The character $|\cdot|_{\mathbb{A}_F}^{2d}$ is trivial on $F^\times$, and its value at -1 is 1 at every real place. Thus it is a polarization character of the required kind. Cuspidality is preserved by twisting. This checks all the hypotheses of the polarized regular-algebraic cuspidal theorem [15, Theorem 2.1.1] for every Π_j'. Its continuous semisimple representations have the direct sum r in the statement.

At a place where π_w is unramified, its local parameter is unramified with zero monodromy. The direct-sum formula for the local parameter shows that each constituent parameter has both properties, since its inertia action and monodromy are direct summands. By the unramified local Langlands correspondence, every $\Pi_{j,w}$ is spherical, as is its unramified twist $\Pi_{j,w}'$. If α is a Satake parameter of $\Pi_{j,w}$, the corresponding parameter of $\Pi_{j,w}'$ is $q_w^{(n-m_j)/2}\alpha$. The cuspidal Galois theorem therefore gives, at geometric Frobenius, the eigenvalue

$$q_w^{(m_j-1)/2} q_w^{(n-m_j)/2} \alpha = q_w^{(n-1)/2}\alpha.$$

The union over j is exactly the Satake multiset of π_w, proving (Ua2), including triviality on inertia. Cayley–Hamilton gives its annihilating-polynomial assertion. The spherical clause of (Ua0) is the unramified base-change assertion of [177, Corollaire 5.3]; its hypotheses here are precisely the stated unramifiedness of the extension and group and the spherical hypothesis on σ_v.

It remains to prove duality and uniqueness. Since each π_i is conjugate self-dual, so is π. Away from finitely many places, the Satake multiset at w^c is the inverse of that at w. At a

geometric Frobenius at w, the eigenvalues of r^c are consequently $q_w^{(n-1)/2}\alpha^{-1}$. Those of $r^\vee \otimes \chi_{\mathrm{cyc}}^{1-n}$ are the same, because χ_{cyc} takes the value q_w^{-1} at geometric Frobenius. Their characteristic polynomials agree at all such places. Chebotarev density and continuity extend equality of their traces to every element of G_E: in every finite quotient, each conjugacy class occurs at infinitely many unramified places outside any fixed finite exceptional set. The characteristic-zero Brauer–Nesbitt theorem now identifies these semisimple representations, proving (Ua1). The identical argument applied to any other continuous semisimple representation satisfying (Ua2) proves uniqueness. □

Theorem 7.1.5. *Let F be a number field and $\mathbb{A}_F$ its adeles.*

(Mw1) *Let $m, k \geq 1$ and let τ be a unitary cuspidal automorphic representation of $\mathrm{GL}_m(\mathbb{A}_F)$. The normalised parabolic induction to $\mathrm{GL}_{km}(\mathbb{A}_F)$, from the standard parabolic subgroup of type $(m, \dots, m)$, of $\tau|\det|^{(k-1)/2} \otimes \tau|\det|^{(k-3)/2} \otimes \cdots \otimes \tau|\det|^{(1-k)/2}$ has a unique irreducible quotient $\mathrm{Sp}(\tau, k)$, and $\mathrm{Sp}(\tau, k)$ occurs in the discrete spectrum of $\mathrm{GL}_{km}(\mathbb{A}_F)$. Conversely, every irreducible automorphic representation of $\mathrm{GL}_N(\mathbb{A}_F)$ in the discrete spectrum is isomorphic to $\mathrm{Sp}(\tau, k)$ for a unique pair (τ, k) with $km = N$.*

(Mw2) *Let $r \geq 1$, and for $1 \leq i \leq r$ let τ_i be a unitary cuspidal automorphic representation of $\mathrm{GL}_{m_i}(\mathbb{A}_F)$ and $k_i \geq 1$; let $\Pi = \mathrm{Sp}(\tau_1, k_1) \boxplus \cdots \boxplus \mathrm{Sp}(\tau_r, k_r)$ be the isobaric sum, an automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$, $n = \sum_i k_i m_i$. Then for every finite place w of F, with $K = F_w$ and $|\cdot|$ the normalised absolute value of K,*

$$\mathrm{rec}_K(\Pi_w) \cong \bigoplus_{i=1}^{r} \bigoplus_{a=0}^{k_i-1} \mathrm{rec}_K(\tau_{i,w}) \otimes \mathrm{rec}_K\big(|\cdot|^{(k_i-1)/2-a}\big) \tag{7.2}$$

as Weil–Deligne representations (monodromy operators included).

Proof. The main theorem of [207], with fixed unitary central character and square-integrability modulo the centre, proves (Mw1). Its quotient $J(\tau, k)$ is precisely $\mathrm{Sp}(\tau, k)$: both use normalised induction from the upper standard parabolic and the descending exponents $((k-1)/2, \dots, (1-k)/2)$. This also gives uniqueness of the pair, including the cuspidal case $k = 1$.

Fix a finite place w, put $K = F_w$, and write $\nu(g) = |\det g|_K$. We first check the hypotheses needed for the local calculation. The local component τ_w is unitary: fix nonzero vectors in the other factors of the restricted tensor product for τ and restrict its positive invariant Hermitian form to the resulting copy of τ_w. It is also generic. Indeed the cuspidal Whittaker expansion of [269, 230] gives a nonzero Whittaker functional Λ on τ for a nontrivial character of $F\backslash\mathbb{A}_F$. Some pure tensor has nonzero value under Λ, since pure tensors span the smooth automorphic representation. Fix its factors away from w. Evaluation of Λ on the remaining factor is a nonzero functional on τ_w transforming under $U_m(K)$ by the local nondegenerate Whittaker character. Each local component of a nontrivial adelic character trivial on F is nontrivial. This proves the required local genericity. When $m = 1$, the unipotent group is trivial and the same assertion is immediate.

The generic unitary classification, as explicitly stated in [207], I.10–I.11, now gives

$$\tau_w \cong \delta_1\nu^{e_1} \times \cdots \times \delta_b\nu^{e_b}, \qquad \tfrac{1}{2} > e_1 \geq \cdots \geq e_b > -\tfrac{1}{2}, \tag{1}$$

where each δ_j is irreducible, unitary and square-integrable, and the displayed induction is irreducible. Thus τ_w is the Langlands quotient for the multiset

$$c = \{\delta_j\nu^{e_j} : 1 \leq j \leq b\}.$$

Here and below multisets retain every multiplicity.

Put $s_a = (k-1)/2 - a$ for $0 \le a < k$. By transitivity of normalised induction the local inducing representation

$$I_w = \tau_w \nu^{s_0} \times \cdots \times \tau_w \nu^{s_{k-1}}$$

is the induction of the square-integrable twists $\delta_j \nu^{e_j + s_a}$, ordered first by increasing a and then by increasing j. This order is the Langlands order. Within a fixed a, the exponents are nonincreasing by (1). If $a < a'$, then

$$(e_j + s_a) - (e_{j'} + s_{a'}) = (a' - a) + (e_j - e_{j'}) > (a' - a) - 1 \ge 0. \tag{2}$$

Consequently every exponent in one level is strictly larger than every exponent in a later level. For two linked Zelevinsky segments, precedence requires both endpoints, and hence their real centre, to be strictly smaller. Therefore this nonincreasing-centre order also has the nonprecedence condition in (Ln6). The standard-module form of the Langlands classification, [207], I.2(1), identifies the unique irreducible quotient of I_w with

$$L(c_k), \qquad c_k = \{\delta_j \nu^{e_j + s_a} : 1 \le j \le b,\ 0 \le a < k\}. \tag{3}$$

We check that (3) is the actual local component of the global quotient. The global inducing representation is the restricted tensor product of the local inducing representations, and its nonzero quotient map to $\mathrm{Sp}(\tau, k)$ gives a nonzero K-local map $I_w \to \mathrm{Sp}(\tau, k)_w$. More explicitly, choose an inducing pure tensor with nonzero image and a linear coefficient functional on the other output factors that does not kill this image. Fix the other inducing factors and apply that coefficient functional. The resulting map intertwines $\mathrm{GL}_{km}(K)$, because this group acts only on the factor at w. Its target is irreducible, so it is surjective. The uniqueness just proved therefore gives

$$\mathrm{Sp}(\tau, k)_w \cong L(c_k). \tag{4}$$

This argument applies to the smooth restricted tensor products; any vector used in extracting the coefficient is a finite sum of pure tensors.

Apply (Ln6) and (Ln2) to (1), (3) and (4). They give, as full Weil–Deligne representations,

$$\begin{aligned} \mathrm{rec}_K(\tau_w) &\cong \bigoplus_{j=1}^{b} \mathrm{rec}_K(\delta_j) \otimes \mathrm{rec}_K(|\cdot|^{e_j}), \\ \mathrm{rec}_K(\mathrm{Sp}(\tau, k)_w) &\cong \bigoplus_{a=0}^{k-1} \bigoplus_{j=1}^{b} \mathrm{rec}_K(\delta_j) \otimes \mathrm{rec}_K(|\cdot|^{e_j + s_a}) \\ &\cong \bigoplus_{a=0}^{k-1} \mathrm{rec}_K(\tau_w) \otimes \mathrm{rec}_K(|\cdot|^{s_a}). \end{aligned} \tag{5}$$

The character identity used in the last equality follows from (Ln1), so it uses the same geometric Artin map on both sides.

It remains to combine the summands in (Mw2). For each i let c_{i,k_i} be the multiset in (3) for τ_i, k_i. The representation $L(c_{i,k_i}) = \mathrm{Sp}(\tau_i, k_i)_w$ is unitary, since its global representation lies in the discrete L^2 spectrum; restricting the invariant positive form to a local factor proves this as above. Hence Tadić's unitary Langlands-data formula, [292], Appendix Corollary A.7, applies successively and gives

$$\mathrm{Sp}(\tau_1, k_1)_w \times \cdots \times \mathrm{Sp}(\tau_r, k_r)_w \cong L\left(\sum_{i=1}^{r} c_{i,k_i}\right). \tag{6}$$

In particular this entire normalised induction is irreducible. The local isobaric construction takes the irreducible constituent associated with the union of the inducing Langlands data. Equivalently, it is the Langlands quotient of that union; (6) shows it is the entire local induced representation here. This is the local component Π_w of the isobaric sum in the hypothesis (for isobaric sums see [149]). No existence assertion for a new global isobaric sum is needed: the automorphic representation Π is given in (Mw2). Applying (Ln6) to the union in (6), and then (5) for each i, proves (7.2).

Finally, (Ln6) is an isomorphism of Weil–Deligne representations, not just of their Weil semisimplifications. On a summand in (5) its monodromy is the monodromy of $\mathrm{rec}_K(\delta_j)$ tensored with the identity of a one-dimensional character, whose own monodromy is zero. Both regrouping in (5) and the direct sum in (6) preserve these operators. Thus the asserted identity includes the full monodromy operators, with no temperedness assumption on τ_w and no replacement by a semisimplified parameter. □

Theorem 7.1.6. *Let F be a CM field with maximal totally real subfield F^+ and complex conjugation c, $n \geq 1$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, and π a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$ which is **polarizable**: there is a continuous character $\chi\colon \mathbb{A}_{F^+}^\times/(F^+)^\times \to \mathbb{C}^\times$, with $\chi_v(-1)$ independent of the infinite place v of F^+, such that $\pi^c \cong \pi^\vee \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det)$. Then there is a continuous semisimple representation $r_{\ell,\iota}(\pi)\colon G_F \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ such that, for every finite place v of F and every place $\bar{v}$ of $\overline{\mathbb{Q}}$ above v, writing $r_{\bar{v}}$ for the restriction of $r_{\ell,\iota}(\pi)$ to $D_{\bar{v}}$ (identified with G_{F_v}), $W_{\bar{v}} \subseteq D_{\bar{v}}$ for its Weil group and $\mathcal{O}_v = \mathcal{O}_{F_v}$:*

(Bg1) *if $v \nmid \ell$ and π_v is unramified, then $r_{\ell,\iota}(\pi)$ is trivial on $I_{\bar{v}}$ and $\iota(\det(X - r_{\ell,\iota}(\pi)(\sigma^{-1}))) = \prod_\alpha (X - q_v^{(n-1)/2}\alpha)$ for every arithmetic Frobenius σ at $\bar{v}$, α running over the Satake parameters of π_v with multiplicity; in particular $r_{\ell,\iota}(\pi) \leftrightarrow_\iota \pi$;*

(Bg2) *if $v \mid \ell$, then $r_{\bar{v}}$ is de Rham, and for every field embedding $\tau\colon F_v \to \overline{\mathbb{Q}}_\ell$ over $\mathbb{Q}_\ell$ the τ-Hodge–Tate weights of $r_{\bar{v}}$ are the n numbers $z - \frac{n-1}{2}$, z running over the infinitesimal character of π at the complex embedding $\iota \circ \tau|_F$ of F;*

(Bg3) *if $U \subseteq \mathcal{O}_v^\times$ is a subgroup and there are characters $\Psi_1, \dots, \Psi_n$ of $W_{\bar{v}}$, each trivial on the image of $\mathrm{Art}_{F_v}(U)$ in $W_{\bar{v}}^{\mathrm{ab}}$, such that the semisimplification of the restriction to $I_{\bar{v}}$ of the representation ρ of $\mathrm{WD}(r_{\bar{v}})$ is isomorphic to $\bigoplus_i \Psi_i|_{I_{\bar{v}}}$ (for $v \mid \ell$, $\mathrm{WD}(r_{\bar{v}})$ is defined by (Bg2), since de Rham representations are potentially semistable), then π_v is isomorphic to an irreducible subquotient of the normalised parabolic induction from the upper triangular Borel subgroup of $\mathrm{GL}_n(F_v)$ of $\xi_1 \otimes \cdots \otimes \xi_n$, for some characters $\xi_1, \dots, \xi_n$ of $F_v^\times$ trivial on U;*

(Bg4) *if $v \mid \ell$ and π_v is unramified, then $r_{\bar{v}}$ is crystalline, $\mathrm{WD}(r_{\bar{v}}) = (V, \rho, N)$ has $N = 0$ and ρ trivial on $I_{\bar{v}}$, and $\iota(\det(X - \rho(\Phi))) = \prod_\alpha (X - q_v^{(n-1)/2}\alpha)$ for every $\Phi \in W_{\bar{v}}$ with $n(\Phi) = -1$ (a geometric Frobenius), α as in (Bg1);*

(Bg5) *if π_v is isomorphic to an irreducible subquotient of the normalised parabolic induction from the upper triangular Borel subgroup of $\mathrm{GL}_n(F_v)$ of $\xi_1 \otimes \cdots \otimes \xi_n$, for characters $\xi_1, \dots, \xi_n$ of $F_v^\times$, then the semisimplification of the representation ρ of $\mathrm{WD}(r_{\bar{v}})$ is isomorphic to $\lambda_1 \oplus \cdots \oplus \lambda_n$, where λ_i is the character of $W_{\bar{v}}$ with $\iota(\lambda_i(\mathrm{Art}_{F_v}(x)^{-1})) = \xi_i(x)\,|x|_v^{(1-n)/2}$ for $x \in F_v^\times$ (characters of $W_{\bar{v}}$ factor through $W_{\bar{v}}^{\mathrm{ab}}$, identified with $F_v^\times$ by Art_{F_v});*

(Bg7) *if $v \nmid \ell$, then the Frobenius-semisimplification of* $\mathrm{WD}(r_{\bar v})$*, transported to* $\mathbb{C}$ *by* ι*, is isomorphic to* $\mathrm{rec}_{F_v}(\pi_v \otimes |\det|_v^{(1-n)/2})$*, where* rec_{F_v} *is the local Langlands correspondence of Harris–Taylor (uniformisers corresponding to geometric Frobenius elements); in particular the monodromy operators of* $\mathrm{WD}(r_{\bar v})$ *and of* $\mathrm{rec}_{F_v}(\pi_v)$ *are conjugate.*

Proof. First normalize the polarizing character. Its common sign at infinity is either $(-1)^n$ or its negative. In the second case replace χ by $\chi\delta_{F/F^+}$, where δ_{F/F^+} is the quadratic character of F^+ associated to F/F^+. At every real place $\delta_{F/F^+}(-1) = -1$, whereas $\delta_{F/F^+} \circ \mathrm{N}_{F/F^+} = 1$ by class field theory. Thus the relation for π^c is unchanged and the normalized pair satisfies the precise hypotheses of Theorem A.4.11. Take its representation r.

For $v \nmid \ell$, conclusion (1) of that theorem gives (Bg7). For $v \mid \ell$, Theorem 7.1.7 gives, on forgetting monodromy and semisimplifying,

$$\iota\, \rho_v^{\mathrm{ss}} \simeq \mathrm{rec}_{F_v}(\pi_v \otimes |\det|_v^{(1-n)/2})^{\mathrm{ss}}. \tag{*}$$

Here and below the superscript on the right means semisimplification of the underlying Weil representation. Frobenius semisimplification does not change that representation's semisimplification. Hence (*) holds at every finite place. The de Rham conclusion of Theorem A.4.11 and Theorem 7.1.10(1) ensure that this Weil–Deligne representation exists above ℓ.

To obtain (Bg2), write $a_i = a_{\iota\tau,i}$. In the convention of the quoted existence theorem the weights are $h_i = a_i + n - i$. The infinitesimal character of the dual algebraic representation is the unordered tuple

$$z_i = -a_i - \frac{n+1}{2} + i = \frac{n-1}{2} - h_i.$$

The project convention assigns the cyclotomic character weight 1, so its Hodge–Tate weights are $-h_i = z_i - (n-1)/2$, as asserted.

Suppose π_v is unramified, with Satake parameters α_i. The unramified local correspondence is the direct sum of the unramified characters with geometric-Frobenius eigenvalues α_i. Twisting by $|\det|_v^{(1-n)/2}$ therefore multiplies each eigenvalue by

$$|\varpi_v|_v^{(1-n)/2} = q_v^{(n-1)/2}.$$

It leaves inertia trivial and monodromy zero. For $v \nmid \ell$, (Bg7) gives these assertions for $\mathrm{WD}(r_v)$. The construction (Wd1) then gives $r_v|_{I_v} = 1$, since its monodromy vanishes. An inverse arithmetic Frobenius is geometric Frobenius, proving (Bg1), including the indicated characteristic polynomial. For $v \mid \ell$, an unramified π_v has an Iwahori fixed vector, so conclusion (3) of Theorem A.4.11 gives crystallinity and the full Weil–Deligne comparison. The identical eigenvalue computation proves all of (Bg4). In (Bg7) the extra twist is unramified and tensoring a Weil–Deligne representation with a character changes its Weil action but leaves its monodromy operator N unchanged, which proves the final monodromy assertion.

We prove (Bg3). Choose the supercuspidal support $(\sigma_j)_j$ of π_v, with σ_j on $\mathrm{GL}_{n_j}(F_v)$. By Theorem A.4.10 and the twisting law, the right hand side of (*) is the sum of the irreducible Weil representations

$$R_j = \mathrm{rec}_{F_v}(\sigma_j) \otimes \mathrm{rec}_{F_v}(|\cdot|_v^{(1-n)/2}).$$

Their irreducibility follows from (Ln5), and the second factor is unramified. Restricting (*) to inertia is compatible with semisimplification: the inertia image of a Weil–Deligne representation is finite, and finite-group representations in characteristic zero are semisimple. Thus $R_j|_{I_v}$ contains some $\iota\Psi_i|_{I_v}$. The nonzero subspace

$$\{x : R_j(t)x = \iota\Psi_i(t)x \text{ for every } t \in I_v\}$$

is W_v-stable: normality of I_v and the fact that Ψ_i is a character of W_v give the same eigenvalue equation after applying $R_j(w)$. Irreducibility implies this subspace is all of R_j. Consequently $R_j \otimes (\iota\Psi_i)^{-1}$ factors through $W_v/I_v \simeq \mathbb{Z}$. An irreducible finite-dimensional complex representation of this group has dimension one: its generator has an eigenvector and that eigenline is invariant. Therefore $n_j = 1$ for every j. The defining support induction is now the required normalized Borel induction of characters $\xi_1, \dots, \xi_n$.

The multiset of their inertia characters equals that of the $\iota\Psi_i$, because the twist in (*) is unramified. Local reciprocity maps units into inertia, and for $x \in U$ each Ψ_i is trivial on $\mathrm{Art}_{F_v}(x)$. Reversing arithmetic to geometric reciprocity replaces x by x^{-1}, which does not affect triviality. The norm character is also trivial on units. Hence every ξ_j is trivial on U, proving (Bg3).

Finally suppose the principal-series hypothesis of (Bg5) holds. Its inducing characters are supercuspidal representations of $\mathrm{GL}_1(F_v)$. Uniqueness of supercuspidal support in Theorem A.4.10 makes their unordered tuple the support of π_v, even when the induction is reducible. Applying that theorem to (*) gives the sum of the characters

$$\mathrm{rec}_{F_v}(\xi_i|\cdot|_v^{(1-n)/2}).$$

By (Ln1), geometric reciprocity sends x to the value $\xi_i(x)|x|_v^{(1-n)/2}$. The map Art_{F_v} in the statement is arithmetic reciprocity, so its inverse element is geometric reciprocity at x. Pulling coefficients back by ι gives precisely the displayed formula for λ_i in (Bg5). □

Theorem 7.1.7. *Let F be an imaginary CM field, $n \geq 1$, ℓ a prime, and $\iota : \overline{\mathbb{Q}}_\ell \longrightarrow \mathbb{C}$ an isomorphism. Let (π, χ) be regular algebraic, essentially conjugate self-dual and cuspidal: π is cuspidal on $\mathrm{GL}_n(\mathbb{A}_F)$ and regular algebraic, $\chi : \mathbb{A}_{F^+}^\times/(F^+)^\times \longrightarrow \mathbb{C}^\times$ is continuous with $\chi_v(-1)$ independent of $v \mid \infty$, and*

$$\pi^c \simeq \pi^\vee \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det).$$

For a place $v \mid \ell$, put

$$D = \iota\,\mathrm{WD}\big(r_{\ell,\iota}(\pi)|_{G_{F_v}}\big)^{F\text{-}ss}, \qquad D' = \mathrm{rec}_{F_v}(\pi_v \otimes |\det|_v^{(1-n)/2}).$$

Then $D \prec D'$ in the following precise sense. Their semisimplified Weil representations are isomorphic. Partition the irreducible Weil representations into equivalence classes modulo unramified character twists. On each such class, decompose the corresponding Weil–Deligne summand as a direct sum of special representations $\mathrm{Sp}_{m_j}(s_j)$, order their positive block lengths $m_1 \geq m_2 \geq \cdots$, and pad the list with zeros. For every class and every $k \geq 1$,

$$\sum_{j=1}^{k} m_j(D) \leq \sum_{j=1}^{k} m_j(D').$$

Moreover $D \simeq D'$ if π has Shin-regular weight: either n is odd, or, writing π_∞ with the infinitesimal character of the dual of an algebraic representation of highest weights $a_{\tau,1} \geq \cdots \geq a_{\tau,n}$, there are an embedding τ and an odd $j < n$ with $a_{\tau,j} > a_{\tau,j+1}$.

Proof. We first justify the associated representation in the opening convention under precisely the displayed hypotheses. Write $s = \chi_v(-1) \in \{1, -1\}$, independent of the real place v of F^+. Global reciprocity Theorem A.2.8, applied to the quadratic CM extension F/F^+, gives a quadratic character κ of C_{F^+} with kernel $\mathrm{N}_{F/F^+}C_F$. Thus $\kappa \circ \mathrm{N}_{F/F^+} = 1$. At every real place the extension is $\mathbb{C}/\mathbb{R}$, so the real-place clause of that theorem gives $\kappa_v(-1) = -1$. Choose $e \in \{0, 1\}$ with $s(-1)^e = (-1)^n$ and put $\chi_0 = \chi\kappa^e$. The character χ_0 is continuous, has the

real signs required by Theorem A.4.11, and has the same norm pullback as χ. Consequently the displayed polarization of π holds with χ_0 as well. Regular algebraicity and cuspidality concern the unchanged π. Applying Theorem A.4.11 to (π, χ_0) therefore gives a continuous semisimple representation r_0 and its stated unramified compatibility.

Apply the published comparison Theorem A.4.15 to the original pair (π, χ), whose common-sign hypothesis is exactly the one in the present statement. Denote its associated continuous semisimple representation by R. We check that this is r_0, so that the auxiliary sign adjustment does not change the representation named here. At every finite place outside the union of the two finite exceptional sets and the places above ℓ, both representations have the characteristic polynomial prescribed by the same unramified local Langlands parameter of π, with the same twist $|\det|^{(1-n)/2}$ and the same geometric-Frobenius convention. Their traces agree at those Frobenius elements.

For completeness, Chebotarev Theorem A.2.6 makes these conjugacy classes dense: in any finite Galois quotient every conjugacy class occurs at a place outside the given finite exceptional set, because its Frobenius set has positive Dirichlet density. Conjugation invariance and continuity of the two trace functions then give equality of their traces on all of G_F. Equivalently, for any open normal subgroup and any conjugacy class in its quotient there is a Frobenius representative in that class; after conjugation this supplies an element in the prescribed coset, which proves the required density. The representations are finite dimensional and semisimple over the algebraically closed characteristic-zero field $\overline{\mathbb{Q}}_\ell$. Item 2 of Lemma 7.7.9 therefore gives $R \simeq r_0$. This also proves independence from the auxiliary character χ_0 and identifies the canonical $r_{\ell,\iota}(\pi)$ in the statement with the representation supplied in the convention Theorem A.4.11.

Now Theorem A.4.15 gives, at the specified $v \mid \ell$, precisely $D \prec D'$ with the underlying Weil semisimplification and the classwise block-length partial sums printed in the statement. Isomorphism $R \simeq r_0$ remains an isomorphism after restriction and after the Weil–Deligne and Frobenius-semisimplification operations. The same quoted theorem gives $D \simeq D'$ under exactly the displayed Shin-regular condition. The normalization agrees on both sides by construction; Frobenius-semisimplification retains monodromy. Thus this step uses the full published monodromy comparison, rather than deducing monodromy from equality of semisimplified Weil representations. □

Theorem 7.1.8. *Let F be a totally real field with $[F : \mathbb{Q}] \geq 2$, E/F a totally imaginary quadratic extension, $n \geq 1$, U an inner form of the quasi-split unitary group in n variables for E/F with $U(F \otimes_{\mathbb{Q}} \mathbb{R})$ compact, σ an automorphic representation of $U(\mathbb{A}_F)$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, π a weak base change of σ to $\mathrm{GL}_n(\mathbb{A}_E)$ in the sense of [177], and $r\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ the continuous semisimple representation such that, for all but finitely many finite places w of E at which π_w is unramified, r is unramified at w and ι carries the characteristic polynomial of a geometric Frobenius at w to $\prod_\alpha (X - q_w^{(n-1)/2}\alpha)$, α over the Satake parameters of π_w. Let $v \nmid \ell$ be a finite place of F that splits in E, $w \mid v$ a place of E, $\iota_w\colon U(F_v) \to \mathrm{GL}_n(E_w)$ the isomorphism determined by w (well defined up to conjugacy), $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above w, and $(V, \rho, N) = \mathrm{WD}(r|_{D_{\bar{w}}})$. Then:*

(Us1) $\pi_w \cong \sigma_v \circ \iota_w^{-1}$;

(Us2) $(V, \rho, N)^{F\text{-}ss} \cong \iota^{-1}\mathrm{rec}_{E_w}(\pi_w \otimes |\det|_w^{(1-n)/2})$;

(Us3) *if the monodromy operator of $\mathrm{rec}_{E_w}(\pi_w)$ is zero, then $N = 0$, $r(\gamma)$ is semisimple for every $\gamma \in I_{\bar{w}}$, and $\iota(\det(X - r(\gamma)))$ is the characteristic polynomial of γ in $\mathrm{rec}_{E_w}(\pi_w)$, for every $\gamma \in I_{\bar{w}}$; this applies in particular when π_w is supercuspidal (for instance of depth zero), since then $\mathrm{rec}_{E_w}(\pi_w)$ is irreducible with zero monodromy;*

(Us4) *let $B \subseteq \mathrm{GL}_n(E_w)$ be the upper triangular Borel subgroup with unipotent radical N_B and modulus character δ_B, and let $r_B(\pi_w) = \delta_B^{-1/2} \otimes (\pi_w)_{N_B}$ be the normalised Jacquet module; if a character $\chi = \chi_1 \otimes \cdots \otimes \chi_n$ of the diagonal torus is a Jordan–Hölder constituent of $r_B(\pi_w)$ and, for a uniformiser ϖ_w,*

$$|\chi_1(\varpi_w)| \;\geq\; |\chi_2(\varpi_w)| \;\geq\; \dots \;\geq\; |\chi_n(\varpi_w)|,$$

then the monodromy operator of $\mathrm{rec}_{E_w}(\pi_w)$ is zero (so (Us3) applies), and $\rho^{ss} \cong \lambda_1 \oplus \cdots \oplus \lambda_n$ with $\iota(\lambda_i(\mathrm{Art}_{E_w}(x)^{-1})) = \chi_i(x)\,|x|_w^{(1-n)/2}$ for $x \in E_w^\times$;

(Us5) *(Steinberg exclusion) for $n \geq 2$ and every character μ of $E_w^\times$, $r_B(\mathrm{St}_n \otimes (\mu \circ \det))$ is the single character $\mu\delta_B^{1/2}$, whose i-th component $\mu|\cdot|_w^{(n+1-2i)/2}$ has $|\mu(\varpi_w)|\,q_w^{-(n+1-2i)/2}$ strictly increasing in i, so the hypothesis of (Us4) fails for it; for the character $\mu \circ \det$ of $\mathrm{GL}_n(E_w)$, r_B is the single character $\mu\delta_B^{-1/2}$, which satisfies it.*

Proof. By Theorem 7.1.4 and its uniqueness assertion, the representation in the hypothesis is the direct sum of the polarized regular-algebraic cuspidal representations attached to $\Pi'_j = \Pi_j|\det|^{(m_j-n)/2}$.

At a split place v, the identification $E \otimes_F F_v = E_w \times E_{w^c}$ identifies the unitary group with $\mathrm{GL}_n(E_w)$: the second matrix is determined by the inverse adjoint of the first. The corresponding split base-change map has first component the identity and second component its conjugate contragredient. Thus its first local representation is $\sigma_v \circ \iota_w^{-1}$. The split-place assertion of [177, Corollaire 5.3] gives (Us1).

For each Π'_j, apply the away-from-ℓ local–global compatibility theorem [15, Theorem 2.1.1]. All its cuspidality, regular algebraicity and polarization hypotheses were checked in Theorem 7.1.4. Its local parameter is

$$\iota\,\mathrm{WD}(r_{\ell,\iota}(\Pi'_j)|_{D_{\bar{w}}})^{F\text{-}ss} \cong \mathrm{rec}_{E_w}(\Pi_{j,w}|\det|^{(1-n)/2}),$$

since $(m_j - n)/2 + (1 - m_j)/2 = (1 - n)/2$. Formation of Weil–Deligne representations and Frobenius semisimplification commutes with direct sums. The parameter of the isobaric sum is the direct sum of the constituent parameters, including monodromy, by the discrete-spectrum parameter formula and local Langlands. Taking their sum proves (Us2).

Frobenius semisimplification leaves monodromy and inertia unchanged. An unramified twist likewise leaves inertia unchanged and preserves the vanishing of monodromy. Consequently zero monodromy of $\mathrm{rec}_{E_w}(\pi_w)$ implies $N = 0$. The Weil–Deligne comparison then gives $r(\gamma) = \rho(\gamma)$ for $\gamma \in I_{\bar{w}}$. The inertia image of ρ is finite, so every such matrix has finite order and is semisimple in characteristic zero. Its characteristic polynomial is that furnished by (Us2). This proves (Us3); the supercuspidal case is (Ln5) of Theorem A.4.9.

We prove the local assertion in (Us4) with the induction direction explicit. The finite-length representation $r_B(\pi_w)$ of the abelian torus is finite dimensional and decomposes into simultaneous generalized character spaces. If χ occurs, its generalized character space has a quotient χ; projection onto that space therefore gives a nonzero quotient $r_B(\pi_w) \to \chi$. Normalized Frobenius reciprocity gives a nonzero map

$$\pi_w \longrightarrow I(\chi_1, \dots, \chi_n).$$

It is injective because π_w is irreducible. Write $\chi_i = \mu_i|\cdot|^{s_i}$ with μ_i unitary. The absolute-value inequality is exactly $s_1 \leq \cdots \leq s_n$. Smooth contragredient duality is exact on admissible representations and carries this normalized induction to $I(\chi_1^{-1}, \dots, \chi_n^{-1})$. Hence $\pi_w^\vee$ is an irreducible

quotient of the latter induction. Its exponents $-s_i$ are nonincreasing, so Theorem A.4.23 identifies it with the singleton-segment Langlands quotient. By (Ln6) and (Ln1) of Theorem A.4.9,

$$\mathrm{rec}_{E_w}(\pi_w^\vee) \cong \bigoplus_i \mathrm{rec}_{E_w}(\chi_i^{-1}).$$

Duality in (Ln3) now gives $\mathrm{rec}_{E_w}(\pi_w) \cong \bigoplus_i \mathrm{rec}_{E_w}(\chi_i)$, so its monodromy vanishes. Combining this equality with (Us2) and the unramified normalization $|\det|^{(1-n)/2}$ gives precisely the characters λ_i of (Us4). Normalized Frobenius reciprocity and admissible smooth duality here are the standard induction–Jacquet adjunction of [24]; no comparison with an Iwahori Hecke operator is being assumed.

For (Us5), we compute the actual normalised Jacquet module by the segment formula of [332, Proposition 9.5]. Put $K = E_w$, let $\nu(g) = |\det g|_w$, and set

$$\xi_0 = |\cdot|_w^{(1-n)/2}$$

as a representation of $\mathrm{GL}_1(K)$. This is a smooth irreducible supercuspidal representation of $\mathrm{GL}_1(K)$: that group has no proper parabolic subgroup. The segment has length n, and its essentially square-integrable representation is

$$\delta([\xi_0, \nu^{n-1}\xi_0]) = \mathrm{St}_n.$$

The equality is the centered-character example in [332, Example 9.2]. In particular it is the ordinary Steinberg representation, not a determinant twist of it. Its segment orientation is the unique irreducible subrepresentation of $\nu^{(n-1)/2} \times \cdots \times \nu^{(1-n)/2}$, with all inductions normalised and all parabolics upper block-triangular.

For a character ξ of $K^\times$ and a segment of length $h > 1$, the published formula with $m = 1$, $i = p = 1$ reads

$$r_{h-1,1}\big(\delta([\xi, \nu^{h-1}\xi])\big) \cong \delta([\nu\xi, \nu^{h-1}\xi]) \boxtimes \xi.$$

The formula applies at each succeeding stage, since $\nu^a\xi$ is still an irreducible character of $\mathrm{GL}_1(K)$. Iterating it in the first block, and using the length-one identity $\delta([\xi,\xi]) = \xi$, gives

$$r_{B_h}\big(\delta([\xi, \nu^{h-1}\xi])\big) \cong \nu^{h-1}\xi \boxtimes \nu^{h-2}\xi \boxtimes \cdots \boxtimes \xi.$$

Here normalised Jacquet transitivity introduces no further twist. Indeed N_{B_h} is the semidirect product of the unipotent radical of $P_{h-1,1}$ and the upper unipotent subgroup in its first Levi block, so taking their coinvariants successively takes precisely N_{B_h}-coinvariants. For $t = \mathrm{diag}(t_1, \dots, t_h)$ the normalising factors multiply correctly because

$$\delta_{P_{h-1,1}}(t)\, \delta_{B_{h-1}}(\mathrm{diag}(t_1, \dots, t_{h-1})) = \left(\prod_{i<h} |t_i/t_h|_w\right)\left(\prod_{i<j<h} |t_i/t_j|_w\right) = \delta_{B_h}(t).$$

These are isomorphisms of modules at every step. The final module is one-dimensional, so there is neither an omitted extension nor a passage to its semisimplification.

Taking $h = n$ and $\xi = \xi_0$, the i-th character is

$$\nu^{n-i}\xi_0 = |\cdot|_w^{(n+1-2i)/2}.$$

On the other hand the determinant of the conjugation action of t on the upper unipotent radical gives

$$\delta_B(t) = \prod_{i<j} |t_i/t_j|_w = \prod_{i=1}^{n} |t_i|_w^{n+1-2i}.$$

Thus the preceding one-dimensional module is exactly $\delta_B^{1/2}$.

Twisting a representation by $\mu\circ\det$ leaves its unipotent coinvariant quotient space unchanged, since $\det u = 1$ for $u \in N_B$. Its torus action is multiplied by $\prod_i \mu(t_i)$. This proves

$$r_B\big(\mathrm{St}_n \otimes (\mu\circ\det)\big) = \boxtimes_{i=1}^{n} \mu|\cdot|_w^{(n+1-2i)/2}.$$

At a uniformiser its i-th absolute value is $|\mu(\varpi_w)|q_w^{-(n+1-2i)/2}$. The ratio of the value at $i+1$ to that at i is $q_w > 1$, so for $n \geq 2$ the descending-absolute-value hypothesis in (Us4) fails. For the character representation $\mu\circ\det$, the unipotent action is already trivial, and the definition of the normalised Jacquet functor directly gives

$$r_B(\mu\circ\det) = \boxtimes_{i=1}^{n} \mu|\cdot|_w^{-(n+1-2i)/2} = \mu\delta_B^{-1/2}.$$

Its successive absolute-value ratios at ϖ_w are $q_w^{-1} < 1$, so it satisfies the hypothesis. This proves (Us5). □

Theorem 7.1.9. *Let F be a totally real field with $[F:\mathbb{Q}] \geq 2$, E/F a totally imaginary quadratic extension, $n \geq 1$, U an inner form of the quasi-split unitary group in n variables for E/F with $U(F\otimes_{\mathbb{Q}}\mathbb{R})$ compact, σ an automorphic representation of $U(\mathbb{A}_F)$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, π a weak base change of σ to $\mathrm{GL}_n(\mathbb{A}_E)$ in the sense of [177], and $r\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ the continuous semisimple representation such that, for all but finitely many finite places w of E at which π_w is unramified, r is unramified at w and ι carries the characteristic polynomial of a geometric Frobenius at w to $\prod_\alpha(X - q_w^{(n-1)/2}\alpha)$, α over the Satake parameters of π_w. Let $w \mid \ell$ be a place of E, $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above it, and $r_{\bar{w}} = r|_{D_{\bar{w}}}$, viewed as a representation of G_{E_w}. Then:*

(Ul1) *$r_{\bar{w}}$ is de Rham, and for every field embedding $\tau\colon E_w \to \overline{\mathbb{Q}}_\ell$ over $\mathbb{Q}_\ell$ its τ-Hodge–Tate weights are the n numbers $z - \frac{n-1}{2}$, z running over the infinitesimal character of π_∞ at the complex embedding $\iota\circ\tau|_E$; this infinitesimal character is the base change of that of σ_∞;*

(Ul2) *writing $\mathrm{WD}(r_{\bar{w}}) = (V,\rho,N)$, the semisimplification of ρ is isomorphic to that of the representation of $W_{\bar{w}}$ in $\iota^{-1}\mathrm{rec}_{E_w}(\pi_w \otimes |\det|_w^{(1-n)/2})$, and if the monodromy operator of $\mathrm{rec}_{E_w}(\pi_w)$ is zero then $N = 0$;*

(Ul3) *if the monodromy operator of $\mathrm{rec}_{E_w}(\pi_w)$ is zero (in particular if π_w is supercuspidal, or satisfies the Jacquet-module condition (Us4) of Theorem 7.1.8 at w), then $r_{\bar{w}}$ is potentially crystalline, $\mathrm{WD}(r_{\bar{w}})^{F\text{-}ss} \cong \iota^{-1}\mathrm{rec}_{E_w}(\pi_w \otimes |\det|_w^{(1-n)/2})$, and $r_{\bar{w}}|_{G_K}$ is crystalline for every finite extension K/E_w inside $\overline{\mathbb{Q}}_\ell$ such that ρ is trivial on the inertia subgroup of W_K;*

(Ul4) *if π_w is unramified, then $r_{\bar{w}}$ is crystalline, $N = 0$, ρ is trivial on the inertia subgroup of $W_{\bar{w}}$, and $\iota(\det(X - \rho(\Phi))) = \prod_\alpha(X - q_w^{(n-1)/2}\alpha)$ for every $\Phi \in W_{\bar{w}}$ with $n(\Phi) = -1$, α running over the Satake parameters of π_w with multiplicity; this holds in particular when w lies above a place v of F at which E/F and U are unramified and σ_v is spherical.*

Proof. By uniqueness in Theorem 7.1.4, the given r is $\bigoplus_j r_{\ell,\iota}(\Pi'_j)$, where $\Pi'_j = \Pi_j|\det|^{(m_j-n)/2}$ is regular algebraic, polarizable and cuspidal. All these hypotheses were proved there. For each summand the cuspidal Galois theorem gives de Rhamness and the Hodge–Tate weights of (Bg2). If z is an infinitesimal-character entry of Π_j, the corresponding entry for Π'_j is $z + (m_j - n)/2$, and its Hodge–Tate weight is

$$z + (m_j - n)/2 - (m_j - 1)/2 = z - (n-1)/2.$$

The infinitesimal character of π is the union of those of the Π_j, so taking the multiset union proves (Ul1). The assertion about the coefficient system of σ_∞ is the infinitesimal-character clause of [177, Corollaire 5.3].

Put

$$D_j = \mathrm{WD}(r_{\ell,\iota}(\Pi'_j)|_{D_{\bar{w}}}), \qquad D'_j = \iota^{-1}\mathrm{rec}_{E_w}(\Pi_{j,w}|\det|^{(1-n)/2}).$$

For $m_j \geq 2$, the monodromy-domination theorem [16, Theorem 1.1] gives $D_j^{F\text{-}ss} \prec D'_j$. In particular their semisimplified Weil representations agree. If D'_j has zero monodromy, each of its special-representation blocks has length one. The partial-sum inequality for its largest block then forces each block of D_j to have length at most one; hence D_j has zero monodromy. For $m_j = 1$, monodromy is automatically zero, and the equality of the Weil characters is (Bg5), applied to the rank-one local representation.

The parameter of $\pi_w|\det|^{(1-n)/2}$ is the direct sum of the D'_j, including monodromy. Indeed the local discrete-spectrum formula gives the constituent direct sum, and

$$(m_j - n)/2 + (1 - m_j)/2 = (1 - n)/2.$$

Weil–Deligne formation commutes with direct sums. Thus summing the semisimplified comparisons proves the first assertion of (Ul2). If the total automorphic monodromy is zero, each summand monodromy is zero; the preceding domination argument then gives zero monodromy for each D_j and hence for their sum. This proves all of (Ul2).

By (Ul1), $r_{\bar{w}}$ is de Rham and hence potentially semistable. When its monodromy is zero, the crystalline descent criterion of Theorem 7.1.10 says that it is potentially crystalline, and that its restriction to any finite extension K/E_w is crystalline whenever its Weil representation is trivial on inertia at K. Both parameters in (Ul2) now have zero monodromy. A Frobenius-semisimple Weil representation with finite inertia image is semisimple, so their equal semisimplifications are the asserted isomorphic Frobenius semisimplifications. This proves (Ul3). The supercuspidal and sorted-Jacquet cases have zero automorphic monodromy by the purely local assertions (Ln5) and (Us4), respectively; the latter argument concerns only $\mathrm{GL}_n(E_w)$ and is independent of whether w divides ℓ.

If π_w is spherical, the direct-sum local parameter formula makes each $\Pi_{j,w}$ spherical: its parameter is a direct summand of an unramified parameter with zero monodromy. Its unramified twist $\Pi'_{j,w}$ is therefore spherical too. For each such summand apply (Bg4) of Theorem 7.1.6. Their sum is crystalline, has zero monodromy and trivial Weil inertia, and its geometric-Frobenius eigenvalues are

$$q_w^{(m_j-1)/2} q_w^{(n-m_j)/2}\alpha = q_w^{(n-1)/2}\alpha.$$

The multiset union over j is the Satake multiset of π_w. Trivial inertia means this characteristic polynomial is the same for every Weil element of degree -1, proving (Ul4). Its last clause is the spherical base-change assertion (Ua0) of Theorem 7.1.4. □

Theorem 7.1.10. *Let ℓ be a prime, K a finite extension of $\mathbb{Q}_\ell$, and $r\colon G_K \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a continuous homomorphism. Then $r(G_K) \subseteq \mathrm{GL}_n(E)$ for some finite extension E of $\mathbb{Q}_\ell$ inside $\overline{\mathbb{Q}}_\ell$; r is called **de Rham**, **semistable** or **crystalline** if the $\mathbb{Q}_\ell$-linear representation E^n of G_K is, and **potentially semistable** (**potentially crystalline**) if $r|_{G_{K'}}$ is semistable (crystalline) for some finite extension K' of K inside $\overline{\mathbb{Q}}_\ell$; these notions do not depend on E.*

1. *Crystalline implies semistable, semistable implies potentially semistable, and r is de Rham if and only if it is potentially semistable. In particular $\mathrm{WD}(r)$ is defined by (Wd2) for every de Rham r.*

2. *Let r be potentially semistable, $\mathrm{WD}(r) = (V, \rho, N)$, and K' a finite extension of K inside $\overline{\mathbb{Q}}_\ell$. Then $r|_{G_{K'}}$ is semistable if and only if ρ is trivial on $I_{K'}$, and crystalline if and only if ρ is trivial on $I_{K'}$ and $N = 0$. In particular r is potentially crystalline if and only if $N = 0$.*

3. *Consequently r is crystalline if and only if r is de Rham and $\mathrm{WD}(r)$ is unramified, that is, ρ is trivial on I_K and $N = 0$.*

Proof. **The continuous representation has a finite coefficient field.** For each positive integer d, let E_d be the compositum in $\overline{\mathbb{Q}}_\ell$ of all extensions of $\mathbb{Q}_\ell$ of degree at most d. There are finitely many such extensions by Krasner's finiteness theorem for local fields, so E_d is finite, complete, and closed. Every algebraic element belongs to some E_d. Set

$$H_d = r^{-1}\big(\mathrm{GL}_n(E_d)\big).$$

This is a closed subgroup of G_K: $\mathrm{GL}_n(E_d)$ is the intersection of $\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ with the closed matrix space $\mathrm{M}_n(E_d)$. The compact Hausdorff space G_K is the countable union of the H_d. Baire's theorem gives an H_d with nonempty interior. Translating an interior neighbourhood by an element of this subgroup shows that H_d contains a neighbourhood of 1, so it is open. Its index is finite by compactness. Choose coset representatives $g_1, \dots, g_s$. Adjoin the finitely many entries of $r(g_i)$ to E_d, obtaining a finite extension E. For $g = g_i h$ with $h \in H_d$, the matrix $r(g) = r(g_i)r(h)$ has entries in E and is invertible over E. This proves the field-of-values assertion. This is also the argument of Lemma 7.1.17(1).

The admissibility notions do not depend on coefficients. For a finite extension E_1/E, choose an E-basis of E_1. It identifies the underlying $\mathbb{Q}_\ell[G_K]$-module $E_1 \otimes_E E^n$ with the direct sum of $[E_1 : E]$ copies of E^n. Period invariants commute with finite direct sums. Their dimensions are bounded above by the representation dimensions for each of the three period rings, and equality for a finite direct sum is therefore equivalent to equality for every summand. Hence de Rham, semistable and crystalline admissibility are unchanged by extending E. Two possible coefficient fields are compared inside their finite compositum. The same argument after each finite extension of K proves independence for the potential notions.

We recall precisely the period facts used here: the comparison maps are injective, $B_{\mathrm{cris}}^{G_K} = B_{\mathrm{st}}^{G_K} = K_0$, $B_{\mathrm{dR}}^{G_K} = K$, and

$$B_{\mathrm{cris}} \subset B_{\mathrm{st}}, \qquad K \otimes_{K_0} B_{\mathrm{st}} \hookrightarrow B_{\mathrm{dR}}.$$

These are the regular-period-ring comparison statements of [44], Theorem 5.2.1, Theorem 9.2.10 and Proposition 9.2.11. They give the preceding dimension bounds, and show directly that crystalline implies semistable and semistable implies de Rham.

De Rham admissibility descends along finite extensions of K. To see this, it suffices to use a finite Galois extension L/K. The space $D_{\mathrm{dR},L}(U) = (B_{\mathrm{dR}} \otimes U)^{G_L}$ has a semilinear action of $\mathrm{Gal}(L/K)$ and its invariants are $D_{\mathrm{dR},K}(U)$. Finite Galois descent gives $L \otimes_K D_{\mathrm{dR},K}(U) \simeq D_{\mathrm{dR},L}(U)$. Thus if the latter has full dimension, so does the former. Passing to a Galois closure proves the assertion for every finite extension. Conversely, a de Rham comparison isomorphism remains an isomorphism after restriction, which proves preservation under restriction. Berger's monodromy theorem [22] now supplies de Rham implies potentially semistable. A potentially semistable representation is de Rham over an extension and hence over K by the descent just proved. This proves item 1.

Restriction preserves the completed module and its inertia and monodromy. Write $U = E^n$ as a $\mathbb{Q}_\ell$-representation, and form the completed module A in Fontaine's theorem

[86], Theorem 2.3.2 and Remark 2.3.3. For a finite extension K'/K, $I_{K'}$ is an open subgroup of I_K. The open subgroups contained in $I_{K'}$ are cofinal among those of I_K: replace any open H by $H \cap I_{K'}$. The defining union for A is therefore unchanged by restriction. The residue algebraic closure, its Witt fraction field P_0, and the operator N are unchanged as well. Fontaine's semistability and crystalline criteria applied over K' consequently say

$$U|_{G_{K'}} \text{ semistable} \iff I_{K'} \text{ acts trivially on } A,$$

$$U|_{G_{K'}} \text{ crystalline} \iff I_{K'} \text{ acts trivially on } A \text{ and } N = 0.$$

These criteria apply to the E-linear representation r with the stated Weil–Deligne coefficients. Indeed the E-action commutes with every period action. Fontaine's Weil functor commutes with scalar extension and direct sums. Extending the coefficient field to $\overline{\mathbb{Q}}_\ell$ decomposes the underlying $\mathbb{Q}_\ell$-representation into the components indexed by embeddings $E \hookrightarrow \overline{\mathbb{Q}}_\ell$; the chosen inclusion gives $\mathrm{WD}(r)$. The other components are its coefficient-Galois conjugates. Triviality of an inertia matrix and vanishing of a monodromy matrix are preserved and reflected by a field embedding, so they hold on the chosen component exactly when they hold on every component. Faithfulness of field extension then reflects them on the original module. In the Weil functor, the Frobenius correction is the identity on inertia; hence the inertia matrices are exactly $\rho|_{I_{K'}}$. Its monodromy is the same operator after the faithful scalar changes. No Frobenius eigenvalue or arithmetic/geometric Frobenius choice enters either criterion. This proves the two equivalences of item 2.

The inertia action has finite image. To kill it after a finite extension, let J be its open kernel in I_K. The subspace topology on $I_K \subset G_K$ gives an open neighbourhood U_0 of 1 in G_K with $U_0 \cap I_K \subset J$. Choose an open normal subgroup $H \subset U_0$ and let K' be its finite fixed field. Then $I_{K'} = H \cap I_K \subset J$. If $N = 0$, the crystalline criterion over this K' proves potential crystallinity. Conversely, crystallinity over any K' forces the same operator N to vanish, by the second equivalence. This proves the final assertion of item 2.

Finally, a crystalline r is de Rham by item 1 and has $\rho|_{I_K} = 1$, $N = 0$ by item 2. If r is de Rham and its Weil–Deligne representation is unramified in the stated sense, item 1 makes it potentially semistable and item 2 with $K' = K$ makes it crystalline. This proves item 3. □

Theorem 7.1.11. *Let F be a totally real field with $[F : \mathbb{Q}] \geq 2$, E/F a totally imaginary quadratic extension, $n \geq 1$, U an inner form of the quasi-split unitary group in n variables for E/F with $U(F \otimes_{\mathbb{Q}} \mathbb{R})$ compact, σ an automorphic representation of $U(\mathbb{A}_F)$, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \to \mathbb{C}$ an isomorphism, π a weak base change of σ to $\mathrm{GL}_n(\mathbb{A}_E)$ in the sense of [177], and $r\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ the continuous semisimple representation such that, for all but finitely many finite places w of E at which π_w is unramified, r is unramified at w and ι carries the characteristic polynomial of a geometric Frobenius at w to $\prod_\alpha (X - q_w^{(n-1)/2}\alpha)$, α over the Satake parameters of π_w. Let $v \nmid \ell$ be a finite place of F split in E, $w \mid v$ a place of E and $\bar{w}$ a place of $\overline{\mathbb{Q}}$ above w; recall $\pi_w \cong \sigma_v \circ \iota_w^{-1}$ for the isomorphism $\iota_w\colon U(F_v) \to \mathrm{GL}_n(E_w)$ determined by w, so the hypothesis below may equally be read on σ_v. Let $n = n_1 + \cdots + n_k$ with $n_a \geq 1$, let $P \subseteq \mathrm{GL}_n$ be the standard (block upper triangular) parabolic subgroup with Levi factor $\mathrm{GL}_{n_1} \times \cdots \times \mathrm{GL}_{n_k}$, let $J \subseteq \mathrm{GL}_n(\mathcal{O}_{E_w})$ be the preimage of $P(k_w)$ under reduction modulo ϖ_w, and let $\chi_1, \ldots, \chi_k\colon k_w^\times \to \mathbb{C}^\times$ be **pairwise distinct** characters. Suppose that π_w has a non-zero vector y with*

$$\pi_w(g)\, y = \prod_{a=1}^{k} \chi_a\big(\det \overline{g_{aa}}\big)\, y \qquad (g \in J),$$

where g_{aa} is the a-th diagonal block of g and the bar is reduction modulo ϖ_w. Then:

(Up1) $\pi_w \cong \mathrm{Ind}_P^{\mathrm{GL}_n}(\rho_1 \otimes \cdots \otimes \rho_k)$ *(normalised induction, irreducible), where* $\rho_a = \rho_a^\circ \otimes (\tilde{\chi}_a \circ \det)$ *with* ρ_a° *an irreducible unramified (spherical) representation of* $\mathrm{GL}_{n_a}(E_w)$ *and* $\tilde{\chi}_a$ *a character of* $E_w^\times$ *whose restriction to* $\mathcal{O}_{E_w}^\times$ *is* χ_a *composed with reduction;*

(Up2) *the monodromy operators of* $\mathrm{rec}_{E_w}(\pi_w)$ *and of* $\mathrm{WD}(r|_{D_{\bar{w}}})$ *are zero;*

(Up3) *for every* $\gamma \in I_{\bar{w}}$, $r(\gamma)$ *is semisimple and*

$$\det(X - r(\gamma)) = \prod_{a=1}^{k} (X - \iota^{-1}\chi_a(\bar{u}))^{n_a},$$

where $u \in \mathcal{O}_{E_w}^\times$ *is such that the image of* γ *in the abelianised Weil group of* E_w *is* $\mathrm{Art}_{E_w}(u)^{-1}$*; in particular* $\prod_a (X - \iota^{-1}\chi_a(\bar{u}))$ *kills* $r(\gamma)$.

This covers in particular: $k = 1$ *(*$J = \mathrm{GL}_n(\mathcal{O}_{E_w})$ *acting through* $\chi_1 \circ \det$*, any* χ_1*); and* $k = 2$*,* $(n_1, n_2) = (1, n-1)$*,* $\chi_2 = 1 \neq \chi_1$ *(*J *the stabiliser of a line modulo* ϖ_w*, acting through* $\chi_1(\overline{g_{11}})$*). It does not cover types with* $\chi_a = \chi_b$ *for some* $a \neq b$ *(for instance the Iwahori subgroup with trivial character, where* St_n *occurs); those are governed by the Jacquet-module criterion with antitone exponents and the Steinberg exclusion stated for split places not above* ℓ.

Proof. Apply Proposition 7.1.12 with local field $K = E_w$, the given block partition, the pairwise distinct characters χ_a and the nonzero vector y. Its hypotheses are exactly the parahoric transformation law in the statement. It yields the irreducible normalized induction and the twisted spherical representations ρ_a in (Up1).

Each spherical block ρ_a° is the Langlands quotient of a normalized induction of unramified characters. Twisting it by $\tilde{\chi}_a \circ \det$ gives the corresponding quotient of the twisted characters. Local Langlands therefore gives a parameter with zero monodromy whose inertia is the scalar character $\mathrm{rec}_{E_w}(\tilde{\chi}_a)|_I$ repeated n_a times. The parameter of the irreducible normalized induction of the ρ_a is their direct sum: concatenate their Langlands multisegments and use (Ln6); irreducibility identifies this induction with its Langlands quotient. Consequently

$$\mathrm{rec}_{E_w}(\pi_w)|_I \cong \bigoplus_a \mathrm{rec}_{E_w}(\tilde{\chi}_a)|_I^{\oplus n_a}, \qquad N_{\mathrm{rec}(\pi_w)} = 0.$$

Here twisting a spherical parameter by a character uses (Ln2), and unramified parameters have zero monodromy.

The global hypotheses and the split place $v \nmid \ell$ meet those of Theorem 7.1.8. Its (Us2) identifies the Frobenius-semisimplified Galois parameter with $\iota^{-1}\mathrm{rec}_{E_w}(\pi_w |\det|^{(1-n)/2})$; the unramified norm twist changes neither inertia nor zero monodromy. By (Us3), the Galois monodromy vanishes and every $r(\gamma)$ for $\gamma \in I_{\bar{w}}$ is semisimple. This proves (Up2).

For u as in (Up3), the arithmetic Artin convention is the inverse of the geometric Artin convention in local Langlands. Write $\lambda_a = \iota^{-1}\mathrm{rec}_{E_w}(\tilde{\chi}_a)$ for the transported one-dimensional parameter. Then

$$\iota(\lambda_a(\mathrm{Art}_{E_w}(u)^{-1})) = \tilde{\chi}_a(u) = \chi_a(\bar{u}).$$

The factor $|u|^{(1-n)/2}$ is 1. The direct sum above consequently gives the characteristic polynomial in (Up3), with multiplicities n_a. Since $r(\gamma)$ is semisimple, its minimal polynomial is a product of distinct linear factors drawn from those eigenvalues. It therefore divides $\prod_a (X - \iota^{-1}\chi_a(\bar{u}))$, even if some of these evaluated character values coincide. This proves the smaller annihilator too.

For one block the stated type is precisely a determinant twist of the maximal compact type. For the partition $(1, n-1)$, the inverse image of the upper block parabolic is the stabilizer

of a line modulo the uniformizer; its determinant character on the first block is $\chi_1(\bar{g}_{11})$. The hypothesis $\chi_1 \neq 1 = \chi_2$ is exactly the distinctness needed by the local block theorem. If two block characters are equal, that hypothesis fails; no conclusion is deduced by this argument. The separate sorted-Jacquet criterion is (Us4) of Theorem 7.1.8. □

Proposition 7.1.12. *Let K be a nonarchimedean local field of characteristic zero, with integer ring $\mathcal{O}_K$, residue field k_K and a uniformizer. Let $n = n_1 + \cdots + n_d$ with $n_a \geq 1$, let P be the standard upper block triangular parabolic of GL_n, and let J be the inverse image of $P(k_K)$ in $\mathrm{GL}_n(\mathcal{O}_K)$. Let $\chi_a : k_K^\times \to \mathbb{C}^\times$ be pairwise distinct characters. Suppose an irreducible smooth representation π of $\mathrm{GL}_n(K)$ contains a nonzero vector v satisfying*

$$\pi(g)v = \prod_{a=1}^{d} \chi_a(\det \overline{g_{aa}})\, v \qquad (g \in J).$$

Then

$$\pi \cong \mathrm{Ind}_{P(K)}^{\mathrm{GL}_n(K)}(\rho_1 \otimes \cdots \otimes \rho_d)$$

with normalized induction, which is irreducible, where $\rho_a = \rho_a^\circ \otimes (\widetilde{\chi}_a \circ \det)$, ρ_a° is irreducible spherical on $\mathrm{GL}_{n_a}(K)$, and $\widetilde{\chi}_a : K^\times \to \mathbb{C}^\times$ restricts on $\mathcal{O}_K^\times$ to χ_a composed with reduction.

Proof. Write $G = \mathrm{GL}_n(K)$ and $M = \prod_a \mathrm{GL}_{n_a}(K)$. Let $I \subseteq J$ be the upper Iwahori subgroup and put $I_M = I \cap M$ and $K_M = \prod_a \mathrm{GL}_{n_a}(\mathcal{O}_K)$. Inflate the character

$$\eta(\mathrm{diag}(t_i)) = \prod_a \chi_a\left(\prod_{i \text{ in block } a} \overline{t_i} \right)$$

from the diagonal residue torus to a character λ of I. The character prescribed in the hypothesis on J will be denoted θ. Its restriction to I is λ, so v belongs to the nonzero (I, λ)-isotypic space of π. Since the block characters are pairwise distinct, the roots on which η is trivial are exactly the roots within individual blocks. Hence the equal-character group in Roche's depth-zero type theorem is precisely M, with no additional permutation of blocks. The theorem applies to general linear groups for every residue characteristic; see [243, Remark4.14 and Theorems7.7,8.2,9.4].

We identify the effect of the larger compact group J under this equivalence. Choose each $\widetilde{\chi}_a$ to have value 1 at the uniformizer. Within a block, untwisting by $\widetilde{\chi}_a \circ \det$ turns λ into the trivial Iwahori character. Let $q = |k_K|$ and $W_M = \prod_a S_{n_a}$. Give I volume 1, and denote by f_w the twisted Iwahori Hecke basis function for $w \in W_M$, normalized by $f_w(w) = \theta(w)^{-1}$. Finite Bruhat decomposition of each diagonal block gives

$$J = \coprod_{w \in W_M} IwI, \qquad \mathrm{vol}(J) = \sum_{w \in W_M} q^{\ell(w)}.$$

The operator projecting onto the θ-isotypic space for J is therefore the Hecke idempotent

$$e_{J,\theta} = \frac{\sum_{w \in W_M} f_w}{\sum_{w \in W_M} q^{\ell(w)}}.$$

Indeed it is integration of $\theta(j)^{-1}\pi(j)$ over J, divided by its volume; integration over any left I-coset has weight 1. On every within-block finite Hecke algebra the type isomorphism, after the determinant untwist just made, sends f_w to the ordinary basis element T_w for (M, I_M). Thus it sends $e_{J,\theta}$ to

$$\frac{\sum_{w \in W_M} T_w}{\sum_{w \in W_M} q^{\ell(w)}} = e_{K_M},$$

the projector onto K_M-fixed vectors. This calculation also checks the scalar normalization; a support correspondence alone would not suffice.

Let $\rho^\circ = \mathcal{F}(\pi)$ under the exact type equivalence. Irreducibility is preserved, and $e_{J,\theta}v = v \neq 0$, so the projector calculation shows that ρ° is spherical on M. By finite-product decomposition and the spherical principal-series parametrization,

$$\rho^\circ \simeq \bigotimes_a \rho_a^\circ,$$

where every ρ_a° is irreducible spherical on $\mathrm{GL}_{n_a}(K)$. Here one uses the classical admissibility of irreducible smooth general-linear representations, so the finite-product decomposition applies. See [23] and [80] for this standard product and admissibility setting, and [318] for the spherical parametrization.

For each a, choose unramified characters $\nu_{a,1}, \dots, \nu_{a,n_a}$ in a Langlands order such that ρ_a° is the unique irreducible quotient of their normalized upper-Borel induction. Let ν be their concatenation on $T(K)$. Then ρ° is the unique irreducible quotient of $i_{B\cap M}^M \nu$. To see uniqueness directly, any irreducible quotient on the product group is a tensor product; restriction of its quotient map to each factor forces that factor to be the unique irreducible quotient of the corresponding ordered principal series. Normalized torus-induction compatibility of $\mathcal{F}$ consequently shows that π is the unique irreducible quotient of

$$i_B^G(\widetilde{\eta}\nu),$$

where $\widetilde{\eta}$ is the concatenation of the extended block characters. No order comparison between two different blocks is required here.

Put $\rho_a = \rho_a^\circ \otimes (\widetilde{\chi}_a \circ \det)$. Its cuspidal support consists of unramified twists of the character $\widetilde{\chi}_a$ of $\mathrm{GL}_1(K)$. For $a \neq b$, these cuspidal lines are different: an unramified twist does not change the restriction to $\mathcal{O}_K^\times$, whereas $\chi_a \neq \chi_b$. Thus

$$\Sigma = i_{P(K)}^G \left(\bigotimes_a \rho_a \right)$$

is irreducible by [332, Proposition8.5]; the hypothesis of that result is satisfied because no segment on one of these lines can be linked to a segment on another. Exactness and transitivity of normalized parabolic induction, applied to the block quotient maps chosen above, give a surjection $i_B^G(\widetilde{\eta}\nu) \twoheadrightarrow \Sigma$. Its unique irreducible quotient is π, so $\Sigma \simeq \pi$. This proves every assertion, with the required unit restrictions on the characters $\widetilde{\chi}_a$. □

Theorem 7.1.13. *Let F be a nonarchimedean local field, $G = \mathrm{GL}_n(F)$, T its diagonal torus, B its upper Borel and I its standard Iwahori subgroup. Let $\eta : T(\mathcal{O}_F) \to \mathbb{C}^\times$ be trivial on $T(1+\mathfrak{p}_F)$, with equal coordinate characters occurring in contiguous blocks. Let M be the corresponding block Levi and $I_M = I \cap M$. Inflate η to a character λ of I. Extend each block character to $F^\times$ with value 1 at a fixed uniformizer, obtaining $\widetilde{\eta}$ on $T(F)$.*

There is an exact equivalence between the category generated by the (I, λ)-isotypic spaces in G and the category generated by the I_M-fixed spaces in M. It comes from a support-preserving Hecke algebra isomorphism and satisfies

$$\mathcal{F}\big(i_B^G(\widetilde{\eta}\nu)\big) \simeq i_{B\cap M}^M(\nu)$$

for every unramified character ν of $T(F)$, with normalized induction. On each finite Weyl-group Hecke subalgebra inside a block, the isomorphism is the usual Iwahori Hecke isomorphism after untwisting by the extended block determinant character.

Proof. Write $\eta(t_1,\dots,t_n)=\prod_i \eta_i(t_i)$ and let q be the residue cardinality. Each ratio $\eta_i\eta_j^{-1}$ is trivial on $1+\mathfrak{p}_F$. Its conductor in the convention of Theorem A.5.32 is therefore one, including when the ratio is trivial. The positive root depth is $\lfloor 1/2\rfloor = 0$, and the negative root depth is $\lceil 1/2\rceil = 1$. Thus the subgroup in that theorem is generated by diagonal units, upper elementary matrices with integral entries and lower elementary matrices with entries in $\mathfrak{p}_F$. These generate exactly I: elimination of the reduction modulo $\mathfrak{p}_F$, followed by integral elementary elimination, gives its Iwahori decomposition. Its character is the prescribed inflation λ, since it is η on diagonal units and trivial on both unipotent factors.

The character on the coroot $u\mapsto \operatorname{diag}(1,\dots,u,\dots,u^{-1},\dots,1)$ is $\eta_i(u)\eta_j(u)^{-1}$. It is trivial exactly when the two coordinate characters agree. Consequently the equal-character root system consists precisely of the roots within the stated contiguous blocks. The associated group is M, with the inherited upper Borel $B\cap M$ and Iwahori I_M. Its Weyl group is the product of the symmetric groups on those blocks. A permutation stabilizes η precisely when it preserves each equal-character class, so this Weyl group is the full stabilizer; there is no additional component group.

Extend a block character by

$$\widetilde{\eta}_a(\varpi^m u)=\eta_a(u)\qquad (m\in\mathbb{Z},\ u\in\mathcal{O}_F^\times).$$

This is a smooth character, has value one at the fixed uniformizer, and extends the prescribed unit character. Its product on the diagonal torus is exactly the extension used in Theorem A.5.32. The type equivalences and support-preserving algebra isomorphism of that theorem therefore have exactly the two categories in the statement. The isotypic functors are exact: averaging a smooth vector over a compact subgroup with its inverse character is an idempotent projector, and applying that projector to a lift in a surjection gives a lift in the isotypic subspace. Restriction of scalars through the Hecke algebra isomorphism is exact as well. Composing with the inverse equivalence gives the asserted exact functor $\mathcal{F}$.

Its torus-induction compatibility is the normalized one in Theorem A.5.32. Explicitly, our induction consists of functions transforming under the upper Borel by $\delta_B^{1/2}\widetilde{\eta}\nu$, and on M by $\delta_{B\cap M}^{1/2}\nu$. These are the same upper Borels and positive roots used in that theorem. For a diagonal element t,

$$\delta_B(t)=\prod_{i<j}|t_i/t_j|_F,\qquad \delta_{B\cap M}(t)=\prod_{\substack{i<j\\ i,j\text{ in one block}}}|t_i/t_j|_F.$$

The remaining factors are the modulus of the block parabolic: on $m=\operatorname{diag}(m_a)$ it is

$$\delta_P(m)=\prod_{a<b}|\det m_a|_F^{n_b}|\det m_b|_F^{-n_a}.$$

Thus the normalized torus embeddings have the prescribed half-moduli, rather than an unnormalized induction with a discarded cross-block factor. The published normalized compatibility yields $\mathcal{F}(i_B^G(\widetilde{\eta}\nu))\simeq i_{B\cap M}^M(\nu)$ with precisely these conventions.

It remains to determine the finite-block scalar of the same support-preserving isomorphism. Give I and I_M mass one, and use the Hecke convention

$$f(i_1gi_2)=\lambda(i_1)^{-1}f(g)\lambda(i_2)^{-1},\qquad f\cdot v=\int_G f(g)\pi(g)v\,dg.$$

For one block define $\theta_a=\widetilde{\eta}_a\circ\det$. It extends λ on that block's Iwahori. Multiplication of a scalar Hecke function by θ_a^{-1} identifies the untwisted convolution algebra on this block with the

twisted one: in the convolution integral the two factors of the character multiply to $\theta_a(g)^{-1}$. In particular it sends the unit to the unit.

Let s interchange two adjacent coordinates within the block, choose its permutation matrix $\dot{s}$, and let f_s be the twisted function supported on $I\dot{s}I$ with value $\theta_a(\dot{s})^{-1}$ there. The character extends to the rank-one parahoric generated by I and $\dot{s}$, through the block determinant. After untwisting, reduction to its two-dimensional residue quotient gives the ordinary double coset of a Borel in $\mathrm{GL}_2(k_F)$. It has q right Borel cosets. For the convolution square, the coefficient at the identity counts these q cosets; the coefficient at $\dot{s}$ counts the $q-1$ nonzero residue parameters. There is no other support, since this rank-one quotient has exactly the two Bruhat cells. Hence, with e_λ the unit,

$$f_s * f_s = q e_\lambda + (q-1) f_s.$$

The identical count for M gives $T_s^2 = q + (q-1)T_s$ for its ordinary Iwahori generator.

Choose the support-preserving isomorphism supplied by Theorem A.5.32, in the direction from the M algebra to the G algebra. Its image of T_s has support exactly $I\dot{s}I$, whose twisted function space is one dimensional. It is therefore $c_s f_s$ for some nonzero scalar c_s. Applying the isomorphism to the quadratic relation and comparing the disjoint identity and reflection supports gives

$$c_s^2 = 1, \qquad c_s^2(q-1) = c_s(q-1).$$

Since $q > 1$, these equalities force $c_s = 1$. Thus the normalized-induction-compatible isomorphism itself, without changing its torus action, has the required simple-generator normalization. For a reduced word in the finite block Weyl group, multiplication of the corresponding root subgroups gives the usual length-additive double-coset product; its residue parameters are independent, so the leading coefficient is one. Multiplying the simple generators therefore gives the same basis element for every finite Weyl-group element. This proves the last assertion on each finite block algebra, with the exact determinant untwist and no undetermined sign or scalar. □

Proposition 7.1.14. *Let F^+ be a totally real field, G a connected reductive group over F^+ such that $G(F^+ \otimes_{\mathbb{Q}} \mathbb{R})$ is compact, $U_0 \supseteq U \supseteq V$ compact open subgroups of $G(\mathbb{A}_{F^+}^\infty)$ with V normal in U, and $\Delta = U/V$. Let A be a commutative ring, W an A-module with an A-linear action of U, and*

$$S(V,W) = \{ f\colon G(\mathbb{A}_{F^+}^\infty) \to W \ :\ f(\gamma g v) = v^{-1} f(g) \text{ for all } \gamma \in G(F^+),\ g \in G(\mathbb{A}_{F^+}^\infty),\ v \in V \},$$

with Δ acting by $(uf)(g) = u\, f(gu)$. Then:

(HM1) *for every $t \in G(\mathbb{A}_{F^+}^\infty)$ the group $\Gamma_t = t^{-1}G(F^+)t \cap U_0$ is finite, and only finitely many orders $\#\Gamma_t$ occur; let c be their least common multiple;*

(HM2) *there is an A-linear endomorphism Ψ of $S(V,W)$ such that*

$$\sum_{u \in \Delta} u^{-1}\, \Psi\, u = c \cdot \mathrm{id}_{S(V,W)};$$

(HM3) *in particular, if c is invertible in A, then $S(V,W)$ is a direct summand of an induced $A[\Delta]$-module, hence projective over $A[\Delta]$ when $S(V,W)$ is projective over A (for instance when W is projective over A and $\Gamma_t \cap V = \{1\}$ for every t); and if $\Gamma_t \cap U = \{1\}$ for every t, one may take $c = 1$.*

Proof. Put $S = S(V, W)$. The action is well defined: for $a \in U$, $v \in V$,

$$(af)(\gamma g v) = af(ga(a^{-1}va)) = a(a^{-1}va)^{-1} f(ga) = v^{-1}(af)(g).$$

Also $(vf)(g) = vf(gv) = f(g)$, so it factors through the finite group Δ.

We first prove (HM1). Choose a faithful algebraic representation of G over F^+. The matrix entries of the compact finite adelic set tU_0t^{-1} lie in a fixed fractional ideal at all finite places. The archimedean matrix entries of $G(F^+)$ lie in a bounded set, because $G(F^+ \otimes_{\mathbb{Q}} \mathbb{R})$ is compact. A fractional ideal is a lattice in the product of archimedean completions, so only finitely many rational matrices meet both conditions. Thus Γ_t is finite. Borel's finiteness of class numbers gives finitely many representatives for $G(F^+)\backslash G(\mathbb{A}_{F^+}^{\infty})/U_0$, by [33]. If $t' = \gamma t a$ with $\gamma \in G(F^+)$ and $a \in U_0$, then $\Gamma_{t'} = a^{-1}\Gamma_t a$. Consequently only finitely many orders occur, and their least common multiple c is a positive integer.

Let $X = G(F^+)\backslash G(\mathbb{A}_{F^+}^{\infty})/V$. This is finite by the same finiteness theorem, applied to V. It has a right Δ action. For $x = G(F^+)tV$ its stabilizer is

$$H_x = (t^{-1}G(F^+)t \cap U)V/V.$$

Indeed $G(F^+)tuV = G(F^+)tV$ if and only if $u \in (t^{-1}G(F^+)t \cap U)V$. Thus H_x is an image of a subgroup of Γ_t, and $\#H_x$ divides c.

Choose one point from each Δ orbit and let $R \subseteq X$ be their set. Define an integer-valued function on X by

$$b(x) = \begin{cases} c/\#H_x, & x \in R, \\ 0, & x \notin R. \end{cases}$$

Define $(\Psi f)(g) = b([g])f(g)$. The scalar function is left $G(F^+)$-invariant and right V-invariant. Hence Ψ is an A-linear endomorphism of S. For $u \in \Delta$, computed using any lift to U,

$$(u^{-1}\Psi u f)(g) = b([g]u^{-1})f(g).$$

For each $x \in X$ there are exactly $\#H_x$ elements $u \in \Delta$ for which xu^{-1} is the selected representative of its orbit. All stabilizers on an orbit have the same order. Therefore

$$\sum_{u \in \Delta} b(xu^{-1}) = c, \qquad \sum_{u \in \Delta} u^{-1}\Psi u = c\,\mathrm{id}_S,$$

which proves (HM2).

If c is invertible, put $\Psi' = c^{-1}\Psi$. The multiplication map $p : A[\Delta] \otimes_A S \to S$, $p(u \otimes s) = us$, has the section

$$j(s) = \sum_{u \in \Delta} u^{-1} \otimes \Psi'(us).$$

The displayed averaging identity gives $pj = \mathrm{id}_S$. For $a \in \Delta$, substituting $v = ua$ shows $j(as) = aj(s)$, so the section is $A[\Delta]$-linear. Thus S is a direct summand of an induced module. If S is A-projective, $A[\Delta] \otimes_A S$ is $A[\Delta]$-projective, and so is S. If $\Gamma_t \cap V = \{1\}$ for every t, evaluation at representatives of X identifies S with a finite direct sum of copies of W: the unique right V expression makes arbitrary values in W permissible. This proves the stated sufficient condition for A-projectivity.

Finally, if $\Gamma_t \cap U = \{1\}$ for all t, all the groups H_x are trivial. Taking b to be the indicator of R gives the same identity with multiplier 1. This is the last assertion of (HM3). □

Theorem 7.1.15. *Let E be a number field, ℓ a prime, $\iota\colon \overline{\mathbb{Q}}_\ell \cong \mathbb{C}$, and χ an algebraic Hecke character of E of infinity type $n = (n_\tau)_{\tau\colon E\to\mathbb{C}}$. Let $\mu\colon \mathrm{Gal}(\overline{E}/E) \to \overline{\mathbb{Q}}_\ell^\times$ be the continuous ℓ-adic character attached to (χ,ι) through the Artin map. Then for every place w of E above ℓ, the restriction of μ to a decomposition group at w is de Rham and potentially crystalline, it is crystalline if χ is unramified at w, and for every embedding $\tau\colon E \to \overline{\mathbb{Q}}_\ell$ inducing w its Hodge–Tate weight at τ is $-n_{\iota\circ\tau}$.*

Proof. Fix $w \mid \ell$, put $K = E_w$, and write $\eta = \mu|_{G_K}$. By Lemma 7.1.17(1), the values of η lie in a finite extension $L/\mathbb{Q}_\ell$. Enlarge L to contain all images of K in $\overline{\mathbb{Q}}_\ell$ and the finitely many roots of unity occurring below. Such enlargement does not change any admissibility property: as an underlying $\mathbb{Q}_\ell$-representation it replaces a representation by finitely many copies, and period invariants commute with finite direct sums. Set $V = L(\eta)$ and $d = [L : \mathbb{Q}_\ell]$. Its image lies in $\mathcal{O}_L^\times$, since the image of the compact group G_K under the valuation homomorphism to $\mathbb{Z}$ is a finite subgroup and hence zero.

The actual reciprocity formula determines the weights and the finite unit factor. For $\tau : K \hookrightarrow L$, let $a_\tau = n_{\iota\circ(\tau|_E)}$ and put

$$A(x) = \prod_{\tau:K\hookrightarrow L} \tau(x)^{a_\tau} \qquad (x \in K^\times).$$

This is the map on $\mathbb{Q}_\ell$-points of a morphism $\mathrm{Res}_{K/\mathbb{Q}_\ell}\mathbb{G}_m \to \mathrm{Res}_{L/\mathbb{Q}_\ell}\mathbb{G}_m$. Apply the defining avatar formula to the idele with component $u \in \mathcal{O}_K^\times$ at w and component 1 elsewhere. The use of arithmetic reciprocity for $\mu = \chi_\iota^{-1}$ gives

$$\eta(\mathrm{Art}_K(u)) = \iota^{-1}\chi_w(u)\,A(u). \tag{1}$$

The local Hecke character is smooth on $\mathcal{O}_K^\times$, so $\epsilon_0(u) = \iota^{-1}\chi_w(u)$ is a finite-image character there. On its open kernel, (1) is exactly the local algebraicity formula. Tate's character theorem [261], Chapter III, Appendix A.5–A.6, therefore gives Hodge–Tate weight $-a_\tau$ at τ. In particular the arithmetic Artin map has not introduced an additional inversion: on a unit its algebraic exponent is a_τ, whereas the weight is $-a_\tau$ when the cyclotomic character has weight 1.

We next prove potential crystallinity using the whole unit group. Choose a uniformiser ϖ_K and extend ϵ_0 to the finite-image continuous character

$$\epsilon_K : K^\times = \varpi_K^{\mathbb{Z}}\mathcal{O}_K^\times \longrightarrow L^\times, \qquad \epsilon_K(\varpi_K^m u) = \epsilon_0(u).$$

Local class field theory gives a finite-image character $\epsilon : G_K^{\mathrm{ab}} \to L^\times$ with $\epsilon \circ \mathrm{Art}_K = \epsilon_K$. The character $\eta_0 = \eta\epsilon^{-1}$ now satisfies

$$\eta_0(\mathrm{Art}_K(u)) = A(u) \quad \text{for every } u \in \mathcal{O}_K^\times.$$

The crystalline unit criterion of Fontaine–Serre [264], Section 2.3, makes $L(\eta_0)$ crystalline over K.

Let F/K be the finite extension cut out by $\ker\epsilon$. On G_F the characters η and η_0 coincide. Crystalline admissibility is preserved under this restriction, as follows directly from crystalline comparison. If $M_0 = D_{\mathrm{cris},K}(L(\eta_0))$, comparison identifies $B_{\mathrm{cris}} \otimes_{K_0} M_0$ with $B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L(\eta_0)$. Thus a K_0-basis of M_0 remains linearly independent over F_0 inside the periods, where F_0 is the maximal unramified subfield of F. The subspace $F_0 \otimes_{K_0} M_0$ of $D_{\mathrm{cris},F}(L(\eta_0))$ has dimension d over F_0; the comparison dimension bound is d, so equality holds. Hence $V|_{G_F}$ is crystalline. This proves potential crystallinity of η. By Theorem 7.1.10(1), crystalline implies semistable and potential semistability implies de Rham over K. Therefore η is de Rham. If χ is unramified

at w, then $\epsilon_0 = 1$ and (1) agrees with A on all of $\mathcal{O}_K^\times$ already; the same crystalline unit criterion proves crystallinity over K itself.

For completeness, the coefficient rank of the semistable period union can be proved rather than inferred from its $\mathbb{Q}_\ell^{\mathrm{ur}}$-dimension. This also supplies the rank-one period assertion with the actual coefficient action. Retain the extension F over which V is crystalline, and set

$$M = (B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} V)^{G_F}, \qquad C = L \otimes_{\mathbb{Q}_\ell} F_0, \qquad R = L \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}.$$

The L-action on V commutes with G_F, so M is a C-module. Crystalline comparison is L-linear and gives an R-module isomorphism

$$R \otimes_C M = B_{\mathrm{cris}} \otimes_{F_0} M \;\simeq\; B_{\mathrm{cris}} \otimes_{\mathbb{Q}_\ell} L = R. \tag{2}$$

The algebra C is finite étale over F_0, hence a finite product of fields. The map $C \to R = C \otimes_{F_0} B_{\mathrm{cris}}$ is faithfully flat, since B_{cris} is a nonzero F_0-vector space. Write $C = \prod_i C_i$ and $M_i = e_i M$ for its field factors and idempotents. Each M_i is a finite-dimensional C_i-space, of some dimension r_i. Faithful flatness gives $R_i = e_i R \neq 0$, and (2) gives $R_i^{r_i} \simeq R_i$. Reducing this isomorphism modulo a maximal ideal of the nonzero commutative ring R_i gives an isomorphism of vector spaces of dimensions r_i and 1. Thus every $r_i = 1$. Choosing a basis in each factor proves

$$M \simeq C$$

as C-modules. In particular freeness of rank one is a consequence of comparison and faithful descent, not of the dimension count alone.

Put $Q = \mathbb{Q}_\ell^{\mathrm{ur}}$ inside the canonical period rings and

$$D = \bigcup_{K'/K \text{ finite}} (B_{\mathrm{st}} \otimes_{\mathbb{Q}_\ell} V)^{G_{K'}}.$$

There is a natural $L \otimes_{\mathbb{Q}_\ell} Q$-linear injection

$$Q \otimes_{F_0} M \;\longrightarrow D. \tag{3}$$

Indeed crystalline comparison makes an F_0-basis of M linearly independent over B_{cris}, and therefore over its subfield Q, proving injectivity. Every element of the left side is a finite sum of products of periods fixed by G_F and elements of finite unramified extensions of $\mathbb{Q}_\ell$. One finite extension of K containing F and all these unramified elements fixes that sum, proving that (3) has image in D. The representation is de Rham, as proved above; Berger's dimension theorem [22] gives $\dim_Q D = d$. The source of (3) also has dimension d over Q. Therefore (3) is an isomorphism, and

$$D \simeq Q \otimes_{F_0} C \simeq L \otimes_{\mathbb{Q}_\ell} Q$$

as modules over $L \otimes_{\mathbb{Q}_\ell} Q$. This proves the asserted coefficient freeness explicitly. Moreover this description represents every element of D by crystalline periods; the canonical monodromy vanishes on B_{cris} and on Q [85], Section 3.2, so it vanishes on D.

Finally, embeddings $\tau : E \to \overline{\mathbb{Q}}_\ell$ inducing w are exactly the restrictions of the embeddings of K used in (1). The weight already computed is therefore $-n_{\iota\circ\tau}$ for every such τ, which proves all the claims. □

Definition 7.1.16. Let $F \subset \overline{\mathbb{Q}}$ be a number field and ℓ a prime. Let L be a field with $\mathbb{Q}_\ell \subseteq L \subseteq \overline{\mathbb{Q}}_\ell$ which is finite over $\mathbb{Q}_\ell$ or equal to $\overline{\mathbb{Q}}_\ell$, with the topology of $|\cdot|_\ell$, and let V be a finite-dimensional L-vector space with a continuous L-linear action of G_F. For a finite place

v of F, a **decomposition group at** v is the image $D_j \subseteq G_F$ of $\mathrm{Gal}(\overline{F_v}/F_v)$ under restriction along an embedding $j\colon \overline{\mathbb{Q}} \to \overline{F_v}$ over F; $I_j \subseteq D_j$ is the image of the inertia group. For a closed subgroup $D \subseteq G_F$, $H^1(D,V)$ is computed with continuous cocycles.

Local conditions. Let v be a place of F and D a decomposition group at v (for v archimedean: the image of $\mathrm{Gal}(\mathbb{C}/F_v)$ under an embedding $\overline{\mathbb{Q}} \to \mathbb{C}$ over F). The subspace $H^1_f(D,V) \subseteq H^1(D,V)$ consists of the classes $[c]$ such that:

- if v is finite and $v \nmid \ell$, $D = D_j$: there is $x \in V$ with $c(g) = gx - x$ for all $g \in I_j$;
- if $v \mid \ell$, $D = D_j$: there is $y \in V \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ with $c(g) \otimes 1 = gy - y$ for all $g \in D_j$, where $D_j \cong \mathrm{Gal}(\overline{F_v}/F_v)$ acts on V and on B_{cris} (formed for $\overline{F_v} = \overline{\mathbb{Q}}_\ell$) diagonally;
- if v is archimedean: $H^1_f(D,V) = 0$.

Rational coefficients. A continuous 1-cocycle $c\colon G_F \to V$ is a **Bloch–Kato cocycle** if for every place v of F and every decomposition group D at v the class of $c|_D$ lies in $H^1_f(D,V)$. The **Bloch–Kato Selmer group**

$$H^1_f(F,V) \subseteq H^1(F,V)$$

is the space of classes of Bloch–Kato cocycles.

Divisible coefficients [158], 14.1. Let L be finite over $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}_L$, and let $T \subset V$ be a G_F-stable $\mathcal{O}_L$-lattice; $V/T \cong T \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$ is a discrete G_F-module. The **Selmer group** of T over F is

$$\mathrm{Sel}(F,T) = \{x \in H^1(F,V/T) \ :\ x|_D \in \mathrm{Im}(H^1_f(D,V) \to H^1(D,V/T)) \\ \text{for every place } v \text{ and every decomposition group } D \text{ at } v\}.$$

Lemma 7.1.17. *Let ℓ be a prime.*

1. *Let Γ be a profinite group and $\rho\colon \Gamma \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ a continuous homomorphism. There is a finite extension $E \subset \overline{\mathbb{Q}}_\ell$ of $\mathbb{Q}_\ell$ with $\rho(\Gamma) \subseteq \mathrm{GL}_n(E)$.*
2. *Let $F \subset \overline{\mathbb{Q}}$ be a number field, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and V a finite-dimensional E-vector space with a continuous E-linear action of G_F. If $H^1_f(F,V) = 0$, then $H^1_f(F, V \otimes_E \overline{\mathbb{Q}}_\ell) = 0$.*
3. *Let Γ be a profinite group, $E \subset \overline{\mathbb{Q}}_\ell$ a finite extension of $\mathbb{Q}_\ell$ and V a finite-dimensional E-vector space with a continuous E-linear action of Γ. Every continuous 1-cocycle $c\colon \Gamma \to V \otimes_E \overline{\mathbb{Q}}_\ell$ takes values in $V \otimes_E E'$ for some finite extension $E' \subset \overline{\mathbb{Q}}_\ell$ of E.*

Proof. For $d \geq 1$ let $E_d \subset \overline{\mathbb{Q}}_\ell$ be the compositum of the finitely many extensions of $\mathbb{Q}_\ell$ of degree at most d (Krasner); E_d is finite over $\mathbb{Q}_\ell$, hence complete and closed in $\overline{\mathbb{Q}}_\ell$, and $\overline{\mathbb{Q}}_\ell = \bigcup_d E_d$. The same holds with $\mathbb{Q}_\ell$ replaced by any finite extension E (write E_d for the compositum of E with the extensions of E of degree at most d).

Item 1. Each $\mathrm{GL}_n(E_d) = \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell) \cap \mathrm{M}_n(E_d)$ is a closed subgroup, so $\Gamma = \bigcup_d \rho^{-1}(\mathrm{GL}_n(E_d))$ is a countable union of closed subgroups. Γ is compact Hausdorff, so by Baire's theorem one of them, U say, has non-empty interior; a subgroup with non-empty interior is open. Let $g_1, \ldots, g_s$

represent Γ/U and let $E \supseteq E_d$ be a finite extension containing the entries of $\rho(g_1), \dots, \rho(g_s)$. Then $\rho(g_i u) = \rho(g_i)\rho(u) \in \mathrm{GL}_n(E)$ for all i and $u \in U$.

Item 3. Put $V' = V \otimes_E \overline{\mathbb{Q}}_\ell$. Each $V \otimes_E E_d$ is a finite-dimensional space over the complete field E_d, hence closed in V', and is Γ-stable. So $\Gamma = \bigcup_d c^{-1}(V \otimes_E E_d)$, and by Baire's theorem one of these closed sets, say for d, contains a coset gH of an open normal subgroup H (open normal subgroups form a basis of neighbourhoods of 1 in a profinite group). For $h \in H$, $c(h) = g^{-1}\big(c(gh) - c(g)\big) \in V \otimes_E E_d$. Let $g_1, \dots, g_s$ represent Γ/H and $E' \supseteq E_d$ finite containing the coordinates of $c(g_1), \dots, c(g_s)$ in an E-basis of V; then $c(g_i h) = c(g_i) + g_i c(h) \in V \otimes_E E'$.

Item 2. Put $V' = V \otimes_E \overline{\mathbb{Q}}_\ell$ and let c be a Bloch–Kato cocycle of V'.

(a) By item 3 (with $\Gamma = G_F$), c takes values in $V \otimes_E E'$ for a finite extension E'/E.

(b) *c is a Bloch–Kato cocycle of $V \otimes_E E'$.* Choose an E'-linear $\varpi\colon \overline{\mathbb{Q}}_\ell \to E'$ with $\varpi|_{E'} = \mathrm{id}$ and put $\Pi = \mathrm{id}_V \otimes \varpi\colon V' \to V \otimes_E E'$, which is G_F-equivariant and the identity on $V \otimes_E E'$. If $c(g) = gx - x$ on an inertia group (or on an archimedean decomposition group), then $c(g) = \Pi(c(g)) = g\Pi(x) - \Pi(x)$ there; at a place above ℓ, the $\mathbb{Q}_\ell$-linear equivariant map $\Pi \otimes \mathrm{id}$ into $(V \otimes_E E') \otimes_{\mathbb{Q}_\ell} B_{\mathrm{cris}}$ fixes $c(g) \otimes 1$ and carries y with $c(g) \otimes 1 = gy - y$ to such an element. The topology of $V \otimes_E E'$ is the subspace topology, so c is continuous into it.

(c) *Conclusion.* An E-basis $b_1, \dots, b_m$ of E' gives a G_F-equivariant E-linear homeomorphism $V \otimes_E E' \cong V^m$. The conditions of Definition 7.1.16 depend only on the underlying topological $\mathbb{Q}_\ell[G_F]$-module and are compatible with the inclusions and projections of a finite direct sum; hence $H^1_f(F, V \otimes_E E') \cong H^1_f(F, V)^m = 0$, and $c(g) = gz - z$ for some $z \in V \otimes_E E' \subseteq V'$. So $H^1_f(F, V') = 0$. □

Theorem 7.1.18. *Let $F/\mathbb{Q}_p$ be finite with residue field k, let $K = \mathrm{GL}_n(\mathcal{O}_F)$ and $K^1 = \ker(K \to \mathrm{GL}_n(k))$. Fix finitely many distinct irreducible cuspidal representations ρ of finite general linear groups over k, of ranks d_ρ, with positive multiplicities m_ρ and $\sum_\rho m_\rho d_\rho = n$. For each ρ choose a depth-zero supercuspidal representation π_ρ of $\mathrm{GL}_{d_\rho}(F)$ containing its inflation. Suppose their inertial cuspidal lines are pairwise distinct. Put $\tau_\rho = \mathrm{rec}_F(\pi_\rho)|_{I_F}$; local Langlands and reciprocity are geometrically normalised.*

For every function P assigning to ρ a partition of m_ρ, let $\bar\sigma_P$ be the finite Green representation with these cuspidal partition data, with the convention that (a) on ρ gives the generalised finite Steinberg representation $\mathrm{St}(\rho, a)$ and that $(1, \dots, 1)$ on the trivial rank-one cuspidal representation gives the trivial representation of $\mathrm{GL}_a(k)$. For another such function P' put

$$\bar\Pi_{P'} = \mathrm{HC}\text{-}\mathrm{Ind} \underset{\rho,j}{\boxtimes} \mathrm{St}(\rho, P'(\rho)_j).$$

There are irreducible finite representations $\bar\nu_P$ of $\mathrm{GL}_n(k)$, in this same finite cuspidal series, satisfying:

1. *for every P',*
$$\dim \mathrm{Hom}_{\mathrm{GL}_n(k)}(\bar\nu_P, \bar\Pi_{P'}) = \dim \mathrm{Hom}_{\mathrm{GL}_n(k)}(\bar\sigma_P, \bar\Pi_{P'});$$
2. *if an irreducible admissible smooth complex representation π of $\mathrm{GL}_n(F)$ contains $\mathrm{Inf}_K \bar\nu_P$, its local Langlands parameter has semisimple inertia $\bigoplus_\rho \tau_\rho^{\oplus m_\rho}$, and its monodromy partition $P_\pi(\rho)$ on each inertial cuspidal line is dominated by $P(\rho)$. Here a Weil–Deligne summand $\mathrm{Sp}(\sigma, a)$ contributes one part a on the line of σ, and domination means*
$$\sum_{j=1}^{b} P_\pi(\rho)_j \le \sum_{j=1}^{b} P(\rho)_j \quad (b \ge 1), \qquad |P_\pi(\rho)| = |P(\rho)| = m_\rho.$$

The square matrix $\left(\dim \mathrm{Hom}(\bar{\sigma}_P, \bar{\Pi}_{P'})\right)_{P,P'}$ *is unitriangular in an order refining dominance.*

Proof. Choose an auxiliary coefficient prime $\ell \neq p$ and transport the characteristic-zero representation theory to an algebraic closure of an ℓ-adic field. A field isomorphism back to $\mathbb{C}$ preserves irreducibility, invariant spaces and the dimensions of the Hom spaces here. No reduction modulo ℓ is taken.

