.4), the main summands (Section 7.5) and the denominators, with Ribet's element and prime triangles of auxiliary places (Section 7.6). Section 7.7 bounds the local loss above ℓ. From earlier sections it uses the ramification and the sizes of the datum, the integral theta jets of Section 4, the exchange identity and the norms of lifts of Section 6, and the equality of traces of Section 5.

7.1 Galois representations of eigenforms on definite unitary groups

The section opens with four conventions used throughout Section 7 and in the Galois-theoretic quotations of the Appendix: class field theory, normalised so that uniformisers correspond to arithmetic Frobenius elements [9, 224, 260, 297]; p-adic Hodge theory, with Fontaine's period rings and Hodge–Tate weights normalised so that the cyclotomic character has weight 1 [85, 86, 44]; continuous Galois cohomology, with local and Poitou–Tate duality and the Greenberg–Wiles formula [265, 295, 201, 225, 63]; and ℓ-adic coefficients, automorphic representations and Satake parameters, in the normalisations of [58, 49, 109, 122, 261, 60, 15, 68].

The congruences of Section 7 are congruences between Hecke eigensystems of algebraic modular forms on definite unitary groups [110], and they become Galois cohomology through the Galois representations attached to these eigensystems. The rest of the section derives what is used about these representations, with explicit normalisations, from published theorems quoted in the Appendix: base change to GL_n [177, 185], the Galois representations of polarised regular

algebraic cuspidal representations [15, 276, 56], and the local Langlands correspondence with supercuspidal supports [122, 130, 254, 318]. For the construction of these representations see also [58], for the endoscopic classification [209, 156], for local–global compatibility [302, 47, 48, 16], for complex conjugation [300], for automorphy lifting [305] and for families and Selmer groups [21]. Weil–Deligne representations and conductors rest on Grothendieck's monodromy theorem and Serre's Artin conductor [267, 263].

The main statement, Theorem 7.1.4, attaches to an automorphic representation of a definite unitary group a conjugate self-dual Galois representation with the Hecke–Frobenius relation at the unramified places. Its local–global compatibility is given at the split places not above ℓ (Theorem 7.1.8), at the places above ℓ (Theorem 7.1.9) and for depth-zero parahoric types (Theorem 7.1.11). The proofs pass through the discrete spectrum of GL_n [207, 292, 149, 269, 230], through Zelevinsky's segments [332, 24], through the Weil–Deligne description of crystalline representations [85, 86, 22] (for modular forms the p-adic Hodge theory at ℓ goes back to [76, 247]), and, for depth-zero types, through twisted spherical blocks (Proposition 7.1.12), proved from Roche's equivalence and the spherical Hecke algebra [243, 248, 50, 23, 80]; for types of depth zero see [217, 218, 46].

The section closes with three further inputs of Section 7: a Higman operator that exhibits algebraic modular forms as direct summands of induced modules over a group ring (Proposition 7.1.14; see [62]), the form of freeness behind the method of Taylor–Wiles [301, 60]; the ℓ-adic avatars of algebraic Hecke characters (Theorem 7.1.15), with the Bloch–Kato Selmer groups (Definition 7.1.16; [28]); and the multiplicities of depth-zero types of compact type, specialised from Shotton [278] (Theorem 7.1.18).

Class field theory is normalised as in [224] and [9]: uniformisers correspond to arithmetic Frobenius elements. For a non-archimedean local field F_v, $\mathrm{Art}_{F_v}\colon F_v^\times \to G_{F_v}^{ab}$ is the local Artin map and F_v^{ur} the maximal unramified extension; for a number field F, $\mathrm{Art}_F\colon C_F \to G_F^{ab}$ is the global Artin map and F^{ab} the maximal abelian extension. The **norm group** of a finite abelian extension E/F (respectively E_w/F_v) is $\mathrm{N}_{E/F}C_E \subseteq C_F$ (respectively $\mathrm{N}_{E_w/F_v}E_w^\times \subseteq F_v^\times$).

Notation for p-adic Hodge theory is that of [85] and [44]. Let K be a finite extension of $\mathbb{Q}_p$, G_K its absolute Galois group and $\mathbb{C}_p$ the completion of $\overline{\mathbb{Q}}_p$. For a perfectoid field L, $L^\flat$ denotes its tilt. Fix a compatible system $\underline{\zeta} = (\zeta_{p^n})_{n\geq 0}$ of p-power roots of unity. The period rings are the following:

- $A_{\mathrm{inf}} = W(\mathcal{O}_{\mathbb{C}_p^\flat})$, with $\theta\colon A_{\mathrm{inf}} \to \mathcal{O}_{\mathbb{C}_p}$;
- B_{dR}^+, the $\ker\theta$-adic completion of $A_{\mathrm{inf}}[1/p]$, and $B_{\mathrm{dR}} = B_{\mathrm{dR}}^+[1/t]$, where $t = \log[\underline{\zeta}]$, with $\mathrm{Fil}^i B_{\mathrm{dR}} = t^i B_{\mathrm{dR}}^+$;
- $A_{\mathrm{cris}} \subset B_{\mathrm{cris}}^+$ and $B_{\mathrm{cris}} = B_{\mathrm{cris}}^+[1/t]$, with Frobenius φ;
- B_{st};
- A_{max}, B_{max}^+, B_{max} (Colmez): with $\varepsilon = (1, \zeta_p, \zeta_{p^2}, \dots) \in \mathcal{O}_{\mathbb{C}_p^\flat}$ given by $\underline{\zeta}$, $\mu = [\varepsilon] - 1$ and $\xi = \sum_{i=0}^{p-1}[\varepsilon^{1/p}]^i \in A_{\mathrm{inf}}$ (a generator of $\ker\theta$, with $\xi\,([\varepsilon^{1/p}] - 1) = \mu$), A_{max} is the p-adic completion of $A_{\mathrm{inf}}[X]/(pX - \xi)$, $B_{\mathrm{max}}^+ = A_{\mathrm{max}}[1/p]$ and $B_{\mathrm{max}} = B_{\mathrm{max}}^+[1/\mu]$, with the Frobenius φ and the action of G_K.

We use, as part of this convention, the standard comparisons $B_{\mathrm{cris}}^+ \subseteq B_{\mathrm{max}}^+ \subseteq B_{\mathrm{dR}}^+$, $\varphi(B_{\mathrm{max}}^+) \subseteq B_{\mathrm{cris}}^+$, $B_{\mathrm{cris}} \subseteq B_{\mathrm{max}} \subseteq B_{\mathrm{dR}}$, and that V is crystalline if and only if $(B_{\mathrm{max}} \otimes_{\mathbb{Q}_p} V)^{G_K}$ has dimension $\dim_{\mathbb{Q}_p} V$ over $B_{\mathrm{max}}^{G_K}$ [85]. A finite-dimensional $\mathbb{Q}_p$-representation V of G_K is **de Rham**, **semistable** or **crystalline** if $(B \otimes_{\mathbb{Q}_p} V)^{G_K}$ has dimension $\dim_{\mathbb{Q}_p} V$ over B^{G_K} for

$B = B_{\mathrm{dR}}, B_{\mathrm{st}}, B_{\mathrm{cris}}$ respectively. Hodge–Tate weights are normalised so that the cyclotomic character χ_{cyc} has Hodge–Tate weight 1.

Galois cohomology is continuous cohomology of profinite groups, as in [265] and [201]. For a discrete module M (or, for $\mathbb{Z}_\ell$-coefficients, a continuous ℓ-adic module M), we write $H^i(F, M)$ for $H^i(G_F, M)$ and $H^i(F_v, M)$ for $H^i(G_{F_v}, M)$. Tate cohomology of a finite group is denoted $\hat{H}^i$. For a prime ℓ, χ_{cyc} is the ℓ-adic cyclotomic character, $\mathbb{Z}_\ell(k)$ and $\mathbb{Q}_\ell/\mathbb{Z}_\ell(k)$ are the twists by χ_{cyc}^k, and μ_{ℓ^r} is the group of ℓ^r-th roots of unity. For a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module M, the Cartier dual is $M^\vee = \mathrm{Hom}(M, \mu_{\ell^r})$. The unramified classes are

$$H^1_{\mathrm{ur}}(F_v, M) = \ker\bigl(H^1(F_v, M) \to H^1(I_v, M)\bigr),$$

and inv_v is the invariant map of the local Brauer group. For a finite set S of places containing those above ℓ and ∞,

$$\mathrm{Sha}^i_S(F, M) = \ker\Bigl(H^i(G_{F,S}, M) \to \prod_{v \in S} H^i(F_v, M)\Bigr).$$

For a number field E, a prime ℓ, the set S_ℓ of places of E above ℓ, the Galois group G_{E,S_ℓ} of the maximal extension of E unramified outside S_ℓ, and $k \in \mathbb{Z}$, put

$$\mathrm{Sha}^1_\ell(E, k) = \ker\Bigl(H^1(G_{E,S_\ell}, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k)) \to \prod_{v \in S_\ell} H^1(E_v, \mathbb{Q}_\ell/\mathbb{Z}_\ell(-k))\Bigr),$$

with continuous cohomology, and let $\mathrm{len}_\ell(E, k) \in \mathbb{N} \cup \{\infty\}$ be its length as a $\mathbb{Z}_\ell$-module.