We first identify the data of the compact construction. For each ρ, its given depth-zero supercuspidal line has the degenerate maximal simple type with order $\mathrm{M}_{d_\rho}(\mathcal{O}_F)$, zero simple character on the principal congruence subgroup, trivial extension $\kappa_\rho = 1$, and finite cuspidal representation ρ. In the zero-stratum notation the stratum field is F itself, not a nontrivial extension. These assertions are the degenerate data in the construction of [278, Sections 6.4 and 6.9]: the stabilizer of the standard lattice is $\mathrm{GL}_{d_\rho}(\mathcal{O}_F)$, its congruence kernel is $1+\varpi_F \mathrm{M}_{d_\rho}(\mathcal{O}_F)$, and their quotient is $\mathrm{GL}_{d_\rho}(k)$; tensoring the trivial extension with ρ is precisely its inflation. The hypothesis that π_ρ contains that inflation matches the finite cuspidal label to the specified supercuspidal line.

All these zero simple characters have the same degenerate endo-class, even though the supercuspidal inertial lines are distinct. Consequently the construction on their total vector space is the homogeneous construction, with one maximal order $\mathrm{M}_n(\mathcal{O}_F)$. In its notation

$$J = K, \qquad J^1 = K^1, \qquad J/J^1 = \mathrm{GL}_n(k), \qquad \kappa = 1.$$

The choices are compatible on every Levi: restriction of the trivial extension remains trivial. The finite cuspidal label matched to the basic inertial type τ_ρ is the original ρ. This also shows why different depth-zero cuspidal lines do not require a nontrivial cover between different endo-classes.

The pairwise-distinct-line hypothesis makes the assignment

$$\mathcal{P}(\tau_\rho) = P(\rho), \qquad \mathcal{P}(\tau_0) = \varnothing \quad (\tau_0 \notin \{\tau_\rho\})$$

unambiguous. Its weighted degree is n. Here the basic type is the restriction of an irreducible Weil parameter: the supercuspidal assertion follows from (Ln5) of Theorem A.4.9. Take the compact representation $\sigma(\mathfrak{S}_{\mathcal{P}})$ in the published construction. Its finite factor is irreducible by the definition of an SZ datum. Since $J = K$ and $\kappa = 1$, induction from J to K is the identity and it is therefore the inflation of an irreducible finite representation; denote that finite representation by $\bar{\nu}_P$. This conclusion uses the degenerate construction and does not identify its finite factor with $\bar{\sigma}_P$.

Fix P'. Choose a discrete pair (M', π') attached to $\mathcal{P}'$ by taking one essentially discrete-series segment of length $P'(\rho)_j$ on the line of π_ρ for every nonzero part. Arbitrary unramified twists of those factors do not affect their compact restrictions. Choose any parabolic Q' with Levi M'. The homogeneous invariant-functor formula of [278, Corollary 6.19], with the just-identified $J^1 = K^1$ and $\kappa = 1$, gives

$$\left(\mathrm{Ind}_{Q'}^{G}\, \pi'\right)^{K^1} \simeq \mathrm{HC}\text{-}\mathrm{Ind} \boxtimes_{\rho,j} \mathrm{St}(\rho, P'(\rho)_j) = \bar{\Pi}_{P'}. \tag{1}$$

Every input of that formula has the same zero simple character; all the required extensions are trivial and compatible; M^0 is the product of the original supercuspidal blocks and is contained in M'. Thus its homogeneous hypothesis is satisfied. The normalization in (1) introduces no finite modulus factor: restriction to K identifies the inducing functions through $G = Q'K$, and the parabolic modulus is 1 on $Q' \cap K$. Taking K^1-invariants therefore reads the finite parabolic and its ordinary Harish–Chandra induction.

A K-map from $\operatorname{Inf}\bar{\nu}_P$ has image in the K^1-fixed space, and reduction modulo K^1 identifies such maps in both directions. Hence (1) and [278, Theorem 6.20] give

$$\begin{aligned}\dim \operatorname{Hom}_{\mathrm{GL}_n(k)}(\bar{\nu}_P, \bar{\Pi}_{P'}) &= \dim \operatorname{Hom}_K\left(\sigma(\mathfrak{S}_{\mathcal{P}}), \operatorname{Ind}_{Q'}^{G}\pi'\right)\\ &= \prod_{\rho} m(P(\rho), P'(\rho)).\end{aligned} \tag{2}$$

The finite formula of [278, Corollary 6.10] identifies the last expression with $\dim \operatorname{Hom}(\bar{\sigma}_P, \bar{\Pi}_{P'})$. Its convention is exactly the convention in the statement: the symmetric-group labeling is twisted by sign, the single part (a) corresponds to $\mathrm{St}(\rho, a)$, and the all-one partition on the trivial rank-one line corresponds to the trivial representation. No transposition of partitions is made. This proves item 1.

Set $P' = P$ in (2). Every diagonal Kostka factor is 1, so $\bar{\nu}_P$ occurs in $\bar{\Pi}_P$. The latter is in the prescribed finite cuspidal series: its generalized Steinberg factors have the prescribed repeated cuspidal supports and Harish–Chandra induction concatenates those supports. Equivalently, by transitivity it is a constituent of induction of exactly the original cuspidal multiset. Thus $\bar{\nu}_P$ is in that same finite series, as asserted.

Now suppose that π is irreducible admissible and contains $\operatorname{Inf}\bar{\nu}_P = \sigma(\mathfrak{S}_{\mathcal{P}})$. Write its Langlands discrete-pair data as (M'', π'') and its corresponding partition function as $\mathcal{P}_\pi$. The parameter compatibility with the Langlands classification in (Ln6) of Theorem A.4.9 identifies a length-a segment with a Weil–Deligne block $\mathrm{Sp}(\sigma, a)$; thus $\mathcal{P}_\pi$ is exactly the list of the monodromy-block sizes on each basic inertial line. Apply [278, Corollary 6.21(1)] to this quotient and the same constructed compact representation. It gives

$$\mathcal{P}_\pi(\tau_0) \preceq \mathcal{P}(\tau_0) \quad \text{for every basic inertial type } \tau_0.$$

By the definition of this order, the sizes agree on every line and all initial partial sums satisfy the displayed dominance inequalities. On every line outside the chosen list, equality of sizes with the empty partition forces the partition to be empty. On the line τ_ρ its size is m_ρ. The semisimple inertia is therefore $\bigoplus_\rho \tau_\rho^{\oplus m_\rho}$, and the inequalities are precisely item 2.

Shotton writes this parameter as $r_\ell(\pi) = \mathrm{rec}_F(\pi \otimes |\det|^{(1-n)/2})$. By (Ln2), the difference from $\mathrm{rec}_F(\pi)$ is tensoring with an unramified one-dimensional parameter. Its restriction to inertia is 1 and its monodromy is 0; tensoring leaves the original monodromy endomorphism and all its Jordan-block sizes unchanged. Thus both the inertia statement and the partition inequalities just proved hold for the geometric normalization in the statement.

Finally the same finite formula gives the matrix entries as the products in (2). They vanish unless $P(\rho)$ dominates $P'(\rho)$ on every line, and all diagonal entries are 1. There are finitely many partition functions with the prescribed sizes. Ordering them by a linear extension of this componentwise dominance order makes the matrix triangular with diagonal 1. This proves the final assertion and completes the specialization. □

7.2 Crystalline classes, auxiliary twists and the odd Sha bound

This section sets up the vocabulary of Section 7 and proves its one global bound on class groups. It opens with the local and global definitions: crystalline classes of local lattices, auxiliary twists, Tate twists with their odd and even classes, Taylor–Wiles places and prime triangles, and the objects of Kolyvagin's method. It closes with the main summands of ℓ-adic representations and the denominators of projections (Definition 7.2.30, Definition 7.2.31).

The theorem of the section, Theorem 7.2.8, bounds the odd classes $\mathrm{Sha}^-(e,\nu)$ of the Tate twists over a CM field $E \subset \mathbb{Q}(\mu_N)$ at all primes at once: there is an integer X with $1 \le X \le 2^{4(N+t+3)^{27}} h_E$ such that $\mathrm{len}_{\mathcal{O}}\mathrm{Sha}^-(e,\nu) \le v_{\mathcal{O}}(X)$ for every prime ℓ, every coefficient ring, every $0 \le e < t$ and every ν. Such bounds belong to the theory of cyclotomic fields, in which the odd parts of class groups and of Selmer groups are controlled by Bernoulli numbers and Stickelberger elements and their orders are described by the main conjecture [317, 197, 327]. Only an integer uniform in ℓ is needed here, and the proof uses Stickelberger's theorem [290] and the Euler system of Gauss sums with its Kolyvagin derivatives [304, 169, 244, 107] (for the Galois cohomology of Tate twists see [287]). It has four steps. An integer X_e satisfies the twisted Stickelberger congruences at every prime, by the theorem of von Staudt and Clausen and the generalised Bernoulli numbers (Lemma 7.2.9). These congruences annihilate the odd cocycles (Proposition 7.2.10). A bounded number of evaluations detects the odd cocycles (Proposition 7.2.27): at large primes by Poitou–Tate duality [295] and a reciprocity law derived from the Brauer group of $\mathbb{Q}$ [297, 202], and at small primes by a detecting set from Minkowski's bound. Finally, for $e = 0$ the odd classes are unramified homomorphisms, which gives the factor h_E (Lemma 7.2.29).

At the end of the section a convention fixes the odd-class integer X_{odd} of the clearing bound (Definition 6.6.15), for which only a size bound was assumed, to be this integer X for $N = q_1 d$, the given t and the field E. From then on $\mathrm{len}_{\mathcal{O}}\mathrm{Sha}^-(e,\nu) \le v_{\mathcal{O}}(X_{\mathrm{odd}})$. The size bound alone makes the sum of the clearing bounds over all primes negligible (Proposition 7.3.3), and the specified value enters the bound for the denominators (Theorem 7.6.6).

Definition 7.2.1. Let ℓ be a prime. Throughout, Γ is a topological group with a homomorphism $j\colon \Gamma \to G_\ell$ which is an open embedding; Γ acts on $B_{\max}$, $\mathbb{C}_\ell$ and $\overline{\mathbb{Q}}_\ell$ through j, and the filter *near* 1 on Γ is the pull-back along j of the neighbourhood filter of 1 in G_ℓ. An element $s \in \Gamma$ is *inertial* if $j(s)$ lies in the inertia group of G_ℓ.

Coefficient rings and lattices. A **coefficient ring at** ℓ is a coefficient ring $\mathcal{O}$ whose fraction field is Galois over $\mathbb{Q}_\ell$ (this Galois condition is a hypothesis of the notions below and of the results that use them, except for the crystalline cocycles, the crystalline relations and the crystalline condition with module coefficients, whose coefficient domain is stated with them); coefficient rings at ℓ are ordered by inclusion, and a property holds **for all large coefficient rings** if there is $\mathcal{O}_0$ such that it holds for every $\mathcal{O} \supseteq \mathcal{O}_0$. The normalised length of a finite-length $\mathcal{O}$-module X is $\mathrm{nl}(X) = \mathrm{length}_{\mathcal{O}}(X) \cdot v(\varpi)$, with ϖ a uniformiser and $v(\ell) = 1$ (so $\mathrm{nl}(\mathcal{O}/\ell) = 1$), and $\mathrm{nl} = \infty$ for infinite length. A **Galois lattice** L over $\mathcal{O}$ is a finite free $\mathcal{O}$-module with an $\mathcal{O}$-linear action ρ_L of Γ. Its **Tate dual** is $L^\vee(1) = \mathrm{Hom}_{\mathcal{O}}(L, \mathcal{O}(1))$, with Γ acting on $\mathcal{O}(1)$ by $\chi_{\mathrm{cyc}} \circ j$; $Y \otimes L$ is $Y \otimes_{\mathcal{O}} L$ with the diagonal action.

Periods. For a filter F on Γ, L is **admissible along** F if the elements $y \in B_{\max} \otimes_{\mathbb{Z}_\ell} L$ with $j(g) \otimes \rho_L(g)\, y = y$ for F-almost all g span $B_{\max} \otimes_{\mathbb{Z}_\ell} L$ over $B_{\max}$; L is **potentially crystalline** if it is admissible along the filter near 1. For the next three constructions only (crystalline cocycles, crystalline relations and the crystalline condition with module coefficients), $\mathcal{O}$ may be the ring of integers of any finite extension of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$, and L any finite free $\mathcal{O}$-module with an $\mathcal{O}$-linear action ρ_L of Γ; their definitions use no Galois condition. The **crystalline cocycles** of L are

$$Z_f(L) = \{c\colon \Gamma \to L \ :\ \exists\, y \in B_{\max} \otimes_{\mathbb{Z}_\ell} L \ \ \forall g \in \Gamma,\ \ 1 \otimes c(g) = (j(g) \otimes \rho_L(g))\, y - y\},$$

an $\mathcal{O}$-submodule of the functions $\Gamma \to L$. The **crystalline relations** of L form the $\mathcal{O}$-module $\mathcal{R}_f(L)$ of finitely supported functions $\theta\colon \Gamma \to \mathrm{End}_{\mathcal{O}}(L)$ with $\sum_{g\in\Gamma} \theta(g)\, c(g) = 0$ for every $c \in Z_f(L)$. For an $\mathcal{O}$-module B, a function $z\colon \Gamma \to B \otimes_{\mathcal{O}} L$ satisfies the **crystalline condition of**

L **with coefficients in** B if

$$\sum_{g\in\Gamma}(\mathrm{id}_B\otimes\theta(g))\,z(g)=0 \ \text{ in } B\otimes_{\mathcal{O}}L \qquad \text{for every } \theta\in\mathcal{R}_f(L)$$

(no cocycle identity or continuity is imposed). For $L=\mathcal{O}^d$, $\mathrm{End}_{\mathcal{O}}(L)=M_d(\mathcal{O})$ and $B\otimes_{\mathcal{O}}L=B^d$. For a $\mathbb{Z}_\ell$-algebra map $\gamma\colon\mathcal{O}\to\mathbb{C}_\ell$ and $u\in\mathbb{Z}$, the **jump multiplicity** $\mathrm{jump}(L,\gamma,u)$ is the $\overline{\mathbb{Q}}_\ell$-dimension (zero if infinite) of the space of γ-semilinear maps $\lambda\colon L\to\mathbb{C}_\ell$ with $\lambda(\rho_L(g)x)=\chi_{\mathrm{cyc}}(j(g))^{-u}\,j(g)\lambda(x)$ for all g near 1. A multiset J of integers **lists the jumps of** L **at** γ if $\mathrm{jump}(L,\gamma,u)$ is the multiplicity of u in J for every u. For potentially crystalline L, an inertial s and $Q\in\mathcal{O}[X]$, Q **kills** s **on** L if Q, evaluated at the $B_{\max}$-linear endomorphism of $B_{\max}\otimes L$ that agrees with $j(s)\otimes\rho_L(s)$ on the potentially crystalline periods, is zero.

Classes. Let F be a filter on Γ, K a relation between elements $s\in\Gamma$ and polynomials $Q\in\mathcal{O}[X]$, and U a map from the $\mathbb{Z}_\ell$-algebra maps $\gamma\colon\mathcal{O}\to\mathbb{C}_\ell$ to finite subsets of $\mathbb{Z}$. A lattice Y lies in the **crystalline class** $\mathrm{Cr}(F,K,U)$ if

(CY1) Y is admissible along the supremum of F and the filter near 1;

(CY2) $\mathrm{jump}(Y,\gamma,u)\neq 0$ implies $u\in U(\gamma)$;

(CY3) if $K(s,Q)$ holds and s is inertial, then Q kills s on Y.

For $K=\bot$ (the empty relation) (CY3) is void.

Pairings and cup-orthogonality. Fix the embedding of $\mathbb{Z}/\ell^m$ into $\overline{\mathbb{Q}}_\ell^{\times}$ given by a compatible system of ℓ-power roots of unity. A **pairing** P of lattices Y and L modulo ℓ^m consists of $m\geq 0$, an element $\psi\in(Y\otimes L)^\vee(1)$, a $\mathbb{Z}_\ell$-linear map $\phi\colon\mathcal{O}\to\mathbb{Z}_\ell$ and a crystalline cocycle $c_P\in Z_f((Y\otimes L)^\vee(1))$ with $\ell^m c_P(g)=g\psi-\psi$ for all $g\in\Gamma$; it gives the $\mathbb{Z}_\ell$-bilinear map $b_P(y,x)=\phi(\psi(y\otimes x))\bmod\ell^m$. For functions $a\colon\Gamma\to Y$ and $c\colon\Gamma\to L$, the **cup product** of a and c under P is the 2-cochain $(g,h)\mapsto b_P(a(g),\rho_L(g)c(h))\in\mathbb{Z}/\ell^m\subset\overline{\mathbb{Q}}_\ell^{\times}$; it is a **cup coboundary** if it is the coboundary of a continuous 1-cochain $\Gamma\to\overline{\mathbb{Q}}_\ell^{\times}$ (Γ acting through j). For a class $\mathcal{Q}$ of lattices, the **cup-orthogonal module** $L^{\perp\mathcal{Q}}$ is the $\mathcal{O}$-module of functions $c\colon\Gamma\to L$ such that for every $Y\in\mathcal{Q}$, every pairing P of Y and L and every $a\in Z_f(Y)$, the cup product of a and c under P is a cup coboundary.

Dual defect and cup exponents. The **dual defect** of L for $\mathcal{Q}$ is

$$\mathrm{dd}(\mathcal{Q},L)=\mathrm{length}_{\mathcal{O}}(Z_f(L)/(Z_f(L)\cap L^{\perp\mathcal{Q}}))\in\mathbb{N}\cup\{\infty\},$$

and $\mathrm{nl}\,\mathrm{dd}(\mathcal{Q},L)$ is its normalised value. An integer $e\geq 0$ is a **cup exponent** of L for $\mathcal{Q}$ if $\ell^e Z_f(L)\subseteq L^{\perp\mathcal{Q}}$.

Definition 7.2.2. Fix a prime ℓ and a prime identification $\iota\colon\mathbb{C}\to\overline{\mathbb{Q}}_\ell$. Let $G_E=\mathrm{Gal}(\overline{\mathbb{Q}}/E)$, let v_ℓ be the valuation of the convention (with $v_\ell(0)=\infty$), and for a finite place w of E prime to ℓ let a **tame generator** at w be an element of an inertia group above w that maps to a generator of its tame quotient. Coefficient rings $\mathcal{O}$ (the rings of integers of the finite extensions of $\mathbb{Q}_\ell$ in $\overline{\mathbb{Q}}_\ell$) are ordered by inclusion, and a property holds **for all large** $\mathcal{O}$ if there is $\mathcal{O}_0$ such that it holds for every $\mathcal{O}\supseteq\mathcal{O}_0$. For a finite $\mathcal{O}$-module X, $\mathrm{nl}(X)=\mathrm{len}_{\mathcal{O}}(X)/\mathrm{len}_{\mathcal{O}}(\mathcal{O}/\ell)$ is its normalised length, and $\mathrm{nl}=\infty$ for modules of infinite length. For a place A of $\overline{\mathbb{Q}}$ write $G_A\supseteq I_A$ for its decomposition and inertia groups in G_E. An **ℓ-adic chart** at a place A above ℓ is an embedding $e\colon\overline{\mathbb{Q}}\to\overline{\mathbb{Q}}_\ell$ inducing A together with the open embedding $j\colon G_A\to G_\ell$ it defines; for every place $v\mid\ell$ of E fix a place A_v of $\overline{\mathbb{Q}}$ over v and a chart (e_v,j_v) at A_v. For a homomorphism $u\colon G_E\to M_n(\mathcal{O})$ the **local lattice** $L_v(u)$ is $\mathcal{O}^n$ with G_{A_v} acting through u, a Galois lattice for $\Gamma=G_{A_v}$ via j_v.

(AX1) Bad places. The **bad places** S_ℓ^{bad} are the finite places of E dividing ℓMN; they contain S_ℓ.

(AX2) Auxiliary sets. A finite set Q of finite places of E is **auxiliary** for a set S of places if every $w \in Q$ has prime norm $\mathrm{N}w$, $w \notin S$, $\bar{w} \notin S$ and $\bar{w} \notin Q$.

(AX3) Characters from the norm-one torus. A continuous character $\chi\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ **comes from** $\mathrm{U}(1)$ **with modulus** Q if $\chi(\mathrm{Art}(x)) = \eta(x/\bar{x})$ for all ideles x of E, for some idele class character η of finite order and modulus supported on Q that is trivial on the local components at the places above ℓ and their conjugates; here Art is the Artin map.

(AX4) Avatar. The **inverse avatar** of a tame character ϑ is the character $\psi_\vartheta\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ with $\psi_\vartheta(\mathrm{Art}(x)) = \iota(\vartheta(x/\bar{x})^{-1})$ for all ideles x of E, where ϑ is read as a character of $\mathrm{U}(1)(\mathbb{A})/\mathrm{U}(1)(E)$ (it has weight 0, hence finite order).

(AX5) Auxiliary twists. For a set S of finite places, a finite set Q, a character $\chi\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ and $c \in [0,\infty]$, the triple (S,Q,χ) is an **auxiliary twist with ramification at most** c if Q is auxiliary for S, no place of Q lies above ℓ, χ comes from $\mathrm{U}(1)$ with modulus Q, and for some tame generators σ_w at the places $w \in Q$

$$\sum_{w\in Q} v_\ell(\chi(\sigma_w) - 1) \le c.$$

(AX6) Crystalline Selmer length. Let $\mathcal{O}$ be a coefficient ring, $\rho\colon G_E \to \mathrm{GL}_n(\mathcal{O})$ continuous, Q a finite set of finite places and $\gamma \in G_E$. The **Selmer group** $\mathrm{Sel}(\rho,Q,\gamma)$ is the $\mathcal{O}$-module of continuous cocycles $c\colon G_E \to (\mathrm{Frac}\,\mathcal{O}/\mathcal{O})^n$ for ρ that are unramified at every finite place not above ℓ, p_0 or p_1 and not in $Q \cup \bar{Q}$, have, for every place $v \mid \ell$ of E, restriction to G_{A_v} satisfying the crystalline condition of the local lattice $L_v(\rho)$ with coefficients in $\mathrm{Frac}\,\mathcal{O}/\mathcal{O}$, and vanish at γ. Its **length** is $\mathrm{nl}\,\mathrm{Sel}(\rho,Q,\gamma) \in [0,\infty]$.

(AX7) Short twisted Selmer groups. Let $R\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ be continuous, $\chi\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ a character, Q a finite set of finite places, $\gamma \in G_E$, $\zeta \in \overline{\mathbb{Z}}_\ell$ and $\mathrm{sel} \in [0,\infty]$. The twist χR has **Selmer length at most** sel **at** (Q,γ,ζ) if γ lies in an inertia group above a place not dividing ℓ, and for all large $\mathcal{O}$ there are a continuous $u\colon G_E \to \mathrm{GL}_n(\mathcal{O})$ conjugate to R over $\overline{\mathbb{Q}}_\ell$ and a character $\chi'\colon G_E \to \mathcal{O}^\times$ equal to χ, with $\zeta \in \mathcal{O}$, such that

$$(\chi' u)(\gamma) = \zeta \cdot 1, \qquad \zeta - 1 \in \mathcal{O}^\times, \qquad \mathrm{nl}\,\mathrm{Sel}(\chi' u, Q, \gamma) \le \mathrm{sel}.$$

Definition 7.2.3. Let ℓ be a prime and let $E \subset \bar{\mathbb{Q}}$ be a CM field, with absolute Galois group $G_E = \mathrm{Gal}(\bar{\mathbb{Q}}/E)$. Fix a complex conjugation $c \in \mathrm{Gal}(\bar{\mathbb{Q}}/\mathbb{Q})$ and write $g^c = cgc$ for $g \in G_E$. Let $\chi_{\mathrm{cyc}}\colon G_E \to \mathbb{Z}_\ell^\times$ be the ℓ-adic cyclotomic character. For a coefficient ring $\mathcal{O}$, $\mathrm{len}_\mathcal{O}$ is length over $\mathcal{O}$ and $v_\mathcal{O}$ its normalised valuation. For a submodule S and a submodule T of one $\mathcal{O}$-module, $\mathrm{len}(S \bmod T) = \mathrm{len}_\mathcal{O}(S/(S \cap T))$. Let S_ℓ be the set of places of E above ℓ; for a set S of finite places, $\bar{S}$ is the set of complex conjugate places.

Twists and Selmer modules. For integers $e, \nu \ge 0$, $\mathcal{O}/\ell^\nu(-e)$ is $\mathcal{O}/\ell^\nu$ with G_E acting through χ_{cyc}^{-e}. For a set S of finite places of E, $\mathrm{Sel}_S(e,\nu)$ is the $\mathcal{O}$-module of locally constant maps $z\colon G_E \to \mathcal{O}/\ell^\nu$ with $z(gh) = z(g) + \chi_{\mathrm{cyc}}(g)^{-e} z(h)$ (cocycles, not taken modulo coboundaries) that vanish on the inertia groups of all places of $\bar{\mathbb{Q}}$ above finite places of E outside S.

The local set. Λ_0 is the union of the inertia groups at the places of $\bar{\mathbb{Q}}$ above ℓ; for $e \neq 0$, $\Lambda_e = \Lambda_1$ is the set of elements g of the decomposition groups at these places with $\chi_{\mathrm{cyc}}(g) = 1$.

Odd and even classes.

(OE1) The **odd classes** $\mathrm{Sha}^-(e,\nu)$ are the $z \in \mathrm{Sel}_{S_\ell}(e,\nu)$ that vanish on Λ_e and, if $e \neq 0$, satisfy $z(g^c) = -z(g)$ for all g. For $e = 0$ these are the everywhere unramified continuous homomorphisms $G_E \to \mathcal{O}/\ell^\nu$.

(OE2) For a set S of finite places, the **even classes** $\mathrm{Ev}_S(e,\nu)$ are the $z \in \mathrm{Sel}_{S_\ell \cup S \cup \bar{S}}(e,\nu)$ with $z(g^c) = z(g)$ for all g and $z|_{\Lambda_1} = 0$.

Tame generators. Fix for every $m \geq 1$ a primitive m-th root of unity $\zeta_m \in \bar{\mathbb{Q}}$. Let A be a place of $\bar{\mathbb{Q}}$ above a finite place v of E, or of the maximal real subfield F of E, of residue characteristic p, with inertia group I_A in G_E, respectively G_F. For m prime to p, an element $\gamma \in I_A$ is a **tame generator of order** m at A if $\gamma(y)/y = \zeta_m$ for a uniformiser ϖ of the completion at v and an m-th root $y \in \bar{\mathbb{Q}}$ of ϖ (the quotient $\gamma(y)/y$ does not depend on the choice of ϖ and y, since inertia fixes the m-th roots of units and of unity). At each place A above a place of E one element $\tau_A \in I_A$ is fixed such that $\tau_A(y)/y$ is a primitive m-th root of unity for every m prime to p and every m-th root y of a uniformiser; it is **the chosen tame generator** at A.

Auxiliary places. A **Frobenius datum** is a finite place w of E of prime norm q_w, a place A of $\bar{\mathbb{Q}}$ above it, a geometric Frobenius φ at A and the chosen tame generator $\tau = \tau_A$. It is **ν-split** if $w \nmid \ell$ and φ fixes μ_{ℓ^ν} (then $\ell^\nu \mid q_w - 1$). For $M \geq 1$ and a finite index set J, **Taylor–Wiles places of level** M are Frobenius data $(w_j, \varphi_j, \tau_j)_{j \in J}$ with no two of the w_j equal or complex conjugate and $M \mid q_{w_j} - 1$ for all j.

Most Frobenii. A set X of Frobenius data contains **most Frobenii** if every nonempty open $V \subseteq G_E$ contains a nonempty open U such that for all but finitely many finite places w of E of prime norm, every Frobenius datum at w whose Frobenius lies in U belongs to X. For $g \in G_E$, a set W contains **most Frobenii near** g if there are such an X and an open neighbourhood U_g of g such that every datum of X with Frobenius in U_g belongs to W.

Kummer maps. With F the maximal real subfield of E as above, let $\chi_{\mathrm{cyc}}^+ \colon G_F \to \mathbb{Z}_\ell^\times$ the character that extends χ_{cyc} and is 1 at c. In this paragraph χ_{cyc} also denotes the ordinary ℓ-adic cyclotomic character of G_F, which restricts to that of G_E and takes the value -1 at c. Let $G_{F,\nu} = G_E \cap \ker(\chi_{\mathrm{cyc}} \bmod \ell^\nu)$, a normal subgroup of G_F that does not contain c. For $e \geq 0$ let M_e be $\mathbb{Z}/\ell^\nu$ with G_F acting through $(\chi_{\mathrm{cyc}}^+)^{-e}$. Let $x = (x_i)_{i \in I}$ be a finite family of ν-split Frobenius data, S_0 the set of primes of F above ℓ or below some x_i, and $T \supseteq S_0$ a finite set of primes of F. A **relation off** T is a locally constant homomorphism $y \colon G_{F,\nu} \to \mathrm{Hom}(M_e, \mathbb{Q}/\mathbb{Z})$, extended by 0 to G_F, with $y(gug^{-1}) = \chi_{\mathrm{cyc}}(g) \cdot y(u) \circ g^{-1}$ for $g \in G_F$ and $u \in G_{F,\nu}$ (ordinary cyclotomic character of G_F), zero on the inertia groups at the primes outside T, and such that $\sum_p y(\varphi_p)(z(\gamma_p)) = 0$ for every finite family of distinct primes $p \notin T$ of F with, for each p, a place A_p of $\bar{\mathbb{Q}}$ above p, an arithmetic Frobenius $\varphi_p \in G_{F,\nu}$ at A_p and a tame generator $\gamma_p \in G_F$ of order ℓ^ν at A_p, and every cocycle $z \colon G_F \to M_e$ that vanishes at the complex conjugations, is unramified outside S_0 and the p, vanishes on the decomposition groups at the primes of S_0 not above ℓ, and vanishes on the elements of the decomposition groups above ℓ with $\chi_{\mathrm{cyc}}^+ = 1$. A **Kummer map of exponent** e **off** T (for x) is a map $\psi \colon G_E \to \mathbb{Z}/\ell^\nu$ with $y(g)(a) = a\psi(g)/\ell^\nu$ for all $g \in G_E$, $a \in M_e$, for some relation y off T.

Prime triangles. Let $\nu, t, h, C \geq 0$ be integers, J a finite linearly ordered set, $\mathrm{ty} \colon J \to \{1, \ldots, t-1\}$ monotone (the **exponent**), $a \in G_E$, and for $j \in J$ let w_j be finite places, $\tau_j, \varphi_j \in G_E$. These form a **prime triangle for** a **with bounds** (h, C) if:

(PT1) $w_j \nmid \ell$, τ_j is the chosen tame generator at a place of $\bar{\mathbb{Q}}$ over w_j, and φ_j fixes μ_{ℓ^ν};

(PT2) there is a finite set $s \subset \ker \chi_{\mathrm{cyc}}$ of **test points** with $(\#J + \#s + 1)h \leq C$ such that for all $\mathcal{O}$ and e, every $z \in \mathrm{Sel}_{S_\ell}(e,\nu)$ with $z(a) = 0$ and $z|_s = 0$ is zero, and for every

$e \in \{1, \dots, t-1\}$ and $g \in s$ there is j with $\mathrm{ty}(j) = e$ and $z(\varphi_j) = 2z(g)$ for all $\mathcal{O}$ and all $z \in \mathrm{Ev}_{\emptyset}(e, \nu)$;

(PT3) for $0 \le e < t$, with $u = \chi_{\mathrm{cyc}}(a^{-1})$, $\prod_{0 \le k < t,\, k \ne e}(u^e - u^k)$ divides ℓ^h in $\mathbb{Z}_\ell$;

(PT4) for all $\mathcal{O}$, all j and all $z \in \mathrm{Ev}_{\{w_i\}}(\mathrm{ty}(j), \nu)$: if $z(\tau_i) = 0$ for all $i < j$ and $z(\varphi_i) = 0$ for all $i < j$ with $\mathrm{ty}(i) = \mathrm{ty}(j)$, then $\ell^h z(\tau_j) = 0$;

(PT5) for $0 < e < t$ and all $\mathcal{O}$, $4(\chi_{\mathrm{cyc}}(a)^e - 1)^2$ divides ℓ^h in $\mathcal{O}$.

Triangle cost. Let $\mathcal{O}$ be a discrete valuation ring, G a set, B an $\mathcal{O}$-module, Z a submodule of the maps $G \to B$, J a finite linearly ordered set, $\tau, \tau', \varphi, \varphi' \colon J \to G$, $I \subseteq J$, $C \in \mathcal{O}$ and $b \in \mathbb{Z}_{\ge 0} \cup \{\infty\}$. Then Z has **triangle cost** b **along** I **up to** C if there is $L \subseteq G$ such that, with $Z_0 = \{z \in Z : z|_L = 0\}$:

(TK1) for $j \in I$ and $z \in Z_0$ with $z(\tau_i) = z(\tau'_i)$ for all $i < j$ and $z(\varphi_i) = z(\varphi'_i)$ for all $i < j$ in I, one has $Cz(\tau_j) = Cz(\tau'_j)$;

(TK2) for every submodule $S \subseteq Z_0$ whose members vanish at all τ_j, τ'_j and satisfy $z(\varphi_j) = z(\varphi'_j)$ for $j \in I$,

$$\mathrm{len}_{\mathcal{O}}(Z/Z_0) + \mathrm{len}\big(S \bmod S[C]\big) \le b,$$

where $S[C]$ is the C-torsion of the maps $G \to B$.

In the application $\tau'_j = (\tau_j^c)^{-1}$ and $\varphi'_j = (\varphi_j^c)^{-1}$, so that $z(\tau_j) - z(\tau'_j)$ is the value at τ_j of the even part of z (up to the cocycle relation).

Definition 7.2.4. Let ℓ be an odd prime and $\mathcal{O}$ a coefficient ring, with maximal ideal $\mathfrak{m}$ and normalised valuation $v_{\mathcal{O}}$ ($v_{\mathcal{O}}$ of a uniformiser is 1), extended to the fraction field of $\mathcal{O}$. Write $\mathcal{O}^\vee = \mathcal{O} \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell/\mathbb{Z}_\ell$, a discrete $\mathcal{O}$-module. Fix an algebraic closure $\overline{\mathbb{Q}}$, so $G_{\mathbb{Q}} = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q})$; for $N \ge 1$ let $\mu_N \subset \overline{\mathbb{Q}}$ be the N-th roots of unity and $U_N = \mathrm{Gal}(\overline{\mathbb{Q}}/\mathbb{Q}(\mu_N))$. A **decomposition group** at a prime p is the stabiliser $D \subseteq G_{\mathbb{Q}}$ of a place of $\overline{\mathbb{Q}}$ above p; $I(D) \subseteq D$ is its inertia group, and a **Frobenius** of D is an element of D inducing $x \mapsto x^p$ on the residue field of that place. Let $\theta \colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ be a continuous character, and let $\check{\theta} = \chi_{\mathrm{cyc}}\theta^{-1}$ be its **dual character** (χ_{cyc} takes values in $\mathbb{Z}_\ell^\times \subseteq \mathcal{O}^\times$).

Kolyvagin levels. A **Kolyvagin level** of θ is a pair (N_0, m) of integers with $m \ge 1$, $N_0 \ge 1$ and $\ell \nmid N_0$ such that, with $N = N_0\ell^m$ (the **modulus** of the level),

(Kv1) $\theta(u) - 1 \in \ell^m\mathcal{O}$ for every $u \in U_N$;

(Kv2) $\theta(g) + 1 \in \ell^m\mathcal{O}$ for every $g \in G_{\mathbb{Q}}$ with $g(\zeta) = \zeta^{-1}$ for all $\zeta \in \mu_N$;

(Kv3) there is $g_1 \in G_{\mathbb{Q}}$ with $\theta(g_1) - \chi_{\mathrm{cyc}}(g_1) \in \mathcal{O}^\times$.

A **normaliser** for θ is an element $\delta \in G_{\mathbb{Q}}$ with $\theta(\delta) - 1 \in \mathcal{O}^\times$.

Normalised strict cocycles. Let δ be a normaliser for θ, Σ a finite set of primes, $a \in \mathcal{O}\backslash\{0\}$ and $n \ge 1$ an integer. Then $\mathrm{Z}_{\theta,\delta}(\Sigma, a; n)$ is the set of continuous maps $z \colon G_{\mathbb{Q}} \to \mathcal{O}^\vee$ such that

(Kd1) $z(gh) = z(g) + \theta(g)z(h)$ for all $g, h \in G_{\mathbb{Q}}$, and $z(\delta) = 0$;

(Kd2) $a\,z(g) = 0$ for all $g \in G_{\mathbb{Q}}$;

(Kd3) $z(g) = 0$ for every g in an inertia group at a prime $p \notin \Sigma$;

(Kd4) for every prime $p \in \Sigma$ and every decomposition group D at p there is $y \in \mathcal{O}^\vee$ with $ay = 0$ and $z(g) = \theta(g)y - y$ for all $g \in D$;

(Kd5) $z(g) = 0$ for every g in a decomposition group at a prime dividing n.

It is an $\mathcal{O}$-submodule of the module of all maps $G_{\mathbb{Q}} \to \mathcal{O}^\vee$; we put $\mathrm{Z}_{\theta,\delta}(\Sigma, a) = \mathrm{Z}_{\theta,\delta}(\Sigma, a; 1)$, and lengths are $\mathcal{O}$-lengths in $\mathbb{N} \cup \{\infty\}$.

Twisted Stickelberger values. Let $N \geq 2$ and b be integers. For $t \in (\mathbb{Z}/N\mathbb{Z})^\times$ let $\tilde{t} \in \{1, \dots, N-1\}$ be its representative and

$$h_N(b,t) = \Big\lfloor \frac{\tilde{t}\, b}{N} \Big\rfloor - \Big\lfloor \frac{(N-\tilde{t})\, b}{N} \Big\rfloor \in \mathbb{Z}.$$

A **family of lifts** modulo N is a family $\sigma = (\sigma_t)_{t \in (\mathbb{Z}/N\mathbb{Z})^\times}$ of elements of $G_{\mathbb{Q}}$ with $\sigma_t(\zeta) = \zeta^{\tilde{t}}$ for all $\zeta \in \mu_N$. The **twisted Stickelberger value** is

$$\mathrm{st}_{N,b}(\theta, \sigma) = \sum_{t \in (\mathbb{Z}/N\mathbb{Z})^\times} h_N(b,t)\, \theta(\sigma_t)^{-1} \in \mathcal{O}. \tag{7.3}$$

Definition 7.2.5. Let $\theta\colon G_{\mathbb{Q}} \to \mathcal{O}^\times$ be a continuous character with a Kolyvagin level (N_0, m) of modulus $N = N_0 \ell^m$, and let r be a prime with $r \equiv 1 \pmod{N}$.

A **Kolyvagin prime** for (N, r) is a prime p with $p \equiv 1 \pmod{N}$, $p \neq r$, and $\ell \nmid \mathrm{ord}_p(r)$, where $\mathrm{ord}_p(r)$ is the order of r in $(\mathbb{Z}/p\mathbb{Z})^\times$. Let $\mathcal{L}(N, r)$ be the set of finite sequences $L = (p_1, \dots, p_k)$, $k \geq 0$, of pairwise distinct Kolyvagin primes for (N, r); put $|L| = p_1 \cdots p_k$ ($|L| = 1$ for the empty sequence $\emptyset$), and for a Kolyvagin prime p not occurring in L put $(p, L) = (p, p_1, \dots, p_k) \in \mathcal{L}(N, r)$.

Let D_0 be a decomposition group at r and $w \in \mathcal{O}^\vee$. A **Kolyvagin system** for $(\theta, N_0, m, r, D_0, w)$ is a family $(\kappa_L)_{L \in \mathcal{L}(N,r)}$ of continuous maps $\kappa_L\colon U_N \to \mathcal{O}^\vee$ such that for every $L \in \mathcal{L}(N, r)$:

(Ks1) $\kappa_L(uv) = \kappa_L(u) + \kappa_L(v)$ and $\ell^m \kappa_L(u) = 0$ for all $u, v \in U_N$;

(Ks2) $\kappa_L(gug^{-1}) = \check{\theta}(g)\, \kappa_L(u)$ for all $g \in G_{\mathbb{Q}}$ and $u \in U_N$;

(Ks3) $\kappa_L(u) = 0$ for every $u \in U_N$ lying in an inertia group at a prime not dividing $Nr|L|$;

(Ks4) for every Kolyvagin prime p for (N, r) not occurring in L, every decomposition group D at p and every Frobenius φ of D, there are $\tau \in I(D)$ and $u \in \mathcal{O}^\times$ with $\kappa_{(p,L)}(\tau) = u\, \kappa_L(\varphi)$;

(Ks5) there are $\tau_0 \in I(D_0)$ and $u_0 \in \mathcal{O}^\times$ with $\kappa_\emptyset(\tau_0) = u_0\, w$.

In (Ks4) and (Ks5) the elements φ, τ, τ_0 lie in U_N: a prime $p \equiv 1 \pmod{N}$ is unramified in $\mathbb{Q}(\mu_N)$ with residue degree 1, so D acts trivially on μ_N; the same holds for r and D_0.

Definition 7.2.6. Let $m \geq 2$ be an integer and $K_m = \mathbb{Q}(\mu_m) \subset \overline{\mathbb{Q}}$. For $t \in (\mathbb{Z}/m\mathbb{Z})^\times$, $\sigma_{m,t} \in \mathrm{Gal}(K_m/\mathbb{Q})$ is the automorphism with $\sigma_{m,t}(\zeta) = \zeta^{\tilde{t}}$ for $\zeta \in \mu_m$; $t \mapsto \sigma_{m,t}$ is an isomorphism $(\mathbb{Z}/m\mathbb{Z})^\times \to \mathrm{Gal}(K_m/\mathbb{Q})$.

Let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_{K_m}$ not dividing m, p its residue characteristic and $k_\mathfrak{p} = \mathcal{O}_{K_m}/\mathfrak{p}$, a field with $|k_\mathfrak{p}| \equiv 1 \pmod{m}$. The **$m$-th power residue character** of $\mathfrak{p}$ is $\chi_\mathfrak{p}\colon k_\mathfrak{p}^\times \to \mu_m$, where $\chi_\mathfrak{p}(x \bmod \mathfrak{p})$ is the element of μ_m congruent to $x^{(|k_\mathfrak{p}|-1)/m}$ modulo $\mathfrak{p}$ ($x \in \mathcal{O}_{K_m} \setminus \mathfrak{p}$). For a primitive p-th root of unity $\zeta_p \in \overline{\mathbb{Q}}$ and $j \in \mathbb{Z}$, the **Gauss sums** of $\mathfrak{p}$ are

$$\mathrm{g}_\mathfrak{p}(j) = \sum_{c \in k_\mathfrak{p}^\times} \chi_\mathfrak{p}(c)^{-j}\, \zeta_p^{\mathrm{Tr}_{k_\mathfrak{p}/\mathbb{F}_p}(c)} \in \mathbb{Q}(\mu_{mp}); \tag{7.4}$$

for $m \nmid j$ they are nonzero, since $\mathrm{g}_{\mathfrak{p}}(j)\mathrm{g}_{\mathfrak{p}}(-j) = \chi_{\mathfrak{p}}(-1)^j |k_{\mathfrak{p}}|$ [317]. For an integer b with $1 \le b < m$, the **Stickelberger quotient** and the **Gauss-sum element** of $(m, b, \mathfrak{p})$ are

$$\mathrm{J}_{m,b}(\mathfrak{p}) = \frac{\mathrm{g}_{\mathfrak{p}}(1)^b}{\mathrm{g}_{\mathfrak{p}}(b)}, \qquad \mathrm{R}_{m,b}(\mathfrak{p}) = \frac{\mathrm{g}_{\mathfrak{p}}(1)^b\, \mathrm{g}_{\mathfrak{p}}(-b)}{\mathrm{g}_{\mathfrak{p}}(b)\, \mathrm{g}_{\mathfrak{p}}(-1)^b}, \tag{7.5}$$

formed with the same ζ_p.

Definition 7.2.7. Let ℓ be an odd prime, $N_0 \ge 1$ and $m \ge 1$ integers with $\ell \nmid N_0$, $N = N_0 \ell^m$, and r a prime with $r \equiv 1 \pmod N$. A **Kolyvagin integer** for (N, r) is an integer $|L|$ with $L \in \mathcal{L}(N, r)$, i.e. 1 or a product of distinct Kolyvagin primes for (N, r). Put $\mathbb{Q}(\mu_\infty) = \bigcup_{n \ge 1} K_n$. For a place w of $\overline{\mathbb{Q}}$ above a prime p, v_w is its valuation with $v_w(p) = 1$; z is a w-unit if $v_w(z) = 0$, and for w-units z, z' we write $z \equiv z' \pmod w$ if $v_w(z - z') > 0$.

Euler systems. An **Euler system for** (N, r) is a family (α_d), indexed by the Kolyvagin integers d for (N, r), with $\alpha_d \in K_{Nd}^{\times}$, together with integers $e_{d,p}$, indexed by the pairs of a Kolyvagin integer d and a Kolyvagin prime $p \nmid d$, such that for all such d and p:

(Eu1) α_d is a w-unit for every place w of $\overline{\mathbb{Q}}$ not above r;

(Eu2) $\ell \nmid e_{d,p}$, and for every $\tau \in G_{\mathbb{Q}}$ that fixes μ_{Nd} pointwise and acts on μ_p by $\zeta \mapsto \zeta^g$ with g a generator of $(\mathbb{Z}/p\mathbb{Z})^{\times}$, and every $\varphi \in G_{\mathbb{Q}}$ with $\varphi(\zeta) = \zeta^p$ for $\zeta \in \mu_{Nd}$,

$$\prod_{i=0}^{p-2} \tau^i(\alpha_{pd}) = \Big(\frac{\alpha_d}{\varphi^{-1}(\alpha_d)}\Big)^{e_{d,p}};$$

(Eu3) for every φ as in (Eu2) and every place w of $\overline{\mathbb{Q}}$ above p, $\alpha_{pd} \equiv \varphi^{-1}(\alpha_d)^{e_{d,p}} \pmod w$.

Kolyvagin derivatives. A **choice of generators** for (N, r) is a family (τ_p), indexed by the Kolyvagin primes p, of elements $\tau_p \in G_{\mathbb{Q}}$ that fix every root of unity of order prime to p and act on μ_p by $\zeta \mapsto \zeta^{g_p}$ with g_p a generator of $(\mathbb{Z}/p\mathbb{Z})^{\times}$. The **Kolyvagin derivatives** are the maps $\overline{\mathbb{Q}}^{\times} \to \overline{\mathbb{Q}}^{\times}$

$$\mathrm{Der}_p(z) = \prod_{i=0}^{p-2} \tau_p^i(z)^i, \qquad \mathrm{Der}_L = \mathrm{Der}_{p_1} \circ \cdots \circ \mathrm{Der}_{p_k} \quad (L = (p_1, \ldots, p_k) \in \mathcal{L}(N, r)), \tag{7.6}$$

with $\mathrm{Der}_{\emptyset}$ the identity.

Descended Kummer characters. Let $\delta \in G_{\mathbb{Q}}$ and $a \in \mathbb{Z}$ with $\delta(\zeta) = \zeta^a$ for $\zeta \in \mu_{\ell^m}$, and put $\mathrm{P}_{\delta,a}(z) = \delta(z)\, z^{-a}$ for $z \in \overline{\mathbb{Q}}^{\times}$. Fix a primitive ℓ^m-th root of unity ζ_{ℓ^m}. An element $y \in \mathbb{Q}(\mu_\infty)^{\times}$ is **ℓ^m-invariant over** K_N if for every $g \in U_N$ the element $g(y)/y$ is an ℓ^m-th power in $\mathbb{Q}(\mu_\infty)^{\times}$. For such y and $g \in U_N$, let $Q_y(g)$ be the set of the quotients

$$\frac{g(\mathrm{P}_{\delta,a}(Y))}{\mathrm{P}_{\delta,a}(Y)\, \mathrm{P}_{\delta,a}(z)}, \qquad Y \in \overline{\mathbb{Q}},\ Y^{\ell^m} = y, \qquad z \in \mathbb{Q}(\mu_\infty),\ z^{\ell^m} = g(y)/y.$$

If $Q_y(g) = \{\zeta_{\ell^m}^k\}$ for a class $k \in \mathbb{Z}/\ell^m\mathbb{Z}$, the **descended Kummer character** of y takes the value $\mathrm{k}_y(g) = k$ at g; it depends on $(\delta, a, \zeta_{\ell^m})$, which are fixed wherever it is used.

Theorem 7.2.8. *Let $N \ge 1$ and $t \ge 0$ be integers and let $E \subset \mathbb{Q}(\mu_N)$ be a CM field with class number h_E. There is an integer X with*

$$1 \le X \le 2^{4(N+t+3)^{27}}\, h_E$$

such that for every prime ℓ, every coefficient ring $\mathcal{O}$ over $\mathbb{Z}_\ell$ containing the roots of unity of order the exponent of $(\mathbb{Z}/N)^\times$, every $0 \le e < t$ and every $\nu \ge 0$,

$$\operatorname{len}_{\mathcal{O}} \operatorname{Sha}^-(e,\nu) \le v_{\mathcal{O}}(X).$$

Proof. Put $y = N + t + 3$. For each integer e with $0 < e < t$, choose an integer X_e from Lemma 7.2.9; these choices depend only on N and e. Thus

$$1 \le X_e \le 2^{(N+e+3)^6} \le 2^{y^6}, \qquad Y_e = 16\varphi(N)X_e^2 \ge 1.$$

Define the positive integer

$$X = h_E \left(\prod_{0<e<t} Y_e \right)^{y^{20}}.$$

An empty product is 1. This choice precedes every prime, coefficient ring and truncation.

We first check its size. Since $y \ge 4$, $\varphi(N) \le N \le y$ and $y \le 2^y$ give

$$16\varphi(N) \le 16y \le 2^{y+4} \le 2^{2y^6}.$$

Consequently $Y_e \le 2^{4y^6}$. The number of indices $0 < e < t$ is at most $t \le y$, whence

$$\left(\prod_{0<e<t} Y_e \right)^{y^{20}} \le \left(2^{4y^6 \cdot y} \right)^{y^{20}} = 2^{4y^{27}}.$$

This proves the stated upper bound and positivity of X.

Fix a prime ℓ, an allowed coefficient ring $\mathcal{O}$, an integer $0 \le e < t$ and a truncation $\nu \ge 0$. If $e = 0$, (OE1) identifies the module with the everywhere unramified homomorphisms to $\mathcal{O}/\ell^\nu$. The injective coefficient map

$$\mathcal{O}/\ell^\nu \longrightarrow \mathcal{O}[\ell^{-1}]/\mathcal{O}, \qquad a \bmod \ell^\nu \longmapsto \ell^{-\nu} a \bmod \mathcal{O}$$

embeds this module in the unramified homomorphism module of Lemma 7.2.29. The CM field E has no real place, so that lemma applies also when $\ell = 2$. Its normalized length is $v_\ell(h_E)$; equivalently its ordinary $\mathcal{O}$-length is $v_{\mathcal{O}}(\ell)v_\ell(h_E) = v_{\mathcal{O}}(h_E)$. Since $h_E \mid X$, this proves the required inequality for $e = 0$.

Suppose now $0 < e < t$. The two congruence properties of X_e are exactly the hypotheses of Proposition 7.2.10; hence Y_e kills every odd cocycle. Also $N + e + 3 \le y$ and $X_e \le 2^{y^6}$, so Proposition 7.2.27 supplies a finite set $\mathcal{S} \subseteq G_E$ of at most y^{20} elements detecting these cocycles. Evaluation therefore gives an injective $\mathcal{O}$-linear map

$$\operatorname{Sha}^-(e,\nu) \longrightarrow \prod_{g \in \mathcal{S}} (\mathcal{O}/\ell^\nu)[Y_e].$$

For a discrete valuation ring, the Y_e-torsion in $\mathcal{O}/\ell^\nu$ has length $\min\{v_{\mathcal{O}}(Y_e), \nu v_{\mathcal{O}}(\ell)\}$: writing Y_e as a unit times a uniformizer power reduces the kernel of multiplication to the final that many steps of the uniformizer filtration. Thus

$$\operatorname{len}_{\mathcal{O}} \operatorname{Sha}^-(e,\nu) \le \#\mathcal{S}\, v_{\mathcal{O}}(Y_e) \le v_{\mathcal{O}}(Y_e^{y^{20}}).$$

Since Y_e is a factor in the defining product, $Y_e^{y^{20}} \mid X$. Monotonicity of the valuation on positive integer divisibility gives the claimed bound by $v_{\mathcal{O}}(X)$. Every choice and estimate was uniform in the prime, coefficient ring and truncation, as required. □

Lemma 7.2.9. *Let $N, e \geq 1$ be integers. There is an integer X with*

$$1 \leq X \leq 2^{(N+e+3)^6}$$

satisfying both conditions below.

1. *For every prime ℓ there is an integer $c \geq 2$ with $c \equiv 1 \pmod{N}$, $(c, \ell) = 1$, and $(c^e - 1)(c^{e+1} - 1) \mid X$.*
2. *For every integer $c \geq 0$ with $c \equiv 1 \pmod{N}$, every characteristic-zero commutative domain $\mathcal{O}$, and every Dirichlet character ψ modulo N with values in $\mathcal{O}$ such that $\psi(-1) = -(-1)^e$, there exists $w \in \mathcal{O}$ such that for every integer $m \geq 1$ prime to c,*

$$m \mid (c^{e+1} - 1)X - 2w \sum_{a=0}^{Nm-1} \left\lfloor \frac{ca}{Nm} \right\rfloor a^e \psi(a) \quad \text{in } \mathcal{O}.$$

Proof. Put $h = (e+2)!$, and for every integer a define

$$\beta(a) = hN^{e+1} B_{e+1}(a/N).$$

These numbers are integers. Indeed $N^{e+1} B_{e+1}(a/N) = \sum_{j=0}^{e+1} \binom{e+1}{j} B_j a^{e+1-j} N^j$, and the denominator theorem of von Staudt–Clausen makes the denominator of B_j a divisor of $(e+2)!$ for $j \leq e+1$.

We first establish the polynomial congruence needed below. Let R be any characteristic-zero domain, let ψ be an R-valued Dirichlet character modulo N, and let $c \equiv 1 \pmod{N}$, $(c, m) = 1$, $m \geq 1$. Write

$$A_\psi = \sum_{a=0}^{N-1} \psi(a)\beta(a), \quad P = \sum_{a=0}^{Nm-1} \psi(a) a^{e+1}, \quad S = \sum_{a=0}^{Nm-1} \left\lfloor \frac{ca}{Nm} \right\rfloor a^e \psi(a).$$

The Bernoulli generating function gives

$$\sum_{i=0}^{m-1} (a + Ni)^{e+1} = \frac{N^{e+1}}{e+2} \big(B_{e+2}(a/N + m) - B_{e+2}(a/N) \big).$$

After multiplying by h, its coefficient of m is $\beta(a)$ and all higher coefficients are integers. For powers m^k, $k \geq 2$, this follows by expanding the Bernoulli polynomial: the coefficient is $(e+1)!\binom{e+2}{k} N^{e+1} B_{e+2-k}(a/N)$, whose Bernoulli denominators divide $(e+1)!$ because $e + 2 - k \leq e$. Consequently

$$hP - mA_\psi \in m^2 R,$$

by writing every integer in $[0, Nm)$ uniquely as $a + Ni$ and using $\psi(a + Ni) = \psi(a)$.

For $0 \leq a < Nm$, put $q_a = \lfloor ca/(Nm) \rfloor$ and $r_a = ca - Nmq_a$. Multiplication by c permutes the residues modulo Nm, since c is coprime to both N and m; moreover $\psi(r_a) = \psi(a)$. The binomial expansion of $(ca - Nmq_a)^{e+1}$, modulo $(Nm)^2$, therefore gives

$$(c^{e+1} - 1)P - (e+1)c^e NmS \in (Nm)^2 R.$$

Multiply by h and insert the preceding congruence for hP. The result is

$$m\big((c^{e+1} - 1)A_\psi - h(e+1)Nc^e S\big) \in m^2 R.$$

As R has characteristic zero and is a domain, multiplication by m is injective. Dividing this divisibility by m proves

$$h(e+1)Nc^eS-(c^{e+1}-1)A_\psi\in mR. \tag{*}$$

We next construct a nonzero integer determinant. On the finite abelian group $H=(\mathbb{Z}/N)^\times$, let $\langle u\rangle$ denote the representative in $[0,N)$ and put

$$g(u)=2\beta(\langle u\rangle)+(-1)^e\mathbf{1}_{u=1}+\mathbf{1}_{u=-1},\qquad T_{s,t}=g(ts^{-1})\quad(s,t\in H).$$

For every complex character ψ of H, the vector $(\psi(t))_{t\in H}$ is an eigenvector of T, with eigenvalue

$$\lambda_\psi=2A_\psi+(-1)^e+\psi(-1).$$

All these eigenvalues are nonzero. To check this with imprimitive characters included, the Bernoulli evaluation and the distribution identity give

$$A_\psi=-h(e+1)NL(-e,\psi).$$

For a primitive character this is [317, Chapter 4, Theorem 4.2]. For the character induced from a primitive ψ_* of conductor $f\mid N$, both sides acquire the factor $\prod_{p\mid N}(1-\psi_*(p)p^e)$. For the Bernoulli side, insert $\mathbf{1}_{(a,N)=1}=\sum_{d\mid(a,\prod_{p\mid N}p)}\mu(d)$, put $a=db$, and use $\sum_{i=0}^{q-1}B_j((x+i)/q)=q^{1-j}B_j(x)$. Terms with $(d,f)>1$ vanish; in the others $f\mid N/d$, so this distribution identity reduces the sum to conductor f and leaves the factor d^e. Summing $\mu(d)\psi_*(d)d^e$ gives the stated Euler product. This also covers $N=1$: $B_{e+1}(0)=B_{e+1}(1)$ since $e+1\geq 2$.

The primitive functional equation, the nonvanishing Euler product at $1+e>1$, and the gamma factor show that $L(-e,\psi_*)$ vanishes exactly when $\psi_*(-1)=(-1)^e$. The conductor-one case is the zeta functional equation. None of the imprimitive Euler factors vanishes, because $|\psi_*(p)p^e|$ is either 0 or $p^e>1$. Thus the same parity criterion holds for ψ. If $\psi(-1)=-(-1)^e$, then $A_\psi\neq 0$ and $\lambda_\psi=2A_\psi\neq 0$; otherwise $A_\psi=0$ and $\lambda_\psi=2(-1)^e\neq 0$. Characters form a basis of the functions on the finite abelian group H, so $D=\det T$ is a nonzero integer.

Set

$$X=\big((N+1)^e-1\big)\big((N+1)^{e+1}-1\big)\big((2N+1)^e-1\big)\big((2N+1)^{e+1}-1\big)|D|.$$

Every factor is positive. For any prime ℓ, at least one of $N+1$ and $2N+1$ is prime to ℓ: a prime dividing both would divide their difference N and then 1. Taking that value for c proves the first required property.

We verify the second property over an arbitrary R, not only over a field of complex numbers. The same eigenvector identity $Tv=\lambda_\psi v$ holds over R, with $v_t=\psi(t)$ and $v_1=1$. Multiplying by the adjugate matrix and taking coordinate 1 proves that λ_ψ divides D in R. It therefore divides X in R. Under the required parity, $\lambda_\psi=2A_\psi$, so choose $u\in R$ with $X=2uA_\psi$ and put

$$w=uh(e+1)Nc^e.$$

This w does not depend on m. Multiplying (*) by $-2u$ gives exactly the required divisibility for every m prime to c.

Finally we check the explicit size. Let $M=hN^{e+1}(e+1)!$ and $z=N+e+3$. The Bernoulli recurrence gives $|B_j|\leq j!$ by induction: after using the induction hypotheses, the normalized bound is $\sum_{r=2}^{j+1}1/r!<1$. Hence, for $0\leq x\leq 1$, $|B_{e+1}(x)|\leq(e+1)!\sum_{r=0}^{e+1}1/r!<3(e+1)!$. Thus $|\beta(a)|\leq 3M$ for $0\leq a<N$, and every entry of T has absolute value at most $6M+2\leq 64M$. If $r=\varphi(N)\leq N$, the determinant expansion yields

$$|D|\leq r!(64M)^r\leq N!(64M)^N.$$

The four remaining factors are at most $(2N+1)^{4e+2}$. Use $2N+1 \le 2^{2N}$, $j! \le 2^{j^2}$ and $N \le 2^N$. These bounds give $X \le 2^H$, where

$$H = 8Ne + 4N + N^2 + N\big(6 + (e+2)^2 + N(e+1) + (e+1)^2\big) = N\big(2e^2 + 14e + 15 + N(e+2)\big).$$

Since $z \ge e+4$, $2e^2 + 14e + 15 \le 2z^2$ and $N(e+2) \le z^2$. Therefore $H \le 3z^3 \le z^6$, proving $X \le 2^{(N+e+3)^6}$. All the asserted properties now hold for this one positive integer. □

Proposition 7.2.10. *Let $N, e \ge 1$, let $E \subseteq \mathbb{Q}(\mu_N)$ be a CM field. Suppose $X \ge 1$ is an integer with the following two properties: for each prime p, some integer $c \ge 2$ satisfies $c \equiv 1 \pmod N$, $(c,p) = 1$ and $(c^e - 1)(c^{e+1} - 1) \mid X$; and for every $c \ge 0$ with $c \equiv 1 \pmod N$, every characteristic-zero commutative domain R and every R-valued Dirichlet character ψ modulo N with $\psi(-1) = -(-1)^e$, some $w \in R$ satisfies*

$$m \mid (c^{e+1} - 1)X - 2w \sum_{a=0}^{Nm-1} \left\lfloor \frac{ca}{Nm} \right\rfloor a^e \psi(a) \quad \text{in } R$$

for every $m \ge 1$ prime to c. Then for every prime ℓ, every coefficient ring $\mathcal{O}$ over $\mathbb{Z}_\ell$ containing roots of unity of order the exponent of $(\mathbb{Z}/N)^\times$, and every $\nu \ge 0$,

$$16\varphi(N)X^2 \operatorname{Sha}^-(e,\nu) = 0.$$

Proof. Fix $\ell, \mathcal{O}, \nu$ and $x \in \operatorname{Sha}^-(e,\nu)$. Apply Lemma 7.2.11, with representatives chosen once. For every character ψ with $\psi(-1) = -(-1)^e$, the projected cocycle Z_ψ satisfies exactly the local conditions in Proposition 7.2.12. Part (OC1) therefore gives

$$4X^2 Z_\psi = 0.$$

Projection is $\mathcal{O}$-linear in x. Consequently all odd projected components of $4X^2 x$ vanish. The comparison conclusion of Lemma 7.2.11, applied to $4X^2 x$, gives

$$4\varphi(N)\,(4X^2 x) = 0.$$

This is the asserted annihilator $16\varphi(N)X^2$. The argument does not invert 2, $\varphi(N)$, or any factor of X, so it applies to every coefficient prime. □

Lemma 7.2.11. *Let $N, e \ge 1$, let $E \subseteq \mathbb{Q}(\mu_N)$ be a CM field, fix a complex conjugation c, and put $A = (\mathbb{Z}/N)^\times$. Choose representatives $s_u \in G_\mathbb{Q}$ for its quotient A with $s_1 = 1$. For $u \in A$ and $g \in G_\mathbb{Q}$ put*

$$b(u,g) = s_u(cgc^{-1}g^{-1})s_u^{-1} \in G_E.$$

For every prime ℓ, every coefficient ring $\mathcal{O}$ containing the roots of unity of order the exponent of A, every $\nu \ge 0$, every $x \in \operatorname{Sha}^-(e,\nu)$ and every character $\psi : A \to \mathcal{O}^\times$, put $\alpha_\psi = \chi_{\mathrm{cyc}}^e \psi$ and

$$Z_\psi(g) = \sum_{u \in A} \alpha_\psi(s_u) x(b(u,g)).$$

Then Z_ψ is locally constant, satisfies

$$Z_\psi(gh) = Z_\psi(g) + \alpha_\psi(g)^{-1} Z_\psi(h), \qquad Z_\psi(c) = 0,$$

and vanishes on every $g \in G_{\mathbb{Q}(\mu_N)}$ which lies in inertia at a prime different from ℓ, or lies in a decomposition group above ℓ with $\chi_{\mathrm{cyc}}(g) = 1$. Moreover, if $Z_\psi = 0$ for every ψ with $\psi(-1) = -(-1)^e$, then $4\varphi(N)x = 0$. The representatives and the maps b are independent of $\ell, \mathcal{O}, e, \nu$ and x.

Proof. The extension $\mathbb{Q}(\mu_N)/\mathbb{Q}$ is abelian. Therefore every commutator $cgc^{-1}g^{-1}$ fixes μ_N, and so do its conjugates. This proves that $b(u,g) \in G_E$. Representatives with $s_1 = 1$ exist by the surjectivity of the action on μ_N.

Fix the coefficient data and x. Write $\delta(g) = cgc^{-1}g^{-1}$. The cyclotomic character is trivial on every commutator, hence on every conjugate of $\delta(g)$. Consequently the cocycle identity for x is additive on products of such elements. It also gives, for $h, t \in G_E$ with $\chi_{\mathrm{cyc}}(t) = 1$,

$$x(hth^{-1}) = \chi_{\mathrm{cyc}}(h)^{-e} x(t).$$

Indeed, expand the three factors and use $x(h^{-1}) = -\chi_{\mathrm{cyc}}(h)^e x(h)$.

For $v, g \in G_{\mathbb{Q}}$ put $T_\psi(v,g) = \alpha_\psi(v) x(v\delta(g)v^{-1})$. The argument of x belongs to G_E. If $v' = hv$ with $h \in G_{\mathbb{Q}(\mu_N)}$, the preceding conjugation identity and $\psi(h) = 1$ give $T_\psi(v', g) = T_\psi(v, g)$. Thus $T_\psi(v,g)$ depends only on the image of v in A. The identity

$$\delta(gh) = \delta(g)\, g\delta(h) g^{-1}$$

then yields

$$T_\psi(v, gh) = T_\psi(v,g) + \alpha_\psi(g)^{-1} T_\psi(vg, h).$$

Right multiplication by the image of g permutes A. Summing over the representatives proves the asserted cocycle identity for Z_ψ. Since $\delta(c) = 1$, it also proves $Z_\psi(c) = 0$. All maps involved are continuous and x is locally constant with finite target, so Z_ψ is locally constant.

To verify the local conditions, let g be one of the specified elements in $G_{\mathbb{Q}(\mu_N)}$. For every $v \in G_{\mathbb{Q}}$, both vgv^{-1} and $vcgc^{-1}v^{-1}$ belong to G_E. In the inertia case they belong to inertia at primes of E not dividing ℓ. In the decomposition case they belong to decomposition groups above ℓ, and their cyclotomic character is 1. The defining local conditions of x therefore make both their values zero. The cocycle identity makes $x(v\delta(g)v^{-1}) = 0$, proving $Z_\psi(g) = 0$.

It remains to prove the comparison factor. Orthogonality in the characteristic-zero ring $\mathcal{O}$, followed by reduction modulo ℓ^ν, gives

$$\sum_\psi \psi(u) = \begin{cases} |A| & u = 1, \\ 0 & u \neq 1. \end{cases}$$

There are exactly $|A|$ characters because $\mathcal{O}$ contains all roots of unity of order the exponent of A. This identity uses no division by $|A|$, even when $\ell \mid |A|$. Since $s_1 = 1$, for $h \in G_E$ it gives

$$\sum_\psi Z_\psi(h) = |A|\, x(\delta(h)) = |A|\big(x(chc^{-1}) - x(h)\big).$$

The last equality follows by expanding $chc^{-1}h^{-1}$ and using equality of the cyclotomic characters at h and chc^{-1}.

The scalar $\alpha_\psi(c)$ is either 1 or -1. If it is 1, the cocycle identity and $Z_\psi(c) = 0$ imply $Z_\psi(chc^{-1}) = Z_\psi(h)$. If it is -1, the parity condition on ψ is exactly $\psi(-1) = -(-1)^e$, and the hypothesis makes Z_ψ zero. Hence the sum over all ψ is invariant under $h \mapsto chc^{-1}$. Comparing the displayed identity at h and at chc^{-1} gives

$$2|A|\big(x(chc^{-1}) - x(h)\big) = 0.$$

Because $e > 0$, oddness means $x(chc^{-1}) = -x(h)$. Thus $4|A|x(h) = 0$ for every h, as required. All the initial choices were made using only N, E, c, proving the final uniformity assertion. □

Proposition 7.2.12. *Let $N, e \geq 1$. Suppose $X \geq 1$ is an integer with the following two properties: for each prime p, some integer $c \geq 2$ satisfies $c \equiv 1 \pmod{N}$, $(c,p) = 1$ and $(c^e - 1)(c^{e+1} - 1) \mid X$; and for every $c \geq 0$ with $c \equiv 1 \pmod{N}$, every characteristic-zero commutative domain R and every R-valued Dirichlet character ψ modulo N with $\psi(-1) = -(-1)^e$, some $w \in R$ satisfies*

$$m \mid (c^{e+1} - 1)X - 2w \sum_{a=0}^{Nm-1} \left\lfloor \frac{ca}{Nm} \right\rfloor a^e \psi(a) \quad \text{in } R$$

for every $m \geq 1$ prime to c. Fix a prime ℓ, a ring of integers $\mathcal{O}$ of a finite extension of $\mathbb{Q}_\ell$, a Dirichlet character $\psi : (\mathbb{Z}/N)^\times \to \mathcal{O}^\times$ with $\psi(-1) = -(-1)^e$, and an integer $\nu \geq 0$. Inflate ψ to $G_\mathbb{Q}$ by its action on μ_N, and put $\alpha = \chi_{\mathrm{cyc}}^e \psi$. Fix a complex conjugation c and put $K_N = G_{\mathbb{Q}(\mu_N)}$. Let $\mathcal{C}$ be the $\mathcal{O}$-module of locally constant maps $z : G_\mathbb{Q} \to \mathcal{O}/\ell^\nu$ satisfying

$$z(gh) = z(g) + \alpha(g)^{-1} z(h), \qquad z(c) = 0,$$

and the following local conditions: $z(g) = 0$ whenever $g \in K_N$ belongs to an inertia group at a prime different from ℓ, or belongs to a decomposition group above ℓ and satisfies $\chi_{\mathrm{cyc}}(g) = 1$. Then:

(OC1) $4X^2\mathcal{C} = 0$.

(OC2) *If $\ell > N + e + 3$, there are $v_\ell(X) + 1$ elements $\gamma_i \in G_\mathbb{Q}$ such that $z \in \mathcal{C}$ and $z(\gamma_i) = 0$ for every i imply $z = 0$.*

Proof. Part (OC1) is Proposition 7.2.13, with exactly the hypotheses displayed here. We prove (OC2). If $\nu = 0$, the module is zero and any list of the required length detects it. Suppose $\nu \geq 1$, and put

$$m = v_\ell(X) + 1, \qquad R_m = \mathcal{O}/\ell^m, \qquad \beta = \chi_{\mathrm{cyc}}^{e+1}\psi, \qquad L = N\ell^m.$$

The field of coefficients and the truncation are fixed throughout this argument.

Choose $1 \leq a < N\ell$ with $a \equiv 1 \pmod{N}$ and with primitive residue in $\mathbb{F}_\ell^\times$. This is possible since $\ell > N$. Both $a^e - 1$ and $a^{e+1} - 1$ are units of $\mathcal{O}$, because $0 < e < e + 1 < \ell - 1$. In particular $a \neq 1$ and $a < L$. Choose γ in inertia above ℓ with $\chi_{\mathrm{cyc}}(\gamma) = a$; inertia fixes μ_N, so $\psi(\gamma) = 1$ and $\beta(\gamma) - 1 = a^{e+1} - 1$ is a unit.

Assume for a contradiction that no m elements detect $\mathcal{C}$. Thus every list of m elements has a nonzero member of $\mathcal{C}$ vanishing at all of them. We will use the following consequence: for every set T of at most m primes congruent to 1 modulo $N\ell$, there exists a nonzero $z \in \mathcal{C}$ killed by ℓ which is zero on every decomposition group above the primes of T. Choose a Frobenius at each prime of T, pad this list to length m, and choose a nonzero cocycle vanishing on the list. Multiply it by its last nonzero power of ℓ. The resulting z is killed by ℓ and still vanishes at the chosen Frobenii. At these primes the coefficient action on its values is trivial, and its inertia values are zero by the component local condition. Its restriction is consequently an unramified homomorphism zero at a generator of the unramified quotient, hence zero on the decomposition group. The cocycle conjugation formula transports this zero to every conjugate decomposition group. This proves the consequence.

We also need a finite simultaneous set of Frobenius tests. Let $\mathcal{Y}$ be the set of locally constant β-cocycles into R_m that vanish on inertia over $\mathbb{Q}(\mu_N)$ away from ℓ. Both $\mathcal{Y}$ and $\mathcal{C}$ are finite. Indeed, outside the primes dividing $N\ell$ the full inertia group fixes μ_N, so these cocycles are

unramified there; their coefficient actions are also unramified there. They therefore belong to the continuous cocycle groups for $G_{\mathbb{Q},S}$ with S consisting of those primes and infinity. The cohomology groups H^1 are finite by global finiteness, and the groups of coboundaries have at most the number of coefficient elements; hence the cocycle groups are finite. This is the finiteness assertion in [201, Chapter I, Theorem4.10].

For any cyclotomic subgroup $G_{\mathbb{Q}(\mu_f)}$, a nonzero $z \in \mathcal{C}$ does not vanish identically on that subgroup. Otherwise every commutator with c would be in its zero subgroup, so the cocycle identity and $z(c) = 0$ would imply $(\alpha(c)^{-1} - 1)z = -2z = 0$, impossible since ℓ is odd. Similarly, a nonzero $y \in \mathcal{Y}$ with $y(\gamma) = 0$ is nonzero on every such cyclotomic subgroup: the same commutator identity would give $(\beta(\gamma) - 1)y = 0$.

Put $f = aL$. For each pair consisting of $z \in \mathcal{C} \setminus \{0\}$ and $y \in \mathcal{Y}$ whose restriction to $G_{\mathbb{Q}(\mu_f)}$ is nonzero, choose a prime $q \equiv 1 \pmod f$, a place above it and a Frobenius φ such that $z(\varphi) \neq 0$ and $y(\varphi) \neq 0$. Such a choice follows from Chebotarev: the zero sets of the two cocycles are open subgroups, their intersections with the cyclotomic subgroup are proper, and a group cannot be the union of two proper subgroups. Thus there is a nonempty open subset of that subgroup on which both values are nonzero. Passing to a finite Galois quotient and choosing the place above a prime in the resulting conjugacy class gives the desired Frobenius representative. Since both cocycle sets are finite, the set Q of primes chosen in this way is finite. Every $q \in Q$ satisfies $q \equiv 1 \pmod{aL}$, and it has the following property:

$$0 \neq z \in \mathcal{C}, \quad y \in \mathcal{Y}, \quad y|_{G_{\mathbb{Q}(\mu_f)}} \neq 0$$
$$\implies \text{some } q \in Q \text{ has a Frobenius } \varphi \text{ with } z(\varphi)y(\varphi) \text{ separately nonzero.}$$

Only the two separate nonzero values are asserted; no product in a coefficient ring with zero divisors is used.

Choose a nonzero ℓ-torsion $z_0 \in \mathcal{C}$ by the preceding consequence with $T = \varnothing$. Odd visibility and Chebotarev give a prime $p \equiv 1 \pmod{L \prod_{q \in Q} q}$ and a Frobenius at p on which z_0 is nonzero. In particular z_0 is not zero on its decomposition group. The prime p is not in Q. Apply Proposition 7.2.17 to a, γ, Q, p, obtaining the actual dual cocycles κ_S and the bottom identity (DS4).

Call a finite set T of primes tight in this proof if all its primes are 1 modulo $N\ell$ and every ℓ-torsion β-cocycle into R_m unramified over $\mathbb{Q}(\mu_N)$ away from ℓ and T is unramified over that field away from ℓ. This is a property of the displayed cocycles, not an additional hypothesis. The empty set is tight. Moreover, if T is tight and an ℓ-torsion $z \in \mathcal{C}$ is zero above every prime in T but not above a prime $r \notin T$ congruent to 1 modulo $N\ell$, then $T \cup \{r\}$ is tight. To prove this, apply Lemma 7.2.15 to remove the possible inertia at r from any such dual cocycle, and then apply tightness of T. The initial choice of z_0, p shows in particular that $\{p\}$ is tight.

We prove by downward induction on $i = m, m-1, \ldots, 0$ that

$$S \subseteq Q, \quad \#S \leq i, \quad \{p\} \cup S \text{ tight}$$
$$\implies \ell^i \kappa_S \text{ is unramified over } \mathbb{Q}(\mu_N) \text{ away from } \ell.$$

For $i = m$ the cocycle is zero. Assume the assertion for $i+1$, and let S satisfy the conditions at $i < m$. By induction, $y = \ell^{i+1}\kappa_S$ belongs to $\mathcal{Y}$ and is zero at γ. If $y \neq 0$, it is visible on $G_{\mathbb{Q}(\mu_f)}$. The set $\{p\} \cup S$ has at most $i + 1 \leq m$ elements, so the consequence of blindness supplies a nonzero ℓ-torsion $z \in \mathcal{C}$ zero above it. The defining property of Q supplies $q \in Q$ and a Frobenius φ with $y(\varphi) \neq 0$ and $z(\varphi) \neq 0$. Hence $q \notin S \cup \{p\}$, and z is not zero above q. The tightness-extension assertion makes $\{p\} \cup S \cup \{q\}$ tight. Apply the induction hypothesis to $S \cup \{q\}$: the cocycle $\ell^{i+1}\kappa_{S \cup \{q\}}$ is unramified away from ℓ over $\mathbb{Q}(\mu_N)$. By (DS3), some inertia

element τ at q satisfies

$$y(\varphi) = \ell^{i+1}\kappa_{S\cup\{q\}}(\tau) = 0.$$

Here the full inertia group at q fixes μ_N, because $q \nmid N$. This contradicts its choice. We have proved $\ell^{i+1}\kappa_S = 0$. Thus $\ell^i\kappa_S$ is killed by ℓ. It is unramified away from $\ell, \{p\} \cup S$ by (DS2), and tightness removes the latter primes. This completes the induction.

Take $i = 0$ and $S = \varnothing$. Since $\{p\}$ is tight, $\kappa_\varnothing$ is unramified away from ℓ over $\mathbb{Q}(\mu_N)$, and hence zero on inertia at p. Its bottom value (DS4), whose scalar is a unit, gives

$$V_m = 0 \quad \text{in } R_m,$$

where V_m is the displayed floor-difference sum at level $N\ell^m$.

Put $A_0 = (a^{e+1} - 1)X$. Apply Lemma 7.2.26 with $n = m$. Here $N, e, m \geq 1$, the chosen a satisfies $a \equiv 1 \pmod N$ and $\ell \nmid a$, and the character has exactly the stated odd parity. The single multiplier w in the hypothesis supplies its two congruences at levels ℓ^m and ℓ^{m-1}, including the case $m = 1$ where the lower congruence is modulo 1. Its floor-difference sum is the present V_m. Since $V_m = 0$ in R_m, the lemma gives $\ell^m \mid A_0$ in $\mathcal{O}$. The factor $a^{e+1} - 1$ is a unit by our primitive-residue choice, so $\ell^m \mid X$. This is impossible:

$$v_\mathcal{O}(X) = v_\mathcal{O}(\ell)v_\ell(X) < v_\mathcal{O}(\ell)(v_\ell(X) + 1) = v_\mathcal{O}(\ell^m).$$

The contradiction proves that $m = v_\ell(X) + 1$ detecting elements exist, establishing (OC2). □

Proposition 7.2.13. *Let $N, e \geq 1$. Suppose $X \geq 1$ is an integer with the following two properties: for each prime p, some integer $c \geq 2$ satisfies $c \equiv 1 \pmod N$, $(c, p) = 1$ and $(c^e - 1)(c^{e+1} - 1) \mid X$; and for every $c \geq 0$ with $c \equiv 1 \pmod N$, every characteristic-zero commutative domain R and every R-valued Dirichlet character ψ modulo N with $\psi(-1) = -(-1)^e$, some $w \in R$ satisfies*

$$m \mid (c^{e+1} - 1)X - 2w \sum_{a=0}^{Nm-1} \left\lfloor \frac{ca}{Nm} \right\rfloor a^e\psi(a) \quad \text{in } R$$

for every $m \geq 1$ prime to c. Fix a prime ℓ, a ring of integers $\mathcal{O}$ of a finite extension of $\mathbb{Q}_\ell$, a Dirichlet character $\psi : (\mathbb{Z}/N)^\times \to \mathcal{O}^\times$ with $\psi(-1) = -(-1)^e$, and an integer $\nu \geq 0$. Inflate ψ to $G_\mathbb{Q}$ by its action on μ_N, and put $\alpha = \chi_{\mathrm{cyc}}^e\psi$. Fix a complex conjugation c and put $K_N = G_{\mathbb{Q}(\mu_N)}$. Let $\mathcal{C}$ be the $\mathcal{O}$-module of locally constant maps $z : G_\mathbb{Q} \to \mathcal{O}/\ell^\nu$ satisfying

$$z(gh) = z(g) + \alpha(g)^{-1}z(h), \qquad z(c) = 0,$$

and the following local conditions: $z(g) = 0$ whenever $g \in K_N$ belongs to an inertia group at a prime different from ℓ, or belongs to a decomposition group above ℓ and satisfies $\chi_{\mathrm{cyc}}(g) = 1$. Then $4X^2\mathcal{C} = 0$.

Proof. Write $R = \mathcal{O}/\ell^\nu$ and fix $z \in \mathcal{C}$. If $\nu = 0$, then $R = 0$ and there is nothing to prove. Choose the integer $a \geq 2$ in the first hypothesis for the prime ℓ, and write

$$X = (a^e - 1)(a^{e+1} - 1)b, \qquad b \in \mathbb{Z}_{\geq 1}.$$

Put $r = \nu + 2$, $L = N\ell^r$, $K = \mathbb{Q}(\mu_L)$, and $d = 2(a^e - 1)$. Thus $L \geq 4$, so K has no real embeddings. The action through α^{-1} is trivial on G_K with values in R. Hence $z|_{G_K}$, and therefore $h = d\,z|_{G_K}$, are continuous homomorphisms to the finite additive group of R.

We first prove that h is everywhere unramified. Away from ℓ this follows directly from the local condition, since $G_K \subseteq K_N$. For each decomposition group D above ℓ, apply Lemma 7.2.14 to the given a and the cocycle z, with coefficient exponent ν and $s = r = \nu + 2$. Its local zero condition is exactly the displayed defining condition of $\mathcal{C}$, and its congruence and coprimality hypotheses are those in the choice of a. Thus $(a^e - 1)z$ vanishes on $D \cap G_K$. The multiple $h = 2(a^e - 1)z|_{G_K}$ therefore vanishes on the entire decomposition group of K above ℓ, proving the required assertion.

The finite-image homomorphism h cuts out a finite abelian extension of K. Global reciprocity, with arithmetic Frobenius, identifies its unramified ideal map with a homomorphism from the ideal class group: local units map to inertia, principal ideles map to 1, and there are no real-place conditions. In particular the value on every principal fractional ideal is zero. This is precisely the finite-extension reciprocity theorem of [202, Chapter V, Proposition5.2 and Theorem5.3].

We next construct the particular principal ideal to which we apply this fact. Let $p \equiv 1 \pmod{L}$ be a rational prime, let $\mathfrak{p}$ be a prime of K above p, and let $\varphi \in G_K$ be an arithmetic Frobenius at a chosen place above $\mathfrak{p}$. For $u \in (\mathbb{Z}/L)^\times$, let $\widetilde{u} \in \{1, \dots, L-1\}$ be its representative and let σ_u act on μ_L by u. The residue field at $\mathfrak{p}$ has order p. Let $G(j)$ be the Gauss sum for the inverse jth power of its Lth power-residue character, using a primitive pth root of unity.

The classical Gauss-sum identities and ideal factorization give $G(j) \neq 0$ when $L \nmid j$ and

$$(G(1)^L) = \prod_u \sigma_u^{-1}(\mathfrak{p})^{\widetilde{u}};$$

see [317, Chapter6]. Define $J_0 = G(1)^a / G(a)$. An automorphism fixing K and sending the chosen pth root to its tth power multiplies $G(j)$ by the jth power of the residue-character value at t. The factors cancel in J_0, so $J_0 \in K^\times$. Extending σ_a to fix that pth root gives $G(a)^L = \sigma_a(G(1)^L)$. Consequently

$$(J_0^L) = \prod_u \sigma_u^{-1}(\mathfrak{p})^{a\widetilde{u} - \widetilde{au}} = \prod_u \sigma_u^{-1}(\mathfrak{p})^{L\lfloor a\widetilde{u}/L \rfloor}.$$

The group of fractional ideals is free abelian; cancelling the common exponent L proves the corresponding formula for (J_0). Thus $J = J_0 / c(J_0)$ lies in $K^\times$, is a unit away from p, and satisfies

$$(J) = \prod_u \sigma_u^{-1}(\mathfrak{p})^{k(u)}, \qquad k(u) = \left\lfloor \frac{a\widetilde{u}}{L} \right\rfloor - \left\lfloor \frac{a(L - \widetilde{u})}{L} \right\rfloor.$$

Choose lifts $s_u \in G_{\mathbb{Q}}$ of the σ_u. Frobenius at $\sigma_u^{-1}(\mathfrak{p})$ is represented by $s_u^{-1} \varphi s_u$. The cocycle identity, together with trivial action of φ on R, gives

$$z(s_u^{-1} \varphi s_u) = \alpha(s_u) z(\varphi) = \widetilde{u}^{\,e} \psi(\widetilde{u}) z(\varphi) \quad \text{in } R.$$

Apply the ideal homomorphism defined by h to the principal ideal (J). We obtain

$$V_r \, 2(a^e - 1) z(\varphi) = 0, \qquad V_r = \sum_{u \in (\mathbb{Z}/L)^\times} k(u) \widetilde{u}^{\,e} \psi(\widetilde{u}) \in \mathcal{O}.$$

Put $A = (a^{e+1} - 1)X$. Apply Lemma 7.2.26 with $n = r$ and the present $N, e, \ell, \mathcal{O}, \psi, a$. Its parity and positive-exponent hypotheses are part of our assumptions. The single multiplier w supplied by the second hypothesis for $a, \mathcal{O}, \psi$ works at both levels ℓ^r and ℓ^{r-1}, because these integers are prime to a. Its floor-difference sum is precisely V_r above. Hence

$$A \equiv q V_r \pmod{\ell^r \mathcal{O}}$$

for some $q \in \mathcal{O}$. This application includes $\ell \mid N$, $\ell = 2$, and ramified coefficient rings without altering the ideal of congruence.

Reducing to R and multiplying the reciprocity identity by bq now gives

$$2X^2 z(\varphi) = 2(a^e - 1)b\, A\, z(\varphi) = 0.$$

This holds at every such split prime and every choice of its Frobenius.

To conclude, put $w_0 = 2X^2 z$ and suppose that $2w_0 \neq 0$. Its restriction to G_K cannot be zero. Otherwise its cocycle would factor through the abelian quotient $\mathrm{Gal}(K/\mathbb{Q})$. Commutativity of this quotient and $w_0(c) = 0$ would give

$$(\alpha(c)^{-1} - 1)w_0(g) = (\alpha(g)^{-1} - 1)w_0(c) = 0$$

for every g. Since $\alpha(c) = -1$, this would imply $2w_0 = 0$, a contradiction.

Choose $g \in G_K$ with $w_0(g) \neq 0$. Local constancy and the finite coefficient action allow passage to a finite Galois quotient in which membership in G_K and this nonzero value are determined. Chebotarev applied to the conjugacy class of the image of g supplies a prime split completely in K and a place above it whose Frobenius has that image. Conjugating the chosen place permits the representative of that image to be exactly the chosen one. This contradicts the preceding vanishing of $2X^2 z(\varphi)$. Thus $2w_0 = 4X^2 z = 0$, as asserted. □

Lemma 7.2.14. *Let $N, e, \nu \geq 1$, let ℓ be a prime, let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$, and let $\psi : (\mathbb{Z}/N)^\times \to \mathcal{O}^\times$ be a Dirichlet character inflated to $G_\mathbb{Q}$. Put $\alpha = \chi_{\mathrm{cyc}}^e \psi$ and $K_N = G_{\mathbb{Q}(\mu_N)}$. Fix a decomposition group D above ℓ. Suppose $z : G_\mathbb{Q} \to \mathcal{O}/\ell^\nu\mathcal{O}$ satisfies*

$$z(gh) = z(g) + \alpha(g)^{-1} z(h), \qquad z(h) = 0 \quad (h \in D \cap K_N,\ \chi_{\mathrm{cyc}}(h) = 1).$$

Let $a \geq 1$ satisfy $a \equiv 1 \pmod N$ and $\ell \nmid a$. Then, for every $s \geq \nu$,

$$(a^e - 1)z(g) = 0 \qquad (g \in D \cap G_{\mathbb{Q}(\mu_{N\ell^s})}).$$

If $a^e - 1$ is a unit of $\mathcal{O}$, the restriction of z to this intersection is zero. Neither a parity condition on ψ nor unramifiedness away from ℓ is needed.

Proof. We use the cyclotomic inertia description in Theorem A.2.10. It gives an element i of inertia in D with $\chi_{\mathrm{cyc}}(i) = a$. Here is the passage from the finite description to that assertion. For each $t \geq 1$, the inertia image on μ_{ℓ^t} is all of $(\mathbb{Z}/\ell^t)^\times$, so the closed subset of inertia having cyclotomic value congruent to a modulo ℓ^t is nonempty. These subsets are nested. Inertia is a closed subgroup of a profinite group and is compact, so their intersection is nonempty. An element in the intersection has the stated exact cyclotomic value. Inertia fixes roots of unity of order prime to ℓ, and $a \equiv 1 \pmod N$ makes its action trivial on the ℓ-primary roots in μ_N as well. Consequently $i \in K_N$, $\psi(i) = 1$ and $\alpha(i) = a^e$.

Fix $g \in D \cap G_{\mathbb{Q}(\mu_{N\ell^s})}$. Its action through ψ is trivial, and $\chi_{\mathrm{cyc}}(g) \equiv 1 \pmod{\ell^s}$. Since $s \geq \nu$, $\alpha(g)$ and its inverse act as 1 on $\mathcal{O}/\ell^\nu\mathcal{O}$. The commutator

$$\delta = igi^{-1}g^{-1}$$

belongs to D, fixes μ_N, and has cyclotomic character 1: the actions on roots of unity and the cyclotomic character are abelian characters. Thus $z(\delta) = 0$ by hypothesis and $\alpha(\delta) = 1$. Since $ig = \delta gi$, the cocycle identity gives $z(ig) = z(gi)$. Expanding both sides and using the trivial coefficient action of g yields

$$z(i) + a^{-e} z(g) = z(g) + z(i).$$

It follows that $(a^{-e}-1)z(g)=0$. Multiplication by the unit $-a^e$ proves the claimed annihilation. When a^e-1 is a unit, this forces $z(g)=0$. All computations take place in the literal quotient $\mathcal{O}/\ell^\nu\mathcal{O}$, so no reduction to an unramified coefficient ring or residue field is involved. □

Lemma 7.2.15. *Let $N, e \geq 1$, let $\ell > N+e+3$ be a prime, let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$, and let $\psi : (\mathbb{Z}/N)^\times \to \mathcal{O}^\times$ satisfy $\psi(-1) = -(-1)^e$. Inflate ψ to $G_\mathbb{Q}$ and put $\alpha = \chi_{\mathrm{cyc}}^e\psi$, $\beta = \chi_{\mathrm{cyc}}^{e+1}\psi$ and $K_N = G_{\mathbb{Q}(\mu_N)}$. Let T be a finite set of primes congruent to 1 modulo $N\ell$, and let $r \notin T$ be another such prime. Suppose $\nu, m \geq 1$ and:*

(CP1) *$z : G_\mathbb{Q} \to \mathcal{O}/\ell^\nu$ is a locally constant α^{-1}-cocycle, killed by ℓ, zero at a fixed complex conjugation c, and zero on every element of K_N which lies in inertia away from ℓ or lies in a decomposition group above ℓ with cyclotomic character 1.*

(CP2) *z is zero on every decomposition group above every prime in T, but is not zero on a decomposition group above r.*

(CP3) *$y : G_\mathbb{Q} \to \mathcal{O}/\ell^m$ is a locally constant β-cocycle, killed by ℓ, and is zero on the intersection with K_N of every inertia group at a prime outside $\{\ell, r\} \cup T$.*

Then y vanishes on every inertia group above r.

Proof. Put $A = \mathcal{O}/\ell\mathcal{O}$. Multiplication by $\ell^{\nu-1}$ identifies A with $(\mathcal{O}/\ell^\nu)[\ell]$, and multiplication by ℓ^{m-1} gives the analogous identification for the target of y. We henceforth regard both cocycles as A-valued. These are equivariant identifications, so every zero and every local condition is preserved.