Local Tate duality, the local and global Euler characteristic formulas and Poitou–Tate duality are used in the form of [201], Ch. I, and the Greenberg–Wiles formula for Selmer groups in the form of [63].

We fix the notation for ℓ-adic coefficients, Galois representations and automorphic representations used in this paper, following [60] and [15].

Coefficients. Let ℓ be a prime, let $\overline{\mathbb{Q}}_\ell$ be an algebraic closure of $\mathbb{Q}_\ell$ with absolute value $|\cdot|_\ell$ and valuation v_ℓ normalised by $v_\ell(\ell) = 1$, and let $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ be an isomorphism of fields. A **coefficient ring** is a $\mathbb{Z}_\ell$-subalgebra $\mathcal{O} \subset \overline{\mathbb{Q}}_\ell$ that is a discrete valuation ring finite over $\mathbb{Z}_\ell$. Its ramification index is $e_{\mathcal{O}} = \mathrm{length}_{\mathcal{O}}(\mathcal{O}/\ell\mathcal{O})$. For an $\mathcal{O}$-module M of finite length, the **normalised length** of M is $\mathrm{length}_{\mathcal{O}}(M)/e_{\mathcal{O}}$, so that $\ell^{[\mathcal{O}:\mathbb{Z}_\ell]\cdot \mathrm{length}_{\mathcal{O}}(M)/e_{\mathcal{O}}} = \#M$. For a character θ of a group with values in $\mathcal{O}^\times$, we write $\mathcal{O}^\vee(\theta)$ for $\mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$ with the discrete topology and with the group acting through θ. Dirichlet characters with values in $\mathcal{O}^\times$ are identified with characters of $G_{\mathbb{Q}}$ by class field theory.

Galois representations. An ℓ-adic representation of G_E is a continuous homomorphism $r\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$. We write $r^\vee$ for its contragredient. For a CM field E with complex conjugation c, we set $r^c(g) = r(cgc)$. Two representations are **isomorphic** if they are conjugate in $\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$.

Automorphic side. For a number field E, the notion of a **regular algebraic** cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_E)$ is that of [58]. For E CM, π is **conjugate self-dual** if $\pi^\vee \cong \pi^c$. An ℓ-adic representation r of G_E is **attached to** π, written $r \leftrightarrow_\iota \pi$, if the following holds for all but finitely many finite places w of E at which π is unramified: r is unramified at w, and ι carries the characteristic polynomial of $r(\mathrm{Frob}_w^{-1})$ (a geometric Frobenius) to $\prod_\alpha (X - \mathrm{N}w^{(n-1)/2}\alpha)$, where α runs over the Satake parameters of π_w.

The **Satake parameters** of π_w are defined as follows. Let $K_w = \mathrm{GL}_n(\mathcal{O}_{E_w})$. For a uniformiser ϖ_w and $0 \le j \le n$, let $d_j = \mathrm{diag}(\varpi_w, \dots, \varpi_w, 1, \dots, 1)$ with j entries ϖ_w, and let T_j be the Hecke operator of the double coset $K_w d_j K_w$, acting on $\pi_w^{K_w}$ by $x \mapsto \sum_{gK_w \subseteq K_w d_j K_w} \pi_w(g)x$.

The Satake parameters of π_w form the multiset $\{\alpha_1,\dots,\alpha_n\}\subset\mathbb{C}^\times$ such that, for every uniformiser ϖ_w and every such j, the operator T_j is the scalar

$$T_j = \mathrm{N}w^{j(n-j)/2}\, e_j(\alpha_1,\dots,\alpha_n),$$

where e_j is the j-th elementary symmetric polynomial. They are the values $\chi_i(\varpi_w)$ of unramified characters $\chi_1,\dots,\chi_n$ of $E_w^\times$ such that π_w is a subquotient of the normalised induction of $\chi_1\otimes\cdots\otimes\chi_n$ [49], [109]. Thus the relation $r\leftrightarrow_\iota\pi$ is the normalisation $\mathrm{rec}(\pi_w\otimes|\det|^{(1-n)/2})$ of [122]. For E CM, r is **automorphic of conjugate self-dual type** if $r\leftrightarrow_\iota\pi$ for some regular algebraic conjugate self-dual cuspidal π. A normalised newform f of weight k, level $\Gamma_1(M)$ and character χ has the Galois representation $\rho_{f,\iota}\colon G_{\mathbb{Q}}\to\mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ constructed in [68].

Algebraic Hecke characters. Let E be a number field and let $n=(n_\varphi)_\varphi$ be integers indexed by the field embeddings $\varphi\colon E\to\mathbb{C}$. A (not necessarily unitary) Hecke character χ of E is **algebraic of infinity type** n if

$$\chi_\infty(k)=\prod_{\varphi\colon E\to\mathbb{C}}\varphi(k)^{n_\varphi}\qquad\text{for every } k\in E^\times \text{ positive at every real place,}$$

where $\chi_\infty=\prod_{v\mid\infty}\chi_v$ and k is embedded diagonally in $\prod_{v\mid\infty}E_v^\times$. For these characters the global Artin map is used in the **geometric normalisation** $\mathrm{Art}_E^{\mathrm{geo}}(x)=\mathrm{Art}_E(x)^{-1}$, which sends uniformisers to geometric Frobenius elements. The **ℓ-adic character attached to** (χ,ι) is the continuous character $\chi_\iota\colon G_E\to\overline{\mathbb{Q}}_\ell^\times$ such that

$$\chi_\iota(\sigma)=\iota^{-1}\Big(\chi(x)\prod_{v\mid\infty}\prod_i i(x_v)^{-n_i}\Big)\cdot\prod_{w\mid\ell}\prod_j j(x_w)^{n_{\iota\circ j}}$$

for every $x\in\mathbb{A}_E^\times$ and every $\sigma\in G_E$ whose image in G_E^{ab} is $\mathrm{Art}_E^{\mathrm{geo}}(x)$. Here i runs over the continuous embeddings $E_v\to\mathbb{C}$, j runs over the continuous embeddings $E_w\to\overline{\mathbb{Q}}_\ell$, and n_i, $n_{\iota\circ j}$ are the exponents of their restrictions to E. This character exists and is unique [261].

Sign of the Hodge jumps. With these normalisations, let $w\nmid\ell$ be a finite place at which χ is unramified. Then χ_ι is unramified at w and $\chi_\iota(\mathrm{Frob}_w^{-1})=\iota^{-1}\chi_w(\varpi_w)$ for an arithmetic Frobenius Frob_w and a uniformiser ϖ_w. At a place $w\mid\ell$, the restriction $\chi_\iota|_{G_{E_w}}$ is de Rham and, for every embedding $\tau\colon E\to\overline{\mathbb{Q}}_\ell$ inducing w, its Hodge–Tate weight at τ is $n_{\iota\circ\tau}$ when χ_{cyc} has weight 1; equivalently, its only Hodge jump at τ (a jump of the Hodge filtration, the negative of a Hodge–Tate weight) is $-n_{\iota\circ\tau}$ [261], [85]. For $E=\mathbb{Q}$ and $\chi=|\cdot|_{\mathbb{A}}$, of infinity type 1, we have $\chi_\iota=\chi_{\mathrm{cyc}}$, with Hodge jump -1. The character defined by the same formula with Art_E in place of $\mathrm{Art}_E^{\mathrm{geo}}$ is χ_ι^{-1}, with Hodge jump $n_{\iota\circ\tau}$ at τ.

Definition 7.1.1. Number fields are subfields of a fixed algebraic closure $\overline{\mathbb{Q}}$; ℓ is a prime and $\iota\colon\overline{\mathbb{Q}}_\ell\to\mathbb{C}$ an isomorphism. For a number field F and a place $\bar v$ of $\overline{\mathbb{Q}}$ above a finite place v of F, $D_{\bar v}\supseteq I_{\bar v}$ are the decomposition and inertia subgroups of G_F at $\bar v$, and an **arithmetic Frobenius at** $\bar v$ is an element of $D_{\bar v}$ acting on the residue field of $\bar v$ as $x\mapsto x^{q_v}$. We write χ_{cyc} also for its restriction to G_F, with values in $\mathbb{Z}_\ell^\times\subset\overline{\mathbb{Q}}_\ell^\times$. For $M\geq1$, a character of G_F is **of level** M if it is trivial on $G_{F(\mu_M)}$. For a subgroup $D\subseteq G_F$ and characters $\kappa_1,\dots,\kappa_n\colon D\to\overline{\mathbb{Q}}_\ell^\times$, a representation $r\colon G_F\to\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ is **triangular on** D **with diagonal** $(\kappa_1,\dots,\kappa_n)$ if there is $g\in\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that, for every $s\in D$, $g\,r(s)\,g^{-1}$ is upper triangular with diagonal entries $\kappa_1(s),\dots,\kappa_n(s)$.