There is a coefficient field $k \subseteq A$, isomorphic to the residue field of A. Indeed, if its order is q, the solutions of $X^q - X = 0$ in the finite local ring A lift its residue-field elements uniquely: the derivative is -1 and the maximal ideal is nilpotent. In characteristic ℓ these solutions are closed under addition and multiplication, so form a field. Every root of unity of order prime to ℓ in A belongs to this field: its reduction has the same order, and uniqueness of such a root's lift follows from its derivative being a unit. Since the order of ψ divides $\varphi(N) < \ell$, the reduction of every $\psi(g)$ belongs to $k^\times$; the reduction of $\chi_{\mathrm{cyc}}(g)$ belongs to $\mathbb{F}_\ell^\times \subseteq k^\times$. Thus A is a finite-dimensional k-vector space on which the two Galois actions are scalar actions through k. Every k-linear map from A to k commutes with the appropriate action.

Let $K_0 = \mathbb{Q}(\mu_{N\ell})$. Its degree is $\varphi(N)(\ell-1)$, which is prime to ℓ, and both coefficient characters are trivial on G_{K_0}. At every place above ℓ, the restriction of z to the decomposition group in G_{K_0} is zero. Indeed choose a positive integer $a \equiv 1 \pmod N$ with primitive residue modulo ℓ by the Chinese remainder theorem, since $\ell > N$. As $0 < e < \ell - 1$, $a^e - 1$ is a unit of $\mathcal{O}$. Apply Lemma 7.2.14 to the present $A = \mathcal{O}/\ell\mathcal{O}$-valued cocycle with coefficient exponent 1 and $s = 1$. Condition (CP1) is exactly its required local vanishing on $D \cap K_N \cap \ker \chi_{\mathrm{cyc}}$, and all its other hypotheses follow from the choice of a. Its unit conclusion gives the asserted zero restriction. This argument uses the quotient by $\ell\mathcal{O}$ itself, and allows its nilpotents when $\mathcal{O}$ is ramified.

Fix a decomposition group D_r at which z is nonzero. Its inertia group lies in K_N and is away from ℓ, so z vanishes on it. The action on A is trivial on D_r, because $r \equiv 1 \pmod{N\ell}$. Thus $z|_{D_r}$ is an unramified homomorphism. If φ_r is an arithmetic Frobenius, then $z(\varphi_r) \neq 0$; otherwise its closed zero subgroup would contain inertia and the topological generator of the unramified quotient, and hence all of D_r. Choose a k-linear map $f : A \to k$ with $f(z(\varphi_r)) \neq 0$. Put $Z = f \circ z$.

Suppose, towards a contradiction, that y is nonzero at an inertia element above r. Conjugation of inertia and the cocycle formula show that its restriction to inertia is nonzero at the

chosen group D_r as well: for an inertia element t above r, its coefficient action is trivial, and $y(gtg^{-1}) = \beta(g)y(t)$. Choose such a $t \in I_r$ and a k-linear map $g : A \to k$ with $g(y(t)) \neq 0$, and put $Y = g \circ y$. Then Z and Y are cocycles for $k(\alpha^{-1})$ and $k(\beta)$ respectively. Multiplication of their values is a Galois-equivariant pairing into $k(1)$, since $\alpha^{-1}\beta = \chi_{\mathrm{cyc}}$. Their cup product gives a global class

$$\xi = [Z] \cup [Y] \in H^2(\mathbb{Q}, k(1)).$$

We show that this class is locally zero outside r. At a prime in T, z is identically zero on the decomposition group, so the cup product is zero. At a prime outside $T \cup \{\ell, r\}$, restrict to any completion of K_0. Both cocycles are unramified there, by (CP1) and (CP3), since the local inertia subgroup of G_{K_0} is contained in K_N. The coefficient modules are trivial over K_0, so their unramified classes are orthogonal by local Tate duality; see [201, Chapter I, Theorem2.6]. Thus the restricted cup product is zero. This includes primes dividing N and requires no local-coboundary hypothesis there. At ℓ, the restriction of z was proved zero, so again the restricted cup product is zero. Each of the local extension degrees divides $[K_0 : \mathbb{Q}]$ and is prime to ℓ. Restriction on the ℓ-torsion group $H^2(-, k(1))$ is injective, because corestriction after restriction is multiplication by that degree. Therefore these local cup products were already zero over $\mathbb{Q}$. Finally $H^2(\mathbb{R}, k(1)) = 0$, since ℓ is odd.

Apply global Brauer reciprocity coordinatewise on the finite-dimensional $\mathbb{F}_\ell$-space k. The class ξ is zero at all places other than r, so it is zero at r as well; see [224] and [201]. On D_r, both coefficient characters are trivial, and the unramified k-cohomology is one-dimensional over k. Its nonzero element $[Z]$ therefore spans it. The vanishing of the k-valued cup product implies that $[Y]$ is orthogonal to every multiple of $[Z]$. Using the perfect trace pairing $k \times k \to \mathbb{F}_\ell$ identifies $k(\beta)$ with the Cartier dual of $k(\alpha^{-1})$, so local Tate orthogonality makes $[Y]$ unramified. Since the local action is trivial, every coboundary is zero; hence the cocycle Y itself vanishes on inertia. This contradicts $Y(t) \neq 0$. Thus y is zero on every inertia group above r. □

Theorem 7.2.16. *Let ℓ be an odd prime and $R \geq 1$. For a place v of $\mathbb{Q}$ write $\mathrm{res}_v \colon H^2(G_{\mathbb{Q}}, \mu_{\ell^R}) \to H^2(G_{\mathbb{Q}_v}, \mu_{\ell^R})$ for the restriction to a decomposition group at v. Then:*

1. *$H^2(G_{\mathbb{R}}, \mu_{\ell^R}) = 0$, and for every prime p the map $\mathrm{inv}_p \colon H^2(G_{\mathbb{Q}_p}, \mu_{\ell^R}) \to \mathbb{Q}/\mathbb{Z}$, the composite of the map to the Brauer group $\mathrm{Br}(\mathbb{Q}_p)$ induced by $\mu_{\ell^R} \subset \overline{\mathbb{Q}}_p^{\times}$ with the Hasse invariant, is injective;*
2. *for every $\xi \in H^2(G_{\mathbb{Q}}, \mu_{\ell^R})$, $\mathrm{res}_p(\xi) = 0$ for all but finitely many primes p, and*

$$\sum_p \mathrm{inv}_p(\mathrm{res}_p\, \xi) = 0.$$

In particular, if $\mathrm{res}_v(\xi) = 0$ for every place $v \neq v_0$, then $\mathrm{res}_{v_0}(\xi) = 0$.

Proof. Put $n = \ell^R$. For $K = \mathbb{Q}$, $\mathbb{Q}_p$ or $\mathbb{R}$, choose a separable closure K^{sep}. All these fields have characteristic zero. Thus the map $x \mapsto x^n$ on $(K^{\mathrm{sep}})^{\times}$ is surjective and gives the exact sequence of discrete continuous G_K-modules

$$1 \longrightarrow \mu_n \longrightarrow (K^{\mathrm{sep}})^{\times} \xrightarrow{x \mapsto x^n} (K^{\mathrm{sep}})^{\times} \longrightarrow 1.$$

Use the canonical cohomological description $\mathrm{Br}(K) = H^2(G_K, (K^{\mathrm{sep}})^{\times})$ ([202], Chapter IV, Corollary 3.16). Hilbert's Theorem 90 gives $H^1(G_K, (K^{\mathrm{sep}})^{\times}) = 0$ ([265]). The relevant part of the long cohomology sequence is consequently

$$0 \longrightarrow H^2(G_K, \mu_n) \xrightarrow{j_K} \mathrm{Br}(K) \xrightarrow{n} \mathrm{Br}(K).$$

Here j_K is precisely the map induced by inclusion of μ_n in the multiplicative group. In particular it is injective, and its image is $\mathrm{Br}(K)[n]$. These assertions use exactness at the two displayed groups, not any assertion about surjectivity onto the whole Brauer group. Functoriality of the cohomology sequence gives

$$j_{\mathbb{Q}_v} \circ \mathrm{res}_v = \mathrm{res}_v^{\mathrm{Br}} \circ j_{\mathbb{Q}} \tag{Br1}$$

for each chosen decomposition group.

The local maps have the stated kernels. The local invariant theorem [202], Chapter IV, Section 4, identifies $\mathrm{Br}(\mathbb{Q}_p)$ with $\mathbb{Q}/\mathbb{Z}$ and $\mathrm{Br}(\mathbb{R})$ with $\frac{1}{2}\mathbb{Z}/\mathbb{Z}$. Since n is odd, the latter group has no n-torsion: if $2b = nb = 0$, integers u, v with $2u + nv = 1$ give $b = 0$. The injective map $j_{\mathbb{R}}$ therefore has zero image, proving $H^2(G_{\mathbb{R}}, \mu_n) = 0$. For each prime p, the map called inv_p in the statement is $\mathrm{inv}_p^{\mathrm{Br}} \circ j_{\mathbb{Q}_p}$. The first factor is an isomorphism and the second is injective, so this composite is injective. This proves item 1, including the specified normalization of its map.

Global reciprocity passes through the Kummer injection. Let $\xi \in H^2(G_{\mathbb{Q}}, \mu_n)$ and put $b = j_{\mathbb{Q}}(\xi)$. Apply the Albert–Brauer–Hasse–Noether theorem with the number field $K = \mathbb{Q}$ ([202], Chapter VIII, Theorem 4.2). The localization of b belongs to the direct sum of the local Brauer groups, so its finite local restrictions vanish outside a finite set. By (Br1) and the injectivity of $j_{\mathbb{Q}_p}$, the same is true of $\mathrm{res}_p(\xi)$. The invariant sum of the localizations of b is zero. The infinite localization is zero, either by (Br1) and item 1 or because it is n-torsion in $\mathrm{Br}(\mathbb{R})$. Hence

$$0 = \sum_v \mathrm{inv}_v^{\mathrm{Br}}(\mathrm{res}_v^{\mathrm{Br}}\, b) = \sum_p \mathrm{inv}_p^{\mathrm{Br}}(j_{\mathbb{Q}_p}\, \mathrm{res}_p\, \xi) = \sum_p \mathrm{inv}_p(\mathrm{res}_p\, \xi).$$

Every sum here has finite support. This proves item 2.

Finally suppose all restrictions except possibly the one at v_0 vanish. If v_0 is the real place, item 1 gives the result. If $v_0 = p_0$ is finite, the sum in item 2 reduces to $\mathrm{inv}_{p_0}(\mathrm{res}_{p_0}\, \xi) = 0$. Injectivity from item 1 forces $\mathrm{res}_{p_0}\, \xi = 0$, as asserted. □

Proposition 7.2.17. *Let $N, e \geq 1$, let $\ell > N + e + 3$ be prime, let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$, and let $\psi : (\mathbb{Z}/N)^\times \to \mathcal{O}^\times$ satisfy $\psi(-1) = -(-1)^e$. Put*

$$\alpha = \chi_{\mathrm{cyc}}^e \psi, \qquad \theta = \alpha^{-1}, \qquad \beta = \chi_{\mathrm{cyc}} \theta^{-1}.$$

Fix $m \geq 1$, put $L = N\ell^m$, and choose $1 \leq a < L$ with $a \equiv 1 \pmod N$, $(a, \ell) = 1$, and $a^{e+1} - 1 \in \mathcal{O}^\times$. Suppose $\gamma \in G_{\mathbb{Q}(\mu_N)}$ has $\chi_{\mathrm{cyc}}(\gamma) = a$. Let Q be a finite set of primes congruent to 1 modulo aL, and let p be a prime congruent to 1 modulo $L \prod_{q \in Q} q$. Fix a place above p. There are maps $\kappa_S : G_{\mathbb{Q}} \to \mathcal{O}/\ell^m$, for every $S \subseteq Q$, such that:

(DS1) *Each κ_S is a locally constant β-cocycle and $\kappa_S(\gamma) = 0$.*

(DS2) *κ_S vanishes on the intersection with $G_{\mathbb{Q}(\mu_N)}$ of every inertia group at a prime outside $\{\ell, p\} \cup S$.*

(DS3) *For $q \in Q \setminus S$, every place above q and every arithmetic Frobenius φ there, some inertia element τ at that place satisfies $\kappa_{S \cup \{q\}}(\tau) = \kappa_S(\varphi)$.*

(DS4) *At the fixed place above p there is an inertia element τ_0 with*

$$\kappa_\varnothing(\tau_0) = 2N(a^{-e} - a)^2 \sum_{u \in (\mathbb{Z}/L)^\times} \left(\left\lfloor \frac{a\widetilde{u}}{L} \right\rfloor - \left\lfloor \frac{a(L - \widetilde{u})}{L} \right\rfloor \right) \widetilde{u}^{\,e} \psi(\widetilde{u}) \quad \text{in } \mathcal{O}/\ell^m,$$

where $1 \leq \widetilde{u} < L$ represents u. The scalar $2N(a^{-e} - a)^2$ is a unit of $\mathcal{O}$.

Proof. Put $U = G_{\mathbb{Q}(\mu_L)}$, $M = \ell^m$ and $R = \mathcal{O}/M$. Since $\ell > N$, the integer N is prime to ℓ. The character θ has Kolyvagin level (N, m): on U its value is 1 modulo M, on elements inverting μ_L its value is -1 modulo M by the parity of ψ, and

$$\theta(\gamma) - \chi_{\mathrm{cyc}}(\gamma) = a^{-e} - a = a^{-e}(1 - a^{e+1}) \in \mathcal{O}^\times.$$

Also $\beta(\gamma) = a^{e+1}$, so $1 - \beta(\gamma)$ is a unit.

We use the explicit construction in Proposition 7.2.18, taking its auxiliary witness to be $\delta = \gamma$ and its auxiliary integer to be a, and taking the element $w_0 = M^{-1} \bmod \mathcal{O}$ in $\mathcal{O}[1/\ell]/\mathcal{O}$. We recall the construction and its properties to specify which system is used. Let $(\alpha_d, e_{d,q})$ be the Euler system provided by Proposition 7.2.19 for base modulus L, auxiliary prime p and exponent a. Every $q \in Q$ is one of its Kolyvagin primes: $q \equiv 1 \pmod{L}$, $q \neq p$, and $p \equiv 1 \pmod{q}$ implies $\mathrm{ord}_q(p) = 1$. Choose its inertia generators and a primitive Mth root of unity. For $S \subseteq Q$, let

$$y_S = \mathrm{Der}_S(\alpha_{\prod_{q \in S} q}).$$

The derivative is independent of the order of the primes, lies in $\mathbb{Q}(\mu_L \prod S)^\times$, is a unit at every place not above p, and is M-invariant over $\mathbb{Q}(\mu_L)$, by Lemma 7.2.23. Its descended Kummer map $k_S : U \to \mathbb{Z}/M$ is therefore a continuous homomorphism by Lemma 7.2.24. Choose lifts s_t of the units modulo L and put

$$\Lambda_S(h) = \sum_{t \in (\mathbb{Z}/L)^\times} k_S(s_t^{-1} h s_t)\, \beta(s_t) \quad (h \in U),$$

with values in R. This is the construction of Proposition 7.2.18 after identifying the M-torsion generated by w_0 with R.

For clarity, its equivariance is $\Lambda_S(ghg^{-1}) = \beta(g)\Lambda_S(h)$. To verify it, right multiplication of the representatives by g permutes their cosets modulo U; the discrepancy in each representative is an element of U. The homomorphism k_S is unchanged by inner conjugation by such an element, and β is 1 modulo M on U. Reindexing the sum gives the displayed identity.

At $q \in Q \setminus S$, the finite–singular identity Lemma 7.2.25, applied to each conjugate in this sum, gives an inertia element τ with

$$\Lambda_{S \cup \{q\}}(\tau) = -e_{\prod S, q} \Lambda_S(\varphi).$$

The multiplier is an integer prime to ℓ. Replacing τ by an integer power whose exponent is inverse to $-e_{\prod S,q}$ modulo M makes this identity exact without the multiplier; on this inertia group the maps are homomorphisms, since the local coefficient action is trivial. This replacement uses an integer unit, not an arbitrary $\mathcal{O}$-unit.

The same construction has the required stronger conductor-prime vanishing. Let $r \notin \{\ell, p\} \cup S$ and let h belong to inertia at r and to $G_{\mathbb{Q}(\mu_N)}$. Since $r \neq \ell$, inertia fixes μ_M, and hence $h \in U$. Each prime in S is different from r, so inertia also fixes their roots of unity. Thus h fixes $\mathbb{Q}(\mu_L \prod S)$ and y_S. The same holds for every conjugate $s_t^{-1} h s_t$ at its conjugate place. Since y_S is a unit at all places above r, item3 of Lemma 7.2.24 gives $k_S(s_t^{-1} h s_t) = 0$ and therefore $\Lambda_S(h) = 0$. This argument includes $r \mid N$; excluding such primes from the ramification assertion would not suffice.

We record the bottom-value calculation as well. Write

$$H(t) = \left\lfloor \frac{a\widetilde{t}}{L} \right\rfloor - \left\lfloor \frac{a(L - \widetilde{t})}{L} \right\rfloor,$$

and let t_γ be the action of γ on μ_L. The Euler-system valuation in Proposition 7.2.19 is $2N(H(tt_\gamma) - aH(t))$ at the chosen prime. The descended Kummer map applies the auxiliary operator once more. Item4 of Lemma 7.2.24 consequently gives an inertia element τ_0 with

$$\Lambda_\varnothing(\tau_0) = 2N \sum_t \bigl(H(tt_\gamma^2) - 2aH(tt_\gamma) + a^2 H(t)\bigr)\theta(s_t)^{-1}.$$

Reindex $t \mapsto tt_\gamma^{-j}$ in the term with exponent j. Since two corresponding representatives differ by U and $\theta|_U = 1$ modulo M, that term is $\theta(\gamma)^j \sum_t H(t)\theta(s_t)^{-1}$. Thus

$$\Lambda_\varnothing(\tau_0) = 2N(\theta(\gamma) - a)^2 \sum_t H(t)\theta(s_t)^{-1}.$$

Here $\theta(\gamma) = a^{-e}$ and $\theta(s_t)^{-1} \equiv \widetilde{t}^{\,e}\psi(\widetilde{t}) \pmod M$. This proves exactly the formula in (DS4). Its scalar is a unit because $\ell \nmid 2N$ and $a^{-e} - a$ is a unit. In particular the two auxiliary operators produce a unit square, not a further denominator.

It remains to extend the homomorphisms from U to the full absolute Galois group. Its quotient by U is abelian, so $g\gamma g^{-1}\gamma^{-1} \in U$ for every g. Define

$$\kappa_S(g) = (1 - \beta(\gamma))^{-1}\Lambda_S(g\gamma g^{-1}\gamma^{-1}).$$

The identity

$$gh\gamma(gh)^{-1}\gamma^{-1} = g(h\gamma h^{-1}\gamma^{-1})g^{-1}(g\gamma g^{-1}\gamma^{-1})$$

and equivariance of Λ_S prove the β-cocycle identity. The formula is locally constant, and it is zero at γ. For $h \in U$,

$$\Lambda_S(h\gamma h^{-1}\gamma^{-1}) = (1 - \beta(\gamma))\Lambda_S(h),$$

so $\kappa_S|_U = \Lambda_S$.

The inertia elements in the strengthened vanishing assertion belong to U, as already checked. The full decomposition groups at $q \in Q$ and at p also belong to U, because these primes split completely in $\mathbb{Q}(\mu_L)$. Hence the extension preserves all the inertia zeros, the finite–singular identities and the bottom value. These are (DS1)–(DS4). □

Proposition 7.2.18. *Let ℓ be an odd prime, $\mathcal{O}$ a coefficient ring and $\theta\colon G_\mathbb{Q} \to \mathcal{O}^\times$ a continuous character with a Kolyvagin level (N_0, m) of modulus $N = N_0\ell^m$. Let r be a prime with $r \equiv 1 \pmod N$, D_0 a decomposition group at r, b an integer with $0 \le b < N$ and $\gcd(b, N) = 1$, σ a family of lifts modulo N, and $w \in \mathcal{O}^\vee$ with $\ell^m w = 0$. Then there is a Kolyvagin system for $(\theta, N_0, m, r, D_0, \mathrm{st}_{N,b}(\theta, \sigma)\, w)$.*

Proof. Write $M = \ell^m$, $\mathrm{st} = \mathrm{st}_{N,b}(\theta, \sigma)$, and let $\bar{\mathfrak{r}}$ be the place stabilised by D_0. As $N \ge 3$ and $\gcd(b, N) = 1$, $1 \le b < N$. For $j \in \mathbb{Z}/M\mathbb{Z}$ and $v \in \mathcal{O}^\vee$ with $Mv = 0$, $j\,v$ means $\tilde{j}v$ for any integer $\tilde{j}$ in the class j. For $h \in U_N$, $\chi_{\mathrm{cyc}}(h) \equiv 1$ and, by (Kv1), $\theta(h) \equiv 1$ modulo $M\mathcal{O}$; hence $\check{\theta}(h) \equiv 1$, and $\check{\theta}(gh)v = \check{\theta}(g)v$, $\theta(gh)^{-1}v = \theta(g)^{-1}v$ for $g \in G_\mathbb{Q}$ and $Mv = 0$.

Step 1: construction. By (Kv3) choose $\delta \in G_\mathbb{Q}$ with $\theta(\delta) - \chi_{\mathrm{cyc}}(\delta) \in \mathcal{O}^\times$, an integer a with $\delta(\zeta) = \zeta^a$ for $\zeta \in \mu_M$ (so $\chi_{\mathrm{cyc}}(\delta) \equiv a \pmod M$), and let $t_\delta \in (\mathbb{Z}/N\mathbb{Z})^\times$ be the class of the action of δ on μ_N. For each Kolyvagin prime p let τ_p be an element of an inertia group at p acting on μ_p by a generator of $(\mathbb{Z}/p\mathbb{Z})^\times$; it exists because p is totally ramified in $\mathbb{Q}(\mu_p)$, and it fixes every root of unity ζ' of order prime to p (as $\tau_p(\zeta') \equiv \zeta'$ modulo the place, and such roots of unity are pairwise incongruent there). So (τ_p) is a choice of generators for (N, r). Fix a primitive M-th root of unity ζ_{ℓ^m}, so that k_y is formed with $(\delta, a, \zeta_{\ell^m})$, and $\rho \in \overline{\mathbb{Q}}$ with $\rho^M = r$.

By Proposition 7.2.19, applied to $(\ell, N_0, m, r, \bar{\mathfrak{r}}, b, \delta, a)$, there is an Euler system $((\alpha_d), (e_{d,p}))$ for (N, r) with

$$v_{\bar{\mathfrak{r}}}(g(\alpha_1)) = 2N_0\big(h_N(b, t\,t_\delta) - a\,h_N(b,t)\big) \quad \text{if } g \in G_{\mathbb{Q}} \text{ acts on } \mu_N \text{ by } t. \tag{7.7}$$

For $L \in \mathcal{L}(N,r)$ let $y_L = \mathrm{Der}_L(\alpha_{|L|})$; by Lemma 7.2.23 it lies in $K^\times_{N|L|}$, is a w'-unit for every place w' not above r, and is ℓ^m-invariant over K_N, so by item 1 of Lemma 7.2.24 $\mathrm{k}_L = \mathrm{k}_{y_L} : U_N \to \mathbb{Z}/M\mathbb{Z}$ is a continuous homomorphism. Put

$$\kappa_L(u) = \sum_{t \in (\mathbb{Z}/N\mathbb{Z})^\times} \mathrm{k}_L(\sigma_t^{-1} u \sigma_t)\, \check{\theta}(\sigma_t)\, w \qquad (u \in U_N),$$

which makes sense as U_N is normal in $G_{\mathbb{Q}}$. We check (Ks1)–(Ks5) for $(\kappa_L)_{L \in \mathcal{L}(N,r)}$.

Step 2: (Ks1). Each $u \mapsto \mathrm{k}_L(\sigma_t^{-1} u \sigma_t)$ is a continuous homomorphism into $\mathbb{Z}/M\mathbb{Z}$, so κ_L is continuous, additive, and killed by M.

Step 3: (Ks2). Let $g \in G_{\mathbb{Q}}$. For $t \in (\mathbb{Z}/N\mathbb{Z})^\times$ let t' be the class of the action of $g^{-1}\sigma_t$ on μ_N and $h_t = \sigma_{t'}^{-1} g^{-1} \sigma_t \in U_N$; $t \mapsto t'$ is a bijection. Then $\sigma_t^{-1}(gug^{-1})\sigma_t = h_t^{-1}(\sigma_{t'}^{-1} u \sigma_{t'}) h_t$, whose image under the homomorphism k_L into an abelian group is $\mathrm{k}_L(\sigma_{t'}^{-1} u \sigma_{t'})$, and $\check{\theta}(\sigma_t)w = \check{\theta}(g)\check{\theta}(\sigma_{t'})\check{\theta}(h_t)w = \check{\theta}(g)\check{\theta}(\sigma_{t'})w$. Summing, $\kappa_L(gug^{-1}) = \check{\theta}(g)\kappa_L(u)$.

Step 4: (Ks3). Let $u \in U_N$ lie in an inertia group I at a prime $p' \nmid Nr|L|$. For each t, $h = \sigma_t^{-1} u \sigma_t$ lies in the inertia group $\sigma_t^{-1} I \sigma_t$ at p'; it fixes the roots of unity of order prime to p' (as in Step 1), hence $K_{N|L|}$ and y_L. As $p' \neq \ell$ ($\ell \mid N$) and y_L is a unit at the places above $p' \neq r$, item 3 of Lemma 7.2.24 gives $\mathrm{k}_L(h) = 0$. So $\kappa_L(u) = 0$.

Step 5: (Ks4). Let $L \in \mathcal{L}(N,r)$, p a Kolyvagin prime not in L, D a decomposition group at p and φ a Frobenius of D. As p is totally ramified in $\mathbb{Q}(\mu_p)$, $I(D)$ maps onto $\mathrm{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$; choose $\tau \in I(D)$ agreeing with τ_p on μ_p. For $t \in (\mathbb{Z}/N\mathbb{Z})^\times$, $\sigma_t^{-1} D \sigma_t$ is a decomposition group at p, $\sigma_t^{-1}\tau\sigma_t$ lies in its inertia group and agrees with τ_p on μ_p ($\mathrm{Gal}(\mathbb{Q}(\mu_p)/\mathbb{Q})$ is abelian), and $\sigma_t^{-1}\varphi\sigma_t$ is a Frobenius of it. Since $y_{(p,L)} = \mathrm{Der}_p(\mathrm{Der}_L(\alpha_{p|L|}))$, Lemma 7.2.25 gives $\mathrm{k}_{(p,L)}(\sigma_t^{-1}\tau\sigma_t) = -e\,\mathrm{k}_L(\sigma_t^{-1}\varphi\sigma_t)$ with $e = e_{|L|,p}$. Summing over t, $\kappa_{(p,L)}(\tau) = (-e)\,\kappa_L(\varphi)$, and $-e \in \mathcal{O}^\times$ as $\ell \nmid e$ by (Eu2).

Step 6: (Ks5). By item 4 of Lemma 7.2.24 there is $\tau_0 \in I(D_0)$ with $\tau_0(\rho) = \zeta_{\ell^m}\rho$. Let $t \in (\mathbb{Z}/N\mathbb{Z})^\times$; σ_t acts on $\mu_M \subseteq \mu_N$ by $\tilde{t}$, and $y_\emptyset = \alpha_1 \in K_N^\times$. Item 4 of Lemma 7.2.24 and (7.7), applied to $\sigma_t\delta$ (acting on μ_N by $t\,t_\delta$) and to σ_t, give in $\mathbb{Z}/M\mathbb{Z}$

$$\tilde{t}\,\mathrm{k}_\emptyset(\sigma_t^{-1}\tau_0\sigma_t) = v_{\bar{\mathfrak{r}}}(\sigma_t\delta(\alpha_1)) - a\,v_{\bar{\mathfrak{r}}}(\sigma_t(\alpha_1)) = H(t) := 2N_0\big(h_N(b, t\,t_\delta^2) - 2a\,h_N(b, t\,t_\delta) + a^2 h_N(b,t)\big).$$

As $\chi_{\mathrm{cyc}}(\sigma_t) \equiv \tilde{t} \pmod M$, $\check{\theta}(\sigma_t)w = \tilde{t}\,\theta(\sigma_t)^{-1}w$, so $\kappa_\emptyset(\tau_0) = \sum_t H(t)\,\theta(\sigma_t)^{-1}w$. For $j \geq 0$, substituting $t = t''t_\delta^{-j}$ and using that $\sigma_{t''t_\delta^{-j}}$ and $\sigma_{t''}\delta^{-j}$ agree on μ_N, hence differ by an element of U_N,

$$\sum_t h_N(b, t\,t_\delta^j)\,\theta(\sigma_t)^{-1}w = \sum_{t''} h_N(b,t'')\,\theta(\sigma_{t''})^{-1}\theta(\delta)^j w = \theta(\delta)^j\,\mathrm{st}\,w$$

by (7.3). Hence $\kappa_\emptyset(\tau_0) = u_0\,\mathrm{st}\,w$ with $u_0 = 2N_0(\theta(\delta)^2 - 2a\theta(\delta) + a^2) = 2N_0(\theta(\delta) - a)^2$. Here $\ell \nmid 2N_0$, and $\theta(\delta) - a = (\theta(\delta) - \chi_{\mathrm{cyc}}(\delta)) + (\chi_{\mathrm{cyc}}(\delta) - a)$ is a unit plus an element of $M\mathcal{O} \subseteq \mathfrak{m}$ ($m \geq 1$), hence a unit; so $u_0 \in \mathcal{O}^\times$.

Hence $(\kappa_L)_{L \in \mathcal{L}(N,r)}$ is a Kolyvagin system for $(\theta, N_0, m, r, D_0, \mathrm{st}\,w)$. □

Proposition 7.2.19. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, r a prime with $r \equiv 1 \pmod N$, $\bar{\mathfrak{r}}$ a place of $\overline{\mathbb{Q}}$ above r, and b an integer with $1 \leq b < N$ and $\gcd(b, N) = 1$. Let $\delta \in G_{\mathbb{Q}}$ and $a \in \mathbb{Z}$ with $\delta(\zeta) = \zeta^a$ for $\zeta \in \mu_{\ell^m}$, and let $t_\delta \in (\mathbb{Z}/N\mathbb{Z})^\times$ be the*

class with $\delta(\zeta) = \zeta^{\tilde{t}_\delta}$ *for* $\zeta \in \mu_N$. *Then there is an Euler system* $((\alpha_d), (e_{d,p}))$ *for* (N, r) *such that, for every* $t \in (\mathbb{Z}/N\mathbb{Z})^\times$ *and every* $\sigma \in G_{\mathbb{Q}}$ *with* $\sigma(\zeta) = \zeta^{\tilde{t}}$ *for* $\zeta \in \mu_N$,

$$v_{\bar{\mathfrak{r}}}(\sigma(\alpha_1)) = 2N_0\big(h_N(b, t\,t_\delta) - a\,h_N(b,t)\big).$$

Proof. We use two classical facts on cyclotomic fields: (C1) for $n \geq 1$ and a prime $p \nmid n$, p is unramified in K_n with residue degree the order of p in $(\mathbb{Z}/n\mathbb{Z})^\times$; (C2) every root of unity in K_n lies in μ_{2n}. Write $\mathrm{P} = \mathrm{P}_{\delta,a}$. It is an endomorphism of the group $\overline{\mathbb{Q}}^\times$, it is trivial on μ_{ℓ^m}, and $g(\mathrm{P}(z)) = \mathrm{P}(g(z))$ for $g \in G_{\mathbb{Q}}$ and $z \in \mathbb{Q}(\mu_\infty)$, since $\mathrm{Gal}(\mathbb{Q}(\mu_\infty)/\mathbb{Q})$ is abelian.

Construction. Let d be a Kolyvagin integer. Its prime factors are $\equiv 1 \pmod N$, hence $> N > b$, so $\gcd(b, Nd) = 1$; also $r \nmid Nd$, as $r \equiv 1 \pmod N$ and Kolyvagin primes differ from r. Let $\mathfrak{r}_d = \{z \in \mathcal{O}_{K_{Nd}} : v_{\bar{\mathfrak{r}}}(z) > 0\}$, a prime of K_{Nd} above r, and put

$$\mathrm{R}_d = \mathrm{R}_{Nd,b}(\mathfrak{r}_d) \in K_{Nd}^\times, \qquad \alpha_d = \mathrm{P}(\mathrm{R}_d)^{2N_0 d} = \big(\delta(\mathrm{R}_d)\,\mathrm{R}_d^{-a}\big)^{2N_0 d} \in K_{Nd}^\times,$$

using item 1 of Lemma 7.2.20 ($Nd \geq N \geq 3$) and that $K_{Nd}/\mathbb{Q}$ is Galois. For a Kolyvagin prime $p \nmid d$ let $s_{d,p} = [k_{\mathfrak{r}_{pd}} : k_{\mathfrak{r}_d}]$ and $e_{d,p} = p\,s_{d,p}$.

Step 1: $\ell \nmid e_{d,p}$. $p \neq \ell$, as $\ell \mid N$ and $p \equiv 1 \pmod N$. By (C1), $s_{d,p} = f_{pd}/f_d$ with f_n the order of r modulo Nn. As $(\mathbb{Z}/Npd\mathbb{Z})^\times \cong (\mathbb{Z}/p\mathbb{Z})^\times \times (\mathbb{Z}/Nd\mathbb{Z})^\times$, $f_{pd} = \mathrm{lcm}(\mathrm{ord}_p(r), f_d)$, so $s_{d,p}$ divides $\mathrm{ord}_p(r)$, which is prime to ℓ because p is a Kolyvagin prime.

Step 2: (Eu1). By item 2 of Lemma 7.2.20, R_d is a unit at every prime of K_{Nd} not above r. Let w be a place of $\overline{\mathbb{Q}}$ not above r; then $v_w(\mathrm{R}_d) = 0$, and $v_w(\delta(\mathrm{R}_d)) = v_{w'}(\mathrm{R}_d) = 0$ for the place $w' = w \circ \delta$, again not above r. So α_d is a w-unit.

Step 3: (Eu2). Let τ and φ be as in (Eu2). As $p \nmid Nd$, $\mathrm{Gal}(K_{Npd}/K_{Nd})$ is cyclic of order $p-1$ and is generated by the restriction of τ; so $\prod_{i=0}^{p-2} \tau^i(z) = \mathrm{N}_{K_{Npd}/K_{Nd}}(z)$ for $z \in K_{Npd}$. Lemma 7.2.21 (with $m := Nd$, $q := p$, $\mathfrak{p}' := \mathfrak{r}_{pd}$, $\mathfrak{p} = \mathfrak{r}_d$; $b < p$, $\gcd(b, Nd) = 1$, $\mathfrak{r}_{pd} \nmid pNd$) gives a root of unity $\eta \in K_{Nd}$ with $\mathrm{N}_{K_{Npd}/K_{Nd}}(\mathrm{R}_{pd}) = \eta\,(\mathrm{R}_d/\varphi^{-1}(\mathrm{R}_d))^{s_{d,p}}$. As P commutes with the norm and with φ^{-1} on K_{Npd},

$$\begin{aligned}\prod_{i=0}^{p-2} \tau^i(\alpha_{pd}) &= \mathrm{N}_{K_{Npd}/K_{Nd}}\big(\mathrm{P}(\mathrm{R}_{pd})\big)^{2N_0 pd} = \mathrm{P}\big(\eta^{2N_0 pd}\big)\Big(\frac{\mathrm{P}(\mathrm{R}_d)}{\varphi^{-1}(\mathrm{P}(\mathrm{R}_d))}\Big)^{2N_0 pd\,s_{d,p}} \\ &= \mathrm{P}\big(\eta^{2N_0 pd}\big)\Big(\frac{\alpha_d}{\varphi^{-1}(\alpha_d)}\Big)^{e_{d,p}}.\end{aligned}$$

By (C2), $\eta^{2Nd} = 1$, so $\eta^{2N_0 d} \in \mu_{\ell^m}$ and $\mathrm{P}(\eta^{2N_0 pd}) = \mathrm{P}(\eta^{2N_0 d})^p = 1$.

Step 4: (Eu3). Let φ be as in (Eu2) and w a place above p; put $\mathfrak{Q} = \{z \in \mathcal{O}_{K_{Npd}} : v_w(z) > 0\}$. By Lemma 7.2.22 (same data as in Step 3), R_{pd} and $\varphi^{-1}(\mathrm{R}_d)$ are w-units and $\mathrm{R}_{pd} \equiv \varphi^{-1}(\mathrm{R}_d)^{s_{d,p}} \pmod w$. The same holds at the place $w \circ \delta$, also above p; since $v_w(\delta(z) - \delta(z')) = v_{w\circ\delta}(z - z')$ and $\delta\varphi^{-1} = \varphi^{-1}\delta$ on K_{Nd}, this gives $\delta(\mathrm{R}_{pd}) \equiv \varphi^{-1}(\delta(\mathrm{R}_d))^{s_{d,p}} \pmod w$. Congruences between w-units are compatible with products and inverses, so $\mathrm{P}(\mathrm{R}_{pd}) \equiv \varphi^{-1}(\mathrm{P}(\mathrm{R}_d))^{s_{d,p}} \pmod w$, and raising to the power $2N_0 pd$ gives $\alpha_{pd} \equiv \varphi^{-1}(\alpha_d)^{e_{d,p}} \pmod w$.

Step 5: the valuations of α_1. By (C1), $r \equiv 1 \pmod N$ splits completely in K_N: the primes $\sigma_{N,t}^{-1}(\mathfrak{r}_1)$, $t \in (\mathbb{Z}/N\mathbb{Z})^\times$, are pairwise distinct, and $v_{\bar{\mathfrak{r}}}$ restricts to the $\mathfrak{r}_1$-adic valuation $\mathrm{ord}_{\mathfrak{r}_1}$ on K_N. By item 2 of Lemma 7.2.20, $\mathrm{ord}_{\sigma_{N,t}^{-1}(\mathfrak{r}_1)}(\mathrm{R}_1) = h_N(b,t)$. If σ acts on μ_N by t, then $\sigma|_{K_N} = \sigma_{N,t}$ and $v_{\bar{\mathfrak{r}}}(\sigma(\mathrm{R}_1)) = \mathrm{ord}_{\mathfrak{r}_1}(\sigma_{N,t}(\mathrm{R}_1)) = \mathrm{ord}_{\sigma_{N,t}^{-1}(\mathfrak{r}_1)}(\mathrm{R}_1) = h_N(b,t)$. As $\sigma\delta$ acts on μ_N by $t\,t_\delta$,

$$v_{\bar{\mathfrak{r}}}(\sigma(\alpha_1)) = 2N_0\big(v_{\bar{\mathfrak{r}}}(\sigma\delta(\mathrm{R}_1)) - a\,v_{\bar{\mathfrak{r}}}(\sigma(\mathrm{R}_1))\big) = 2N_0\big(h_N(b, t\,t_\delta) - a\,h_N(b,t)\big).$$

□

Lemma 7.2.20. *Let $m \geq 2$, let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_{K_m}$ not dividing m, with residue characteristic p, and let b be an integer with $1 \leq b < m$ and $\gcd(b, m) = 1$. Then:*

1. *$\mathrm{J}_{m,b}(\mathfrak{p})$ and $\mathrm{R}_{m,b}(\mathfrak{p})$ lie in $K_m^\times$ and do not depend on the choice of ζ_p;*

$$\mathrm{R}_{m,b}(\mathfrak{p})\,\sigma_{m,-1}(\mathrm{R}_{m,b}(\mathfrak{p})) = 1,$$

   and $|\iota(\mathrm{R}_{m,b}(\mathfrak{p}))| = 1$ for every field embedding $\iota\colon K_m \to \mathbb{C}$;

2. *as fractional ideals of K_m,*

$$\mathrm{R}_{m,b}(\mathfrak{p})\,\mathcal{O}_{K_m} = \prod_{t \in (\mathbb{Z}/m\mathbb{Z})^\times} \sigma_{m,t}^{-1}(\mathfrak{p})^{h_m(b,t)};$$

   in particular $\mathrm{R}_{m,b}(\mathfrak{p})$ is a unit at every prime of K_m not above p.

Proof. Write $\mathrm{g}(j) = \mathrm{g}_\mathfrak{p}(j)$, $\chi = \chi_\mathfrak{p}$, $k = k_\mathfrak{p}$, $\mathrm{J} = \mathrm{J}_{m,b}(\mathfrak{p})$, $\mathrm{R} = \mathrm{R}_{m,b}(\mathfrak{p})$ and $L = K_m(\zeta_p) = \mathbb{Q}(\mu_{mp})$. As $p \nmid m$, restriction gives $\mathrm{Gal}(L/\mathbb{Q}) \cong \mathrm{Gal}(K_m/\mathbb{Q}) \times \mathrm{Gal}(\mathbb{Q}(\zeta_p)/\mathbb{Q})$. For $c \in \mathbb{F}_p^\times$ let $\rho_c \in \mathrm{Gal}(L/K_m)$ be the element with $\rho_c(\zeta_p) = \zeta_p^c$ (these are all the elements of $\mathrm{Gal}(L/K_m)$), and for $t \in (\mathbb{Z}/m\mathbb{Z})^\times$ let $\tilde{\sigma}_t \in \mathrm{Gal}(L/\mathbb{Q}(\zeta_p))$ be the element restricting to $\sigma_{m,t}$. The Gauss sum $\mathrm{g}(j)$ depends only on j modulo m, as χ takes values in μ_m.

Step 1: Galois action on Gauss sums. For $c \in \mathbb{F}_p^\times \subseteq k^\times$ we have $c\,\mathrm{Tr}_{k/\mathbb{F}_p}(x) = \mathrm{Tr}_{k/\mathbb{F}_p}(cx)$, so substituting $x \mapsto c^{-1}x$,

$$\rho_c(\mathrm{g}(j)) = \sum_{x \in k^\times} \chi(x)^{-j} \zeta_p^{\mathrm{Tr}(cx)} = \chi(c)^j\,\mathrm{g}(j). \tag{7.8}$$

As $\tilde{\sigma}_t$ fixes ζ_p and raises elements of μ_m to the power $\tilde{t}$, $\tilde{\sigma}_t(\mathrm{g}(j)) = \mathrm{g}(j\tilde{t})$. By item 1 of Theorem A.2.13, $\mathrm{g}(j) \neq 0$ for $m \nmid j$; this applies to $j = \pm 1, \pm b$, since $1 \leq b < m$.

Step 2: item 1. By (7.8), $\rho_c(\mathrm{J}) = \chi(c)^b \mathrm{g}(1)^b/(\chi(c)^b \mathrm{g}(b)) = \mathrm{J}$ for all c, so $\mathrm{J} \in L^{\mathrm{Gal}(L/K_m)} = K_m$, and $\mathrm{J} \neq 0$. By Step 1, $\tilde{\sigma}_{-1}(\mathrm{J}) = \mathrm{g}(-1)^b/\mathrm{g}(-b)$, so $\mathrm{R} = \mathrm{J}/\tilde{\sigma}_{-1}(\mathrm{J}) = \mathrm{J}/\sigma_{m,-1}(\mathrm{J}) \in K_m^\times$. Replacing ζ_p by ζ_p^c replaces each $\mathrm{g}(j)$ by $\rho_c(\mathrm{g}(j))$ (ρ_c fixes the values of χ), hence J by $\rho_c(\mathrm{J}) = \mathrm{J}$ and R by R. Since $\sigma_{m,-1}^2 = 1$, $\mathrm{R}\,\sigma_{m,-1}(\mathrm{R}) = \frac{\mathrm{J}}{\sigma_{m,-1}(\mathrm{J})} \cdot \frac{\sigma_{m,-1}(\mathrm{J})}{\mathrm{J}} = 1$. For an embedding $\iota\colon K_m \to \mathbb{C}$, $\iota \circ \sigma_{m,-1}$ and $\bar{\iota}$ agree on μ_m (both send ζ to $\iota(\zeta)^{-1} = \overline{\iota(\zeta)}$), hence on $K_m = \mathbb{Q}(\mu_m)$; so $|\iota(\mathrm{R})|^2 = \iota(\mathrm{R})\,\overline{\iota(\mathrm{R})} = \iota(\mathrm{R}\,\sigma_{m,-1}(\mathrm{R})) = 1$.

Step 3: item 2. By item 2 of Theorem A.2.13, $\mathrm{g}(1)^m \in K_m$ generates $\prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\tilde{t}}$. As $\gcd(b, m) = 1$, $\mathrm{g}(b)^m = \tilde{\sigma}_b(\mathrm{g}(1)^m) = \sigma_{m,b}(\mathrm{g}(1)^m)$ generates

$$\prod_t \sigma_{m,b}\sigma_{m,t}^{-1}(\mathfrak{p})^{\tilde{t}} = \prod_{t'} \sigma_{m,t'}^{-1}(\mathfrak{p})^{\widetilde{bt'}} \qquad (t = bt').$$

Hence $\mathrm{J}^m = \mathrm{g}(1)^{bm}/\mathrm{g}(b)^m$ generates $\prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{b\tilde{t} - \widetilde{b\tilde{t}}}$, and $b\tilde{t} - \widetilde{b\tilde{t}} = m\lfloor b\tilde{t}/m \rfloor$, because $b\tilde{t} \equiv \widetilde{b\tilde{t}} \pmod m$ and $0 < \widetilde{b\tilde{t}} < m$. The group of fractional ideals of K_m is free abelian, so

$$\mathrm{J}\,\mathcal{O}_{K_m} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\lfloor b\tilde{t}/m \rfloor}, \qquad \sigma_{m,-1}(\mathrm{J})\,\mathcal{O}_{K_m} = \prod_t \sigma_{m,-t}^{-1}(\mathfrak{p})^{\lfloor b\tilde{t}/m \rfloor} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\lfloor b(m-\tilde{t})/m \rfloor},$$

and $\mathrm{R}\,\mathcal{O}_{K_m} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{\lfloor \tilde{t}b/m \rfloor - \lfloor (m-\tilde{t})b/m \rfloor} = \prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{h_m(b,t)}$. All the primes $\sigma_{m,t}^{-1}(\mathfrak{p})$ lie above p. □

Lemma 7.2.21. *Let $m \geq 2$, let q be a prime with $q \nmid m$, and let b be an integer with $1 \leq b < m$, $b < q$ and $\gcd(b, m) = 1$. Let $\mathfrak{p}'$ be a prime ideal of $\mathcal{O}_{K_{qm}}$ not dividing qm, $\mathfrak{p} = \mathfrak{p}' \cap \mathcal{O}_{K_m}$, and $s = [k_{\mathfrak{p}'} : k_{\mathfrak{p}}]$. Let $\varphi \in G_{\mathbb{Q}}$ satisfy $\varphi(\zeta) = \zeta^q$ for $\zeta \in \mu_m$. Then there is a root of unity $\eta \in K_m$ with*

$$\mathrm{N}_{K_{qm}/K_m}(\mathrm{R}_{qm,b}(\mathfrak{p}')) = \eta \Big(\frac{\mathrm{R}_{m,b}(\mathfrak{p})}{\varphi^{-1}(\mathrm{R}_{m,b}(\mathfrak{p}))}\Big)^s.$$

Proof. Put $n = qm$, $\mathrm{R}' = \mathrm{R}_{n,b}(\mathfrak{p}')$, $\mathrm{R} = \mathrm{R}_{m,b}(\mathfrak{p})$, and let $u \in (\mathbb{Z}/m\mathbb{Z})^\times$ be the class of q, so that $\varphi|_{K_m} = \sigma_{m,u}$. For $t' \in (\mathbb{Z}/n\mathbb{Z})^\times$ with image $t \in (\mathbb{Z}/m\mathbb{Z})^\times$ (written $t' \mapsto t$), $\sigma_{n,t'}|_{K_m} = \sigma_{m,t}$. As $1 \leq b < q$, $\gcd(b, n) = 1$, so Lemma 7.2.20 applies at both levels.

Step 1: a distribution identity. We show, for every $t \in (\mathbb{Z}/m\mathbb{Z})^\times$,

$$\sum_{t' \mapsto t} h_n(b, t') = h_m(b, t) - h_m(b, u^{-1}t). \tag{7.9}$$

The integers in $[1, n-1]$ congruent to $\tilde{t}$ modulo m are $\tilde{t} + mj$, $0 \leq j \leq q-1$; they are prime to m, and since m is invertible modulo q exactly one of them, for $j = j_0$, is divisible by q. So the representatives $\tilde{t}'$ of the classes $t' \mapsto t$ are the $\tilde{t} + mj$ with $j \neq j_0$. Write $\tilde{t} + mj_0 = qt_1$; then $1 \leq t_1 \leq m-1$ and $qt_1 \equiv \tilde{t} \pmod m$, so $t_1 = \widetilde{u^{-1}}t$. Write $bj = qa_j + i_j$ with $0 \leq i_j < q$; as $\gcd(b, q) = 1$, $j \mapsto i_j$ permutes $\{0, \dots, q-1\}$. With $z = b\tilde{t}/m$ and Hermite's identity $\sum_{i=0}^{q-1} \lfloor (z+i)/q \rfloor = \lfloor z \rfloor$,

$$\sum_{j=0}^{q-1} \Big\lfloor \frac{b(\tilde{t} + mj)}{n} \Big\rfloor = \sum_{j=0}^{q-1} \Big(a_j + \Big\lfloor \frac{z + i_j}{q} \Big\rfloor \Big) = C_b + \Big\lfloor \frac{b\tilde{t}}{m} \Big\rfloor, \qquad C_b = \sum_{j=0}^{q-1} \Big\lfloor \frac{bj}{q} \Big\rfloor,$$

and the term $j = j_0$ is $\lfloor bqt_1/n \rfloor = \lfloor bt_1/m \rfloor$. Hence $A(t) := \sum_{t' \mapsto t} \lfloor b\tilde{t}'/n \rfloor = \lfloor b\tilde{t}/m \rfloor + C_b - \lfloor b\,\widetilde{u^{-1}}t/m \rfloor$. Since $n - \tilde{t}' = \widetilde{-t'}$ and $t' \mapsto t$ if and only if $-t' \mapsto -t$, $\sum_{t' \mapsto t} \lfloor b(n - \tilde{t}')/n \rfloor = A(-t) = \lfloor b(m - \tilde{t})/m \rfloor + C_b - \lfloor b(m - \widetilde{u^{-1}}t)/m \rfloor$. Subtracting gives (7.9).

Step 2: ideals. The ideal norm $\mathrm{N} = \mathrm{N}_{K_n/K_m}$ on fractional ideals is multiplicative, satisfies $\mathrm{N}(\mathfrak{p}') = \mathfrak{p}^s$, $\mathrm{N}(x\mathcal{O}_{K_n}) = \mathrm{N}_{K_n/K_m}(x)\mathcal{O}_{K_m}$, and $\mathrm{N}(\sigma(\mathfrak{a})) = \sigma|_{K_m}(\mathrm{N}(\mathfrak{a}))$ for $\sigma \in \mathrm{Gal}(K_n/\mathbb{Q})$ ($K_n/\mathbb{Q}$ is abelian). By item 2 of Lemma 7.2.20 at level n and (7.9),

$$\mathrm{N}_{K_n/K_m}(\mathrm{R}')\mathcal{O}_{K_m} = \prod_{t'} \sigma_{m,t}^{-1}(\mathfrak{p})^{s\,h_n(b,t')} = \prod_{t} \sigma_{m,t}^{-1}(\mathfrak{p})^{s\,(h_m(b,t) - h_m(b,u^{-1}t))}.$$

Substituting $t = ut_1$, $\prod_t \sigma_{m,t}^{-1}(\mathfrak{p})^{h_m(b,u^{-1}t)} = \sigma_{m,u}^{-1}\big(\prod_{t_1} \sigma_{m,t_1}^{-1}(\mathfrak{p})^{h_m(b,t_1)}\big) = \varphi^{-1}(\mathrm{R})\mathcal{O}_{K_m}$ by item 2 of Lemma 7.2.20 at level m. Hence $\mathrm{N}_{K_n/K_m}(\mathrm{R}')$ and $(\mathrm{R}/\varphi^{-1}(\mathrm{R}))^s$ generate the same fractional ideal.

Step 3: the unit is a root of unity. So $\beta = \mathrm{N}_{K_n/K_m}(\mathrm{R}')\,(\varphi^{-1}(\mathrm{R})/\mathrm{R})^s$ is a unit of $\mathcal{O}_{K_m}$. Let $\iota\colon K_m \to \mathbb{C}$ be an embedding and ι' an extension to K_n. Then $\iota(\mathrm{N}_{K_n/K_m}(\mathrm{R}')) = \prod_{\rho \in \mathrm{Gal}(K_n/K_m)} (\iota' \circ \rho)(\mathrm{R}')$ has absolute value 1, and so do $\iota(\mathrm{R})$ and $\iota(\varphi^{-1}(\mathrm{R})) = (\iota \circ \varphi^{-1}|_{K_m})(\mathrm{R})$, by item 1 of Lemma 7.2.20 applied to the embeddings $\iota' \circ \rho$, ι, $\iota \circ \varphi^{-1}|_{K_m}$. So every conjugate of the algebraic integer β has absolute value 1, and β is a root of unity by Kronecker's theorem [317]. Put $\eta = \beta^{-1}$. □

Lemma 7.2.22. *Let $m \geq 2$, let q be a prime with $q \nmid m$, and let b be an integer with $1 \leq b < m$, $b < q$ and $\gcd(b, m) = 1$. Let $\mathfrak{p}'$ be a prime ideal of $\mathcal{O}_{K_{qm}}$ not dividing qm, $\mathfrak{p} = \mathfrak{p}' \cap \mathcal{O}_{K_m}$, $s = [k_{\mathfrak{p}'} : k_{\mathfrak{p}}]$, and let $\varphi \in G_{\mathbb{Q}}$ satisfy $\varphi(\zeta) = \zeta^q$ for $\zeta \in \mu_m$. Then for every prime ideal $\mathfrak{Q}$ of $\mathcal{O}_{K_{qm}}$ above q, the elements $\mathrm{R}_{qm,b}(\mathfrak{p}')$ and $\varphi^{-1}(\mathrm{R}_{m,b}(\mathfrak{p}))$ are $\mathfrak{Q}$-adic units and*

$$\mathrm{R}_{qm,b}(\mathfrak{p}') \equiv \varphi^{-1}(\mathrm{R}_{m,b}(\mathfrak{p}))^s \pmod{\mathfrak{Q}}.$$

Proof. Put $n = qm$, $\mathrm{R}' = \mathrm{R}_{n,b}(\mathfrak{p}')$, $\mathrm{R} = \mathrm{R}_{m,b}(\mathfrak{p})$; let p be the residue characteristic of $\mathfrak{p}'$, so $p \neq q$; $k = k_{\mathfrak{p}} \subseteq k' = k_{\mathfrak{p}'}$ (via $\mathcal{O}_{K_m}/\mathfrak{p} \to \mathcal{O}_{K_n}/\mathfrak{p}'$), $\chi = \chi_{\mathfrak{p}}$, $\chi' = \chi_{\mathfrak{p}'}$, and $\mathrm{g}(j) = \mathrm{g}_{\mathfrak{p}}(j)$, $\mathrm{g}'(j) = \mathrm{g}_{\mathfrak{p}'}(j)$, formed with the same ζ_p. As $1 \leq b < q$, $\gcd(b, n) = 1$. Let $L = \mathbb{Q}(\mu_{np})$.

Step 1: the residue characters. For $c \in k'^{\times}$, $\chi'(c)^q = \chi(\mathrm{N}_{k'/k}(c))$. Indeed, let $x \in \mathcal{O}_{K_n}$ lift c and $y \in \mathcal{O}_{K_m}$ lift $\mathrm{N}_{k'/k}(c) = c^{(|k'|-1)/(|k|-1)}$. Modulo $\mathfrak{p}'$, $\chi'(c)^q \equiv x^{(|k'|-1)/m}$ and $\chi(\mathrm{N}_{k'/k}(c)) \equiv y^{(|k|-1)/m} \equiv x^{(|k'|-1)/m}$; both sides lie in μ_n, whose elements are pairwise incongruent modulo $\mathfrak{p}'$ as $p \nmid n$.

Step 2: q-th powers of Gauss sums. Let $j \in \{\pm 1, \pm b\}$; then $m \nmid j$ and χ^{-j} is a nontrivial character of $k^{\times}$. In a commutative ring $(a_1 + \cdots + a_r)^q \equiv a_1^q + \cdots + a_r^q$ modulo q. Hence, in $\mathcal{O}_L$ modulo q, using $q \operatorname{Tr}_{k'/\mathbb{F}_p}(c) = \operatorname{Tr}_{k'/\mathbb{F}_p}(qc)$, the substitution $c \mapsto q^{-1}c$ in $k'^{\times}$ ($q \in \mathbb{F}_p^{\times}$), Step 1, and Theorem A.2.14 for $\alpha = \chi^{-j}$:

$$\begin{aligned} \mathrm{g}'(j)^q &\equiv \sum_{c \in k'^{\times}} \chi'(c)^{-jq} \zeta_p^{\operatorname{Tr}(qc)} = \chi'(q)^{jq} \sum_{c \in k'^{\times}} \chi\big(\mathrm{N}_{k'/k}(c)\big)^{-j} \zeta_p^{\operatorname{Tr}(c)} \\ &= \chi'(q)^{jq}\, \mathrm{g}_{k'}(\chi^{-j} \circ \mathrm{N}_{k'/k}) = \chi'(q)^{jq} (-1)^{s-1} \mathrm{g}(j)^s. \end{aligned} \tag{7.10}$$

Step 3: $\mathrm{R}'^q \equiv \mathrm{R}^s$ modulo $\mathfrak{Q}$. By item 1 of Theorem A.2.13, $\mathrm{g}(j)\mathrm{g}(-j) = \pm|k|$ and $\mathrm{g}'(j)\mathrm{g}'(-j) = \pm|k'|$ are powers of p up to sign, so these Gauss sums are units at every prime of L above q. Let $\widetilde{\mathfrak{Q}}$ be a prime of $\mathcal{O}_L$ above $\mathfrak{Q}$. Dividing the congruences (7.10) according to (7.5) in the local ring at $\widetilde{\mathfrak{Q}}$, the factors $\chi'(q)^{\pm q}$, $\chi'(q)^{\pm bq}$ and the signs cancel:

$$\mathrm{R}'^q = \frac{\mathrm{g}'(1)^{qb}\, \mathrm{g}'(-b)^q}{\mathrm{g}'(b)^q\, \mathrm{g}'(-1)^{qb}} \equiv \frac{\chi'(q)^{qb}\chi'(q)^{-bq}}{\chi'(q)^{bq}\chi'(q)^{-qb}} \cdot \frac{(-1)^{(s-1)(b+1)}}{(-1)^{(s-1)(1+b)}} \cdot \mathrm{R}^s = \mathrm{R}^s.$$

Both sides lie in K_n, so $\mathrm{R}'^q \equiv \mathrm{R}^s$ modulo $\mathfrak{Q} = \widetilde{\mathfrak{Q}} \cap \mathcal{O}_{K_n}$.

Step 4: Frobenius. Since $q \nmid m$, q is unramified in K_m and the Frobenius of every prime $\mathfrak{q}$ of K_m above q is $\sigma_{m,u} = \varphi|_{K_m}$, u the class of q; so $\varphi(z) \equiv z^q$ modulo $\mathfrak{q}$ for z in the local ring at $\mathfrak{q}$. By item 2 of Lemma 7.2.20, R, $\varphi^{-1}(\mathrm{R})$ and R' are units at every prime not above p, in particular at $\mathfrak{q} = \mathfrak{Q} \cap \mathcal{O}_{K_m}$ and at $\mathfrak{Q}$. Applied to $z = \varphi^{-1}(\mathrm{R})$ this gives $\mathrm{R} \equiv \varphi^{-1}(\mathrm{R})^q$ modulo $\mathfrak{q}$, hence $\mathrm{R}'^q \equiv \big(\varphi^{-1}(\mathrm{R})^s\big)^q$ modulo $\mathfrak{Q}$.

Step 5: conclusion. In the residue field $\mathcal{O}_{K_n}/\mathfrak{Q}$, of characteristic q, the images of R' and $\varphi^{-1}(\mathrm{R})^s$ have the same q-th power; as $x \mapsto x^q$ is injective on a field of characteristic q, they are equal. □

Lemma 7.2.23. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, r a prime with $r \equiv 1 \pmod{N}$, $((\alpha_d), (e_{d,p}))$ an Euler system for (N, r) and (τ_p) a choice of generators for (N, r). For $L \in \mathcal{L}(N, r)$ put $y_L = \mathrm{Der}_L(\alpha_{|L|})$. Then $y_L \in K_{N|L|}^{\times}$, y_L does not change when the primes of L are permuted, y_L is a w-unit for every place w of $\overline{\mathbb{Q}}$ not above r, and for every $g \in U_N$ there is $z \in K_{N|L|}^{\times}$ with*

$$z^{\ell^m} = g(y_L)/y_L.$$

In particular y_L is ℓ^m-invariant over K_N.

Proof. Write $M = \ell^m$ in this proof. For a Kolyvagin prime p put $\mathrm{N}_p(z) = \prod_{i=0}^{p-2} \tau_p^i(z)$.

Step 1: elementary properties. Let n be a Kolyvagin integer. Every element of $G_{\mathbb{Q}}$ maps K_{Nn} onto itself, and elements of $G_{\mathbb{Q}}$ commute on K_{Nn} ($K_{Nn}/\mathbb{Q}$ is abelian). Hence each Der_p

is an endomorphism of the group $K_{Nn}^\times$, $\mathrm{Der}_p \circ \mathrm{Der}_{p'} = \mathrm{Der}_{p'} \circ \mathrm{Der}_p$ on $K_{Nn}^\times$, and $g(\mathrm{Der}_p(z)) = \mathrm{Der}_p(g(z))$, $g(\mathrm{N}_p(z)) = \mathrm{N}_p(g(z))$ for $g \in G_\mathbb{Q}$ and $z \in K_{Nn}^\times$. So $y_L \in K_{N|L|}^\times$ and y_L depends only on the set of primes of L. If z is a w-unit for every place w not above r, so is $g(z)$, as $v_w(g(z)) = v_{w\circ g}(z)$; with (Eu1) this shows that y_L is such a unit.

Step 2: telescoping. Let $p \mid n$. Then τ_p^{p-1} fixes K_{Nn}: it fixes the roots of unity of order prime to p and acts on μ_p by $g_p^{p-1} = 1$. For $z \in K_{Nn}^\times$,

$$\frac{\tau_p(\mathrm{Der}_p(z))}{\mathrm{Der}_p(z)} = \frac{z^{p-1}}{\mathrm{N}_p(z)}. \tag{7.11}$$

Step 3: induction on the length of L. If $L = \emptyset$, $y_L = \alpha_1 \in K_N$ is fixed by U_N and $z = 1$ works. Let L have length $k \geq 1$ and assume the claim for sequences of length $k-1$. Put $n = |L|$ and let S be the set of $g \in U_N$ for which some $z \in K_{Nn}^\times$ has $z^M = g(y_L)/y_L$.

(a) $U_{Nn} \subseteq S$, with $z = 1$, since $y_L \in K_{Nn}$.

(b) S is closed under products: if z_g, z_h serve for g, h, then $g(z_h)z_g \in K_{Nn}^\times$ and $(g(z_h)z_g)^M = g(h(y_L)/y_L) \cdot g(y_L)/y_L = gh(y_L)/y_L$.

(c) $\tau_p \in S$ for every prime p of L. First $\tau_p \in U_N$, as $p \nmid N$. By Step 1 we may write $L = (p, L_0)$ with $L_0 \in \mathcal{L}(N, r)$ of length $k-1$; put $n_0 = |L_0|$, so $n = pn_0$, and $w_0 = \mathrm{Der}_{L_0}(\alpha_n)$, so $y_L = \mathrm{Der}_p(w_0)$. Choose $\varphi \in G_\mathbb{Q}$ with $\varphi(\zeta) = \zeta^p$ for $\zeta \in \mu_{Nn_0}$ (possible as $p \nmid Nn_0$); as $p \equiv 1 \pmod N$, $\varphi \in U_N$. Since τ_p fixes μ_{Nn_0} and acts on μ_p by a generator, (Eu2) for $d = n_0$ gives $\mathrm{N}_p(\alpha_n) = (\alpha_{n_0}/\varphi^{-1}(\alpha_{n_0}))^e$ with $e = e_{n_0,p}$. Applying Der_{L_0}, which commutes with N_p on $K_{Nn}^\times$ and with φ^{-1} on $K_{Nn_0}^\times$ (Step 1), $\mathrm{N}_p(w_0) = (y_{L_0}/\varphi^{-1}(y_{L_0}))^e$. By the induction hypothesis, applied to L_0 and $\varphi^{-1} \in U_N$, there is $z_0 \in K_{Nn_0}^\times$ with $z_0^M = \varphi^{-1}(y_{L_0})/y_{L_0}$. By (7.11), and as $M \mid N \mid p-1$,

$$\frac{\tau_p(y_L)}{y_L} = \frac{w_0^{p-1}}{\mathrm{N}_p(w_0)} = w_0^{p-1}\Big(\frac{\varphi^{-1}(y_{L_0})}{y_{L_0}}\Big)^e = (w_0^{(p-1)/M} z_0^e)^M,$$

with $w_0^{(p-1)/M} z_0^e \in K_{Nn}^\times$.

(d) $S = U_N$. Restriction maps U_N onto $\mathrm{Gal}(K_{Nn}/K_N)$ with kernel U_{Nn}, and $\mathrm{Gal}(K_{Nn}/K_N) \cong (\mathbb{Z}/n\mathbb{Z})^\times \cong \prod_{p|n}(\mathbb{Z}/p\mathbb{Z})^\times$ through the action on μ_n; the image of τ_p is a generator of the factor at p and trivial at the other factors. So every element of this finite group is a product of nonnegative powers of the images of the τ_p, every $g \in U_N$ is of the form $\tau_{p_1}^{c_1} \cdots \tau_{p_k}^{c_k} h$ with $c_i \geq 0$ and $h \in U_{Nn}$, and $g \in S$ by (a)–(c).

Finally, $K_{N|L|} \subseteq \mathbb{Q}(\mu_\infty)$, so y_L is ℓ^m-invariant over K_N. □

Lemma 7.2.24. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, $\delta \in G_\mathbb{Q}$ and $a \in \mathbb{Z}$ with $\delta(\zeta) = \zeta^a$ for $\zeta \in \mu_{\ell^m}$, ζ_{ℓ^m} a primitive ℓ^m-th root of unity, and $y \in \mathbb{Q}(\mu_\infty)^\times$ ℓ^m-invariant over K_N. Write $\mathrm{P} = \mathrm{P}_{\delta,a}$.*

1. *For every $g \in U_N$, $Q_y(g)$ consists of one ℓ^m-th root of unity; the map $\mathrm{k}_y \colon U_N \to \mathbb{Z}/\ell^m\mathbb{Z}$ so defined is a continuous homomorphism.*

2. *If $g \in U_N$ fixes y, then $\zeta_{\ell^m}^{\mathrm{k}_y(g)} = g(\mathrm{P}(Y))/\mathrm{P}(Y)$ for every $Y \in \overline{\mathbb{Q}}$ with $Y^{\ell^m} = y$.*

3. *Let $p' \neq \ell$ be a prime such that y is a w-unit for every place w of $\overline{\mathbb{Q}}$ above p', and let $g \in U_N$ fix y and lie in an inertia group $I(D)$ at p'. Then $\mathrm{k}_y(g) = 0$.*

4. *Let r be a prime with $r \equiv 1 \pmod N$, D_0 a decomposition group at r, the stabiliser of the place $\bar{\mathfrak{r}}$, and $\rho \in \overline{\mathbb{Q}}$ with $\rho^{\ell^m} = r$. There is $t_0 \in I(D_0)$ with $t_0(\rho) = \zeta_{\ell^m}\rho$. If moreover $y \in K_N^\times$, then for every $\sigma \in G_\mathbb{Q}$, with $c \in \mathbb{Z}$ such that $\sigma(\zeta) = \zeta^c$ for $\zeta \in \mu_{\ell^m}$, one has $\sigma^{-1}t_0\sigma \in U_N$ and*

$$c \cdot \mathrm{k}_y(\sigma^{-1}t_0\sigma) = v_{\bar{\mathfrak{r}}}(\sigma(\mathrm{P}(y))) \quad \text{in } \mathbb{Z}/\ell^m\mathbb{Z}.$$

Proof. Write $M = \ell^m$ and $\zeta = \zeta_{\ell^m}$. The map P is an endomorphism of $\overline{\mathbb{Q}}^\times$, trivial on μ_M, and $g(\mathrm{P}(x)) = \mathrm{P}(g(x))$ for $g \in G_\mathbb{Q}$ and $x \in \mathbb{Q}(\mu_\infty)$, as $\mathrm{Gal}(\mathbb{Q}(\mu_\infty)/\mathbb{Q})$ is abelian. Elements of U_N fix $\mu_M \subseteq \mu_N$.

Item 1. Let $g \in U_N$, $Y^M = y$, and $z \in \mathbb{Q}(\mu_\infty)$ with $z^M = g(y)/y$ (it exists by invariance). Then $\mathrm{P}(Y)^M = \mathrm{P}(y)$, $g(\mathrm{P}(Y))^M = g(\mathrm{P}(y)) = \mathrm{P}(g(y))$ and $\mathrm{P}(z)^M = \mathrm{P}(g(y))/\mathrm{P}(y)$, so the quotient $g(\mathrm{P}(Y))/(\mathrm{P}(Y)\mathrm{P}(z))$ lies in μ_M. Any other choices are ξY and $\xi' z$ with $\xi, \xi' \in \mu_M$, and $\mathrm{P}(\xi Y) = \mathrm{P}(Y)$, $\mathrm{P}(\xi' z) = \mathrm{P}(z)$; so $Q_y(g)$ is one element $\zeta^{\mathrm{k}_y(g)}$. For $g, h \in U_N$ with z_g, z_h as above, $z = g(z_h)z_g \in \mathbb{Q}(\mu_\infty)$ satisfies $z^M = gh(y)/y$ and $\mathrm{P}(z) = g(\mathrm{P}(z_h))\mathrm{P}(z_g)$, so

$$\frac{gh(\mathrm{P}(Y))}{\mathrm{P}(Y)\mathrm{P}(z)} = g\Big(\frac{h(\mathrm{P}(Y))}{\mathrm{P}(Y)\mathrm{P}(z_h)}\Big) \cdot \frac{g(\mathrm{P}(Y))}{\mathrm{P}(Y)\mathrm{P}(z_g)} = g\big(\zeta^{\mathrm{k}_y(h)}\big)\zeta^{\mathrm{k}_y(g)} = \zeta^{\mathrm{k}_y(h)+\mathrm{k}_y(g)},$$

and k_y is a homomorphism. The subgroup U' of the $h \in U_N$ fixing y and $\mathrm{P}(Y)$ is open; for $h \in U'$ one may take $z = 1$, so $\zeta^{\mathrm{k}_y(h)} = h(\mathrm{P}(Y))/\mathrm{P}(Y) = 1$. A homomorphism into a finite group that vanishes on an open subgroup is continuous.

Item 2. Take $z = 1$ in the definition.

Item 3. Let w be the place of which D is the stabiliser, and $V = \mathrm{P}(Y)$, so $V^M = \mathrm{P}(y) = \delta(y)y^{-a}$. As $v_w(\delta(y)) = v_{w\circ\delta}(y) = 0$, $\mathrm{P}(y)$ and hence V are w-units. Since $g \in I(D)$ acts trivially on the residue field of w, $g(V)/V \equiv 1 \pmod w$; it lies in μ_M, whose elements are pairwise incongruent modulo w as $p' \nmid M$. So $g(V)/V = 1$, and $\mathrm{k}_y(g) = 0$ by item 2.

Item 4: the element t_0. Let $E = K_N(\rho)$; it contains μ_M and all the roots $\xi\rho$ of $X^M - r$, so $E/\mathbb{Q}$ is Galois. As $r \equiv 1 \pmod N$, r splits completely in K_N, so the completion of K_N at $\bar{\mathfrak{r}}$ is $\mathbb{Q}_r$; there $X^M - r$ is an Eisenstein polynomial, so the completion of E is totally ramified of degree M over $\mathbb{Q}_r$. Hence $[E : K_N] = M$, $X^M - r$ is irreducible over K_N, and the inertia group of $E/\mathbb{Q}$ at $\bar{\mathfrak{r}}$, which lies in $\mathrm{Gal}(E/K_N)$ (K_N is unramified at r) and has order M, is all of $\mathrm{Gal}(E/K_N)$. It contains the automorphism $\rho \mapsto \zeta\rho$. Since $I(D_0)$ maps onto the inertia group of E at $\bar{\mathfrak{r}}$, some $t_0 \in I(D_0)$ satisfies $t_0(\rho) = \zeta\rho$.

Item 4: the value. As $r \nmid N$, inertia groups at r fix K_N, so $t_0 \in U_N$ and $h = \sigma^{-1}t_0\sigma \in U_N$; h fixes $y \in K_N$. Let $Y^M = y$, $V = \sigma(\mathrm{P}(Y))$ and $u = \sigma(\mathrm{P}(y)) = V^M \in K_N^\times$. By item 2, $\zeta^{\mathrm{k}_y(h)} = h(\mathrm{P}(Y))/\mathrm{P}(Y) = \sigma^{-1}(t_0(V)/V)$. Let $v = v_{\bar{\mathfrak{r}}}(u) \in \mathbb{Z}$ (K_N is unramified at r) and $V_0 = V\rho^{-v}$; then $V_0^M = ur^{-v}$ is a $\bar{\mathfrak{r}}$-unit, hence so is V_0, and as in item 3 ($r \nmid M$) $t_0(V_0) = V_0$. So $t_0(V)/V = (t_0(\rho)/\rho)^v = \zeta^v$, and $\zeta^{\mathrm{k}_y(h)} = \sigma^{-1}(\zeta^v) = \zeta^{vc'}$ with $cc' \equiv 1 \pmod M$. Hence $c\,\mathrm{k}_y(h) = v$ in $\mathbb{Z}/M\mathbb{Z}$. □

Lemma 7.2.25. *Let ℓ be an odd prime, $N_0 \geq 1$ and $m \geq 1$ integers with $\ell \nmid N_0$, $N = N_0\ell^m$, r a prime with $r \equiv 1 \pmod N$, $((\alpha_d), (e_{d,p}))$ an Euler system for (N, r), (τ_p) a choice of generators, and δ, a, ζ_{ℓ^m} as in the definition of k_y. For $L \in \mathcal{L}(N, r)$ put $y_L = \mathrm{Der}_L(\alpha_{|L|})$. Let $L \in \mathcal{L}(N, r)$, p a Kolyvagin prime for (N, r) not occurring in L, D a decomposition group at p, φ a Frobenius of D, and $t \in I(D)$ with $t(\zeta) = \tau_p(\zeta)$ for $\zeta \in \mu_p$. Then $\varphi, t \in U_N$ and*

$$\mathrm{k}_{y_{(p,L)}}(t) = -\,e_{|L|,p}\,\mathrm{k}_{y_L}(\varphi) \quad \text{in } \mathbb{Z}/\ell^m\mathbb{Z}.$$

Proof. Write $M = \ell^m$, $\zeta = \zeta_{\ell^m}$, $\mathrm{P} = \mathrm{P}_{\delta,a}$, $n = |L|$, $e = e_{n,p}$, $k' = (p-1)/M \in \mathbb{Z}$ ($M \mid N \mid p-1$), $\mathrm{N}_p(z) = \prod_{i=0}^{p-2} \tau_p^i(z)$, and let w be the place stabilised by D. Put $y = y_L \in K_{Nn}^\times$, $w_0 = \mathrm{Der}_L(\alpha_{pn}) \in K_{Npn}^\times$ and $y' = y_{(p,L)} = \mathrm{Der}_p(w_0)$. Elements of $G_\mathbb{Q}$ commute on the abelian field K_{Npn}, so Der_L, Der_p, N_p and P commute with them there.

Step 1: t and φ. For $\zeta' \in \mu_{Nn}$ we have $t(\zeta') \equiv \zeta'$ and $\varphi(\zeta') \equiv \zeta'^p$ modulo w; both sides lie in μ_{Nn}, whose elements are pairwise incongruent modulo w as $p \nmid Nn$; so t fixes μ_{Nn} and $\varphi(\zeta') = \zeta'^p$. As $p \equiv 1 \pmod N$, $t, \varphi \in U_N$. Since τ_p also fixes μ_{Nn} and agrees with t on μ_p, t and τ_p agree on K_{Npn}.

Step 2: a root of $t(y')/y'$. As τ_p^{p-1} fixes K_{Npn}, $\tau_p(\mathrm{Der}_p(w_0))/\mathrm{Der}_p(w_0) = w_0^{p-1}/\mathrm{N}_p(w_0)$.

By (Eu2) for $d = n$, with τ_p (which fixes μ_{Nn} and acts on μ_p by a generator) and φ, and as Der_L is multiplicative and commutes with N_p and φ^{-1}, $\mathrm{N}_p(w_0) = \mathrm{Der}_L(\mathrm{N}_p(\alpha_{pn})) = (y/\varphi^{-1}(y))^e$. By Lemma 7.2.23 applied to $\varphi^{-1} \in U_N$, there is $z' \in K_{Nn}^\times$ with $z'^M = \varphi^{-1}(y)/y$. Then $z = w_0^{k'} z'^e \in K_{Npn}^\times$ satisfies

$$z^M = w_0^{p-1}\Big(\frac{\varphi^{-1}(y)}{y}\Big)^e = \frac{\tau_p(y')}{y'} = \frac{t(y')}{y'}.$$

Step 3: an identity. Choose $Y, Y' \in \overline{\mathbb{Q}}$ with $Y^M = y'$ and $Y'^M = y$, and put $c = w_0/\varphi^{-1}(y)^e \in K_{Npn}^\times$. By the definition of k, $\zeta^{\mathrm{k}_{y'}(t)} = t(\mathrm{P}(Y))/(\mathrm{P}(Y)\mathrm{P}(z))$ and $\zeta^{\mathrm{k}_y(\varphi^{-1})} = \varphi^{-1}(\mathrm{P}(Y'))/(\mathrm{P}(Y')\mathrm{P}(z'))$. Hence

$$\zeta^{\mathrm{k}_{y'}(t) - e\,\mathrm{k}_y(\varphi^{-1})} = \frac{t(\mathrm{P}(Y))}{\mathrm{P}(Y)} \cdot \Big(\frac{\mathrm{P}(Y')}{\varphi^{-1}(\mathrm{P}(Y'))^p}\Big)^e \cdot \mathrm{P}(c)^{-k'}. \tag{7.12}$$

Step 4: each factor is $\equiv 1 \pmod w$. The elements y, y', w_0 are products of integer powers of Galois conjugates of α_n, α_{pn}, hence w-units by (Eu1) ($p \neq r$); so are $\mathrm{P}(y)$, $\mathrm{P}(y')$ ($v_w \circ \delta = v_{w\circ\delta}$), hence $\mathrm{P}(Y)$, $\mathrm{P}(Y')$, and $x = \varphi^{-1}(\mathrm{P}(Y'))$ (φ stabilises w). As $t \in I(D)$ acts trivially on the residue field of w, $t(\mathrm{P}(Y)) \equiv \mathrm{P}(Y)$. As φ is a Frobenius of D, $\mathrm{P}(Y') = \varphi(x) \equiv x^p$. Finally, by (Eu3) for $d = n$, $\alpha_{pn}/\varphi^{-1}(\alpha_n)^e \equiv 1$ modulo every place above p; $c = \mathrm{Der}_L(\alpha_{pn}/\varphi^{-1}(\alpha_n)^e)$ is a product of integer powers of its conjugates $g(\cdot)$, $g \in G_\mathbb{Q}$, and $v_{w'}(g(x') - 1) = v_{w'\circ g}(x' - 1)$; so $c \equiv 1$ modulo every place above p, hence $\delta(c) \equiv 1$, $c^{-a} \equiv 1$ and $\mathrm{P}(c) \equiv 1 \pmod w$.

Step 5: conclusion. By (7.12) and Step 4, the M-th root of unity $\zeta^{\mathrm{k}_{y'}(t) - e\mathrm{k}_y(\varphi^{-1})}$ is $\equiv 1 \pmod w$; as $p \nmid M$ it equals 1. So $\mathrm{k}_{y'}(t) = e\,\mathrm{k}_y(\varphi^{-1}) = -e\,\mathrm{k}_y(\varphi)$, k_y being a homomorphism. □

Lemma 7.2.26. *Let $N, e, n \geq 1$, let ℓ be a prime, and let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$. Let $\psi : (\mathbb{Z}/N)^\times \to \mathcal{O}^\times$ be a Dirichlet character, extended to all integers by zero on nonunits, and assume $\psi(-1) = -(-1)^e$. Let $a \geq 1$ satisfy $a \equiv 1 \pmod N$ and $\ell \nmid a$. For $j \geq 0$ put*

$$T_j = \sum_{x=0}^{N\ell^j - 1} \Big\lfloor \frac{ax}{N\ell^j} \Big\rfloor x^e \psi(x).$$

Put $L = N\ell^n$ and

$$V_n = \sum_{\substack{1 \leq u < L \\ (u,L)=1}} \Big(\Big\lfloor \frac{au}{L} \Big\rfloor - \Big\lfloor \frac{a(L-u)}{L} \Big\rfloor \Big) u^e \psi(u).$$

Suppose $A, w \in \mathcal{O}$ satisfy

$$A \equiv 2wT_n \pmod{\ell^n\mathcal{O}}, \qquad A \equiv 2wT_{n-1} \pmod{\ell^{n-1}\mathcal{O}}.$$

Then

$$(1 - \ell^e\psi(\ell))A \equiv wV_n \pmod{\ell^n\mathcal{O}}.$$

The factor $1-\ell^e\psi(\ell)$ is a unit in $\mathcal{O}$. In particular $A \equiv qV_n \pmod{\ell^n\mathcal{O}}$ for some $q \in \mathcal{O}$, and $V_n \equiv 0 \pmod{\ell^n\mathcal{O}}$ implies $A \equiv 0 \pmod{\ell^n\mathcal{O}}$. No assumption $\ell \nmid N$, $\ell > 2$, or unramifiedness of $\mathcal{O}$ is required.

Proof. Write

$$U_n = \sum_{\substack{1 \le u < N\ell^n \\ (u, N\ell^n)=1}} \left\lfloor \frac{au}{N\ell^n} \right\rfloor u^e\psi(u), \qquad H = \ell^e\psi(\ell).$$

Partition the defining sum for T_n according as ℓ divides x. A term with $\ell \nmid x$ and $(x, N) > 1$ is zero, so the terms in the first part sum to U_n. If $\ell \nmid N$, write $x = \ell y$ in the second part, with $0 \le y < N\ell^{n-1}$. Its floor is $\lfloor ay/(N\ell^{n-1}) \rfloor$ and $x^e\psi(x) = Hy^e\psi(y)$, including the cases where the character is zero. If $\ell \mid N$, every term in the second part is zero and $H = 0$. Thus in all cases

$$T_n = U_n + HT_{n-1}.$$

The second assumed congruence may be multiplied by H modulo ℓ^n: indeed $H \in \ell\mathcal{O}$ because $e \ge 1$. Subtracting it from the first gives

$$(1-H)A \equiv 2wU_n \pmod{\ell^n\mathcal{O}}. \tag{1}$$

The map $u \mapsto L - u$ permutes the unit representatives $1 \le u < L$. In the second floor sum defining V_n, make this substitution. As $N \mid L$, one has $\psi(L-u) = \psi(-1)\psi(u)$ exactly, and

$$(L-u)^e \equiv (-u)^e \pmod{\ell^n\mathcal{O}}.$$

Their product is congruent to $-u^e\psi(u)$ by the parity hypothesis. Multiplying by the integer floor and summing therefore shows that this second sum is congruent to $-U_n$. Hence $V_n \equiv 2U_n \pmod{\ell^n\mathcal{O}}$. Together with (1) this proves the asserted congruence, without cancelling 2.

Finally H lies in the maximal ideal of $\mathcal{O}$, since ℓ does. Therefore $1-H$ is a unit. Multiplication by its inverse gives the last two conclusions, with $q = (1-H)^{-1}w$. This uses the actual ideal $\ell^n\mathcal{O}$ throughout and so is unchanged when $\mathcal{O}$ is ramified. □

Proposition 7.2.27. *Let $N, e \ge 1$, let $E \subseteq \mathbb{Q}(\mu_N)$ be a CM field, and let y be an integer with $y \ge N + e + 3$. Suppose $X \ge 1$ is an integer with the following two properties: for each prime p, some integer $c \ge 2$ satisfies $c \equiv 1 \pmod N$, $(c, p) = 1$ and $(c^e - 1)(c^{e+1} - 1) \mid X$; and for every $c \ge 0$ with $c \equiv 1 \pmod N$, every characteristic-zero commutative domain R and every R-valued Dirichlet character ψ modulo N with $\psi(-1) = -(-1)^e$, some $w \in R$ satisfies*

$$m \mid (c^{e+1} - 1)X - 2w \sum_{a=0}^{Nm-1} \left\lfloor \frac{ca}{Nm} \right\rfloor a^e\psi(a) \quad \text{in } R$$

for every $m \ge 1$ prime to c. Assume also $X \le 2^{y^6}$. For every prime ℓ, every coefficient ring $\mathcal{O}$ over $\mathbb{Z}_\ell$ containing roots of unity of order the exponent of $(\mathbb{Z}/N)^\times$, and every $\nu \ge 0$, there is a finite set $\mathcal{S} \subseteq G_E$ with $\#\mathcal{S} \le y^{20}$ such that

$$z \in \mathrm{Sha}^-(e, \nu), \qquad z(g) = 0 \ \ (g \in \mathcal{S}) \quad \Longrightarrow \quad z = 0.$$

Proof. Fix $\ell, \mathcal{O}, \nu$. If $\ell \le y^2$, apply Lemma 7.2.28. Since $N \le y$, its fixed set has at most y^{20} elements and detects every unramified-outside-ℓ Tate-twist cocycle, hence also the submodule $\mathrm{Sha}^{-}(e,\nu)$.

Suppose now that $\ell > y^2$. In particular $\ell > N + e + 3$. Choose the representatives and the elements $b(u,g)$ of Lemma 7.2.11. For every character ψ with $\psi(-1) = -(-1)^e$, choose the $r+1$ detecting elements $\gamma_{\psi,i}$ supplied by (OC2) of Proposition 7.2.12, where $r = v_\ell(X)$. Let

$$\mathcal{S} = \{b(u, \gamma_{\psi,i}) : u \in (\mathbb{Z}/N)^\times,\ \psi(-1) = -(-1)^e,\ 0 \le i \le r\}.$$

There are at most $\varphi(N)$ characters, and $\varphi(N) \le N \le y$. Also

$$2^r \le \ell^r \le X \le 2^{y^6},$$

so $r \le y^6$. As $y \ge N + e + 3 \ge 5$,

$$\#\mathcal{S} \le \varphi(N)^2(r+1) \le y^2(y^6+1) \le 2y^8 \le y^{20}.$$

If $x \in \mathrm{Sha}^{-}(e,\nu)$ vanishes on $\mathcal{S}$, the projection formula of Lemma 7.2.11 makes every odd Z_ψ vanish at every $\gamma_{\psi,i}$. Its local conditions are precisely those in Proposition 7.2.12, so (OC2) makes every odd Z_ψ zero. The comparison conclusion gives $4\varphi(N)x = 0$. Finally

$$0 < 4\varphi(N) \le 4N < (N+e+3)^2 \le y^2 < \ell.$$

Thus $4\varphi(N)$ is a unit in $\mathcal{O}$, and $x = 0$. This proves detection in the large-prime case as well. □

Lemma 7.2.28. *Let $N \ge 1$ be an integer, let $E \subseteq \mathbb{Q}(\mu_N)$ be a number field, and let ℓ be a prime. There is a finite set $D \subseteq G_E$ such that*

$$\#D \le y^{20} \qquad (N \le y,\ \ell \le y^2,\ y \in \mathbb{Z}_{\ge 0}).$$

The same set D has the following property for every ring of integers $\mathcal{O}$ of a finite extension of $\mathbb{Q}_\ell$ and every $e, \nu \ge 0$: if a locally constant map $z : G_E \to \mathcal{O}/\ell^\nu$ satisfies

$$z(gh) = z(g) + \chi_{\mathrm{cyc}}(g)^{-e} z(h),$$

vanishes on every inertia group above a finite place of E not dividing ℓ, and vanishes on D, then $z = 0$.

Moreover, for every $a \in G_E$ such that $\chi_{\mathrm{cyc}}(a)$ topologically generates $\chi_{\mathrm{cyc}}(G_E)$, there is a finite set $D_a \subseteq \ker \chi_{\mathrm{cyc}}$, chosen independently of $\mathcal{O}, e, \nu$, with the same bound $\#D_a \le y^{20}$, such that any such cocycle vanishing at a and on D_a is zero.

Proof. Put $M = N\ell^2$, $K = \mathbb{Q}(\mu_M)$ and $d = [K : \mathbb{Q}] = \varphi(M)$. Thus $M \ge 4$, K is totally complex and $E \subseteq K$. We first bound the number of generators needed to detect homomorphisms on G_K.

Let A be the maximal abelian profinite quotient of G_K which has exponent dividing M and in which all inertia groups away from ℓ vanish. For every finite quotient B of A, global reciprocity for its finite abelian extension gives a surjection from the idele class group of K onto B, with local units mapping onto inertia; see [202, Chapter V, Proposition 5.2 and Theorem 5.3]. Let U be the image in B of the product of the local unit groups at the places above ℓ. The quotient B/U is an everywhere unramified quotient. Its reciprocity map factors through the ideal class group: the ideal map on finite ideles has kernel the product of all local unit groups,

and principal ideles map to principal ideals. The infinite local groups are connected, so have trivial image in B. Consequently

$$|B| \le h_K \prod_{v|\ell} [\mathcal{O}_{K_v}^\times : (\mathcal{O}_{K_v}^\times)^M].$$

The local unit structure theorem gives, for a finite extension $F/\mathbb{Q}_\ell$, a topological decomposition $\mathcal{O}_F^\times \simeq \mu(F) \times \mathbb{Z}_\ell^{[F:\mathbb{Q}_\ell]}$, where $\mu(F)$ is finite cyclic. In particular

$$[\mathcal{O}_F^\times : (\mathcal{O}_F^\times)^M] = \gcd(M, |\mu(F)|)\ell^{[F:\mathbb{Q}_\ell]v_\ell(M)} \le M^{[F:\mathbb{Q}_\ell]+1}.$$

Here the decomposition includes the case $\ell = 2$; no assertion that the entire principal-unit group is torsion free is needed. Summing the local degrees and bounding the number of places by d shows that the product is at most M^{2d}. These local unit and reciprocity facts are the standard local and global class field theorems of [224].

We next bound h_K explicitly. The cyclotomic discriminant formula gives

$$|\operatorname{disc}(K)| = \frac{M^{\varphi(M)}}{\prod_{p|M} p^{\varphi(M)/(p-1)}} \le M^d.$$

Write $d = 2r$. In Minkowski's ideal-class bound the constant is at most $2^{-r}(4/\pi)^r = (2/\pi)^r \le 1$: the first r factors of $(2r)!/(2r)^{2r}$ are at most $1/2$, and the rest are at most 1. Thus every ideal class has an integral ideal of norm at most $X = |\operatorname{disc}(K)|^{1/2}$. At a rational prime, the Euler factor counting ideals is a product of at most d factors $(1 - T^f)^{-1}$ with $f \ge 1$. Its coefficients are bounded by those of $(1-T)^{-d}$. Hence the number of ideals of norm n is at most the number of ordered d-tuples of positive integers with product n. The number with product at most X is at most $\lfloor X \rfloor^d \le X^d$, since every entry is at most X. It follows that

$$h_K \le |\operatorname{disc}(K)|^{d/2} \le M^{d^2/2}.$$

The discriminant formula and Minkowski bound used here are classical; see [224]. Combining the estimates, and using $d \le M$ and $\log_2 M \le M$, gives

$$|B| \le M^{d^2/2+2d} \le 2^{M^3/2+2M^2} \le 2^P, \qquad P = M^3 + 5M^2 + M.$$

This bound holds for every finite quotient of A, so A is finite. Indeed, an infinite profinite group has finite quotients of arbitrarily large order: otherwise a finite quotient of maximal order would have kernel contained in every open normal subgroup and hence trivial kernel. A finite group of order at most 2^P has a generating set of at most P elements, by adjoining an element outside the subgroup already generated and observing that the order at least doubles at every strict enlargement. Choose lifts $b_1, \dots, b_q \in G_K$ of such generators, with $q \le P$. Every continuous homomorphism from G_K to a finite abelian group killed by M, unramified outside ℓ, vanishes if it vanishes at the b_i.

Choose coset representatives C for G_K in G_E and put $D = C \cup \{b_1, \dots, b_q\}$, viewing G_K as a subgroup of G_E. These choices depend only on E, N, ℓ. Since $[K : E] \le \varphi(M) \le M$,

$$\#D \le M^3 + 5M^2 + 2M \le 8M^3.$$

If $N \le y$ and $\ell \le y^2$, then $y \ge 2$, $M \le y^5$, and $8M^3 \le 8y^{15} \le y^{20}$.

We prove detection by induction on an integer k such that $\ell^k z = 0$, allowing all the coefficient rings and twists in the statement throughout the induction. The case $k = 0$ is immediate. If

$\ell^{k+1}z = 0$, then $\ell^k Mz = 0$, since $\ell \mid M$. The cocycle Mz has the same unramifiedness and vanishes on D, so the induction hypothesis gives $Mz = 0$.

For $x \in G_K$, the cyclotomic character satisfies $\chi_{\mathrm{cyc}}(x) \equiv 1 \pmod{\ell^{v_\ell(M)}}$. Consequently $\chi_{\mathrm{cyc}}(x)^{-e} - 1 \in M\mathbb{Z}_\ell$, because the factor of M prime to ℓ is a unit in $\mathbb{Z}_\ell$. As every value of z is killed by M, the cocycle identity therefore becomes

$$z(xg) = z(x) + z(g) \qquad (x \in G_K,\ g \in G_E).$$

In particular $z|_{G_K}$ is an M-torsion continuous homomorphism. It is unramified outside ℓ: inertia in G_K at such a place is contained in inertia at the place below it in E, which also does not divide ℓ. It vanishes on all b_i, so is zero by their construction. Writing $g = xc$ with $x \in G_K$ and $c \in C$ now gives $z(g) = z(x) + z(c) = 0$. This completes the induction and proves the first assertion.