Level and weights. Let $n,M\geq1$ and $m=(m_1,\dots,m_n)\in\mathbb{Z}^n$. A continuous $r\colon G_F\to\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ has **level** M **and weights** m if

(Lw1) for every finite place $v \nmid \ell$ of F there are a place $\bar{v} \mid v$ and characters $\chi_1, \dots, \chi_n$ of G_F of level M such that $r|_{I_{\bar{v}}}$ is conjugate to $s \mapsto \mathrm{diag}(\chi_1(s), \dots, \chi_n(s))$;

(Lw2) for every place $v \mid \ell$ of F there are a place $\bar{v} \mid v$, characters $\chi_1, \dots, \chi_n$ of G_F of level M and characters $\kappa_1, \dots, \kappa_n$ of $D_{\bar{v}}$ such that r is triangular on $D_{\bar{v}}$ with diagonal $(\kappa_1, \dots, \kappa_n)$, $\kappa_i(s) = \chi_{\mathrm{cyc}}(s)^{m_i}\chi_i(s)$ for all i and $s \in I_{\bar{v}}$, and either $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}}$ for all i, j, or $r|_{D_{\bar{v}}}$ is potentially crystalline.

It is **generic ordinary of level** M **and weights** m if for every place $v \mid \ell$ of F there are $\bar{v}$, χ_i and κ_i as in (Lw2) with $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}}$ for all i, j.

Witness conditions. Let F be a CM field and $r\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a representation. For a place $v \mid \ell$ of F, r is **generic at** v if for every place $\bar{v} \mid v$ it is triangular on $D_{\bar{v}}$ with some diagonal (κ_i) such that $\kappa_i \neq \kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}}$ for all i, j; it is **potentially generic at** v if for every $\bar{v} \mid v$ it is triangular on $D_{\bar{v}}$ with some diagonal (κ_i) such that $\kappa_i^a \neq (\kappa_j\chi_{\mathrm{cyc}}|_{D_{\bar{v}}})^a$ for all i, j and all integers $a \geq 1$. The representation r satisfies the **witness conditions** if

(Wc1) r is potentially generic at every place $v \mid \ell$ at which it is generic;

(Wc2) for every regular algebraic cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_F)$ such that r is semisimple and $r \leftrightarrow_\iota \pi$, there is a real number τ_π such that at every finite place v of F with $v \nmid \ell$, or with $v \mid \ell$ and r potentially generic at v, the local component π_v has a cuspidal support consisting of characters of $F_v^\times$, and every character ξ occurring in a cuspidal support of π_v satisfies $q_v^{\tau_\pi - 1/2} < |\xi(\varpi_v)| < q_v^{\tau_\pi + 1/2}$.

(The number $|\xi(\varpi_v)|$ does not depend on the uniformiser, since ξ has finite image on $\mathcal{O}_{F_v}^\times$.) A representation W of $G_\mathbb{Q}$ satisfies the **witness conditions over imaginary quadratic fields** if $W|_{G_{K'}}$ satisfies the witness conditions for every imaginary quadratic field K' such that $W|_{G_{K'}}$ is irreducible.

Admissible representations. Let K be an imaginary quadratic field with discriminant d_K and let $e, N \geq 1$ be integers. A representation $\rho\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ is **admissible of stable type** for (ι, e, N) if

(Sb1) ρ is irreducible;

(Sb2) $\rho \otimes \chi_{\mathrm{cyc}}^{-1}$ is automorphic of conjugate self-dual type and satisfies the witness conditions;

(Sb3) ρ has level N and weights $(e, 0, -e)$;

(Sb4) ρ is generic ordinary of level N and weights $(e, 0, -e)$.

For $M \geq 1$, ρ is **admissible of endoscopic type** for (ι, e, M) if there is a representation $W\colon G_\mathbb{Q} \to \mathrm{GL}_2(\overline{\mathbb{Q}}_\ell)$ such that

(Eo1) W is irreducible and satisfies the witness conditions over imaginary quadratic fields;

(Eo2) $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is semisimple, and there is a normalised newform $f = \sum_{n \geq 1} a_n q^n$ of weight $2e + 1$, some level and Nebentypus ε_f such that for all but finitely many primes p and every place $\bar{p}$ of $\overline{\mathbb{Q}}$ above p, $W \otimes \chi_{\mathrm{cyc}}^{-e}$ is trivial on $I_{\bar{p}}$ and $\iota(\det(X - (W \otimes \chi_{\mathrm{cyc}}^{-e})(\sigma^{-1}))) = X^2 - a_p X + \varepsilon_f(p)p^{2e}$ for every arithmetic Frobenius σ at $\bar{p}$;

(Eo3) W has level M and weights $(e, -e)$, and $\det W$ is a character of level M' for some $M' \geq 1$;

(Eo4) ρ is conjugate to $s \mapsto \begin{pmatrix} a(s) & 0 & b(s) \\ 0 & 1 & 0 \\ c(s) & 0 & d(s) \end{pmatrix}$, where $W(s) = \begin{pmatrix} a(s) & b(s) \\ c(s) & d(s) \end{pmatrix}$ for $s \in G_K \subseteq G_{\mathbb{Q}}$.

A representation $\rho\colon G_K \to \mathrm{GL}_3(\overline{\mathbb{Q}}_\ell)$ is **admissible of weight** e **and level** N (for K and ι) if it is admissible of stable type for (ι, e, N) or admissible of endoscopic type for $(\iota, e, N|d_K|)$.

Definition 7.1.2. Let v and ℓ be primes and $I_v \subset G_{\mathbb{Q}_v}$ the inertia subgroup. For w in the Weil group $W_{\mathbb{Q}_v} \subseteq G_{\mathbb{Q}_v}$ let $n(w) \in \mathbb{Z}$ be the integer with $w(x) = x^{v^{n(w)}}$ on the residue field of $\overline{\mathbb{Q}}_v$.

A **Weil–Deligne representation** of $W_{\mathbb{Q}_v}$ over $\overline{\mathbb{Q}}_\ell$ is a triple $D = (V, \rho, N)$ of a finite-dimensional $\overline{\mathbb{Q}}_\ell$-vector space V, a homomorphism $\rho\colon W_{\mathbb{Q}_v} \to \mathrm{GL}(V)$ trivial on an open subgroup of I_v, and a nilpotent endomorphism N of V (the **monodromy**) with

$$\rho(w)\, N\, \rho(w)^{-1} = v^{n(w)} N \qquad (w \in W_{\mathbb{Q}_v}). \tag{7.1}$$

Its **conductor exponent** is

$$\mathrm{a}(D) = \mathrm{a}\big(\rho|_{I_v}\big) + \dim V^{I_v} - \dim\big(\ker N\big)^{I_v},$$

where, for a finite-dimensional representation θ of I_v trivial on an open subgroup, $\mathrm{a}(\theta)$ is its Artin conductor ([263], Chapter VI, §2: the sum of the codimension of the invariants and the Swan conductor, computed on any finite quotient of I_v through which θ factors).

For a continuous representation $r\colon G_{\mathbb{Q}_v} \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$, the **Weil–Deligne representation** $\mathrm{WD}(r)$ is defined when $v \neq \ell$, or when $v = \ell$ and r is potentially semistable:

(Wd1) if $v \neq \ell$: by Grothendieck's monodromy theorem there are a unique nilpotent N and an open subgroup $J \subseteq I_v$ with $r(\sigma) = \exp(t_\ell(\sigma)N)$ for $\sigma \in J$, where $t_\ell\colon I_v \to \mathbb{Z}_\ell$ is a nonzero homomorphism (a choice of tame character); $\mathrm{WD}(r) = (\overline{\mathbb{Q}}_\ell^{\,n}, \rho, N)$ with $\rho(\Phi^m\sigma) = r(\Phi^m\sigma)\exp(-t_\ell(\sigma)N)$ for a fixed $\Phi \in W_{\mathbb{Q}_v}$ with $n(\Phi) = -1$, $m \in \mathbb{Z}$ and $\sigma \in I_v$;

(Wd2) if $v = \ell$ and r is potentially semistable: $\mathrm{WD}(r)$ is the Weil–Deligne representation attached by Fontaine to the filtered $(\varphi, N, G_{\mathbb{Q}_\ell})$-module $D_{\mathrm{pst}}(r)$ ([86]).

Both are well defined up to isomorphism (independent of the choices), and the **conductor exponent of** r is $\mathrm{a}(r) = \mathrm{a}(\mathrm{WD}(r))$.

Frobenius-semisimplification. Let $D = (V, \rho, N)$ be a Weil–Deligne representation and $\Phi \in W_{\mathbb{Q}_v}$ an element with $n(\Phi) = -1$ (a lift of geometric Frobenius). Write $\rho(\Phi) = \rho(\Phi)_s\rho(\Phi)_u$ for the Jordan decomposition into commuting semisimple and unipotent parts. The **Frobenius-semisimplification** of D is $D^{F\text{-}ss} = (V, \rho_s, N)$, where $\rho_s(\Phi^m\sigma) = \rho(\Phi)_s^m\rho(\sigma)$ for $m \in \mathbb{Z}$ and $\sigma \in I_v$. It is a Weil–Deligne representation, independent of Φ up to isomorphism, and D is **Frobenius-semisimple** if $D \cong D^{F\text{-}ss}$, i.e. if $\rho(\Phi)$ is semisimple.

All of the above applies without change to a finite extension K of $\mathbb{Q}_v$ in place of $\mathbb{Q}_v$, with $W_K \supseteq I_K$, and the cardinality q_K of the residue field of K in place of v in the definition of $n(\cdot)$ and in (7.1).