Finally fix a as in the second assertion and let H be the closure of the cyclic subgroup generated by a. Compactness and continuity imply $\chi_{\mathrm{cyc}}(H) = \chi_{\mathrm{cyc}}(G_E)$. For each $p \in D$, choose $q_p \in H$ with $\chi_{\mathrm{cyc}}(q_p) = \chi_{\mathrm{cyc}}(p)$ and put $h_p = pq_p^{-1} \in \ker \chi_{\mathrm{cyc}}$. Take $D_a = \{h_p : p \in D\}$, so its cardinality does not increase. The zero set of a continuous cocycle is a closed subgroup: the cocycle identity proves closure under products, and its value at gg^{-1} proves closure under inverses. If $z(a) = 0$, this subgroup contains H. If also $z(h_p) = 0$ for all p, then $z(p) = z(h_p q_p) = 0$. The first assertion yields $z = 0$. □

Lemma 7.2.29. *Let E be a number field, ℓ a prime and $\mathcal{O}$ a coefficient ring for ℓ. Let*

$$\mathrm{Hom}_{\mathrm{ur}}(G_E, \mathcal{O}[\ell^{-1}]/\mathcal{O})$$

be the $\mathcal{O}$-module of continuous homomorphisms $G_E \to \mathcal{O}[\ell^{-1}]/\mathcal{O}$ (discrete topology) that vanish on the inertia group I_w of every finite place w of E. If ℓ is odd or E has no real place, this module has finite length and its normalised length is $v_\ell(\#\mathrm{Cl}(E))$.

Proof. Write $K = \mathcal{O}[\ell^{-1}]$, $U = \mathrm{Hom}_{\mathrm{ur}}(G_E, K/\mathcal{O})$, and let H be the Hilbert class field of E, the maximal abelian extension of E unramified at all places, finite and infinite; by class field theory the Artin map induces $\mathrm{Gal}(H/E) \cong \mathrm{Cl}(E)$ [224] (Ch. VI, the Hilbert class field).

Every $\varphi \in U$ factors through $\mathrm{Gal}(H/E)$. The kernel of φ is open (continuity into a discrete group) and contains the commutator subgroup (the target is abelian), so its fixed field L is a finite abelian extension of E and φ induces an injection $\mathrm{Gal}(L/E) \hookrightarrow K/\mathcal{O}$. For a finite place w the inertia group of L/E at w is the image of I_w, on which φ vanishes, so L/E is unramified at w. For a real place, the decomposition group of L/E is generated by the image σ of a complex conjugation and has order at most 2, so $2\varphi(\sigma) = 0$; if ℓ is odd, multiplication by 2 is injective on $K/\mathcal{O}$ and $\varphi(\sigma) = 0$, and if E has no real place there is nothing to check. Hence L/E is unramified at all places, $L \subseteq H$, and φ factors through $\mathrm{Gal}(H/E)$. Conversely, every homomorphism $\mathrm{Gal}(H/E) \to K/\mathcal{O}$ composed with the restriction $G_E \to \mathrm{Gal}(H/E)$ is continuous and vanishes on every I_w, because H/E is unramified at w. So restriction induces an isomorphism of $\mathcal{O}$-modules $U \cong \mathrm{Hom}(\mathrm{Gal}(H/E), K/\mathcal{O}) \cong \mathrm{Hom}(\mathrm{Cl}(E), K/\mathcal{O})$.

The length. Write $\mathrm{Cl}(E) \cong \bigoplus_i \mathbb{Z}/n_i\mathbb{Z}$, a finite sum, and $n_i = \ell^{a_i}u_i$ with $\ell \nmid u_i$. Then $\mathrm{Hom}(\mathbb{Z}/n_i\mathbb{Z}, K/\mathcal{O})$ is the n_i-torsion of $K/\mathcal{O}$; as u_i is a unit of $\mathcal{O}$ this is the ℓ^{a_i}-torsion $\ell^{-a_i}\mathcal{O}/\mathcal{O} \cong \mathcal{O}/\ell^{a_i}\mathcal{O}$, of length $a_i e_{\mathcal{O}}$ (the quotients $\ell^j\mathcal{O}/\ell^{j+1}\mathcal{O} \cong \mathcal{O}/\ell\mathcal{O}$ have length $e_{\mathcal{O}}$). Hence U has length $e_{\mathcal{O}} \sum_i a_i = e_{\mathcal{O}}\, v_\ell(\#\mathrm{Cl}(E))$, and its normalised length is $v_\ell(\#\mathrm{Cl}(E))$. □

From now on, for all admissible data D, the odd-class integer X_{odd} of (CX3) of Definition 6.6.15 is the integer X of Theorem 7.2.8 for the modulus $N = q_1 d$, the given t and the field

E, chosen once for each D. The theorem applies: $E = K(\zeta_{q_1})$ with $K = \mathbb{Q}(\sqrt{-d}) \subseteq \mathbb{Q}(\zeta_d)$, as $d \equiv 3 \pmod 4$, so E is a CM field contained in $\mathbb{Q}(\mu_{q_1 d})$. Its bound $1 \le X \le 2^{4(q_1 d+t+3)^{27}}\,\#\mathrm{Cl}(E)$ is the property that (CX3) assumes, and in addition

$$\operatorname{len}_{\mathcal{O}} \mathrm{Sha}^{-}(e,\nu) \le v_{\mathcal{O}}(X_{\mathrm{odd}})$$

for every prime ℓ, every coefficient ring $\mathcal{O}$ over $\mathbb{Z}_\ell$ containing the roots of unity of order the exponent of $(\mathbb{Z}/q_1 d)^\times$, every $0 \le e < t$ and every $\nu \ge 0$. The denominator errors e_ℓ and the clearing bounds β_ℓ are taken with this value of X_{odd}.

Definition 7.2.30. Fix a prime ℓ and a prime identification $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$. An **$\ell$-adic representation** of rank n is a continuous homomorphism $R\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$. Let $c \in G_{\mathbb{Q}}$ be a complex conjugation, $g^c = cgc^{-1}$, and let χ_{cyc} be the ℓ-adic cyclotomic character. A **lattice in** R over a coefficient ring $\mathcal{O}$ is a continuous $u\colon G_E \to \mathrm{GL}_n(\mathcal{O})$ conjugate to R over $\overline{\mathbb{Q}}_\ell$. Let $t \ge 0$ be an integer and J a function from the embeddings $E \to \mathbb{C}$ to finite multisets of integers.

(MS1) Conjugate self-duality. R is **conjugate self-dual of twist** t if the trace form on the $\overline{\mathbb{Q}}_\ell$-span of $R(G_E)$ is nondegenerate and $\operatorname{tr} R(g^c) = \chi_{\mathrm{cyc}}(g)^{1-\max(t,1)} \operatorname{tr} R(g^{-1})$ for all $g \in G_E$.

(MS2) Level $\emptyset$. It is moreover **of level $\emptyset$ with jumps** J if at every finite place v of E: R is of finite type at v, has Hodge–Tate jumps J at v (read through ι), and is good at v (unramified, and crystalline if $v \mid \ell$) when $v \nmid p_0 p_1$.

(MS3) Main summand like. R of rank n is **main-summand like with string length t and jumps** J if (MS1) and (MS2) hold, J is a main-summand weight system of rank n and string length t, and:

1. at every place A of $\overline{\mathbb{Q}}$ over a place $v \mid p_0 p_1$ of E with $v \nmid \ell$ there are γ in the inertia group of A, equal to the tame generator of A if v is chosen, and an integer N_v prime to v, such that R is trivial on the N_v-th powers of inertia at A and
$$v_\ell \det\bigl(R(\gamma) - 1\bigr) \le n\, v_\ell(N_{\mathrm{ch}}), \qquad v_\ell \det\bigl(R((\gamma^c)^{-1}) - 1\bigr) \le n\, v_\ell(N_{\mathrm{ch}});$$
2. for all large $\mathcal{O}$ and every lattice u in R over $\mathcal{O}$, the $\mathcal{O}$-span of $u(G_E)$ is $M_n(\mathcal{O})$, and some $g \in G_E$ with $\chi_{\mathrm{cyc}}(g) \in \{p_0^n, p_1^n\}$ has $u(g)$ scalar;
3. some γ in an inertia group above a place $v \mid p_0 p_1$, $v \nmid \ell$, has $R(\gamma) = y \cdot 1$ with $\|y^{\ell^a j} - 1\| = 1$ for all $a \ge 0$ and $1 \le j \le 4n+2$.

(MS4) Main summand. Let O be a descent pair with rank difference t_O and let $z = (z_{w,i})$ be a system of Hecke eigenvalues. R is a **main summand for** (O, z) if R is main-summand like with string length t_O for some jumps, and: for every tame character ϑ and every descent pair O' with the same source rank and the same target rank as O and with $\mu_{O'} = \mu_O \vartheta$ for the characters of (DP2) of Definition 3.2.23, every Hecke eigenform y for O' whose lift Hecke polynomials are those of z, and every representation S attached to y, the normalised representation S' of S for O' (MS6) satisfies

$$\operatorname{tr} S'(g) = \psi_\vartheta(g) \operatorname{tr} R(g) + \sum_{e=0}^{t_{O'}-1} \chi_{\mathrm{cyc}}(g)^{-e} \qquad (g \in G_E).$$

(MS5) Lift settings. A descent pair O of source rank n with labels $c = (c_i)$ at its chosen places is a **lift setting** for a twist ϑ if its places are the level places of ϑ, its tame part is $\omega^j\psi$ for some $1 \le j \le m$ (with ω the fixed residue characters of the chosen places and ψ the tame part of ϑ), n and t_O are odd with $n \le r_D$ and $t_O \le t_D$, every c_i is a label of degree n whose scaled type polynomial does not vanish at 1, and over each of p_0, p_1 some c_i is primitive with $n = r_D$ or equals $X - 1$ with $n = 1$.

(MS6) Normalising character. Let O be a descent pair whose space $W(O)$ has rank r_O (the source rank) and whose character is χ_O, a character of $\mathrm{U}(1)(\mathbb{A})$. The **normalising character** $\nu_O \colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ is the ℓ-adic character attached through ι to the algebraic Hecke character

$$x \longmapsto \chi_O(x/\bar{x})^{-1}\, \upsilon(x)^{r_O}\, |x|_{\mathbb{A}_E}^{r_O/2} \qquad (x \in \mathbb{A}_E^\times),$$

so that $\nu_O(\varphi_w) = \iota\big(\chi_O(\varpi_w/\bar{\varpi}_w)^{-1}\upsilon(\varpi_w)^{r_O} q_w^{-r_O/2}\big)$ for a geometric Frobenius φ_w at every finite place $w \nmid \ell$ where this character is unramified, ϖ_w the idele with a uniformiser at w and 1 elsewhere. The **normalised representation** of an ℓ-adic representation S for O is $S' = \nu_O \otimes S$.

Definition 7.2.31. Let $\iota \mid \ell$ be a prime identification, O a descent pair with space of forms $\mathcal{A}(V)$ and source rank $n = \operatorname{rk} W$, e an idempotent of the group algebra of $\prod_{w \in S_M} \mathrm{GL}_n(k_w)$ acting on $\mathcal{A}(V)$, $Z \subseteq \mathcal{A}(V)$ a subspace with orthogonal projection pr_Z, and $\beta \in \mathbb{R}$.

(DR1) Denominator of a projection. The projection to Z has **denominator at most** β **at** ι **for** e if there is $B \in \mathrm{End}_{\mathbb{C}}(Z)$ with

$$\|\iota(\det B)\| \ge \exp\big(-(\dim Z)\, n\, \beta\big)$$

such that for every $y \in \mathcal{A}(V)$ that is integral at ι and orthogonal to the false lifts for $(e, Z^\perp)$, the form $B(\mathrm{pr}_Z\, y)$ is integral at ι and $\|\iota\langle y', B(\mathrm{pr}_Z\, y)\rangle\| \le 1$ for every $y' \in \mathcal{A}(V)$ integral above ℓ.

(DR2) Lift generators. Let ϑ be a twist and $\mathrm{sel} \in [0, \infty]$. A form $y \in Z$ is a **lift generator of** Z **for** $(\vartheta, e, \mathrm{sel})$ if (i) y lies in the range of the type projection of a tuple of labels c such that (O, c) is a lift setting for ϑ and that range lies in $e\,\mathcal{A}(V)$; (ii) there are a system of Hecke eigenvalues z whose lift Hecke polynomials are those of y, a descent pair O' whose character times ϑ is the character of O, and a main summand R for (O', z) such that $\psi_\vartheta R$ has Selmer length at most sel at (Q, γ, ζ) for some $\gamma \in G_E$ and $\zeta \in \overline{\mathbb{Z}}_\ell$, where Q is the modulus of ϑ.

(DR3) Negligible numbers. For an integer $C \ge 0$, a family (e_ℓ) of reals indexed by the primes is **negligible with exponent** C if $e_\ell \ge 0$ for all ℓ and $\sum_{\ell \in T} e_\ell \log \ell \le x^C$ for every finite set T of primes.

(DR4) Class number at the chosen level. The **chosen level** $\mathrm{K}_{\mathrm{ch}} \subseteq \mathrm{U}(1)(\mathbb{A}_f)$ is the group of u with $u_w \in \mathcal{O}_{E_w}^\times$ for every finite place w and $u_w \equiv 1$ modulo w for every chosen place w. The **class number at the chosen level** is $h_{\mathrm{ch}} = \#\big(\mathrm{U}(1)(E)\backslash \mathrm{U}(1)(\mathbb{A}_f)/\mathrm{K}_{\mathrm{ch}}\big)$.

(DR5) Weak lifts. A system x of Hecke eigenvalues of forms for O, with attached ℓ-adic representation r_x, is a **weak lift** if $\det\big(1 - r'_x(g)\big) = 0$ for every $g \in G_E$, where $r'_x = \nu_O \otimes r_x$ is the normalised representation of r_x for O.

7.3 Existence of regular families

This section proves Theorem 7.3.1. The family is chosen one prime identification at a time: for $\iota \mid \ell$, Proposition 7.3.2 gives an m-fold twist with modulus prime to ℓ whose ratios of L-values and denominators are bounded at ι by the twist error e'_ℓ and by $\gamma_\ell = (\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log \ell$, with β_ℓ the clearing bound of Definition 6.6.15. The twist is assembled from the next three sections: the main summands (Section 7.5), the twisting theorem applied to them (Section 7.4), and the passage from Selmer bounds to denominators (Lemma 7.6.2, Section 7.6). In our reading, the freedom to take a different twist at each prime identification is what makes this possible: only the sum of the bounds over the primes is controlled.

The family is regular because these bounds add up (Proposition 7.3.3). Apart from the local defect bounds, every term of β_ℓ and of e'_ℓ is a multiple of the ℓ-adic valuation of the chosen group order N_{ch} or of the odd-class integer X_{odd}, or the summable term $2^{-\ell}$, and for $1 \le a \le n$ the sum $\sum_\ell v_\ell(a)\log \ell$ is at most $\log n$ (Lemma 7.3.4). It therefore suffices to bound these integers by the sizes of the datum (Lemma 7.3.5, Lemma 7.3.6); the local defect bounds are summed directly.

Theorem 7.3.1. *For all admissible data D there is a regular family $\theta = (\theta_\iota)$ of m-fold twists, one for each prime identification ι.*

Proof. **Choice of the family.** For each prime identification $\iota \mid \ell$, Proposition 7.3.2 gives an m-fold twist θ_ι with $\ell \nmid \mathrm{N}Q(\theta_\iota)$, with

$$\left\|\iota(r_p(\theta_\iota^j, s)^{-1})\right\| \le \ell^{e'_\ell}$$

for every $1 \le j \le m$, every ramified critical pair p and every $s \in \{\pm 1\}$, and such that for every $1 \le j \le m$ the twist θ_ι^j has denominators at most $\gamma_\ell = (\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log \ell$ at ι for j. Choose one such twist for each ι. Then (SR1) holds.

Small ratios (SR2). Fix j, p and s, and let $y_\iota = r_p(\theta_\iota^j, s)^{-1}$. Take $H = 1$, $\alpha = 0$ and $h_\ell = e'_\ell \ge 0$ in the definition of height. (HG1) holds as $|\sigma(1)| = 1$; (HG2) is the displayed bound of the choice; for (HG3), every finite set S of primes has

$$\sum_{\ell \in S} e'_\ell \log \ell \le x^{999} \le x_1$$

by Proposition 7.3.3(c) and $x^{10^6} \le x_1$ (Proposition 2.3.5, with $x \ge 1$). So the family (y_ι) has height at most x_1.

Denominators (RW). For each $1 \le j \le m$ the family (γ_ℓ) is a denominator bound for (θ, j): (DB2) holds by the choice of θ_ι, and (DB1) is Proposition 7.3.3(b), which gives $\sum_{\ell \in T} \gamma_\ell \le \beta_{\mathrm{den}}$ for every finite set T of primes. Hence θ is regular. □

Proposition 7.3.2. *Let D be admissible data, ℓ a prime and $\iota \mid \ell$ a prime identification. There is an m-fold twist τ such that:*

1. *$\ell \nmid \mathrm{N}Q(\tau)$;*
2. *for every $1 \le j \le m$, every ramified critical pair p and every $s \in \{\pm 1\}$, $\left\|\iota(r_p(\tau^j, s)^{-1})\right\| \le \ell^{e'_\ell}$;*
3. *for every $1 \le j \le m$, τ^j has denominators at most $(\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log \ell$ at ι for j.*

Proof. **Step 1: finitely many main summands.** The systems z of Hecke eigenvalues occurring in the good forms on W_m are finitely many, as these forms span a finite-dimensional space. For each $1 \le j \le m$ and each such z, Proposition 7.5.1(1) gives a main summand $R_{j,z}$ of rank r for $((W_j, V^{\mathrm{def}})$ at $1, z)$. The main pairs are ramified (by (RH2), as $\omega_w^j \neq 1$ exactly at the chosen places) and finitely many; for each main pair p for j, Proposition 7.5.1(2) gives a rank-one main summand $R_{p,j}$ for $(O_{p,1}, 1)$. All are main-summand like.

Step 2: the twist. Theorem 7.4.3, applied to the finite family of all $R_{j,z}$ and $R_{p,j}$, gives an m-fold twist τ such that every $\xi = \tau^j$ $(1 \le j \le m)$ satisfies its items 1–3.

Item 1. The modulus Q of τ is that of τ^1, auxiliary for S_ℓ: each $w \in Q$ has prime norm and does not lie above ℓ, so $\mathrm{N}w \neq \ell$ and $\ell \nmid \mathrm{N}Q$.

Item 2. By item 3 of Theorem 7.4.3, $v_\ell(\iota(r_p(\tau^j, s))) \le e'_\ell < \infty$; so $r_p(\tau^j, s) \neq 0$ and $\|\iota(r_p(\tau^j, s)^{-1})\| = \ell^{\,v_\ell(\iota(r_p(\tau^j,s)))} \le \ell^{\,e'_\ell}$.

Item 3. Fix j and put $\beta' = (\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log\ell \ge \beta_\ell \log\ell$. By items 1–2 of Theorem 7.4.3, $(S_\ell, Q, \psi_{\tau^j})$ is an auxiliary twist with ramification at most e'_ℓ and each $\psi_{\tau^j} R_{j,z}$, $\psi_{\tau^j} R_{p,j}$ has Selmer length at most e'_ℓ at (Q, γ, ζ) for some γ, ζ. Then Lemma 7.6.2(2) gives (DL1) for τ^j at ι for j with β', and Lemma 7.6.2(3), for every main pair p for j, gives (DL2) with $e^{\beta'}$. □

Proposition 7.3.3. *For admissible data D and every finite set T of primes:*

(a) $\displaystyle\sum_{\ell\in T} \mathrm{loc}_\ell \log\ell \le 4\cdot 10^6 e^{180}\, f\,\frac{m}{k}\, b\log b;$

(b) $\displaystyle\sum_{\ell\in T} (\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log\ell \le \beta_{\mathrm{den}} = \frac{f\,a\,(\log b)^3}{m\,k};$

(c) the families (e'_ℓ), $(v_\ell(X_{\mathrm{odd}}))$, (e_ℓ) and $(v_\ell(h_{\mathrm{ch}}))$ are negligible with exponents 999, 2000, 4000 *and* 30 *respectively.*

Proof. All sums below run over $\ell \in T$; every summand is non-negative. Sizes are from Lemma 4.2.67: $f \le x^{12}$, $q_1 d \le x^{13}$, $r \le 3x^5$, $t \le 15x^5$, $h \le 3^8 x^{40}$, $m^2 \le 4x$, $\log b \le x^{1/100}$, $x^{10^{12}} \le b$, $\log b \ge e^{6.4\cdot 10^{13}}$. Weighted valuation sums are bounded by Lemma 7.3.4.

Step 1: item (c). For the twist error, by Lemma 6.7.10,

$$\sum e'_\ell \log\ell = (4f+3)r\sum v_\ell(N_{\mathrm{ch}})\log\ell + \sum 2^{-\ell}\log\ell \le 7x^{12}\cdot 3x^5\cdot x^{33} + 2 \le x^{999}.$$

For the odd-class integer, $1 \le X_{\mathrm{odd}} \le 2^{4(q_1 d+t+3)^{27}} h_E$ by Theorem 7.2.8, so with Lemma 7.3.5

$$\sum v_\ell(X_{\mathrm{odd}})\log\ell \le \log X_{\mathrm{odd}} \le 4(2x^{13})^{27} + x^{29} \le x^{2000}.$$

For the denominator error, put $c = 8ft + 2 + (4t+1)h^{22} + h \le x^{900}$; then

$$\sum e_\ell \log\ell = t\sum v_\ell(X_{\mathrm{odd}})\log\ell + c\sum v_\ell(N_{\mathrm{ch}})\log\ell \le 15x^{2005} + x^{933} \le x^{4000}.$$

Finally $\sum v_\ell(h_{\mathrm{ch}})\log\ell \le \log h_{\mathrm{ch}} \le x^{30}$ by Lemma 7.3.6.

Step 2: item (a). Let $Y = (2b)!\,\Pi^{h^3}$ with $\Pi = \prod_{\max(b-30h^3,0)<a\le b+30h^3} a \le (b+30h^3)^{60h^3}$, so $\lambda_\ell = v_\ell(Y)$. Then

$$\sum \mathrm{loc}_\ell \log\ell = 4f\cdot 10^6 \frac{m}{k}\Big(b\sum v_\ell(M)\log\ell + \sum v_\ell(Y)\log\ell\Big) \le 4f\cdot 10^6\frac{m}{k}(b\log M + \log Y).$$

Here $\log M \le 22\log b$, $\log(2b)! \le 2b\log(2b) \le 4b\log b$, and $\log \Pi^{h^3} \le 60h^6\log(b+30h^3) \le 120h^6\log b \le b\log b$, as $120h^6 \le 120\cdot 3^{48}x^{240} \le b$ and $b+30h^3 \le b^2$. So $b\log M + \log Y \le 27\,b\log b \le e^{180}b\log b$.

Step 3: item (b). By (CX5), $\beta_\ell + v_\ell(h_{\mathrm{ch}}) = \mathrm{loc}_\ell + (1+2t)e'_\ell + e_\ell + v_\ell(N_{\mathrm{ch}}) + v_\ell(h_{\mathrm{ch}})$. By Steps 1–2 (with the sharper constant 27) and Lemma 6.7.10,

$$\sum(\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log\ell \le 1.08\cdot 10^8 f\frac{m}{k}b\log b + (1+30x^5)x^{999} + x^{4000} + x^{33} + x^{30}.$$

The first term is at most $\beta_{\mathrm{den}}/2 = fxb(\log b)^3/(2mk)$, since this amounts to $2.16\cdot 10^8 m^2 \le x(\log b)^2$, and $m^2 \le 4x$. The remaining terms are at most $2x^{4000}$, and

$$\frac{\beta_{\mathrm{den}}}{2} \ge \frac{xb}{2mk} \ge \frac{xb}{2\cdot 2\sqrt{x}\cdot 3x^5} \ge \frac{x^{10^{12}}}{12x^{4.5}} \ge 2x^{4000},$$

using $f \ge 1$, $\log b \ge 1$, $k \le r$. Adding gives (b). □

Lemma 7.3.4. *Let T be a finite set of primes. For all integers $1 \le a \le n$,*

$$\sum_{\ell\in T} v_\ell(a)\log\ell \le \log n, \qquad \text{and} \qquad \sum_{\ell\in T} 2^{-\ell}\log\ell \le 2.$$

Proof. By unique factorisation, $\sum_{\ell\in T} v_\ell(a)\log\ell \le \sum_{\ell \text{ prime}} v_\ell(a)\log\ell = \log a \le \log n$, all terms being non-negative. For the second sum, $\log\ell \le \ell$, so it is at most $\sum_{n\ge1} n2^{-n} = \frac{1/2}{(1-1/2)^2} = 2$. □

Lemma 7.3.5. *For admissible data D, $\log h_E \le 26x^{24}\log x \le x^{29}$.*

Proof. **Discriminant.** As $d \equiv 3 \pmod 4$, $K \subseteq \mathbb{Q}(\zeta_d)$, so $E \subseteq L = \mathbb{Q}(\zeta_{q_1 d})$. The root discriminant does not decrease in towers ($|d_L| = |d_E|^{[L:E]}\,\mathrm{N}(\mathfrak{d}_{L/E})$), so $\mathrm{rd}_E \le \mathrm{rd}_L \le q_1 d$ (for $L = \mathbb{Q}(\zeta_n)$, $|d_L|^{1/[L:\mathbb{Q}]} = n/\prod_{p\mid n} p^{1/(p-1)} \le n$). With $[E:\mathbb{Q}] = 2f$ this gives $\log|d_E| \le 2f\log(q_1 d)$.

Class number. Every ideal class contains an integral ideal of norm at most the Minkowski bound $B_E \le |d_E|^{1/2}$. The number of integral ideals of norm j is at most the coefficient $\tau_{2f}(j)$ of $\zeta(s)^{2f}$ (compare the Euler products of ζ_E and $\zeta^{[E:\mathbb{Q}]}$), and $\tau_{2f}(j) \le \tau(j)^{2f-1} \le j^{2f-1}$. So $h_E \le \sum_{j\le B_E} j^{2f-1} \le B_E^{2f}$ and

$$\log h_E \le 2f\cdot\tfrac{1}{2}\log|d_E| \le 2f^2\log(q_1 d) \le 2x^{24}\cdot 13\log x$$

by Lemma 4.2.67, item 4. Finally $26\log x \le x^5$ as $x \ge e^{6.4\cdot 10^{15}}$. □

Lemma 7.3.6. *For admissible data D, $1 \le h_{\mathrm{ch}}$ and $\log h_{\mathrm{ch}} \le x^{30}$.*

Proof. **Maximal level.** Let $K_{\max} = \prod_w \mathrm{U}(1)(\mathcal{O}_w)$, where $\mathrm{U}(1)(\mathcal{O}_w)$ is the group of u_w with $u_w\bar{u}_w = 1$ and u_w a unit at the places of E above the place v of E^+ under w. At a place v of E^+ inert or ramified in E, $\mathrm{U}(1)(E_v^+)$ is compact, so it equals $\mathrm{U}(1)(\mathcal{O}_v)$. At a split $v = w\bar{w}$, $u \mapsto u_w$ identifies $\mathrm{U}(1)(E_v^+)$ with $E_w^\times$, and $\mathrm{U}(1)(E_v^+)/\mathrm{U}(1)(\mathcal{O}_v) \cong \mathbb{Z}$ by the valuation at w. Thus $u \mapsto \prod_{v \text{ split}} w^{\mathrm{ord}_w(u_w)}$ identifies $\mathrm{U}(1)(\mathbb{A}_f)/K_{\max}$ with the group I^1 of fractional ideals $\mathfrak{a}$ of E with $\mathfrak{a}\bar{\mathfrak{a}} = \mathcal{O}_E$. Each $\mathfrak{a} \in I^1$ is $\mathfrak{b}/\bar{\mathfrak{b}}$ for an ideal $\mathfrak{b}$ supported on one place above each split v, and $z \in \mathrm{U}(1)(E)$ maps to (z), where by Hilbert 90 $z = y/\bar{y}$ with $y \in E^\times$. Hence $[\mathfrak{b}] \mapsto \mathfrak{b}/\bar{\mathfrak{b}}$ is a well-defined surjection from the class group of E onto $\mathrm{U}(1)(E)\backslash\mathrm{U}(1)(\mathbb{A}_f)/K_{\max}$, and the latter has at most h_E elements.

Chosen level. Each double coset for $K_{\max}$ is the union of at most $[K_{\max} : K_{\mathrm{ch}}]$ double cosets for K_{ch}. At a chosen place w (split over E^+, as $\bar{w}$ contains $\bar{\pi}_M$, which is prime to w), the condition $u_w \equiv 1$ modulo w has index $\mathrm{N}w - 1$ in $\mathcal{O}_w^\times$. By Lemma 4.2.66, item 3, $[K_{\max} : K_{\mathrm{ch}}] \le \prod_{w \text{ chosen}} \mathrm{N}w = M^f$. So

$$\log h_{\mathrm{ch}} \le \log h_E + f \log M \le x^{29} + 22x^{12} \log b \le x^{30}$$

by Lemma 7.3.5 and Lemma 4.2.67, items 2, 4 and 5. □

7.4 The twisting theorem

The twisting theorem (Theorem 7.4.3) chooses the twist at one prime. For finitely many main-summand-like representations it gives an m-fold twist τ, anticyclotomic of ℓ-power order and ramified only at auxiliary places, such that every power τ^j, $1 \le j \le m$, at once has ramification at most e'_ℓ, twists each representation to Selmer length at most e'_ℓ, and keeps the ℓ-adic valuations of the ratios of L-values at most e'_ℓ.

The theorem is reduced in two steps to a general form for Selmer data and Stickelberger systems (Definition 7.4.1). Main-summand-like representations give Selmer data whose local conditions above ℓ are the crystalline cocycles (Proposition 7.4.4; see [28, 85]). The ratios of L-values are governed by Stickelberger systems (Proposition 7.4.9), built from a class sum of theta values at the critical integer one (Lemma 7.4.10) through the exchange identity and the expression of Hecke L-values as squared norms of lifts. In our reading they are a finite, integral analogue of Stickelberger elements and of the ℓ-adic interpolation of Hecke L-values [290, 317, 159]; for the valuations of L-values in families of twists see [78, 283].

The general form (Theorem 7.4.11) is proved in three steps. Ties at auxiliary places, found by class field theory and Chebotarev's theorem [54], cut the Selmer modules down until their length is bounded by the global and local terms (Proposition 7.4.13), through the Greenberg–Wiles formula and Poitou–Tate duality [328, 63, 225, 295, 201]. The twisted Selmer lengths and the Stickelberger values then become valuations of polynomials in the variables $\zeta_{\mathfrak{q}} - 1$ (Proposition 7.4.12; with Mazur's finiteness condition [196]). Finally the roots of unity are chosen so that every polynomial loses little at all m powers at once (Lemma 7.4.22). Auxiliary primes that control Selmer groups go back to Kolyvagin [169, 244] and to Taylor and Wiles [301]; in our reading the dependence on the variables $\zeta - 1$ is of the kind studied in Iwasawa theory. For bounds of Selmer groups of automorphic Galois representations of unitary type see also [306, 226].

Definition 7.4.1. Fix a prime ℓ, a finite set S_0 of finite places of E containing the places above ℓ, and $g_0 \in G_E$. For every finite place v of E fix a place A_v of $\bar{\mathbb{Q}}$ above v, for $v \mid \ell$ the place A_v fixed in Definition 7.2.2, and let $D_v \supseteq I_v$ be its decomposition and inertia groups in G_E. Let $\mathcal{O}$ be a coefficient ring with uniformiser ϖ and normalised valuation v_ϖ ($v_\varpi(0) = \infty$), and for $0 \ne a \in \mathcal{O}$ and a continuous $\rho\colon G_E \to \mathrm{GL}_n(\mathcal{O})$ let $W_a = (\mathcal{O}/a)^n$ with the action ρ. Then $\mathrm{Hom}_{G_E}(W_a, W_a^{*c})$ is the $\mathcal{O}$-module of $\mathcal{O}$-linear maps $\eta\colon W_a \to \mathrm{Hom}_{\mathbb{Z}}(W_a, \mathbb{Q}/\mathbb{Z})$ with

$$\eta(\rho(g)u)(m) = \eta(u)\big(\chi_{\mathrm{cyc}}(g^c)\,\rho(g^c)^{-1}m\big) \qquad (g \in G_E,\ u, m \in W_a).$$

For an $\mathcal{O}$-module M and a finite set Σ of finite places, a cocycle $c\colon G_E \to M^n$ (for ρ or a twist of ρ) is **unramified outside** Σ if it vanishes on the inertia groups of all places of $\bar{\mathbb{Q}}$ above the finite places not in Σ; cocycles are not taken modulo coboundaries.

(SD) Selmer datum. A **Selmer datum** for (S_0, g_0) over $\mathcal{O}$ of rank $n \ge 1$ is

$$T = (\rho, S, (Z_w)_{w\mid\ell}, \gamma_*, \zeta_*) :$$

a continuous $\rho\colon G_E \to \mathrm{GL}_n(\mathcal{O})$ with $\mathcal{O}$-span of $\rho(G_E)$ equal to $M_n(\mathcal{O})$; a finite set S with $\{w \mid \ell\} \subseteq S \subseteq S_0$ outside which ρ is unramified; for each $w \mid \ell$ a finitely generated $\mathcal{O}$-module Z_w of cocycles $D_w \to \mathcal{O}^n$ for $\rho|_{D_w}$, containing the coboundaries $g \mapsto \rho(g)b - b$ ($b \in \mathcal{O}^n$), with $\sum_{w|\ell} \operatorname{rk} Z_w \le (\#\{w \mid \ell\} + f_E)\, n$ (f_E the number of infinite places); an element γ_* of an inertia group above a place of S prime to ℓ and $\zeta_* \in \mathcal{O}$ with $\rho(\gamma_*) = \rho((\gamma_*^c)^{-1}) = \zeta_* \cdot 1$ and $\zeta_*^2 - 1 \in \mathcal{O}^\times$.

(SF) Terms. The **global term** of T is $\sup_{a \neq 0} \operatorname{len}_{\mathcal{O}} \operatorname{Hom}_{G_E}(W_a, W_a^{*c})$; the **local term** at $v \in S$, $v \nmid \ell$, is

$$\sup_{a \neq 0} \big(\operatorname{len}_{\mathcal{O}} C_v(a) \mathbin{\dot{-}} \operatorname{len}_{\mathcal{O}} W_a\big),$$

where $C_v(a)$ is the $\mathcal{O}$-module of the restrictions to D_v of all continuous cocycles $G_E \to W_a$ for ρ (no local condition) and $x \mathbin{\dot{-}} y = \max(x - y, 0)$ on $[0, \infty]$ ($\infty \mathbin{\dot{-}} y = \infty$); the **first-prime term** is $v_\varpi \det(\rho(g_0) - 1) + v_\varpi \det(\rho((g_0^c)^{-1}) - 1)$, both summands counted also when $g_0 = (g_0^c)^{-1}$. The datum requires all three finite, and β_T is their sum (local terms summed over $v \in S$, $v \nmid \ell$).

(SW) Twisted Selmer groups. A **relation** of Z_w ($w \mid \ell$) is a finitely supported family $(A_g)_{g \in D_w}$ of matrices in $M_n(\mathcal{O})$ with $\sum_g A_g z(g) = 0$ for every $z \in Z_w$. For an $\mathcal{O}$-algebra $\mathcal{O}'$ and an $\mathcal{O}'$-module M, a function $c\colon G_E \to M^n$ **obeys the local conditions of** T if $\sum_g A_g c(g) = 0$ in M^n for every $w \mid \ell$ and every relation (A_g) of Z_w (the matrices acting through $\mathcal{O} \to \mathcal{O}'$). For a finite set Q and a character $\psi\colon G_E \to \mathcal{O}'^\times$ with $\mathcal{O} \subseteq \mathcal{O}'$ coefficient rings, $\mathrm{Sel}_Q(T\psi)$ is the $\mathcal{O}'$-module of continuous cocycles $c\colon G_E \to (\operatorname{Frac}\mathcal{O}'/\mathcal{O}')^n$ for $g \mapsto \psi(g)\rho(g)$ that are unramified outside $S \cup Q \cup \bar{Q}$, obey the local conditions of T, and satisfy $c(\gamma_*) = 0$. The twist has **length at most** B if for all large $\mathcal{O}' \supseteq \mathcal{O}$ the character ψ takes values in $\mathcal{O}'$ and $\operatorname{nl} \mathrm{Sel}_Q(T\psi) \le B$.

(SK) Stickelberger system. For a finite set Q, Cl_Q is the class group $\mathrm{U}(1)(E)\backslash\mathrm{U}(1)(\mathbb{A}_f)/\mathrm{K}_Q$, with K_Q the integral units congruent to 1 at the places of Q; a character ψ from U(1) with modulus Q factors through Cl_Q and extends linearly to $\overline{\mathbb{Z}}_\ell[\mathrm{Cl}_Q]$. A **Stickelberger system** for (S_0, g_0) is $Y = (\vartheta, (e_1, \dots, e_u), (\Theta_Q)_Q)$: a continuous character $\vartheta\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ unramified outside S_0 with $\vartheta(g_0) \neq 1$, integers $e_1, \dots, e_u$, and $\Theta_Q \in \overline{\mathbb{Z}}_\ell[\mathrm{Cl}_Q]$ for every finite Q, with $1(\Theta_\emptyset) \neq 0$ and, whenever $Q \cup \{P\}$ is auxiliary for S_0, $P \notin Q$, ψ comes from U(1) with modulus Q and φ is a Frobenius at P,

$$\psi(\Theta_{Q\cup\{P\}}) = \psi(\Theta_Q) \prod_{i=1}^{u} \big(1 - \alpha\, \mathrm{N}P^{-e_i}\big)\big(1 - \alpha^{-1}\mathrm{N}P^{-e_i}\big), \qquad \alpha = \vartheta(\varphi)\psi(\varphi).$$

Its number is $\beta_Y = v_\ell(1(\Theta_\emptyset)) + 2u\, v_\ell(\vartheta(g_0) - 1)$.

(SM) Small twists. For Selmer data T_i over $\mathcal{O}$, Stickelberger systems Y_k, $\varepsilon > 0$, a finite set Q and $\psi\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$: ψ is an **ε-small twist** at Q if ψ comes from U(1) with modulus Q, has ℓ-power order, is ramified at every place of Q, the twist of each T_i by ψ has length at most $\operatorname{nl}(\beta_{T_i}) + \varepsilon$, $v_\ell(\psi(\Theta_Q^{(k)})) \le \beta_{Y_k} + \varepsilon$ for each k, and $\sum_{w \in Q \cup \bar{Q}} v_\ell(\psi(\gamma_w) - 1) \le \varepsilon$ for all tame generators γ_w.

(SQ) Torsion level. An integer M_0 is a **torsion level** for the data T_i if $\operatorname{nl}(\beta_{T_i}) + 1 < M_0$ and $\#(\mathcal{O}/\varpi) > 2n_i \operatorname{len}_{\mathcal{O}}(\mathcal{O}/\ell^{M_0}) + 1$ for each i (n_i the rank of T_i).

Definition 7.4.2. Let p be a prime, K a finite extension of $\mathbb{Q}_p$, L a finite extension of $\mathbb{Q}_p$, and V a finite-dimensional L-vector space with a continuous L-linear action of G_K. Put

$$D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}, \qquad \mathrm{Fil}^j D_{\mathrm{dR}}(V) = D_{\mathrm{dR}}(V) \cap (\mathrm{Fil}^j B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V) \quad (j \in \mathbb{Z}).$$

This is a module over $K \otimes_{\mathbb{Q}_p} L$, where $K \subset B_{\mathrm{dR}}$ acts on the first factor and L on V, with a decreasing filtration by $K \otimes_{\mathbb{Q}_p} L$-submodules. For a $\mathbb{Q}_p$-embedding $\tau\colon K \to L$ let

$$D_{\mathrm{dR},\tau}(V) = L \otimes_{K \otimes_{\mathbb{Q}_p} L,\, \tau \otimes \mathrm{id}} D_{\mathrm{dR}}(V),$$

with the filtration $\mathrm{Fil}^j D_{\mathrm{dR},\tau}(V)$ given by the image of $L \otimes \mathrm{Fil}^j D_{\mathrm{dR}}(V)$. An integer a is a **Hodge jump of V at τ** if $\mathrm{Fil}^{a+1} D_{\mathrm{dR},\tau}(V) \neq \mathrm{Fil}^a D_{\mathrm{dR},\tau}(V)$.

If $F \subseteq K$ is a subfield and $\tau_0\colon F \to L$ is a $\mathbb{Q}_p$-embedding, the **embeddings of K over τ_0** are the $\mathbb{Q}_p$-embeddings $\tau\colon K \to L$ with $\tau|_F = \tau_0$.

Theorem 7.4.3. *Let D be admissible data, ℓ a prime, $\iota \mid \ell$ a prime identification, and $(R_i)_{i \in I}$ finitely many ℓ-adic representations, each main-summand like for some string length and jumps. Then there is an m-fold twist τ such that for every $1 \le j \le m$ the twist $\xi = \tau^j$, with modulus Q, satisfies:*

1. *$(S_\ell^{\mathrm{bad}}, Q, \psi_\xi)$ is an auxiliary twist with ramification at most e'_ℓ;*
2. *for every i there are $\gamma_i \in G_E$ and $\zeta_i \in \overline{\mathbb{Z}}_\ell$ such that $\psi_\xi R_i$ has Selmer length at most e'_ℓ at (Q, γ_i, ζ_i);*
3. *for every ramified critical pair p and every $s \in \{\pm 1\}$, $v_\ell\big(\iota(r_p(\xi, s))\big) \le e'_\ell$.*

Proof. Put $c_\ell = (4f+3)r\, v_\ell(N_{\mathrm{ch}})$ and $\varepsilon = 2^{-\ell}$, so $e'_\ell = c_\ell + \varepsilon$.

Step 1: data and systems. By Proposition 7.4.4 there are a chosen place $w_0 \nmid \ell$ of norm p_{i_0}, a tame generator g_0 at w_0 (inertial above a place of S_ℓ^{bad} not above ℓ, as $p_{i_0} \mid M$), a coefficient ring $\mathcal{O}$ and Selmer data T_i for $(S_\ell^{\mathrm{bad}}, g_0)$ with representation a lattice u_i in R_i, places those above $\ell p_0 p_1$, local modules the crystalline cocycles, $\mathrm{nl}(\beta_{T_i}) \le c_\ell$, and torsion level $c_\ell + 2$. There are finitely many ramified critical pairs. Their weights and integers $z \le t$ lie in finite sets. For each fixed weight, the ratio of any two such characters has weight zero and factors through the finite tame class group at the chosen places, which has finitely many characters. Thus only finitely many characters occur for each weight; for each such p and each s, Proposition 7.4.9(1) gives a Stickelberger system $Y_{p,s}$ for $(S_\ell^{\mathrm{bad}}, g_0)$.

Step 2: the twist. Theorem 7.4.11, applied with $S_0 = S_\ell^{\mathrm{bad}}$, m and ε, gives Q auxiliary for S_ℓ^{bad} and ψ such that ψ^j is an ε-small twist at Q for (T_i), $(Y_{p,s})$, for $1 \le j \le m$. As ψ comes from $\mathrm{U}(1)$ with modulus Q, Proposition 7.4.9(2) gives a tame character τ with modulus Q and $\psi = \psi_\tau$; then $\psi^j = \psi_{\tau^j}$. Since ψ^j is ramified at every $w \in Q$ and, by local class field theory, its restriction to inertia at w is the tame part of τ^j at w transported by ι, the tame part of τ^j is nontrivial at every $w \in Q$ for $1 \le j \le m$: τ is an m-fold twist.

Step 3: the three conclusions for $\xi = \tau^j$. Item 1: Q is auxiliary for S_ℓ^{bad}, so no place of Q is above ℓ; ψ_ξ comes from $\mathrm{U}(1)$ with modulus Q; and $\sum_{w \in Q} v_\ell(\psi_\xi(\sigma_w) - 1) \le \varepsilon \le e'_\ell$ for tame generators σ_w. Item 2: take $\gamma_i = \gamma_*$ and $\zeta_i = \zeta_*$ of T_i. The element γ_* is inertial at a place of S_ℓ^{bad} not above ℓ, where ψ_ξ is unramified, so $(\psi_\xi u_i)(\gamma_*) = \zeta_* \cdot 1$; $\zeta_* - 1$ is a unit since $\zeta_*^2 - 1$ is. The actual crystalline Selmer group over every sufficiently large $\mathcal{O}' \supseteq \mathcal{O}$ is contained in the group cut out by the mapped relations of T_i. We verify the local inclusion. At a place above ℓ, ψ_ξ is trivial, so the integral local lattice is $L' = L \otimes_{\mathcal{O}} \mathcal{O}'$ with the original action. For

every $\mathcal{O}$-linear functional $f : \mathcal{O}' \to \mathcal{O}$, coordinatewise application to a crystalline cocycle z' for L' gives a crystalline cocycle for L: apply $1 \otimes f$ to its period witness to obtain

$$1 \otimes f(z'(g)) = g(1 \otimes f)y - (1 \otimes f)y.$$

The map is equivariant since the matrices of L have entries in $\mathcal{O}$. If $\sum_g A(g)z(g) = 0$ is any fixed matrix relation holding on $Z_f(L)$, it follows that $f(\sum_g A(g)z'(g)) = 0$ for every f. The dual basis of the finite free $\mathcal{O}$-module $\mathcal{O}'$ separates its elements, hence this relation holds on $Z_f(L')$. Thus every mapped relation of T_i is a relation of the extended integral crystalline module. A torsion cocycle satisfying all the latter relations satisfies the former ones. The ramification and γ_* conditions are identical, giving the claimed inclusion of Selmer groups. Length is monotone under inclusion, so (AX6) has normalized length at most $\mathrm{nl}(\beta_{T_i})+\varepsilon \le e'_\ell$ over every sufficiently large coefficient ring. Item 3: $v_\ell(\psi_\xi(\Theta_Q)) \le \beta_{Y_{p,s}}+\varepsilon$, so by Proposition 7.4.9(1), $v_\ell(\iota(r_p(\xi,s))) \le 4v_\ell(p_{i_0}-1)+\varepsilon$. As $p_{i_0}-1 = \#\mathrm{GL}_1(k_{w_0})$ divides $\#\mathrm{GL}_{rt}(k_{w_0})$, which divides N_{ch}, $4v_\ell(p_{i_0}-1) \le 4v_\ell(N_{\mathrm{ch}}) \le c_\ell$. □

Proposition 7.4.4. *Let D be admissible data, ℓ a prime, $\iota \mid \ell$ a prime identification, and $c_\ell = (4f+3)\,r\,v_\ell(N_{\mathrm{ch}})$.*

1. *There is a chosen place w_0 not above ℓ; it has norm p_{i_0} for some $i_0 \in \{0,1\}$. Let g_0 be a tame generator at w_0.*
2. *Let $(R_i)_{i\in I}$ be finitely many ℓ-adic representations, each main-summand like for some string length and jumps. Then there are a coefficient ring $\mathcal{O}$ and Selmer data T_i for $(S_\ell^{\mathrm{bad}}, g_0)$ over $\mathcal{O}$ such that, for every i: the representation of T_i is a lattice in R_i; the set of places of T_i is the set of places above ℓ, p_0 or p_1; its local modules Z_w ($w \mid \ell$) are the crystalline cocycles Z_f; and $\mathrm{nl}(\beta_{T_i}) \le c_\ell$. Moreover $c_\ell + 2$ is a torsion level for the T_i.*

Proof. By Lemma 4.2.66, each of the distinct primes p_0, p_1 has f chosen places, of norm p_0, p_1 respectively. At most one equals ℓ. Choose w_0 above the other and fix the indicated tame generator g_0.

We first fix a coefficient ring and lattices for the finite family. A continuous representation of the profinite group G_E in $\mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ is defined over a finite extension of $\mathbb{Q}_\ell$. Indeed, there are countably many finite extensions inside $\overline{\mathbb{Q}}_\ell$, and their matrix groups are closed. Their inverse images cover G_E. The Baire category theorem gives one inverse image with nonempty interior; being a subgroup, it is open. Adjoining the entries of the images of finitely many coset representatives gives a finite extension containing the whole image. The image is compact, hence bounded, and the $\mathcal{O}$-span of the translates of $\mathcal{O}^n$ is contained in a fixed fractional lattice. This span is a finite free stable lattice of rank n. For the finitely many representations take a common finite Galois coefficient extension, sufficiently large for the full matrix-span assertion in (MS3)(ii). Further extensions preserve lattices and that assertion.

Fix one representation, of rank n and string length t', and a lattice ρ. Put $q = \max(t',1)-1$ and $V_\ell = v_\ell(N_{\mathrm{ch}})$. We have $1 \le n \le r$, $t' \le t$, and $q+1 \le t$ because $t = 5r \ge 1$. We prove the required bounds uniformly after any further coefficient extension.

Conjugating a scalar. If $\rho(g) = uI$, then u is a unit and

$$\rho(g^{-c}) = \chi_{\mathrm{cyc}}(g)^q u I, \qquad g^{-c} = (g^c)^{-1}.$$

Here is a direct derivation that uses only (MS1). For every $x \in G_E$, apply its trace identity at $x^c g^{-1}$ and at x^c. Since $\chi_{\mathrm{cyc}}(x^c) = \chi_{\mathrm{cyc}}(x)$, the two identities give

$$\mathrm{tr}(\rho(x)\rho(g^{-c})) = \chi_{\mathrm{cyc}}(g)^q u \,\mathrm{tr}\,\rho(x).$$

The matrices $\rho(x)$ span $M_n(\mathcal{O})$, so the identity holds with every matrix in place of $\rho(x)$. Testing against the matrix units proves the asserted matrix equality. The scalar u is a unit because uI is invertible.

The global term. By (MS3)(ii) choose g acting by uI and with $\chi_{\mathrm{cyc}}(g) = p_i^n$ for some $i \in \{0, 1\}$. This equality also implies $p_i \neq \ell$, as a cyclotomic value is an ℓ-adic unit. On the conjugate Cartier dual of $W = (\mathcal{O}/\eta)^n$, the element g acts by $\chi_{\mathrm{cyc}}(g^c)\chi_{\mathrm{cyc}}(g)^q u$. Consequently every equivariant map $F : W \to W^{*c}$ is killed by

$$\delta = u(1 - p_i^d), \qquad d = n(q+1), \qquad 1 \leq d \leq rt.$$

Evaluation at the first basis vector injects these maps into $W^{*c}[\delta]$. To check injectivity, a map vanishing there vanishes on all its G_E-translates by equivariance; these translates span W, since the matrices $\rho(G_E)$ span all matrix units. The δ-torsion of the character module of a finite module has the same length as its quotient by δ, hence as its δ-torsion: this follows by taking the dual of the quotient and comparing the kernel and cokernel of multiplication by δ on a finite group. Thus

$$\operatorname{len}_{\mathcal{O}} \operatorname{Hom}_{G_E}(W, W^{*c}) \leq \operatorname{len}_{\mathcal{O}} W[\delta] \leq n v_{\varpi}(\delta).$$

The last inequality follows coordinatewise from $\operatorname{len}(\mathcal{O}/\eta)[\delta] = \min(v_{\varpi}(\eta), v_{\varpi}(\delta))$. Since $p_i^d - 1$ is a factor in

$$\#\mathrm{GL}_{rt}(\mathbb{F}_{p_i}) = p_i^{rt(rt-1)/2} \prod_{\nu=1}^{rt} (p_i^{\nu} - 1),$$

and a chosen place above p_i occurs in N_{ch}, we obtain $v_{\varpi}(\delta)/e_{\mathcal{O}} \leq V_\ell$. Taking the supremum over $\eta \neq 0$ bounds the normalized global term by nV_ℓ.

The terms away from ℓ. Let $v \mid p_0 p_1$, $v \nmid \ell$, and take an inertia element γ_v with the determinant bound of (MS3)(i). For any finite quotient $W = (\mathcal{O}/\eta)^n$, restriction of global cocycles has length at most the length of all local cocycles. The coboundaries have length $\operatorname{len} W - \operatorname{len} H^0(E_v, W)$. Local Tate duality and the local Euler characteristic formula, [201, Chapter I, Corollary 2.3 and Theorem 2.8], therefore give

$$\operatorname{len} Z^1(E_v, W) = \operatorname{len} W + \operatorname{len} H^2(E_v, W) = \operatorname{len} W + \operatorname{len} H^0(E_v, W^\vee).$$

The inertia element γ_v has cyclotomic value 1. Hence the last fixed module embeds into the kernel of the dual of $\rho(\gamma_v) - I$. That kernel has the same length as the cokernel of $\rho(\gamma_v) - I$ on W, hence as its kernel on W. Smith normal form over $\mathcal{O}$ bounds this length by $v_{\varpi} \det(\rho(\gamma_v) - I)$. Taking the nonnegative excess over $\operatorname{len} W$ and the supremum proves that the normalized local term at v is at most nV_ℓ. There are at most $4f$ places above $p_0 p_1$, by complete splitting in Lemma 4.2.66. The total normalized local term is consequently at most $4fnV_\ell$. At the chosen w_0, (MS3)(i) applies to the specified g_0 and to g_0^{-c}, so the two-index first-prime term is at most $2nV_\ell$. All these terms are finite and

$$\operatorname{nl}(\beta_T) \leq (4f + 3)nV_\ell \leq c_\ell.$$

The local modules and distinguished inertia element. Take S to be the places above ℓ, p_0, p_1 and $Z_w = Z_f(L_w(\rho))$ via the fixed chart j_w at A_w for $w \mid \ell$. The local finite-type condition of (MS2) is potentially crystalline at these places. The modules are finite free by Lemma 7.4.5, and contain coboundaries: the coboundary of v has period witness $1 \otimes v$. The same lemma gives

$$\sum_{w \mid \ell} \operatorname{rank}_{\mathcal{O}} Z_w \leq \#\{w \mid \ell\}\, n + \sum_{\sigma : E \hookrightarrow \mathbb{C}} \#\{u \in J(\sigma) : u < 0\} \leq (\#\{w \mid \ell\} + f)n.$$

For the last inequality group embeddings into the f conjugate pairs and apply (DW3) of Definition 6.6.14. The representation is unramified outside S by (MS2).

Choose γ_* and its scalar ζ_* by (MS3)(iii). Its place is prime to ℓ, so $\chi_{\mathrm{cyc}}(\gamma_*) = 1$; the scalar-conjugation calculation proves $\rho(\gamma_*^{-c}) = \zeta_* I$ as well. Taking $a = 0, j = 2$ in (MS3)(iii) shows that $\zeta_*^2 - 1$ is a unit. We have now checked every requirement on the Selmer datum, including its distinguished inertia element.

Finally put $M_0 = c_\ell + 2$, an integer. Choose a further unramified coefficient extension whose residue field has more than $2n_i e_{\mathcal{O}} M_0 + 1$ elements for every member of the finite family. This is possible because unramified extensions have arbitrarily large residue fields and leave $e_{\mathcal{O}}$ unchanged. The constructions and bounds above apply over that extension. They give $\mathrm{nl}(\beta_{T_i}) + 1 \le c_\ell + 1 < M_0$ and precisely the residue-field inequalities in the torsion-level definition. Thus M_0 is a common torsion level. If the family is empty, only the initial choice of w_0 is needed. □

Lemma 7.4.5. *Let E be a number field, ℓ a prime, $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$ an isomorphism, $e\colon E \to \overline{\mathbb{Q}}_\ell$ an embedding, and $j\colon \Gamma \to G_\ell$ an open embedding onto the subgroup of elements fixing $e(E)$ pointwise. Let $\mathcal{O}$ be a coefficient ring, L a potentially crystalline Galois lattice over $\mathcal{O}$, and J a family of finite multisets of integers indexed by the complex embeddings of E such that, for every $g \in G_\ell$, $J(\sigma_{e,g})$ lists the jumps of L at the embedding $\gamma_g\colon a \mapsto g(a)$ of $\mathcal{O}$ into $\mathbb{C}_\ell$. Then $Z_f(L)$ is a finitely generated free $\mathcal{O}$-module and*

$$\mathrm{rank}_{\mathcal{O}} Z_f(L) = \mathrm{rank}_{\mathcal{O}} L + \sum_{\sigma \in \{\sigma_{e,g}\colon g \in G_\ell\}} \#\{u \in J(\sigma) : u < 0\}.$$

Proof. Put $K_\ell = \overline{e(E)} \subset \overline{\mathbb{Q}}_\ell$, $n_v = [K_\ell : \mathbb{Q}_\ell]$, $F_{\mathrm{c}} = \mathrm{Frac}\,\mathcal{O}$, $n_{\mathrm{c}} = [F_{\mathrm{c}} : \mathbb{Q}_\ell]$, and $V = L \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$. Thus $j(\Gamma) = G_{K_\ell}$. By Lemma 7.4.6, the action and crystalline cocycles are continuous, V is de Rham, $Z_f(L)$ is finite free, and

$$Z_f(L) \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell = Z_f(V), \tag{1}$$

$$\dim_{\mathbb{Q}_\ell} Z_f(V) = \dim_{\mathbb{Q}_\ell} V + \dim_{\mathbb{Q}_\ell} (D_{\mathrm{dR}}(V)/\mathrm{Fil}^0). \tag{2}$$

The lemma applies to this actual completion, with exactly the potentially crystalline period condition assumed here.

We check the filtration sign before counting. In the jump definition a functional of jump u satisfies $\lambda(\rho(g)x) = \chi_{\mathrm{cyc}}(g)^{-u} g\lambda(x)$. It is thus an equivariant functional to $\mathbb{C}_\ell(-u)$. The comparison of Theorem A.3.11 identifies its multiplicity with the multiplicity of filtration degree u. In particular for $L = \mathbb{Z}_\ell(1)$ the identity functional has $u = -1$, agreeing with its nonzero gr^{-1}. The jumps here are the negatives of the cyclotomic-positive weights in the Hodge–Tate convention; there is no index shift. Passing to the open subgroup used for potential crystallinity does not change these multiplicities: the Hodge–Tate comparison is preserved under finite extension and the dimensions of the filtered de Rham pieces are preserved by scalar extension.

For each embedding $\gamma : F_{\mathrm{c}} \to \mathbb{C}_\ell$, let $\mathcal{J}_\gamma$ be the jump multiset of its coefficient component, and put $\mathcal{J}_{\mathrm{tot}} = \sum_\gamma \mathcal{J}_\gamma$. The Hodge–Tate decomposition of the underlying $\mathbb{Q}_\ell$-representation is obtained by summing these components. Therefore Theorem A.3.11, or equivalently the filtered count in Lemma 7.4.7(3) applied after extending coefficients, gives

$$\dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 = n_v \,\#\{u \in \mathcal{J}_{\mathrm{tot}} : u < 0\}. \tag{3}$$

Here the factor n_v converts the dimension over K_ℓ into dimension over $\mathbb{Q}_\ell$.

It remains to identify the multiplicity in (3) with that in the statement; this is a finite double count, so it does not require any choice of compatible coset representatives. Choose a finite Galois extension $F_*/\mathbb{Q}_\ell$ containing K_ℓ and F_{c}. The maps

$$g \longmapsto g|_{F_{\mathrm{c}}}, \qquad g \longmapsto \iota^{-1} g^{-1} e$$

factor through $G_* = \mathrm{Gal}(F_*/\mathbb{Q}_\ell)$. The first has n_{c} values, each with $\#G_*/n_{\mathrm{c}}$ preimages. The second has n_v values, each with $\#G_*/n_v$ preimages: embeddings of E inducing this place extend uniquely to embeddings of its completion, and there are n_v of those. By the hypothesis on J, for each g the two resulting multisets are equal. Summing over G_* and cancelling its order gives

$$n_v \, \mathcal{J}_{\mathrm{tot}} = n_{\mathrm{c}} \sum_{\sigma \in \{\sigma_{e,g}\}} J(\sigma). \tag{4}$$

Taking negative multiplicities in (4), then using (1)–(3) and $\dim_{\mathbb{Q}_\ell} V = n_{\mathrm{c}} \operatorname{rank}_{\mathcal{O}} L$, yields

$$n_{\mathrm{c}} \operatorname{rank}_{\mathcal{O}} Z_f(L) = n_{\mathrm{c}} \operatorname{rank}_{\mathcal{O}} L + n_{\mathrm{c}} \sum_{\sigma} \#\{u \in J(\sigma) : u < 0\}.$$

Division by $n_{\mathrm{c}} > 0$ proves the formula. □

Lemma 7.4.6. *Let $K_\ell/\mathbb{Q}_\ell$ be finite, let $\mathcal{O}$ be a coefficient ring, and let L be a finite free $\mathcal{O}$-module with an $\mathcal{O}$-linear action of G_{K_ℓ} that is potentially crystalline in the $B_{\max}$-period sense. Put $V = L[1/\ell]$, $n_v = [K_\ell : \mathbb{Q}_\ell]$, and $n_{\mathrm{c}} = [\mathrm{Frac}\,\mathcal{O} : \mathbb{Q}_\ell]$. Then:*

1. *The action on L, and every cocycle in $Z_f(L)$, are continuous. The representation V is potentially crystalline in the usual B_{cris}-sense and is de Rham.*
2. *For any continuous finite-dimensional $\mathbb{Q}_\ell$-representation W and any cocycle $c : G_{K_\ell} \to W$, the existence of a $B_{\max}$-coboundary witness is equivalent to the existence of a B_{cris}-coboundary witness.*
3. *$Z_f(L)$ is finite free over $\mathcal{O}$, its rationalization is the space of crystalline cocycles of V, and*

$$n_{\mathrm{c}} \operatorname{rank}_{\mathcal{O}} Z_f(L) = \dim_{\mathbb{Q}_\ell} V + \dim_{\mathbb{Q}_\ell} (D_{\mathrm{dR}}(V)/\mathrm{Fil}^0).$$

In particular

$$\operatorname{rank}_{\mathcal{O}} Z_f(L) \le (1 + n_v) \operatorname{rank}_{\mathcal{O}} L \le 2 n_v \operatorname{rank}_{\mathcal{O}} L.$$

Proof. We first record the integral period-ring calculation, including the prime 2. Choose a compatible system of ℓ-power roots of ℓ, and put $\xi_0 = [\ell^\flat] - \ell$, a generator of $\ker\theta$. The ring $A_{\max}$ is the ℓ-adic completion of $A_{\mathrm{inf}}[\xi_0/\ell]$, and A_{cris} is the ℓ-adic completion of its divided-power envelope with divided powers compatible with those of (ℓ). Both embed in B_{dR}^+. The divided power $\xi_0^{[j]} = \xi_0^j/j!$ belongs to $A_{\max}$, since

$$\xi_0^{[j]} = (\xi_0/\ell)^j \, \frac{\ell^j}{j!}, \qquad v_\ell(j!) \le j.$$

The resulting map of the divided-power envelope extends by ℓ-adic completion, giving $A_{\mathrm{cris}} \subset A_{\max}$. Conversely Frobenius sends the generator ξ_0/ℓ into A_{cris}:

$$\frac{\varphi(\xi_0)}{\ell} = \frac{(\xi_0 + \ell)^\ell - \ell}{\ell} = (\ell - 1)!\, \xi_0^{[\ell]} + \sum_{j=1}^{\ell-1} \binom{\ell}{j} \ell^{\ell-j-1} \xi_0^j + \ell^{\ell-1} - 1.$$

All coefficients are integral. Frobenius is continuous and preserves A_{inf}, so it extends from $A_{\max}$ into A_{cris}. Inverting ℓ and the Tate period, whose Frobenius is ℓ times itself, yields

$$\varphi(B_{\max}) \subset B_{\mathrm{cris}} \subset B_{\max}. \tag{1}$$

These maps commute with Galois and Frobenius fixes $\mathbb{Q}_\ell$.

For (2), if $1 \otimes c(g) = gy - y$ in $B_{\max} \otimes W$, applying $\varphi \otimes 1$ gives the same identity with witness $(\varphi \otimes 1)y$ in $B_{\mathrm{cris}} \otimes W$. The reverse implication is the second inclusion of (1).

To prove continuity in (1) of the statement, choose finitely many potentially crystalline periods spanning $B_{\max} \otimes L$, and intersect the finitely many open subgroups on which they are fixed. For a rational basis e_i of V, write $e_i = \sum_j b_{ij} v_j$ in those periods. On the resulting open subgroup, $ge_i = \sum_j g(b_{ij}) v_j$. The coefficients of the latter expression in the rational basis are continuous functions into $B_{\max}$, and belong to $\mathbb{Q}_\ell$. The usual topology of $B_{\max}$ induces the ℓ-adic topology on $\mathbb{Q}_\ell$; hence the representation matrices are continuous. The finitely many cosets give continuity on the full group. A crystalline cocycle has a period witness, and the same calculation, now using the continuous action just proved, shows that $gy - y$ and thus $c(g)$ are continuous. No basis of $B_{\max} \otimes V$ needs to be extracted from the chosen generators.

Applying φ to all coefficients and periods in the spanning expressions shows that the $\varphi(v_j)$ span $B_{\mathrm{cris}} \otimes V$ and are fixed on that open subgroup. Thus V is crystalline over its finite fixed field. It is de Rham there because $B_{\mathrm{cris}} \subset B_{\mathrm{dR}}$. It is de Rham over K_ℓ as well: enlarge that field extension to a finite Galois extension, take its finite-dimensional de Rham period space, and descend its semilinear action by ordinary Galois descent. The invariants have the same dimension over K_ℓ as the original space over the extension. This proves (1).

For (3), local Tate finiteness Theorem A.3.1 supplies the finite-cohomology hypotheses of Theorem A.3.2, so $H^1(G_{K_\ell}, L)$ is a finitely generated $\mathcal{O}$-module. Continuous coboundaries form a quotient of L; therefore the continuous cocycle module, and its submodule $Z_f(L)$, are finitely generated. The latter is torsion free as a module of functions into L, hence free over the discrete valuation ring $\mathcal{O}$.

Every continuous rational cocycle has bounded image, by compactness of G_{K_ℓ}. Scaling it and its period witness by a power of ℓ puts it in $Z_f(L)$. This proves the rationalization assertion. Its quotient by the rational coboundaries is $H^1_f(K_\ell, V)$, by (2). The rational coboundaries have dimension $\dim V - \dim H^0(K_\ell, V)$. The formula of Theorem A.3.6 therefore gives

$$\dim_{\mathbb{Q}_\ell} Z_f(V) = \dim_{\mathbb{Q}_\ell} V + \dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(V)/\mathrm{Fil}^0.$$

This is the asserted rank formula. Finally $D_{\mathrm{dR}}(V)$ has dimension $\dim_{\mathbb{Q}_\ell} V$ over K_ℓ; its quotient has $\mathbb{Q}_\ell$-dimension at most $n_v \dim_{\mathbb{Q}_\ell} V$. Divide by n_{c} and use $n_v \geq 1$. □

Lemma 7.4.7. *Let F be a number field, ℓ a prime, v a place of F above ℓ, $D \subseteq G_F$ a decomposition group at v, and $n_v = [F_v : \mathbb{Q}_\ell]$. Let K be a finite extension of $\mathbb{Q}_\ell$ with ring of integers $\mathcal{O}$ and uniformiser ϖ, W a K-vector space of finite dimension d with a continuous K-linear action of D which is de Rham as a $\mathbb{Q}_\ell$-representation, $\Lambda \subset W$ a D-stable $\mathcal{O}$-lattice,* $\mathrm{Cs} = W/\Lambda$, $H = H^1(D, \mathrm{Cs})$ *and* $F' = H^1_f(D, \mathrm{Cs})$, *the image of $H^1_f(D, W)$ under $H^1(D, W) \to H$. Put*

$$d^0(W) = \dim_K \mathrm{Fil}^0 D_{\mathrm{dR}}(W), \qquad D_{\mathrm{dR}}(W) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} W)^D,$$

K acting through W. Let $W' = \mathrm{Hom}_{\mathbb{Q}_\ell}(W, \mathbb{Q}_\ell(1))$ and $\Lambda' = \mathrm{Hom}_{\mathbb{Z}_\ell}(\Lambda, \mathbb{Z}_\ell(1))$, with D acting by $(gf)(w) = g\, f(g^{-1}w)$ and $\mathcal{O}$ by $(\alpha f)(w) = f(\alpha w)$, and $A' = W'/\Lambda'$. For an integer $a \geq 0$ let $Y_a = \{z \in H : \varpi^a z \in F'\}$. Then:

1. $\mathrm{nl}(Y_a/F') = \dfrac{a}{e_{\mathcal{O}}}\, d^0(W) + \mathrm{nl}\big(H^2(D, \Lambda/\varpi^a\Lambda)\big)$;

2. $\mathrm{nl}\big(H^2(D,\Lambda/\varpi^a\Lambda)\big) = \mathrm{nl}\big(H^0(D,A')[\varpi^a]\big) \le \mathrm{nl}\big(H^0(D,A')\big)$, *and* $H^0(D,A')$ *is finite if* $H^0(D,W')=0$;

3. $d^0(W) \le n_v\, d$; *and if* K *contains* $\tau(F_v)$ *for every* $\mathbb{Q}_\ell$*-embedding* τ *of* F_v *into* $\overline{\mathbb{Q}}_\ell$, *then* $d^0(W) = \sum_\tau \sum_{a\ge 0} \dim_K\big(\mathrm{Fil}^a D_{\mathrm{dR},\tau}(W)/\mathrm{Fil}^{a+1} D_{\mathrm{dR},\tau}(W)\big)$, *the number of Hodge jumps* $a\ge 0$ *of* W *counted with multiplicity over all* τ.

Proof. **Step 0: two facts on torsion modules.** (i) A torsion $\mathcal{O}$-module X with $X[\varpi]$ finite is isomorphic to $(K/\mathcal{O})^c \oplus X_0$ with X_0 finite (dual form of the structure theorem for finitely generated $\mathcal{O}$-modules); c is the *corank* of X, and it is the corank of any divisible submodule X_1 with X/X_1 finite (the image of X_1 in $X/(K/\mathcal{O})^c \cong X_0$ is divisible and finite, hence 0, so $X_1 \subseteq (K/\mathcal{O})^c$ with finite divisible quotient, hence $X_1 = (K/\mathcal{O})^c$). Every $\mathcal{O}$-submodule of $\mathrm{Cs} \cong (K/\mathcal{O})^d$ satisfies the hypothesis. (ii) For such X and $a \ge 0$,

$$\operatorname{length} X[\varpi^a] - \operatorname{length} X/\varpi^a X = a\, c,$$

because on $(K/\mathcal{O})^c$ multiplication by ϖ^a is onto with kernel of length ac, and on the finite X_0 its kernel and cokernel have equal length.

Step 1: $F' \cong (K/\mathcal{O})^{c_f}$ **with** $c_f = \dim_K H^1_f(D,W)$**.** The long exact sequence of $0\to\Lambda\to W\to \mathrm{Cs}\to 0$ (a set-theoretic section of $W\to\mathrm{Cs}$ is continuous, Cs being discrete) shows that the kernel of $H^1_f(D,W)\to H$ is $L = \iota(H^1(D,\Lambda))\cap H^1_f(D,W)$, $\iota\colon H^1(D,\Lambda)\to H^1(D,W)$. By Theorem A.3.2, $H^1(D,\Lambda)$ is finitely generated, so L is finitely generated, and torsion-free as a submodule of a K-vector space, hence free. L spans $H^1_f(D,W)$: if $x=[c]\in H^1_f(D,W)$, the image $c(D)$ of the compact group D is compact, hence contained in $\varpi^{-s}\Lambda$ for some s (the open sets $\varpi^{-s}\Lambda$ increase and cover W), so $\varpi^s c$ is a continuous cocycle with values in Λ and $\varpi^s x\in L$ ($H^1_f(D,W)$ is a K-subspace). Thus L is a lattice in $H^1_f(D,W)$ and $F'\cong H^1_f(D,W)/L \cong (K/\mathcal{O})^{c_f}$. In particular F' is divisible and $\operatorname{length} F'[\varpi^a] = a\, c_f$.

Step 2: $X = H^0(D,\mathrm{Cs})$ **has corank** $h^0 = \dim_K H^0(D,W)$**.** In $0\to H^0(D,\Lambda)\to H^0(D,W)\to X \xrightarrow{\partial} H^1(D,\Lambda)$, $H^0(D,\Lambda)=\Lambda\cap H^0(D,W)$ is a lattice in $H^0(D,W)$ (finitely generated as a submodule of Λ; it spans, since $\varpi^s w\in\Lambda$ for $w\in W$ and large s), so the image of $H^0(D,W)$ in X is $\cong (K/\mathcal{O})^{h^0}$. The image of ∂ consists of torsion elements of the finitely generated module $H^1(D,\Lambda)$ (Theorem A.3.2), so it is finite. By Step 0(i), X has corank h^0.

Step 3: the length of Y_a/F'**.** Since F' is divisible, $Y_a = H[\varpi^a]+F'$: if $\varpi^a z=\varpi^a f'$ with $f'\in F'$, then $z-f'\in H[\varpi^a]$. Hence $Y_a/F' \cong H[\varpi^a]/(H[\varpi^a]\cap F') = H[\varpi^a]/F'[\varpi^a]$, and by Step 1

$$\operatorname{length}(Y_a/F') = \operatorname{length} H[\varpi^a] - a\, c_f.$$

Let $M = \mathrm{Cs}[\varpi^a] = \varpi^{-a}\Lambda/\Lambda \cong \Lambda/\varpi^a\Lambda$, a finite $\mathcal{O}$-module of length ad killed by ℓ^r, $r=\lceil a/e_{\mathcal{O}}\rceil$. The sequence $0\to M\to \mathrm{Cs}\xrightarrow{\varpi^a}\mathrm{Cs}\to 0$ is exact (Cs is divisible) and gives the exact sequence

$$0\to X/\varpi^a X\to H^1(D,M)\to H[\varpi^a]\to 0,$$

and $H^0(D,M)=X[\varpi^a]$. By Theorem A.3.1(4),

$$\operatorname{length} H^1(D,M) = \operatorname{length} H^0(D,M) + \operatorname{length} H^2(D,M) + n_v\, a\, d.$$

With Step 0(ii) and Step 2,

$$\begin{aligned}\operatorname{length} H[\varpi^a] &= \big(\operatorname{length} X[\varpi^a] - \operatorname{length} X/\varpi^a X\big) + \operatorname{length} H^2(D,M) + n_v ad\\ &= a\, h^0 + \operatorname{length} H^2(D,M) + n_v ad,\end{aligned}$$

so $\mathrm{length}(Y_a/F') = a\,(h^0 + n_v d - c_f) + \mathrm{length}\, H^2(D, M)$.

Step 4: the dimension count. W is de Rham as a $\mathbb{Q}_\ell$-representation, so by Theorem 7.4.8

$$\dim_{\mathbb{Q}_\ell} H^1_f(D, W) = \dim_{\mathbb{Q}_\ell} H^0(D, W) + \dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(W) - \dim_{\mathbb{Q}_\ell} \mathrm{Fil}^0 D_{\mathrm{dR}}(W).$$

All four spaces are K-vector spaces (K acts through W, commuting with D and preserving $\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes W$, and Definition 7.1.16 defines H^1_f by a K-linear condition), so we may divide by $[K : \mathbb{Q}_\ell]$. Being de Rham, $\dim_{F_v} D_{\mathrm{dR}}(W) = \dim_{\mathbb{Q}_\ell} W = d[K : \mathbb{Q}_\ell]$ ($B^D_{\mathrm{dR}} = F_v$), so $\dim_K D_{\mathrm{dR}}(W) = n_v d$. Hence $c_f = h^0 + n_v d - d^0(W)$, and Step 3 gives $\mathrm{length}(Y_a/F') = a\, d^0(W) + \mathrm{length}\, H^2(D, M)$. Dividing by $e_{\mathcal{O}}$ gives item 1.

Item 2. By Theorem A.3.1(2) with $i = 2$, $\#H^2(D, M) = \#H^0(D, M^\vee)$. Since Λ is free over $\mathbb{Z}_\ell$, $\mathrm{Hom}_{\mathbb{Z}_\ell}(\Lambda, \mathbb{Q}_\ell/\mathbb{Z}_\ell(1)) = W'/\Lambda' = A'$, and $M^\vee = \mathrm{Hom}(\Lambda/\varpi^a\Lambda, \mu_{\ell^r})$ is the submodule of homomorphisms vanishing on $\varpi^a\Lambda$, i.e. $A'[\varpi^a]$ for the $\mathcal{O}$-structure of the statement; the identification is D-equivariant. So $H^0(D, M^\vee) = H^0(D, A')[\varpi^a]$; both $H^2(D, M)$ and this group are finite $\mathcal{O}$-modules ($M^\vee$ is an $\mathcal{O}$-module through M), and equal orders give equal lengths. If $H^0(D, W') = 0$, the sequence $0 = H^0(D, W') \to H^0(D, A') \xrightarrow{\partial} H^1(D, \Lambda')$ of $0 \to \Lambda' \to W' \to A' \to 0$ embeds the torsion module $H^0(D, A')$ into the torsion of $H^1(D, \Lambda')$, which is finite by Theorem A.3.2 (Λ' is a finitely generated $\mathcal{O}$-module with continuous action).

Item 3. $d^0(W) \le \dim_K D_{\mathrm{dR}}(W) = n_v d$ (Step 4). If K contains every $\tau(F_v)$, then $F_v \otimes_{\mathbb{Q}_\ell} K \cong \prod_\tau K$ ($F_v/\mathbb{Q}_\ell$ is separable), with idempotents e_τ; $D_{\mathrm{dR}}(W)$ and each $\mathrm{Fil}^a D_{\mathrm{dR}}(W)$ are $F_v \otimes K$-modules, so $\mathrm{Fil}^a D_{\mathrm{dR}}(W) = \bigoplus_\tau e_\tau \mathrm{Fil}^a D_{\mathrm{dR}}(W)$ and $e_\tau \mathrm{Fil}^a D_{\mathrm{dR}}(W) = \mathrm{Fil}^a D_{\mathrm{dR},\tau}(W)$. The filtration of the finite-dimensional space $D_{\mathrm{dR},\tau}(W)$ is decreasing, with $\mathrm{Fil}^a = 0$ for large a (as $\bigcap_a t^a B^+_{\mathrm{dR}} = 0$), so $\dim_K \mathrm{Fil}^0 D_{\mathrm{dR},\tau}(W) = \sum_{a \ge 0} \dim_K(\mathrm{Fil}^a/\mathrm{Fil}^{a+1})$, and summing over τ gives the formula. □

Theorem 7.4.8. *Let p be a prime, K a finite extension of $\mathbb{Q}_p$ and V a finite-dimensional continuous $\mathbb{Q}_p$-linear representation of G_K which is de Rham. Put $D_{\mathrm{dR}}(V) = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K}$ and $\mathrm{Fil}^0 D_{\mathrm{dR}}(V) = D_{\mathrm{dR}}(V) \cap (\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)$. Then*

$$\dim_{\mathbb{Q}_p} H^1_f(G_K, V) = \dim_{\mathbb{Q}_p} H^0(G_K, V) + \dim_{\mathbb{Q}_p}(D_{\mathrm{dR}}(V)/\mathrm{Fil}^0 D_{\mathrm{dR}}(V)).$$

Proof. Apply Theorem A.3.6 with $\ell = p$, $M = K$ and the given V. Its hypotheses hold: $K/\mathbb{Q}_p$ is finite and V is finite-dimensional, continuous and de Rham.

The two descriptions of the filtration agree inside $B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V$. Indeed $\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V$ is a G_K-stable subspace, and for every stable subspace U of a representation W one has $U^{G_K} = U \cap W^{G_K}$: membership in either side says precisely that the vector lies in U and is fixed by every element of G_K. Thus

$$(\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K} = (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V)^{G_K} \cap (\mathrm{Fil}^0 B_{\mathrm{dR}} \otimes_{\mathbb{Q}_p} V) = \mathrm{Fil}^0 D_{\mathrm{dR}}(V).$$

The local finite condition is the same kernel in both statements: a cocycle class maps to zero after tensoring with B_{cris} exactly when it has a coboundary witness there, as in Definition 7.1.16. The invariant space $H^0(G_K, V)$ is unchanged. Consequently the dimension formula of Theorem A.3.6, with all dimensions over $\mathbb{Q}_p$, is the displayed formula after interchanging its two summands.

□

Proposition 7.4.9. *Let D be admissible data, ℓ a prime, $\iota \mid \ell$ a prime identification, w_0 a chosen place not above ℓ and g_0 a tame generator at w_0.*

1. *For every ramified critical pair p and every $s \in \{\pm 1\}$ there is a Stickelberger system Y for $(S_\ell^{\mathrm{bad}}, g_0)$ such that for every twist ξ whose modulus Q is auxiliary for S_ℓ^{bad} and whose inverse avatar ψ_ξ comes from* $\mathrm{U}(1)$ *with modulus Q, and every $b \in [0,\infty]$:*

$$v_\ell(\psi_\xi(\Theta_Q)) \le \beta_Y + b \implies v_\ell(\iota(r_p(\xi,s))) \le 4\, v_\ell(\mathrm{N}w_0 - 1) + b.$$

2. *Every character $\psi\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ that comes from* $\mathrm{U}(1)$ *with a modulus Q auxiliary for S_ℓ^{bad} is the inverse avatar of a tame character with modulus Q.*

Proof. We construct the required normalized measures. At critical integer $z = 1$ use the literal rank-two measure of Lemma 7.4.10; its Euler exponents are $\{0,1\}$, and its ratio exponent is two.

Suppose $z \ge 2$, put $n = 2z$, $j = \sum_\tau (c_\tau - z)$ and

$$n_\nu = M^{4fz}(Md)^j, \qquad C = N_{\mathrm{ch}}^3 \det(G_\kappa) n_\nu^2, \qquad F(\xi) = C\,\mathrm{alg}_p(\xi). \tag{A}$$

The positive integer C depends on p and D, not on ξ or Q. Here κ is the fixed one-row weight of these L-value data. The matrix $G_\kappa = F_\kappa^{\mathsf{T}} F_\kappa$ is a positive-definite integer matrix, since the filling matrix contains the standard-basis rows. Thus its determinant is a positive integer. We prove directly that (A) is an integral finite-character measure, retaining every stabilizer weight.

For a fixed declared modulus Q, expand the source class sum and its finite residue data. Choose source-line classes indexed by a and target classes indexed by t, at their actual levels, and include the finitely many twist-residue indices in a. They are independent of ξ among characters with this declared modulus. In the kernel, replace ξ by the weight-zero trivial character with this same modulus; write $K_a(t)$ for the resulting OL4-normalized point kernel, and u_a for its source norm-one point, including its residue translate. The determinant factor in (WR4) and the residue-character expansion isolate all the character dependence:

$$\varphi_{p,\xi}(t) = \sum_a \gamma_a^{-1} \xi(u_a)^{-1} K_a(t), \qquad \gamma_a = |\Gamma_a|. \tag{B}$$

This is an expansion of the original datum, not an integration over a refined source level: write its multiplicative residue character as the sum of its values times the residue indicators; a compact lift moves each indicator to the base indicator. Covariance then moves that lift to the point and contributes exactly the character value in (B). Every sum is finite, and no inverse cardinality is introduced by this indicator expansion.

Let γ_t be the original target-class stabilizer. Expanding the Petersson norm in (OL4) gives

$$\mathrm{alg}_p(\xi) = \sum_{a,b,t} \frac{\langle K_b(t), K_a(t)\rangle_\kappa}{(\mathrm{N}Q)^{2z-1}\gamma_a\gamma_b\gamma_t}\, \xi(u_b u_a^{-1}). \tag{C}$$

The coefficients and points in (C) precede ξ. The maximal-level class sets are finite by Lemma 4.6.4; the actual levels are finite-index residue refinements, so their class sets remain finite. Every one of the three stabilizer orders divides N_{ch}, by Lemma 6.7.9. Indeed apply that lemma to the same class representative and its actual open level subgroup $K' \subset K_0(m)$, with $m = 1$ on the source and $m = 2z$ on the target. These are standard definite spaces, so the E-matrix points are precisely the rational points of the indicated unitary group over E^+. A critical pair has $z \le t_D$, and admissibility gives $r_D \ge 3$, hence $1 \le m \le 2t_D \le r_D t_D$. The residue refinements only shrink K' and do not replace the class representative. Thus the lemma applies separately to γ_a, γ_b, γ_t. Its auxiliary odd reduction prime is independent of the coefficient prime ℓ; in particular this argument includes $\ell = 2$.

We establish the needed point-kernel integrality with the exact OL4 scale. Let $\ell \nmid \mathrm{N}Q$ and fix any identification ι. Move each target representative and each source-line representative rationally to be integral above ℓ. Indeed apply Lemma 4.2.64 separately to the actual standard target space I_n and source line I_1, with the finite set of all places of E above ℓ. Its auxiliary finite factor is 1 at these places, so the rational unitary components are dense there. The local inverses of the representatives lie in the nonempty open sets of movers making the translated representatives integral with integral inverse. Density gives the required rational movers. The DP covariance is an exact unitary change of coordinates on the Weyl module, so it preserves the Gram pairing in (C). On the source line the form being lifted has weight zero, so its rational move introduces no extra coefficient. Movers can depend on ℓ, ι, but the original points and the Gram coefficient in (C) are unchanged.

We now check preservation of the precise finite span to which the theta estimate applies. Put $\mathcal{O}_\iota = \{c : |\iota(c)|_\ell \le 1\}$ and let

$$\mathcal{V}_{M,\iota} = \mathrm{span}_{\mathcal{O}_\iota}\{\rho(f_v(x))c_s^n v_0 : \ Mx_w \in \mathcal{O}_{E_w}^n \text{ for every } w \mid \ell\}. \tag{E}$$

There is no restriction on x away from ℓ. This is the actual finite Heisenberg span of Proposition 4.2.35, in the scaled coordinates of Lemma 4.1.3; it is not a lattice selected from a complex isomorphism.

First the finite datum in (OL4), multiplied by $M^{2fn} = M^{4fz}$, belongs to (E). To see this, use the self-dual integral polarization and the actual coefficient transform of Lemma 4.1.3(1)–(4). An indicator of a residue class modulo $\mathfrak{m}$ is

$$\mathbf{1}_{b+\mathfrak{m}}(v) = \frac{1}{|\mathcal{O}_E/\mathfrak{m}|} \sum_{\chi \in (\mathcal{O}_E/\mathfrak{m})^\vee} \chi(v-b).$$

Here $v \in \mathcal{O}_E$; both sides are extended by zero off the integral position lattice. Apply this in each of the n coordinates, with the unchanged vacuum off the finitely many indicated places. Self-duality identifies its additive characters with frequencies in $\mathfrak{m}^{-1}$ times the dual integral lattice. Here $\mathfrak{m}$ divides $(M\mathrm{N}Q)$ and $\ell \nmid \mathrm{N}Q$, so at every $w \mid \ell$ these frequencies are M-integral. The ℓ-part of the Fourier denominator divides the ℓ-part of $|\mathcal{O}_E/(M)|^n = M^{2fn}$. All character coefficients are roots of unity. Thus this multiplier clears every denominator in $\mathcal{O}_\iota$. In the polarized realization these characters times the integral indicator are exactly the Heisenberg translates in Lemma 4.1.3(2); a pure dual-polarization translate has no extra quadratic term. Any phase from another permitted realization is a root of unity and hence a unit. The multiplicative residue-character expansion used in (B) adds only root-of-unity coefficients and integral residue lifts. This proves the assertion for the actual finite datum, with its specified factor c_s^n.

Next let (g, h) be one of the integral-at-ℓ pair points obtained above, including a residue lift. On the Hom coordinates its linear transformation is the actual map induced by g, h; denote it by G. Both G and G^{-1} preserve the standard local lattice at every $w \mid \ell$. The scaled coordinates multiply by a scalar and therefore have the same property. The product-coordinate identification in Proposition 4.1.14 identifies this finite pair action with the normalized operator of Lemma 4.1.13, with its specified determinant-character factors. This is the same realization as Lemma 4.1.3, not an abstract equivalent representation. Write L for its standard finite lattice,

$$J = L \cap G^{-1}L, \qquad I = [L : J].$$

At $w \mid \ell$ one has $J_w = L_w$, so I is prime to ℓ. Representatives of L/J may be chosen with component zero at every such w. The finite-vacuum formula and covariance in Lemma 4.1.13 give, for a generator in (E),

$$\Omega(G)\rho(f_v(x))c_s^n v_0 = \frac{\Delta(G)}{I} \sum_{y \in L/J} \epsilon_y \, \rho(f_v(Gx + Gy))c_s^n v_0, \tag{F}$$

where the ϵ_y include precisely the Heisenberg multiplication phases. They are roots of unity. Every $Gx + Gy$ in this formula remains M-integral above ℓ.

We check the scalar in (F), including the pair-character factors. In the definition of $\Delta(G)$ choose the lattice matrix carrying L onto J to be integral with integral inverse above ℓ; this is possible since $J_w = L_w$ there. Its determinant is a unit above ℓ. The finite absolute-value factors of this determinant involve only rational primes different from ℓ, and are ℓ-adic units, also for their square roots. The algebraic Hecke-character factors at an idele integral and invertible above ℓ are units as well. Here is the elementary reason. Raise its fractional ideal to the order of its ideal class and write the resulting idele as a principal idele times a finite integral unit idele. The principal generator is a unit at every place above ℓ. Its algebraic infinity-type value, at any identification above ℓ, is a product of integral powers of the images of this generator and its conjugates, hence is a unit. The value on the compact finite unit group is of finite order, since the character is smooth there, hence is a root of unity. Taking the positive power back preserves valuation zero. If the normalization has half-integral weights, first square it to clear those weights and use the same argument. This proves the assertion for the character in $\Delta(G)$ and for both prescribed determinant twists of the pair action. Since I is also a unit, every coefficient in (F) lies in $\mathcal{O}_\iota^\times$. Consequently the actual finite pair operator preserves (E).

For completeness, the residue substitution in this application is the one in Lemma 4.1.16: its integral pair action sends the residue function to the function obtained by the indicated left and right changes of variables and multiplies it by the two determinant characters. These are exactly the integral residue lifts and unit factors just checked, so no projection average or extra denominator is hidden in (F). The same lemma and the product compatibility of Proposition 4.1.14 leave the real Fock vector unchanged under this finite action. We have therefore proved preservation of the actual finite span with the actual real polynomial, in Hom rank n, rather than inferring it from unitarity. At $\ell = 2$ no division by 2 has been made in the coefficient ring: the phases in the exact Heisenberg formula, including its quadratic phases, are roots of unity and are still units. The Fourier denominator is the only denominator cleared by M^{4fz}.

Apply Proposition 4.2.35 with $\zeta_{\mathrm{sc}} = \pi_M$ to the integral polynomial tested in (OL2), namely the integer polynomial obtained from $\mathrm{Pol}_\kappa(e_i)$ under the integral theta substitution. Its degree is exactly j. The germ identity Lemma 4.2.2 gives the same factor $c_s^{2z}(\pi_M\eta_P)^j$ as (OL4), and the estimate is

$$\left|\iota\big(M^{4fz}\, e_i^{\mathsf{T}} G_\kappa K_a(t)\big)\right|_\ell \le |\iota(\pi_M/(Md))|_\ell^j .$$

The element π_M is an algebraic integer. Multiplying by $(Md)^j$ proves that every coordinate of

$$A_a = n_\nu G_\kappa K_a(t)$$

is integral at this identification. The assertion holds at every identification, including $\iota \circ \mathrm{conj}$. It follows that

$$\det(G_\kappa) n_\nu^2 \langle K_b(t), K_a(t)\rangle_\kappa = \overline{A_b}^{\mathsf{T}} \operatorname{adj}(G_\kappa) A_a$$

is integral. The remaining denominator $(\mathrm{N}Q)^{2z-1}$ is an ℓ-adic unit, and $N_{\mathrm{ch}}^3/(\gamma_a\gamma_b\gamma_t)$ is an integer. Multiplying (C) by C therefore proves the simultaneous all-prime integral finite expansion for (A). No assertion about integrality of arbitrary coherent coefficients, or of the scalar c_s itself, was used.

The scale in (OL4) is nonzero by Proposition 4.2.1 and Lemma 4.2.3. Hence Proposition 6.7.13 applies at every tame character, and gives $F(1) > 0$ and

$$F(\xi)/F(1) = r_p(\xi). \tag{D}$$

The same proposition identifies $\mathrm{alg}_p(\xi)$ with one fixed nonzero multiple of the partial L-value. On adding an unramified split place of norm q, deleting the two local Euler factors therefore multiplies it by

$$(1 - yq^{-z})(1 - y^{-1}q^{-z}), \qquad y = (\nu\xi)(\varpi_v/\bar{\varpi}_v).$$

The second coefficient is y^{-1} because the base-change character is anti-conjugate. The finite Euler deletion is valid in the absolutely convergent region $z \geq 2$. It applies even when the character has smaller conductor than its declared modulus. This proves all the required measure properties in the higher-integer case.

We now pass from either of these actual measures to the system. For the resulting measure put $K = \{0, 1\}$ and $d_{\mathrm{rat}} = 2$ if $z = 1$, and $K = \{z\}$ and $d_{\mathrm{rat}} = 1$ otherwise. Fix the sign s. For an auxiliary modulus Q, choose the finite expansion of F for all tame characters with declared modulus Q, including characters with smaller conductor. A weight-zero character is trivial on the archimedean norm-one group, so $t(u_a)$ depends only on the finite class of u_a in Cl_Q. Define

$$\Theta_Q = \sum_a \iota(b_a)[u_a]_Q^{-s}.$$

Since $\ell \nmid \mathrm{N}Q$, all its coefficients are integral at ℓ. The inverse-avatar convention gives

$$\psi_\xi(\Theta_Q) = \iota F(\xi^s). \tag{1}$$

This identity holds for every character of declared modulus Q, whether or not its conductor is all of Q. At nonauxiliary moduli set $\Theta_Q = 0$; every transition required in (SK) has both its moduli auxiliary.

Let ϑ be the geometric avatar of the base change of ν^{-s}. The local avatar formula shows that it is unramified off S_ℓ^{bad}. On g_0 its value is the ramified residue-character value, or its inverse. It is therefore different from 1 and its order divides $L = \mathrm{N}w_0 - 1$. At an auxiliary arithmetic Frobenius φ the same formula yields

$$\vartheta(\varphi)\psi_\xi(\varphi) = \iota\big((\nu\xi^s)(\varpi_P/\bar{\varpi}_P)^s\big).$$

The product over the two signs is unchanged by raising this value to s. Apply the Euler relation for F to (1), using the character ξ with its enlarged declared modulus. This proves exactly the required norm relation, with exponent list K. Moreover

$$1(\Theta_\emptyset) = \iota F(1) \neq 0.$$

Thus these data form the required Stickelberger system.