Definition 7.1.3. Let $K \subset \overline{\mathbb{Q}}$ be an imaginary quadratic field with a fixed embedding $\tau\colon K \to \mathbb{C}$, $\bar\tau = \overline{\tau(\cdot)}$ the other one, and $n \geq 1$. Put $G_\infty = \mathrm{GL}_n(K \otimes_{\mathbb{Q}} \mathbb{R})$, identified with $\mathrm{GL}_n(\mathbb{C})$ through τ; $K_\infty = \mathrm{U}(n)\cdot\mathbb{R}_{>0} \subset G_\infty$ ($\mathbb{R}_{>0}$ as scalar matrices); $\mathfrak{g} = \mathrm{Lie}(G_\infty)\otimes_{\mathbb{R}}\mathbb{C} \cong \mathfrak{gl}_n(\mathbb{C})\times\mathfrak{gl}_n(\mathbb{C})$, the two factors corresponding to τ and $\bar\tau$. Put $\widehat{\mathcal{O}}_K = \prod_{v\nmid\infty} \mathcal{O}_{K_v} \subset \mathbb{A}_{K,f}$. For $N \geq 1$, $\mathrm{K}_n(N) \subset \mathrm{GL}_n(\widehat{\mathcal{O}}_K)$ is the kernel of reduction modulo $N\widehat{\mathcal{O}}_K$.

Infinitesimal characters. For a cuspidal automorphic representation π of $\mathrm{GL}_n(\mathbb{A}_K)$, the **infinitesimal character of π at τ** (resp. at $\bar\tau$) is the multiset of n complex numbers given by the τ- (resp. $\bar\tau$-) factor of the infinitesimal character of π_∞, in the normalisation of [58], in which the trivial representation has infinitesimal character $\{\frac{n-1}{2}, \frac{n-3}{2}, \dots, -\frac{n-1}{2}\}$ at both embeddings.

Coefficient systems. For $\mu \in \mathbb{Z}^n$ with $\mu_1 \geq \cdots \geq \mu_n$ let (ρ_μ, V_μ) be the irreducible algebraic representation of $\mathrm{GL}_n(\mathbb{C})$ of highest weight μ; its infinitesimal character is $\{\mu_i + \frac{n+1}{2} - i : 1 \leq i \leq n\}$ and that of its dual is $\{-\mu_i - \frac{n+1}{2} + i\}$. For two such μ, μ', $V_{\mu,\mu'} = V_\mu \otimes_{\mathbb{C}} V_{\mu'}$ with $g \in G_\infty$ acting by $\rho_\mu(g) \otimes \rho_{\mu'}(\bar g)$; $\mathrm{GL}_n(K) \subset G_\infty$ acts by restriction. For a cuspidal π, $H^*(\mathfrak{g}, K_\infty; \pi_\infty \otimes V_{\mu,\mu'})$ is the relative Lie algebra cohomology of the $(\mathfrak{g}, K_\infty)$-module of K_∞-finite vectors of π_∞ tensored with $V_{\mu,\mu'}$; π is **cohomological for** $V_{\mu,\mu'}$ if it is nonzero in some degree.

Arithmetic groups of a level. For an open compact subgroup $U \subseteq \mathrm{GL}_n(\mathbb{A}_{K,f})$ the double coset space $\mathrm{GL}_n(K)\backslash \mathrm{GL}_n(\mathbb{A}_{K,f})/U$ is finite ([33]); for representatives $g_1, \dots, g_h$ put $\Gamma_j(U) = \mathrm{GL}_n(K) \cap g_j U g_j^{-1}$, acting on $V_{\mu,\mu'}$ through $\mathrm{GL}_n(K) \subset G_\infty$, and

$$h^*(U, V_{\mu,\mu'}) = \sum_{j=1}^{h} \sum_{q \geq 0} \dim_{\mathbb{C}} H^q(\Gamma_j(U), V_{\mu,\mu'}) \in \mathbb{Z}_{\geq 0} \cup \{\infty\},$$

which does not depend on the representatives (replacing g_j by $\gamma g_j u$ with $\gamma \in \mathrm{GL}_n(K)$, $u \in U$ conjugates $\Gamma_j(U)$ by γ, compatibly with the action on $V_{\mu,\mu'}$). It is the total dimension of the cohomology of the locally symmetric space of level U with coefficients in $V_{\mu,\mu'}$.

Theorem 7.1.4. *Let F be a totally real field with $[F : \mathbb{Q}] \geq 2$, let E/F be a totally imaginary quadratic extension with non-trivial automorphism c, let $n \geq 1$, and let U be an inner form of the quasi-split unitary group in n variables for E/F such that $U(F \otimes_{\mathbb{Q}} \mathbb{R})$ is compact. Let σ be an automorphic representation of $U(\mathbb{A}_F)$, ℓ a prime and $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism. Let $\pi = \boxplus_{i=1}^{s} \pi_i$ be a weak base change of σ in the sense of [177], Corollaire 5.3: each π_i is a discrete automorphic representation of $\mathrm{GL}_{n_i}(\mathbb{A}_E)$ with $\pi_i^c \cong \pi_i^\vee$, $\sum_i n_i = n$, and π_∞ is cohomological with infinitesimal character the base change of that of σ_∞. Write $\pi = \Pi_1 \boxplus \cdots \boxplus \Pi_k$ as an isobaric sum of cuspidal automorphic representations Π_j of $\mathrm{GL}_{m_j}(\mathbb{A}_E)$, $\sum_j m_j = n$. Then:*

(Ua0) *each $\Pi'_j := \Pi_j \otimes |\det|^{(m_j - n)/2}$ is a regular algebraic polarizable cuspidal automorphic representation of $\mathrm{GL}_{m_j}(\mathbb{A}_E)$, and π_w is unramified at every finite place w of E above a finite place v of F at which E/F and U are unramified and σ_v is spherical;*

and the continuous semisimple representation

$$r = r_{\ell,\iota}(\sigma) := \bigoplus_{j=1}^{k} r_{\ell,\iota}(\Pi'_j)\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$$

satisfies:

(Ua1) $r^c \cong r^\vee \otimes \chi_{\mathrm{cyc}}^{1-n}$;

(Ua2) *for every finite place $w \nmid \ell$ of E at which π_w is unramified, every place $\bar w$ of $\overline{\mathbb{Q}}$ above w and every arithmetic Frobenius element* Frob *at $\bar w$, r is trivial on $I_{\bar w}$ and*

$$\iota\Big(\det\big(X - r(\mathrm{Frob}^{-1})\big)\Big) = \prod_{\alpha} (X - q_w^{(n-1)/2}\alpha),$$

α running over the Satake parameters of π_w with multiplicity; in particular the polynomial on the right, transported by ι^{-1}, kills $r(\mathrm{Frob}^{-1})$.

Up to isomorphism, r is the unique continuous semisimple representation satisfying (Ua2) at all but finitely many w.

Proof. Write each discrete summand as $\pi_i = \mathrm{Sp}(\tau_i, a_i)$, with τ_i unitary cuspidal, by the discrete-spectrum classification of [207]. Its cuspidal isobaric constituents are

$$\tau_i |\det|^{s_{i,b}}, \qquad s_{i,b} = (a_i - 1)/2 - b, \quad 0 \le b < a_i.$$

The uniqueness in this classification, applied to $\mathrm{Sp}(\tau_i^c, a_i) \cong \pi_i^c \cong \pi_i^\vee \cong \mathrm{Sp}(\tau_i^\vee, a_i)$, gives $\tau_i^c \cong \tau_i^\vee$. Here duality reverses the list of exponents, which is symmetric about zero. The local parameters of the isobaric sum, including monodromy, are the direct sums of the parameters of its cuspidal constituents.

We check regular algebraicity, including the rank-dependent shift. At each complex embedding, the infinitesimal-character entries of the cohomological representation π are n distinct numbers in $(n-1)/2 + \mathbb{Z}$. This follows also directly from its algebraic coefficient system: for a dominant integral highest weight λ, the entries are $\lambda_i + (n + 1 - 2i)/2$, and consecutive entries differ by at least one. Infinitesimal characters are preserved under taking subquotients of normalized parabolic induction, and the infinitesimal character of the induced representation is the union of the inducing infinitesimal characters. Thus the entries of a rank-m_j constituent Π_j form a subset of this distinct list. Twisting by $|\det|^{(m_j-n)/2}$ adds $(m_j - n)/2$ to each entry, putting them in $(m_j - 1)/2 + \mathbb{Z}$. If these entries, in decreasing order, are $z_1, \dots, z_{m_j}$, then

$$\lambda_i' = z_i - (m_j + 1 - 2i)/2$$

are integers with $\lambda_i' \ge \lambda_{i+1}'$. They are therefore the highest weight of an irreducible algebraic representation. The same computation applies at the conjugate embedding. This proves that Π_j' is regular algebraic.

If $\Pi_j = \tau_i |\det|^s$, put $d = s + (m_j - n)/2$. Then

$$(\Pi_j')^c \cong \tau_i^\vee |\det|^d \cong (\Pi_j')^\vee \otimes (|\cdot|_{\mathbb{A}_F}^{2d} \circ \mathrm{N}_{E/F} \circ \det).$$