Write $\zeta = \vartheta(g_0)$. Since $\zeta \neq 1$ and $\zeta^L = 1$, the equality $\sum_{i=0}^{L-1} \zeta^i = 0$ shows that $L = \sum_{i=0}^{L-1}(1 - \zeta^i)$ is divisible by $1 - \zeta$ in the ring of integers of the coefficient field. Hence

$$v_\ell(\zeta - 1) \leq v_\ell(L), \qquad \beta_Y \leq v_\ell(\iota F(1)) + 4v_\ell(L). \tag{2}$$

For a twist ξ, its power ξ^s is again a twist. The asserted value of F and the fact that $\mathrm{N}Q$ is an ℓ-adic unit give

$$|\psi_\xi(\Theta_Q)|_\ell = |\iota F(1)|_\ell \, |\iota r_p(\xi, s)|_\ell^{d_{\mathrm{rat}}}. \tag{3}$$

If $|\iota r_p(\xi, s)|_\ell \geq 1$, its nonnegative truncated valuation is zero. Otherwise $\iota F(1)$ is integral, so (3) gives additivity for those nonnegative valuations:

$$v_\ell(\psi_\xi(\Theta_Q)) = v_\ell(\iota F(1)) + d_{\mathrm{rat}}\, v_\ell(\iota r_p(\xi, s)).$$

As $d_{\mathrm{rat}} \geq 1$, (2) and the hypothesis imply the asserted bound. This argument also covers an infinite value of the ratio valuation; for finite b it would contradict the finite bound, and for $b = \infty$ the conclusion is immediate.

Finally let ψ be a character from $\mathrm{U}(1)$ of modulus Q. By its defining descent it is a character of Cl_Q. Invert it according to the inverse-avatar reciprocity convention, pull it back to the finite adelic norm-one group, and extend trivially on its archimedean factor. Rational invariance follows from the quotient by $\mathrm{U}(1)(E)$. The resulting automorphic character has weight zero; its local characters are trivial outside Q and on the principal units at Q. It is therefore a tame character of modulus Q, and its inverse avatar is ψ. This proves the second assertion. □

Lemma 7.4.10. *Let $p = (\nu, 1)$ be a ramified critical pair, of weight $-c_\tau$. Put $B = 2\sum_{\tau\in\Phi}(c_\tau - 1)$ and*

$$N = M^{16f} c_s^4 (M^2 d\eta_P)^B \neq 0.$$

For a tame character ξ with declared modulus Q, put $\alpha_\xi = \nu\xi\upsilon$, let $\mathfrak{m}_Q$ have exponent two at the chosen places and exponent one at Q, and let χ_ξ be the character modulo $\mathfrak{m}_Q$ formed from the tame part of $\nu\xi$. Let $P(Z) = \prod_\tau \det(Z_\tau)^{c_\tau - 1}$, and let

$$\Lambda_\xi = \sum_{h \bmod \mathbf{K}_2}^{\mathrm{cl}} \theta^{I_2, I_2}_{\alpha_\xi, \alpha_\xi; \mathfrak{m}_Q}[\chi_\xi \circ \det, P](1, h), \qquad F(\xi) = |N_{\mathrm{ch}} N \Lambda_\xi|^2.$$

Then:

1. *$F(1) \neq 0$. For every declared modulus Q there are finitely many norm-one finite adelic points u_a and coefficients $b_a \in \mathbb{C}$, all chosen before ξ, such that*

$$F(\xi) = \sum_a b_a \xi(u_a)$$

   for every tame character with declared modulus Q. Every b_a is integral under every prime identification at every rational prime not dividing $\mathrm{N}Q$.

2. *If ξ' is the same automorphic character and tame part as ξ, with declared modulus $Q \cup \{v\}$, where $v \notin Q$ and this enlarged modulus is conjugate-disjoint from the chosen places and their conjugates, then, writing $q = \mathrm{N}v$ and $y = (\nu\xi)(\varpi_v/\bar{\varpi}_v)$,*

$$F(\xi') = F(\xi) \prod_{\epsilon = \pm 1} (1 - y^\epsilon)(1 - y^\epsilon/q).$$

3. *For every genuine twist ξ,*

$$F(\xi) = F(1)\, \mathrm{N}Q\, r_p(\xi)^2.$$

The last assertion is not imposed on tame characters whose actual conductor is smaller than their declared modulus.

Proof. Put $\delta = M^2$. We use the same theta functional and finite coordinates throughout.

We first prove the uniform clearing assertion needed for the finite class expansion. The underlying positive Hom space has rank four. Finite Fourier inversion modulo $\mathfrak{m}$ writes its residue datum as a sum of finite Heisenberg translates of the vacuum, with coefficients equal to residue values times roots of unity divided by $\mathrm{Norm}(\mathfrak{m})^4$. This is the ordinary character orthogonality formula on the additive residue group; the self-duality and phase convention are precisely those of Lemma 4.1.3. If $q = \mathrm{N}Q$, then $(q\delta) \subseteq \mathfrak{m}_Q$, so

$$\mathrm{Norm}(\mathfrak{m}_Q)^4 \mid (q\delta)^{8f}.$$

At a rational prime $\ell \nmid q$, multiplication by δ^{8f} therefore clears the Fourier denominator. The resulting vectors belong to the integral span of

$$\rho(\mathrm{fv}(x))c_s^4 v^0, \qquad \delta x_w \in \mathcal{O}_{E,w}^4 \quad (w \mid \ell). \tag{1}$$

No integrality of c_s itself is asserted.

Finite pair operators integral above ℓ preserve this module. Indeed the literal finite vacuum formula in Lemma 4.1.13 is

$$\Omega(g)v^0 = \frac{\Delta(g)}{I(g)} \sum_{y \in L/(L \cap g^{-1}L)} H(gy)v^0.$$

When g is integral above ℓ, this finite quotient has no ℓ-part, its representatives may be chosen with zero component above ℓ, and $I(g)$ and $\Delta(g)$ are ℓ-adic units. For $\Delta(g)$ the latter assertion follows from its defining unramified determinant character and norm factor: both local valuation and norm exponent above ℓ vanish. Covariance sends a vector x in (1) to gx, still satisfying (1). The determinant-character factors of the pair operator are also units. To check the algebraic-character valuation, take a finite ideal-class power of the finite idele to make its ideal principal, generated by $a \in E^\times$. Since the original idele is a unit at all places above ℓ, so is a. The principal-idele weight formula expresses that power of the character value as a product of conjugates of a and a finite-unit character value. Every conjugate of a is an ℓ-adic unit at every identification, and finite-unit values are roots of unity. The original character value consequently has valuation zero. These are the literal pair operators by Proposition 4.1.14, so no separately normalized action is being substituted.

Apply Proposition 4.2.35 with $\zeta_{\mathrm{sc}} = \delta d$ to this module and the integral homogeneous polynomial P. Its ordinary degree-B derivative is integral at every prime identification. By Lemma 4.2.2 it is exactly

$$\delta^{8f} c_s^4 (\delta d \eta_P)^B \theta_{\mathrm{Hom}(I_2, I_2)}(v_P \otimes \text{the translated finite datum}).$$

Thus the scalar clearing the actual standard kernel is precisely the stated N. All its factors are nonzero by Proposition 4.2.1 and Lemma 4.2.3. The construction is independent of Q, the point, the prime and the identification.

We explain why this applies to the actual class representatives. The determinant polynomial transforms at infinity by $\prod_\tau \det^{c_\tau - 1}$, which cancels the archimedean factor of α_ξ, of weight $-(c_\tau - 1)$. At the finite standard level its residue character is canceled by $\chi_\xi \circ \det$. The kernel defining the period is therefore rationally invariant and has the original standard right level. For a fixed rational prime ℓ, apply Lemma 4.2.64 to the standard space I_2, with the finite set of all places of E above ℓ. Its auxiliary finite factor is 1 at these places, so the rational unitary components are dense there. For each finite class representative h, the conditions that $\gamma_w h_w$ and its inverse are integral above ℓ form a nonempty open set of possible rational movers, containing the local inverse of h. Choose such a γ. The mover may depend on the prime and identification; rational invariance leaves the original kernel value unchanged. Hence the clearing assertion holds at the fixed representatives.

Apply the stated common supplier Lemma 6.7.9 to $n = 2$, $K' = \mathbf{K}_2 = \mathbf{K}_0(2)$ and each SAME finite class representative h. The rank bound holds because the admissible target rank is a positive integer, $t = 5r$, and thus $1 \le 2 \le rt$. The standard level is an open subgroup of itself. It follows that

$$\Gamma_h = \mathrm{U}(I_2)(F) \cap h\mathbf{K}_2 h^{-1} \quad \text{is finite}, \qquad |\Gamma_h| \mid N_{\mathrm{ch}}.$$

Here the rational unitary matrices are those called $\mathrm{U}(I_2)(E)$ in that supplier; their entries lie in E and their unitary group is the group over F. No change of the class representative or of its original maximal-level stabilizer has been made. The class set is finite by Lemma 4.6.4, and $N_{\mathrm{ch}}/|\Gamma_h|$ is an integer for every one of its original weights.

Fix Q. Expand the residue determinant character as a sum of indicators of invertible residue matrices. Move each indicator to the identity indicator by a lift in the standard compact group. The representation law and the determinant-character factor show that all dependence on ξ is a value $\xi(u_a)$; the remaining kernel has the fixed base character $\nu\upsilon$ and the identity residue datum of this same declared modulus. Thus, over the finite set of original lattice classes and residue matrices,

$$N_{\mathrm{ch}} N\Lambda_\xi = \sum_a d_a \xi(u_a), \qquad d_a = \frac{N_{\mathrm{ch}}}{|\Gamma_a|}\, N\theta_Q(g_a). \tag{2}$$

The representatives, points and coefficients are chosen before ξ. No refinement of the standard class weights is used. The preceding two paragraphs prove that each d_a is integral at every identification away from q. Since ξ is unitary,

$$F(\xi) = \sum_{a,b} d_a \overline{d_b}\, \xi(u_a u_b^{-1}). \tag{3}$$

For a fixed identification ι, apply the same integrality assertion also to $\iota \circ \mathrm{conj}$. This proves integrality of the conjugated coefficient in (3). It proves the finite expansion simultaneously at all identifications.

We prove the Euler relation without requiring full conductor. At a new place v, the old finite datum is the vacuum. For a subspace $U \subseteq k_v^2$ of dimension i, take its transposed basic Hecke representative, and put $X = (qy)^{-1}$. Write g_U for the basic representative, so its reduction has kernel U, and the action uses $h_U = g_U^{\mathsf{T}}$. Its precise position coefficient is

$$(qy)^i\, \mathbf{1}_{Z \text{ integral}}\, \mathbf{1}_{U \subseteq \ker(\bar{Z}^{\mathsf{T}})}.$$

Indeed the split-place formula of Lemma 4.1.16 gives the scalar $q^i y^i$ and the position condition $h_U^{-1} Z$ integral. To check its support, Smith form gives

$$g_U^{-1}\mathcal{O}_v^2 = \{\varpi_v^{-1} u : u \in \mathcal{O}_v^2,\ \bar{u} \in U\}.$$

Consequently $Z^{\mathsf{T}} g_U^{-1}$ is integral if and only if Z is integral and $\bar{Z}^{\mathsf{T}}$ kills U. This is equivalent to the asserted condition on $h_U^{-1} Z$; each individual term is zero outside integral positions. Multiplication by $(-X)^i q^{i(i-1)/2}$ cancels the scalar. Summing over U therefore inserts

$$\sum_{U \subseteq \ker(\bar{Z}^{\mathsf{T}})} (-1)^{\dim U} q^{\binom{\dim U}{2}} = \prod_{j=0}^{\dim \ker(\bar{Z}^{\mathsf{T}})-1} (1 - q^j) = \mathbf{1}_{\det \bar{Z} \neq 0}. \tag{4}$$

For dimension at most two the product formula follows directly: the respective sums are 1, $1-1$, and $1-(q+1)+q$. This is precisely the new residue datum, since its new local character is trivial. Apply the theta functional to this finite vector identity and integrate over the same compact quotient. The total weighted kernel has standard right level, so its integral is its standard class sum. We integrate each translated term before using Haar invariance; an individual translated function is not asserted to have that right level or to have its bare fixed-class sum equal to its integral. Each translated integral equals the original period. There are $1, q+1, 1$ subspaces in the three dimensions, so

$$\Lambda_{\xi'} = (1 - (q+1)X + qX^2)\Lambda_\xi = (1 - X)(1 - qX)\Lambda_\xi.$$

Taking squared complex absolute values and using $|y| = 1$ gives assertion 2.

It remains to prove nonvanishing and the ratio for genuine twists. We use the stated class-sum identity of Proposition 6.3.67; in particular no kernel-calculus assertion is borrowed only from a proof. Here is its complete specialization. Put

$$n = m = a = \{1, 2\}, \qquad l = b = p = \emptyset, \qquad W = I_2, \quad V' = 0, \quad d_{\mathrm{ex}} = 1, \quad |\iota_\tau| = c_\tau - 1.$$

Use the natural bijections $m \sqcup \emptyset \to n$, $\emptyset \sqcup \emptyset \to \emptyset$, $\emptyset \sqcup a \to m$ and $\emptyset \sqcup a \to n$. Then $|a| = |b| + 2d_{\mathrm{ex}} = 2$ and $2|l| + 2 = |n| = 2$, so both numerical hypotheses of that proposition hold. Each $\eta_{\tau k}$ is the unique 0×2 matrix. The defining stacked matrix consists of its two variable rows; hence $\Delta^j(e; \eta) = P$. Both matrices defining the matched polynomial have zero rows and columns, so their determinants, and therefore $Q_{f,j}(\eta)$, are 1.

The fixed index sets and ι give ONE real constant C, chosen before every modulus and automorphic character in Proposition 6.3.67. Fix a genuine twist ξ and specialize that proposition to

$$\mathfrak{m} = \mathfrak{m}_Q, \qquad \alpha = \beta = \alpha_\xi = \nu\xi\upsilon, \qquad \chi = \chi_\xi, \qquad \Phi(X) = \chi_\xi(\det X), \qquad \Psi = 1.$$

Its character weight is $-(c_\tau - 1) = |l| - |\iota_\tau|$, since υ has weight 1. Its tame part is the tame part of $\nu\xi$, since υ has trivial tame part. The chosen places and Q are disjoint, ν is ramified exactly at the chosen places, and a genuine twist has nontrivial tame component at every place of Q. Thus α is tame for the WHOLE declared modulus, as that proposition requires. The functions are matched for (σ, χ_ξ^{-1}): the only matrices in the support of Φ are the invertible 2×2 matrices, every such matrix is k^{-1} for some invertible k, and

$$\Phi(k^{-1}) = \chi_\xi(\det k)^{-1} = \chi_\xi^{-1}(\det k)\Psi(k_b).$$

Here k_b is the unique matrix with zero columns. These statements also verify the zero-extended values off the required supports.

Consequently Proposition 6.3.67 gives γ_ξ with

$$L_\xi \neq 0, \qquad L_\xi|\gamma_\xi|^2 = C, \qquad \gamma_\xi\Lambda_\xi = \int_{[\mathrm{U}(0)]} \theta^{0,I_2}_{1,\alpha_\xi;\mathfrak{m}_Q}[1,1](x,1)\,dx, \quad L_\xi = L_*(\mathfrak{m}_Q, \alpha_\xi^{-1}\upsilon; 1). \quad (5)$$

The right side is literally 1. Indeed $\mathrm{Hom}(0, I_2)$ is zero, its Fock and finite data are the empty tensor 1, and its normalized theta functional has value 1. In (XD2) the only possible character factor is $(\alpha_\xi/\beta)(\det 1) = 1$; the source determinant is the empty determinant 1. The group $\mathrm{U}(0)$ and its rational quotient have one element and measure one, from the empty-product quotient measure of (XD1). There is therefore no unspecified Haar mass or character-dependent normalization on this side.

It follows from (5) that $\gamma_\xi\Lambda_\xi = 1$, so both factors are nonzero. Moreover $\alpha_\xi^{-1}\upsilon = (\nu\xi)^{-1}$ and the set of places of $\mathfrak{m}_Q$ is $S_M \cup Q$. Thus the definition (XD7) gives

$$L_\xi = \Big(\prod_{w \in S_M \cup Q} \mathrm{N}w\Big)|L^{S_M \cup Q}(1, (\nu\xi)^{-1})|^2 > 0.$$

Since $|\gamma_\xi|^2|\Lambda_\xi|^2 = 1$, equation (5) yields

$$C|\Lambda_\xi|^2 = L_\xi. \quad (6)$$

The trivial character with empty Q is a genuine twist, so (5) at $\xi = 1$ also proves $\Lambda_1 \neq 0$ and $C > 0$. Divide (6) by its value at $\xi = 1$. The fixed chosen-place norm product cancels, and the ratio in Definition 4.2.4 is defined with the now nonzero denominator. Therefore

$$\frac{|\Lambda_\xi|^2}{|\Lambda_1|^2} = \mathrm{N}Q\,\frac{|L^{S_M \cup Q}(1, (\nu\xi)^{-1})|^2}{|L^{S_M}(1, \nu^{-1})|^2} = \mathrm{N}Q\, r_p(\xi)^2.$$

Multiplication by the SAME nonzero $|N_{\mathrm{ch}}N|^2$ proves assertion 3 and $F(1) \neq 0$. The full-conductor check above applies only to genuine twists; no such nonvanishing assertion is made for a tame character with an enlarged declared modulus. □

Theorem 7.4.11. *Let ℓ be a prime, S_0 a finite set of finite places of E containing those above ℓ, $g_0 \in G_E$ in an inertia group above a place of S_0 not above ℓ, $\mathcal{O}$ a coefficient ring, $(T_i)_{i\in I}$ finitely many Selmer data for (S_0, g_0) over $\mathcal{O}$ with a torsion level M_0, and $(Y_k)_{k\in\kappa}$ finitely many Stickelberger systems for (S_0, g_0). Let $m \geq 1$ and $\varepsilon > 0$. Then there are a set Q of places, auxiliary for S_0, and a character $\psi\colon G_E \to \overline{\mathbb{Q}}_\ell^\times$ such that ψ^j is an ε-small twist at Q for (T_i), (Y_k) for every $1 \leq j \leq m$.*

Proof. Write $b_i = \mathrm{nl}(\beta_{T_i})$ and $d_k = \beta_{Y_k}$. These are finite by the defining finiteness conditions. Replacing the requested error by $\varepsilon_0 = \min(\varepsilon, 1/2) > 0$ is sufficient, since every inequality defining a small twist is preserved on increasing the allowance.

Apply Proposition 7.4.12 to obtain its integer $s_0 \geq 1$. Choose a rational number $r > 0$ such that

$$s_0 r \leq \varepsilon_0/2.$$

In particular $r < 1$ and $s_0 r < 1$. Put

$$B = \sum_{i\in I}(b_i + 1) + \sum_{k\in\kappa}(d_k + 1).$$

Apply Lemma 7.4.22 with this B, the variable bound s_0, the given m, radius r, and error $\varepsilon_0/2$. Let H be its uniform order bound. Only now choose $N \geq H$ sufficiently large for Proposition 7.4.12, and choose its auxiliary set Q, characters $\lambda_{\mathfrak{q}}$, polynomials P_i, P_k, and points x_i, x_k.

The number of variables is $\#Q \leq s_0$. Their point coordinates have valuation at least r, and

$$v_\ell(P_i(x_i)) \leq b_i + s_0 r \leq b_i + 1, \qquad v_\ell(P_k(x_k)) \leq d_k + s_0 r \leq d_k + 1.$$

Thus the sum of their evaluation valuations is at most B, as required by the torsion specialization lemma. It gives roots $\zeta_{\mathfrak{q}}$ of order dividing ℓ^H, hence also ℓ^N, such that for $1 \leq j \leq m$, on writing $y_j = (\zeta_{\mathfrak{q}}^j - 1)_{\mathfrak{q}\in Q}$,

$$0 < v_\ell(\zeta_{\mathfrak{q}}^j - 1) \leq r, \qquad v_\ell(P_i(y_j)) \leq b_i + \varepsilon_0, \qquad v_\ell(P_k(y_j)) \leq d_k + \varepsilon_0. \tag{1}$$

Define

$$\psi(g) = \prod_{\mathfrak{q}\in Q} \zeta_{\mathfrak{q}}^{\lambda_{\mathfrak{q}}(g)} \quad (g \in G_E).$$

The exponent is read modulo ℓ^N; the definition is independent of its representative because each root has order dividing ℓ^N. This is a continuous character of ℓ-power order. Each factor comes from the norm-one torus with modulus $\{\mathfrak{q}\}$, so their product comes from that torus with modulus Q, is anticyclotomic, and is trivial on the decomposition groups above ℓ. The same holds for every power of ψ.

Fix $1 \leq j \leq m$. The evaluation identity of Proposition 7.4.12, applied to $(\zeta_{\mathfrak{q}}^j)_{\mathfrak{q}}$, gives

$$v_\ell(\psi^j(\Theta_Q^{(k)})) = v_\ell(P_k(y_j)) \leq d_k + \varepsilon_0.$$

Since $\varepsilon_0 < 1$, (1) also gives $v_\ell(P_i(y_j)) < b_i + 1$. The Selmer-length conclusion of the same proposition therefore applies and bounds the twisted Selmer length of T_i by

$$v_\ell(P_i(y_j)) \leq b_i + \varepsilon_0.$$

It remains to check ramification and the sum at tame generators. Let $\gamma_{\mathfrak{q}}$ be any tame generator at $\mathfrak{q}$. Every other $\lambda_{\mathfrak{p}}$ is unramified there, since Q is auxiliary and disjoint from $\bar{Q}$. Moreover the residue characteristic at $\mathfrak{q}$ differs from ℓ. Its wild inertia has no nontrivial image in the finite ℓ-group, and a tame generator maps to a generator of the cyclic image of inertia. Because $\lambda_{\mathfrak{q}}$ is onto on inertia, $\lambda_{\mathfrak{q}}(\gamma_{\mathfrak{q}})$ is a unit modulo ℓ. Raising an ℓ-power root of unity to such a unit preserves its order and the valuation of its difference from one. It follows from (1) that

$$0 < v_\ell(\psi^j(\gamma_{\mathfrak{q}}) - 1) = v_\ell(\zeta_{\mathfrak{q}}^j - 1) \le r.$$

In particular ψ^j is ramified at $\mathfrak{q}$. Conjugate inertia has the inverse character by anticyclotomicity, and inversion preserves this valuation. The same bound consequently holds for any tame generator at $\bar{\mathfrak{q}}$, including generators in any conjugate choice of decomposition subgroup. Hence

$$\sum_{w \in Q \cup \bar{Q}} v_\ell(\psi^j(\gamma_w) - 1) \le 2\#Q\, r \le s_0 r \le \varepsilon_0.$$

All conditions for an ε_0-small twist are now proved simultaneously for every j. Increasing the allowance to ε proves the assertion. If Q or either indexing family is empty, the products and sums used here have their usual empty values, and the same argument applies. □

Proposition 7.4.12. *Let ℓ, S_0, g_0, $\mathcal{O}$, the Selmer data $(T_i)_{i\in I}$ and the torsion level M_0 be as in Proposition 7.4.13, and let $(Y_k)_{k\in\kappa}$ be finitely many Stickelberger systems for (S_0, g_0). Then there is an integer $s_0 \ge 1$ such that for every rational $r > 0$ with $s_0 r < 1$ and every sufficiently large N there are:*

- *a set Q of places, auxiliary for S_0, with $2\#Q \le s_0$;*
- *for each $\mathfrak{q} \in Q$ a continuous homomorphism $\lambda_{\mathfrak{q}} \colon G_E \to \mathbb{Z}/\ell^N$ from $\mathrm{U}(1)$ with modulus $\{\mathfrak{q}\}$ that is onto on inertia at $\mathfrak{q}$;*
- *polynomials $P_i, P_k \in \overline{\mathbb{Z}}_\ell[X_{\mathfrak{q}} : \mathfrak{q} \in Q]$ and points $x_i, x_k \in \overline{\mathbb{Z}}_\ell^{\,Q}$ whose coordinates have valuation at least r, with*

$$v_\ell(P_i(x_i)) \le \mathrm{nl}(\beta_{T_i}) + s_0 r, \qquad v_\ell(P_k(x_k)) \le \beta_{Y_k} + s_0 r;$$

such that for all ℓ^N-th roots of unity $(\zeta_{\mathfrak{q}})_{\mathfrak{q}\in Q}$, with $\psi = \prod_{\mathfrak{q}} \zeta_{\mathfrak{q}}^{\lambda_{\mathfrak{q}}}$ and $y = (\zeta_{\mathfrak{q}} - 1)_{\mathfrak{q}}$: $\psi(\Theta_Q^{(k)}) = P_k(y)$ for every k, and for every i with $v_\ell(P_i(y)) < \mathrm{nl}(\beta_{T_i}) + 1$ the twist of T_i by ψ has length at most $v_\ell(P_i(y))$ at Q.

Proof. Write $b_i = \mathrm{nl}(\beta_{T_i})$, and let n_i be the rank of T_i. For the system Y_k write its character as ϑ_k, its number of exponents as u_k, and put $c_k = v_\ell(\vartheta_k(g_0) - 1)$. These numbers are finite. Every value of ϑ_k is an ℓ-adic unit: its image is compact, and its absolute values form a compact subgroup of $\mathbb{R}_{>0}$, which must be $\{1\}$.

Choose a neighborhood W of g_0 so that for every $g \in W$,

$$\rho_i(g^b) \equiv \rho_i(g_0^b) \pmod{\ell^{M_0}} \quad (i \in I,\ b \in \{+,-\}), \qquad v_\ell(\vartheta_k(g) - \vartheta_k(g_0)) > c_k \quad (k \in \kappa).$$

Here $g^+ = g$ and $g^- = (g^c)^{-1}$; if I is empty its congruences are omitted. Continuity gives such a neighborhood. Let J_W be the bound in the strengthened conclusion of Proposition 7.4.13. Choose an integer $C \ge 1$ with $n_i, u_k \le C$ for every index, and set

$$s_0 = 2C(J_W + 1).$$

This choice precedes r and N.

Fix a rational $r > 0$ with $s_0 r < 1$. Choose an integer $K \geq 0$ with $\ell^K r \geq 1$, and a positive integer H larger than every $\beta_{Y_k} + 1$. Take N sufficiently large that

$$N > M_0, \qquad N > c_k \ \ (k \in \kappa), \qquad N \geq K + H, \qquad N \geq K + M_0$$

(the last condition is omitted if I is empty). The strengthened descent statement gives Q, its first place v_0, characters λ_v, elements γ_v, φ_v and slopes $s_{v,i}$. In particular $\#Q \leq J_W$, so $2\#Q \leq s_0$. Each λ_v is onto inertia since $\lambda_v(\gamma_v) = 1$, is trivial on the decomposition groups above ℓ, and comes from the norm-one torus with modulus $\{v\}$. It is anticyclotomic, so $\lambda_v(g^c) = -\lambda_v(g)$. Characters at other auxiliary places are unramified, giving $\lambda_w(\gamma_v) = \delta_{wv}$. All hypotheses about these characters used below are therefore supplied.

We use the following elementary fact about a finite family of nonzero polynomials $F(T)$ with integral algebraic ℓ-adic coefficients. Put

$$G_r(F) = \min_d \{v_\ell(F_d) + dr\}.$$

There is a point t in a finite coefficient extension with $v_\ell(t) = r$ and $v_\ell(F(t)) = G_r(F)$ for every polynomial in the family. To prove this, choose an algebraic element π_r with valuation r. For each F, divide $F(\pi_r Z)$ by a coefficient of least valuation. The resulting polynomial is integral and has nonzero reduction. Enlarge the residue field so that one nonzero residue avoids the finitely many roots of all these reductions, and lift it to a unit z. Then $t = \pi_r z$ works. This argument also proves all the asserted points lie in $\overline{\mathbb{Z}}_\ell$.

We first construct the Selmer polynomials. Fix i, and let $\mathscr{L}_i$ be the fixed relations of T_i, including vanishing at γ_*. In all finite-coefficient modules take ramification set $S_i \cup Q \cup \bar{Q}$ and coefficient module $(\mathcal{O}'/\ell^{M_0})^{n_i}$. Let $\mathcal{A}_i(x)$ denote the module of Lemma 7.4.20 for these relations and characters, and let $\mathcal{B}_i(x)$ have in addition the ties at $Q \setminus \{v_0\}$. At $x = 0$ these are the original untwisted cocycle equations.

The all-ties module at zero has unnormalised length at most $\beta^\circ_{T_i}$ by descent. Apply Lemma 7.4.21 at $y = 0$ (using $r = 1, K = 0$ there) to remove just the ties at v_0, retaining all the other relations, with $w_{v_0,b} = g_0^b$. The required matrix congruences hold since $\varphi_{v_0} \in W$. The cost is the first-prime term. Consequently

$$\operatorname{nl} \mathcal{B}_i(0) \leq b_i.$$

Here $M_0 \geq 1$ whenever I is nonempty, because $b_i + 1 < M_0$.

By Lemma 7.4.20, choose a polynomial $G_i(X)$ sharp for $\mathcal{B}_i$ at zero and bounding its normalized length at every point over every coefficient extension. Restrict it to the line

$$x_{v_0} = T, \qquad x_v = s_{v,i} T \quad (v \neq v_0)$$

and call the resulting polynomial $g_i(T)$. Its constant term is nonzero and has valuation at most b_i, so $G_r(g_i) \leq b_i$. For every $v \neq v_0$ and $b \in \{+, -\}$ the polynomial

$$D_{v,b}(T) = \det\big((1 + T)\rho_i(\varphi_v^b) - I\big)$$

has degree n_i and unit leading coefficient. Thus $G_r(D_{v,b}) \leq n_i r$. Choose t_i attaining these finitely many Gauss valuations as above, and let x_i be its point on the line. All its coordinates have valuation at least r, and

$$\operatorname{nl} \mathcal{B}_i(x_i) \leq v_\ell(g_i(t_i)) \leq b_i.$$

Remove the ties at $Q\setminus\{v_0\}$ by Lemma 7.4.21, with $y = t_i$ and $w_{v,b} = \varphi_v^b$. The choice $N \geq K+M_0$ supplies its geometric-sum condition. It follows that

$$\operatorname{nl} \mathcal{A}_i(x_i) \leq b_i + 2n_i(\#Q-1)r \leq b_i + s_0 r.$$

Apply Lemma 7.4.20 once more, now sharply for $\mathcal{A}_i$ at x_i. Its polynomial P_i has the required small value there and bounds $\mathcal{A}_i(x)$ at every point.

At a tuple of ℓ^N-th roots of unity ζ, the polynomial twist is the actual character $\psi = \prod_v \zeta_v^{\lambda_v}$. Its local action above ℓ is unchanged, and it is unramified at the place of γ_*, since that place belongs to S_0 and not to $Q \cup \bar{Q}$. Thus $\mathcal{A}_i(\zeta - 1)$ is exactly the ℓ^{M_0}-torsion of the divisible-coefficient twisted Selmer module defined by the same fixed relations, under the map $a \mapsto a/\ell^{M_0}$. This assertion holds over every sufficiently large coefficient ring.

For completeness the strict threshold in the statement passes from this torsion to the whole module. A continuous cocycle into the discrete module $(\operatorname{Frac}\mathcal{O}'/\mathcal{O}')^{n_i}$ has finite image, so is killed by a power of ℓ. If an ℓ-primary torsion $\mathcal{O}'$-module A has

$$\operatorname{nl} A[\ell^{M_0}] < M_0,$$

then $A = A[\ell^{M_0}]$: an element not killed by ℓ^{M_0} would generate a cyclic submodule whose ℓ^{M_0}-torsion has length at least $M_0 v_{\varpi'}(\ell)$, a contradiction. Since $b_i + 1 < M_0$, the hypothesis $v_\ell(P_i(\zeta-1)) < b_i + 1$ gives precisely this strict bound. It follows that the full twisted module has normalized length at most $v_\ell(P_i(\zeta-1))$, as required.

We next construct the system polynomials, using only the defining norm relations. Fix k, and suppress its index. A character λ_v from the norm-one torus gives a cyclic character of Cl_Q. Fix a primitive ℓ^N-th root to identify its values with $\mathbb{Z}/\ell^N$. For each class d let $a_v(d)$ be this additive value. If $\Theta_Q = \sum_d A_d[d]$, put

$$P(X) = \sum_d A_d \prod_{v\in Q} (1+X_v)^{[a_v(d)]_{\ell^N}}.$$

It has integral coefficients and, for every root tuple, satisfies $P(\zeta-1) = \psi(\Theta_Q)$.

Let $F_A(T)$ be the corresponding one-variable polynomial obtained from Θ_A using just the character λ_{v_0}, for $v_0 \in A \subseteq Q$. In particular

$$F_Q(T) = P(X_{v_0} = T,\ X_v = 0 \text{ for } v \neq v_0).$$

The first-prime norm relation at the trivial character gives

$$v_\ell(F_{\{v_0\}}(0)) = \beta_Y.$$

Indeed $\varphi_{v_0} \in W$ makes $\vartheta(\varphi_{v_0}) - \vartheta(g_0)$ have valuation greater than $c = v_\ell(\vartheta(g_0)-1)$; and $\mathrm{N}v_0 \equiv 1 \pmod{\ell^N}$ with $N > c$ makes $(\mathrm{N}v_0)^{-e} - 1$ have valuation greater than c for every exponent e. Each of the two Euler factors for that exponent therefore has valuation exactly c. Their product contributes $2uc$, added to $v_\ell(1(\Theta_\emptyset))$.

Write $q = \ell^N$ and $f_N(T) = (1+T)^q - 1$. For $v \in Q \setminus \{v_0\}$ put

$$d_{v,e} = \vartheta(\varphi_v)(\mathrm{N}v)^{-e}, \qquad d'_{v,e} = \vartheta(\varphi_v)^{-1}(\mathrm{N}v)^{-e}.$$

Both are units. Applied to every character $\zeta^{\lambda_{v_0}}$, $\zeta^q = 1$, the system norm relation and $\lambda_{v_0}(\varphi_v) = 1$ imply

$$(1+T)^{u(\#Q-1)} F_Q(T) \equiv F_{\{v_0\}}(T) \prod_{v\in Q\setminus\{v_0\}} \prod_e [1 - d_{v,e}(1+T)]\,[(1+T) - d'_{v,e}] \pmod{f_N(T)}.$$

To justify the polynomial congruence, first do one insertion. After multiplying by $(1+T)^u$ its difference vanishes at all q distinct values $\zeta-1$, and hence is divisible by the monic polynomial f_N. Monic division preserves integrality. Iterate the insertions to obtain the displayed congruence.

Each linear factor in the product has unit leading coefficient, so has Gauss valuation at most r; and $G_r(F_{\{v_0\}}) \le \beta_Y$. Choose t_k of valuation r attaining the Gauss valuations of that polynomial and all these factors. The right side at t_k has valuation at most

$$\beta_Y + 2u(\#Q-1)r \le \beta_Y + s_0 r < \beta_Y + 1 < H.$$

The binomial inequality $v_\ell((1+t)^\ell - 1) \ge \min\{\ell v_\ell(t), v_\ell(t)+1\}$ shows that $v_\ell((1+t_k)^{\ell^K}-1) \ge 1$. Each further ℓ-th power raises this valuation by at least 1. Consequently $v_\ell(f_N(t_k)) \ge 1 + N - K > H$, since $N \ge K+H$. The congruence error is therefore of valuation at least H. Also $1+t_k$ is a unit. The ultrametric inequality consequently makes $v_\ell(F_Q(t_k))$ equal to the valuation of the right side, so it is at most $\beta_Y + s_0 r$. Set the first coordinate of x_k equal to t_k and all other coordinates equal to zero. Their valuations are at least r, and $P(x_k) = F_Q(t_k)$. This is the required polynomial and point for Y_k.

The constructions apply to every sufficiently large N after r is fixed. Empty families simply omit their corresponding steps. All polynomials and chosen points involve only finitely many algebraic coefficients and so lie in the specified algebraic closure. This proves every conclusion. □

Proposition 7.4.13. *Let ℓ be a prime, S_0 a finite set of finite places of E containing those above ℓ, $g_0 \in G_E$ in an inertia group above a place of S_0 not above ℓ, $\mathcal{O}$ a coefficient ring, $(T_i)_{i\in I}$ finitely many Selmer data for (S_0, g_0) over $\mathcal{O}$ with representations ρ_i and places S_i, and $M_0 \ge 0$ a torsion level for them. Then there is an integer J_0 such that for every $N \ge 1$ there are a set J of at most J_0 places, auxiliary for S_0, and for each $v \in J$ a tame generator γ_v and a Frobenius element φ_v at v, a character $h_v\colon G_E \to \mathbb{Z}/\ell^N$ from $\mathrm{U}(1)$ with modulus $\{v\}$ and $h_v(\gamma_v) = 1$, and slopes $s_{v,i} \in \mathcal{O}$ $(i \in I)$, such that for every i the $\mathcal{O}$-module of continuous cocycles $z\colon G_E \to (\mathcal{O}/\ell^{M_0})^{n_i}$ for ρ_i that are unramified outside $S_i \cup J \cup \bar{J}$, satisfy the local relations of T_i above ℓ, vanish at γ_*, and satisfy the ties*

$$z(\gamma_v) = s_{v,i}\, z(\varphi_v) \quad \text{and} \quad z(\bar{\gamma}_v) = s_{v,i}\, z(\bar{\varphi}_v) \qquad (v \in J)$$

(with $\bar{\gamma}_v, \bar{\varphi}_v$ the conjugate elements at $\bar{v}$) has $\mathcal{O}$-length at most β_{T_i}.

More precisely, let W be any neighborhood of g_0 in G_E. There is a bound J_W such that, for every integer $N > M_0$, there are data of the same kind with $\#J \le J_W$ and a distinguished $v_0 \in J$ satisfying all of the following:

1. *Each $\mathrm{N}v$ is a rational prime congruent to 1 modulo ℓ^N. The elements γ_v, φ_v lie in one chosen decomposition group at v, with γ_v a tame generator and φ_v arithmetic Frobenius. Write $\lambda_v = h_v$ additively. The characters λ_v are trivial on the decomposition groups at the places above ℓ.*
2. *The first slopes vanish: $s_{v_0,i} = 0$ for all i, and $\varphi_{v_0} \in W$.*
3. *For $v \in J \setminus \{v_0\}$ and $w \in J$,*

$$\lambda_w(\varphi_v) = \begin{cases} 1, & w = v_0, \\ 0, & w \ne v_0. \end{cases}$$

4. *No place in S_0 and no member of $J \setminus \{v_0\}$ lies above the rational prime $\mathrm{N}v_0$.*

5. *If $s_{v,i} \neq 0$, then*
$$\rho_i(\varphi_v) \equiv \rho_i((\varphi_v^c)^{-1}) \equiv I \pmod{\ell^{M_0}}.$$

6. *Let $\beta^{\circ}_{T_i}$ be the global term of T_i plus its local terms at the places of S_i prime to ℓ, with no first-prime term. The module with all the preceding cocycle, ramification and local relations and with the ties written as*
$$z(\gamma_v) = s_{v,i} z(\varphi_v), \qquad z((\gamma_v^c)^{-1}) = s_{v,i} z((\varphi_v^c)^{-1}) \quad (v \in J)$$
has unnormalised $\mathcal{O}$-length at most $\beta^{\circ}_{T_i}$.

For these choices the conjugate-inverse ties in the last clause are equivalent to the conjugate ties in the first conclusion. Indeed ρ_i is unramified at the auxiliary places, and for a nonzero slope both Frobenius matrices are the identity on the coefficient module; the cocycle identity $z(g^{-1}) = -\rho_i(g^{-1})z(g)$ then gives the equivalence. For a zero slope both versions simply require vanishing of the inertial value.

Proof. We use the cocycle local terms in (SF): at $v \nmid \ell$ they are the supremum of the nonnegative excess of the length of the restrictions of global cocycles over the coefficient-module length. Thus $\beta^{\circ}_{T_i}$ is exactly the sum occurring in Lemma 7.4.16. At $w \mid \ell$ the local relations are all finitely supported matrix-evaluation relations satisfied by Z_w.

First suppose the datum family is nonempty. The torsion-level inequality implies $M_0 \geq 1$. Fix a uniformizer ϖ and put $e = \mathrm{len}_{\mathcal{O}}(\mathcal{O}/\ell^{M_0})$. For $1 \leq k \leq e$, use coefficients $V_{i,k} = (\mathcal{O}/\varpi^k)^{n_i}$. All modules of continuous cocycles considered below are finite: their ramification is restricted to a finite set, the coefficient module is finite, and finiteness of global H^1 follows from Proposition 7.4.17 with unrestricted local conditions; the coboundaries also form a finite module.

Call a configuration any choice of J, v_0, the prime data, characters and slopes satisfying clauses 1–5 of the enriched conclusion, except for the length assertion, with the characters at every later Frobenius having the displayed first-prime pattern. Write $C_{i,k}(J)$ for its normalized tied cocycle module over $V_{i,k}$, using conjugate-inverse ties. Let $C_{i,k}(\emptyset)$ be the module with no auxiliary primes or ties, retaining the old ramification, local relations and vanishing at γ_*, and set
$$L = \sum_{i \in I} \sum_{k=1}^{e} \mathrm{len}_{\mathcal{O}} C_{i,k}(\emptyset), \qquad B = 1 + L.$$
These numbers depend only on the data and M_0.

Fix $N > M_0$ and a neighborhood W of g_0. A singleton configuration exists by Lemma 7.4.14. Apply it near g_0 with no prescribed auxiliary decomposition groups, and exclude all places above the rational primes below S_0. The normal-inertia hypothesis holds because g_0 is inertial at a place of S_0 prime to ℓ. Take its supplied prime as v_0 and set every first slope to zero. This gives all the required character and Frobenius clauses; the later-prime conditions are empty. No old place lies above $\mathrm{N}v_0$ by the avoidance just imposed. For every i, k, the singleton tied module equals $C_{i,k}(\emptyset)$. Indeed the zero ties at $v_0, \bar{v}_0$ kill their tame inertial values, hence all their inertia, and so restore the old unramified condition. Thus
$$\#J + \sum_{i,k} \mathrm{len}\, C_{i,k}(J) = B$$
for this singleton.

Among configurations satisfying

$$\#J + \sum_{i,k} \operatorname{len} C_{i,k}(J) \le B, \tag{1}$$

choose one minimizing the integer $\sum_{i,k} \operatorname{len} C_{i,k}(J)$. This is possible by well-ordering. We show that at this configuration every new-prime Frobenius pair of a member of $C_{i,k}(J)$ lies in the tame-pair image of the module relaxed at the new prime.

Fix i, an admissible new tuple $(P, \gamma, \phi, \lambda)$ as in Lemma 7.4.16, with $M = M_0$, and a level k. Let $Y_{i,k}$ be the module with ramification also allowed at $P, \bar{P}$ but retaining the old ties. On it define

$$\Phi_0(u) = \big(u(\gamma), u((\gamma^c)^{-1})\big), \qquad \Phi_1(u) = \big(u(\phi), u((\phi^c)^{-1})\big).$$

Then $C_{i,k}(J) = Y_{i,k} \cap \ker \Phi_0$: a zero tame pair is equivalent to unramifiedness at the two new places, because the representation is unramified there and the coefficient module is an ℓ-group.

Apply Lemma 7.4.15 at each of the e levels for this datum. At level k it excludes at most $2n_i$ residues, and for every remaining residue represented by $t \in \mathcal{O}$ gives

$$\operatorname{len}\big(Y_{i,k} \cap \ker(t\Phi_0 - \Phi_1)\big) \le \operatorname{len}\big(C_{i,k}(J) \cap \Phi_1^{-1}(\Phi_0 Y_{i,k})\big). \tag{2}$$

The torsion-level residue-field bound is $\#(\mathcal{O}/\varpi) > 2n_i e + 1$. We may therefore choose one t avoiding all these exceptional residues and also zero. It is a unit. Add P to J, give datum i the slope t^{-1} at P, and give every other datum slope zero. The new module for datum i is the kernel on the left of (2), at every level. The modules for the other data are unchanged, since their new zero ties simply enforce unramifiedness at $P, \bar{P}$.

This is again a configuration. Residual triviality for the selected datum is part of admissibility; the other new slopes are zero. The old first-prime Frobenius pattern is preserved because the new character is trivial on the decomposition groups at $J \setminus \{v_0\}$. The pattern at P and its own zero character value are part of admissibility. The avoidance clauses and the first prime are preserved as well. If some member of some $C_{i,k}(J)$ had its Frobenius pair outside $\Phi_0 Y_{i,k}$, the right side of (2) would be a proper submodule of the finite module $C_{i,k}(J)$ and its length would drop by at least one. All other lengths would not increase. The new prime increases $\#J$ by one, so (1) would still hold while its minimized sum strictly decreased, a contradiction. Consequently for every i, k and every admissible tuple,

$$\Phi_1(C_{i,k}(J)) \subseteq \Phi_0(Y_{i,k}). \tag{3}$$

We now bound all the levels for this one configuration. Fix i and induct on k from 0 to e, with the level-zero module zero. If $C_{i,k}(J)$ has a cocycle with a unit coordinate, equation (3) supplies exactly its new-prime evaluation hypothesis in Lemma 7.4.16. That lemma gives

$$\operatorname{len} C_{i,k}(J) \le \beta^{\circ}_{T_i}. \tag{4}$$

Otherwise every value of every cocycle lies in $\varpi(\mathcal{O}/\varpi^k)^{n_i}$. The map $\mathcal{O}/\varpi^{k-1} \to \varpi\mathcal{O}/\varpi^k$, $x \mapsto \varpi x$, is an isomorphism onto that submodule. Dividing all values through this map identifies $C_{i,k}(J)$ with $C_{i,k-1}(J)$. The cocycle equations, all matrix-evaluation relations, the ties, the vanishing condition and unramifiedness all pass through this identification because they are homogeneous integral linear equations. Continuity is preserved since the coefficient modules are finite and discrete. Thus (4) follows from induction in this case too.

At $k = e$, the ideal (ϖ^e) is (ℓ^{M_0}), so (4) is the required strengthened length bound. Equation (1) gives $\#J \le B$. The same bound works for every $N > M_0$ and every chosen W, and hence supplies the stated J_W.

If the datum family is empty, the singleton auxiliary-character construction alone proves the enriched conclusion, with bound 1; there are no length or residue-field conditions to check. Here the explicit hypothesis $M_0 \geq 0$ ensures that $N > M_0$ is a positive exponent.

Finally fix any $N \geq 1$. Perform the enriched construction at an integer $N' > \max\{M_0, N\}$, with $W = G_E$, and reduce its characters modulo ℓ^N. They are still one-prime characters with value 1 on the chosen tame generators; the norm congruence and all required auxiliary clauses persist. The primes, slopes and cocycle modules are unchanged. Their lengths are at most $\beta^{\circ}_{T_i} \leq \beta_{T_i}$, since the first-prime term is nonnegative. Thus one uniform bound J_0 gives the first conclusion for every N.

To compare the two displayed kinds of ties, inertia acts trivially on the coefficient module at each auxiliary prime. If the slope is nonzero, the relevant Frobenius also acts trivially. The cocycle identity $u(g^{-1}) = -\rho(g^{-1})u(g)$ therefore changes both sides of the conjugate tie by the same minus sign. For zero slope both versions say that the inertial value is zero. This proves the final equivalence and completes the descent. □

Lemma 7.4.14. *Let E be a CM field, c complex conjugation on G_E, ℓ a prime, $N \geq 1$, and S, R finite sets of finite places of E. Write $\bar{S}$ for the conjugate set and Σ_ℓ for the places above ℓ. Suppose $z \in G_E$ belongs to the closed normal subgroup generated by the inertia groups above the places of $R \setminus (S \cup \bar{S} \cup \Sigma_\ell)$, and let W be a neighborhood of z. Then there are a place P outside $S \cup \bar{S} \cup \Sigma_\ell \cup R \cup \bar{R}$, of rational-prime norm Q, a decomposition group at P, a tame generator γ in that group, an arithmetic Frobenius ϕ in the same group, and a continuous homomorphism $\lambda : G_E \to \mathbb{Z}/\ell^N$ such that*

$$P \neq \bar{P}, \qquad Q \equiv 1 \pmod{\ell^N}, \qquad \phi \in W, \qquad \lambda(\gamma) = 1, \qquad \lambda(\phi) = 0.$$

The character λ is unramified outside $\{P, \bar{P}\}$ and trivial on every decomposition group at the places of $S \cup \bar{S} \cup \Sigma_\ell$. More precisely there is a continuous homomorphism $\eta : \mathbb{A}_{E,f}^{\times}/E^{\times} \to \mathbb{Z}/\ell^N$ of conductor dividing P, trivial on each local multiplicative group at the places of $S \cup \bar{S} \cup \Sigma_\ell$, for which

$$\lambda(\mathrm{Art}_E(x)) = \eta(x/\bar{x}) \qquad (x \in \mathbb{A}_{E,f}^{\times}).$$

In particular $\lambda(c(g)) = -\lambda(g)$, and λ has exact order ℓ^N.

Proof. Put $q = \ell^N$ and $A = S \cup \bar{S} \cup \Sigma_\ell$. We first choose a finite conjugation-stable set T of places containing A, disjoint from $(R \cup \bar{R}) \setminus A$, such that the ideal class group is generated by the classes of primes in T. The class group is finite by Minkowski's theorem. For each of its finitely many classes choose a fractional ideal and multiply by a principal fractional ideal to make its valuations zero at $(R \cup \bar{R}) \setminus A$. Such a multiplier exists by weak approximation at these finitely many places. The prime factors of these representatives, their conjugates, and A give the required T.

Let $U_T = \mathcal{O}_{E,T}^{\times}$. Its valuation map into $\mathbb{Z}^T$ has kernel $\mathcal{O}_E^{\times}$. Dirichlet's theorem and finite generation of subgroups of $\mathbb{Z}^T$ imply that U_T has finitely many generators $u_1, \ldots, u_d$. Choose qth roots of these generators and let L/E be the splitting field of their binomials together with μ_q. This is a finite Galois extension unramified outside T: at a place outside T, the residue characteristic is prime to q and each u_j is a unit. Over the maximal unramified extension its residue has a qth root and Hensel's lemma lifts that root, since q is a unit. The roots of unity are unramified there for the same reason. Consequently the inertia groups used to generate the normal subgroup in the hypothesis act trivially on L. Their closed normal closure does too, and z fixes L.

Choose an open normal subgroup $K \subseteq G_E$ with $zK \subseteq W$, and replace it by $K \cap G_L$. Thus zK is a nonempty open coset contained in $W \cap G_L$. Apply Chebotarev to the conjugacy class of the image of z in the finite quotient G_E/K. After choosing a place above the resulting prime, its Frobenius has exactly that image, rather than just a conjugate image. We may exclude any prescribed finite set of primes, in particular $T \cup R \cup \bar{R}$, the primes ramified in the field fixed by K, and the primes above rational primes ramified in $E/\mathbb{Q}$. We may also require the norm to be a rational prime: primes of residue degree at least two over $\mathbb{Q}$ have Dirichlet density zero, since their contribution is bounded by $[E : \mathbb{Q}] \sum_p p^{-2s}$ as $s \downarrow 1$, whereas the Chebotarev class has positive density. We obtain P with prime norm Q, and an arithmetic Frobenius σ such that every Frobenius in the chosen decomposition group lies in zK. Indeed their quotients lie in inertia, which maps trivially to G_E/K. The image of σ on μ_q is trivial, so $Q \equiv 1 \pmod{q}$.

We have $P \neq \bar{P}$. Otherwise the rational prime below P, which is unramified in E, would be inert in the quadratic CM extension E/E^+ at that place; its residue degree in $E/\mathbb{Q}$ would be even, contrary to $\mathrm{N}P = Q$. Since T is conjugation-stable, both P and $\bar{P}$ lie outside T.

Choose a tame generator γ at the chosen place above P. By local reciprocity its image in the tame abelian inertia quotient corresponds to a generator $\bar{u}$ of the cyclic group $\mathbb{F}_Q^\times$. More explicitly tame inertia is procyclic, Frobenius acts on it by the Qth power, and its maximal abelian quotient inside the local Galois group is its quotient by $Q - 1$, identified by reciprocity with $\mathbb{F}_Q^\times$. Fix a uniformizer π of E_P and let

$$f : E_P^\times \longrightarrow \mathbb{Z}/q$$

be the homomorphism which takes the residue of $t\pi^{-\operatorname{ord}_P(t)}$ to its discrete logarithm to base $\bar{u}$, reduced modulo q. It is continuous, kills π and $1 + \mathfrak{m}_P$, If $u \in \mathcal{O}_{E_P}^\times$ lifts $\bar{u}$, then the local Artin image of u and γ have the same image in tame abelian inertia. Thus this discrete logarithm is normalized to take the value 1 on that image.

Each u_j is a qth power modulo P. In fact σ fixes its chosen qth root in L; reduction of that root at the chosen place above P is therefore fixed by the Qth power map, hence belongs to $\mathbb{F}_Q^\times$. Thus $f(u_j) = 0$, and f kills every T-unit.

Let I_T be the subgroup of finite ideles that are units outside T. Define $F : I_T \to \mathbb{Z}/q$ by $F(x) = f(x_P)$. Since the classes of the primes in T generate the class group, every finite idele belongs to $E^\times I_T$. The intersection $E^\times \cap I_T$ is exactly U_T, which F kills. Therefore the formula $\eta(ax) = F(x)$ for $a \in E^\times$, $x \in I_T$ is well-defined on all finite ideles, kills $E^\times$, and is a homomorphism. It is continuous because I_T is open and F is continuous. At a place in T it kills the entire local multiplicative group. At every place other than P it kills local units, and at P it kills $1 + \mathfrak{m}_P$. Thus its conductor divides P.

For completeness this idelic character is a character of the usual ray class group modulo P: the quotient of finite ideles by $E^\times$, all local units away from P, and $1 + \mathfrak{m}_P$ at P, is the ideal ray class group. To see the identification, use weak approximation to make the P-component congruent to 1, send the other local uniformizers to their fractional ideal, and observe that changing the multiplier changes that ideal by a principal ideal generated by an element congruent to 1 at P. This also proves that the kernel is exactly the indicated ray subgroup. The ray class field theorem therefore supplies a continuous Galois character $\mu : G_E \to \mathbb{Z}/q$ with $\mu(\mathrm{Art}_E(x)) = \eta(x)$.

Set $\lambda(g) = \mu(g) - \mu(c(g))$. Naturality of the Artin map under conjugation gives the displayed formula $\lambda(\mathrm{Art}_E(x)) = \eta(x/\bar{x})$. That naturality follows already on prime ideals from conjugation of arithmetic Frobenius, and hence on the finite ray class quotients by their Artin surjectivity. Because η is trivial on the local components in A, and $A = \bar{A}$, local reciprocity shows that λ is trivial on their decomposition groups. The same local compatibility shows that it is unramified

outside $P, \bar{P}$. At γ, the first term $\mu(\gamma)$ is 1, by the normalization of f, and $\mu(c(\gamma)) = 0$, since μ is unramified at $\bar{P}$. Thus $\lambda(\gamma) = 1$.

Finally choose an integer a representing $-\lambda(\sigma) \in \mathbb{Z}/q$ and put $\phi = \sigma\gamma^a$. This is still arithmetic Frobenius in the same decomposition group. Every such Frobenius lies in $zK \subseteq W$, and $\lambda(\phi) = \lambda(\sigma) + a = 0$. Surjectivity, exact order q, and $\lambda(c(g)) = -\lambda(g)$ now follow directly from the construction. □

Lemma 7.4.15. *Let $\mathcal{O}$ be a discrete valuation ring with residue field k, let $0 \neq a \in \mathcal{O}$, let $m \geq 0$, and let B be an $\mathcal{O}$-module. Given $\mathcal{O}$-linear maps*

$$\Phi_0, \Phi_1 : B \longrightarrow (\mathcal{O}/a)^m$$

and a submodule $Y \subseteq B$, there is a set $\mathcal{E} \subseteq k$ with $\#\mathcal{E} \leq m$ such that, for every $s \in \mathcal{O}$ whose residue is outside $\mathcal{E}$,

$$\mathrm{len}_{\mathcal{O}}\big(Y \cap \ker(s\Phi_0 - \Phi_1)\big) \leq \mathrm{len}_{\mathcal{O}}\big(Y \cap \ker \Phi_0 \cap \Phi_1^{-1}(\Phi_0(Y))\big).$$

Lengths are allowed to be infinite.

Proof. Write $N = (\mathcal{O}/a)^m$, and form the submodule

$$Z = \sum_{s \in \mathcal{O}} \big(Y \cap \ker(s\Phi_0 - \Phi_1)\big) \subseteq Y.$$

On the summand indexed by s one has $\Phi_1(z) = \Phi_0(sz)$. By additivity, therefore,

$$\Phi_1(Z) \subseteq \Phi_0(Z).$$

Let $\pi : \mathcal{O}^m \to N$ be reduction, and let $\mathcal{M} = \pi^{-1}(\Phi_0(Z))$. It is a submodule of a finite free module over the principal ideal domain $\mathcal{O}$, hence finite free of some rank $h \leq m$. Reduction gives a surjection $p : \mathcal{M} \to \Phi_0(Z)$.

Choose a basis of $\mathcal{M}$ and lift the images of its basis vectors through the surjection $\Phi_0 : Z \to \Phi_0(Z)$. This gives an $\mathcal{O}$-linear map $\sigma : \mathcal{M} \to Z$ with $\Phi_0\sigma = p$. Since $\Phi_1\sigma$ takes values in $\Phi_0(Z)$, lift its values on the same basis through p to obtain an endomorphism U of $\mathcal{M}$ satisfying

$$pU = \Phi_1\sigma.$$

Let $\mathcal{E}$ be the roots in k of the reduction of the characteristic polynomial of U. That polynomial is monic of degree h, so $\#\mathcal{E} \leq h \leq m$; if $h = 0$ it is 1 and the set is empty.

If the residue of s avoids $\mathcal{E}$, the determinant of $sI - U$ is a unit. Thus $sI - U$ is an automorphism of $\mathcal{M}$, by the adjugate formula, and

$$(s\Phi_0 - \Phi_1)\sigma = p(sI - U).$$

Consequently the image of $s\Phi_0 - \Phi_1$ on Z contains $p(\mathcal{M}) = \Phi_0(Z)$. The reverse inclusion follows from $\Phi_1(Z) \subseteq \Phi_0(Z)$, so the two images are equal.

Both images have finite length, as submodules of N. The two exact sequences on Z with maps Φ_0 and $s\Phi_0 - \Phi_1$ therefore show that their kernels have the same length. If Z has finite length this follows by ordinary length additivity and subtraction of the common finite image length. If Z has infinite length, both kernels have infinite length, since a module with a finite-length submodule and finite-length quotient has finite length. This proves the assertion about kernel lengths also in that case.

By definition of Z, the whole module $Y \cap \ker(s\Phi_0 - \Phi_1)$ lies in Z. Hence it equals $Z \cap \ker(s\Phi_0 - \Phi_1)$, whose length equals that of $Z \cap \ker \Phi_0$. Finally

$$Z \cap \ker \Phi_0 \subseteq Y \cap \ker \Phi_0 \cap \Phi_1^{-1}(\Phi_0(Y)),$$

because $Z \subseteq Y$ and $\Phi_1(Z) \subseteq \Phi_0(Z) \subseteq \Phi_0(Y)$. Monotonicity of length proves the claimed inequality. □

Lemma 7.4.16. *Let $T = (\rho, S, (Z_w), \gamma_*, \zeta_*)$ be a Selmer datum over $\mathcal{O}$ of rank n, with $S \subseteq S_0$. Let $1 \leq M < N$, let $0 \neq a \in \mathcal{O}$ divide ℓ^M, and put $V = (\mathcal{O}/a)^n$. In this statement B_{gl} and B_v denote the global term and the local terms of T already defined in (SF) of Definition 7.4.1; its restriction modules are denoted there by $C_v(b)$. These terms are finite by the Selmer-datum requirement.*

Let J be auxiliary for S_0, with $v_0 \in J$. For each $v \in J$, choose in one decomposition group a tame generator γ_v, an arithmetic Frobenius ϕ_v, a slope $s_v \in \mathcal{O}$, and an additive one-prime character $\lambda_v : G_E \to \mathbb{Z}/\ell^N$ with $\lambda_v(\gamma_v) = 1$, trivial on the decomposition groups above ℓ. Suppose $\mathrm{N}v$ is a rational prime congruent to 1 modulo ℓ^N, $s_{v_0} = 0$, and

$$s_v \neq 0 \implies \rho(\phi_v) \equiv \rho((\phi_v^c)^{-1}) \equiv I \pmod{\ell^M}.$$

At a place above ℓ, impose every finitely supported matrix-evaluation relation $\sum_g A_g u(g) = 0$ that holds for every $u \in Z_w$. For this statement only, let C be the module of continuous global cocycles into V, unramified outside $S \cup J \cup \bar{J}$, satisfying these local relations, vanishing at γ_*, and satisfying

$$u(\gamma_v) = s_v u(\phi_v), \qquad u((\gamma_v^c)^{-1}) = s_v u((\phi_v^c)^{-1}) \qquad (v \in J).$$

For a new place P, let C_P, also local to this statement, be the same module with ramification also allowed at $P, \bar{P}$, retaining only the ties at J.

Suppose there is $z \in C$ with a unit coordinate at some element of G_E, having the following property. For every tuple $(P, \gamma, \phi, \lambda)$ satisfying all of these conditions:

- *P has rational-prime norm congruent to 1 modulo ℓ^N, lies outside $S_0 \cup \bar{S}_0 \cup J \cup \bar{J}$, and does not lie above $\mathrm{N}v_0$;*
- *γ, ϕ are a tame generator and arithmetic Frobenius in one decomposition group at P;*
- *$\lambda : G_E \to \mathbb{Z}/\ell^N$ is a one-prime character of modulus $\{P\}$, trivial on the decomposition groups above ℓ and at $J \setminus \{v_0\}$, with $\lambda(\gamma) = 1$ and $\lambda(\phi) = 0$;*
- *for every $w \in J$, $\lambda_w(\phi) = 1$ if $w = v_0$ and 0 otherwise, and $\rho(\phi) \equiv \rho((\phi^c)^{-1}) \equiv I \pmod{\ell^M}$;*

there is $z_P \in C_P$ with

$$z_P(\gamma) = z(\phi), \qquad z_P((\gamma^c)^{-1}) = z((\phi^c)^{-1}).$$

Then

$$\mathrm{len}_{\mathcal{O}} C \leq B_{\mathrm{gl}} + \sum_{\substack{v \in S \\ v \nmid \ell}} B_v.$$

Proof. We first check the finite-level local conditions. For a finitely generated rank-d module Z of integral vector-valued functions, regard its elements as scalar functions on the set I of pairs consisting of an argument and a vector coordinate. Put

$$L = (\mathrm{Frac}(\mathcal{O})Z) \cap \mathcal{O}^I.$$

Some d coordinates are injective on the fraction-field span of Z. Their nonzero determinant bounds the denominators of every element of L in a basis of Z. Thus $L \subseteq \varpi^{-b}Z$ for some b, and L is finite free of rank d. A basis of L stays linearly independent modulo ϖ as a family of functions. Otherwise a primitive linear combination of that basis would be divisible coordinatewise by ϖ, and its quotient by ϖ would belong to L, a contradiction. Consequently some d coordinates give a unit determinant on this basis. Projection on them identifies L with $\mathcal{O}^d$; every other coordinate is an integral linear combination of these selected coordinates.

Every finite-coordinate linear relation on Z also holds on L, since they have the same fraction-field span. Conversely the graph equations just obtained are such relations. Over $\mathcal{O}/a$, therefore, the solution module of all the relations is the image of L, isomorphic to $(\mathcal{O}/a)^d$. Scalar coordinate relations are equivalent to matrix-evaluation relations: place any scalar relation in a fixed row of the output vector. It follows that the local continuous cocycles satisfying the prescribed relations at $w \mid \ell$ have length at most

$$(\mathrm{rk}_{\mathcal{O}} Z_w)\,\mathrm{len}_{\mathcal{O}}(\mathcal{O}/a). \tag{1}$$

They contain all local coboundaries, because each finite-level vector lifts to an integral vector and its integral coboundary lies in Z_w. This proves the needed bound without identifying this solution module with the reduction of Z_w.

The inputs from (SD) used below are the following: ρ is unramified outside S; its image spans $M_n(\mathcal{O})$; each Z_w is finitely generated and contains integral coboundaries; its ranks have the stated total bound; and γ_* is inertial at a place of S prime to ℓ, with $\rho(\gamma_*) = \zeta_* I$, $\rho(\gamma_*^c) = \zeta_*^{-1} I$ and $\zeta_*^2 - 1$ a unit. In particular both $\zeta_* - 1$ and $\zeta_* + 1$ are units, and these properties survive reduction modulo a. Auxiliary places and their conjugates are outside S_0, so inertia acts trivially on V there. We now apply global duality with local conditions containing coboundaries. At a place $v \in S$ prime to ℓ, take $C_v(a)$. At $w \mid \ell$, take the continuous local cocycles satisfying the relations just considered. At a place in $J \cup \bar{J}$, take all local cocycles satisfying its displayed tie, using γ_v, ϕ_v at v and $(\gamma_v^c)^{-1}, (\phi_v^c)^{-1}$ at $\bar{v}$. These local conditions contain coboundaries. For a zero slope they are unramified conditions. For a nonzero slope, inertia acts trivially and the relevant Frobenius acts as I on V, so both evaluations of a coboundary are zero.

At an auxiliary place a tied local cocycle is determined by its Frobenius value. Indeed a zero Frobenius value forces a zero value at the tame generator. Wild inertia has no nonzero additive homomorphism to the finite ℓ-group V, and the tame generator detects every such homomorphism on tame inertia. The cocycle then vanishes on inertia and on Frobenius, hence everywhere by continuity. Thus each auxiliary local condition has length at most $\mathrm{len}_{\mathcal{O}} V$. At the first prime, where the slope is zero, it is exactly the unramified condition.

Let $\mathcal{L}_v \subseteq H^1(E_v, V)$ be the images of these local cocycle conditions, and let $\mathcal{D}$ be the ordinary dual Selmer group in $H^1(G_{E,S\cup J\cup\bar{J}}, V^\vee)$ for their local Tate annihilators, where $V^\vee = \mathrm{Hom}_{\mathbb{Z}}(V, \mathbb{Q}/\mathbb{Z})(1)$. The module C is isomorphic to $H^1_{\mathcal{L}}(V)$. To see this, every cohomology class has a unique representative vanishing at γ_*, since $\rho(\gamma_*) - I = (\zeta_* - 1)I$ is invertible on V. Adding a coboundary preserves every local condition above. Conversely their membership says exactly that the normalized representative satisfies the local relations and ties defining C. The conditions at old primes away from ℓ impose no further restriction on a global cocycle, by the definition of $C_v(a)$.

Both global invariant groups $H^0(V)$ and $H^0(V^\vee)$ are zero. The inertial element γ_* acts by ζ_* on the first and by ζ_*^{-1} on the second, since the cyclotomic character is trivial on inertia away from ℓ. Both scalars differ from 1 by units. If Z_v denotes a local cocycle condition, then

$$\operatorname{len}\mathcal{L}_v - \operatorname{len}H^0(E_v,V) = \operatorname{len}Z_v - \operatorname{len}V, \tag{2}$$

because the local coboundaries have length $\operatorname{len}V - \operatorname{len}H^0(E_v,V)$. The formula of Proposition 7.4.17, converted from orders to $\mathcal{O}$-lengths, therefore gives

$$\operatorname{len}C = \operatorname{len}\mathcal{D} + \sum_{v\in S\cup J\cup\bar{J}} (\operatorname{len}Z_v - \operatorname{len}V) - f_E \operatorname{len}V. \tag{3}$$

Here every complex place contributes $\operatorname{len}V$. The formula applies at every ℓ, including 2, because E has no real places. Using (1), the rank bound in (SD), the auxiliary-place bound, and the definition of B_v, equation (3) implies

$$\operatorname{len}C \le \operatorname{len}\mathcal{D} + \sum_{\substack{v\in S\\ v\nmid\ell}} B_v. \tag{4}$$

All the groups used here are finite by the same global and local duality theorems.

It remains to bound $\mathcal{D}$. Fix a compatible system of ℓ-power roots of unity to write the underlying additive dual as $D = \operatorname{Hom}_{\mathbb{Z}}(V,\mathbb{Q}/\mathbb{Z})$; its action is

$$(gd)(v) = d(\chi_{\mathrm{cyc}}(g)\rho(g)^{-1}v).$$

Normalize each dual cocycle by requiring its value at γ_* to be zero; this representative is unique because $\zeta_*^{-1}-1$ is a unit. Let H be the subgroup generated by $[g,\gamma_*]$ and $[g,\gamma_*^c]$. By Lemma 7.4.18, it is normal, conjugation-stable, killed by ρ and every abelian character, and $z(H)$ spans V. Restrict the normalized dual cocycles to H and call the image Y. These are additive homomorphisms with

$$y(ghg^{-1})(v) = y(h)\big(\chi_{\mathrm{cyc}}(g)\rho(g)^{-1}v\big).$$

Restriction is injective. Indeed, if the normalized dual cocycle is zero on H, expanding it at $[g,\gamma_*]$ gives $(1-\zeta_*^{-1})y(g)=0$ for every g, so it is zero. Hence $\operatorname{len}Y = \operatorname{len}\mathcal{D}$.

We prove diagonal mirror isotropy on H. Fix $y\in Y$, its normalized global representative, $h\in H$, and $r\in\mathcal{O}$. Put $\tau_0=\gamma_{v_0}$. The dual class is unramified at $v_0,\bar{v}_0$: its local condition is the annihilator of the unramified condition, which is again unramified by local Tate duality [201, Chapter I, Theorem 2.6]. Inertia acts trivially there on both modules, so this means

$$y(\tau_0) = y(\tau_0^c) = 0.$$

Likewise $z(\tau_0)=z(\tau_0^c)=0$ by the zero first slope. Therefore the diagonal expression

$$y(g)(rz(g)) - y(g^c)(rz(g^c)) \tag{5}$$

has the same value at $g=h$ and $g=\tau_0 h$.

Apply Lemma 7.4.14 with its forbidden set $S_{\mathrm{aux}} = J\setminus\{v_0\}$. Choose its set R to contain $S_0\cup\bar{S}_0\cup J\cup\bar{J}$ and all places above $\mathrm{N}v_0$. The forbidden decomposition groups are therefore those above $S_{\mathrm{aux}}\cup\bar{S}_{\mathrm{aux}}\cup\Sigma_\ell$. The normal-inertia hypothesis is satisfied by $\tau_0 h$: the old place containing γ_* and its conjugate belong to $S\cup\bar{S}$, are prime to ℓ, and lie outside $J\cup\bar{J}$ by (AX2). Each generating commutator of H lies in the normal subgroup generated by those two inertia

groups. Also v_0 belongs to R and lies outside $S_{\mathrm{aux}} \cup \bar{S}_{\mathrm{aux}} \cup \Sigma_\ell$, so τ_0 belongs to the permitted inertia. Thus $\tau_0 h$ belongs to the required closed normal subgroup generated by inertia above $R \setminus (S_{\mathrm{aux}} \cup \bar{S}_{\mathrm{aux}} \cup \Sigma_\ell)$. Enlarging R only enlarges this subgroup. The supplied prime is outside $R \cup \bar{R}$, so it meets all the required exclusions; the supplied character has modulus $\{P\}$ and is trivial on the required decomposition groups.

Choose the neighborhood of $\tau_0 h$ so that (5) is constant, the two representation matrices are I modulo ℓ^M, and the old characters take the required values. These conditions hold at $\tau_0 h$: ρ kills both τ_0 and H; conjugation preserves H and ρ also kills τ_0^c; every λ_w kills H; and $\lambda_w(\tau_0) = 1$ for $w = v_0$ and 0 otherwise. The last assertion follows from the normalization at v_0 and unramifiedness at the other disjoint auxiliary primes. The finite-valued cocycles and characters are locally constant, so this is indeed a neighborhood. The supplied tuple $(P, \gamma, \phi, \lambda)$ is admissible in the statement. In particular (5) at ϕ equals (5) at h.

Choose z_P using the hypothesis. Since $\rho(\gamma^c) = I$ and $\rho(\phi^c) = I$ on V, the cocycle identity for inverses converts the second equality into $z_P(\gamma^c) = z(\phi^c)$. Global cup reciprocity for rz_P and y says that the sum of their local cup invariants is zero [201, Chapter I, Theorem 4.10]. At the old places it is zero by the dual local conditions. Away from the old places and $P, \bar{P}$, both classes are unramified, so local unramified orthogonality makes it zero. Only the two new places remain.

We spell out their common normalization. Put $q = \ell^M$. At P the local action on V and its Cartier dual is trivial, and μ_q is contained in E_P. Scalar homomorphisms $G_{E_P} \to \mathbb{Z}/q$ have independent coordinates given by evaluation on γ, ϕ: wild inertia contributes nothing and the tame relation is $\phi\gamma\phi^{-1} = \gamma^{\mathrm{N}P}$, with $\mathrm{N}P \equiv 1 \pmod q$. Thus this scalar cohomology is $(\mathbb{Z}/q)^2$. Local Tate perfectness and unramified orthogonality [201, Chapter I, Corollary 2.3 and Theorem 2.6] show that pairing a tame-coordinate generator with the unramified line is multiplication by a unit $u_P \in (\mathbb{Z}/q)^\times$. Perfectness is essential here: it makes this multiplication invertible, rather than merely nonzero.

For an arbitrary finite $\mathbb{Z}/q$-module V, naturality under the map $\mathbb{Z}/q \to V$ taking 1 to v gives the same formula with $u_P d(v)$, where d is the dual Frobenius value. Indeed a cocycle with tame value v differs from the image of the scalar tame-coordinate generator by an unramified cocycle, whose pairing with an unramified dual class is zero. This argument does not require V to be free over $\mathbb{Z}/q$. At $\bar{P}$ use the transported generators γ^c, ϕ^c. To compare coefficients, transport the scalar tame generator and scalar unramified character from P to $\bar{P}$ by c. Their evaluation coordinates remain $(1, 0)$ and $(0, 1)$ on γ^c, ϕ^c. The invariant map on the Brauer group is preserved by this field isomorphism. However the identification of the Cartier dual scalar module with $\mathbb{Z}/q$ uses a fixed primitive root ξ_q, and its transported identification uses $c(\xi_q) = \xi_q^{-1}$. Expressing that transported dual generator in the original fixed-root identification multiplies it by -1. By bilinearity and naturality, the cup coefficient at $\bar{P}$ in that original identification is therefore exactly $-u_P$, with no change of the invariant map itself. The two new local contributions consequently give

$$u_P\big(y(\phi)(rz_P(\gamma)) - y(\phi^c)(rz_P(\gamma^c))\big) = 0.$$

Cancel the unit and substitute the two prescribed values. Expression (5) at ϕ, and therefore at h, is zero. This proves the diagonal isotropy for every h, r, y; the argument includes $\ell = 2$, when the displayed negative may equal the positive at exponent 2.

All the hypotheses of Lemma 7.4.19 now hold for Y, H, z and the scalar inertial element. It gives an injection

$$Y \hookrightarrow \mathrm{Hom}_{\mathcal{O}, G_E}(V, V^{*c}).$$

Thus $\operatorname{len} \mathcal{D} = \operatorname{len} Y \le B_{\mathrm{gl}}$. Combining this with (4) proves the assertion. □

Proposition 7.4.17. *Let F be a number field and ℓ a prime; assume that ℓ is odd or that F has no real place. Let S be a finite set of places of F containing the places above ℓ and the archimedean places, $S_f \subseteq S$ its finite places, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of $G_{F,S}$. For $v \in S_f$ let*

$$\langle\ ,\ \rangle_v \colon H^1(F_v, M) \times H^1(F_v, M^\vee) \to H^2(F_v, \mu_{\ell^r}) \xrightarrow{\mathrm{inv}_v} \mathbb{Q}/\mathbb{Z}$$

*be the cup product pairing. A **family of local conditions** for M is a family $\mathcal{L} = (L_v)_{v \in S_f}$ of subgroups $L_v \subseteq H^1(F_v, M)$; its **dual family** is $\mathcal{L}^\perp = (L_v^\perp)_{v \in S_f}$, $L_v^\perp \subseteq H^1(F_v, M^\vee)$ the annihilator of L_v under $\langle\ ,\ \rangle_v$; the **Selmer groups** are*

$$H^1_{\mathcal{L}}(M) = \{x \in H^1(G_{F,S}, M) :\ \mathrm{res}_v(x) \in L_v \text{ for all } v \in S_f\},$$
$$H^1_{\mathcal{L}^\perp}(M^\vee) = \{y \in H^1(G_{F,S}, M^\vee) :\ \mathrm{res}_v(y) \in L_v^\perp \text{ for all } v \in S_f\}.$$

Then $H^1_{\mathcal{L}}(M)$ and $H^1_{\mathcal{L}^\perp}(M^\vee)$ are finite and

$$\#H^1_{\mathcal{L}}(M) \cdot \#H^0(G_{F,S}, M^\vee) \cdot \prod_{v \in S} \#H^0(F_v, M) = \#H^1_{\mathcal{L}^\perp}(M^\vee) \cdot \#H^0(G_{F,S}, M) \cdot \prod_{v \in S_f} \#L_v,$$

where the product on the left runs over all places of S, the archimedean ones included ($H^0(F_v, M)$ is the subgroup fixed by a complex conjugation at a real place v, and M at a complex place).

Proof. We extend the prescribed conditions to all places, identify the two Selmer groups, and then specialize the classical quotient formula.

First, inflate M from $G_{F,S}$ to G_F. Since S contains every place above ℓ, the roots of unity μ_{ℓ^r} are unramified outside S: locally at residue characteristic different from ℓ, roots of unity of ℓ-power order lie in an unramified extension, by lifting their simple residue-field roots. Thus $M^\vee$ also factors through $G_{F,S}$, and it is the Cartier dual in the classical theorem with $n = \ell^r$. In particular its global invariants, and those of M, agree for G_F and $G_{F,S}$.

At finite $v \in S$ retain the given L_v. At finite $v \notin S$ set

$$\widetilde{L}_v = H^1_{\mathrm{ur}}(F_v, M) = H^1(G_{F_v}/I_v, M).$$

Here inertia acts trivially on both modules. The residue characteristic is different from ℓ, so Theorem A.3.1(3) identifies $\widetilde{L}_v^\perp$ with the unramified subgroup for $M^\vee$. At each infinite place set $\widetilde{L}_v = 0$. Under the hypothesis in the statement, $H^1(F_v, M)$ and $H^1(F_v, M^\vee)$ are both zero: at a complex place the Galois group is trivial, and at a real place its order is two and is invertible on these odd-primary modules. Averaging over that finite group contracts positive-degree cohomology. Thus zero is the whole local group for each module at infinity, and the two infinite local conditions are exact annihilators. In particular this argument includes $\ell = 2$ when F has no real place, without imposing an odd-prime hypothesis there.

The all-place Selmer group for $\widetilde{L}$ is exactly the inflation of the displayed group $H^1_{\mathcal{L}}(M)$. Here is the descent check. Put $N = \ker(G_F \to G_{F,S})$; it acts trivially on M. The restriction to an inertia subgroup outside S of a global cocycle representing an unramified local class is zero as a function: coboundaries on that inertia subgroup vanish because its action is trivial. The cocycle is consequently zero on every conjugate of such an inertia subgroup, since its action factors through $G_{F,S}$. These inertia subgroups topologically normally generate N, by the definition of the maximal extension unramified outside S. The cocycle restricted to N is a continuous homomorphism to the finite group M, and therefore vanishes on N. It descends to a continuous cocycle of $G_{F,S}$. Inflation is injective on cohomology: if an inflated cocycle is a coboundary

on G_F, the same coboundary formula already holds on its quotient. Conversely every quotient cocycle is unramified outside S. This proves the asserted equality of groups, with the local conditions inside S unchanged. The identical argument applies to the dual module and its annihilator conditions.

For $v \notin S$ the unramified cohomology is the cokernel of $\mathrm{Fr}_v - 1$ on the finite group M, while $H^0(F_v, M)$ is its kernel. Indeed continuous cocycles of the procyclic unramified quotient are determined by their value on Frobenius, modulo these coboundaries; every value gives a continuous cocycle, by taking a multiple of the order of the action and of the exponent of M. An endomorphism of a finite group has equally sized kernel and cokernel. Hence

$$\#\widetilde{L}_v = \#H^0(F_v, M) \qquad (v \notin S).$$

All corresponding factors in the classical product are one. At infinity $\#\widetilde{L}_v = 1$, whereas the denominator is the ordinary invariant group, not a Tate quotient: it is M^{c_v} at a real place and M at a complex place.

The classical Greenberg–Wiles theorem, [63], Theorem 2.19, now gives finiteness of both identified Selmer groups and

$$\frac{\#H^1_{\mathcal{L}}(M)}{\#H^1_{\mathcal{L}^\perp}(M^\vee)} = \frac{\#H^0(G_{F,S}, M)}{\#H^0(G_{F,S}, M^\vee)} \frac{\prod_{v \in S_f} \#L_v}{\prod_{v \in S} \#H^0(F_v, M)}.$$

Every denominator is the positive order of a finite group, so multiplying by them gives exactly the asserted identity. □

Lemma 7.4.18. *Let R be a commutative ring, $n \geq 1$, G a group with an involutive automorphism c, and $\rho : G \to \mathrm{GL}_n(R)$ a representation whose image spans $\mathrm{Mat}_n(R)$ over R. Suppose $\gamma \in G$ and $\zeta \in R^\times$ satisfy*

$$\rho(\gamma) = \zeta I, \qquad \rho(c(\gamma)) = \zeta^{-1} I, \qquad \zeta - 1 \in R^\times.$$

Let H be the subgroup generated by $[g, \gamma]$ and $[g, c(\gamma)]$ for $g \in G$, where $[u, v] = uvu^{-1}v^{-1}$. Then H is normal, $c(H) = H$, and $\rho(H) = \{I\}$. Every homomorphism from G to an abelian group is trivial on H. If $z : G \to R^n$ is a cocycle for ρ with $z(\gamma) = 0$ and some coordinate of some $z(g)$ is a unit, then

$$\mathrm{span}_R\, z(H) = R^n.$$

Proof. For $\delta \in \{\gamma, c(\gamma)\}$ and $a, g \in G$, direct multiplication gives

$$a[g, \delta]a^{-1} = [ag, \delta][a, \delta]^{-1}.$$

Thus conjugation by every a preserves the subgroup generated by these commutators; applying the same assertion to a^{-1} proves normality. Applying c interchanges the two families of generators, so $c(H) = H$. Both $\rho(\gamma)$ and $\rho(c(\gamma))$ are scalar matrices, hence the images of all the generating commutators are I. Any homomorphism to an abelian group also kills each generating commutator.

Put $X = \mathrm{span}_R\, z(H)$. Since $\rho(H) = \{I\}$, the cocycle identity and $z(g^{-1}) = -\rho(g)^{-1} z(g)$ give

$$z(aha^{-1}) = \rho(a) z(h) \qquad (a \in G,\ h \in H).$$

Normality therefore makes X stable under $\rho(G)$, and hence under every matrix in $\mathrm{Mat}_n(R)$ by the spanning hypothesis. Also $z(\gamma) = z(\gamma^{-1}) = 0$, and expanding the cocycle at the commutator yields

$$z([g,\gamma]) = z(g) + \rho(g)\rho(\gamma)z(g^{-1}) = (1-\zeta)z(g).$$

Choose g and a coordinate j for which $z(g)_j$ is a unit. Since $1-\zeta$ is a unit, the vector $u = z([g,\gamma]) \in X$ has a unit jth coordinate. For every coordinate i, stability under the matrix unit E_{ij} gives $u_j e_i \in X$. Multiplication by u_j^{-1} gives $e_i \in X$. All standard basis vectors belong to X, which proves the asserted equality. $\square$

Lemma 7.4.19. *Let $\mathcal{O}$ be a commutative ring, V an $\mathcal{O}$-module, G a group, c an involutive automorphism of G, and H a normal subgroup with $c(H) = H$. Let $\rho : G \to \mathrm{Aut}_{\mathcal{O}}(V)$ and $\chi : G \to \mathcal{O}^{\times}$ be homomorphisms, both trivial on H, and let $z : G \to V$ be a cocycle for ρ. Suppose that $z(H)$ generates V over $\mathcal{O}$. Put $D = \mathrm{Hom}_{\mathbb{Z}}(V, \mathbb{Q}/\mathbb{Z})$, with $(r\lambda)(v) = \lambda(rv)$. Let Y be an $\mathcal{O}$-submodule of the additive homomorphisms $H \to D$ such that, for every $y \in Y$, $g \in G$, $h \in H$, $v \in V$,*

$$y(ghg^{-1})(v) = y(h)\big(\chi(g)\rho(g)^{-1}v\big).$$

Assume that there are $\gamma \in G$ and $\zeta \in \mathcal{O}^{\times}$ with

$$\rho(\gamma) = \zeta I, \qquad \rho(c(\gamma)) = \zeta^{-1} I, \qquad \chi(\gamma) = \chi(c(\gamma)) = 1, \qquad \zeta^2 - 1 \in \mathcal{O}^{\times},$$

and that for every $y \in Y$, $h \in H$, $r \in \mathcal{O}$,

$$y(h)(rz(h)) = y(c(h))(rz(c(h))).$$

Then for each $y \in Y$ there is a unique $\mathcal{O}$-linear map $A_y : V \to D$ with

$$A_y(z(h)) = y(c(h)) \qquad (h \in H).$$

The assignment $y \mapsto A_y$ is an injective $\mathcal{O}$-linear map into the module of $\mathcal{O}$-linear maps $A : V \to D$ satisfying

$$A(\rho(g)v)(w) = A(v)\big(\chi(c(g))\rho(c(g))^{-1}w\big) \qquad (g \in G,\ v, w \in V).$$

In particular, if $\mathcal{O}$ is a discrete valuation ring, the length of Y is at most the length of this latter module.

Proof. Fix $y \in Y$. For $r \in \mathcal{O}$ and $h, k \in H$ write

$$F_r(h,k) = y(k)(rz(h)) - y(c(h))(rz(c(k))) \in \mathbb{Q}/\mathbb{Z}.$$

Because ρ is trivial on H, the restriction of z to H is additive. Thus F_r is additive in each group argument, and additive in r. The isotropy hypothesis is $F_r(h,h) = 0$. Expanding at hk gives

$$F_r(h,k) + F_r(k,h) = 0. \tag{1}$$

For $h \in H$ the cocycle identity gives $z(ghg^{-1}) = \rho(g)z(h)$: in its expansion the terms involving $z(g)$ cancel because $\rho(h) = I$. Using this identity and the covariance of y, the scalar hypotheses give

$$F_r(\gamma h \gamma^{-1}, k) = F_{\zeta r}(h,k), \qquad F_{\zeta r}(k, \gamma h \gamma^{-1}) = F_r(k,h).$$

Indeed in the first equality both $z(h)$ and the functional $y(c(h))$ acquire a factor ζ; in the second, both occurrences involving h acquire a factor ζ^{-1}, which cancels the displayed factor ζ. Apply

(1) with parameter ζr and arguments $\gamma h \gamma^{-1}, k$. Subtract (1) with parameter r and arguments h, k. It follows that

$$F_{(\zeta^2-1)r}(h,k) = 0.$$

Since $\zeta^2 - 1$ is a unit, we have

$$y(k)(rz(h)) = y(c(h))(rz(c(k))) \qquad (r \in \mathcal{O},\ h,k \in H). \tag{2}$$

We next show that the prescribed values of A_y respect all linear relations among the $z(h)$. Suppose $\sum_{j=1}^{q} r_j z(h_j) = 0$. Put $\lambda = \sum_j r_j y(c(h_j)) \in D$. For $k \in H$ and $r \in \mathcal{O}$, equation (2) gives

$$\lambda(rz(c(k))) = \sum_j y(c(h_j))(rr_j z(c(k))) = y(k)\left(r \sum_j r_j z(h_j)\right) = 0.$$

The vectors $z(c(k))$ generate V, since $c(H) = H$. Every vector of V is therefore a finite sum of the tested vectors $rz(c(k))$. The additive functional λ is zero. Consequently

$$A_y\left(\sum_j r_j z(h_j)\right) = \sum_j r_j y(c(h_j))$$

is a well-defined $\mathcal{O}$-linear map $V \to D$. Generation also proves uniqueness.

For $g \in G$, $h \in H$ and $w \in V$, normality of H and the cocycle identity yield

$$\begin{aligned} A_y(\rho(g)z(h))(w) &= A_y(z(ghg^{-1}))(w) \\ &= y(c(g)c(h)c(g)^{-1})(w) \\ &= y(c(h))(\chi(c(g))\rho(c(g))^{-1}w) \\ &= A_y(z(h))(\chi(c(g))\rho(c(g))^{-1}w). \end{aligned}$$

Extend this equality $\mathcal{O}$-linearly from the generating set $z(H)$ to obtain the required equivariance. The formula on this generating set shows that $y \mapsto A_y$ preserves addition and scalar multiplication. If $A_y = 0$, then $y(c(h)) = 0$ for all $h \in H$, hence $y = 0$ because $c(H) = H$. This proves injectivity. The final assertion follows from monotonicity of module length under an injection. □

Lemma 7.4.20. *Let E be a number field, ℓ a prime, $\mathcal{O}$ the integer ring of a finite extension of $\mathbb{Q}_\ell$, $M, q \geq 1$ integers, $n \geq 1$, J a finite set, and*

$$\rho : G_E \longrightarrow \mathrm{GL}_n(\mathcal{O}), \qquad \lambda_j : G_E \longrightarrow \mathbb{Z}/q\mathbb{Z} \quad (j \in J)$$

continuous homomorphisms. Let S be a finite set of finite places and $\mathscr{L}$ any family of finitely supported functions $G_E \to M_n(\mathcal{O})$. For $g \in G_E$ let $[\lambda_j(g)]_q \in \{0, \ldots, q-1\}$ be its least nonnegative representative. For any coefficient extension $\mathcal{O}' \supseteq \mathcal{O}$ and $x \in (\mathcal{O}')^J$, put

$$\rho_x(g) = \left(\prod_{j \in J} (1 + x_j)^{[\lambda_j(g)]_q}\right) \rho(g).$$

Let $\mathcal{S}_{\mathcal{O}'}(x)$ be the $\mathcal{O}'$-module of continuous functions $z : G_E \to (\mathcal{O}'/\ell^M)^n$ satisfying

$$z(gh) = z(g) + \rho_x(g)z(h) \quad (g,h \in G_E), \qquad z(\gamma) = 0 \quad (\gamma \in I_v,\ v \notin S),$$

where all choices of inertia groups above v are included, and

$$\sum_{g\in G_E} A(g)z(g) = 0 \quad (A \in \mathscr{L}).$$

The coefficients in these formulas are reduced modulo ℓ^M. No multiplicativity of the function ρ_x is required.

For every coefficient extension $\mathcal{O}_0 \supseteq \mathcal{O}$ and every $x_0 \in (\mathcal{O}_0)^J$, there is a nonzero polynomial $P \in \mathcal{O}[X_j : j \in J]$ such that

$$v_\ell(P(x_0)) = \mathrm{nl}_{\mathcal{O}_0}\mathcal{S}_{\mathcal{O}_0}(x_0), \qquad \mathrm{nl}_{\mathcal{O}'}\mathcal{S}_{\mathcal{O}'}(x) \le v_\ell(P(x))$$

for every coefficient extension $\mathcal{O}' \supseteq \mathcal{O}$ and every $x \in (\mathcal{O}')^J$. All the displayed modules have finite length.

Proof. We first produce a finite quotient that works for every point and coefficient extension. Let

$$H = \ker(\rho \bmod \ell^M) \cap \bigcap_{j\in J} \ker \lambda_j.$$

This is an open normal subgroup of G_E. Write F for its fixed field, so $H = G_F$, and let S_F be the places of F above S. The set of continuous characters

$$H \longrightarrow \mathbb{Z}/\ell^M\mathbb{Z}$$

unramified outside S_F is finite. Indeed the cited finiteness condition gives this for $M = 1$. Reduction modulo ℓ maps the set for exponent ℓ^a into the finite set for exponent ℓ; the difference of two elements in one fiber takes values in $\ell(\mathbb{Z}/\ell^a) \simeq \mathbb{Z}/\ell^{a-1}$, so induction proves finiteness for every a.

Intersect their kernels, obtaining an open subgroup of H, and take its normal core in G_E. Denote the resulting open normal subgroup by $K \subseteq H$. Thus every such character of H vanishes on K. We claim that every function z in every module of the statement vanishes on K. On H the matrices $\rho_x(g)$ act identically modulo ℓ^M for every x, because each $\lambda_j(g)$ is zero and $\rho(g) \equiv I$. The cocycle equation therefore makes $z|_H$ additive. For any additive character $\nu : (\mathcal{O}'/\ell^M)^n \to \mathbb{Z}/\ell^M$, its composite with $z|_H$ is a continuous character unramified outside S_F: inertia over F at a place outside S_F is contained in the corresponding inertia over E, where z vanishes. Hence $\nu z(k) = 0$ for $k \in K$. These additive characters separate points. Explicitly, a finite abelian group killed by ℓ^M is a direct sum of cyclic groups of orders ℓ^a with $a \le M$, and the map $\mathbb{Z}/\ell^a \to \mathbb{Z}/\ell^M$ given by multiplication by ℓ^{M-a} detects every nonzero element in that summand. Thus $z(K) = 0$. The cocycle equation now gives

$$z(gk) = z(g) + \rho_x(g)z(k) = z(g) \qquad (g \in G_E,\ k \in K).$$

All the functions in question factor through the same finite set $\Delta = G_E/K$.

We next write their equations over one polynomial ring. Put $\Lambda = \mathcal{O}[X_j : j \in J]$, and for $g \in G_E$ put

$$U_g(X) = \prod_{j\in J}(1 + X_j)^{[\lambda_j(g)]_q}, \qquad R_g(X) = U_g(X)\rho(g).$$

There are $c = n\#\Delta$ scalar coordinates, indexed by $(d, i) \in \Delta \times \{1, \dots, n\}$. Writing w_d for their n-component column, form the rows of all the linear equations

$$w_{[gh]} - w_{[g]} - R_g(X)w_{[h]} = 0, \qquad w_{[\gamma]} = 0 \quad (\gamma \in I_v,\ v \notin S), \qquad \sum_g A(g)w_{[g]} = 0 \quad (A \in \mathscr{L}).$$

Each component is a row in Λ^c. Include also the rows $\ell^M e_i$, $1 \le i \le c$, and let $\mathscr{R}$ be the submodule generated by all these rows. Since $\mathcal{O}$ is Noetherian and J is finite, Λ is Noetherian. Consequently $\mathscr{R}$ is generated by finitely many of the displayed rows: start with a finite set of module generators and expand them as finite linear combinations of the displayed rows. Let $A(X)$ be the resulting finite matrix, with c columns.

For every $\mathcal{O}'$ and x, pullback along $G_E \to \Delta$ identifies $\mathcal{S}_{\mathcal{O}'}(x)$ with

$$\ker\bigl(A(x) : (\mathcal{O}'/\ell^M)^c \longrightarrow (\mathcal{O}'/\ell^M)^{\#\mathrm{rows}(A)}\bigr).$$

One direction follows from the factorization just proved. Conversely a vector satisfying the specialized rows gives a function on Δ, hence a continuous function on G_E, and the rows impose exactly every equation in the statement. Finite row generation is preserved under specialization, so there are no additional equations to check.

We finally compute these lengths by maximal minors. Fix $\mathcal{O}'$ and x, write ϖ' for a uniformizer and $e' = v_{\varpi'}(\ell)$. The row module of $A(x)$ contains $\ell^M(\mathcal{O}')^c$, since this containment already held over Λ. Smith normal form therefore has exactly c nonzero diagonal invariant factors $(\varpi')^{d_1}, \dots, (\varpi')^{d_c}$, with $0 \le d_i \le Me'$. On $\mathcal{O}'/\ell^M$, the kernel of multiplication by $(\varpi')^{d_i}$ has length d_i. Thus the module above has length $\sum_i d_i$. The ideal generated by the c by c minors of $A(x)$ is $(\varpi')^{\sum_i d_i}$. To see this last assertion directly, invertible row and column operations preserve the ideal of maximal minors, by the determinant expansion and their inverse operations; for the Smith matrix the only nonzero maximal minors generate the product of the diagonal factors. It follows that

$$\mathrm{nl}_{\mathcal{O}'}\mathcal{S}_{\mathcal{O}'}(x) = \min_D v_\ell(D(x)),$$

where D ranges over the finitely many maximal-minor polynomials of $A(X)$. There is a nonzero evaluated minor, because the row module contains $\ell^M(\mathcal{O}')^c$.

At $(\mathcal{O}_0, x_0)$ choose a minor attaining this minimum and call its polynomial P. Its evaluation at x_0 is nonzero, so P itself is nonzero. The same minimum formula at every other point gives the required upper bound by $v_\ell(P(x))$, and at x_0 it gives equality. The matrix kernel lies in a finite module for each coefficient ring, proving finite length as well. □

Lemma 7.4.21. *Let E be a CM field with complex conjugation c, let ℓ be a prime, $\mathcal{O}$ a coefficient ring, $M, N, n \ge 1$, and $\rho : G_E \to \mathrm{GL}_n(\mathcal{O})$ continuous. Let J be a finite set of places with a distinguished $v_0 \in J$, disjoint from its conjugate and from the places above ℓ. Assume that ρ is unramified at every place of $J \cup \bar{J}$. For each $v \in J$ fix a tame generator γ_v and an arithmetic Frobenius φ_v in the same decomposition group, and require $\mathrm{N}v \equiv 1 \pmod{\ell^N}$. Put $g^+ = g$ and $g^- = (g^c)^{-1}$.*

Suppose that continuous additive characters $\lambda_w : G_E \to \mathbb{Z}/\ell^N$ satisfy

$$\lambda_w(g^c) = -\lambda_w(g), \qquad \lambda_w(\gamma_v) = \delta_{wv}, \qquad \lambda_w(\varphi_v) = \delta_{wv_0} \quad (v \ne v_0),$$

and are unramified outside $\{w, \bar{w}\}$. Let $s_v \in \mathcal{O}$, with $s_{v_0} = 0$, and assume

$$s_v \ne 0 \implies \rho(\varphi_v^+) \equiv \rho(\varphi_v^-) \equiv I \pmod{\ell^M}.$$

Let $\mathcal{O}' \supseteq \mathcal{O}$ be a coefficient extension, $r > 0$, $K \ge 0$ an integer with $\ell^K r \ge 1$, $N \ge K + M$, and $y \in \mathcal{O}'$ with $v_\ell(y) \ge r$. Put $u = 1 + y$ and

$$a_{v_0} = u, \qquad a_v = 1 + s_v y \quad (v \ne v_0), \qquad \eta_y(g) = \prod_{v \in J} a_v^{[\lambda_v(g)]_{\ell^N}},$$

where brackets denote the least nonnegative representative. Modulo ℓ^M, this defines a character with unit values, hence $\sigma_y = \eta_y\rho$ defines a representation on $W = (\mathcal{O}'/\ell^M)^n$.

Let $I \subseteq J$, with $y = 0$ if $v_0 \in I$, and let V be any $\mathcal{O}'$-submodule of the continuous σ_y-cocycles $G_E \to W$. Let V_I be cut out by

$$z(\gamma_v^b) = s_v z(\varphi_v^b) \qquad (v \in I,\ b \in \{+,-\}).$$

For each such (v,b) choose $w_{v,b} \in G_E$ with $\rho(w_{v,b}) \equiv \rho(\varphi_v^b) \pmod{\ell^M}$. Then V/V_I has finite length and

$$\mathrm{nl}_{\mathcal{O}'}(V/V_I) \le \sum_{v\in I}\sum_{b\in\{+,-\}} v_\ell \det(u\rho(w_{v,b}) - I).$$

Proof. We first prove the geometric-sum estimate that makes the affine local calculation exact. Let $a = 1 + t \in \mathcal{O}'$ with $v_\ell(t) \ge r$, allowing $t = 0$. The binomial theorem gives

$$v_\ell(a^\ell - 1) \ge \min\{\ell v_\ell(a-1),\, v_\ell(a-1) + 1\}.$$

Induction implies $v_\ell(a^{\ell^j} - 1) \ge \min\{\ell^j r, 1\}$ for $j \le K$, and hence this valuation is at least 1 for all $j \ge K$. For $j \ge K$ the integral polynomial

$$1 + a^{\ell^j} + \cdots + (a^{\ell^j})^{\ell-1}$$

has valuation at least 1: modulo an element of valuation at least 1 all its ℓ summands are 1, and its constant sum is ℓ. The factorization

$$\sum_{h=0}^{\ell^N-1} a^h = \prod_{j=0}^{N-1}\left(\sum_{b=0}^{\ell-1}(a^{\ell^j})^b\right)$$

therefore has valuation at least $N - K \ge M$. Multiplication by $a - 1$ also gives $a^{\ell^N} \equiv 1 \pmod{\ell^M}$. These assertions hold for every a_v, since s_v is integral, and for u. Each a_v is a unit because $v_\ell(a_v - 1) > 0$. The cyclic character $g \mapsto a_v^{\lambda_v(g)}$ is thus well defined modulo ℓ^M, proving the assertion about η_y and σ_y.

Fix a cocycle $z \in V$. It defines a continuous affine action on the finite set W by

$$T_g(m) = \sigma_y(g)m + z(g), \qquad T_gT_h = T_{gh}.$$

At a place $v \in J$ the linear action of wild inertia is trivial. The representation ρ is unramified there, and each λ_w kills wild inertia, which is pro-residue-characteristic, whereas its target is an ℓ-group. Restriction of z to wild inertia is then a continuous homomorphism to the additive ℓ-group W, so it vanishes. Thus the affine action kills wild inertia.

We recall explicitly the tame relation used here. In the maximal tame quotient of a local Galois group of residue cardinality Q, arithmetic Frobenius acts on inertia by the Q-power map. Indeed over the maximal unramified extension, every finite tame extension of ramification degree d prime to the residue characteristic is obtained by adjoining a d-th root of a uniformizer: units have d-th roots by Hensel's lemma, and the residue field is algebraically closed. Inertia multiplies this root by a d-th root of unity; arithmetic Frobenius raises those roots of unity to their Q-th powers. Passing over all d gives the relation. Changing the Frobenius lift by an inertia element does not change it, since tame inertia is abelian.

At γ_v, the linear part of T_{γ_v} is $a_v I$, by the character-coordinate identities and unramifiedness of ρ. Its ℓ^N-th iterate has linear part $a_v^{\ell^N} I = I$ on W, and translation part

$$\left(\sum_{h=0}^{\ell^N-1} a_v^h\right) z(\gamma_v) = 0.$$

Hence $T_{\gamma_v}^{\ell^N} = 1$. Since $\mathrm{N}v \equiv 1 \pmod{\ell^N}$, the tame Frobenius relation gives

$$T_{\varphi_v} T_{\gamma_v} = T_{\gamma_v} T_{\varphi_v}.$$

At the conjugate place, the linear part at γ_v^c is $a_v^{-1} I$. Since $v_\ell(a_v^{-1} - 1) = v_\ell(a_v - 1) \geq r$, the same geometric-sum argument proves $T_{\gamma_v^c}^{\ell^N} = 1$. The transported arithmetic Frobenius φ_v^c therefore commutes with it. Inverting this commuting pair proves the same assertion for γ_v^-, φ_v^-.

For clarity, the character values at both signs agree: $\lambda_w(g^-) = \lambda_w(g)$. At $v \neq v_0$ we consequently have

$$\sigma_y(\gamma_v^b) = a_v I, \qquad \sigma_y(\varphi_v^b) = u\rho(\varphi_v^b).$$

The equality of the translation parts of the two commuting affine transformations yields, with $B_{v,b} = u\rho(\varphi_v^b) - I$,

$$B_{v,b} z(\gamma_v^b) = (a_v - 1) z(\varphi_v^b).$$

It follows that

$$B_{v,b}\big(z(\gamma_v^b) - s_v z(\varphi_v^b)\big) = s_v u\big(I - \rho(\varphi_v^b)\big) z(\varphi_v^b) = 0.$$

If $s_v = 0$ this is immediate; otherwise the residual Frobenius hypothesis makes the matrix on the right zero on W. If $v = v_0 \in I$, the imposed condition $y = 0$ makes every $a_w = 1$ and $\eta_y = 1$; also $s_{v_0} = 0$. The same commuting identity then says $(\rho(\varphi_{v_0}^b) - I) z(\gamma_{v_0}^b) = 0$. Thus the displayed kernel assertion is valid for every $(v, b) \in I \times \{+, -\}$.

Send $z \in V$ to its tuple of tie errors

$$\big(z(\gamma_v^b) - s_v z(\varphi_v^b)\big)_{v,b}.$$

Its kernel is exactly V_I, and its image is contained in the product of the kernels of $B_{v,b}$ on W. The same kernels are obtained on replacing φ_v^b by $w_{v,b}$, by the assumed congruence. This product is a finite module, proving finite length of V/V_I.

Finally, for any matrix $B \in M_n(\mathcal{O}')$, Smith normal form shows

$$\mathrm{len}_{\mathcal{O}'} \ker(B : W \to W) \leq v_{\varpi'}(\det B).$$

If $\det B = 0$, the right side is infinite and the assertion is immediate. Otherwise the diagonal invariant factors of B give kernel length $\sum_j \min\{v_{\varpi'}(d_j), M v_{\varpi'}(\ell)\}$, at most the valuation of their product. Sum this inequality over (v, b) and divide by $v_{\varpi'}(\ell)$ to obtain the required normalized bound. □

Lemma 7.4.22. *Let ℓ be prime, let v be the valuation on $\overline{\mathbb{Q}}_\ell$ normalized by $v(\ell) = 1$ and $v(0) = +\infty$, and put $\overline{\mathbb{Z}}_\ell = \{a : v(a) \geq 0\}$. Let $s_0 \geq 0$ and $m \geq 1$ be integers, let $0 < \rho < 1$ be rational, and let $B \geq 0$ and $\varepsilon > 0$ be real. There is an integer $H \geq 1$, depending only on $\ell, s_0, m, \rho, B, \varepsilon$, with the following property.*

For any finite set U with $\#U \leq s_0$, any finite set I, any polynomials $P_i \in \overline{\mathbb{Z}}_\ell[X_u : u \in U]$, and any points $x_i \in \overline{\mathbb{Z}}_\ell^U$ satisfying

$$v(x_{i,u}) \geq \rho, \qquad \sum_{i \in I} v(P_i(x_i)) \leq B,$$

there are ℓ^H-th roots of unity $(\zeta_u)_{u\in U}$ such that, for every $u \in U$ and $1 \le j \le m$,

$$0 < v(\zeta_u^j - 1) \le \rho,$$

and, simultaneously for every $i \in I$ and $1 \le j \le m$,

$$v\Big(P_i((\zeta_u^j - 1)_{u\in U})\Big) \le v(P_i(x_i)) + \varepsilon.$$

In particular H is chosen before the sets, polynomials and points.

Proof. **Gauss valuations reduce the one-variable problem to roots at one radius.** For a nonzero integral polynomial $g(Y) = \sum a_d Y^d$ and a rational $t \ge 0$, write

$$G_t(g) = \min_d (v(a_d) + dt).$$

These valuations are additive on products. Indeed choose an algebraic number of valuation t, scale the variable by it, and divide each polynomial by a coefficient of minimum valuation. The normalized polynomials have integral coefficients and nonzero reduction; their product has nonzero reduction because the residue ring is a field. This proves multiplicativity. Factoring g over the algebraic closure therefore gives

$$G_t(g) = C + \sum_{\alpha:\, v(\alpha)\ge 0} \min(t, v(\alpha)), \qquad C = G_0(g) \ge 0, \tag{1}$$

with roots counted with multiplicity. The factors belonging to roots of negative valuation are absorbed in C. For an integral y with $v(y) = t > 0$, only roots of valuation t can contribute an excess over (1). If R_t is their multiset, then

$$v(g(y)) = G_t(g) + \sum_{\alpha\in R_t} (v(y - \alpha) - t). \tag{2}$$

Both formulas also cover a nonzero constant polynomial.

For $h \ge 1$ put $r_h = 1/\varphi(\ell^h)$. Every primitive ℓ^h-th root ζ has $v(\zeta - 1) = r_h$. One elementary proof uses the Eisenstein polynomial $\Phi_{\ell^h}(1 + Y)$: its constant term is ℓ, its reduction is $Y^{\varphi(\ell^h)}$, and its roots are conjugate under the local Galois group, which preserves the valuation. Their valuations are consequently all $1/\varphi(\ell^h)$. The r_h are distinct and decrease to zero.

Fix positive rational t_0, a finite bound B_0, and $0 < \delta < 1$. Choose $H_0 \ge 1$ such that

$$B_0 < \delta \sum_{\substack{1\le h\le H_0\\ r_h\le t_0}} \frac{1}{h+1}. \tag{3}$$

Such an integer exists because the condition $r_h \le t_0$ holds eventually and the harmonic series diverges. Formula (1), and distinctness of the radii, show that every integral polynomial $g \ne 0$ with $G_{t_0}(g) \le B_0$ satisfies

$$\sum_{\substack{1\le h\le H_0\\ r_h\le t_0}} \#R_{r_h}\, r_h \le G_{t_0}(g) \le B_0.$$

Thus some h in this sum has

$$\#R_{r_h}\, r_h \le \frac{\delta}{h+1}. \tag{4}$$

Otherwise summing the strict reverse inequalities contradicts (3).

We next choose a primitive root at this radius. If $v(\alpha) > 0$, then $1+\alpha$ is a unit. For $f(Y) = (Y+1+\alpha)^{\ell^h} - 1$, all its roots are integral and its linear coefficient has valuation h. Factoring this monic polynomial and applying its Gauss valuation at radius one gives

$$\sum_{\zeta^{\ell^h}=1} \min(v(\zeta - 1 - \alpha), 1) = G_1(f) \le h + 1. \tag{5}$$

Restricting to primitive roots preserves the inequality. There are $\varphi(\ell^h) = 1/r_h$ such roots. Summing (5) over $\alpha \in R_{r_h}$, then averaging, gives a primitive ζ with

$$\sum_{\alpha \in R_{r_h}} \min(v(\zeta - 1 - \alpha), 1) \le \#R_{r_h}\, r_h(h+1) \le \delta.$$

Because $\delta < 1$, each summand is strictly less than one. Its truncation can therefore be removed. Formula (2), with $y = \zeta - 1$, proves

$$v(g(\zeta - 1)) \le G_{r_h}(g) + \delta. \tag{6}$$

In particular this evaluation is nonzero. The integer H_0 in (3) depends on t_0, B_0, δ, ℓ, not on the degree or coefficients of g.

One coordinate can be replaced simultaneously for all polynomials. First consider the assertion with $m = 1$, an arbitrary rational radius $t_0 > 0$, and error $e > 0$; no upper bound on t_0 is needed here. Choose

$$0 < \delta < \min(1, e/(s_0 + 1)),$$

and choose H_0 by (3) with $B_0 = B + e$. Order U. Suppose some coordinates have already been replaced by common values of the form $\zeta_u - 1$, with $0 < v(\zeta_u - 1) \le t_0$, while the remaining coordinates of the i-th point retain their original values. Let b_i be the current evaluation valuation. Initially $\sum_i b_i \le B$.

For the next coordinate, specialize all other coordinates in P_i at its current point and call the resulting integral polynomial $g_i(Y)$. Its evaluation at the unchanged coordinate is nonzero, since the current b_i are finite; hence $g_i \neq 0$. The unchanged coordinate has valuation at least t_0, so $G_{t_0}(g_i) \le b_i$. Apply (6) to $g = \prod_i g_i$; when I is empty this product is one. At every stage $\sum_i b_i \le B + \#U\,\delta < B + e$, so the same integer H_0 applies.

For the chosen root ζ, write $a_i = G_{r_h}(g_i)$ and $b_i' = v(g_i(\zeta - 1))$. Each $b_i' \ge a_i$, and (6) with multiplicativity gives

$$\sum_i b_i' \le \sum_i a_i + \delta.$$

Consequently $b_i' \le a_i + \delta \le b_i + \delta$ for each i, and also $\sum_i b_i' \le \sum_i b_i + \delta$. These two inequalities prove the induction assertions for both the individual valuations and their sum. After at most s_0 replacements, each valuation has increased by less than e. Every chosen root has order dividing ℓ^{H_0}. This proves the one-power assertion uniformly in the number of polynomials. If U is empty, no replacement is needed and the same conclusion is immediate.

Polynomial substitution makes the first m powers simultaneous. Return to the hypotheses of the statement. For each i, each $1 \le j \le m$, and each coordinate u, choose $x'_{i,j,u}$ with

$$(1 + x'_{i,j,u})^j = 1 + x_{i,u}, \qquad v(x'_{i,j,u}) \ge \rho/m. \tag{7}$$

To justify this choice, if $x_{i,u} = 0$ take $x' = 0$. Otherwise the j roots y of $y^j = 1 + x_{i,u}$ are units. The product of $1 - y$ over these roots is $-x_{i,u}$. All factors have nonnegative valuation, so one has valuation at least $v(x_{i,u})/j \ge \rho/m$. Take $x' = y - 1$.

Set

$$Q_{i,j}(X) = P_i(((1 + X_u)^j - 1)_{u \in U}).$$

These have integral coefficients, and (7) gives $Q_{i,j}(x'_{i,j}) = P_i(x_i)$. Thus their total evaluation valuation is at most mB. Apply the one-power assertion, with radius $t_0 = \rho/m$, bound mB, and error $e = \varepsilon$, to this finite family indexed by (i, j). It supplies roots ζ_u of order dividing a uniformly fixed ℓ^H, with

$$0 < v(\zeta_u - 1) \le \rho/m, \qquad v(Q_{i,j}((\zeta_u - 1)_u)) \le v(P_i(x_i)) + \varepsilon.$$

The latter is the required polynomial inequality.

It remains to check the stated distances for powers. A selected ζ_u is primitive of order ℓ^h, for some $h \ge 1$, and has distance valuation $r_h \le \rho/m < 1/m$. If $b = v_\ell(j)$, then $\ell^b \le j \le m$. Necessarily $h > b$: otherwise $r_h \ge 1/\ell^h \ge 1/j \ge 1/m$, a contradiction. Hence ζ_u^j is primitive of order ℓ^{h-b}, and

$$v(\zeta_u^j - 1) = r_{h-b} = \ell^b r_h \le j\rho/m \le \rho.$$

It is positive and finite. All choices of H were made before the polynomials and points, which proves the full quantifier assertion. □

7.5 Main summands from eigensystems

This section supplies the Galois representations to which the twisting theorem is applied (Proposition 7.5.1): for each Hecke eigensystem of the good forms, and for each main pair, a main summand (Definition 7.2.30). This is an ℓ-adic representation R that describes at once the Galois representations of all eigenforms with the same lift Hecke polynomials, with normalised traces $\psi_\vartheta \operatorname{tr} R + \sum_{e<t} \chi_{\mathrm{cyc}}^{-e}$. This reducible shape is what Ribet's method turns into cohomology classes (Theorem 7.6.6). In our reading it is the Galois shadow of the lift from rank r to rank $r + t$, of the kind met for non-tempered forms on unitary groups by Bellaïche and Chenevier [20, 21, 19]. The representation R is also main-summand like: conjugate self-dual, crystalline where required, with controlled tame inertia and large image. These are the hypotheses under which it gives a Selmer datum.

The representations come from those attached to eigenforms on definite unitary groups through base change [177], as derived in Section 7.1 (see [58, 122, 276, 56, 15, 302, 47, 48, 110]). The rank-one summands are the ℓ-adic characters of algebraic Hecke characters, and Chebotarev's theorem [54] enters the proof. The one local statement proved here recognises the inertia type at the places above $p_0 p_1$ (Lemma 7.5.2), from the local Langlands correspondence [122, 130] and the depth-zero types of Shotton [278]; for Green's cuspidal representations and for types see [106, 46, 253]. The section closes with the representations of a type and the Ribet cocycles (Definition 7.5.3), read by the next two sections, and with one calibration of local reciprocity (Lemma 7.5.4).

Proposition 7.5.1. *Let D be admissible data, ℓ a prime and $\iota \mid \ell$ a prime identification.*

1. *For every $1 \le j \le m$ and every system $z = (z_{w,i})$ of Hecke eigenvalues that occurs in the good forms on W_m, there is an ℓ-adic representation R of rank r that is a main summand for the descent pair (W_j, V^{def}) at the trivial twist and z.*

2. *For every $1 \le j \le m$ and every main pair p for j there is an ℓ-adic representation of rank one that is a main summand for $O_{p,1}$ and the constant system 1.*

Proof. We first construct the initial representation. In the first assertion choose a nonzero form with eigensystem z. Since the good idempotent is the sum of the mutually orthogonal products of its Green idempotents, one good family of labels has a nonzero projection of this form. Hecke operators away from the level commute with these idempotents, so the projection retains z. Decomposing its automorphic span into irreducible constituents gives a constituent with this eigensystem and these finite types. The group at infinity is compact because the space is W_m. The discrete-series parameter is the specified regular integral parameter ς. Definite-unitary base change [177] and attachment Theorem 7.1.4 therefore give a semisimple representation R_0 of rank r_D, with

$$R_0^c \simeq R_0^\vee \chi_{\mathrm{cyc}}^{1-r_D}, \qquad J_{0,\sigma} = \{(r_D-1)/2 - \epsilon\varsigma_q : 1 \le q \le r_D\}, \quad \epsilon = \mathrm{sgn}(\sigma). \tag{1}$$

For the tame normalization use Lemma 7.5.4 with the local chosen field, the fixed faithful character of the Green labels, and $f = n!$. Every irreducible-factor degree d satisfies $1 \le d \le n$ and $d \mid n!$. The lemma identifies its regular Green character on an inertia element of exponent a with $T(x)^a$, not its inverse, for every root and its Frobenius conjugates. This is the same finite inertia representation on the potentially crystalline Weil–Deligne module when the place divides ℓ. The inverse-character clause of the lemma gives exactly the scaled roots after the inverse avatar of μ_O is applied. The local statements in Theorem 7.1.8 and Theorem 7.1.9, together with the case $t = 0$ of Lemma 7.5.2, identify its chosen tame types with the label roots and give zero monodromy. Away from the chosen places it is unramified, and crystalline at places over ℓ; at the chosen places over ℓ it is potentially crystalline with the specified finite inertia type. Apply the squarefree-label clause of Theorem A.5.29 to the distinct irreducible factors of the label. It gives precisely the irreducible finite Harish–Chandra product of their distinct regular cuspidal representations, so the hypothesis of Lemma 7.5.2 with $t = 0$ is the type selected by the idempotent. The harmless sign of the Green character cancels in that idempotent.

In the second assertion put $R_0 = 1$, of rank $n = 1$ with jump zero and labels $X - 1$. In the first assertion put $n = r_D$. In either case let O be the descent pair in question, let $t = t_O$, and put $A = (n - t)/2 \in \mathbb{Z}$. Define

$$\eta_O = \mathrm{avatar}^{\mathrm{geo}}\big(\mu_O^{-1} |\cdot|_E^A\big), \qquad R = \eta_O R_0. \tag{2}$$

Here μ_O is the character in (DP2). Its base change is understood in (2). Since this character is anti-conjugate apart from its norm power,

$$\eta_O^c \eta_O = \chi_{\mathrm{cyc}}^{2A}, \qquad R^c \simeq R^\vee \chi_{\mathrm{cyc}}^{1-t}. \tag{3}$$

The algebraic-character theorem [261], [85], in the avatar convention stated above, gives the jump shift

$$J_\sigma = J_{0,\sigma} - (A - \epsilon\,\mathrm{weight}_O(\sigma)). \tag{4}$$

It also preserves the required potential crystallinity and gives crystallinity away from the chosen places. Its finite character is trivial away from those places, because the descent pair here is at the trivial twist. Thus R has level $\emptyset$. The trace form on the image algebra is nondegenerate: for a semisimple representation in characteristic zero that algebra is a product of full matrix algebras, and the representation trace on each factor is a positive integral multiplicity times the matrix trace. Twisting by a character changes neither this conclusion nor semisimplicity. This proves (MS1)–(MS2).

We check the weight conditions explicitly. Write $h = h_D$, $\Delta = 2h$ and $\kappa_j = \kappa + j\Delta + h$. For the first assertion, (1)–(4) give

$$J_\sigma = \{(t_D - 1)/2 - \epsilon(\varsigma_q + \kappa_j) : 1 \le q \le r_D\}. \tag{5}$$

For the first $k-1$ entries, $\varsigma_q = k/2 - q$, hence $|\epsilon u + \kappa_j| \le (t_D-1)/2 + k/2 - 1 \le t_D$. For the remaining entries $\varsigma_q = -\kappa - i\Delta$, $1 \le i \le m$. Their jumps are

$$u = (t_D-1)/2 - \epsilon((j-i)\Delta + h),$$

and therefore $\Delta/4 \le |u| \le 2m\Delta$. These m entries are inside $2h^2$, because $2m \le h$; the other entries are outside it because $\kappa_j - t_D > 2h^2$. For completeness, the scale inequalities and the numerical bounds of Lemma 4.2.67 imply

$$\Delta^2 = 4r_D^{16} \le x^{81} \le x_1, \qquad \kappa \ge b/x_1 \ge x_1,$$

which give the last strict inequality. Thus k times the number of small jumps is $km \le r_D m$. Conjugate jumps pair to $t_D - 1 \ge 0$, so at most r_D are negative in each conjugate pair of embeddings.

For the second assertion, write the main pair as (ν, z) and its weight as $-c$. Its string length is $t = 2z-1$ and (4) gives $u = z - 1 - \epsilon c$. Since $\kappa_j + r_D - t_D \le c \le \kappa_j$ and $z \le r_D$,

$$|\epsilon u + \kappa_j| \le t_D, \qquad |u| > 2h_D^2.$$

There are no small jumps, and the conjugate jumps sum to $2z - 2 \ge 0$. These are all the weight conditions for rank one.

We next verify the three arithmetic conditions in (MS3). By Lemma 4.2.66, the chosen completions above p_i are $\mathbb{Q}_{p_i}$ and their residue fields are $\mathbb{F}_{p_i}$. At a chosen place over p_i, (2) scales the original label roots by the inverse of the residue character of μ_O. This multiplier lies in $\mathbb{F}_{p_i}^\times$ and has order dividing q_2. The allowed-label condition implies that the scaled polynomial does not vanish at 1. At a primitive place its degree is $n = r_D$; in the rank-one case it is the scaled root of $X - 1$.

Fix any $p \in \{p_0, p_1\}$ different from ℓ. Every scaled inertia root belongs to $\mathbb{F}_{p^a}^\times$ for some $a \le n$, so its order divides $p^{n!} - 1$. Inertia is semisimple of this tame type, and hence is killed by that integer, which is prime to p. At a chosen tame generator every eigenvalue λ is different from 1. Since $\lambda^{p^a-1} = 1$,

$$v_\ell(\lambda - 1) \le v_\ell(p^a - 1) \le v_\ell(N_{\mathrm{ch}}).$$

The last inequality follows because $a \le n \le r_D t_D$ and $p^a - 1$ is a factor of the order of $\mathrm{GL}_{r_D t_D}(\mathbb{F}_p)$, one of the factors defining N_{ch}. Summing over the eigenvalues gives the determinant bound. Conjugate duality (3) on inertia gives the same characteristic polynomial at the inverse conjugate element, hence the second determinant bound. At an unchosen conjugate place choose the inverse conjugate of the chosen generator. This proves (MS3)(1).

At a primitive place scaling preserves primitivity. Indeed $q_2^2 \mid p - 1$, and multiplication of a generator of order $H = p^n - 1$ by a q_2-th root changes its exponent by a multiple of H/q_2. Every prime dividing H still divides H/q_2, so the new exponent remains coprime to H. The roots $\zeta, \zeta^p, \dots, \zeta^{p^{n-1}}$ have pairwise unit differences at every ℓ. To see this, write $n = 3^d$. If $\ell \ne 3$, the 3-primary part separates them, since

$$v_3(p^n - 1) = v_3(p-1) + d, \quad v_3(p^a - p^b) = v_3(p-1) + v_3(a-b) < v_3(p^n - 1)$$

for distinct $0 \le a, b < n$. If $\ell = 3$, the integer $\Phi_{3^d}(p) = p^{2n/3} + p^{n/3} + 1$ has 3-valuation one and is greater than 3. A prime divisor $L \ne 3$ of it has $\mathrm{ord}_L(p) = n$: the order divides n and cannot divide $n/3$, since the common divisor of this cyclotomic value with $p^{n/3} - 1$ divides 3. The surviving L-primary part separates the roots. Prime-to-ℓ roots of unity reduce injectively, proving the claim.

Take the coefficient field large enough to contain these roots. For every lattice, the integral Lagrange projectors

$$E_a = \prod_{b \neq a} \frac{u(\gamma) - \zeta_b}{\zeta_a - \zeta_b}$$

belong to the algebra spanned by the image and split the lattice into rank-one free direct summands. Arithmetic Frobenius cycles them by invertible maps. Products $E_b u(F)^v E_a$ give unit multiples of all matrix units. The image span is therefore the full matrix algebra on every lattice. Moreover $u(F)^n$ is diagonal and commutes with $u(F)$, so its diagonal entries are equal. It is scalar, and $\chi_{\mathrm{cyc}}(F^n) = p^n$. The rank-one case is immediate. This proves (MS3)(2).

The common power $e = (p^n - 1)/(p - 1)$ of primitive inertia gives a scalar Y; its residue value has order $p - 1$. In rank one take $e = 1$; its residue value has order $q_2/\gcd(q_2, j)$, where $1 \leq j \leq m$. In both cases $y^v = 1$ implies $q_2 \mid jv$. If $Y^{\ell^a v} - 1$ were nonunit, then $Y^{\ell^a v}$ would have ℓ-power order, so $q_2 \mid j\ell^{a+b}v$ for some $b \geq 0$. Choose $p^* \in \{2, 5\}$ different from ℓ. This forces $(p^*)^s \mid jv$, whereas

$$0 < jv \leq m(4r_D + 2) < 2^s = m^{22} \leq (p^*)^s$$

for $1 \leq v \leq 4n + 2$. The strict inequality follows from $m \leq 2\sqrt{x}$, $r_D \leq 3x^5$, $m^{22} \geq x^{11}$ and the lower bound on x. This proves (MS3)(3).

Finally we verify the trace identity. Let O' have the same source rank n and target rank $n+t$ as O, and let $\mu_{O'} = \mu_O \vartheta$. Fix any eigenform y and any attached representation S quantified in (MS4). Throughout this comparison write $S' = \nu_{O'} \otimes S$, the normalized representation of this very S for this very O' in (MS6). At an unramified split place put $q = \mathrm{N}w$, $\alpha = \chi_{O',w}\{n\}$ and $\beta = \chi'_{O',w}\{n + t\}$. The coefficient of $-X$ in the defining lift polynomial is

$$s_{w,1} = q^t \alpha \beta^{-1} z_{w,1} + \alpha \sum_{e=0}^{t-1} q^e.$$

The geometric Frobenius value of the normalizing character is α^{-1}. Since the target rank is even, (DP6) gives

$$q^t/\beta = \vartheta(\varpi_w/\bar{\varpi}_w)^{-1} \mu_O(\varpi_w/\bar{\varpi}_w)^{-1} q^{(t-n)/2}.$$

Attachment and (2) now give

$$\operatorname{tr} S'(g) = \psi_\vartheta(g) \operatorname{tr} R(g) + \sum_{e=0}^{t-1} \chi_{\mathrm{cyc}}(g)^{-e}$$

on those geometric Frobenii. They are dense for continuous class functions: Chebotarev applies outside every prescribed finite set, and places of residue degree greater than one have density zero. The same equality therefore holds for every $g \in G_E$. □

Lemma 7.5.2. *Let F be a finite extension of $\mathbb{Q}_p$, with residue field k of order q, let $K_n = \mathrm{GL}_n(\mathcal{O}_F)$, and use the local Langlands correspondence with geometric Artin reciprocity. Let $d_1, \ldots, d_s \geq 1$ and $t \geq 0$, with $n = d_1 + \cdots + d_s + t \geq 1$. For each j let k_j/k be the extension of degree d_j, and let $\theta_j : k_j^\times \to \mathbb{C}^\times$ be a regular character, meaning that its Frobenius orbit has size d_j. Let ρ_j be the irreducible cuspidal Green representation of $\mathrm{GL}_{d_j}(k)$ associated to θ_j. Suppose that the pairs $(d_j, [\theta_j])$ are distinct, where brackets denote Frobenius orbit. If $t > 0$, let $\xi : k^\times \to \mathbb{C}^\times$ be a character, and suppose that no $d_j = 1$ has $\theta_j = \xi$.*

Let λ be the inflation to K_n of the finite Harish–Chandra induction

$$\operatorname{Ind}_{\bar{P}}^{\mathrm{GL}_n(k)} \left(\rho_1 \boxtimes \cdots \boxtimes \rho_s \boxtimes (\xi \circ \det_{\mathrm{GL}_t(k)}) \right),$$

where $\bar{P}$ has the displayed blocks, and the last factor is omitted when $t = 0$. If an irreducible admissible smooth complex representation π of $\mathrm{GL}_n(F)$ contains λ on restriction to K_n, then its Weil–Deligne representation (r_π, N_π) satisfies $N_\pi = 0$ and

$$r_\pi|_{I_F} \simeq \bigoplus_{j=1}^{s} \bigoplus_{\sigma \in \mathrm{Gal}(k_j/k)} (\theta_j^\sigma \circ \mathrm{Art}_{F_j}^{-1})|_{I_F} \ \oplus \ (\xi \circ \mathrm{Art}_F^{-1})|_{I_F}^{\oplus t}.$$

Here F_j/F is the unramified extension of degree d_j, the characters are inflated through residue units, and the last summand is omitted if $t = 0$.

Proof. We first identify the compact representation to which the depth-zero occurrence theorem applies. For every finite cuspidal representation ρ occurring here choose a depth-zero supercuspidal representation π_ρ containing it. Such a representation is obtained by extending ρ to $F^\times \mathrm{GL}_{d_\rho}(\mathcal{O}_F)$ with any compatible unitary central character and compactly inducing. The intertwining test is particularly simple: in the Cartan decomposition, unequal valuations in a diagonal representative induce a proper parabolic on the finite block; its unipotent radical has no invariants on the cuspidal ρ. Thus the intertwining is exactly $F^\times \mathrm{GL}_{d_\rho}(\mathcal{O}_F)$, and the compact-induction irreducibility criterion applies. For a rank-one character choose its extension to $F^\times$ directly.

For the Green factor ρ_j, the regular depth-zero local Langlands theorem [74, Proposition 2.4.1(i)] identifies

$$\tau_j := \mathrm{rec}_F(\pi_{\rho_j})|_{I_F} = \bigoplus_{\sigma \in \mathrm{Gal}(k_j/k)} (\theta_j^\sigma \circ \mathrm{Art}_{F_j}^{-1})|_{I_F}, \qquad N_{\pi_{\rho_j}} = 0.$$

Regularity gives the full orbit; distinct pairs $(d_j, [\theta_j])$ give distinct inertial cuspidal lines. If $t > 0$, the line of the extension of ξ is different from all these lines: a basic tame orbit can equal a rank-one orbit only if its degree is one, and the latter equality is excluded by hypothesis. Local Langlands for a character identifies its inertia with $\xi \circ \mathrm{Art}_F^{-1}$.

Let S be the finite cuspidal support consisting of one copy of every ρ_j and, when $t > 0$, t copies of the rank-one cuspidal character ξ. Let P_0 put the partition (1) on each ρ_j and $(1, \dots, 1)$, with t parts, on ξ. The finite Green representation $\bar{\sigma}_{P_0}$ is precisely

$$\mathrm{HC}{-}\mathrm{Ind}(\rho_1 \boxtimes \cdots \boxtimes \rho_s \boxtimes (\xi \circ \det_{\mathrm{GL}_t(k)})). \tag{*}$$

We justify the particular spherical choice in this equality. For the trivial rank-one cuspidal character, the partition $(1, \dots, 1)$ is the trivial representation of $\mathrm{GL}_t(k)$, while (t) is Steinberg. Twisting by $\xi \circ \det$ gives the stated character block for ξ. If $s = 0$, (*) is just the character $\xi \circ \det$ by the partition convention in Theorem 7.1.18; no distinct-cuspidal theorem is needed. For $s \geq 1$, for the product of the distinct cuspidal factors ρ_j, use Theorem A.5.29: they satisfy its distinctness hypothesis by the distinct Frobenius orbits, so their finite Harish–Chandra product is the irreducible Green representation on those factors. When $t = 0$ this is already (*). When $t > 0$ it remains to check the additional, possibly noncuspidal, character block; this is the following finite comparison. In this case its irreducibility can also be read directly from Mackey's formula. A double coset contributing to its endomorphism algebra must carry every cuspidal block whole to a block of the same rank and the same cuspidal representation; splitting one induces proper-parabolic unipotent invariants and gives zero. Distinctness rules out whole-block exchanges, and the ξ-block cannot exchange a constituent with a ρ_j by the disjointness just checked. The remaining double coset is the identity and has one-dimensional intertwining. Thus the induced representation in (*) has endomorphism algebra $\mathbb{C}$, so it is irreducible by

finite-group semisimplicity. Its Green data are the union of the displayed factor data, proving (*).

There is a literal finite averaging check of this spherical block. Refine the last block into t one-dimensional blocks and twist its character to 1. The finite Iwahori Hecke operators T_w, $w \in \mathfrak{S}_t$, are the double-coset sums with value 1 at the chosen Weyl representative. They satisfy

$$T_s^2 = (q-1)T_s + q, \qquad e_t = \frac{\sum_{w\in\mathfrak{S}_t} T_w}{\sum_{w\in\mathfrak{S}_t} q^{\ell(w)}}.$$

Pairing w with sw in the sum gives $T_s e_t = e_t T_s = q e_t$, and the square of the numerator is the numerator times the displayed denominator. Hence e_t is an idempotent. It is exactly averaging over $\mathrm{GL}_t(k)$ on the trivial block, since its Bruhat cell has $q^{\ell(w)}$ cosets. Therefore its image in the refined parahoric multiplicity space is the multiplicity space for the coarser parahoric with its trivial $\mathrm{GL}_t(k)$ block. Frobenius reciprocity identifies the latter with the compact type in (*). For $t = 0, 1$ this is the identity. For $t = 2$ the idempotent is $(1+T)/(1+q)$: it fixes the spherical eigenvalue $T = q$ and kills the Steinberg eigenvalue $T = -1$. This calculation fixes both the normalization and the choice of partition.

We now compare this actual finite representation with the compact representations in the published occurrence theorem, without using an abstract uniqueness assertion about inertial types. Apply [278, Theorem 6.20 and Corollary 6.21(1)] in the depth-zero form of Theorem 7.1.18. Write $\bar{\nu}_{P_0}$ for the finite representation there. For every partition function P' in the fixed cuspidal series S, that theorem gives

$$\langle \bar{\nu}_{P_0}, \bar{\Pi}_{P'} \rangle = \langle \bar{\sigma}_{P_0}, \bar{\Pi}_{P'} \rangle.$$

Here the brackets are ordinary finite character inner products. The finite irreducible characters $\bar{\sigma}_Q$, indexed by the partition functions Q in S, are an orthonormal basis for its representation group. The test characters $\bar{\Pi}_{P'}$ are another basis after tensoring with $\mathbb{Q}$, since their multiplicity matrix is unitriangular. Write $[\bar{\nu}_{P_0}] - [\bar{\sigma}_{P_0}] = \sum_Q b_Q [\bar{\sigma}_Q]$. The displayed equalities multiply the vector (b_Q) by that invertible matrix and give zero. Hence every $b_Q = 0$. Finite complex representations are semisimple, so equality of their classes is an actual isomorphism:

$$\bar{\nu}_{P_0} \simeq \bar{\sigma}_{P_0}.$$

In the depth-zero construction the compact group is K_n itself, the simple character is trivial and its extension is trivial; thus these finite representations are inflated to exactly the same K_n. This comparison uses the published multiplicity characterization and the explicit finite averaging above.

By hypothesis $\pi|_{K_n}$ contains the representation in (*), and hence contains $\mathrm{Inf}_{K_n} \bar{\nu}_{P_0}$. The occurrence theorem now says that the inertial cuspidal support of its local Langlands parameter is S, with the basic parameters τ_j and the character of ξ identified above, and that its monodromy partition on each line is dominated by P_0. A partition of an integer m dominated by $(1, \dots, 1)$ can have no part greater than 1: the dominance inequality with one part already gives this. As its total is m, all its parts are 1. Consequently every Weil–Deligne segment has length one and $N_\pi = 0$. The same occurrence assertion gives its full semisimple inertia. Finite inertia is semisimple in characteristic zero, so this is the actual inertia representation and is the direct sum displayed in the statement.

All arguments take place over $\mathbb{C}$. The unramified rank-dependent twist in the published local Langlands normalization is trivial on inertia and preserves zero monodromy, so it does not alter either conclusion. The coefficient-prime application therefore requires no exclusion of a residue prime at this local step. □

Definition 7.5.3. Fix a prime ℓ and an isomorphism $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$. The decomposition and inertia groups $G_A \supseteq I_A$, the ℓ-adic charts, the fixed places A_v and charts (e_v, j_v) for $v \mid \ell$, and the local lattices $L_v(u)$ are those of Definition 7.2.2. For $g \in G_\ell$ let $\gamma_g\colon \mathcal{O} \to \mathbb{C}_\ell$, $a \mapsto g(a)$.

Let $R\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$ be continuous.

(RT1) Killing. Let A be a place of $\overline{\mathbb{Q}}$, $s \in I_A$ and $Q \in \overline{\mathbb{Q}}_\ell[X]$. Q **kills** s **on** R **at** A if $Q(R(s)) = 0$ when $A \nmid \ell$, and, when $A \mid \ell$, for every chart (e, j) at A and every lattice u of R over a coefficient ring containing the coefficients of Q, Q kills s on $\mathcal{O}^n$ with G_A acting through u (via j).

(RT2) Tame exponents. Let w be a finite place of E with residue field $\mathbb{F}_w$, A a place of $\overline{\mathbb{Q}}$ over w, $T\colon \overline{\mathbb{F}}_w^\times \to \mathbb{C}^\times$ an injective character (one is fixed once and for all, the **faithful character** of $\mathbb{F}_w$) and $f \geq 1$. An element $s \in I_A$ has **tame exponent** $a \in \mathbb{N}$ (for T, f) if there are a uniformiser π of E at w and $z \in \overline{\mathbb{Q}}$ with $z^{\mathrm{N}(w)^f - 1} = \pi$ such that $s(z)/z$ is integral at A and T sends its residue at A (in $\overline{\mathbb{F}}_w$, through a residue map extending $\mathcal{O}_E \to \mathbb{F}_w$) to $\exp(2\pi i\, a/(\mathrm{N}(w)^f - 1))$.

(RT3) Labels. For $c \in \mathbb{F}_w[X]$, R is **labelled by** c **at** A (for T, f) if for every $s \in I_A$ of tame exponent a the polynomial

$$\prod_x (X - \iota(T(x)^a)), \qquad x \text{ over the roots of } c \text{ in } \overline{\mathbb{F}}_w \text{ with multiplicity},$$

kills s on R at A. For a character χ of $\mathbb{F}_w^\times$, $x_\chi \in \mathbb{F}_w^\times$ is the element that **names** χ: $T^a(x_\chi) = \chi(\bar{u})$ whenever s has tame exponent a and is the local Artin symbol of a unit u with residue $\bar{u}$; $\chi \mapsto x_\chi$ is a group isomorphism.

(RT4) Level S**.** Let $k \geq 0$, J a function from the embeddings $E \to \mathbb{C}$ to finite multisets of integers, and S a set of finite places of E. R is **conjugate self-dual of twist** k**, jumps** J **and level** S if it is conjugate self-dual of twist k (MS1) and at every finite place v with $v \notin S$ or $v \mid \ell p_0 p_1$, and every A over v, R is of finite type at A, has the Hodge–Tate jumps J at A, and is good at A if $v \nmid p_0 p_1$. Level $\emptyset$ is (MS2).

(RT5) Galois data of a descent pair. Of a descent pair O the Galois side uses only: its index set I_O of chosen places w_i ($i \in I_O$); its source rank r_O (the rank of its space W) and rank n_O (that of V); the rank difference $t_O = n_O - r_O$; the tame part $\psi_O = (\psi_{O,w})_w$ of its character of $\mathrm{U}(1)$.

(RT6) Representations of a type. Let $c = (c_i)_{i \in I_O}$ with $c_i \in \mathbb{F}_{w_i}[X]$. R is a **representation of type** (O, k, J, c, S) if (RT4) holds and, for every $i \in I_O$ and every place A of $\overline{\mathbb{Q}}$, R is labelled by c_i at A for the faithful character of $\mathbb{F}_{w_i}$ and $f = r_O!$ (the condition is empty unless A lies over w_i).

(RT7) Scaled type polynomial and Ribet type. The **scaled type polynomial** $\mathrm{tl}(c, i) \in \mathbb{F}_{w_i}[X]$ is the polynomial of degree $\deg c_i$ whose roots are those of c_i multiplied by the element $x_{\psi_{O,w_i}^{-1}}$ naming the inverse of the tame part at w_i; this is the scaled type polynomial of (MS5). For $t \geq 0$ the **Ribet type** of (O, c) is $c^{\sharp,t} = \big(\mathrm{tl}(c, i)\,(X-1)^t\big)_i$, and R is **of Ribet type** $(O, c; t, J, S)$ if it is a representation of type $(O, t, J, c^{\sharp,t}, S)$.

Block lattices. Let $r' \geq 1$, $t \geq 0$ and $T\colon G_E \to M_{r'}(\mathcal{O})$. The **summands** of T with string t are $\mathrm{blk}_T(*) = T$ and $\mathrm{blk}_T(e) = \mathcal{O}(-e)$, $g \mapsto \chi_{\mathrm{cyc}}(g)^{-e}$, for $0 \leq e < t$ (χ_{cyc} the ℓ-adic cyclotomic character). For a bijection ϵ from $\{*\} \times \{1, \dots, r'\} \sqcup \{0, \dots, t-1\}$ to an index set n,

the **block lattice** $u = \epsilon_*(T \oplus \bigoplus_{e<t} \mathcal{O}(-e)) \colon G_E \to M_n(\mathcal{O})$ is the block-diagonal homomorphism with these blocks, placed by ϵ.

Ribet cocycles and crystalline colength. Let $w = (w_x)_{x \in Y}$ be homomorphisms $G_E \to M_\sigma(\mathcal{O})$, $\rho \colon G_E \to M_d(\mathcal{O})$ and $a \in \mathcal{O}$. A **relation** is a finitely supported $\theta \colon G_E \to M_d(\mathcal{O})$, and $c \colon G_E \to B^d$ **obeys** θ if $\sum_g \theta(g)c(g) = 0$. The **Ribet cocycles**

$$\mathcal{Z}_w(\rho; a) = \Big\{ c \colon G_E \to (\mathcal{O}/a)^d \text{ a cocycle for } \rho : \sum_g \vartheta(g)\, c(g) = 0$$
$$\text{for every finitely supported } \vartheta \colon G_E \to \mathcal{O} \text{ with } \sum_g \vartheta(g)(w_x(g) - 1) = 0 \ \forall x \Big\}$$

form an $\mathcal{O}$-module (no continuity is imposed). The **crystalline relations** $\mathcal{R}_{\mathrm{cris}}(\rho)$ are the elements $\theta \colon G_{A_v} \to M_d(\mathcal{O})$ of $\mathcal{R}_f(L_v(\rho))$ (the relations obeyed by every element of $Z_f(L_v(\rho))$, Definition 7.2.1), for some $v \mid \ell$, extended by zero to G_E. The **crystalline colength** is

$$\mathrm{cc}(\rho; w, M) = \mathrm{length}_{\mathcal{O}}\Big(\mathcal{Z}_w(\rho; \ell^M) / \big(\mathcal{Z}_w(\rho; \ell^M) \cap \{c \text{ obeying every } \theta \in \mathcal{R}_{\mathrm{cris}}(\rho)\} \big) \Big)$$
$$\in \mathbb{N} \cup \{\infty\} \qquad (M \geq 0).$$

Lemma 7.5.4. *Let $F/\mathbb{Q}_p$ be finite with residue field k of cardinality q, and fix an injective character $T : \overline{k}^\times \to \mathbb{C}^\times$. Let $f \geq 1$, let $s \in I_F$ have tame exponent a at level f, and let $d \mid f$, $d \geq 1$. For $x \in k_d^\times$, where k_d/k has degree d, define its cyclic-pairing character θ_x by*

$$\theta_x(u) = T(x)^b \quad \text{if} \quad T(u) = \exp(2\pi i b/(q^d - 1)).$$

Let F_d/F be the unramified extension of degree d. Then

$$(\theta_x \circ \mathrm{Art}^{-1}_{F_d,\mathrm{geo}})(s) = T(x)^a.$$

The left side uses inflation from residue units, so it is independent of the chosen unit representative under reciprocity. This identity holds for every Frobenius conjugate of x. If $\chi : k^\times \to \mathbb{C}^\times$ is named by x_χ as in (RT3), multiplying this inertial character by $\chi \circ \mathrm{Art}^{-1}_{F,\mathrm{geo}}$ replaces its parameter x by $x_\chi x$. In particular an inverse character replaces it by $x_\chi^{-1} x$.

Proof. Put $m = q^d - 1$ and $N = q^f - 1$. Choose the uniformiser π and z in the tame-exponent definition, so $z^N = \pi$ and

$$T(\overline{s(z)/z}) = \exp(2\pi i a/N).$$

Set $z_d = z^{N/m}$. Inertia fixes all prime-to-p roots of unity and F_d, and therefore

$$z_d^m = \pi, \qquad T(\overline{s(z_d)/z_d}) = \exp(2\pi i a/m). \tag{1}$$

The quotient in (1) is an mth root of unity; reduction on such roots is injective.

Here is the reciprocity sign calculation. In any local field K with residue cardinality Q and containing μ_m, $m \mid Q - 1$, the Hilbert symbol with arithmetic reciprocity satisfies

$$\mathrm{Art}_{K,\mathrm{ar}}(b)(a^{1/m})/a^{1/m} = (a, b)_m, \qquad (a, b)_m = (b, a)_m^{-1}. \tag{2}$$

These are [202, Chapter III, Theorem 4.4(b), Remark 4.5]. To evaluate them for a unit u and uniformiser π, choose $v^m = u$. Such a root lies in an unramified extension: choose a residue root

and lift it by Hensel's lemma, since m is prime to p. Arithmetic Frobenius sends its residue to its Qth power. Hence

$$\overline{(u,\pi)_m} = \bar{u}^{(Q-1)/m}, \qquad \overline{\mathrm{Art}_{K,\mathrm{geo}}(u)(\pi^{1/m})/\pi^{1/m}} = \bar{u}^{(Q-1)/m}. \tag{3}$$

The second equality follows by first using skew symmetry in (2), then inverting the arithmetic Artin map. This accounts for both inversions; it is not the arithmetic formula with its sign unchanged.

Apply (3) to $K = F_d$, whose residue cardinality is $Q = q^d$, with the present $m = Q - 1$. The image of inertia in the abelianized local group is the image of the unit group, by local reciprocity Theorem A.2.7. Thus take a unit u representing the abelianized image of s. Equation (3) and (1) give

$$T(\bar{u}) = \exp(2\pi i a/m).$$

Changing the representative changes neither its residue nor the value of any residue character: its tame abelian image is detected faithfully by its action on z_d. By the defining cyclic pairing, $\theta_x(\bar{u}) = T(x)^a$, as required. Replacing x by any q-power conjugate proves the conjugate assertions.

For the final assertion apply the already proved identity with $d = 1$ to $\chi = \theta_{x_\chi}$. It gives

$$(\chi \circ \mathrm{Art}^{-1}_{F,\mathrm{geo}})(s) = T(x_\chi)^a.$$

Multiplying this equality by the identity for x gives $T(x_\chi x)^a$, which is the identity for parameter $x_\chi x$. This holds for every inertia element: its quotient $s(z)/z$ belongs to μ_N, and injectivity of T therefore assigns it some exponent a modulo N. The inverse-character version follows by inversion. No regularity assumption, factorial bound or coefficient-prime restriction is used. □

7.6 Denominators: Ribet elements and prime triangles

This section bounds the denominators of the projections to the spaces of lifts. For the twist at one prime the result is Lemma 7.6.2: if the twisted main summands have Selmer length at most e'_ℓ, the projection to the lifts has denominator at most $\beta_\ell \log \ell$ at ι. It is the case of the lifts of a general bound (Theorem 7.6.3).

A denominator measures congruences between lifts and the forms orthogonal to them. The systems of the lifts are weak: their normalised Galois representations contain the trivial character, so the functions $\delta_g(x) = \det(1 - N_x(g))$, which lie in the integral Hecke algebra (Lemma 7.6.13), vanish on them. Ribet's idea [241], in the form of Mazur and Wiles [197, 327], is that the congruences between such systems and the others are measured by Galois cohomology classes of the reducible representation. Here it takes the form of a common Ribet element of the functions δ_g (Theorem 7.6.6), whose top coefficient is bounded by the Selmer length, the ramification of the twist, the local loss above ℓ, and the odd classes with the cost of a prime triangle; under the hypotheses this is at most $r'\beta_\ell$. Auxiliary operators turn the Ribet element into an integral operator that clears the projection (Proposition 7.6.11).

Ribet's element rests on Ribet's lemma to first order in tie variables over a discrete valuation ring (Lemma 7.6.7), through Fitting ideals [79, 227], Amitsur's formula for the determinant of a sum of matrices [6] and a Cayley–Hamilton argument; working with the traces and determinants of families goes back to the pseudo-representations of Wiles [326] (see [55, 21, 19]). The cocycles of the block are bounded by the Selmer length and the local loss of Section 7.7. The cocycles of the Tate twists are controlled by prime triangles, and no bound for their even classes is used: along a triangle their Selmer modules are bounded by the odd classes (Proposition 7.6.10), which Theorem 7.2.8 bounds at all primes at once.

The auxiliary places come from two existence results. Prime triangles exist at every level (Theorem 7.6.15); they are built from Kummer maps and Chebotarev's theorem, in the manner of Kolyvagin [169, 244], with a reciprocity law from Poitou–Tate duality [295, 201]. Taylor–Wiles places give chains of Hecke roots (Proposition 7.6.12), from a local statement on spherical and pro-p Iwahori Hecke operators (Lemma 7.6.5; see [248, 35, 50, 114]); places of this kind go back to Taylor and Wiles [301, 328] (see [63, 60, 305]). In the dictionary at an auxiliary place (Lemma 7.6.13) tame generators act as diamond operators, Frobenius acts through U_{ϖ}, and the pro-p Iwahori eigencharacters are read as Jacquet exponents [51, 310].

Definition 7.6.1. Let E be a CM field, $n \geq 1$, V the standard definite hermitian space of rank n over E with unitary group $\mathrm{U}(V)$, κ a weight, ℓ a prime and $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$ an isomorphism; $\bar{\mathbb{Z}}_\ell$ is the ring of integers of $\bar{\mathbb{Q}}_\ell$. For a finite place w of E, k_w is its residue field, $q_w = \#k_w$.

(AL1) Base data. Base data B consist of a finite set B_{pl} of finite places of E, a space of forms of weight κ on V of a fixed type at B_{pl}, and a common multiple c_B of the orders of the finite groups $\mathrm{U}(V)(E^+) \cap g\mathrm{K}_0 g^{-1}$, where K_0 is the standard maximal level.

(AL2) Level L and systems. For a finite family $L = (w_j)$ of places split over E^+ and outside $B_{\mathrm{pl}} \cup \bar{B}_{\mathrm{pl}}$, the **forms of level** L have the type of B at B_{pl}, principal level at the w_j (the kernel of reduction to $\mathrm{GL}_n(k_{w_j})$) and maximal level elsewhere; $L = \emptyset$ is the **base level**. A form is **integral** if its values are ι-integral. A **system of level** L is a space of forms with given Hecke eigenvalues at almost all places that contains a nonzero form of level L; it has a semisimple Galois representation $r_x\colon G_E \to \mathrm{GL}_n(\bar{\mathbb{Q}}_\ell)$, and at a split place $w \nmid \ell$ where it is unramified a **Hecke polynomial** $P_{x,w} = \prod_\alpha (X - q_w^{(n-1)/2}\alpha)$, α over its Satake parameters. A place w is **off level** L if it lies outside $B_{\mathrm{pl}} \cup \bar{B}_{\mathrm{pl}}$, does not divide ℓ, and the forms of level L of every system are Hecke eigenforms at w.

(AL3) Integral Hecke algebra. $\mathbb{T}_L$ is the ring of functions t from the systems of level L to $\bar{\mathbb{Q}}_\ell$ such that the operator acting on each system x by the scalar $\iota^{-1}(t(x))$ preserves the integral forms of level L.

(AL4) Traces and the tied ideal. Let $a\colon G_E \to \bar{\mathbb{Z}}_\ell^\times$ be a character and $N_x = a \otimes r_x$. Two systems x, x' are **congruent** if for all $g \in G_E$ and $i \geq 0$ the i-th coefficients $c_i(x,g)$, $c_i(x',g)$ of the characteristic polynomials of $N_x(g)$ and $N_{x'}(g)$ satisfy $|c_i(x,g) - c_i(x',g)|_\ell < 1$. For $P \in \bar{\mathbb{Z}}_\ell[X]$ and $g, h \in G_E$ write $\mathrm{tr}[P(h)g]$ for $x \mapsto \mathrm{tr}\big(P(N_x(h))N_x(g)\big)$. For Taylor–Wiles places $Q = (w_j, \varphi_j, \tau_j)_{j\in J}$ of level ℓ^ν, polynomials $H_j \in \bar{\mathbb{Z}}_\ell[X]$ and variables α_j, the **tied ideal** $\mathfrak{a} \subseteq \mathbb{T}_Q[\alpha_j]_{j\in J}$ is generated by the $\ell^\nu \mathrm{tr}[g]$ and the traces $\mathrm{tr}[r_j g]$ of the **tied relations** $r_j = \tau_j - 1 - \alpha_j(\varphi_j - 1)H_j(\varphi_j)$, $g \in G_E$ (when these traces lie in $\mathbb{T}_Q[\alpha_j]$).

(AL5) Root chains. A system x of base level has a **root chain** at w_j for (a, t, H_j) if there is $S \in \mathbb{C}[X]$ dividing $\iota^{-1}(H_j)$ (the polynomial obtained by applying ι^{-1} to the coefficients of H_j) with

$$P_{x,w_j}\big(\iota^{-1}(a(\varphi_j))^{-1}X\big) = \prod_{0\leq i<t} (X - q_{w_j}^i) \cdot S(X).$$

(AL6) Trace ideals and Ribet elements. Let $\mathcal{O}$ be a discrete valuation ring with fraction field K, G a group, Y a set, $u_x\colon G \to M_m(K)$ for $x \in Y$, $p \in \mathcal{O}$, $H_j \in \mathcal{O}[X]$ for $j \in J$, and a finite set T of relations with $\tau_t, \varphi_t \in G$ and an index $j_t \in J$ for each $t \in T$ (several relations may share one variable); let S be an $\mathcal{O}$-algebra of families $Y \to K[X_j]_{j\in J}$ containing the variables and the coefficients of the characteristic polynomials of the $u_x(g)$, and $\mathcal{J}$ an S-submodule. Then $\mathcal{J}$ is a **trace ideal** if it contains $x \mapsto p\,\mathrm{tr}\,u_x(g)$ and $x \mapsto \mathrm{tr}\big(u_x(\rho_t)u_x(g)\big)$

for the tied relations $\rho_t = \tau_t - 1 - X_{j_t}(\varphi_t - 1)H_{j_t}(\varphi_t)$, $t \in T$, and all $g \in G$ (with u_x extended linearly). For functions $\beta_i \colon Y \to K$ that vanish on a subset $\mathcal{X} \subseteq Y$, a point $\pi \in \mathcal{X}$ and $d \in K$, a **common Ribet element** with coefficient d at π is $f \in S$ such that the constant families β_i lie in S, $f\beta_i \in \mathcal{J}$ for all i, for $x \in \mathcal{X}$ the polynomial $f(x)$ has no monomial properly dividing $\prod_j X_j$, and the coefficient of $\prod_j X_j$ in $f(\pi)$ is d.

(AL7) Iwahori operator. Let w be a finite place of E and ϖ a uniformiser of E_w. The **prounipotent Iwahori subgroup** $\mathrm{Iw}_1(w) \subseteq \mathrm{GL}_n(\mathcal{O}_{E_w})$ is the group of matrices whose reduction modulo ϖ is upper triangular with all diagonal entries 1; let $t_\varpi = \mathrm{diag}(\varpi, 1, \dots, 1)$. For a smooth representation π of $\mathrm{GL}_n(E_w)$ on a complex vector space W, the **Iwahori operator** U_ϖ on the $\mathrm{Iw}_1(w)$-fixed vectors is

$$U_\varpi y = \sum_{h \in \mathrm{Iw}_1(w) t_\varpi \mathrm{Iw}_1(w)/\mathrm{Iw}_1(w)} \pi(h)\, y,$$

the sum over representatives h of the finitely many cosets $h\,\mathrm{Iw}_1(w)$ contained in

$$\mathrm{Iw}_1(w) t_\varpi \mathrm{Iw}_1(w);$$

it does not depend on the representatives and maps $\mathrm{Iw}_1(w)$-fixed vectors to $\mathrm{Iw}_1(w)$-fixed vectors.

Lemma 7.6.2. *Let D be admissible data, ℓ a prime, $\iota \mid \ell$ a prime identification, ϑ a twist such that $(S_\ell, Q_\vartheta, \psi_\vartheta)$ is an auxiliary twist with ramification at most e'_ℓ, and $1 \le j \le m$.*

1. *The space $\mathcal{L}_{j,\vartheta}$ is spanned by forms $y \in \mathcal{L}_{j,\vartheta}$ that lie in the range of the type projection of a lift setting for ϑ contained in $e_0\mathcal{A}(V^{\mathrm{def}})$, and whose lift Hecke polynomials are those of a system z of Hecke eigenvalues occurring in the good forms on W_m.*
2. *Suppose every such system z has a main summand R_z for $((W_j, V^{\mathrm{def}})$ at $1, z)$ with $\psi_\vartheta R_z$ of Selmer length at most e'_ℓ at $(Q_\vartheta, \gamma, \zeta)$ for some γ, ζ. Then the projection to $\mathcal{L}_{j,\vartheta}$ has denominator at most $\beta_\ell \log \ell$ at ι for e_0, and ϑ satisfies (DL1) at ι for j with every $\beta' \ge \beta_\ell \log \ell$.*
3. *Let p be a main pair for j and R a main summand for $(O_{p,1}, 1)$ with $\psi_\vartheta R$ of Selmer length at most e'_ℓ at some $(Q_\vartheta, \gamma, \zeta)$. Then the projection to $\mathbb{C}\lambda_{p,\vartheta}$ has denominator at most $\beta_\ell \log \ell$ at ι for e_{X-1}, and for all test forms Ξ, Ξ' for ℓ of $O_{p,\vartheta}$*

$$\left\|\iota\langle \mathrm{pr}_{p,\vartheta}\Xi, \mathrm{pr}_{p,\vartheta}\Xi'\rangle\right\| \le \exp((\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log \ell).$$

Proof. Put $\beta = \beta_\ell \log \ell$. First the auxiliary-twist hypothesis also holds with S_ℓ^{bad} in place of S_ℓ. Indeed a twist has $\mathrm{N}Q_\vartheta$ prime to MN, so neither a place of Q_ϑ nor its conjugate divides MN. The assumed auxiliary condition excludes the places above ℓ, their conjugates, and conjugate pairs in Q_ϑ. Thus Q_ϑ is auxiliary for the places dividing ℓMN. The character and ramification conditions in (AX5) are unchanged. This verifies exactly the auxiliary hypothesis whenever we use Theorem 7.6.3.

Spanning forms and their actual types. Write $O = O_{j,\vartheta}$, $\mathcal{A}_j = \mathcal{A}_M(W_j)$, and $E_c = \bigotimes_w e_{c_w}$ for a good family c. The finiteness and spectral decomposition in Proposition 5.8.4 give

$$e_0\mathcal{A}_j = \bigoplus_z (e_0\mathcal{A}_j \cap \mathcal{A}_j[z]),$$

with only finitely many nonzero summands. Chosen-place translations commute with the spherical operators off the chosen places: the adelic translations have disjoint local supports. Consequently every E_c preserves every eigenpart. Since $e_0 = \sum_{c\ \mathrm{good}} E_c$, the good forms are spanned by vectors $a = E_c a_z$, where $a_z \in \mathcal{A}_j[z]$. Their images

$$y = \Theta_{j,\vartheta}(a)$$

span $\mathcal{L}_{j,\vartheta}$. By Lemma 6.6.10(i), extended linearly to the group algebra,

$$\Theta_{j,\vartheta}(E_c a_z) = p_c \Theta_{j,\vartheta}(a_z). \tag{1}$$

Thus y lies in the range of this very type projector. Moreover $e_0 E_c = E_c$, so the whole range of p_c, not just the vector y, lies in $[e_0]\mathrm{Form}(O)$.

We check that (O, c) is a lift setting. Its source rank is r, its rank difference is $t = 5r$, and both are odd by (AD2). Its places are the chosen places and Q_ϑ. By (LF1)–(LF4) its tame part is $\omega^j \psi_\vartheta$, with $1 \le j \le m$. Every c_w is a label of degree r, and over each of p_0, p_1 one is primitive, by goodness. At a chosen place the twist has trivial tame part, because its modulus is prime to M. Let $x_w \in k_w^\times$ be the element naming the character ω_w^j under the fixed faithful character. Then $x_w^{q_2} = 1$. The scaled type polynomial is

$$x_w^{-r} c_w(x_w X).$$

It vanishes at 1 precisely when $c_w(x_w) = 0$, which the allowed-for-q_2 condition excludes. This checks every condition of (MS5). The scaling in this check concerns the type polynomial in the lift setting; the tuple in (1) is the same c, since the action (DP5) already incorporates its determinant character.

The full Hecke polynomials of these images. We give the polynomial identity, rather than infer it from vanishing at the lift root. Let $w \ne \bar{w}$ be off the places of O, put $q = \mathrm{N}w$, $n = r + t$, and

$$\alpha = \chi_{O,w}\{r\}, \qquad \alpha' = \chi'_{O,w}\{n\}, \qquad c_w^* = q^t \alpha/\alpha', \qquad P_w(X) = \prod_{b=0}^{t-1} (1 - q^b \alpha X).$$

In this paragraph c_w^* is just a scalar, distinct from the label c_w. For $a \in \mathcal{A}_j[z]$ we claim

$$H_w(X)\Theta_{j,\vartheta}(a) = P_w(X)\, H^{(r)}_{z(w)}(c_w^* X)\, \Theta_{j,\vartheta}(a) \qquad (X \in \mathbb{C}). \tag{2}$$

Here are the hypotheses and the transposition giving (2). By Lemma 6.5.11 and Lemma 6.4.15, the theta datum in (LF5) is an edge from the prescribed source type to the target type. Therefore the lift L before algebraic attachment and its transpose L^{t} satisfy Lemma 6.3.76(1)–(2). The datum is the vacuum at $w, \bar{w}$: these places are outside the finite block datum, and Lemma 6.2.33(5) fixes its finite vacuum under integral Heisenberg translations. These translations commute with the real creation operators, as their supports are disjoint. Its invariance under the target spherical subgroup follows from Lemma 4.1.1(6). The base change of $\chi_O = \upsilon^{r_-(O)}$ is unramified there. Thus Lemma 6.6.11 applies.

For clarity, this application uses the bilinear transpose, so no conjugation of X is involved. If F is a spherical form of the conjugate target type, transposition of the finite double cosets and Lemma 6.3.76(2) give

$$\int F\, H_w^{(n)}(X) L a = \int a\, L^{\mathsf{t}}(H_{\bar{w}}^{(n)}(X) F). \tag{3}$$

The inverse double coset at w is the positive double coset at $\bar{w}$, under the unitary identification; inversion preserves Haar measure. More explicitly the inverse of the coset of $\mathrm{diag}(\varpi_w 1_i, 1)$ at w acts at $\bar{w}$ by $\overline{(\,\cdot\,)^{-1}}^{\mathsf{T}}$, which is the positive coset of $\mathrm{diag}(\bar{\varpi}_w 1_i, 1)$. This proves the transposition coefficient by coefficient.

The actual kernel of L^{t} is $\chi'_O(\det g)^{-1}$ times the kernel with characters $(\chi_O, 1)$. Apply Lemma 6.6.11 at $\bar{w}$ to the latter kernel. Its first scalar is α; before this determinant twist its second scalar is $\upsilon(\varpi_w)^{-n} q^{n/2}$. Moving the factor $\chi'_O(\det g)^{-1}$ through the source double coset of number i multiplies its coefficient by $\chi'_O(\varpi_{\bar{w}}/\bar{\varpi}_{\bar{w}})^i = \widetilde{\chi'_O}(\varpi_w)^{-i}$. Consequently the second scalar becomes exactly $\alpha' = \widetilde{\chi'_O}(\varpi_w)\upsilon(\varpi_w)^{-n} q^{n/2}$, and the transfer reads

$$L^{\mathsf{t}}(H^{(n)}_{\bar{w}}(X)F) = P_w(X)\, H^{(r)}_{\bar{w}}(c_w^* X) L^{\mathsf{t}} F. \tag{4}$$

Transposing the source double cosets back in (3), and using $H^{(r)}_w(c_w^* X)a = H^{(r)}_{z(w)}(c_w^* X)a$, proves that the difference in (2), before algebraic attachment, pairs to zero with every such F. All the integrals and their finite translates are justified by Lemma 6.3.76(2). The difference G is itself a spherical form of the target type, so take $F = \bar{G}$. Positivity and full support of the quotient measure give $G = 0$. Algebraic attachment in (LF5) commutes with finite right translations, which proves (2) on $\mathrm{Form}(O)$. This is precisely (DP10), at every required place and every X.

For a nonzero spanning image $y = \Theta_{j,\vartheta}(a)$, its source vector a is nonzero. Hence z occurs in the good forms on W_j. By Proposition 5.8.4(ii)–(iii), the good z-parts on W_j and W_m have the same dimension, so z also occurs on W_m. Together with (1), (2), and the lift-setting check, this proves item 1. Zero images can be omitted from the spanning family.

Apply the denominator theorem to the space of lifts. Assume the hypothesis of item 2 and take one of the nonzero spanning forms just constructed. In (DR2) choose the tuple c from (1), the system z, the supplied main summand R_z, and $O' = O_{j,1}$. These two descent pairs have the same source and target ranks, and their characters in (DP2) satisfy the exact identity

$$\mu_{O_{j,\vartheta}} = \mu_{O_{j,1}}\, \vartheta. \tag{5}$$

This follows from $\mu_j^0 \vartheta$ in (LF4); it is an identity of the characters μ, not of the splitting factor χ_O. The hypothesis supplies the required γ, ζ and Selmer bound. Thus every chosen spanning form satisfies every clause of (DR2), with $\mathrm{sel} = e'_\ell$. Apply Theorem 7.6.3 to $Z = \mathcal{L}_{j,\vartheta}$ and $e = e_0$, using the auxiliary check at the beginning. It gives (DR1) with $\beta = \beta_\ell \log \ell$. The source rank here is exactly r. The integrality part of (DR1) is the clearing assertion (DL1), and for $\beta' \geq \beta$ the same endomorphism has

$$\|\iota(\det B)\| \geq e^{-(\dim Z) r\beta} \geq e^{-(\dim Z) r\beta'}.$$

This proves all of item 2, including $Z = 0$, where the determinant on the zero space is 1.

The actual rank-one lift generator. For item 3 write $p = (\nu, z_p)$, $X = X(p, \vartheta)$, $O = O_{p,\vartheta}$, and $\lambda = \lambda_{p,\vartheta} = \lambda_X$. Its source has rank 1, its target rank is $2z_p$, and its rank difference is $2z_p - 1$, an odd integer at most $2r - 1 \leq t$. Its character is $\nu\vartheta$, whose tame part is $\omega^j \psi_\vartheta$. Choose every label equal to $X - 1$. These are labels of degree one and satisfy the rank-one alternative over each level prime. Their scaled polynomials do not vanish at 1: the tame character of ν at a chosen place is $\omega_w^j \neq 1$. Indeed ω_w has order q_2, $1 \leq j \leq m < q_2$; the last inequality follows from $2^s = m^{22}$ and $q_2 = (q_0 d)^{s+6} > 2^s$. The twist is trivial at the chosen places. Thus $(O, (X-1)_w)$ is a lift setting for ϑ.

We verify the type projection on the actual form. By Lemma 6.7.14(a),(c), λ is the specified finite index times the algebraic theta lift of the constant function on U(1). For residue units

$s = (s_w)$, choose an integral source point a_s with these reductions at the chosen places and reduction 1 at Q_ϑ; choose a target point k_s acting by s_w on the inc-line and as the identity on its complement. The finite function in (DP7) satisfies $\Psi_O(k_s^{-1}(\,\cdot\,)a_s) = \Psi_O$: the chosen-place condition $X_w = \mathrm{Inc}_O$ is preserved by $k_s\mathrm{Inc}_O = \mathrm{Inc}_O a_s$, and the twist-place factors are unchanged. Since $\chi_O = 1$, Lemma 4.1.1(6) gives

$$\omega_O(a_s, k_s)\mathrm{J}_O(\xi) = \Big(\prod_w \psi_{O,w}(s_w)\Big)^{-1}\mathrm{J}_O(\xi).$$

The constant source function is unchanged by a_s; Lemma 6.3.76(3) therefore shows that target translation by k_s multiplies its lift by the reciprocal displayed character. The action (DP5) includes the character itself, so every $[s]$ fixes λ. For GL_1, the Green character of the label $X-1$ is the trivial character. Its tensor type projector is consequently the literal finite mean of the operators $[s]$, and fixes λ.

The same full polynomial calculation (3)–(4) applies here: Lemma 6.7.14(c) supplies the edge and the actual lift of $\mathbf{1}$, while each source Hecke operator on this constant function has eigenvalue 1. Explicitly, with $N = 2z_p$, $q = \mathrm{N}w$, $\alpha = \chi_{O,w}\{1\}$ and $\alpha' = \chi'_{O,w}\{N\}$, the source identity is $H_w^{(1)}(Y)\mathbf{1} = (1-Y)\mathbf{1}$, and hence

$$H_w^{(N)}(X)\lambda = \prod_{b=0}^{N-2}(1-q^b\alpha X)\,(1-q^{N-1}\alpha(\alpha')^{-1}X)\lambda.$$

This is exactly (DP10) for the system 1, for all X. Also

$$\mu_{O_{p,\vartheta}} = \mu_{O_{p,1}}\,\vartheta.$$

The given main summand and Selmer bound now verify (DR2) for λ in its line, with the actual projector e_{X-1}. Scalar multiples remain lift generators, and this line is spanned by λ. If $\lambda = 0$, its space is zero and the spanning assertion is vacuous. Applying Theorem 7.6.3 proves the denominator assertion of item 3 in either case.

Central averaging changes the test subspace. It remains to deduce the stated pairing bound; test forms are orthogonal to false lifts in $\ker \mathrm{Th}_O$, which need not equal $(\mathbb{C}\lambda)^\perp$. We make this change explicitly.

Let $A_f = \mathrm{U}(1)(\mathbb{A}_f)$ and define the normalised central action

$$T(a)f = \chi'_O(a)\,R(\mathrm{scalar}(a))f \qquad (a \in A_f). \tag{6}$$

Characters in (6) are evaluated at the finite point with infinite part 1. These operators are unitary, $T(a)^* = T(a^{-1})$, and commute with the chosen-place action and all Hecke polynomial operators, since scalar matrices commute with every right translation. The scalar-pair formula in (WR4), with $\chi_O = 1$, says that the pair $(a, \mathrm{scalar}(a))$ acts on the theta datum by $\chi'_O(a)^{-1}$. Applying (OL2) therefore gives the exact identities

$$T(a)^{-1}k_X(g) = k_X(ga), \qquad T(a)\lambda = \lambda. \tag{7}$$

The second follows by translating the class sum (OL3); multiplication by a^{-1} permutes the classes with their stabiliser weights. These identities also check the normalisation of (6).

Let $C_{\mathrm{ch}} = \mathrm{U}(1)(E)\backslash A_f/\mathrm{K}_{\mathrm{ch}}$ and $h = \#C_{\mathrm{ch}} = h_{\mathrm{ch}}$. It is finite by Lemma 6.7.22(a) and is nonempty because it contains the identity class. By Lemma 4.6.2(c), all its rational stabilisers are trivial. Choose representatives a_c integral at every place above ℓ. Apply Lemma 4.2.64

to the standard rank-one space I_1, with the finite set of all places of E above ℓ. Its auxiliary finite factor has component 1 there, so rational norm-one elements are dense in the product of these local groups. For an initial representative, the local inverse lies in the nonempty open set of multipliers making its product integral with integral inverse above ℓ. Choose a rational norm-one multiplier in that set. Left multiplication by it changes no double coset, giving the required representatives.

For these representatives $T(a_c)^{-1}$ preserves forms integral at every embedding above ℓ. In the gauge of Definition 6.1.3, translation by their scalar matrices and its inverse preserve the integral coordinate lattice, since all their ℓ-components are units. The scalar $\chi'_O(a_c)^{-1}$ is an ℓ-adic unit at every embedding. To check the latter from its algebraic weight, take a positive power killing the class of a_c in the finite abelian group C_{ch}, and write $a_c^d = \gamma u$, with $\gamma \in \mathrm{U}(1)(E)$ and $u \in \mathrm{K}_{\mathrm{ch}}$. The value on u is a product of tame character values, hence roots of unity. The value on γ_f is the inverse of its archimedean algebraic monomial. Every conjugate of γ above ℓ is a unit because both a_c and u are, so this monomial is an ℓ-adic unit. Taking the d-th power proves the assertion.

For any $v \perp \lambda$, (DP9), (OL2), and (7) show

$$\sum_{c \in C_{\mathrm{ch}}} T(a_c) v \in \ker \mathrm{Th}_O. \tag{8}$$

Indeed evaluation of the descent at a finite point g is pairing with $k_X(g)$; the infinite factor is scalar in rank one. By adjointness of T, its value on the sum is the pairing of v with $\sum_c T(a_c)^{-1} k_X(g) = \sum_c k_X(g a_c) = \lambda$. Here the last equality is the unweighted class sum, since the stabilisers are trivial; multiplying all classes by g permutes them.

Let Ξ, Ξ' be the test forms in the statement and put

$$\Psi = \sum_{c \in C_{\mathrm{ch}}} T(a_c)^{-1} \Xi'. \tag{9}$$

It is integral at ι. We claim that it is orthogonal to the false lifts for $(e_{X-1}, (\mathbb{C}\lambda)^{\perp})$. Fix an allowed split place w and a vector v in that false-lift subspace. Each $T(a_c)v$ remains in the range of e_{X-1} and in $\ker H_w(X_*(w))$, by the commutation just proved. By (8) their sum is in $\ker \mathrm{Th}_O$. The test condition on Ξ' therefore gives

$$\langle v, \Psi \rangle = \left\langle \sum_c T(a_c) v, \Xi' \right\rangle = 0.$$

This proves the claim at every allowed place. Since every $T(a_c)$ fixes λ and is unitary,

$$P_{\mathbb{C}\lambda} \Psi = h P_{\mathbb{C}\lambda} \Xi'. \tag{10}$$

If $\lambda = 0$, the desired pairing is zero. Otherwise its line has dimension one, so the endomorphism B furnished by (DR1) is multiplication by a scalar b, with $\|\iota(b)\| \geq e^{-\beta}$, because the source rank is one. Apply the pairing part of (DR1) to the integral, line-tested vector Ψ and the form Ξ, which is integral above ℓ. Using (10) gives

$$1 \geq \|\iota \langle \Xi, b P_{\mathbb{C}\lambda} \Psi \rangle\| = \|\iota(b)\| \, \|\iota(h \langle \Xi, P_{\mathbb{C}\lambda} \Xi' \rangle)\|.$$

Hence

$$\|\iota(h \langle \Xi, P_{\mathbb{C}\lambda} \Xi' \rangle)\| \leq e^{\beta}.$$

Orthogonal projection is self-adjoint, so the pairing here equals $\langle P_{\mathbb{C}\lambda}\Xi, P_{\mathbb{C}\lambda}\Xi'\rangle$. Finally $\|\iota(h)\| = \ell^{-v_\ell(h)}$, with $h \geq 1$. Dividing by this norm proves

$$\|\iota\langle \mathrm{pr}_{p,\vartheta}\Xi, \mathrm{pr}_{p,\vartheta}\Xi'\rangle\| \leq \exp\big((\beta_\ell + v_\ell(h_{\mathrm{ch}}))\log \ell\big).$$

This is exactly the remaining conclusion. □

Theorem 7.6.3. *Let D be admissible data, ℓ a prime, $\iota \mid \ell$ a prime identification, and ϑ a twist such that $(S_\ell^{\mathrm{bad}}, Q_\vartheta, \psi_\vartheta)$ is an auxiliary twist with ramification at most e'_ℓ. Let O be a descent pair, e an idempotent of the group algebra of the product of the groups $\mathrm{GL}_{\mathrm{rk}W}(k_w)$ over the chosen places, and $Z \subseteq \mathcal{A}(V)$ a subspace spanned by lift generators of Z for (ϑ, e, e'_ℓ). Then the projection to Z has denominator at most $\beta_\ell \log \ell$ at ι for e.*

Proof. Put $r' = \mathrm{rk}\, W(O)$, $t = t_O$, $n = r' + t$, $C = N_{\mathrm{ch}}$, and

$$L = e'_\ell + 2te'_\ell + r'\mathrm{loc}_\ell + e_\ell.$$

All these bounds are finite. If $Z = 0$, take its identity operator: its determinant is the empty product 1, and every projected form is zero. Hence suppose $Z \neq 0$. A nonzero lift generator supplies a lift setting, so $1 \leq r' \leq r_D$ and $1 \leq t \leq t_D$. We first construct an operator for each nonzero lift generator v_0 and then make their eigenvalue bounds simultaneous.

Admissibility gives $E = E_s$ and $5 \mid q_0 \mid q_1(s)$, so $\mathbb{Q}(\zeta_5 + \zeta_5^{-1}) \subseteq E_s^+$. The real number $\zeta_5 + \zeta_5^{-1}$ satisfies $X^2 + X - 1 = 0$, whose discriminant 5 is not a rational square; hence $[E^+ : \mathbb{Q}] \geq 2$, as required by the dictionary and auxiliary-operator inputs.

Choose the tuple c in (DR2) for v_0, and write p_c for its orthogonal type projection. The actual Green character projectors are mutually orthogonal and commute with the spherical Hecke algebra. Every lift generator belongs to the range of one of them; therefore p_c either fixes it or kills it. It follows that Z and $Z^\perp$ are stable under p_c. They are also stable under the Hecke polynomial operators and their adjoints: each generator has the Hecke polynomials of a lift, so its line is stable, and the spherical Hecke algebra is closed under adjoints. Thus all these operators commute with pr_Z.

Apply Lemma 7.6.4 to (O, c) and ϑ. It supplies actual base data B with $c_B = C$, containing $p_c\mathrm{Form}(O)$ at base level; Cp_c preserves integral forms at ι; and every deeper-level normalised representation

$$N_x = \nu_O \otimes r_x$$

has the Ribet type and the quadratic inertia relation required by Theorem 7.6.6. In particular their characteristic coefficients are integral. One may also see this directly from continuity: the eigenvalues of a compact group image have valuation zero. Let x_0 be the system of v_0, and let $\mathcal{X}$ be the systems containing nonzero lift generators of Z, allowing arbitrary Selmer-length bounds. At every deeper level we use the inverse image of this same set of systems.

For $x \in \mathcal{X}$, (DR2) and (MS4) give a main-summand-like representation R_x with

$$\mathrm{tr}\, N_x(g) = \psi_\vartheta(g)\,\mathrm{tr}\, R_x(g) + \sum_{a<t} \chi_{\mathrm{cyc}}(g)^{-a}.$$

They also give the scalar lattice element with scalar minus 1 a unit needed in the Ribet theorem. For the system x_0 choose these data from v_0, so that its twisted Selmer length is at most e'_ℓ. If several lift generators have the same system, this choice is made once for that system; their normalized representations and their traces agree. Every $x \in \mathcal{X}$ is weak, since the term $a = 0$ in this semisimple trace decomposition contributes a trivial character. Indeed semisimple

characteristic-zero representations with equal traces are isomorphic, so the decomposition has the indicated trivial direct summand.

Write

$$\delta_g(x) = \det(1 - N_x(g)).$$

These functions vanish on $\mathcal{X}$. Their characteristic-coefficient expressions belong to the integral operator algebra by Lemma 7.6.13; the same holds at every deeper level. There are only finitely many systems at base level. For each that is not weak choose g_k with $\lambda_k = \delta_{g_k}(x_k) \neq 0$, and put

$$\delta_0 = \prod_k (\lambda_k - \delta_{g_k}), \qquad n_0 = \prod_k \lambda_k.$$

The factors are integral, $n_0 \neq 0$, $\delta_0 = n_0$ on $\mathcal{X}$, and δ_0 vanishes on every nonweak base system. Empty products are 1.

We choose the cyclotomic element with its prescribed cost. The image of G_E under χ_{cyc} is procyclic: for odd ℓ it is a closed subgroup of $\mathbb{Z}_\ell^\times$, and for $\ell = 2$ it lies in $1 + 16\mathbb{Z}_2$ because $\mu_{16} \subset E$. Let u be a topological generator. If $\ell > h_D^2$, then ℓ is unramified in E, by Lemma 4.2.66 and the size bounds in Lemma 4.2.67. The extension $E \cap \mathbb{Q}(\mu_{\ell^\infty})$ is unramified at ℓ and totally ramified at ℓ, hence is $\mathbb{Q}$. The cyclotomic image is therefore all of $\mathbb{Z}_\ell^\times$. Choose u with primitive residue; since $0 < a < t_D < \ell - 1$, every $u^a - 1$ is a unit. Set $h = 0$ in this case.

For $\ell \leq h_D^2$ set $h = v_\ell(C)$. Choose $i \in \{0, 1\}$ with $p_i \neq \ell$; the cyclotomic image contains p_i, the value at an arithmetic Frobenius above this split rational prime. For $0 < a < t_D$, the integer $p_i^a - 1$ divides $\#\mathrm{GL}_{r_D t_D}(\mathbb{F}_{p_i})$, since its order formula contains that factor, and hence divides C. Since u topologically generates the image, p_i is a limit of integral powers of u. Each $u^{ab} - 1$ is divisible in $\mathbb{Z}_\ell$ by $u^a - 1$, also for negative integers b. Passing to the limit gives $u^a - 1 \mid p_i^a - 1$, and consequently $u^a - 1 \mid \ell^h$. Choose g_1 with cyclotomic value u. In both cases $h \leq v_\ell(C)$ and the hypotheses of Proposition 7.6.12 hold.

That proposition supplies one finite index set J, independent of the truncation, and for each $\nu > 0$ auxiliary Taylor–Wiles places forming a prime triangle for g_1^{-1} with the required bounds. At these places every weak base system congruent to x_0 has the root chain with integral complementary polynomials H_j satisfying $H_j(1) = 1$. Choose ν large enough that

$$2n!(n_0 C^2)^{\#J+1} \mid \ell^\nu.$$

This is possible since the scalar on the left is nonzero and J was fixed before ν. The places avoid all bad places, and ν_O is trivial on their inertia. The supplied Ribet types and quadratic inertia relations hold simultaneously at this deeper level.

For every trace ideal of the deeper-level N_x, apply Theorem 7.6.6, with $\mathcal{X}$ as above, the chosen main summands, $\mathrm{ram} = \mathrm{sel} = e'_\ell$, and the prime triangle just obtained. Every hypothesis has now been supplied: the local types and quadratic relation come from the actual base-level construction, the trace decompositions and scalar lattices from the lift generators, and the bounded Selmer length at x_0 from v_0. It gives a common Ribet element whose coefficient d satisfies

$$v_\ell(C^2 d) \leq L.$$

Apply item 2 of Proposition 7.6.11 with $m = C^2$, $c_B = C$, the functions δ_g, and the displayed δ_0, n_0. A base system with $\delta_0 \neq 0$ is weak, so the root-chain hypothesis follows from the preceding construction. We obtain a function s on the deeper-level systems with

$$v_\ell(C^2 s(x_0)) \leq L.$$

If l, z are base-level forms, Cl is integral, z is supported on $\mathcal{X}$, and $z = l$ on every system where $\delta_0 \neq 0$, the same conclusion gives that $C^2 sz$ is integral.

We apply this assertion to

$$l = p_c y, \qquad z = p_c \mathrm{pr}_Z y$$

for an integral form y orthogonal to the false lifts. The first required integrality follows from the base-level projector estimate. The form z is supported on $\mathcal{X}$ because Z is spanned by lift generators and p_c either fixes or kills each generator. We justify their agreement at the weak base systems; it is this step that uses false-lift orthogonality.

Choose a split place w off the base level, not dividing ℓ, at which all base-level systems have their Hecke polynomials; there are infinitely many such places. For a weak system its normalised Frobenius matrix has eigenvalue 1. The local chain theorem Lemma 7.6.5, with the normalization of (MS6) and (DP10), continues this root to the full string of length t. Its last root is $X_*(w)^{-1}$, so the reversed Hecke polynomial operator $H_w(X_*(w))$ kills its base-level vectors. This holds for all weak base systems at this same good place.

Put $q = p_c(y - \mathrm{pr}_Z y)$. It lies in $p_c \mathrm{Form}(O) \cap Z^{\perp}$. This space is stable under the commuting normal Hecke operators, so it decomposes orthogonally into their simultaneous systems. Its weak-system component q_{wk} is killed by $H_w(X_*(w))$, lies in the range of p_c, and lies in $Z^{\perp}$. By (DR2), the range of p_c is contained in $e\mathrm{Form}(O)$. Thus q_{wk} is a false lift. Self-adjointness of p_c and $p_c q_{\mathrm{wk}} = q_{\mathrm{wk}}$ give

$$\langle q_{\mathrm{wk}}, q \rangle = \langle q_{\mathrm{wk}}, y - \mathrm{pr}_Z y \rangle = 0.$$

The last equality uses the assumed orthogonality of y to false lifts and the orthogonality of q_{wk} to Z. As this is the orthogonal weak component, its squared norm is zero; hence it vanishes. Therefore l and z agree at every weak base system, in particular wherever $\delta_0 \neq 0$. The auxiliary-operator conclusion proves that

$$G_{v_0} \mathrm{pr}_Z y := C^2 \, \mathrm{diag}(s) \, p_c \mathrm{pr}_Z y$$

is integral. On every lift generator v, this operator is scalar: p_c kills v or fixes it, and in the latter case v belongs to one system. Its scalar at v_0 has valuation at most L.

Choose a basis $b_1, \ldots, b_a$ of Z among the nonzero lift generators. For each b_i, the preceding construction gives an endomorphism G_i diagonal on this basis, preserving the required integrality after projection, with

$$G_i b_j = a_{ij} b_j, \qquad v_\ell(\iota(a_{ii})) \leq L.$$

The image of G_i on Z lies in Z because it is diagonal on the generators, so these are indeed endomorphisms. Choose integral coefficients d_i such that

$$\left| \sum_i d_i \iota(a_{ij}) \right|_\ell = \max_i |\iota(a_{ij})|_\ell \quad \text{for every } j.$$

Here is a simultaneous choice, with the coefficient fields specified. The coefficient field of Z and its endomorphisms in (DR1) is $\mathbb{C}$; the CM field E is not a required field of definition for the operator. By Definition 3.1.3, $\iota \colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$ is a field isomorphism on all of $\mathbb{C}$. The finite set of coefficients $\iota(a_{ij})$ lies in a finite extension $K_\ell / \mathbb{Q}_\ell$ inside the fixed algebraic closure. In each nonzero column divide by an entry of maximal absolute value; its reduction is a nonzero linear form in the variables $\bar{d}_i$. Enlarge the residue field until its cardinality exceeds the number of columns. The union of the resulting proper hyperplanes then has cardinality at most a times a codimension-one hyperplane and cannot fill that field's a-dimensional vector space. Choose

a point outside this union and lift its coordinates integrally. This gives the equality in every column.

Take the residue-field enlargement inside a finite unramified extension K'_ℓ/K_ℓ in the same fixed algebraic closure, and take each $d_i \in \mathcal{O}_{K'_\ell}$. Define $c_i = \iota^{-1}(d_i) \in \mathbb{C}$ and $\Lambda = \sum_i c_i G_i \in \mathrm{End}_{\mathbb{C}}(Z)$. These are permitted complex scalars in (DR1), not a change of the datum E or of any representation's field of definition. Since $|\iota(c_i)|_\ell = |d_i|_\ell \le 1$, the ring $\mathcal{O}_\iota$ of integral complex scalars acts on integral forms: in every gauge, multiplication of every coordinate by c_i preserves integrality. Thus Λ still sends all the projected test forms to integral forms. Its eigenvalue on b_j is $\mu_j = \sum_i c_i a_{ij}$, so $\iota(\mu_j) = \sum_i d_i \iota(a_{ij})$. The extended absolute value restricts to the original one on K_ℓ; the simultaneous equality therefore introduces no valuation loss. Its eigenvalue μ_j on b_j satisfies

$$v_\ell(\iota(\mu_j)) \le L$$

by the diagonal bound for G_j. Put $B = C\Lambda$. By (CX5), $t \le t_D$ and $r' \ge 1$,

$$\begin{aligned} L + v_\ell(C) &= r'\mathrm{loc}_\ell + (1+2t)e'_\ell + e_\ell + v_\ell(C) \\ &\le r'\big(\mathrm{loc}_\ell + (1+2t_D)e'_\ell + e_\ell + v_\ell(C)\big) = r'\beta_\ell. \end{aligned}$$

Multiplying the eigenvalues therefore gives

$$|\iota(\det B)|_\ell \ge \exp\big(-(\dim Z) r' \beta_\ell \log \ell\big).$$

Also $B\mathrm{pr}_Z y$ is integral, since $\Lambda \mathrm{pr}_Z y$ is integral and C is an integer.

It remains to prove the pairing clause, for which self-adjointness of the type projector alone would not suffice. Let f be integral above ℓ and $h = \Lambda \mathrm{pr}_Z y$ integral at ι. At an adelic representative g, let A_τ be its matrices in the gauge at ι. Unitarity identifies the matrices in the gauge at $\iota \circ$ complex conjugation with $(A_\tau^{-1})^{\mathsf{T}}$. Thus the gauged coordinate vectors of f and h are integral and their contractions equal $\iota\langle f(g), h(g)\rangle_{\kappa_O}$. To check this equality, write G_{κ_O} for the integer Gram matrix of the Schur module. The tensor/exterior-power construction of (WM1)–(WM2) gives

$$\rho_{\kappa_O, e_O}(A)^{\mathsf{T}} G_{\kappa_O} = G_{\kappa_O} \rho_{\kappa_O, e_O}(A^{\mathsf{T}}).$$

On tensor powers this is the ordinary transpose identity; restricting to exterior powers and then to the Schur image preserves it. The determinant twist satisfies the same identity. The two gauge factors are inverse transposes, so they cancel in this contraction. Since the Gram matrix has integer entries, each local contracted value is integral.

The global inner product is the class sum of these values divided by the finite rational stabiliser orders. Every such order divides C, as proved in the base-level construction; this also holds at the smaller level of the forms because its stabiliser is a subgroup of the maximal-level stabiliser. Hence

$$|\iota(C\langle f, h\rangle)|_\ell \le 1.$$

Since $B = C\Lambda$, this is exactly the pairing condition of (DR1). Together with the determinant and integrality assertions it proves the claimed denominator bound. □

Lemma 7.6.4. *Let (O, c) be a lift setting for a twist ϑ, and suppose that Q_ϑ is auxiliary for S_ℓ^{bad}. Write $r' = r_O$, $n = n_O$, $t = n - r'$, $S_O = M_O \cup Q_O$, and N_{ch} for the chosen group order. There are a multiset of jumps J at every embedding of E and base data B of the weight of O, with $B_{\mathrm{pl}} = S_O$ and $c_B = N_{\mathrm{ch}}$, such that:*

1. *every $p_c y$, $y \in \mathrm{Form}(O)$, is a form of base level for B;*

2. *if y is integral at ι (respectively above ℓ), then $N_{\mathrm{ch}}p_c y$ is integral at ι (respectively above ℓ);*

3. *for every finite family U of auxiliary level places outside S_ℓ^{bad} and every system x of level U for B, its normalised representation $N_x = \nu_O \otimes r_x$ is of Ribet type*

$$(O, c; t, J, Q_\vartheta \cup \bar{Q}_\vartheta \cup U \cup \bar{U}),$$

and for every element g of inertia above $Q_\vartheta \cup \bar{Q}_\vartheta$,

$$(N_x(g) - \psi_\vartheta(g)1)(N_x(g) - 1) = 0.$$

In particular, when a chosen place divides ℓ, its label polynomial kills the inertia operator on the potentially crystalline Weil–Deligne period module, in the sense of (RT1), for every chart and lattice; it is not asserted to kill the raw Galois matrix there.

Proof. Write $\mathscr{F}$ for the smooth automorphic forms of the weight of O on the definite standard unitary group. At the finite set S_O, let π_O act by right translation at these places and their conjugates, and by the identity at the other places. Let $\mathscr{V}$ be its subspace with the level and character prescribed in (DP4)–(DP5). On $\mathscr{V}$ the chosen finite groups act by (DP5). Put

$$\rho_c = \prod_{i \in I_O} e_{c_i}, \qquad \mathscr{Y} = \{v \in \mathscr{V} : \rho_c v = v\}.$$

The idempotents in this formula are the actual Green character idempotents. Define B to have type $\mathscr{Y}$ at S_O, maximal level away from S_O, and the weight of O. If an operator T on $\mathscr{F}$ commutes with $\pi_O(k)$ for every k in the maximal compact group, then it preserves $\mathscr{V}$: applying T to the equation $\pi_O(k)v = \eta_O(k)v$ gives the same equation for Tv. It also commutes with the action of every element of the chosen finite group algebra, since each such action is a linear combination of these translations. Thus $T\mathscr{Y} \subseteq \mathscr{Y}$. In particular all translations at places outside S_O and their conjugates preserve this type. The level defining $\mathscr{V}$ is open. These assertions give the form and level conditions for base data.

We check their prescribed stabiliser multiplier. By the lift-setting bounds,

$$n = r' + t \le r_D + t_D \le r_D t_D;$$

here $r_D \ge 3$ and $t_D = 5r_D$. Apply Lemma 6.7.9 to the same maximal-level representative, with the standard definite space of rank n and $K' = \mathrm{K}_0(n)$. The preceding bound checks $1 \le n \le r_D t_D$; hence its stabiliser is finite and its order divides N_{ch}. The group written using E-matrix points there is the same rational unitary group over E^+ here. This argument is independent of the coefficient prime, including when it is 2. Thus $c_B = N_{\mathrm{ch}}$ has precisely the common-multiple property required in (AL1) of Definition 7.6.1. Finiteness of the class set and its stabilisers follows from definiteness and the usual compact adelic quotient. The definition of p_c is the action of ρ_c on the forms of O; its image lies in $\mathscr{Y}$, and those forms have maximal level away from S_O. This proves item 1.

For item 2 let $G_c = \prod_i \mathrm{GL}_{r'}(k_{w_i})$. The central projector onto an irreducible finite representation λ has coefficients

$$\frac{\dim \lambda}{\#G_c} \operatorname{tr} \lambda(g^{-1}).$$

Every trace in this expression is an algebraic integer, because the eigenvalues of every finite-order matrix are roots of unity. A sum of distinct such projectors has the same integrality property

after multiplication by $\#G_c$. The Green projector ρ_c is such a sum (in the squarefree case it is a single irreducible projector at each place). The chosen group order is divisible by $\#G_c$: each $\mathrm{GL}_{r'}(k_w)$ embeds block diagonally into $\mathrm{GL}_{r_D t_D}(k_w)$. Consequently $N_{\mathrm{ch}}\rho_c$ has algebraic-integral coefficients. The additional factors in (DP5) are roots of unity. Each translating element belongs to the maximal level, so it preserves integral values in every Schur gauge, also when its residue characteristic is ℓ. Taking the finite sum proves the asserted integrality at every identification above ℓ.

Let now x be a system of level U. Choose a nonzero simultaneous eigenform f in its type space, so $\rho_c f = f$. Its associated automorphic representation has a weak base change and the semisimple attached representation r_x by Theorem 7.1.4. Multiplicity spaces cause no ambiguity: all constituents with this system have isomorphic attached representations, by the uniqueness there. At a place split over E^+, the local representation on the unitary side identifies with the corresponding general-linear representation in the base change. This is the split local assertion of [177, Corollaire 5.3], with no restriction on the coefficient prime.

At a chosen place w_i, the first block of the parahoric has rank r' and carries the Green representation labelled by the scaled polynomial $\mathrm{tl}(c,i)$; the complementary block of rank t is trivial. To see the scaling directly, (DP5) makes the action on the first block equal to its ordinary translation multiplied by $\psi_{O,w_i}(\det)$. Thus ordinary translation carries its inverse determinant twist, whose Green parameters are multiplied by $x_{\psi_{O,w_i}^{-1}}$. Since $\rho_c f = f \neq 0$, its local factor cannot annihilate f. Finite-group Frobenius reciprocity gives the actual finite Harish–Chandra product of this first-block Green representation and the trivial representation of $\mathrm{GL}_t(k_{w_i})$ in the compact restriction. Factor $\mathrm{tl}(c,i)$ into distinct irreducible polynomials. The squarefree-label clause of Theorem A.5.29, applied to these distinct monic irreducible factors, identifies its signed Green character with the irreducible finite Harish–Chandra product of their regular cuspidal representations. The sign cancels in the central idempotent, since both the character degree and its conjugate character acquire that sign. No factor is the trivial rank-one character, since $\mathrm{tl}(c,i)(1) \neq 0$ in a lift setting. Hence the hypotheses of Lemma 7.5.2 hold.

For the tame normalization apply Lemma 7.5.4 with $F = E_{w_i}$, $f = r'!$ and d the degree of the chosen irreducible factor. One has $1 \leq d \leq r'$, hence $d \mid r'!$. The faithful character is exactly the fixed character used in the Green label and in (RT2). That lemma gives $T(x)^a$ for each root x, including every Frobenius conjugate, with geometric Artin reciprocity. Its inverse-character clause also gives the multiplier $x_{\psi_{O,w_i}^{-1}}$ already found from (DP5). The complementary trivial block has value 1. Thus Lemma 7.5.2 gives zero monodromy and exactly the roots of $\mathrm{tl}(c,i)(X-1)^t$, with the required tame values.

Away from ℓ, apply Theorem 7.1.8, (Us2)–(Us3). The unramified normalising factor in its local Langlands comparison changes neither inertia nor monodromy. Inertia acts through a finite group and is semisimple in characteristic zero, so the displayed label polynomial kills the actual matrix. At a chosen place above ℓ, apply Theorem 7.1.9, (Ul2)–(Ul3). It gives potential crystallinity and the same finite inertia action on the Weil–Deligne module. This action is semisimple, so the same polynomial kills it. The potentially crystalline period comparison transports this equality to the period operator of (RT1): on the potentially crystalline periods inertia acts as the Weil operator, and extension of scalars is faithful. Identifying the crystalline invariants computed using $B_{\max}$ and B_{cris} is legitimate: $\varphi(B_{\max}) \subset B_{\mathrm{cris}} \subset B_{\max}$ and the finite-dimensional invariant space is stable under bijective Frobenius, so their invariant spaces coincide. This argument applies to every lattice after tensoring with its fraction field. Changing a chart conjugates the decomposition group and transports both the period ring and its operator, preserving the polynomial identity. Thus all charts and lattices in (RT1) are covered.

Off $S_O \cup \bar{S}_O \cup U \cup \bar{U}$, the eigenform is spherical. The extension E/E^+ is unramified at every

finite place: if the residue characteristic is not 3, inertia cannot act by complex conjugation on the roots $\mu_3 \subset E$; at residue characteristic 3 use $\mu_4 \subset E$ instead. Roots of unity of order prime to the residue characteristic lie in the maximal unramified extension, and complex conjugation acts nontrivially on either indicated group. The standard hermitian lattice is self-dual, so its maximal compact subgroup is hyperspecial over this unramified extension. The spherical local parameter is unramified with monodromy zero. The unramified local assertions in Theorem 7.1.4 and Theorem 7.1.9, (Ul4), now give good reduction at all the required places. At the chosen places the preceding argument supplies finite type, including potential crystallinity at ℓ. The de Rham property and jumps at all embeddings follow from (Ul1). This proves the required local level assertions for r_x.

The normalising character ν_O is unramified at every finite place away from ℓ, crystalline at the places above ℓ, and has an unramified Weil–Deligne character there: $\chi_O = \upsilon^{r_-(O)}$ has trivial finite tame part and υ is trivial on finite units. Algebraic Hecke-character reciprocity therefore gives these assertions, and its Hodge jump is minus its infinity exponent. Let J be the jumps of the weight of O shifted by these Hodge jumps. Tensoring preserves the local finite-type and good-reduction assertions and leaves every label unchanged. Moreover

$$\nu_O\, \nu_O^c = \chi_{\mathrm{cyc}}^{r'}, \qquad r_x^c \simeq r_x^\vee \chi_{\mathrm{cyc}}^{1-n},$$

the first equality following by multiplying the defining Hecke characters and the second from (Ua1). Thus

$$N_x^c \simeq N_x^\vee \chi_{\mathrm{cyc}}^{1-t}.$$

Its matrix span is a semisimple algebra, since r_x is semisimple, and the trace pairing on each simple factor is a positive integral multiple of its usual nondegenerate matrix trace pairing. Hence it is nondegenerate. Since $t \geq 1$, this is exactly (MS1) with twist t. Together with the local conclusions it proves the Ribet-type assertion.

At a twist place $w \in Q_\vartheta$, (DP4) says that a parahoric block of rank r' acts on f by $\psi_{O,w}^{-1} \circ \det$, and its rank-$t$ complement acts trivially. The lift-setting identity gives $\psi_{O,w} = \vartheta_w$, since the fixed chosen-place character is trivial here. These two characters are distinct because w belongs to the modulus of the tame twist. The scalar-block parahoric theorem 7.1.11 gives zero monodromy, finite semisimple inertia and its two characters. Geometric reciprocity and the inverse-avatar definition identify their values at g as 1 and $\psi_\vartheta(g)$. A semisimple matrix with these eigenvalues is killed by $(X - \psi_\vartheta(g))(X - 1)$. The normalising character is trivial on this inertia, as $w \nmid \ell$; hence the same polynomial kills $N_x(g)$. At a conjugate place apply conjugate self-duality to $(g^c)^{-1}$. Cyclotomic twists are trivial on inertia away from ℓ, and the torus character satisfies $\psi_\vartheta((g^c)^{-1}) = \psi_\vartheta(g)$. Transporting the polynomial through the duality therefore gives the identical quadratic relation. All the assertions in item 3 follow. □

Lemma 7.6.5. *Let F be a nonarchimedean local field, $\mathcal{O}_F$ its valuation ring, ϖ a uniformiser and q the cardinality of its residue field. Let $N \geq 1$, $K = \mathrm{GL}_N(\mathcal{O}_F)$, and let $I_1 \subset K$ be the inverse image of the upper unitriangular subgroup modulo ϖ. Let Π be a smooth complex representation of $\mathrm{GL}_N(F)$ with an invariant positive definite Hermitian form B, conjugate linear in its first argument. For $0 \leq j \leq N$, let T_j be the sum-normalised spherical Hecke operator of $\mathrm{diag}(\varpi 1_j, 1_{N-j})$. Suppose $0 \neq x \in \Pi^K$ and $T_j x = \lambda_j x$, and put*

$$P(X) = \sum_{j=0}^{N} (-1)^j q^{j(j-1)/2} \lambda_j X^{N-j}.$$

Let U be the sum of the right-coset operators in $I_1 \,\mathrm{diag}(\varpi, 1, \ldots, 1) I_1 / I_1$, acting on Π^{I_1}. Then:

1. *If $P(c) = 0$ and $P(qc) \neq 0$, then $|c|^2 \geq q^{N-2}$. If $k \geq 0$, $P(c) = 0$ and $|c|^2 q^k = q^N$, then $P(cq^i) = 0$ for every $0 \leq i < k$.*

2. *Let $d \neq 0$, $k \geq 0$, and $R \in \mathbb{C}[X]$. If*

$$P(d^{-1}X) = \prod_{i=0}^{k} (X - q^i)\, S(X), \qquad S \mid R,$$

then for every $y \in \Pi^{I_1}$,

$$B\big(x,\, (dU - q^k)R(dU)y\big) = 0.$$

Proof. **The lattice count.** For $0 \leq a \leq N$ and $j \geq 0$, define $A_{a,j}x$ to be the sum of $\Pi(g)x$ over the right K-cosets gK whose lattices $g\mathcal{O}_F^N$ satisfy

$$\varpi\mathcal{O}_F^N \subseteq g\mathcal{O}_F^N \subseteq \mathcal{O}_F^N, \quad \dim_{\mathbb{F}_q}(\mathcal{O}_F^N / g\mathcal{O}_F^N) = j, \quad e_1, \ldots, e_a \in g\mathcal{O}_F^N.$$

These sums are finite and independent of representatives. Write $v_j = A_{1,j}x$, and put $n = N - 1$. Then $v_0 = x$, $v_{n+1} = 0$, and $A_{0,j}x = \lambda_j x$. Each v_j is fixed by I_1, since its defining lattice condition is stable under upper triangular matrices.

Let M be the mean over I_1, and on Π put

$$V = q^n M\Pi(\mathrm{diag}(\varpi, 1, \ldots, 1))M, \qquad V' = q^n M\Pi(\mathrm{diag}(\varpi^{-1}, 1, \ldots, 1))M.$$

The mean is an orthogonal projection: smoothness makes each mean a finite average, and invariance of B gives self-adjointness. Thus V' is the adjoint of V. On Π^{I_1}, V is exactly U. Indeed the right cosets of the indicated double coset are represented by $u\ \mathrm{diag}(\varpi, 1, \ldots, 1)$, where u is upper unitriangular with its first row to the right of the diagonal running independently through $\mathbb{F}_q$. There are q^n such cosets, and their sum is $q^n M\Pi(\mathrm{diag}(\varpi, 1, \ldots, 1))$ on an I_1-fixed vector.

We give the count that will be used twice. With coordinates numbered $0, \ldots, N-1$, let b_a have ϖ in position a and 1 elsewhere. If a linear map L is unchanged by upper unitriangular row operations supported in row a, then

$$q^{N-1-a} L\Pi(b_a) A_{a+1,j}x = q^j L(A_{a,j+1}x - A_{a+1,j+1}x). \tag{1}$$

To verify (1), sum the row vectors $(0, \ldots, 0, 1, u_{a+1}, \ldots, u_{N-1})$ over all q^{N-1-a} choices and use the corresponding upper unitriangular matrices. For a lattice counted by $A_{a,j+1}$, a row contributes precisely when it annihilates the reduction of that lattice. There are no such rows if the lattice contains e_a. Otherwise restriction of the coordinate at a to its annihilator is a nonzero linear functional on a vector space of dimension $j+1$. Its fibre over 1 has q^j elements. These are all the contributions, giving exactly the difference on the right of (1).

Taking $a = 0$ and $L = M$ in (1) gives the first recurrence below. Apply (1) also to the representation $g \mapsto \Pi((g^{\mathsf{t}})^{-1})$. Duality of lattices, $L \mapsto \varpi L^\vee$, interchanges colength j with $N - a - j$ among lattices containing the first a basis vectors. For $a = 0$ its diagonal correction is $\varpi^{-1}1_N$; for $a = 1$ it is $\mathrm{diag}(1, \varpi^{-1}, \ldots, \varpi^{-1})$. Substituting these two corrections in (1), and applying M, gives

$$\begin{aligned} Vv_j &= q^j(\lambda_{j+1}x - v_{j+1}) \quad (0 \leq j \leq n), \\ V'v_{i+1} &= q^{n-i-1}\big((\lambda_{i+1}/q^n)V'x - v_i\big) \quad (0 \leq i < n), \\ V'x &= q^n\lambda_N^{-1}v_n, \qquad Vv_n = q^n\lambda_N x. \end{aligned} \tag{2}$$

For clarity, the dual count before substituting $A_{0,i+1}x = \lambda_{i+1}x$ is

$$q^n M\Pi(b_0^{-1})A_{1,i+1}x = q^{n-i-1}(M\Pi(b_0^{-1})A_{0,i+1}x - A_{1,i}x).$$

At top degree $A_{0,N}x = \Pi(\varpi 1_N)x = \lambda_N x$, and multiplication by b_0^{-1} gives $A_{1,n}x$. This proves the third formula of (2); $\lambda_N \neq 0$ because the central translation is invertible. The fourth formula follows by reversing that translation. Thus all the recurrences, including their endpoint normalisations, follow from the single finite count (1).

The adjoint calculation. Let

$$P_m(X) = \sum_{j=0}^{m} (-1)^j q^{j(j-1)/2} \lambda_j X^{m-j}.$$

Put $a_m = (-1)^m q^{m(m-1)/2}$. Thus $a_0 = 1$ and $a_{m+1} = -q^m a_m$. Since $\lambda_0 = 1$, $P_0(V)x = x = a_0 v_0$. For $0 \leq m \leq n$, the polynomial recurrence and the first line of (2) give

$$\begin{aligned} P_{m+1}(V)x &= VP_m(V)x + a_{m+1}\lambda_{m+1}x \\ &= a_m q^m(\lambda_{m+1}x - v_{m+1}) + a_{m+1}\lambda_{m+1}x \\ &= a_{m+1}v_{m+1}. \end{aligned}$$

This proves by induction, including $m = N = n+1$ and $v_N = 0$, that

$$P_m(V)x = a_m v_m \quad (0 \leq m \leq N), \qquad P(V)x = 0. \tag{3}$$

The span of $v_0, \ldots, v_n$ is preserved by V' by (2).

For $c \in \mathbb{C}$, define the polynomial

$$D_{m,c}(X) = \sum_{j=0}^{m-1} a_j \lambda_j \sum_{\ell=0}^{m-j-1} X^{m-j-1-\ell} c^\ell \quad (m \geq 1), \qquad D_{0,c} = 0.$$

The identity $(X-c)\sum_{\ell=0}^{h-1} X^{h-1-\ell}c^\ell = X^h - c^h$ shows, without division by any scalar, that

$$(X-c)D_{m,c}(X) = P_m(X) - P_m(c).$$

It also gives $D_{m+1,c} = P_m + cD_{m,c}$. Iterating this recurrence, starting with $D_{0,c} = 0$, yields the universal polynomial identity

$$D_{m,c}(X) = \sum_{h=0}^{m-1} c^{m-1-h} P_h(X).$$

Indeed multiplication by c gives the terms with $h < m$, and addition of P_m gives the last term for $m+1$. Thus, with $D_c = D_{N,c}$ and $z_c = D_c(V)x$, (3) gives

$$z_c = \sum_{m=0}^{n} a_m c^{n-m} v_m.$$

Here and below $c^0 = 1$, including at $c = 0$, and an empty sum is zero.

For $1 \leq m \leq n$, the second recurrence of (2), with $i = m-1$, reads

$$V' v_m = q^{n-m}\big((\lambda_m/q^n)V'x - v_{m-1}\big).$$

Apply this formula term by term to the preceding expression for z_c, keeping its $m = 0$ term separate. It gives

$$cV'z_c = \left(c^{n+1} + \sum_{m=1}^{n} a_m \lambda_m q^{-m} c^{n+1-m} \right) V'x \\ - \sum_{m=1}^{n} a_m q^{n-m} c^{n+1-m} v_{m-1}.$$

Since $-a_m q^{n-m} = q^{n-1} a_{m-1}$, the last sum, with its displayed minus sign, equals

$$q^{n-1} \sum_{h=0}^{n-1} a_h c^{n-h} v_h = q^{n-1} z_c - q^{n-1} a_n v_n.$$

This remains valid when $n = 0$: the sum is empty and its right side is $q^{-1}(z_c - v_0) = 0$. The endpoint recurrence in (2) gives $v_n = \lambda_N q^{-n} V'x$, so the correction term is $-a_n \lambda_N q^{-1} V'x = a_N \lambda_N q^{-N} V'x$. Together with $\lambda_0 = a_0 = 1$, the complete coefficient of $V'x$ is therefore

$$\sum_{m=0}^{N} a_m \lambda_m q^{-m} c^{N-m} = q^{-N} P(qc).$$

We have proved, for every $c \in \mathbb{C}$, the exact identity

$$cV'z_c = \frac{P(qc)}{q^N} V'x + q^{N-2} z_c. \tag{4}$$

All divisions in this coefficient calculation are by powers of q, which is nonzero. The endpoint $\lambda_N \neq 0$ and the endpoint recurrence used above were proved in (2). In particular no root hypothesis or division by c was used. When $N = 1$ the same computation has $n = 0$, $z_c = x$ and $V'x = \lambda_1^{-1} x$; its two sides are both $c\lambda_1^{-1} x$. When $c = 0$, (4) follows from the same finite polynomial calculation, with its constant powers interpreted as above. If $P(c) = 0$, (3) also gives $Vz_c = cz_c$. Pair (4) with $V'x$, using $VV'x = q^{2n}x$, which follows from the last two formulas of (2). The result is

$$c(q^N - 1) B(x, z_c) = P(qc) B(x, x). \tag{5}$$

If $P(qc) \neq 0$, (5) implies $z_c \neq 0$. Pairing (4) with z_c and using (5) and adjointness gives

$$(|c|^2 - q^{N-2}) B(z_c, z_c) = \frac{|P(qc)|^2 B(x, x)}{q^N (q^N - 1)} \geq 0. \tag{6}$$

Positive definiteness proves the first assertion of item 1.

We record also the case of two consecutive roots. Suppose $c \neq 0$, $P(c) = P(qc) = 0$ and $P = (X - c)F$. Then $F = D_c$. By (4), $V'z_c = c^{-1} q^{N-2} z_c$, and by (5), $B(x, z_c) = 0$. Adjointness and induction on degree now give $B(G(V)x, z_c) = 0$ for every polynomial G: the constant case is (5), and multiplication by V moves to the scalar action of V' on z_c. Taking $G = D_c$ and using positivity gives

$$F(V)x = 0. \tag{7}$$

Continuation of roots. The roots of P, with multiplicity, are stable under $c \mapsto q^{N-1}/\bar{c}$. Here is a coefficient check. The adjoint of T_j is the central translation by $\varpi^{-1} 1_N$ followed by T_{N-j}. Pairing this identity with x gives $\bar{\lambda}_j = \bar{\lambda}_N \lambda_{N-j}$. Insert these equations in the displayed formula for P, reverse the indices j and $N - j$, and use $\binom{N}{2} + \binom{j}{2} + j = \binom{N-j}{2} + Nj$. The

conjugate reciprocal polynomial has the same roots as P, with precisely the factor q^{N-1}. Its constant coefficient is nonzero, so its roots are all nonzero.

Now suppose $|c|^2 q^k = q^N$. The assertion is empty for $k = 0$. The reflection just proved sends cq^i to cq^{k-1-i}. If $i \geq 1$ is the first missing root before the midpoint, then cq^{i-1} is a root and cq^i is not. Equation (6) gives

$$q^{N-k+2i-2} = |cq^{i-1}|^2 \geq q^{N-2}, \quad \text{hence } 2i \geq k.$$

This contradicts $i < k/2$. Consequently every root in the lower half of the proposed chain occurs, and reflection supplies the upper half. In the middle case $k = 2i$, the desired root is the reflection of the already present root at $i - 1$. This proves item 1 in all cases.

Cancellation and orthogonality. We first give the cancellation step without a multiplicity assumption. Suppose

$$P(X) = \prod_{i=0}^{k-1} (dX - q^i)\, G(X), \qquad P(q^k/d) = 0, \quad d \neq 0.$$

Then

$$G(V)x = 0. \tag{8}$$

Induct on k. For $k = 0$ this is (3). At the next step, the induction hypothesis says $(dV - q^k)G(V)x = 0$. Thus $w = G(V)x$ is a V-eigenvector of eigenvalue q^k/d. Apply (7) to the root q^k/d and its successor. The factorisation of P shows that (7) says $Q(V)w = 0$, where $Q(X) = \prod_{i<k}(dX - q^i)$, up to a nonzero scalar. Since $Q(q^k/d) \neq 0$ for $q > 1$, this forces $w = 0$. This proves (8).

In item 2 put

$$G(X) = (dX - q^k)S(dX).$$

The assumed factorisation gives $P(X) = \prod_{i<k}(dX - q^i)G(X)$, and q^k/d is a root. Hence (8) gives $G(V)x = 0$. By (3), every v_j is a nonzero scalar multiple of a polynomial in V applied to x; consequently $G(V)$ kills every v_j. Let W be their span. It is V'-stable by (2), so $\bar{G}(V')x \in W$ and

$$B(\bar{G}(V')x, \bar{G}(V')x) = B(x, G(V)\bar{G}(V')x) = 0.$$

Thus $\bar{G}(V')x = 0$. Adjointness gives $B(x, G(V)y) = 0$ for every y. Write $R = SF$. The operator in item 2 is $F(dV)G(V)$ on I_1-fixed vectors; moving the additional polynomial across the pairing, or applying the same argument to $F(dX)G(X)$, gives the required zero. The operator V preserves Π^{I_1} and equals U there, so this is exactly the stated sum-normalised identity. □

Theorem 7.6.6. *Let D be admissible data, ℓ a prime, $\iota\colon \mathbb{C} \to \bar{\mathbb{Q}}_\ell$, ϑ a twist, (O, c) a lift setting for ϑ with source rank r' and rank difference t', $n = r' + t'$, and (S_ℓ, Q, ψ) an auxiliary twist with ramification at most* ram. *Let $(w_j, \tau_j, \varphi_j)_{j\in J}$ with exponent* ty$\colon J \to \{1, \dots, t' - 1\}$ *be a prime triangle for some g_0 with bounds $(h_D h,\ h_D^{22} h)$, where $h \leq v_\ell(N_{\mathrm{ch}})$; put $W = \{w_j\}$. Let u_x $(x \in Y$, Y finite$)$ be ℓ-adic representations of rank n such that:*

(a) each u_x is of Ribet type $(O, c; t', J', Q \cup \bar{Q} \cup W \cup \bar{W})$ (RT7), for one function J' of jumps;

(b) on inertia above $Q \cup \bar{Q}$, $(u_x(g) - \psi(g))(u_x(g) - 1) = 0$.

Let $\mathcal{X} \subseteq Y$, and for $x \in \mathcal{X}$ let R_x be main-summand like of rank r' and string length t' with

$$\operatorname{tr} u_x(g) = \psi(g) \operatorname{tr} R_x(g) + \sum_{e<t'} \mathrm{cyc}(g)^{-e} \qquad (g \in G_E),$$

and with $\gamma_x \in G_E$ in an inertia group off ℓ and $\zeta_x \in \bar{\mathbb{Z}}_\ell$, $\zeta_x - 1$ a unit, such that for all large $\mathcal{O}$ some lattice of ψR_x has γ_x acting by ζ_x. Let S, $\mathcal{J}$ be a trace ideal for the u_x, $p = \ell^\nu$ and the tied relations at (τ_j, φ_j) with $H_j \in \bar{\mathbb{Z}}_\ell[X]$, $H_j(1) = 1$. Let $\pi \in \mathcal{X}$ be such that ψR_π has Selmer length at most $\mathrm{sel} < \infty$ *at $(Q, \gamma_\pi, \zeta_\pi)$. Then the functions $x \mapsto \det(1 - u_x(g))$, $g \in G_E$, have a common Ribet element at π whose coefficient d of $\prod_j X_j$ satisfies*

$$v_\ell(d) + 2\, v_\ell(N_{\mathrm{ch}}) \le \mathrm{sel} + 2t'\, \mathrm{ram} + r'\, \mathrm{loc}_\ell + e_\ell.$$

Proof. We verify the hypotheses of item 2 of Lemma 7.6.7 and keep track of its constants. Valuation inequalities are understood in $[0, \infty]$, so a zero value of an inertia polynomial causes no exceptional case.

Integral models and blocks. The character ψ has finite order, is unramified outside $Q \cup \bar{Q}$, is trivial on the decomposition groups above ℓ, and satisfies

$$\psi(g^c) = \psi(g)^{-1}, \qquad \psi((g^c)^{-1}) = \psi(g).$$

Indeed these identities hold on Artin symbols by (AX3), since conjugation exchanges $x/\bar{x}$ with its inverse; local compatibility and density in Theorem A.2.7 give the assertions on Galois groups.

All the finitely many representations and characters can be defined over one finite extension of $\mathbb{Q}_\ell$. Here is the usual descent argument for this assertion. There are countably many finite subextensions of $\overline{\mathbb{Q}}_\ell/\mathbb{Q}_\ell$. The compact image of a continuous representation is the union of its closed intersections with the matrix groups over these fields. The Baire theorem gives one such intersection with nonempty relative interior. Its inverse image is a subgroup with nonempty interior, hence an open subgroup. Adjoining the matrix entries of representatives for its finitely many cosets gives a finite coefficient field for the whole representation. A compact subgroup over this field preserves a lattice: the span of its orbit of the standard lattice is bounded, contains the standard lattice, and is a finite module over the valuation ring.

All these representations are finite dimensional over the algebraically closed characteristic-zero field $\overline{\mathbb{Q}}_\ell$. By (RT7), (RT6), (RT4) and (MS1), the trace pairing on the matrix span of each u_x is nondegenerate. By (MS3) and (MS1), the same holds for each R_x. Item1 of Lemma 7.7.9 therefore makes them semisimple. Multiplication by the nonzero scalar character $\psi(g)$ leaves invariant subspaces and invariant complements unchanged, so $T_x = \psi R_x$ is semisimple. The one-dimensional characters χ^{-e} are simple, and their direct sum with T_x is semisimple. The trace equality in the hypothesis and item2 of Lemma 7.7.9 now give

$$u_x \simeq T_x \oplus \bigoplus_{0 \le e < t} \chi^{-e}, \qquad T_x = \psi R_x, \quad x \in \mathcal{X}. \tag{1}$$

Choose a coefficient ring $\mathcal{O}$, large for all these models, all coefficients H_j, all scalars ζ_x, the assertions (MS3), the Selmer bound at π, and Corollary 7.7.4. Replace the representations by conjugate integral models. For $x \in \mathcal{X}$ choose (1) as the integral model, using at π the lattice supplied by (AX7). Thus $T_\pi(\gamma_\pi) = \zeta_\pi$, its Selmer module has normalised length at most sel, and $\zeta_\pi - 1$ is a unit. Since ψ is trivial above ℓ, T_π agrees there with a lattice of R_π. The span of $T_\pi(G_E)$ is $M_r(\mathcal{O})$: multiplication of the individual matrices of R_π by the units $\psi(g)$ leaves their span unchanged. Also $\chi(\gamma_x) = 1$, because γ_x is inertial away from ℓ. These prove (R1) and (R2). Conjugating a model leaves all trace and determinant functions and their trace ideal unchanged.

The doubled relations. Put $h^- = (h^c)^{-1}$ for any $h \in G_E$. Conjugate self-duality gives, for $i \ge 0$,

$$\mathrm{tr}\, u_x((h^-)^i g) = \chi((h^-)^i g)^{1-t}\, \mathrm{tr}\, u_x(h^i g^-). \tag{2}$$

Here cyclic invariance of the trace moves h^i past g^-. On the two inertia generators τ_j, τ_j^- the cyclotomic character is 1; on φ_j, φ_j^- it is congruent to 1 modulo $p = \ell^\nu$. Expand $(X-1)H_j(X)$ in monomials and use (2). The trace of the negative tied relation, multiplied on the right by $u_x(g)$, is $\chi(g)^{1-t}$ times the positive tied relation at g^-, plus X_j times an integral linear combination of the functions $p \operatorname{tr} u_x(k)$. All these functions belong to $\mathcal{J}$. This proves the trace-ideal assertion for both signs. Moreover

$$H_j(\chi(\varphi_j^\pm)^{-e}) \equiv H_j(1) = 1 \pmod{p} \quad (0 \le e < t).$$

This is (R3). Take $a = g_0$ and $C = \ell^{Hh}$. Condition (PT3), with $u = \chi(a^{-1})$, is precisely (R4), since $\chi(a)^{-e} = u^e$.

Continuity and the block count. We spell out why the scalar-relation condition in (R5)–(R7) supplies continuity, although continuity was not imposed in the definition of Ribet cocycles. Let

$$L_0 = \operatorname{span}_{\mathcal{O}}\{(u_x(g) - 1)_{x \in Y} : g \in G_E\} \subseteq \prod_{x \in Y} M_n(\mathcal{O}).$$

This is a finite free $\mathcal{O}$-module. The relation condition on a map z says exactly that $z(g)$ is the value on $(u_x(g)-1)_x$ of an $\mathcal{O}$-linear map on L_0. Such a map with values in $\mathcal{O}/\ell^M$, or in $(K/\mathcal{O})^r$, has finite image: choose a finite basis of L_0 and one common annihilator for its images. It is continuous. Indeed the topology induced on L_0 by the ambient finite free module is its valuation topology, by the elementary-divisor theorem. The original representations are continuous, so z is locally constant. If $u_x(g) = 1$ for all x, the same relation condition gives $z(g) = 0$.

In particular these cocycles are unramified outside the allowed ramification of the u_x. If, at a place away from ℓ where the coefficient representation is unramified, a cocycle vanishes at a tame generator, it vanishes on inertia: its restriction is a continuous homomorphism, the wild pro-residue-characteristic subgroup has zero image in an ℓ-primary group, and the pro-ℓ part of tame inertia is topologically generated by that generator. This argument applies at the places of $W \cup \bar{W}$ outside the already allowed set above $p_0 p_1$ and $Q \cup \bar{Q}$.

Let Z_M be the module in (R5) with values in $(\mathcal{O}/\ell^M)^r$, vanishing at all $\tau_j^\pm$ and at γ_π. The preceding argument makes its members continuous and unramified away from the places above $\ell p_0 p_1$ and $Q \cup \bar{Q}$. Let $Z_{M,f}$ be its submodule obeying the crystalline relations. Multiplication by ℓ^{-M} embeds $Z_{M,f}$ into $\operatorname{Sel}(T_\pi, Q, \gamma_\pi)$; both the crystalline relations and the vanishing conditions are preserved by this injection. Consequently

$$\operatorname{length} Z_M \le \operatorname{cc}(T_\pi; u, M) + \operatorname{length} \operatorname{Sel}(T_\pi, Q, \gamma_\pi) \le \operatorname{loss}_T + \operatorname{length} \operatorname{Sel}(T_\pi, Q, \gamma_\pi). \tag{3}$$

The second inequality is Corollary 7.7.4, item 1. Every $K/\mathcal{O}$-valued relation-obeying cocycle has bounded denominator by the finite generation of L_0 just proved. Thus the module in (R5) is the increasing union of these finite-level modules. A uniform finite bound on their lengths bounds the length of the union: any finite strictly increasing chain is already contained in one finite level. We may therefore take

$$b_0 = \operatorname{loss}_T + \operatorname{length} \operatorname{Sel}(T_\pi, Q, \gamma_\pi). \tag{4}$$

Old inertia relations. First take the tame generators δ_w in (AX5), for $w \in Q$, and also δ_w^-. The polynomial

$$o_w(X) = X - \psi(\delta_w)$$

has $o_w(X)(X-1)$ killing every $u_x(\delta_w)$ by hypothesis (b). The same holds for the negative generator since it lies above $\bar{w}$ and $\psi(\delta_w^-) = \psi(\delta_w)$. Their combined cost is at most $2\,\mathrm{ram}$.

Next, at each place above p_0p_1 away from ℓ, take a tame generator and its negative conjugate. One can use at most $8f$ elements, since $[E:\mathbb{Q}] = 2f$ and there are two rational level primes. Their images under every u_x are killed by $X^{N_{\mathrm{ch}}}-1$. To check this assertion, at a chosen place the roots of the labelled polynomial lie in extensions of the residue field of degrees at most r', together with the root 1 of the string. Their multiplicative orders therefore divide numbers $\#k_w^a - 1$, $1 \le a \le r'$, each of which divides $\#\mathrm{GL}_{r_D t_D}(k_w)$ and hence N_{ch}. Inertia has finite image by the finite-type condition, so its matrices are semisimple in characteristic zero; a repeated root 1 in the label does not produce a nontrivial Jordan block. At the conjugate place the same assertion follows from (MS1): the semisimple inertia representation is the inverse conjugate of the one just considered, and inversion preserves these orders. These places cover the level places. The resulting polynomial is valid on every lattice, as it is already zero over the coefficient field.

For all these level generators use

$$o_w(X) = 1 + X + \cdots + X^{N_{\mathrm{ch}}-1}.$$

Its value at 1 is N_{ch}, including when the label has a multiple root 1. All the old generators are inertial away from ℓ, so $\chi^{-e}(\delta_w) = 1$. We have proved (R6) with

$$\sum_w v_\ell(o_w(1)) \le 2\,\mathrm{ram} + 8fh_N. \tag{5}$$

The character counts. For $0 \le e < t$ write

$$c_e = \mathrm{cc}(\mathcal{O}(-e); u, \nu), \qquad b_e = c_e + \mathrm{length}_{\mathcal{O}} \mathrm{Sha}^-(e,\nu). \tag{6}$$

Consider any module Z occurring in (R7). Its members are continuous by the L_0 argument. Vanishing at the old inertia generators makes them unramified at $Q \cup \bar{Q}$ and at the level primes away from ℓ, since their coefficient character is unramified there. Away from these and $W \cup \bar{W}$ all the u_x are unramified. Hence

$$Z \subseteq \mathrm{Sel}_{S_\ell \cup W \cup \bar{W}}(e,\nu).$$

If a member is unramified outside ℓ, it vanishes at γ_π, since that element is inertial away from ℓ. The normalising relation in (R7), evaluated at $g = a$, then gives

$$(\chi(a)^{-e} - 1) z(a) = 0.$$

The crystalline colength of Z is at most c_e, since intersecting a submodule with the crystalline-relation module injects its quotient into the defining quotient for c_e. Item 3 of Proposition 7.6.10 now proves triangle cost b_e along $\mathrm{ty}^{-1}(e)$ up to C.

Let s_0 be the test set of (PT2) and put

$$s' = s_0 \cup \{a\} \cup \{\tau_j, \tau_j^- : j \in J\}.$$

If a member of Z vanishes on s', it is unramified at the triangle places by the tame-inertia argument, hence lies in $\mathrm{Sel}_{S_\ell}(e,\nu)$. It vanishes at a and on s_0, so (PT2) makes it zero. This proves every part of (R7). Put $K_0 = \#J + \#s_0 + 1$. Then

$$\#s' \le 2K_0, \qquad K_0 H h \le H^{22} h. \tag{7}$$

By item 2 of Corollary 7.7.4, (4), (6), (AX7), and Theorem 7.2.8,

$$\frac{b_0 + \sum_{e<t} b_e}{v_{\mathcal{O}}(\ell)} \le \mathrm{sel} + r'\mathrm{loc}_\ell + t\, v_\ell(X_{\mathrm{odd}}). \tag{8}$$

The coefficient ring was enlarged to contain the finitely many roots of unity required by the odd-class bound.

Application and constants. Apply Lemma 7.6.7, item 2, over $\mathcal{O}$, with the blocks (1), $p = \ell^{\nu}$, the tied relations indexed by $J \times \{+,-\}$, $C = \ell^{Hh}$, the old generators just constructed, and the test set s'. Equations (3)–(8) verify all its hypotheses. Divide its length-valued inequality by $v_{\mathcal{O}}(\ell)$, so that its valuation becomes v_ℓ. It supplies a common Ribet element with top coefficient d satisfying

$$\begin{aligned} v_\ell(d) &\le \mathrm{sel} + r'\mathrm{loc}_\ell + t\, v_\ell(X_{\mathrm{odd}}) + 2t\,\mathrm{ram} + 8fth_N \\ &\quad + (2t\,\#s' + \#J + 1)Hh \\ &\le \mathrm{sel} + r'\mathrm{loc}_\ell + 2t\,\mathrm{ram} + t_D v_\ell(X_{\mathrm{odd}}) + \big(8ft_D + (4t_D+1)H^{22}\big)h_N. \end{aligned} \tag{9}$$

For the second inequality, use $t \le t_D$, $h \le h_N$, $\#s' \le 2K_0$, and $(2t\,\#s' + \#J + 1)Hh \le (4t+1)K_0Hh \le (4t_D+1)H^{22}h$. After adding $2h_N$ to the left, (CX4) bounds the right by $\mathrm{sel} + 2t\,\mathrm{ram} + r'\mathrm{loc}_\ell + e_\ell$; its additional term Hh_N is nonnegative. Finally $\det(1 - u_x(g))$ is among the determinant combinations in that lemma, by taking the coefficient -1 at g and zero elsewhere. This is exactly the required common Ribet element. □

Lemma 7.6.7. *Let $\mathcal{O}$ be a discrete valuation ring with valuation v and fraction field K, G a group, J a finite linearly ordered set, $R = \mathcal{O}[X_j]_{j\in J}$, $C \in \mathcal{O}$ and $0 \ne p \in \mathcal{O}$.*

1. *(Fitting block.) Let s be a finite set, $\Phi\colon \mathcal{O}^n \to R^s$ $\mathcal{O}$-linear, $z\colon G \to \mathcal{O}^n$, $y(g) = \Phi(z(g))$, $\mathcal{N} \subseteq R^s$ a submodule with $\Phi(p\,\mathcal{O}^n) \subseteq \mathcal{N}$, and $\tau, \tau', \varphi, \varphi'\colon J \to G$, $I \subseteq J$. Suppose that modulo $\mathcal{N}$ the basis vector of R^s at $g \in s$ is $y(g)$, $y(\tau_j) \equiv X_j y(\varphi_j)$ and $y(\tau'_j) \equiv X_j y(\varphi'_j)$ for all j, and every i below a member of I lies in I or has $X_i R^s \subseteq \mathcal{N}$. Let Z be the module of the maps $\Psi \circ z\colon G \to \mathcal{O}/p$ for $\mathcal{O}$-linear $\Psi\colon \mathcal{O}^n \to \mathcal{O}/p$ vanishing on $\Phi^{-1}(\mathcal{N})$, and suppose Z has triangle cost b along I up to C. Then the Fitting ideal of $R^s/\mathcal{N}$ contains $F\prod_{j\in I} X_j$ for some $F \in R$ whose constant coefficient has valuation at most $b + (\#I + \#s)\,v(C)$.*

2. *(Ribet's lemma.) Let $u_x\colon G \to \mathrm{GL}_m(\mathcal{O})$, $x \in Y$ (Y finite), be representations, L an $\mathcal{O}$-algebra, S and $\mathcal{J}$ as in (AL6) with values in $L[X_j]$, and $\mathcal{X} \subseteq Y$, $\pi \in \mathcal{X}$. Assume:*

   (R1) *for $x \in \mathcal{X}$, $u_x = \rho_x \oplus \bigoplus_{e<t} \xi_e$ (a block of rank r and characters $\xi_e\colon G \to \mathcal{O}^\times$, $\xi_0 = 1$, $t \ge 1$), and $\rho_\pi(G)$ spans $M_r(\mathcal{O})$;*

   (R2) *$\rho_x(\gamma_x) = y_x \cdot 1$ with $y_x - 1 \in \mathcal{O}^\times$ and $\xi_e(\gamma_x) = 1$;*

   (R3) *$\mathcal{J}$ is a trace ideal for (u,p) and the relations at τ_k, φ_k, $k = (j,\pm) \in J \times \{\pm\}$, with polynomials ε_j such that $p \mid \varepsilon_j(\xi_e(\varphi_k)) - 1$;*

   (R4) *for some $a \in G$ and every e, $\prod_{k\ne e}(\xi_e(a) - \xi_k(a))$ divides C; $\mathrm{ty}\colon J \to \{0,\dots,t-1\}$ is monotone;*

   (R5) *the module of cocycles $c\colon G \to (K/\mathcal{O})^r$ of ρ_π with*

$$\sum_g \theta_g c(g) = 0 \quad \text{whenever} \quad \sum_g \theta_g (u_x(g) - 1) = 0 \text{ for all } x,$$

   vanishing at all τ_k and at γ_π, has length at most b_0;

   (R6) *finitely many $\delta_w \in G$ are trivial on the characters and $o_w(X)(X-1)$ kills every $u_x(\delta_w)$;*

   (R7) *for each e, every module of character cocycles $G \to \mathcal{O}/p$ for ξ_e (cocycles with the same relation condition, vanishing at the δ_w, and with $(\xi_e(g) - 1)c(a) = 0$ for all g when $c(\gamma_\pi) = 0$) has triangle cost b_e along $\mathrm{ty}^{-1}(e)$ up to C for $\tau'_j = \tau_{(j,-)}$, $\varphi'_j = \varphi_{(j,-)}$, and its members vanishing on a fixed finite set $s \subseteq G$ are 0.*

Then the determinants of all combinations $\sum_g \omega_g(u_x(g)-1)$ lie in S and vanish on $\mathcal{X}$, and they have a common Ribet element at π whose coefficient of $\prod_j X_j$ is the image of some $d \in \mathcal{O}$ with

$$v(d) \le b_0 + \sum_{e<t} b_e + t\Big(\sum_w v(o_w(1)) + 2\,\#s\,v(C)\Big) + (\#J+1)\,v(C).$$

Proof. Item 1. Write $d_s = \#s$ and $I_0 = (X_j : j \in J) \subset R$. If the asserted upper bound is infinite, take $F = 0$. If s is empty, the module presented has rank zero, its Fitting ideal is R, and $F = 1$ suffices. We may therefore assume that s is nonempty and the bound is finite. In particular $C \neq 0$ and $b < \infty$. The basis congruences and $\Phi(p\mathcal{O}^n) \subseteq \mathcal{N}$ imply $pR^s \subseteq \mathcal{N}$: multiply each congruence $\Phi(z(g)) \equiv e_g$ by p.

We use two elementary facts about modules of rows. If $U \subset R^s$, $a \in R^s$, and $da \in U$ for $d \in R$, then

$$d\ \mathrm{Fitt}(R^s/(U+Ra)) \subseteq \mathrm{Fitt}(R^s/U).$$

Indeed expand any determinant with rows in $U + Ra$ by multilinearity. Terms with two rows proportional to a are zero. After multiplication by d, a term with one such row has all its rows in U, as does the term with none. The claim follows for the ideal generated by those determinants.

Here is the corresponding length version. For any R-submodule $U \supseteq \mathcal{N}$ put

$$H_U = \mathcal{O}^n/\Phi^{-1}(U), \qquad \mathcal{Z}(U) = \{\Psi \circ z : \Psi \in \mathrm{Hom}_{\mathcal{O}}(H_U, \mathcal{O}/p)\}.$$

The module H_U has finite length and is killed by p. The functor $D(H) = \mathrm{Hom}_{\mathcal{O}}(H, \mathcal{O}/p)$ is an exact length-preserving duality on the finite-length modules killed by p, as is seen by writing them as sums of $\mathcal{O}/\varpi^a$ with $a \le v(p)$.

Let L_0 be a set supplied by triangle cost and let Z_0 be the submodule of $Z = \mathcal{Z}(\mathcal{N})$ vanishing on L_0. Pull Z_0 back under the surjection $D(H_{\mathcal{N}}) \to Z$, obtaining $B \subseteq D(H_{\mathcal{N}})$. Let $A \subseteq H_{\mathcal{N}}$ be the annihilator of B. By finite-length duality,

$$\mathrm{length}(A) = \mathrm{length}(D(H_{\mathcal{N}})/B) = \mathrm{length}(Z/Z_0) =: \delta.$$

Choose generators of a direct-sum decomposition of A into cyclic modules, and lift them to vectors $a_i \in \mathcal{O}^n$. If the corresponding annihilators are $d_i\mathcal{O}$, then $d_i\Phi(a_i) \in \mathcal{N}$. Set

$$K = \mathcal{N} + \sum_i R\Phi(a_i), \qquad e_0 = \prod_i d_i.$$

The determinant fact just proved, applied successively, gives

$$e_0\,\mathrm{Fitt}(R^s/K) \subseteq \mathrm{Fitt}(R^s/\mathcal{N}), \qquad v(e_0) = \delta.$$

A form factoring through H_K annihilates A and therefore belongs to B by double annihilation. Consequently $\mathcal{Z}(U) \subseteq Z_0$ for every $U \supseteq K$.

Next put $a_j = y(\varphi_j) - y(\varphi'_j)$. Starting with K, adjoin the rows a_j for $j \in I$ in increasing order. We claim that at the stage before adjoining a_j one has $CX_ja_j \in U$, where U is the current module of rows. For $i < j$, the hypothesis on the earlier indices gives $X_ia_i \in U$: if $i \in I$ its row was adjoined already, and otherwise $X_iR^s \subseteq \mathcal{N}$. The tie congruences now give

$$\Phi(z(\tau_i) - z(\tau'_i)) \in U \quad (i < j).$$

Every $\Psi \in D(H_U)$ thus gives a function in Z_0 agreeing at the earlier tame pairs. It also agrees at the earlier Frobenius pairs with indices in I, since their rows a_i lie in U. Condition (TK1) implies

$$\Psi\big(C(z(\tau_j) - z(\tau_j'))\big) = 0.$$

Duality separates points of the finite module H_U, so $\Phi(C(z(\tau_j) - z(\tau_j'))) \in U$. Subtracting C times the difference of the two tie congruences yields $CX_j a_j \in U$, as claimed. The determinant fact therefore gives, at the end of these ordered additions, a module $T \supseteq K$ with all $a_j \in T$ for $j \in I$ and

$$\left(\prod_{j\in I} CX_j\right) \operatorname{Fitt}(R^s/T) \subseteq \operatorname{Fitt}(R^s/K).$$

It remains to find an element of $\operatorname{Fitt}(R^s/T)$ with controlled constant coefficient. Put $T_0 = T + I_0 R^s$. A form defining a member of $\mathcal{Z}(T_0)$ kills every $z(\tau_j)$ and $z(\tau_j')$: their images under Φ are, modulo $\mathcal{N}$, multiples of X_j. It also kills $z(\varphi_j) - z(\varphi_j')$ for $j \in I$, since the corresponding rows were added to T. Moreover $\mathcal{Z}(T_0) \subseteq Z_0$. Hence (TK2), with $S = \mathcal{Z}(T_0)$, gives

$$\delta + \operatorname{length}\big(\mathcal{Z}(T_0)/\mathcal{Z}(T_0)[C]\big) \le b.$$

Specialise all variables to zero and let $M = \mathcal{O}^s/\operatorname{ct}(T)$, where ct is the coordinatewise constant coefficient. This module is killed by p. The map induced by $\operatorname{ct}\circ\Phi$ surjects onto M, since it sends each $z(g)$, $g \in s$, to the corresponding basis class. It induces an isomorphism $H_{T_0} \simeq M$. Evaluation on all the $z(g)$ is injective on $D(M)$, because those basis classes generate M. Thus

$$\mathcal{Z}(T_0) \simeq D(M), \qquad \operatorname{length}\big(\mathcal{Z}(T_0)/\mathcal{Z}(T_0)[C]\big) = \operatorname{length}(CM).$$

Write the elementary divisors of M as $\mathcal{O}/\varpi^{a_i}$, with at most d_s summands. Then

$$\operatorname{length}(M) = \sum_i a_i \le \sum_i \max(a_i - v(C), 0) + d_s v(C) = \operatorname{length}(CM) + d_s v(C).$$

Formation of the Fitting ideal commutes with this specialisation, directly from its determinant generators. Over the discrete valuation ring, $\operatorname{Fitt}_{\mathcal{O}}(M)$ is generated by an element of valuation $\operatorname{length}(M)$. Lift a linear combination of specialised determinant generators giving such a generator. This gives $D_0 \in \operatorname{Fitt}(R^s/T)$ with

$$v(\operatorname{ct}(D_0)) \le \operatorname{length}(CM) + d_s v(C).$$

Now take $F = e_0 C^{\#I} D_0$. The two determinant inclusions show $F \prod_{j\in I} X_j \in \operatorname{Fitt}(R^s/\mathcal{N})$, while

$$\begin{aligned} v(\operatorname{ct}(F)) &\le \delta + \#I\, v(C) + \operatorname{length}(CM) + d_s v(C) \\ &\le b + (\#I + \#s) v(C). \end{aligned}$$

This proves item 1.

Item 2. First, every determinant in the conclusion belongs to S, by Lemma 7.6.9, applied to the family u_x with coefficients in S. On $\mathcal{X}$ it vanishes because the summand $\xi_0 = 1$ kills every $u_x(g) - 1$. If the asserted valuation bound is infinite, the zero multiplier and $d = 0$ give the conclusion. Assume henceforth that the bound is finite. Then $C \neq 0$, every b_e is finite and every $o_w(1)$ is nonzero.

We construct the group-algebra rows to which Lemma 7.6.8 will apply. In the remainder of this proof the letter s denotes the finite test set in (R7). Put $A = R[G]$, and extend the representations and the characters R-linearly to A. Let $\mathfrak{k}$ be the common kernel of all these

extended u_x, and let $I_{\mathrm{aug}} \subset A$ be the augmentation ideal. Choose a finite ordered list of generators consisting of the δ_w, a further finite list indexed by s_0, and the test points indexed by s, such that the families $(u_x(g_i)-1)_x$ span the families $(u_x(g)-1)_x$ over $\mathcal{O}$. Such a list exists because Y is finite and a submodule of the finite free $\mathcal{O}$-module $\prod_x \mathrm{M}_m(\mathcal{O})$ is finitely generated. Write its index set as

$$\mathcal{I} = W \amalg s_0 \amalg s, \qquad u_x(g) - 1 = \sum_{i \in \mathcal{I}} z_i(g)(u_x(g_i) - 1), \quad z_i(g) \in \mathcal{O}.$$

Coordinates may be chosen independently for each g; uniqueness is unnecessary. Set $v_i = g_i - 1$, and let $I = \sum_i A v_i$. The coordinate equation shows $I_{\mathrm{aug}} \subseteq I + \mathfrak{k}$.

Put $\gamma = \gamma_\pi$ and choose $c_1 \in \mathcal{O}$ with $c_1(y_\pi - 1) = 1$. Define

$$n_0 = c_1(\gamma - 1), \qquad \theta = n_0 + (1 - n_0)(a - 1).$$

The character ξ_0 kills θ, while $\rho_\pi(n_0) = 1$. Let $N \subseteq A^{\mathcal{I}}$ be the module of rows r for which $\sum_i r_i v_i$ lies in

$$\mathfrak{k} + pI_{\mathrm{aug}} + \sum_{j,\pm} A\big(\tau_{(j,\pm)} - 1 - X_j \varepsilon_j(\varphi_{(j,\pm)})(\varphi_{(j,\pm)} - 1)\big) + I_{\mathrm{aug}}\theta.$$

All kernels and ideals in this display are taken inside A; the last three terms are left submodules. Let $\mathfrak{a}$ be the two-sided trace ideal after extending coefficients from R to S, as in Lemma 7.6.8. The trace hypotheses (R3) put the first three displayed terms in $\mathfrak{a}$. For pI_{aug} use the differences $p\,\mathrm{tr}(u_x(gh)) - p\,\mathrm{tr}(u_x(h))$; for a tie use its prescribed trace against every group element, then S-linearity and cyclicity of trace. Since $I_{\mathrm{aug}} \subseteq I + \mathfrak{k}$, every row of N has

$$\sum_i r_i v_i \in \mathfrak{a} + I\theta.$$

Thus every square matrix whose rows are in N satisfies the row hypothesis of that lemma.

Here are the row identities needed to construct those matrices. Regard $z(g)$ as a row with central coefficients. The coordinate equation gives rows in N of the following forms:

$$z(gh) - z(g) - gz(h), \qquad z(g_i) - e_i, \qquad \sum_g \omega_g z(g) \quad \text{if } \sum_g \omega_g(u_x(g) - 1) = 0 \text{ for every } x.$$

Indeed their row values $\sum_i r_i v_i$ are killed by every u_x. Also $pA^{\mathcal{I}} \subseteq N$. For each auxiliary tie there is the row

$$z(\tau_{(j,\pm)}) - X_j \varepsilon_j(\varphi_{(j,\pm)}) z(\varphi_{(j,\pm)}) \in N.$$

Finally set $r_0 = c_1 z(\gamma) + (1 - n_0) z(a)$. Its row value is θ modulo $\mathfrak{k}$, so $(g-1)r_0 \in N$ for every g.

We next construct one matrix B_0 of rows in N with

$$D_x = \det\big(\rho_x((B_0)_{ij})\big)_{i,j} \in R, \qquad v(\mathrm{ct}(D_\pi)) \le b_0.$$

Read rows at $X = 0$ through ρ_π. Their image is a left $\mathrm{M}_r(\mathcal{O})$-submodule of the rows of $r \times r$ blocks, because $\rho_\pi(G)$ spans that matrix ring. For $r > 0$, multiplication by the elementary matrices shows that this image consists exactly of the $r \times (r\#\mathcal{I})$ matrices all of whose scalar rows lie in one lattice $M \subseteq \mathcal{O}^{r\#\mathcal{I}}$. It contains $p\mathcal{O}^{r\#\mathcal{I}}$.

A vector $(w_i)_i \in ((K/\mathcal{O})^r)^{\mathcal{I}}$ annihilating these rows gives $c(g) = \sum_i z_i(g) w_i$. The first and third row identities make c a cocycle satisfying the relation condition in (R5); the second gives $c(g_i) = w_i$. The tie rows at $X = 0$ give $c(\tau_{(j,\pm)}) = 0$. The row $(\gamma - 1)r_0$, read through ρ_π, is

precisely $z(\gamma)$: its entries are $(y_\pi - 1)c_1 z_i(\gamma)$, because $\rho_\pi(n_0) = 1$. Thus $c(\gamma) = 0$. The map from the annihilator to the module in (R5) is injective, since $c(g_i) = w_i$. Duality with $K/\mathcal{O}$ therefore gives

$$\operatorname{length}(\mathcal{O}^{r\#\mathcal{I}}/M) \le b_0.$$

Choose a basis of M, group its rows into blocks of r rows, and lift each block to a row in N. This gives B_0 with the asserted determinant bound by elementary divisors. If $r = 0$, take $B_0 = 0$; its represented determinant is the empty determinant 1 and the same bound holds.

We now construct matrices controlling all characters simultaneously. Under a character ξ_e, forget the W-coordinates of rows. If an R-linear map of these remaining coordinates sends the image of N into a module U, every function $\Psi \circ z$ obtained from a form modulo p annihilating its inverse image is a character cocycle of the kind in (R7). To check this, apply the first three row identities to get respectively the cocycle law, the values at generators, and the relation condition. The δ_w-generator row gives value zero at δ_w after its coordinate is forgotten. Since $\xi_e(\gamma) = 1$, the normaliser row gives

$$(\xi_e(g) - 1)\big(c_1 c(\gamma) + c(a)\big) = 0.$$

If $c(\gamma) = 0$ this is exactly the last condition of (R7). These verifications also hold after enlarging the image module U.

For each fixed e, project these character rows to the s_0-coordinates alone. Every corresponding dual function vanishes at the test points s, by $z(g_i) - e_i \in N$, and hence is zero by (R7). The finite $\mathcal{O}/p$ duality used in item 1 now shows that every unit vector on s_0 is in this projected row module: it is the image of $z(g_i)$ for the corresponding generator, and all dual forms kill it. Choose rows in N whose s_0-part under ξ_e is the identity matrix, and call their s_0-entry matrix E_e before evaluating the character. If s_0 is empty, there are no such rows and all subsequent elimination statements use the empty identity matrix.

These choices can be made simultaneous without a division. Expand

$$\mathbf{1} - \prod_{e<t} (\mathbf{1} - E_e)$$

by telescoping, using any fixed order of e. Each term is a left matrix multiple of one E_e, so its rows lift to rows of N. At ξ_h the product contains the zero matrix $\mathbf{1} - \xi_h(E_h)$; hence the displayed matrix evaluates to the identity at every ξ_h. We have therefore obtained rows $U_i \in N$, $i \in s_0$, whose s_0-part is the identity under every character.

For each e, use the rows U_i to eliminate the s_0-coordinates from the character image of N, and let $K_e \subseteq R^s$ be the remaining image. Explicitly, a row with character coordinates $(b_i)_{i\in s_0}$ and $(c_j)_{j\in s}$ maps to

$$(c_j - \sum_{i\in s_0} b_i\, \xi_e((U_i)_j))_{j\in s}.$$

Put

$$M_e = \prod_{\mathrm{ty}(j)=e} X_j, \qquad M_{<e} = \prod_{\mathrm{ty}(j)<e} X_j, \qquad \mathfrak{q} = (X_j^2 : j \in J), \qquad \mathfrak{q}_e = (\mathfrak{q} : M_{<e}).$$

Apply item 1 to $K_e + \mathfrak{q}_e R^s$. Its map Φ is obtained from the constant coordinate row $z(g)$ by the character evaluation and elimination just described. The s-generator congruences give its basis vectors; p times its image lies in K_e. The tie congruences hold with factor 1: under ξ_e, $\varepsilon_j(\varphi_{(j,\pm)}) = 1 + pc$ by (R3), and adding the row $pX_j c\, z(\varphi_{(j,\pm)}) \in N$ removes the extra term. Its module of forms has the character-cocycle properties checked above, so has the required triangle

cost b_e by (R7). Finally, if $i < j$ and $\mathrm{ty}(j) = e$, monotonicity gives either $\mathrm{ty}(i) = e$ or $\mathrm{ty}(i) < e$. In the latter case $X_i \in \mathfrak{q}_e$, because $X_i M_{<e}$ is divisible by X_i^2. These check every hypothesis of item 1.

We obtain polynomials G_e with

$$v(\mathrm{ct}(G_e)) \le b_e + (\#\{j : \mathrm{ty}(j) = e\} + \#s)v(C), \qquad G_e M_e \in \mathrm{Fitt}(R^s/(K_e + \mathfrak{q}_e R^s)).$$

Expanding determinant generators of the enlarged module gives

$$d_e + \eta_e = G_e M_e, \qquad d_e \in \mathrm{Fitt}(R^s/K_e), \quad \eta_e \in \mathfrak{q}_e.$$

Indeed every determinant term using a row from $\mathfrak{q}_e R^s$ lies in $\mathfrak{q}_e$. Express d_e as a finite sum

$$d_e = \sum_i w_{e,i} \det B_{e,i}, \qquad w_{e,i} \in R,$$

where the rows of $B_{e,i}$ lie in K_e. Lift these rows to rows $B'_{e,i,j} \in N$ whose s_0-part under ξ_e is zero and whose s-part is $B_{e,i,j}$. Such lifts follow from the definition of K_e by subtracting the corresponding multiples of the rows U_i.

Condition (R4) gives elements $q_e \in \mathcal{O}[G]$ with

$$\xi_h(q_e) = \begin{cases} C & h = e, \\ 0 & h \ne e. \end{cases}$$

Namely multiply $\prod_{h \ne e}(a - \xi_h(a))$ by $C/\prod_{h \ne e}(\xi_e(a) - \xi_h(a)) \in \mathcal{O}$. For each choice of one i_e for every e, form a square matrix $M_{\mathbf{i}}$ of rows in N as follows. Its W-rows have the single entry $o_w(\delta_w)$ in coordinate w; they lie in N by (R6). Its s_0-rows are U_i. Its s-rows are $\sum_e q_e B'_{e,i_e,j}$. Under ξ_h this is block upper triangular, with diagonal blocks $(o_w(1))_w$, the identity on s_0, and CB_{h,i_h} on s. Consequently, with

$$c_0 = \left(\prod_w o_w(1)\right) C^{\#s},$$

one has

$$\det \xi_e(M_{\mathbf{i}}) = c_0 \det B_{e,i_e}, \qquad \sum_{\mathbf{i}} \left(\prod_e w_{e,i_e}\right) \prod_e \det \xi_e(M_{\mathbf{i}}) = c_0^t \prod_e d_e.$$

If one determinant sum is empty, the same formulas hold with the empty index set.

It remains to combine these character matrices with B_0. There is an element $k_0 \in \mathcal{O}[G]$ which is 1 on every character and zero on every block ρ_x, $x \in \mathcal{X}$. Take an ordered product, over $x \in \mathcal{X}$, of $(y_x - \gamma_x)/(y_x - 1)$: every character reads each factor as 1, and at any block the corresponding factor is zero. For each $\mathbf{i}$ put

$$\widetilde{B}_{\mathbf{i}} = (1 - k_0)B_0 + k_0 M_{\mathbf{i}}.$$

Its rows lie in N, it reads as B_0 on each block and as $M_{\mathbf{i}}$ on each character. Apply Lemma 7.6.8 after extending scalars to S, with this matrix and with the testing element $k_0 q_0$. This element is zero on the blocks and on all characters except ξ_0, where its value is C; moreover its product with θ is zero on every u_x, $x \in \mathcal{X}$, since $\xi_0(\theta) = 0$. The resulting trace multiplier $f_{\mathbf{i}} \in S$ therefore has

$$f_{\mathbf{i}}(x) = CD_x \prod_{e<t} \det \xi_e(M_{\mathbf{i}}) \quad (x \in \mathcal{X}),$$

and multiplies the determinant of every represented element of I into $\mathcal{J}$. The same holds for every combination of the $g-1$, since it agrees in all the representations with an element of I. Taking the weighted sum gives $f \in S$ with the common multiplier property and

$$f(x) = Cc_0^t D_x \prod_{e<t} d_e \quad (x \in \mathcal{X}).$$

To read its required coefficients, telescope the product using $d_e + \eta_e = G_e M_e$ in increasing order of e. Every error contains $\eta_e M_{<e}$ and hence lies in $\mathfrak{q}$. Thus

$$\prod_e d_e \equiv \left(\prod_e G_e\right) \prod_{j\in J} X_j \pmod{\mathfrak{q}}.$$

No monomial dividing $\prod_j X_j$ belongs to $\mathfrak{q}$. This congruence proves both the vanishing of all properly dividing monomials of $f(x)$ and the assertion that its full squarefree coefficient at π is the image of

$$d = Cc_0^t \operatorname{ct}(D_\pi) \prod_e \operatorname{ct}(G_e) \in \mathcal{O}.$$

Finally,

$$\begin{aligned} v(d) &\le v(C) + t\left(\sum_w v(o_w(1)) + \#s\, v(C)\right) + b_0 + \sum_e \Big(b_e + (\#\mathrm{ty}^{-1}(e) + \#s)v(C)\Big) \\ &= b_0 + \sum_e b_e + t\left(\sum_w v(o_w(1)) + 2\#s\, v(C)\right) + (\#J+1)v(C). \end{aligned}$$

This proves item 2 and the lemma. □

Lemma 7.6.8. *Let L be a commutative ring, Y a set, $n \ge 1$, G a group, and $u_y : \mathrm{G} \to \mathrm{GL}_n(L)$ representations for $y \in Y$. Let $S \subseteq L^Y$ be a subring containing the functions given by every coefficient of the characteristic polynomial of $u_y(g)$, for every $g \in \mathrm{G}$. Put $A = S[\mathrm{G}]$ and let*

$$\rho : A \longrightarrow \mathrm{M}_n(L^Y)$$

be the induced S-algebra homomorphism. Let $\mathfrak{J} \subseteq L^Y$ be an S-submodule and put

$$\mathfrak{a} = \{a \in A : \operatorname{tr}(\rho(ab)) \in \mathfrak{J} \text{ for every } b \in A\}.$$

Let $v_1, \dots, v_k \in A$, let $I = \sum_i Av_i$ be their left ideal, and let $\theta \in A$. Suppose $B \in \mathrm{M}_k(A)$ satisfies

$$\sum_j B_{ij} v_j \in \mathfrak{a} + I\theta \qquad (1 \le i \le k).$$

Then there is $P(T) \in S[T]$ such that

$$P(0) = \det\big(\rho(B_{ij})\big)_{i,j}, \qquad IP(\theta) \subseteq \mathfrak{a},$$

where the first determinant is taken after flattening the $n \times n$ blocks and is viewed in L^Y. Moreover, for every $w \in I$ and $a \in A$,

$$D_w := \det \rho(w) \in S, \qquad f_a := \operatorname{tr}(\rho(aP(\theta))) \in S, \qquad D_w f_a \in \mathfrak{J}.$$

Proof. The module $\mathfrak{a}$ is a two-sided ideal of A. Right multiplication preserves its defining condition, and for left multiplication use $\operatorname{tr}(\rho(cab)) = \operatorname{tr}(\rho(abc))$. It contains $\ker \rho$.

We first record the coefficient-ring consequence of the determinant lemma. Every entry of $\rho(a)$ is a finite S-combination of the matrices $u_y(g)$. Thus Lemma 7.6.9 applies to every square block matrix with entries from $\rho(A)$ and puts its determinant in S. It applies also with extra commuting polynomial variables: embed $S[T_1, \dots, T_d]$ coefficientwise in $(L[T_1, \dots, T_d])^Y$, and use the same representations, regarded as constant matrices. In particular all characteristic coefficients of such block matrices lie in the corresponding polynomial ring over S, by applying the determinant assertion to $Z\mathbf{1} - M$ and reading its coefficients in Z. All hypotheses of that lemma hold here: L is commutative, the representations are multiplicative, and their characteristic coefficients are in S by assumption.

If $k = 0$, then $I = 0$, and $P = 1$ has all the required properties, including $D_0 = 0$ since $n \geq 1$. Hence assume $k \geq 1$. Choose $a_i \in \mathfrak{a}$ and coefficients $C_{ij} \in A$ such that

$$\sum_j B_{ij} v_j = a_i + \sum_j C_{ij} v_j \theta.$$

Put $\mathcal{B}(T) = B - TC \in \mathrm{M}_k(A[T])$ and flatten its image under ρ to a matrix $\widetilde{\mathcal{B}}(T)$ of size kn over $(L^Y)[T]$. The preceding coefficient statement shows

$$P(T) := \det \widetilde{\mathcal{B}}(T) \in S[T].$$

The adjugate identity, expressed using the Cayley–Hamilton polynomial, gives a matrix $Q(T) \in \mathrm{M}_k(A[T])$ for which

$$\rho\big(Q(T)\mathcal{B}(T)\big) = P(T)\mathbf{1}.$$

Indeed the adjugate of the $kn \times kn$ represented matrix is a polynomial of degree at most $kn - 1$ in that matrix, with coefficients among its characteristic coefficients. Those coefficients lie in $S[T]$. Apply exactly that polynomial to $\mathcal{B}(T)$ before representing and flattening. This proves the displayed identity without requiring surjectivity of ρ. Evaluation at $T = 0$ gives the stated formula for $P(0)$.

To use this identity without commuting θ with the coefficients, act on $A/\mathfrak{a}$ by left multiplication of A and let T act by right multiplication by θ. These actions commute. Our row relation says $\mathcal{B}(T)\bar{v} = 0$ for the column $\bar{v} = (v_i \bmod \mathfrak{a})_i$. Every coefficient of $Q(T)\mathcal{B}(T) - P(T)\mathbf{1}$ lies in $\ker \rho \subseteq \mathfrak{a}$, so its action on this quotient is zero. It follows that

$$P(T)\bar{v} = 0, \qquad v_i P(\theta) \in \mathfrak{a} \quad (1 \leq i \leq k).$$

Since $\mathfrak{a}$ is a left ideal, $IP(\theta) \subseteq \mathfrak{a}$.

Finally the coefficient statement shows $D_w \in S$ and $f_a \in S$, the latter because the trace is minus the next-to-leading characteristic coefficient. Cayley–Hamilton for $\rho(w)$ gives an element $w' \in A$, polynomial in w with coefficients in S, such that

$$\rho(w'w) = D_w \mathbf{1}.$$

As $w \in I$, the element $w'w$ belongs to I, and therefore $a(w'w)P(\theta) \in \mathfrak{a}$. Its trace belongs to $\mathfrak{J}$ by the definition of $\mathfrak{a}$, taking the testing element to be 1. Its represented matrix is $D_w \rho(aP(\theta))$, whose trace is $D_w f_a$. This proves the final assertion. □

Lemma 7.6.9. *For a square matrix Z over a commutative ring and an integer $j \geq 0$, let $\sigma_j(Z)$ be the sum of the principal $j \times j$ minors of Z, so that $\sigma_0(Z) = 1$. A $g \times g$ matrix $\mathbf{X} = (\mathbf{X}_{pq})$*

whose entries are $n \times n$ matrices is identified with the $gn \times gn$ matrix having $\mathbf{X}_{pq}$ as its block in position (p,q), and $\det \mathbf{X}$ is the determinant of the latter.

Let F be a commutative ring, Y a set, $n \geq 1$, G a monoid, and for every $y \in Y$ let $\varrho_y \colon G \to \mathrm{M}_n(F)$ be a homomorphism of monoids. Let A be a subring of the ring F^Y of functions $Y \to F$ (pointwise operations) such that the functions $y \mapsto \sigma_j(\varrho_y(h))$ lie in A for every $h \in G$ and $1 \leq j \leq n$. Call a function $f \colon Y \to \mathrm{M}_n(F)$ an A-combination *if $f(y) = \sum_{h \in H} a_h(y)\, \varrho_y(h)$ for a finite $H \subseteq G$ and $a_h \in A$. Then for every $g \geq 1$ and every $g \times g$ matrix $\mathbf{X} = (\mathbf{X}_{pq})$ of A-combinations, the function $y \mapsto \det \mathbf{X}(y)$ lies in A, where $\mathbf{X}(y) = (\mathbf{X}_{pq}(y))_{p,q}$.*

Proof. **Step 1: words.** Choose a finite $H \subseteq G$ and $a_{pqh} \in A$ with $\mathbf{X}_{pq}(y) = \sum_{h \in H} a_{pqh}(y) \varrho_y(h)$ for all p, q (take the union of the finite sets of the entries and coefficients 0 elsewhere). For $Z \in \mathrm{M}_n(F)$ let $e_{pq} \otimes Z \in \mathrm{M}_{gn}(F)$ be the matrix with Z in the block (p,q) and 0 elsewhere; $(e_{pq} \otimes Z)(e_{p'q'} \otimes Z')$ is $e_{pq'} \otimes ZZ'$ if $q = p'$ and 0 otherwise. Enumerate the triples $i = (p,q,h)$ $(1 \leq p, q \leq g,\ h \in H)$ as $1, \ldots, k$, and for $y \in Y$ put $A_i(y) = a_{pqh}(y)\, e_{pq} \otimes \varrho_y(h)$, so that $\mathbf{X}(y) = \sum_i A_i(y)$, of size $N = gn$. For a word $w = i_1 \cdots i_m$, $i_\nu = (p_\nu, q_\nu, h_\nu)$, put $a_w = \prod_\nu a_{p_\nu q_\nu h_\nu} \in A$ and $h_w = h_1 \cdots h_m \in G$. As ϱ_y is multiplicative, $A_w(y) = A_{i_1}(y) \cdots A_{i_m}(y)$ equals $a_w(y)\, e_{p_1 q_m} \otimes \varrho_y(h_w)$ if $q_\nu = p_{\nu+1}$ for all $\nu < m$, and 0 otherwise. For $j \geq 1$, $\sigma_j(e_{pq} \otimes Z) = 0$ if $p \neq q$ (a principal minor of positive size of this matrix has a zero row or column) and $\sigma_j(e_{pp} \otimes Z) = \sigma_j(Z)$ (the principal minors that do not lie in the block (p,p) vanish). With $\sigma_j(bZ) = b^j \sigma_j(Z)$ for $b \in F$, for every word w and $j \geq 1$

$$\sigma_j\big(A_w(y)\big) = \epsilon_w\, a_w(y)^j\, \sigma_j\big(\varrho_y(h_w)\big), \qquad \epsilon_w \in \{0, 1\},$$

where $\epsilon_w = 1$ exactly when $q_\nu = p_{\nu+1}$ for all $\nu < m$ and $p_1 = q_m$; ϵ_w, a_w, h_w do not depend on y.

Step 2: Amitsur's formula. Fix y. By Theorem A.6.6 over $C = F$ with the matrices $A_i(y)$,

$$\det\Big(1 - \sum_i t_i A_i(y)\Big) = \prod_{w \text{ Lyndon}} \det(1 - t_w A_w(y)) = \prod_w \sum_{j=0}^{N} (-1)^j \sigma_j\big(A_w(y)\big)\, t_w^j$$

in $F[[t_1, \ldots, t_k]]$ (for an $N \times N$ matrix Z, $\det(1 - XZ) = \sum_j (-1)^j \sigma_j(Z) X^j$). The left side is $\sum_{j=0}^{N} (-1)^j \sigma_j(\sum_i t_i A_i(y))$, and $\sigma_j(\sum_i t_i A_i(y))$ is homogeneous of degree j in t; so its homogeneous part of degree N is $(-1)^N \det(\sum_i t_i A_i(y))$. On the right, t_w has degree the length $|w|$ of w, so only the finitely many Lyndon words of length at most N contribute in degree N, and the homogeneous part of degree N is the finite sum, over the families (j_w) of non-negative integers indexed by these words with $\sum_w j_w |w| = N$, of $\prod_w (-1)^{j_w} \sigma_{j_w}(A_w(y))\, t_w^{j_w}$. Equating the two homogeneous polynomials of degree N and evaluating at $t_1 = \cdots = t_k = 1$, with Step 1,

$$\det \mathbf{X}(y) = (-1)^N \sum_{(j_w)} \prod_w (-1)^{j_w} \big(\epsilon_w a_w(y)^{j_w}\big)^{[j_w \geq 1]}\, \sigma_{j_w}\big(\varrho_y(h_w)\big),$$

where the index set, the signs, ϵ_w, a_w and h_w do not depend on y, and $\sigma_0 = 1$.

Step 3: conclusion. Each a_w is in A, each function $y \mapsto \sigma_j(\varrho_y(h_w))$ with $j \geq 1$ is in A by hypothesis, and the constants $0, \pm 1$ are in A; A is closed under sums and products. So the right side of the last display, as a function of y, lies in A. □

Proposition 7.6.10. *Let ℓ be a prime, E a CM field containing μ_{5040}, $\mathcal{O}$ a coefficient ring and $\nu \geq 0$.*

1. *Let $e \neq 0$, let S be a set of finite places of E, and let $z \in \mathrm{Sel}_{\Sigma_\ell \cup S \cup \bar{S}}(e,\nu)$ vanish on Λ_e. Then $z + z \circ (g \mapsto g^c) \in \mathrm{Ev}_S(e,\nu)$.*

2. *Let $(w_j, \tau_j, \varphi_j)_{j \in J}$ with exponent* ty *form a prime triangle for g_0 with bounds (h, C), and let $0 < e < t$. Let S be a submodule of $\mathrm{Sel}_{\Sigma_\ell}(e,\nu)$ whose members z vanish on Λ_e, satisfy $(\mathrm{cyc}(g_0)^{-e} - 1)z(g_0) = 0$, and satisfy $(z + z \circ (g \mapsto g^c))(\varphi_j) = 0$ for all j with $\mathrm{ty}(j) = e$. Then*
$$\mathrm{len}(S \bmod S[\ell^h]) \leq \mathrm{len}_{\mathcal{O}} \mathrm{Sha}^-(e,\nu).$$

3. *With the triangle of item 2, let $0 \leq e < t$, $W = \{w_j\}$, and let $Z \subseteq \mathrm{Sel}_{\Sigma_\ell \cup W \cup \bar{W}}(e,\nu)$ be a submodule such that $(\mathrm{cyc}(g_0)^{-e} - 1)z(g_0) = 0$ for every $z \in Z \cap \mathrm{Sel}_{\Sigma_\ell}(e,\nu)$. Let Z_f be the module of maps $z\colon G_E \to \mathcal{O}/\ell^\nu$ such that, for every $v \mid \ell$, the restriction $z|_{G_{A_v}}$ satisfies the crystalline condition of the local lattice $L_v = \mathcal{O}(-e)|_{G_{A_v}}$, with action $g \mapsto \mathrm{cyc}(g)^{-e}$, with coefficients in $\mathcal{O}/\ell^\nu$, for $\Gamma = G_{A_v}$ via the fixed chart $j_v\colon G_{A_v} \to G_\ell$ of Definition 7.2.2, and let $b \in \mathbb{Z}_{\geq 0} \cup \{\infty\}$ with*
$$\mathrm{len}(Z \bmod Z_f) + \mathrm{len}_{\mathcal{O}} \mathrm{Sha}^-(e,\nu) \leq b.$$
Then Z has triangle cost b along $I = \{j : \mathrm{ty}(j) = e\}$ up to ℓ^h, for $\tau'_j = (\tau_j^c)^{-1}$ and $\varphi'_j = (\varphi_j^c)^{-1}$.

Proof. Preliminaries. As E is CM, c normalises G_E, and $g \mapsto g^c$ is a continuous involutive automorphism of G_E with $\mathrm{cyc}(g^c) = \mathrm{cyc}(g)$. Conjugation by c maps the inertia (decomposition) group of a place A of $\bar{\mathbb{Q}}$ onto that of cA, which lies above the complex conjugate place; so it preserves Λ_e, and it maps inertia above places outside a conjugation-stable set Σ to inertia above places outside Σ. Hence for $z \in \mathrm{Sel}_\Sigma(e,\nu)$ with Σ conjugation-stable, $z^c \in \mathrm{Sel}_\Sigma(e,\nu)$: it is locally constant, it vanishes on the required inertia groups, and
$$z^c(gh) = z(g^c) + \mathrm{cyc}(g^c)^{-e} z(h^c) = z^c(g) + \mathrm{cyc}(g)^{-e} z^c(h).$$
If z vanishes on Λ_e, so does z^c.

Item 1. $\Sigma_\ell \cup S \cup \bar{S}$ is conjugation-stable, so $w = z + z^c \in \mathrm{Sel}_{\Sigma_\ell \cup S \cup \bar{S}}(e,\nu)$; $w(g^c) = z^c(g) + z(g) = w(g)$ since $(g^c)^c = g$; and w vanishes on $\Lambda_1 = \Lambda_e$ ($e \neq 0$). So $w \in \mathrm{Ev}_S(e,\nu)$.

Item 2. Let $\theta\colon S \to \mathrm{Sel}_{\Sigma_\ell}(e,\nu)$, $\theta(z) = z^c - z$. By the preliminaries $\theta(z)$ lies in $\mathrm{Sel}_{\Sigma_\ell}(e,\nu)$ and vanishes on Λ_e, and $\theta(z)(g^c) = z(g) - z^c(g) = -\theta(z)(g)$; so $\theta(S) \subseteq \mathrm{Sha}^-(e,\nu)$. Let $z \in \ker\theta$, so $z^c = z$. By item 1 with $S = \emptyset$, $2z = z + z^c \in \mathrm{Ev}_\emptyset(e,\nu)$. Let $g \in s$, the test points of (PT2); there is j with $\mathrm{ty}(j) = e$ and $(2z)(\varphi_j) = 2 \cdot (2z)(g)$; by hypothesis $(2z)(\varphi_j) = (z + z^c)(\varphi_j) = 0$, so $4z(g) = 0$. Put $d = \mathrm{cyc}(g_0)^{-e} - 1$. Then $4d\,z \in \mathrm{Sel}_{\Sigma_\ell}(e,\nu)$ vanishes on s and at g_0 (as $d\,z(g_0) = 0$), so $4d\,z = 0$ by the detection clause of (PT2). By (PT5), $4(\mathrm{cyc}(g_0)^e - 1)^2$ divides ℓ^h; as $d = -\mathrm{cyc}(g_0)^{-e}(\mathrm{cyc}(g_0)^e - 1)$ with $\mathrm{cyc}(g_0)^{-e}$ a unit, $\ell^h = 4d^2\alpha$ for some $\alpha \in \mathcal{O}$, and $\ell^h z = \alpha d\,(4d\,z) = 0$. Hence $\ker\theta \subseteq S \cap S[\ell^h]$, and
$$\mathrm{len}(S \bmod S[\ell^h]) \leq \mathrm{len}_{\mathcal{O}}(S/\ker\theta) = \mathrm{len}_{\mathcal{O}}\theta(S) \leq \mathrm{len}_{\mathcal{O}}\mathrm{Sha}^-(e,\nu).$$

Item 3. We first establish the local vanishing used below. Put $K = E_v$ for a place $v \mid \ell$, $L = \mathcal{O}(-e)$ and $V = L \otimes_{\mathbb{Z}_\ell} \mathbb{Q}_\ell$. A crystalline integral cocycle of L determines a class in the usual $H^1_f(G_K, V)$. The rational representation V is finite dimensional and continuous: it is a direct sum over $\mathbb{Q}_\ell$ of cyclotomic Tate twists, since the coefficient action is trivial. Thus Lemma 7.4.6(2), with $K_\ell = K$ and $W = V$, identifies the $B_{\max}$-coboundary condition with the usual B_{cris}-condition. Its statement covers every coefficient prime, including $\ell = 2$, and uses the

same Frobenius, fixing $\mathbb{Q}_\ell$ and satisfying $\varphi(t) = \ell t$; hence no Tate-twist scalar is introduced in the witness comparison. Continuity of an integral cocycle follows from its period witness and the natural continuous Galois action on the period ring.

Suppose first that $e > 0$. As a $\mathbb{Q}_\ell$-representation, V is a direct sum of copies of $\mathbb{Q}_\ell(-e)$. Its filtered de Rham module has $\mathrm{Fil}^0 D_{\mathrm{dR}}(V) = D_{\mathrm{dR}}(V)$, and $H^0(G_K, V) = 0$, since the cyclotomic image of G_K is open and its eth power is nontrivial. The dimension formula of Bloch–Kato, [28, Corollary 3.8.4], gives $H^1_f(G_K, V) = 0$. Consequently every integral crystalline cocycle c has the form $c(g) = (\mathrm{cyc}(g)^{-e} - 1)x$ for an $x \in V$. It vanishes whenever $\mathrm{cyc}(g) = 1$. If $e = 0$, the action is trivial, so cocycles are homomorphisms and coboundaries are zero. By [28, Example 3.9, the case $r = 0$], the finite local classes of the trivial representation are unramified. Thus every integral crystalline cocycle vanishes on inertia. These arguments apply after restriction of scalars from $\mathcal{O}$ and at every finite extension $K/\mathbb{Q}_\ell$, including $\ell = 2$.

The crystalline condition on a map modulo ℓ^ν is expressed by the linear evaluation relations of the integral module $Z_f(L)$. Explicitly, if finitely many $a_i \in \mathcal{O}$ and $s_i \in G_K$ satisfy $\sum_i a_i c(s_i) = 0$ for every $c \in Z_f(L)$, the map is required to satisfy the same relation modulo ℓ^ν. In particular, the one-term relation at any element of the local set just considered holds for every such map. If charts at one chosen extension of each v to $\bar{\mathbb{Q}}$ are used, this also gives vanishing on the other charts. Conjugate an element g of such a chart to sgs^{-1} in the chosen chart. In both cases in question $\mathrm{cyc}(g)^{-e} = 1$, and the cocycle identity gives

$$z(sgs^{-1}) = \mathrm{cyc}(s)^{-e} z(g).$$

The scalar is a unit, so vanishing transports back to g. We have therefore proved

$$z \in Z \cap Z_f \quad \Longrightarrow \quad z|_{\Lambda_e} = 0.$$

Take $L_0 = \Lambda_e$ as the set in the definition of triangle cost, and put $Z_0 = \{z \in Z : z|_{\Lambda_e} = 0\}$. The inclusion $Z \cap Z_f \subseteq Z_0$ yields the surjection $Z/(Z \cap Z_f) \twoheadrightarrow Z/Z_0$ and hence

$$\mathrm{len}_{\mathcal{O}}(Z/Z_0) \le \mathrm{len}(Z \bmod Z_f).$$

At each τ_j the cyclotomic character is 1, and at each φ_j it is 1 modulo ℓ^ν, by (PT1). The cocycle identity at an inverse therefore gives, for every $z \in Z$,

$$z(\tau_j') = -z(\tau_j^c), \qquad z(\varphi_j') = -z(\varphi_j^c).$$

Thus agreement at either of these pairs is exactly the vanishing of $z + z^c$ at the corresponding unprimed element.

For (TK1), take $j \in I$ and $z \in Z_0$ with the required earlier agreements. Then $\mathrm{ty}(j) = e > 0$, since every triangle exponent is positive. Item 1 shows that $z + z^c$ is in $\mathrm{Ev}_W(e, \nu)$. The earlier agreements give all the vanishing hypotheses in (PT4), which implies

$$\ell^h(z + z^c)(\tau_j) = 0 \quad \Longleftrightarrow \quad \ell^h z(\tau_j) = \ell^h z(\tau_j').$$

If $e = 0$, I is empty and (TK1) has no instances.

For (TK2), let $S \subseteq Z_0$ be a submodule as in that condition. Each $z \in S$ vanishes on every τ_j and τ_j', so it is unramified at all the w_j and their conjugates. To check this last assertion, the cyclotomic action on inertia away from ℓ is trivial; the restriction of z is therefore a continuous homomorphism to an ℓ-primary group. Wild inertia, being pro-residue-characteristic, maps to zero, and on tame inertia only the pro-ℓ factor can have nonzero image. Its chosen generator has

value zero by hypothesis. The same argument at conjugate places proves the assertion there. All other inertia groups away from ℓ were already killed by membership in Z. Hence $S \subseteq \mathrm{Sel}_{\Sigma_\ell}(e,\nu)$.

If $e = 0$, each member of S also vanishes on Λ_0, so $S \subseteq \mathrm{Sha}^-(0,\nu)$ by (OE1), without a sign condition. Therefore $\mathrm{len}(S \bmod S[\ell^h]) \le \mathrm{len}_{\mathcal{O}}\mathrm{Sha}^-(0,\nu)$. If $e > 0$, the agreement at φ_j, φ_j' for $j \in I$ says exactly $(z + z^c)(\varphi_j) = 0$. The hypothesis concerning g_0 holds on S, since its members are unramified outside ℓ. The local vanishing holds since $S \subseteq Z_0$. Item 2 consequently gives $\mathrm{len}(S \bmod S[\ell^h]) \le \mathrm{len}_{\mathcal{O}}\mathrm{Sha}^-(e,\nu)$. Adding this inequality to the bound for Z/Z_0 proves (TK2) in both cases, and completes the proof. □

Proposition 7.6.11. *Assume $[E^+ : \mathbb{Q}] \ge 2$. Let B be base data of rank n, $Q = (w_j, \varphi_j, \tau_j)_{j\in J}$ Taylor–Wiles places of level ℓ^ν off the base level, $a : G_E \to \overline{\mathbb{Z}}_\ell^\times$ a character with $a(\tau_j) = 1$, $N_x = a \otimes r_x$, $H_j \in \overline{\mathbb{Z}}_\ell[X]$ and $t \ge 1$. In this statement a root chain at w_j for (a, t, H_j) means the identity*

$$P_{x,w_j}(a(\varphi_j)^{-1}X) = \prod_{i<t}(X - q_{w_j}^i)S(X), \qquad S \mid H_j$$

over $\mathbb{C}$, with coefficients transported through ι^{-1}. Write $\mathrm{Nm} = \sum_{g\in\prod_j \mathrm{GL}_n(k_{w_j})} g$, and $\equiv$ for equality after any ring map on the integral operator ring that kills each T for which $2n!\,T$ is divisible by ℓ^ν.

1. *Let $\delta = c_B^2\delta'$ with $\delta' \in \mathbb{T}_Q$. Suppose every system of base level with $\delta'(x) \ne 0$ has a root chain at every w_j. Then there are integral operators $\mathcal{N}_S$ ($S \subseteq J$) on the forms of level Q, commuting with $\mathbb{T}_Q$, with $\mathcal{N}_\emptyset = \mathrm{Nm}$, such that, for $\mathcal{N} = \sum_S \mathcal{N}_S\alpha_S$ and $\alpha_S = \prod_{j\in S}\alpha_j$, the coefficient of $\prod_j \alpha_j$ in $\mathcal{N}F$ is $\equiv 0$ for every $F \in \mathfrak{a}$, and*

$$\delta^{\#J}\mathcal{N} \equiv \mathcal{Y}\,\mathrm{Nm}$$

   for an integral operator polynomial $\mathcal{Y} = \sum_S \mathcal{Y}_S\alpha_S$ with $\mathcal{Y}_\emptyset = \delta^{\#J}$.

2. *Let $\mathcal{X}$ be a subset of the systems of level Q, let $\pi \in \mathcal{X}$ be of base level, and let δ_i be functions on the systems vanishing on $\mathcal{X}$. Let $\mathrm{sel}(k)$ be finitely many indices, let $\lambda_k \in \overline{\mathbb{Z}}_\ell$, and put*

$$\delta_0 = \prod_k(\lambda_k - \delta_{\mathrm{sel}(k)}), \qquad n_0 = \prod_k \lambda_k.$$

   Two systems are called congruent if all characteristic coefficients of $N_x(g)$ and $N_\pi(g)$ are equal modulo the maximal ideal of $\overline{\mathbb{Z}}_\ell$, for every $g \in G_E$. Suppose the N_x have integral characteristic polynomials; every system of base level congruent to π with $\delta_0(x) \ne 0$ has a root chain at every w_j; $2n!(n_0c_B^2)^{\#J+1}$ divides ℓ^ν; and, for a fixed scalar m and a bound β, every trace ideal of the N_x has a common Ribet element for the δ_i relative to $\mathcal{X}$, at π, whose coefficient d satisfies $v_\ell(md) \le \beta$. Then there is a function s on the systems with $v_\ell(m\,s(\pi)) \le \beta$ such that $d'c_B\,s\,y$ is integral for every integer $d' \ge 1$ and every pair of forms l, y of base level for which $d'l$ is integral, y is supported on $\mathcal{X}$, and y agrees with l at every system where $\delta_0 \ne 0$.

Proof. **Integral averaging with the prescribed multiplier.** Every subgroup of Γ acts through the standard maximal level, and the stabiliser of a point of its finite double-coset set is an image of a subgroup of $\mathrm{U}(V)(E^+) \cap gK_0g^{-1}$. Its order divides c by the common-multiple hypothesis (AL1) of Definition 7.6.1 and Lagrange's theorem: pass first to the subgroup of that finite rational stabiliser, then to its image. Here B is arbitrary base data; no admissible-datum rank restriction or replacement of c_B by N_{ch} is being imposed. Therefore Proposition 7.1.14, or

its explicit orbit weights $c/\#H$, gives an integral endomorphism Ψ_Δ for every subgroup $\Delta \subseteq \Gamma$ such that

$$\sum_{g\in\Delta} g^{-1}\Psi_\Delta g = c. \tag{1}$$

The averaging operator may be chosen to preserve the prescribed base type: form its orbit weights after quotienting by the maximal compact factors at the fixed base places, and pull those weights back. The resulting scalar multiplication commutes with translation by those factors; the base-type space is stable under every such operator. The stabilisers on this quotient are still images of subgroups of the same finite rational stabilisers, so the same integer c works. There is no need for trivial stabilisers. In particular, for $\Delta = \Gamma$ and any base-level vector z,

$$\operatorname{Nm}\Psi_\Gamma z = cz. \tag{2}$$

Indeed every g fixes z, and one can replace g^{-1} by g in the sum.

The local derivative. Fix j, write $q = q_{w_j}$, $\tau = \tau_j$, $\varphi = \varphi_j$, and $G = \mathrm{GL}_n(k_{w_j})$. Let $H \subseteq G$ stabilise the first coordinate line. Choose $\bar z$ and $\mathrm{ind} : k_{w_j}^\times \to \mathbb{Z}/m_\nu$ as in Lemma 7.6.13, with $\mathrm{ind}(\bar z) = 1$, and put

$$b(h) = \mathrm{ind}(h_{11}) \quad (h \in H), \qquad b_G(g) = \mathrm{ind}(\det g) \quad (g \in G).$$

The transfer of b is b_G, by item 4 of that lemma. All actions in the formulas below are the integral actions on forms.

For an integer-valued function F on $\mathbb{Z}/m_\nu$ let

$$W_H(F) = \sum_{h\in H} F(b(h))h, \qquad W_G(F) = \sum_{g\in G} F(b_G(g))g.$$

Let λ be any integer lift of the identity on $\mathbb{Z}/m_\nu$ and put

$$p_j(X) = (X - q^{t-1})H_j(X), \qquad \widetilde U = a(\varphi)U_\varpi, \qquad B(F) = p_j(\widetilde U)W_H(F).$$

These are integral operators supported at w_j. To check the domain, $W_H(F)$ maps into the vectors fixed by I_1: the character b is trivial there. The sum-normalised U_ϖ maps I_1-fixed forms into themselves and is an integral sum of local translates. Thus the displayed polynomial defines the required operator on all deep-level forms. It also preserves a parahoric character on the first entry. This follows directly from its q^{n-1} representatives $u\,\mathrm{diag}(\varpi, 1, \dots, 1)$: the parahoric permutes these representatives modulo the same parahoric, retaining their first-entry character. In particular $HB(1) = B(1)$. Right multiplication gives the weight-shift identity

$$B(F)h = B(F(\,\cdot - b(h))). \tag{3}$$

Choose left-coset representatives s for G/H, set $T_+ = \sum_s s$, $T_- = \sum_s s^{-1}$, and define

$$\partial_j = -T_+ B(\lambda) T_-. \tag{4}$$

Let $\sigma : \mathcal{E} \to A$ be any reduction killing each operator T for which $\kappa_0 T \in m_\nu\mathcal{E}$. We prove the two local identities

$$\mathrm{Nm}_j \operatorname{tr}[(\tau - 1)g] = 0, \qquad \partial_j \operatorname{tr}[(\tau - 1)g] \equiv \mathrm{Nm}_j \operatorname{tr}[(\varphi - 1)H_j(\varphi)g]. \tag{5}$$

Here and below congruence means equality after σ. Differences of integer weights divisible by m_ν disappear after σ.

Write $t_g = \mathrm{tr}[(\tau-1)g]$ and $t_{p,g} = \mathrm{tr}[(\tau-1)g\,p_j(\varphi)]$. By item 3 of Lemma 7.6.13,

$$B(\lambda)t_g \equiv W_H(\lambda)t_{p,g}. \tag{6}$$

We include the factor in this deduction. Set $E(F) = B(F)t_g - W_H(F)t_{p,g}$. Fourier decomposition for the finite cyclic group shows $E(F(\cdot - n!) - F) = 0$: on a character ψ with $\psi(n!) \neq 1$ this is exactly the dictionary, and on the other characters the difference is zero. For $F(u) = \lambda(u)(\lambda(u) + n!)$ one has

$$F(u - n!) - F(u) \equiv -2n!\lambda(u) \pmod{m_\nu}.$$

Applying the additive map E shows that $2n!E(\lambda)$ is a multiple of m_ν by an integral operator. The definition of σ proves (6), including at $\ell = 2$.

Two finite-group calculations finish (5). First,

$$T_+ W_H(\lambda)T_- \equiv W_G(\lambda), \tag{7}$$

because the coefficient of a fixed g on the left is the sum of the lifts of b on the coset components of gs; modulo m_ν that sum is the transfer $b_G(g)$. Second, for $\gamma = \mathrm{diag}(\bar{z}, 1, \ldots, 1)$,

$$(\gamma - 1)W_G(\lambda) \equiv -\mathrm{Nm}_j. \tag{8}$$

This is the change of variable $g \mapsto \gamma g$ and $\lambda(u-1) - \lambda(u) \equiv -1$. Item 2 of Lemma 7.6.13, applied to the determinant-character Fourier components, says

$$W_G(\lambda)t_{p,g} = (\gamma - 1)W_G(\lambda)\mathrm{tr}[p_j(\varphi)g].$$

The same formula with constant weight gives $\mathrm{Nm}_j t_g = 0$. Since all Hecke operators commute with local translations, (4), (6)–(8) give $\partial_j t_g \equiv \mathrm{Nm}_j \mathrm{tr}[p_j(\varphi)g]$. Finally $q \equiv 1 \pmod{m_\nu}$ replaces p_j by $(X-1)H_j$ and proves (5).

We also need the exact form of the failure of ∂_j to commute with G: for each $g \in G$ there is $Z_g \in \mathcal{E}$ such that

$$c\,\partial_j(g-1) \equiv \mathrm{Nm}_j Z_g, \qquad \delta' \,\mathrm{Nm}\, Z_g = 0. \tag{9}$$

Here δ' is any diagonal integral operator with the root-chain hypothesis in item 1. That hypothesis and Lemma 7.6.5, item 2, give

$$\delta' \,\mathrm{Nm}\, B(1) = 0. \tag{10}$$

To see the passage from pairings to (10), $\mathrm{Nm}\, B(1)$ has base level. A base-level spherical eigenvector in a system with $\delta' \neq 0$ is orthogonal to every value of $B(1)$ by the local chain lemma, and hence to every value of its norm since that eigenvector is fixed by Γ. The local operators preserve each Hecke system and commute with δ'. Expanding a base-level form in its orthogonal spherical Hecke eigenspaces and using positive definiteness proves (10).

For completeness, the finite calculation proving (9) is as follows. Right multiplication by g permutes the terms s^{-1} of T_- up to left factors in H. Equation (3) and the linear congruence for λ therefore give an integral operator Q_g with

$$B(\lambda)T_-(g-1) \equiv B(1)Q_g.$$

Choose Ψ_H as in (1). Since H fixes $B(1)$ from the left,

$$cB(1) = \Big(\sum_{h \in H} h\Big)\Psi_H B(1).$$

Multiplying by T_+ turns the sum over H into Nm_j, so (9) holds with $Z_g = -\Psi_H B(1) Q_g$. To check its vanishing assertion, put $L = \delta' \mathrm{Nm}$. Then $Lh = L$ for $h \in H$ and $LB(1) = 0$ by (10). Consequently

$$\#H\, L\Psi_H B(1) = L\Big(\sum_{h\in H} h\Big)\Psi_H B(1) = cLB(1) = 0.$$

The operator ring acts on a complex vector space and has no nonzero integer torsion. Thus $L\Psi_H B(1) = 0$, proving (9).

The family and its factorisation. Local operators at distinct auxiliary places commute: their supporting adelic groups commute. Put

$$\mathcal{N}_S = \prod_{j\in S} \partial_j \prod_{j\notin S} \mathrm{Nm}_j, \qquad \mathcal{N} = \prod_j (\mathrm{Nm}_j + \alpha_j \partial_j). \tag{11}$$

These are integral, commute with $\mathbb{T}_Q$, and $\mathcal{N}_\emptyset = \mathrm{Nm}$. For a generator $t_g - \alpha_j r_g$ of the tied ideal, pair in the top coefficient of $\mathcal{N}F(t_g - \alpha_j r_g)$ the subsets not containing j with those containing it. Formula (5) makes the two terms cancel; the remaining terms contain $\mathrm{Nm}_j t_g = 0$. Generators divisible by m_ν disappear after σ. Additivity and multiplication by arbitrary polynomials then give the first assertion of item 1.

We prove the second assertion without dividing by a stabiliser order. Put $D = c^2\delta'$. For every subset S, induction on $\#S$ gives an integral Y'_S with

$$D^{\#S}\mathcal{N}_S \equiv Y'_S \mathrm{Nm}, \qquad Y'_\emptyset = 1. \tag{12}$$

For the induction step let $\#S = e+1$ and set $A_0 = c\delta' D^e \mathcal{N}_S$. For a group element in a factor $j \notin S$, the right factor Nm_j makes $A_0(g-1) = 0$. For $j \in S$, write $\mathcal{N}_S = N'\partial_j$ and $\mathcal{N}_{S\setminus\{j\}} = N'\mathrm{Nm}_j$. By (9),

$$A_0(g-1) \equiv \delta' D^e \mathcal{N}_{S\setminus\{j\}} Z_g = 0.$$

Indeed (12) for the smaller subset factors $D^e\mathcal{N}_{S\setminus\{j\}}$ through Nm; move δ' to its right before using that factorisation, and then use $\delta'\mathrm{Nm}Z_g = 0$. Thus A_0 is right Γ-invariant after reduction. Applying (1) for Γ yields $cA_0 \equiv A_0\Psi_\Gamma \mathrm{Nm}$, which is (12) since $cA_0 = D^{e+1}\mathcal{N}_S$. Multiply (12) by the remaining power $D^{\#J-\#S}$ and take $\mathcal{Y}_S = D^{\#J-\#S}Y'_S$. This gives $D^{\#J}\mathcal{N} \equiv \mathcal{Y}\mathrm{Nm}$ with $\mathcal{Y}_\emptyset = D^{\#J}$, as required.

The integral congruence projector. We now prove item 2. Congruence means equality modulo the maximal ideal of all characteristic coefficients of $N_x(g)$ and $N_\pi(g)$, for every g and every coefficient. There is an integral idempotent $A \in \mathbb{T}_Q$ whose value is 1 on the systems congruent to π and 0 on the others. Here is an explicit construction. For each of the finitely many noncongruent systems x, choose one characteristic-coefficient difference b_x which is a unit at x and is zero at π. All these functions lie in $\mathbb{T}_Q$ by item 1 of Lemma 7.6.13. Their values lie in one finite coefficient extension. If its residue cardinality is Q_0, then $b_x^{(Q_0-1)Q_0^a}$ tends, as $a \to \infty$, to 1 at its unit values and to 0 at its nonunits. Thus the product of $1 - b_x^{(Q_0-1)Q_0^a}$ tends to the desired indicator. The Hecke algebra is closed: a convergent family of diagonal operators preserves the integral lattice in the limit, as that lattice is closed and the space is finite dimensional. Hence A belongs to it. This construction also proves $A(\pi) = 1$.

Choose a common finite coefficient field for the finitely many representation models, the coefficients of H_j, and the scalars used here; the representations descend by the compact-image and Baire argument, and their integral models are obtained from a bounded orbit of a lattice. Intersect $\mathbb{T}_Q$ with the families valued in this field. Apply the common-Ribet hypothesis to the polynomial ring over this integral Hecke algebra, embedded in the ring of polynomial families on the finite set of systems, and to the image of the tied ideal. This is a trace ideal by Lemma 7.6.13,

item 1. The embedding is injective, as comparison of every coefficient at every system shows. The resulting common element therefore gives a polynomial $f \in \mathbb{T}_Q[\alpha_j]$ such that

$$f\delta_i \in \mathfrak{a}, \quad f_S(x) = 0 \ (x \in \mathcal{X},\ S \subsetneq J), \quad v_\ell(m f_J(\pi)) \le \beta. \tag{13}$$

It also shows that each δ_i belongs to $\mathbb{T}_Q$, by taking the constant coefficient of a polynomial representing its constant family. Set

$$d_0 = \prod_k (\lambda_k - \delta_{\mathrm{sel}(k)}), \quad n_* = n_0 c^2, \quad i_0 = \#J + 1, \quad D = c^2 A d_0.$$

The annihilator of f modulo $\mathfrak{a}$ is an ideal containing every δ_i. Reducing the displayed product modulo that ideal gives

$$(d_0 - n_0) f \in \mathfrak{a}. \tag{14}$$

The root-chain hypothesis applies to Ad_0, since its nonzero values at base level are precisely among the congruent systems with $d_0 \neq 0$. Item 1 consequently applies with $\delta' = Ad_0$.

Extraction of the top coefficient. Let $k_0 = \#J$. Put

$$G_0 = \sum_{S \subseteq J} \mathcal{N}_{J \setminus S} f_S, \qquad G_1 = \sum_{S \subseteq J} \mathcal{Y}_{J \setminus S} \mathrm{Nm}\, D f_S.$$

Here the $\mathcal{Y}$ are those of item 1 for D, so $\mathcal{Y}_\emptyset = D^{k_0}$. There is an integral operator W with

$$n_*^{i_0} A^{i_0} G_0 - G_1 = n_*^{i_0} b W \tag{15}$$

for some integral scalar b. To obtain (15), take the quotient of $\mathcal{E}$ by the scalar $\ell^\nu/(2n!)$. This is allowed by the divisibility hypothesis, and its kernel is that scalar times $\mathcal{E}$; the quotient has the reduction property used in item 1 since $\mathcal{E}$ has no integer torsion. Also $\ell^\nu/(2n!) = n_*^{i_0} b$ with b integral. Modulo this quotient, (14) and the top-coefficient annihilation give

$$n_*^{i_0} A^{i_0} G_0 \equiv D^{i_0} G_0,$$

because $D^{i_0} - n_*^{i_0} A^{i_0}$ is a multiple of $d_0 - n_0$. The factorisation of item 1, applied term by term, gives $D^{i_0} G_0 \equiv G_1$. This proves (15).

Let l, y, d' be as in item 2. Since all δ_i vanish on $\mathcal{X}$ and y is supported on $\mathcal{X}$,

$$d_0 y = n_0 y, \qquad f_S y = 0 \quad (S \subsetneq J).$$

Since y agrees with l on the systems where $d_0 \neq 0$, one also has $Ad_0 l = n_0 A y$. The vector $u = \Psi_\Gamma(d' l)$ is integral, and (2) gives $\mathrm{Nm}\, u = d' c\, l$. Move the diagonal Hecke operators past the norm in the expression for $G_1 u$. The preceding identities eliminate every proper subset S, while the last term uses $\mathcal{Y}_\emptyset = D^{k_0}$. The result is

$$G_1 u = n_*^{i_0} d' c\, A^{i_0} f_J y. \tag{16}$$

Indeed the norm first contributes $d'c$, the factor $D = c^2 A d_0$ contributes $n_* A$ on y, and D^{k_0} contributes $n_*^{k_0} A^{k_0}$.

Apply (15) to u, insert (16), and cancel the nonzero scalar $n_*^{i_0}$. It is nonzero because it divides $\ell^\nu/(2n!)$. We obtain

$$d' c\, A^{i_0} f_J y = (A^{i_0} G_0 - bW) u.$$

The right side is an integral operator applied to an integral vector. Thus it is integral. Taking $s = A^{i_0} f_J$, one has $s(\pi) = f_J(\pi)$, so (13) gives the required valuation bound and the claimed clearing for every d'. □

Proposition 7.6.12. *Let ℓ be prime, $\iota : \mathbb{C} \to \overline{\mathbb{Q}}_\ell$, and let ϑ have modulus Q_ϑ with $(S_\ell, Q_\vartheta, \psi_\vartheta)$ an auxiliary twist. Let (O, c) be a lift setting for ϑ, with source rank r', rank difference t_O, and $n = r' + t_O$. Put $\widetilde{\chi}_O(z) = \chi_O(z/\bar{z})$. The normalising character ν_O of (MS6) of Definition 7.2.30 is the geometric ℓ-adic avatar, read through ι, of*

$$\widetilde{\chi}_O^{-1} \upsilon^{r'} |\cdot|_E^{r'/2},$$

where υ is the splitting character of (WD3) of Definition 3.2.12. Let B be base data of rank n, and for every system x set $u_x = \nu_O \otimes r_x$. Suppose these representations have integral characteristic polynomials. Let x_0 be a system of base level, and let R be main-summand like of rank r' and string length t_O, with

$$\operatorname{tr} u_{x_0}(g) = \psi_\vartheta(g) \operatorname{tr} R(g) + \sum_{e<t_O} \chi_{\mathrm{cyc}}(g)^{-e}.$$

Let $g_1 \in G_E$ have cyclotomic image a topological generator of the cyclotomic image of G_E, let $h \geq 0$ satisfy $\chi_{\mathrm{cyc}}(g_1)^a - 1 \mid \ell^h$ for $0 < a < t_D$, and suppose $\ell \leq h_D^2$ or $h = 0$. Then there are a finite linearly ordered J and monotone $\mathrm{ty} : J \to \{1, \dots, t_O - 1\}$, independent of ν, such that for every $\nu > 0$ there are Taylor–Wiles places (w_j, φ_j, τ_j) of level ℓ^ν with:

1. *they form a prime triangle for g_1^{-1} with bounds $(h_D h, h_D^{22} h)$;*
2. *the places avoid S_ℓ^{bad}, are off the base level, and ν_O is unramified there;*
3. *there are $e_j \in \overline{\mathbb{Z}}_\ell[X]$ with $e_j(1) = 1$ such that every weak base system x congruent to x_0 satisfies*
$$P_{x,w_j}(\nu_O(\varphi_j)^{-1} X) = \prod_{i<t_O} (X - q_{w_j}^i)\, S_{x,j}(X), \qquad S_{x,j} \mid e_j,$$
with coefficients transported through ι^{-1}. Here weak means $\det(1 - u_x(g)) = 0$ for all $g \in G_E$, and congruence means equality modulo the maximal ideal of every characteristic coefficient at every g.

Proof. **Normalisation and weak lifts.** At a split place w away from the ramification of a, write

$$X_0(w) = \widetilde{\chi}_O(\varpi_w) \upsilon(\varpi_w)^{-r'} q_w^{r'/2}.$$

Here $\widetilde{\chi}_O(z) = \chi_O(z/\bar{z})$. The Hecke character defining a is algebraic: at an infinite place where χ_O has weight w, its infinity factor is $z^{r'-w}\bar{z}^w$. Thus its geometric avatar exists by the algebraic-character convention. The characters in the formula for X_0 are unitary, so $|X_0(w)|^2 = q_w^{r'}$. Evaluation of the defining Hecke character $\widetilde{\chi}_O^{-1}\upsilon^{r'}|\cdot|_E^{r'/2}$ at a uniformiser, using $|\varpi_w|_E = q_w^{-1}$ and geometric reciprocity, gives

$$a(\varphi_w) = \iota(X_0(w)^{-1}), \qquad \chi(\varphi_w) = q_w^{-1}. \tag{1}$$

Let x be a weak lift of base level. At a split unramified place where the Hecke–Frobenius equality of Theorem 7.1.4 holds, the root 1 of $C_x(\varphi_w)$ makes $X_0(w)$ a root of $P_{x,w}$. A nonzero base-level eigenform is a spherical vector in the unitary local representation on automorphic forms. Its invariant positive definite form is the class-sum inner product. Since $|X_0(w)|^2 q_w^t = q_w^n$, item 1 of Lemma 7.6.5 gives the distinct roots $X_0(w) q_w^e$, $0 \leq e < t$. Therefore

$$P_{x,w}(a(\varphi_w)^{-1} X) = \prod_{e<t} (X - q_w^e)\, A_{x,w}(X). \tag{2}$$

Coefficients in (2) are transported through ι^{-1}.

The integral cofactor. If B is monic integral and AB is integral, then A is integral, by division by a monic integral polynomial. If also $AB \equiv A'B$ coefficientwise modulo the maximal ideal, then $A \equiv A'$ coefficientwise. Indeed the Gauss norm of a monic integral polynomial is 1, and multiplicativity gives $\|A - A'\|_{\mathrm{G}} = \|(A - A')B\|_{\mathrm{G}} < 1$. In particular, if $|A'(1)|_\ell = 1$, then $|A(1)|_\ell = 1$, and $A/A(1)$ is integral with value 1 at 1.

Put $b = a(\varphi_w)$ and transport (2) to $\overline{\mathbb{Q}}_\ell$. Exact unramified compatibility and twisting give

$$C_x(\varphi_w; X) = b^n P_{x,w}(b^{-1}X) = \big(b^n A_{x,w}(X)\big) B_{\varphi_w}(X). \tag{3}$$

The character a has unit values by compactness, and B_{φ_w} is monic integral. Newton identities applied to the trace hypothesis at all powers g^j give

$$C_{x_0}(g; X) = \det(X - \psi_\vartheta(g)R(g))\, B_g(X). \tag{4}$$

Suppose

$$|\det(1 - \psi_\vartheta(\varphi_w)R(\varphi_w))|_\ell = 1. \tag{5}$$

If x is congruent to x_0, the monic-factor argument applied to (3), (4) makes $b^n A_{x,w}$ integral with unit value at 1. Since b is a unit, the same holds for $A_{x,w}$. Dividing by that value gives an integral polynomial $e_{x,w}$ with $e_{x,w}(1) = 1$ such that the cofactor in (2) divides $e_{x,w}$.

Frobenius data near suitable translates. Put $T(g) = \psi_\vartheta(g)R(g)$. Let $\mathcal{W}$ consist of the Frobenius data whose places avoid the bad places, are off the base level and the ramification of a, satisfy the Hecke–Frobenius equalities for the finitely many base systems, and satisfy $|\det(1 - T(\varphi))|_\ell = 1$. All conditions except the last exclude only finitely many places, including the exceptions to (1).

For every $v \geq 0$ and $g \in G_E$, we show that some $\delta \in \ker \chi$ makes $\mathcal{W}$ contain most Frobenii near $\delta^{\ell^v} g$. By (MS3), there is an inertial γ above $p_0 p_1$, away from ℓ, with

$$R(\gamma) = z\,1, \qquad |z^{\ell^a j} - 1|_\ell = 1 \quad (a \geq 0,\ 1 \leq j \leq 4r' + 2). \tag{6}$$

The modulus of a twist is prime to MN, by Definition 3.1.2; hence $\psi_\vartheta(\gamma) = 1$. Also $\chi(\gamma) = 1$. Thus

$$T((\gamma^i)^{\ell^v} g) = (z^{\ell^v})^i T(g). \tag{7}$$

For each eigenvalue μ of $T(g)$, among $0 \leq i \leq r'$ at most one can have $|1 - (z^{\ell^v})^i \mu|_\ell < 1$. Two such integers would give $|(z^{\ell^v})^{i-i'} - 1|_\ell < 1$, contrary to (6). There are r' eigenvalues and $r' + 1$ integers, so some i avoids all these inequalities. Compactness supplies an integral lattice for T, so its eigenvalues are units; consequently all r' factors have norm exactly 1. Equation (7) proves $|\det(1 - T((\gamma^i)^{\ell^v} g))|_\ell = 1$. The unit condition is open by continuity. Take $\delta = \gamma^i$ and shrink a neighbourhood of $\delta^{\ell^v} g$. Its Frobenius data satisfy (5), and all but finitely many satisfy the other conditions defining $\mathcal{W}$. This is precisely the required most-Frobenii property. Nonemptiness of the Frobenius filters and removal of the finite exceptional sets follow from Theorem A.2.6.

The triangle and the common polynomial. Apply Theorem 7.6.15 with conductor $q_1 d$, length t and $y = H$. By Lemma 4.2.67 and Lemma 4.2.66,

$$q_1 d + t \leq x^{13} + 15x^5 < x^{40} \leq H, \qquad E \subseteq \mathbb{Q}(\mu_{q_1 d}).$$

The tower formula gives $5040 \mid q_1$, so E contains μ_{5040} and has at least four infinite places. The generator, separation and coefficient-prime assumptions are those of the statement, restricted to $t \leq t_D$. The near-Frobenius hypothesis was just proved. The resulting finite ordered J and

monotone exponent are independent of ν; for each $\nu > 0$ the theorem gives the required triangle, all its Frobenius data in $\mathcal{W}$.

There are finitely many weak base systems congruent to x_0. For each resulting place use their polynomials constructed from (2)–(5) and put

$$e_j = \prod_{\substack{x \text{ weak, base} \\ x \equiv x_0}} e_{x,w_j}.$$

The empty product is 1. Every factor is integral and has value 1 at 1, so e_j does too; every cofactor in (2) divides it. This proves all three conclusions simultaneously. □

Lemma 7.6.13. *Assume $[E^+ : \mathbb{Q}] \geq 2$. Let B be base data, L a level, $a\colon G_E \to \bar{\mathbb{Z}}_\ell^\times$ a character and $N_x = a \otimes r_x$.*

1. *For every $g \in G_E$ and $i \geq 0$, the function sending a system x of level L to the i-th coefficient of the characteristic polynomial of $N_x(g)$ lies in $\mathbb{T}_L$; hence $\operatorname{tr}[P(h)g] \in \mathbb{T}_L$ for $P \in \bar{\mathbb{Z}}_\ell[X]$, $g, h \in G_E$.*

Let now $Q = (w_j, \varphi_j, \tau_j)_{j \in J}$ be Taylor–Wiles places of level ℓ^ν, all off the base level, let $a(\tau_j) = 1$ for all j, fix j, $w = w_j$, $\varphi = \varphi_j$, $\tau = \tau_j$, and identify the decomposition group at the place of $\bar{\mathbb{Q}}$ of the datum with G_{E_w}. Let $\varpi \in E_w$ be a uniformiser and $u \in \mathcal{O}_{E_w}^\times$ a unit such that $\operatorname{Art}_{E_w}(\varpi)^{-1}$ and $\operatorname{Art}_{E_w}(u)^{-1}$ are the images of φ and of τ in $G_{E_w}^{\mathrm{ab}}$, let $\bar{z} \in k_w^\times$ be the reduction of u (a generator of $k_w^\times$, as τ generates tame inertia), and fix a homomorphism $\operatorname{ind}\colon k_w^\times \to \mathbb{Z}/\ell^\nu$ with $\operatorname{ind}(\bar{z}) = 1$, and let $\psi\colon \mathbb{Z}/\ell^\nu \to \bar{\mathbb{Z}}_\ell^\times$ be a character. Let y be a form of level Q in a system x.

2. *(Tame generator.) If $\mathrm{GL}_n(k_w)$ acts on y through $\psi \circ \operatorname{ind} \circ \det$, then for all $g \in G_E$ and $p \in \bar{\mathbb{Z}}_\ell[X]$,*

$$\operatorname{tr}\big[(\tau - 1)\, g\, p(\varphi)\big]\, y = (\langle \bar{z} \rangle - 1)\operatorname{tr}\big[g\, p(\varphi)\big]\, y, \qquad \langle \bar{z} \rangle = \operatorname{diag}(\bar{z}, 1, \ldots, 1).$$

3. *(Frobenius.) If the stabiliser in $\mathrm{GL}_n(k_w)$ of the line spanned by the first basis vector acts on y through $g \mapsto \psi(\operatorname{ind}(g_{11}))$ and $\psi(n!) \neq 1$, then for all g and p,*

$$\operatorname{tr}\big[(\tau - 1)\, g\, p(\varphi)\big]\, y = p(\tilde{U}) \operatorname{tr}\big[(\tau - 1)\, g\big]\, y, \qquad \tilde{U} = a(\varphi)\, U_\varpi,$$

where, with $I_1 \subseteq \mathrm{GL}_n(\mathcal{O}_{E_w})$ the pro-p Iwahori subgroup (the matrices whose reduction is upper unitriangular) and $t_\varpi = \operatorname{diag}(\varpi, 1, \ldots, 1)$, $U_\varpi y = \sum_{h \in I_1 t_\varpi I_1 / I_1} h\, y$ is the double-coset operator of t_ϖ on I_1-fixed forms, for the uniformiser ϖ fixed above (under the hypothesis of this item I_1 fixes y, since its elements reduce into the stabiliser of the line with $g_{11} = 1$, and U_ϖ maps I_1-fixed forms to I_1-fixed forms).

4. *(Transfer.) Over a finite field k, the transfer from $\mathrm{GL}_n(k)$ to the stabiliser of a line, composed with the first diagonal entry, is the determinant.*

Proof. Put $F = E^+$; the stated degree hypothesis gives $[F : \mathbb{Q}] \geq 2$. The space of forms of a fixed weight and finite level is finite-dimensional: by Theorem A.4.5, the adelic quotient is compact, and its quotient by the compact group at infinity and an open compact finite level has finitely many points. Evaluation at representatives embeds the space into a finite direct sum of copies of the weight space. Its integral forms are the intersection with the corresponding integral value modules; in particular that set is closed for the ℓ-adic topology transported by ι.

We will also use the irreducible automorphic decomposition on these spaces. There is no proper F-parabolic subgroup of $\mathrm{U}(V)$: such a subgroup would give a nonzero isotropic vector over E, contrary to definiteness at a real place. The cuspidality condition is therefore vacuous. Apply Theorem 7.6.14(a) to the compact quotient, take the prescribed infinity type and finite-level fixed vectors, and use their finite dimension. This gives a finite sum of irreducible automorphic components. Their projections commute with the local group action, the away-from-level Hecke operators and the finite type projectors. The factorisation Theorem A.4.25, with the finite adelic group separated into its factor at w and the remaining factors, supplies the irreducible local components used below. The compact infinity factor consists of discrete-series representations, and property $(*)$ in Theorem A.4.16 is automatic; that theorem therefore supplies weak base change for every such component. Every component in a system x has the same attached semisimple Galois representation r_x: its unramified characteristic polynomials are those of x, and the uniqueness assertion of Theorem 7.1.4 identifies the representations.

Integral characteristic coefficients. For a split place w off level and $0 \le k \le n$, let $T_{w,k}$ denote the double-coset sum for $\mathrm{diag}(\varpi_w 1_k, 1_{n-k})$. Each summand preserves the integral value condition, so $T_{w,k}$ preserves integral forms. By Theorem A.4.24, its scalar on x is

$$q_w^{k(n-k)/2} e_k(\alpha_{x,w,1}, \dots, \alpha_{x,w,n}).$$

Consequently the coefficient of X^{n-k} in the Hecke polynomial is the scalar of

$$(-1)^k q_w^{k(k-1)/2} T_{w,k}.$$

The multiplier is an integer. All coefficients of these Hecke polynomials therefore lie in $\mathbb{T}_L$.

The algebra $\mathbb{T}_L$ is closed in the finite product of the coefficient fields indexed by the systems occurring at this level. Indeed the diagonal-scalar map from that product to the endomorphisms of the finite-dimensional form space is continuous; preservation of integral forms is a closed condition, since for each integral form its image must belong to the closed integral value module. This argument does not require that $\bar{\mathbb{Z}}_\ell$ be a discrete valuation ring or that an integral basis over that ring be chosen.

Fix $g \in G_E$. Chebotarev, Theorem A.2.6, applied to simultaneous finite quotients for the finitely many representations at this level, approximates g, up to conjugacy, by geometric Frobenius elements at places off level. These places can be required to split over F: take the finite Galois extensions stable under $\mathrm{Gal}(E/F)$ and apply Chebotarev over F to an element restricting to the identity on E, choosing the place above it which gives the required conjugacy class over E. Finitely many forbidden places may be omitted. Continuity of characteristic coefficients and (Ua2) of Theorem 7.1.4 now imply that every characteristic coefficient of $r_x(g)$, simultaneously as a function of x, belongs to $\mathbb{T}_L$.

For $0 \le i \le n$, the coefficient of X^i in $\det(X - a(g) r_x(g))$ is $a(g)^{n-i}$ times the corresponding coefficient for $r_x(g)$. Since $a(g)$ is integral, this coefficient belongs to $\mathbb{T}_L$; coefficients with $i > n$ are zero. Finally, writing $P(X) = \sum_j P_j X^j$ gives directly

$$\mathrm{tr}[P(h)g] = \sum_j P_j \ \mathrm{tr}[h^j g].$$

A trace is minus the coefficient of X^{n-1}, so this expression lies in $\mathbb{T}_L$. No division by a factorial or by an integer is used.

The tame scalar. Write $\zeta = \psi(1)$. Apply (Up3) of Theorem 7.1.11 with one block and the character $\iota^{-1}\psi \circ \mathrm{ind}$. The prescribed relation $\mathrm{Art}_{E_w}(u)^{-1} = \tau$ in the abelianisation gives

$$r_x(\tau) = \zeta I.$$

Here semisimplicity is essential and is part of (Up3). Since $a(\tau)=1$, also $N_x(\tau)=\zeta I$. The diamond operator in the statement acts on y by ζ. Thus, for every g and p,

$$\operatorname{tr}\big((N_x(\tau)-I)N_x(g)p(N_x(\varphi))\big)=(\zeta-1)\operatorname{tr}\big(N_x(g)p(N_x(\varphi))\big),$$

which proves item 2. No commutation of $N_x(g)$ with a local operator is being asserted.

The line type and its double-coset scalar. For item 3 suppose first that $n\geq 2$. Set $K=\mathrm{GL}_n(\mathcal{O}_{E_w})$, let J be the inverse image in K of the line stabiliser, and put $\chi=\iota^{-1}\psi\circ\det$. The hypothesis $\psi(n!)\neq 1$ implies $\chi\neq 1$. On each nonzero irreducible automorphic component of y, (Up1) of Theorem 7.1.11, with the two blocks $(1,n-1)$, identifies the local representation with the irreducible normalised induction

$$\pi_w=\operatorname{Ind}_P^{\mathrm{GL}_n(E_w)}(\rho_1\otimes\rho_2),$$

where ρ_1 is a character restricting to χ on units and ρ_2 is irreducible spherical. Write a vector in this induction as f, with right translation action and $f(pg)=\delta_P(p)^{1/2}(\rho_1\otimes\rho_2)(p)f(g)$.

We verify explicitly the part of this induced model seen by the original line type. The double quotient $(P\cap K)\backslash K/J$ has two elements, represented by 1 and the transposition $w_0=(12)$. Indeed the finite parabolic stabilising the first line has two orbits on lines: that line and its complement. Reduction gives these two cells since its kernel is contained in J. A J-eigenvector of character $j\mapsto\chi(\bar{j}_{11})$ is determined on a cell by its value at its representative.

Choose a unit b with $\chi(\bar{b})\neq 1$, and put $h=\operatorname{diag}(1,bI_{n-1})$. It belongs to $P\cap w_0Jw_0^{-1}$. Its inducing action is trivial. To see this on the entire space of ρ_2, not just on a spherical line, observe that the central unit bI_{n-1} fixes a nonzero K_{n-1}-fixed vector, commutes with $\mathrm{GL}_{n-1}(E_w)$, and that vector generates the irreducible representation ρ_2. On the other hand the first diagonal entry of $w_0^{-1}hw_0$ is b. Comparing left and right equivariance at w_0 therefore gives

$$f(w_0)=\chi(\bar{b})f(w_0),\qquad f(w_0)=0.$$

Evaluation $f\mapsto f(1)$ is consequently injective on the J-eigenspace. No assertion that all compact elements act trivially on a spherical representation has been used.

Put $t=\operatorname{diag}(\varpi,1,\dots,1)$ and $n(v)=\left(\begin{smallmatrix}1 & v\\ 0 & I_{n-1}\end{smallmatrix}\right)$. For v running through $\mathcal{O}_{E_w}^{n-1}/\varpi\mathcal{O}_{E_w}^{n-1}$, the matrices $n(v)t$ represent both JtJ/J and I_1tI_1/I_1. This follows by reducing the first upper row: conjugation by t multiplies those entries by ϖ, while all other quotient coordinates are unchanged. In particular there are exactly q_w^{n-1} representatives.

This sum preserves the actual J-eigenspace. For $j\in J$, write $jn(v)t=n(v')th_v$ with $h_v\in J$. The map $v\mapsto v'$ is a permutation of the quotient. Comparing first columns shows $(h_v)_{i1}\in\varpi^2\mathcal{O}_{E_w}$ for $i>1$ and $(h_v)_{11}\equiv j_{11}\pmod{\varpi}$. Hence $\chi(\overline{(h_v)_{11}})=\chi(\bar{j}_{11})$, and summing proves the required equivariance. Thus injective evaluation may be applied to $U_\varpi f$. Since all $n(v)t$ belong to P,

$$(U_\varpi f)(1)=q_w^{n-1}\delta_P(t)^{1/2}\rho_1(\varpi)f(1)=q_w^{(n-1)/2}\rho_1(\varpi)f(1).$$

It follows that

$$U_\varpi f=\alpha f,\qquad \alpha=q_w^{(n-1)/2}\rho_1(\varpi).\tag{$*$}$$

This is the double-coset sum, not the mean.

Identification with the Frobenius on the ramified line. By (Up2)–(Up3) of Theorem 7.1.11, inertia is semisimple, the monodromy is zero, and its nontrivial character $\psi\circ\det$ occurs once, the remaining inertia characters being trivial. Thus

$$\mathcal{L}=\operatorname{im}(r_x(\tau)-I)$$

is that one-dimensional character space. It is stable under Frobenius: its inertia character is obtained from local reciprocity and hence is invariant under conjugation by the local Weil group. By (Us2) of Theorem 7.1.8, the parameter is the direct sum of the parameters of $\rho_1|\cdot|^{(1-n)/2}$ and $\rho_2|\det|^{(1-n)/2}$. Here the compatibility with this irreducible induction follows from (Ln6) of Theorem A.4.9; equivalently, order the unramified segments of the spherical factor in a Langlands order. Its parameter is unramified by the spherical description in Theorem A.4.24 and (Ln1), (Ln6). Therefore the unique nontrivial inertia line is the first summand.

Our Artin map takes uniformisers to arithmetic Frobenius, whereas (Ln1) uses geometric Frobenius. Its value at the prescribed $\varphi = \mathrm{Art}_{E_w}(\varpi)^{-1}$ is consequently $\rho_1(\varpi)|\varpi|^{(1-n)/2} = \alpha$. Frobenius semisimplification cannot change a scalar on a one-dimensional invariant space. We have proved the exact identity

$$r_x(\varphi)(r_x(\tau) - I) = \iota(\alpha)(r_x(\tau) - I). \tag{**}$$

In particular the scalar $\iota(\alpha)$ is determined by r_x, independently of the irreducible automorphic component. By (*) it follows that U_ϖ acts on the entire original vector y by $\iota^{-1}(\lambda)$, where λ is this scalar; decomposing y into its finitely many nonzero automorphic components justifies this even when y is not initially specified to belong to a single irreducible representation.

For $n = 1$ the same conclusion is immediate without a two-block assertion: the local irreducible representation is a character ρ_1, there is one double-coset representative, $U_\varpi = \rho_1(\varpi)$, and (Ln1) gives (**). In all ranks $a(\tau) = 1$ and multiplication by $a(\varphi)$ therefore give, with $D = N_x(\tau) - I$, $F_x = N_x(\varphi)$ and $\tilde\lambda = a(\varphi)\lambda$,

$$F_x D = \tilde\lambda D, \qquad p(F_x)D = p(\tilde\lambda)D, \qquad p(\tilde U)y = \iota^{-1}(p(\tilde\lambda))y.$$

Finally cyclicity of trace, valid for arbitrary $N_x(g)$, yields

$$\operatorname{tr}(DN_x(g)p(F_x)) = \operatorname{tr}(p(F_x)DN_x(g)) = p(\tilde\lambda)\operatorname{tr}(DN_x(g)).$$

This is item 3 with exactly the fixed uniformiser, twist and double-coset convention of the statement.

Transfer. Let $\mathscr{L}$ be the set of lines of k^n, and choose $v_L \neq 0$ on every line, with $v_{ke_1} = e_1$. Define $c(g, L) \in k^\times$ by $gv_L = c(g, L)v_{gL}$. The coset formula for transfer, followed by the first entry on the stabiliser, is

$$T(g) = \prod_{L \in \mathscr{L}} c(g, L).$$

Changing any v_L cancels between the factors indexed by L and $g^{-1}L$, and $c(gh, L) = c(h, L)c(g, hL)$ proves that T is a homomorphism. A transvection has order the characteristic of k, whereas $k^\times$ has order $\#k - 1$, so its image under T is 1.

For $d = \mathrm{diag}(b, 1, \dots, 1)$, the line ke_1 contributes b and every line in $H = \langle e_2, \dots, e_n\rangle$ contributes 1. The remaining lines are uniquely $k(e_1 + w)$ with $0 \neq w \in H$. Their permutation is $w \mapsto b^{-1}w$. If b has order m, each orbit has length m and its product of scalar factors is $b^m = 1$. Hence $T(d) = b = \det d$. Transvections together with these diagonal matrices generate $\mathrm{GL}_n(k)$ by Gaussian elimination, proving $T = \det$. For $n = 1$ the transfer is the identity; if $k = \mathbb{F}_2$, the target group is trivial. This completes all four assertions. □

Theorem 7.6.14. *Let E/F be a CM extension, V a hermitian space over E of rank $r \geq 1$, $G = \mathrm{U}(V)$, $G_\infty = \prod_\rho G(F_\rho)$ the product over the real places of F, μ a Haar measure on $G(\mathbb{A}_F)$, R the right regular representation of $G(\mathbb{A}_F)$ on $L^2 = L^2(G(F)\backslash G(\mathbb{A}_F))$ (quotient of μ by counting measure), and $L^2_{\mathrm{cusp}} \subseteq L^2$ the cuspidal subspace: for a nonzero totally isotropic*

E-subspace $C \subseteq V$ let N_C be the unipotent radical of the parabolic subgroup of G stabilising C; then L^2_{cusp} is the set of classes that have a left $G(F)$-invariant Borel representative ϕ such that for every such C and almost every $x \in G(\mathbb{A}_F)$ the integral $\int_{N_C(F)\backslash N_C(\mathbb{A}_F)} \phi(nx)\,dn$ converges absolutely and vanishes, dn being the quotient of a Haar measure of $N_C(\mathbb{A}_F)$ by the counting measure on $N_C(F)$. Let $C_c^\infty(G(\mathbb{A}_F))$ be the span of the functions $g \mapsto f_\infty(g_\infty)f_{\mathrm{f}}(g_{\mathrm{f}})$ with f_∞ smooth with compact support on G_∞ and f_{f} locally constant with compact support on $G(\mathbb{A}_{F,\mathrm{f}})$, and $R(f) = \int f(g)R(g)\,d\mu(g)$.

(a) L^2_{cusp} is a closed $G(\mathbb{A}_F)$-invariant subspace of L^2. For every irreducible unitary representation π of $G(\mathbb{A}_F)$ on a Hilbert space H_π, the space $\mathrm{Hom}_{G(\mathbb{A}_F)}(H_\pi, L^2_{\mathrm{cusp}})$ of bounded linear maps intertwining π with R has finite dimension $m(\pi)$. Let $L^2_{\mathrm{cusp}}[\pi]$ be the closure of the span of the images of these maps. Then $L^2_{\mathrm{cusp}}[\pi]$ is unitarily equivalent, as a representation of $G(\mathbb{A}_F)$, to the orthogonal direct sum of $m(\pi)$ copies of π; $L^2_{\mathrm{cusp}}[\pi]$ and $L^2_{\mathrm{cusp}}[\pi']$ are orthogonal for inequivalent π, π'; and L^2_{cusp} is the Hilbert direct sum of the $L^2_{\mathrm{cusp}}[\pi]$, π running over the equivalence classes of irreducible unitary representations of $G(\mathbb{A}_F)$.

(b) For every $f \in C_c^\infty(G(\mathbb{A}_F))$ the operator $R(f)$ maps L^2_{cusp} into itself, and its restriction to L^2_{cusp} is of trace class.

Proof. The published inputs are the cuspidal decomposition and Hilbert–Schmidt theorem in [7], Section 12, Theorem 12.1 and its proof, printed p.64, and the finite convolution factorisation theorem [72], Theorem 3.1. We give the normalization and trace-class deduction.

Apply the former to the connected reductive $\mathbb{Q}$-group $\mathrm{Res}_{F/\mathbb{Q}}\,\mathrm{U}(V)$. Its rational points and adelic points identify with $G(F)$ and $G(\mathbb{A}_F)$, respectively. There is no nontrivial rational character: over F every character factors through the determinant torus $\mathrm{U}(1)$, which is anisotropic, and the same assertion for the restriction of scalars follows by base change and Galois invariance. Consequently Arthur's subgroup of adelic points on which all rational-character absolute values equal 1 is the entire adelic group. Thus no central split direction or fixed-central-character quotient is missing here. Haar measures differ only by positive scalars; scaling the Hilbert norm and convolution operator by constants preserves the stated decomposition and operator ideals.

The cuspidality conditions agree. A proper parabolic of a unitary group is a stabilizer of a nonempty isotropic flag. If C is its smallest member, its unipotent radical N contains N_C as a normal subgroup. Integration of its constant term first over $N_C(F)\backslash N_C(\mathbb{A}_F)$ and then over the quotient gives zero under the stated hypothesis. These unipotent adelic quotients are compact; Fubini applies for almost every translate to a locally integrable representative, and the L^2 representative is locally integrable by Cauchy–Schwarz. Conversely the parabolic stabilizing each nonzero isotropic C is one of the proper parabolics. Hence vanishing of all proper-parabolic constant terms is equivalent to the displayed condition.

Arthur's theorem gives a closed invariant Hilbert subspace and an orthogonal discrete decomposition into irreducible unitary representations with finite multiplicities. If π is one of these irreducibles, bounded Hilbert-space Schur's lemma identifies its intertwining maps into this direct sum with its finite-dimensional multiplicity space: maps to an inequivalent irreducible vanish, and maps to an equivalent copy are scalar multiples of a unitary equivalence. Thus the isotypic closures, the dimensions $m(\pi)$, and their orthogonality are precisely those of part (a), including zero multiplicity for absent π.

The proof of Arthur's theorem states that $R_{\mathrm{cusp}}(h)$ is Hilbert–Schmidt for every smooth compactly supported test function h. We derive part (b), rather than identify trace class with that assertion. Factor the chosen Haar measure as a product of archimedean and finite Haar

measures. It suffices by the definition of the test space to take $f = f_\infty \otimes f_{\mathrm{f}}$. By the Dixmier–Malliavin theorem there are finitely many $a_i, b_i \in C_c^\infty(G_\infty)$ with

$$f_\infty = \sum_i a_i * b_i.$$

Choose a compact open subgroup U of the finite adelic group fixing f_{f} under left translation, and put $e_U = \mathbf{1}_U/\mu_{\mathrm{f}}(U)$. Local constancy and compact support permit such a U; averaging gives $e_U * f_{\mathrm{f}} = f_{\mathrm{f}}$. Consequently

$$f = \sum_i (a_i \otimes e_U) * (b_i \otimes f_{\mathrm{f}}), \qquad R_{\mathrm{cusp}}(f) = \sum_i R_{\mathrm{cusp}}(a_i \otimes e_U) R_{\mathrm{cusp}}(b_i \otimes f_{\mathrm{f}}).$$

Every factor is Hilbert–Schmidt by the cited cuspidal theorem. A product of two Hilbert–Schmidt operators is trace class, and a finite sum of trace-class operators is trace class. Invariance of the cusp subspace, already proved in part (a), justifies each restriction and composition. This proves part (b). □

Theorem 7.6.15. *Let ℓ be a prime, $N \geq 1$, and let $E \subseteq \mathbb{Q}(\mu_N)$ be a CM field containing μ_{5040} with at least four infinite places. Let $t, y, h \geq 0$ be integers with $N + t < y$, and let $\gamma \in G_E$ be such that $\operatorname{cyc}(\gamma)$ generates the closure of $\operatorname{cyc}(G_E)$ topologically, $\operatorname{cyc}(\gamma)^a - 1$ divides ℓ^h in $\mathbb{Z}_\ell$ for $0 < a < t$, and $\ell \leq y^2$ or $h = 0$. Let W be a set of Frobenius data such that for every $\nu \geq 0$ and $g \in G_E$ there is $\delta \in \ker \operatorname{cyc}$ for which W contains most Frobenii near $\delta^{\ell^\nu} g$.*

Then there are a finite linearly ordered set J and a monotone map $\operatorname{ty}\colon J \to \{1, \dots, t-1\}$ such that for every $\nu > 0$ there are Taylor–Wiles places $(w_j, \varphi_j, \tau_j)_{j \in J}$ of level ℓ^ν, all in W, that form a prime triangle for γ^{-1} with bounds $(yh,\, y^{22}h)$.

Proof. Write $\chi = \chi_{\mathrm{cyc}}$, $u = \chi(\gamma)$ and $a = \gamma^{-1}$. By Lemma 7.2.28, applied to a, choose a finite set $s \subseteq \ker \chi$, independently of the coefficient ring, exponent and truncation, which detects every cocycle unramified outside ℓ after its value at a is prescribed to be zero. If $\ell \leq y^2$, it satisfies $\#s \leq y^{20}$. The existence of a finite such set holds also without this inequality. Order s and set

$$J = \{1, \dots, t-1\} \times s$$

with lexicographic order and $\operatorname{ty}(e, g) = e$. When $t \leq 1$ the first factor and hence J are empty. This choice is independent of ν.

We record the elementary divisibility estimates used in the construction. The hypothesis on u implies, for distinct b, k in $\{0, \dots, t-1\}$,

$$u^b - u^k \mid \ell^h, \qquad D_b := \prod_{\substack{0 \leq k < t \\ k \neq b}} (u^b - u^k) \mid \ell^{(t-1)h}.$$

Indeed one factors out a unit and uses $0 < |b - k| < t$. Since E contains μ_4, $u^b - 1$ is divisible by 4 in $\mathbb{Z}_\ell$. If $0 < b < t$, it also divides ℓ^h, and consequently $4 \mid \ell^h$. Thus, whenever $J \neq \emptyset$,

$$4D_b \mid \ell^{(t+2)h} \mid \ell^{yh}, \qquad 4(u^b - 1)^2 \mid \ell^{3h} \mid \ell^{yh} \quad (0 < b < t).$$

Here $t + 2 \leq y$ follows from $N + t < y$ and $N \geq 1$. These statements include $\ell = 2$: the factor 4 is retained rather than cancelled.

Fix $\nu > 0$ and put $R_\nu = \mathbb{Z}/\ell^\nu$ and $G_\nu = \ker(\chi \bmod \ell^\nu)$. We construct, in the order of J, a datum (w_j, φ_j, τ_j), a Kummer map ψ_j of exponent $\operatorname{ty}(j)$, and a finite exceptional set T_j of primes of the maximal real field F. The set T_j contains the primes above ℓ and those below

the earlier w_i of the same exponent. The reductions of the maps of any fixed exponent will be linearly independent as functions $G_\nu \to \mathbb{F}_\ell$. We require the prime below w_j to avoid T_i for all $i \le j$ and all previously chosen primes. At later stages we require

$$\psi_i(\varphi_j) = 0 \quad (i < j), \qquad 2\psi_j(\varphi_j) \mid \ell^{yh} \quad \text{in } R_\nu,$$

and, if $j = (e, g)$,

$$z(\varphi_j) = 2z(g) \quad \text{for every coefficient ring } \mathcal{O} \text{ and } z \in \mathrm{Ev}_\emptyset(e, \nu).$$

Here is the induction step, including the simultaneous choice of the values. Let $j = (e, g)$ and let x be the family of earlier data whose exponent is e. Item 3 of Proposition 7.6.16 gives a finite T_j and a Kummer map ψ_j whose reduction does not lie in the span of the reductions of the earlier maps of exponent e. To see this directly from that item, if every available reduction belonged to that span, their whole span would have dimension at most $\#x$, contrary to its conclusion. Items 1 and 3 therefore preserve linear independence at the new stage.

The homomorphisms on G_ν consisting of ψ_j and these earlier maps jointly map onto $R_\nu^{1+\#x}$. In fact their image is an R_ν-submodule, and independence of the component linear forms modulo ℓ says that its reduction modulo ℓ is the whole target. If its quotient were nonzero, multiplication by ℓ would be surjective on that finite quotient and hence, on iterating ν times, would force it to be zero, a contradiction. Choose $v_0 \in G_\nu$ with $\psi_j(v_0) = 1$ and every earlier map of exponent e zero at v_0.

Conjugation separates the other exponents without imposing independence between different exponents. If ψ has exponent d, item 1 of Proposition 7.6.16 gives

$$\psi(\gamma v \gamma^{-1}) = u^{d+1}\psi(v) \qquad (v \in G_\nu).$$

Choose integers representing u^{-1} and $-u^k$ modulo ℓ^ν. Replacing v by the product of the corresponding powers of $\gamma v \gamma^{-1}$ and v multiplies every such $\psi(v)$ by $u^d - u^k$. Perform this operation once for every $0 \le k < t$ other than e. The resulting $v \in G_\nu$ satisfies

$$\psi_i(v) = 0 \quad (i < j), \qquad \psi_j(v) = D_e \bmod \ell^\nu.$$

Maps of exponent e remain zero from their initial value; every map of another exponent acquires its zero factor in the product. The construction takes place in G_ν because that subgroup is normal.

Apply the hypothesis on W to

$$g\, g^c\, v (v^c)^{-1}.$$

It supplies $\delta \in \ker \chi$ such that W contains most Frobenii near

$$\sigma = \delta^{\ell^\nu}\, g\, g^c\, v (v^c)^{-1}.$$

All factors lie in G_ν. Every Kummer map under consideration is a homomorphism on this subgroup and is odd under c, so

$$\psi_i(\sigma) = 2\psi_i(v) = 0 \quad (i < j), \qquad \psi_j(\sigma) = 2D_e.$$

The term involving δ is zero because its multiple is ℓ^ν. Every even cocycle z of exponent e unramified outside ℓ is a homomorphism on G_ν and is invariant under c. Consequently

$$z(\sigma) = 2z(g).$$

These equalities hold on one open neighbourhood of σ, simultaneously for all the Kummer maps already chosen and all coefficient rings and even cocycles in the last assertion. For the latter uniformity it suffices to use scalar cocycles with values in R_ν: every additive map $\mathcal{O}/\ell^\nu \to R_\nu$ is R_ν-linear, carries a cocycle to a scalar cocycle, and these maps separate points. There are only finitely many scalar cocycles unramified outside ℓ. For completeness, finiteness follows from the finiteness condition in Theorem A.3.19, applied to the open subgroup killing the finite action: its homomorphisms to $\mathbb{F}_\ell$ are finite in number; successive exact sequences for the target $\mathbb{Z}/\ell^m$ give finiteness for R_ν, and a cocycle on the whole group is determined by its restriction and finitely many coset values. Intersect their finitely many neighbourhoods of constancy. Also intersect with the open subgroup G_ν.

The definition of most Frobenii, followed by Theorem A.2.6, now gives a prime-norm datum in this neighbourhood and in W, outside the finitely many primes above ℓ, the T_i for $i \le j$, and the previously used primes of F. More explicitly, inside the neighbourhood and the neighbourhood witnessing most Frobenii near σ, that definition supplies a nonempty open subset on which all sufficiently large prime-norm data are allowed. Chebotarev supplies infinitely many such data there, so the finite exclusions can be imposed. Take this as (w_j, φ_j, τ_j), using the fixed chosen tame generator. The divisibility estimate above gives

$$2\psi_j(\varphi_j) = 4D_e \mid \ell^{yh} \quad \text{in } R_\nu.$$

This proves every induction requirement.

The primes below the w_j are pairwise distinct. A prime-norm place of E cannot be fixed by complex conjugation here: E/F is unramified at finite places, while an inert place has residue degree 2. To check the unramified assertion without imposing an additional hypothesis, use the cyclotomic subfield $\mathbb{Q}(\mu_{5040}) \subseteq E$. At a prime of residue characteristic p, complex conjugation acts nontrivially on a root of unity of order prime to p in this subfield (use μ_3 if $p \neq 3$ and μ_4 if $p = 3$); inertia acts trivially on these prime-to-p roots. Thus inertia in E/F cannot be its nontrivial element. It follows that the w_j are pairwise distinct and not conjugate. Since $\varphi_j \in G_\nu$ and $w_j \nmid \ell$, the cyclotomic Frobenius formula gives $\ell^\nu \mid q_{w_j} - 1$. The family is therefore a Taylor–Wiles family and satisfies (PT1).

The detecting set s gives the detection clause of (PT2) for $a = \gamma^{-1}$, and the index (e, g) supplies its asserted equality. If $\ell \le y^2$, then

$$\#J = (t-1)\#s, \qquad \#J + \#s + 1 = t\#s + 1 \le (t+2)y^{20} \le y^{21}.$$

Multiplying by yh proves its cost bound. If $h = 0$, the same cost bound is automatic, without a bound for $\#s$. The initial product estimate proves (PT3), since $\chi(a^{-1}) = u$. The second estimate, and the fact that $u^{-e} - 1$ differs from $u^e - 1$ by a unit, prove (PT5).

Finally fix j and an even cocycle z as in (PT4). Vanishing at the earlier chosen tame generators makes z unramified at their places and their conjugates. Indeed inertia acts trivially on the Tate twist away from ℓ, its wild pro-residue-characteristic subgroup has no nonzero image in an ℓ-primary group, and its pro-ℓ tame quotient is generated topologically by any chosen tame generator; evenness gives the assertion at the conjugate place. Thus z is an even class supported at the places with indices $i \ge j$. Apply item 2 of Proposition 7.6.16 to ψ_j, with its initial family the earlier places of exponent $\mathrm{ty}(j)$ and its final family the places $i \ge j$. The prescribed Frobenius zeros are exactly the hypothesis of (PT4); all final primes avoid T_j. Every term of its reciprocity sum except the jth term is zero, because $\psi_j(\varphi_i) = 0$ for $i > j$. Hence

$$2\psi_j(\varphi_j) z(\widetilde{\tau}_j) = 0$$

for a tame generator normalised over F. The value of z at the fixed chosen tame generator τ_j is an integer multiple of its value at $\widetilde{\tau}_j$: both maps factor through the same finite cyclic pro-ℓ tame quotient. The divisibility $2\psi_j(\varphi_j) \mid \ell^{yh}$ therefore gives $\ell^{yh} z(\tau_j) = 0$. This is (PT4) and completes the proof. □

Proposition 7.6.16. *Let ℓ be a prime, $\nu \geq 0$, E a CM field containing μ_{5040}, x a finite family of ν-split Frobenius data and $e \geq 0$. Write $G_\nu = G_E \cap G_{F,\nu}$.*

1. *Every Kummer map ψ of exponent e off a finite set T is locally constant, and on G_ν it is a homomorphism with $\psi(h^c) = -\psi(h)$ and $\psi(ghg^{-1}) = \chi_{\mathrm{cyc}}(g)^{e+1}\psi(h)$ for $g \in G_E$, $h \in G_\nu$.*
2. *(Reciprocity.) Let T contain the primes of F above ℓ or below x, let $(w_j, \varphi_j, \tau_j)_j$ be a finite family of ν-split Frobenius data above distinct primes of F outside T, with tame generators τ_j normalised over F, and let ψ be a Kummer map of exponent e off T. Then for every $z \in \mathrm{Ev}_{\{w_j\}}(e, \nu)$ that vanishes at the Frobenius elements of x,*

$$\sum_j \psi(\varphi_j) \cdot 2z(\tau_j) = 0.$$

3. *If $\nu > 0$, E has at least four infinite places and the x_i lie above distinct primes of F, there is a finite set T of primes of F containing those above ℓ or below the x_i such that the reductions modulo ℓ of the Kummer maps of exponent e off T, as functions $G_\nu \to \mathbb{F}_\ell$, span a space of dimension greater than the number of the x_i.*

Proof. First note that E/F is unramified at every finite place. If its inertia at a place of residue characteristic p were nontrivial, it would act on E as complex conjugation. This is impossible on the prime-to-p roots of unity in E: conjugation acts nontrivially on μ_3 when $p \neq 3$ and on μ_4 when $p = 3$, whereas inertia fixes them. It follows that κ is unramified outside ℓ, since χ is. At every real place κ is trivial. Also

$$\kappa(G_F) = \chi(G_E).$$

For $\ell = 2$ this image lies in $1 + 16\mathbb{Z}_2$, since E contains μ_{16}. For odd ℓ every closed subgroup of $\mathbb{Z}_\ell^\times$ is procyclic; for $\ell = 2$ the same is true for closed subgroups of $1 + 4\mathbb{Z}_2$. The image of κ on a decomposition group above ℓ is infinite: its restriction to the index-at-most-two subgroup belonging to E is a local cyclotomic character and has open image in $\mathbb{Z}_\ell^\times$.

For item 1, let y be the defining relation. Its restriction to $G_{F,\nu} \cap G_E = G_\nu$ is a homomorphism. Evaluate its character at $1 \in M_e$ and identify $(1/\ell^\nu)\mathbb{Z}/\mathbb{Z}$ with R_ν. This gives the homomorphism assertion for ψ and its local constancy. Equivariance of the relation is

$$y(gvg^{-1})(a) = \chi(g)\, y(v)(\kappa(g)^e a) \qquad (v \in G_\nu,\ g \in G_F).$$

At $g = c$ the scalar is -1, and at $g \in G_E$ it is $\chi(g)^{e+1}$. Evaluation at $a = 1$ proves both asserted transformation laws. When $\nu = 0$ all target groups are zero.

For item 2, it is enough to test the asserted equality after every additive map $f : \mathcal{O}/\ell^\nu \to R_\nu$. These maps are R_ν-linear and separate points: a finite abelian group of exponent dividing ℓ^ν is separated by its characters with values in R_ν. Replace z temporarily by $f \circ z$. Its evenness permits an extension

$$z^+(g) = z(g), \qquad z^+(gc) = z(g) \quad (g \in G_E).$$

The cocycle rule on $G_F = G_E \rtimes \langle c \rangle$ follows directly from the rule on G_E, the identity $z(g^c) = z(g)$, and $\kappa(c) = 1$. We use $2z^+$, rather than assume that z^+ itself vanishes at every complex

conjugation. If c' is any complex conjugation, then $(c')^2 = 1$ and $\kappa(c') = 1$, so the cocycle identity gives $2z^+(c') = 0$.

This extension satisfies all the finite local conditions required in the defining reciprocity relation. Away from ℓ inertia in G_F lies in G_E by the unramified assertion above, so it has the stated unramifiedness. At a decomposition group above ℓ, if $\kappa(g) = 1$ then $g^2 \in G_E$, $\chi(g^2) = 1$, and g^2 belongs to the corresponding decomposition group over E. Thus

$$2z^+(g) = z^+(g^2) = 0$$

by the defining local condition of an even class. At a prime below an initial x_i, the class is unramified, since this prime is outside the final family and outside ℓ. Its value at the specified Frobenius is zero. Inertia and that Frobenius topologically generate the decomposition group, so the cocycle vanishes on the whole group; the same holds for $2z^+$. Therefore the defining relation may be applied to $2z^+$ and to the primes below the final w_j.

Its Frobenius convention is arithmetic, whereas φ_j is geometric. Item 1 gives $\psi(\varphi_j^{-1}) = -\psi(\varphi_j)$, because $\varphi_j \in G_\nu$. The relation, with this common minus sign removed, is exactly

$$\sum_j \psi(\varphi_j)\, 2f(z(\tau_j)) = 0.$$

Separation by the maps f proves the asserted equality for $\mathcal{O}/\ell^\nu$.

We prove item 3 by a finite-level duality count. Let $d = [F : \mathbb{Q}]$, let k be the number of the x_i, and let S_f be the primes of F above ℓ or below the x_i. A prime-norm place of E splits over F: the extension is unramified and an inert place would have residue degree two. Thus these latter primes are distinct, are not above ℓ, and their decomposition groups act trivially on κ mod ℓ^ν.

For every $0 \le m \le \nu$, set

$$A_m = R_m(\kappa^{-e}), \qquad A_m^\vee = \mathrm{Hom}(A_m, \mu_{\ell^m}).$$

After compatible choices of bases, the latter is R_m with character $\chi\kappa^e$. At $m = 0$ all groups below have order one. Let $\mathcal{Z}_m$ be the literal group of cocycles in A_m which are unramified outside S_f, vanish at every complex conjugation, are zero on the whole decomposition groups below x, and vanish on the kernel of κ in decomposition groups above ℓ. It is essential here that these are cocycles, before quotienting by coboundaries.

Let $L_{v,m} \subseteq H^1(F_v, A_m)$ be the cohomological local conditions just specified. At a real place it is zero. Let $\mathcal{Y}_m$ be the dual Selmer group in $H^1(G_{F,S_f\cup S_\infty}, A_m^\vee)$: at each finite $v \in S_f$ impose $L_{v,m}^\perp$ for local Tate duality, and at every real place impose the whole group $H^1(F_v, A_m^\vee)$. All these groups are finite by finite-module Galois duality. We shall prove the exact identity

$$|\mathcal{Y}_m| = |\mathcal{Z}_m|\,|H^0(F, A_m^\vee)|\ell^{m(d+k-1)}. \tag{1}$$

Here are the real-place terms in this identity. Use Theorem A.3.3, with Tate cohomology at the real places, together with the global Euler characteristic of Theorem A.3.5 and the finite local Euler characteristic of Theorem A.3.1. For clarity the order calculation is given explicitly. Write $H^i = H^i(G_{F,S_f\cup S_\infty}, A_m)$, $P^i = \prod_{v\in S_f\cup S_\infty} H^i(F_v, A_m)$ for $i = 1, 2$, and let $\Lambda = \prod_v L_{v,m}$. Let $\mathcal{S}_m$ be the cohomological primal Selmer group. The annihilator identity for the two global localisation images gives

$$\frac{|\mathcal{S}_m|}{|\mathcal{Y}_m|} = \frac{|H^1|\,|\Lambda|}{|\mathrm{Sha}^1(F, A_m^\vee)|\,|P^1|}.$$

Indeed if B is the image of primal localisation, its dual image is $B^\perp$, and $|B^\perp \cap \Lambda^\perp| = |P^1|\,|B \cap \Lambda|/(|B|\,|\Lambda|)$. The perfect pairing between $\mathrm{Sha}^1(F, A_m^\vee)$ and $\mathrm{Sha}^2(F, A_m)$, and the end of the Poitou–Tate sequence, give

$$|\mathrm{Sha}^1(F, A_m^\vee)| = \frac{|H^2|\,|H^0(F, A_m^\vee)|}{|P^2|}.$$

These are the all-place assertions, not assertions with the real summands omitted.

The module A_m is fixed by every real conjugation and F is totally real. Its truncated global Euler characteristic is therefore one: $|H^0|\,|H^2| = |H^1|$. At a real place

$$H^1(F_v, A_m) = A_m[2], \qquad H^2(F_v, A_m) = A_m/2A_m,$$

which have equal order, also when $\ell = 2$. At the finite places local Euler characteristic gives

$$\frac{|P^1|}{|P^2|} = |A_m|^d \prod_{v \in S_f} |H^0(F_v, A_m)|.$$

Consequently

$$\frac{|\mathcal{S}_m|}{|\mathcal{Y}_m|} = \frac{|H^0(F, A_m)|}{|H^0(F, A_m^\vee)|} |A_m|^{-d} \prod_{v \in S_f} \frac{|L_{v,m}|}{|H^0(F_v, A_m)|}. \tag{2}$$

This calculation displays the cancellation of the real Tate groups; none is presumed to vanish at $\ell = 2$.

At a place above ℓ, allowed local cocycles are precisely the inflations from the infinite procyclic group $\kappa(G_{F_v})$. Such a cocycle is determined by its value at a topological generator, and every value in A_m occurs. To verify the latter assertion, write its action as multiplication by b. If $b-1$ is a unit, any desired value is the coboundary of its quotient by $b-1$. Otherwise the finite subgroup of order prime to ℓ acts trivially, and on the pro-ℓ cyclic factor the formula on integer powers is $(1 + b + \cdots + b^{n-1})a$; it extends continuously to that factor for every $a \in A_m$. The assertion follows, and these cocycles lift through every reduction $A_m \to A_{m-1}$. Their group has order $|A_m|$. Since the local coboundary group has order $|A_m|/|H^0(F_v, A_m)|$, we obtain

$$|L_{v,m}| = |H^0(F_v, A_m)| \quad (v \mid \ell).$$

At each prime below x, $L_{v,m} = 0$ and A_m is fixed, so the factor in (2) is $|A_m|^{-1}$.

All global coboundaries belong to $\mathcal{Z}_m$. They vanish at real conjugations and factor through κ above ℓ, and at a prime below x the action on A_m is trivial, so their restriction is zero. They number $|A_m|/|H^0(F, A_m)|$. Substitute $|\mathcal{S}_m| = |\mathcal{Z}_m|\,|H^0(F, A_m)|/|A_m|$ and the just-computed local factors into (2). This proves (1).

We next compare consecutive levels without assuming that arbitrary dual classes lift. Reduction of the primal local condition from m to $m-1$ is surjective on cohomology: above ℓ the preceding one-generator description lifts every allowed cocycle; below x and at the real places the condition is zero. Compatibility of the local cup products therefore implies the following precise assertion. If a class $b \in H^1(G_{F,S_f \cup S_\infty}, A_{m-1}^\vee)$ has image in $\mathcal{Y}_m$ under the injection $A_{m-1}^\vee \hookrightarrow A_m^\vee$, then $b \in \mathcal{Y}_{m-1}$. Indeed every element of $L_{v,m-1}$ lifts to $L_{v,m}$, so its pairing with b is the pairing of that lift with the image of b, and is zero.

Apply the long exact sequence for

$$0 \longrightarrow A_{m-1}^\vee \longrightarrow A_m^\vee \longrightarrow A_1^\vee \longrightarrow 0.$$

Its exactness and the preceding assertion give

$$|\ker(\mathcal{Y}_m \longrightarrow H^1(F, A_1^\vee))| \le |\mathcal{Y}_{m-1}|.$$

No injectivity on H^1 of the first coefficient injection is needed. The coefficient injection $A_{m-1} \hookrightarrow A_m$ does inject the literal cocycle groups $\mathcal{Z}_{m-1} \hookrightarrow \mathcal{Z}_m$, and $H^0(F, A_{m-1}^\vee)$ also injects into $H^0(F, A_m^\vee)$. Dividing the two identities (1) consequently shows that the image of $\mathcal{Y}_m$ in $H^1(F, A_1^\vee)$ has at least

$$\ell^{\,d+k-1}$$

elements. It is an $\mathbb{F}_\ell$-subspace, hence has dimension at least $d + k - 1$.

Take $m = \nu$ and put $U = G_E \cap \ker(\chi \bmod \ell^\nu)$. This subgroup fixes $A_1^\vee$. The quotient G_F/U is generated by two elements: the map

$$G_F/U \longrightarrow \{1, -1\} \times \mathrm{im}(\kappa \bmod \ell^\nu)$$

given by (η, κ) is an isomorphism. Its kernel is U, and it is surjective because c gives $(-1, 1)$ and a generator of the cyclic second factor has a lift in G_E. The second factor is cyclic, including for $\ell = 2$ by the containment in $1 + 16\mathbb{Z}_2$. A cocycle on a two-generated group with values in the one-dimensional space $A_1^\vee$ is determined by two values, so

$$\dim_{\mathbb{F}_\ell} H^1(G_F/U, A_1^\vee) \le 2.$$

Inflation–restriction thus shows that the restrictions to U of the primitive reductions from $\mathcal{Y}_\nu$ have dimension at least $d + k - 3 \ge k + 1$.

It remains to check that these restricted classes really give the relations in the statement. Choose a cocycle representative of a class in $\mathcal{Y}_\nu$. On U the dual action is trivial, so its restriction is a homomorphism, independent of the representative. View it as

$$y : U \longrightarrow \mathrm{Hom}(A_\nu, \mathbb{Q}/\mathbb{Z})$$

and extend it by zero off U. It is locally constant, is unramified outside S_f, and has the equivariance with the ordinary cyclotomic prefactor: this follows either from the cocycle identity or from the dual action $\chi\kappa^e$. To verify reciprocity, take any further finite family of split primes outside S_f and any primal cocycle satisfying the required conditions and unramified outside this family and S_f. Apply the annihilator assertion of the same all-prime global duality, equivalently global cup-product reciprocity as in Theorem A.2.8, to their two global cohomology classes. The contributions at S_f vanish by the dual local conditions, and those at real places vanish because the primal class is zero there. Outside the new family both local classes are unramified, so their pairing is zero by unramified orthogonality. At a new split prime the dual class is unramified; the unramified–tame local pairing is

$$y(\varphi_{\mathrm{arith}})(z(\tau)).$$

Here τ multiplies an ℓ^ν-th root of a uniformiser by the chosen root of unity. This normalisation follows by pairing an unramified character taking the arithmetic Frobenius to $1/\ell^\nu$ with the Kummer class of that uniformiser; bilinearity gives the displayed formula. Reversing the order of the cup product changes every term by the same sign, which does not affect the zero sum. The sum of these terms is therefore zero. This proves all the requirements of a relation off $T = S_f$.

Identify its restriction to G_E with the corresponding Kummer map ψ. Reducing this map modulo ℓ and restricting it to $U = G_\nu$ is precisely the restriction in the preceding dimension estimate. Hence the reductions of the Kummer maps off this finite T span a space of dimension at least $k + 1 > k$. Since T contains the primes above ℓ and below x, this proves item 3 and the proposition. □

7.7 Local loss at the places above ℓ

Ribet's method produces an extension class from a congruence [241, 197, 327, 284, 20, 19]. At the places above ℓ, however, the class is only known to be crystalline up to a loss: the lattice that carries the congruence is crystalline, but the cocycle cut out of it need not satisfy the Bloch–Kato condition [28] on the nose. This section bounds the loss (Corollary 7.7.4): the Ribet cocycles of a lift setting lose at most $r'\,\mathrm{loc}_\ell$, the local term of Ribet's element. The organisation follows [259].

The loss is measured by dual defects of crystalline classes of lattices (Definition 7.2.1), with the crystalline cocycles defined through Colmez's ring $B_{\max}$ [85, 87, 61, 44]. Local Tate duality [295, 201, 225] turns a bound for the dual defect into a bound for the Ribet cocycles (Lemma 7.7.6), and the defect is bounded by a cup exponent: an explicit power of ℓ that makes a cup product of crystalline cocycles a coboundary (Proposition 7.7.13). The idea of the section is to produce cup exponents from Breuil–Kisin modules, in the form of Kisin and of Bhatt, Morrow and Scholze [160, 25]. After its definitions the section has two groups: the first assembles the bound from one place to all places above ℓ and all summands (Proposition 7.7.7, Proposition 7.7.11), and the second proves the bound at one place (Theorem 7.7.12) with the cup exponents behind it.

Definition 7.7.1. Let ℓ be a prime and Γ, j as above.

Kummer charts. A **Kummer chart** for Γ consists of an integer $f \geq 1$, with $\Lambda = W(\mathbb{F}_{\ell^f})$ (where $\mathbb{F}_{\ell^f} \subset \mathcal{O}^\flat_{\mathbb{C}_\ell}$ is the set of solutions of $x^{\ell^f} = x$), an element $\varpi^\flat \in \mathcal{O}^\flat_{\mathbb{C}_\ell}$ with $z = [\varpi^\flat]$ not a unit of A_{inf}, an integer $e \geq 1$, and a Λ-algebra map $\Lambda[[X]] \to A_{\mathrm{inf}}$, $X \mapsto z$, sending $X^e A + \ell$ to ξ times a unit, for a unit power series A; the image of $X^e A + \ell$ is written E. A Kummer chart also carries a subgroup $\Gamma' \subseteq \Gamma$ of index prime to ℓ, containing every g near 1, with $j(\Gamma')$ fixing Λ and $\theta(z)$ and containing every element of G_ℓ that fixes them, and such that for every $l \geq 0$ some $g \in \Gamma'$ has $j(g)z = [\epsilon]^l z$ (ϵ a compatible system of ℓ-power roots of unity in $\mathcal{O}^\flat_{\mathbb{C}_\ell}$). It is a chart **for** Γ if $j(\Gamma)$ fixes Λ pointwise and $\theta(z)$, $ef = [G_\ell : j(\Gamma)]$, the chart is unramified when $j(\Gamma)$ contains the inertia group, and $j(\Gamma)$ contains an element acting as $x \mapsto x^{\ell^f}$ on the residue field of $\overline{\mathbb{Z}}_\ell$. The numbers e and f are the **ramification** and the **residue degree**; the chart is **unramified** if $e = 1$ and $E = z + \ell$; its **different bound** is $d = 0$ if $e = 1$ and $d = v_\ell(e) + 1$ otherwise.

Letters. The **letters** of a chart are the elements of $\mathbb{F}_{\ell^f}^\times$; the **letter Frobenius** is $i \mapsto i^\ell$. A **letter root** is $\zeta \in \mathcal{O}$ with $\zeta^{\ell^f - 1} = 1$; an embedding $\gamma\colon \mathcal{O} \to \mathbb{C}_\ell$ **lies over** the letter i if $\gamma(\zeta) = \theta([i])$. For jump sets U (finite sets $U(\gamma) \subset \mathbb{Z}$, one for each γ), the **letter jump set** is $U_\zeta(i) = \{0\} \cup \bigcup_{\gamma \text{ over } i} U(\gamma)$.

Windows and gaps. For $\eta, b, W \in \mathbb{N}$ and a sign $\varepsilon \in \{\pm 1\}$, a finite set $V \subset \mathbb{Z}$ **fits the windows** $(\eta, \varepsilon, b, W)$ if every $u \in V$ satisfies $|u| \leq \eta$ or $b \leq \varepsilon u \leq b + W$. For a prime q, $n \in \mathbb{N}$ and $b \in \mathbb{Z}$, the **gap condition** $\mathrm{Ng}(q, n, b)$ says that q divides no nonzero integer y with $|y| \leq n$, $|y - b| \leq n$ or $|y + b| \leq n$.

Tame types. For $r, N \in \mathbb{N}$, a set $\mathcal{K}$ of polynomials over $\mathcal{O}$ is of **tame type** (ℓ, r, N) if $X^{e'} - 1 \in \mathcal{K}$ with $e' = \mathrm{lcm}\{\ell^i - 1 : 1 \leq i \leq r\}$, and $\mathcal{K}$ contains the image of a monic $q \in \mathbb{Z}_\ell[X]$ of degree at most N.

Size conditions. Natural numbers $(Q, m, h, G, b, \delta, \eta, W)$ satisfy the **crystalline size conditions** if

(KZ1) $Q > 0$ and $99\,(Q^2 + (W+1)Q + Q + W + m) \leq h$;

(KZ2) $99\,h^3 \leq G$ and $99\,(Gh^3 + G) \leq b$;

(KZ3) $2\log(4b) < m$;

(KZ4) $\delta < \eta$ and $99\,((\eta + W)Q + \eta + h) \le h^3$.

For a lattice L, $h, \mu, \eta \in \mathbb{N}$ and jump sets U, U', L has **few low jumps** (h, μ, η, U, U') if at every γ each negative $u \in U(\gamma) \cup U'(\gamma)$ satisfies $2u \le -h$, and $\sum_{|u| \le \eta} \mathrm{jump}(L, \gamma, u) \le \mu$.

Letters reading thickness. Let k be a Kummer chart for Γ, an index set I with values $\mathrm{lt}(g) \in \mathbb{C}_\ell$ $(g \in I)$, a predicate th (*thick*) and signs $\varepsilon(g)$ on I, $Q, h \in \mathbb{N}$, and functions T (a predicate) and s (a sign) on $\mathbb{C}_\ell$. The letters **read thickness** if: $ef = [G_\ell : j(\Gamma)]$ and $e \le h$; for every g with $\mathrm{th}(g)$ or $Q < \ell$, $\mathrm{th}(g) \Leftrightarrow T(\mathrm{lt}(g))$ and $\varepsilon(g) = s(\mathrm{lt}(g))$; either k is unramified and $\ell \ge 7$, or $\ell \le Q$ and s is constant; and, if $\ell \le Q$, there are no $z \in \mathbb{C}_\ell$ and $a, a' \in [1, \lfloor \log_\ell h^3 \rfloor]$ with $T(z)$, $T(z^{\ell^a})$ and $T(z^{\ell^{a+a'}})$.

Pairing sides. Over a Kummer chart with letter root $\zeta \in \mathcal{O}$, a **pairing side** S consists of a lattice Y that is crystalline over Γ' (admissible along the filter of subsets of Γ containing Γ'), finite jump sets $S(i) \ni 0$ at the letters i containing the jumps of Y at the embeddings over i, a Galois lattice C (the **parameter lattice**) and an $\mathcal{O}$-linear map $\alpha\colon C \to Z_f(Y)$. For a pairing P of the lattices of two sides S, S', $e \in \mathbb{N}$, $c \in C$ and $c' \in C'$, P is a **scaled cup coboundary** at (e, c, c') if the cup product of $\alpha(c)$ and $\ell^e \alpha'(c')$ under P is a cup coboundary. The **Tate dual side** of P has lattice $(Y \otimes Y')^\vee(1)$, parameter lattice $\mathcal{O}$ with $1 \mapsto c_P$, and jump sets $\{0\} \cup \{-u - u' - 1 : u \in S(i), u' \in S'(i)\}$.

Definition 7.7.2. Fix a prime ℓ, Γ and j, and a Kummer chart for Γ with data $f, \Lambda, z, e, E, \Gamma'$ as in Definition 7.7.1; G_ℓ acts on B_{dR}, and $g \in \Gamma'$ acts through $j(g)$. Let $C^\flat$ be the fraction field of $\mathcal{O}^\flat_{\mathbb{C}_\ell}$ and $W(C^\flat)$ its ring of Witt vectors, with Frobenius φ and the action of G_ℓ; $A_{\mathrm{inf}} \subseteq W(C^\flat)$. Put $\tau = [\varepsilon^{1/\ell}] - 1 \in A_{\mathrm{inf}}$, and for $n \in \mathbb{Z}$ write $\mathrm{Fil}^n = t^n B^+_{\mathrm{dR}}$.

(BF1) Lattices with letter jump sets. A **lattice with letter jump sets** over a coefficient ring $\mathcal{O}$ with a letter root $\zeta \in \mathcal{O}$ is a Galois lattice L for Γ over $\mathcal{O}$ (via j) that is crystalline over Γ' with jumps at each embedding $\gamma\colon \mathcal{O} \to \mathbb{C}_\ell$ in a finite set $U(\gamma) \subset \mathbb{Z}$ (that is, of class Cr for the filter of subsets of Γ containing Γ' and the jump sets U), together with finite sets $U(i) \subset \mathbb{Z}$, one for each letter i, such that $U(\gamma) \subseteq U(i)$ for every γ over i. The **multiplicity** of u at i is $\sum_{\gamma \text{ over } i} \mathrm{jump}(L, \gamma, u)$.

(BF2) Ambient module, letter parts. The **ambient module** of L is $W(C^\flat) \otimes_{\mathbb{Z}_\ell} L$, with φ acting as $\varphi \otimes 1$ and $g \in \Gamma$ as $j(g) \otimes g$; these actions are semilinear over A_{inf}. The element ζ acts through L. For a letter i, the **letter-i part** is the A_{inf}-submodule $\{x : \zeta x = [i]x\}$, and the **letter projector** is

$$\mathrm{pr}_i = \frac{1}{\ell^f - 1} \sum_{n=0}^{\ell^f - 2} \left([i]^{-1}\zeta\right)^n,$$

an idempotent onto the letter-i part; the pr_i sum to the identity.

(BF3) Forms. A **form** of L is an A_{inf}-linear map $\lambda\colon W(C^\flat) \otimes L \to B_{\mathrm{dR}}$ with $\lambda(1 \otimes gy) = j(g)\,\lambda(1 \otimes y)$ for all $g \in \Gamma'$ and $y \in L$. It is **crystalline** if there is a $\mathbb{Z}_\ell$-linear map $m\colon L \to B_{\mathrm{max}}$ with $\lambda(1 \otimes y) = m(y)$ in B_{dR} for all y. It is **of type** $u \in \mathbb{Z}$ **at the letter** i if moreover $\lambda(\mathrm{pr}_i(1 \otimes y)) \in \mathrm{Fil}^{-u}$ for all $y \in L$.

(BF4) Chart rings and value fields. The **chart ring** $\mathcal{S}_{\mathrm{ch}} \subseteq A_{\mathrm{inf}}$ is the image of the chart map $\Lambda[[X]] \to A_{\mathrm{inf}}$, $X \mapsto z$. The ring $\mathcal{S}_B$ is the set of $y \in B^+_{\mathrm{max}}$ such that multiplication by y commutes with every $\mathcal{S}_{\mathrm{ch}}$-linear endomorphism of B^+_{max} that maps A_{max} into A_{max}.

For $a \geq 0$ the **value field** $\mathcal{K}_a \subseteq B_{\mathrm{dR}}$ is the subfield generated over the fixed field in $\overline{\mathbb{Q}}_\ell$ of $j(\Gamma')$ by the products $b \cdot \varphi^{-a}(s)$ with $b \in \mathcal{S}_B$ and $s \in \mathcal{S}_{\mathrm{ch}}$ (images in B_{dR}).

(BF5) The modules. Let

$$M(L) = \{x : \tau^n x \in A_{\mathrm{inf}} \otimes L \text{ for some } n \geq 0, \\ \text{and } \lambda(\varphi^{n+1}x) \in B_{\mathrm{dR}}^+ \text{ for all } n \geq 0 \text{ and all forms } \lambda\},$$

an A_{inf}-submodule of the ambient module; for $l \geq 0$, $\varphi^l M(L) = \{x : \varphi^{-l}x \in M(L)\}$. The **Breuil–Kisin module** of L is the $\mathcal{S}_{\mathrm{ch}}$-module

$$N(L) = \{x \in M(L) : \ \lambda(x) \in \mathcal{K}_0 \text{ for every form } \lambda\},$$

and its **localisation** is

$$N_{\mathrm{loc}}(L) = \{x : Px \in M(L) \text{ for some finite product } P \text{ of elements } \varphi^a(E),\ a \geq 0, \\ \text{and } \lambda(x) \in \mathcal{K}_0 \text{ for every form } \lambda\}.$$

For a letter i, the **letter-i part** of an element x is $\mathrm{pr}_i(x)$.

Definition 7.7.3. Fix a Kummer chart for Γ. The constructions (BF2)–(BF5) of Definition 7.7.2 are used for any Galois lattice L with finite sets $U(i)$ of integers at the letters i. For a letter i and $a \geq 0$, $i^{(a)}$ is the letter whose ℓ^a-th power is i (so that φ^a maps the letter-$i^{(a)}$ part to the letter-i part).

(DQ1) Orders. An **exponent function** is a map $o\colon \mathbb{N} \times \mathbb{Z} \to \mathbb{Z}$. Let $M_{\mathrm{loc}}(L)$ be the A_{inf}-module of the x in the ambient module with $Px \in M(L)$ for some finite product P of elements $\varphi^a(E)$, $a \geq 0$. The module of elements **with orders o at the letter i** is

$$\mathfrak{X}_L(i;o) = \Big\{x \in M_{\mathrm{loc}}(L) \text{ in the letter-}i \text{ part} : \ \lambda(\varphi^{-a}x) \in \mathrm{Fil}^{o(a,u)} \\ \text{for all } a \geq 0,\ u \in U(i^{(a)}) \text{ and forms } \lambda \text{ of type } u \text{ at } i^{(a)}\Big\},$$

an A_{inf}-submodule.

(DQ2) Standard orders. For $l \geq 0$ the **standard orders of level l** are $\mathrm{std}_l(a,u) = 0$ for $a < l$ and $\mathrm{std}_l(a,u) = -u$ for $a \geq l$. The **standard part** of level l at i is $\mathfrak{N}_{l,i}(L) = N_{\mathrm{loc}}(L) \cap \mathfrak{X}_L(i;\mathrm{std}_l)$.

(DQ3) Extension of a side and constants. For a pairing side $S = (Y, (S(i)), C, \alpha)$, the **extension** $\tilde{Y}_S$ is the Galois lattice $Y \times C$ with $g(y,c) = (gy + \alpha(c)(g),\ c)$ and the sets $S(i)$ at the letters; the **trivial lattice** is C with the trivial action and the set $\{0\}$ at every letter; π_S is the extension to ambient modules of the projection $\tilde{Y}_S \to C$. For $c \in C$ the **constant** of c at i is $\mathrm{cst}_{S,i}(c) = \mathrm{pr}_i(1 \otimes c)$ in the ambient module of C.

(DQ4) Lift ideals and cokernel killers. For $l, r \geq 0$ the **lift ideal** $J_l(i;r) \subseteq A_{\mathrm{inf}}$ of S is the ideal generated by r and by the $s \in A_{\mathrm{inf}}$ with

$$s \cdot \mathrm{pr}_i(A_{\mathrm{inf}} \otimes C) \subseteq \pi_S\big(\mathfrak{X}_{\tilde{Y}_S}(i;\mathrm{std}_l)\big),$$

where $A_{\mathrm{inf}} \otimes C$ is the A_{inf}-span of the $1 \otimes c$. An element $s \in A_{\mathrm{inf}}$ **kills the cokernel** of S at i if $s \in J_0(i;0)$; for $\kappa, \rho \geq 0$ write $\mathrm{Kill}_S(i;\kappa,\rho)$ if $\ell^\kappa E^\rho$ kills the cokernel of S at i.

Corollary 7.7.4. *Let D, ℓ, ι, ϑ, (O,c), r', t, $n=r'+t$, R, J, J', S, Y, π, $(\rho_x)_{x\in Y}$, ϵ and the classes $\mathcal{Q}_v$ be as in Proposition 7.7.7. Then for all large coefficient rings $\mathcal{O}$: whenever $T,T_0\colon G_E\to M_{r'}(\mathcal{O})$ and $u=(u_x)_{x\in Y}$, $u_x\colon G_E\to M_n(\mathcal{O})$, satisfy the hypotheses there (u_x a lattice in ρ_x, u_π the block lattice of T placed by ϵ, T_0 a lattice in R agreeing with T on G_{A_v} for all $v\mid\ell$), the **loss** $\operatorname{loss}_T=\sum_{v\mid\ell}\operatorname{dd}(\mathcal{Q}_v,L_v(T)^\vee(1))$ satisfies*

1. $\operatorname{cc}(T;u,M)\le\operatorname{loss}_T$ *for every* $M\ge 0$;
2. $\operatorname{nl}(\operatorname{loss}_T)+\sum_{e<t}\operatorname{nl}\operatorname{cc}(\mathcal{O}(-e);u,\nu)\le r'\cdot\operatorname{loc}_\ell$ *for every* $\nu\ge 0$;

in particular $\sum_{i\in\{*,0,\dots,t-1\}}\operatorname{nl}\operatorname{cc}(\operatorname{blk}_T(i);u,M)\le r'\operatorname{loc}_\ell$ *for every* M. *Here* $\operatorname{nl}=v(\varpi)\cdot\operatorname{length}$ *for a uniformiser* ϖ *of* $\mathcal{O}$, $v(\ell)=1$.

Proof. Take $\mathcal{O}$ large for Proposition 7.7.7, and T,T_0,u as in the statement. By Proposition 7.7.7, for every $v\mid\ell$ the class $\mathcal{Q}_v$ contains $L_v(u_x)$ for all $x\in Y$ and $L_v(\operatorname{blk}_T(i))$ for all i, and

$$\sum_i\sum_{v\mid\ell}\operatorname{nl}\operatorname{dd}(\mathcal{Q}_v,L_v(\operatorname{blk}_T(i))^\vee(1))\le r'\operatorname{loc}_\ell. \tag{$*$}$$

For every i and every $M\ge 0$, Lemma 7.7.5 with $\rho=\operatorname{blk}_T(i)$ and the classes $\mathcal{Q}_v$ gives

$$\operatorname{cc}\big(\operatorname{blk}_T(i);u,M\big)\le\sum_{v\mid\ell}\operatorname{dd}\big(\mathcal{Q}_v,L_v(\operatorname{blk}_T(i))^\vee(1)\big).$$

For $i=*$ the right side is loss_T, which is item 1. For $i=e<t$ apply nl (monotone and additive) with $M=\nu$, add $\operatorname{nl}(\operatorname{loss}_T)$, and use $(*)$: this is item 2. The last claim follows from items 1 and 2 with $\nu=M$. □

Lemma 7.7.5. *Let E be a CM field as in Definition 2.3.4, ℓ a prime, $\mathcal{O}$ a coefficient ring, Y a finite set, $u_x\colon G_E\to M_n(\mathcal{O})$ ($x\in Y$) and $\rho\colon G_E\to M_d(\mathcal{O})$ homomorphisms. For every place $v\mid\ell$ of E let $\mathcal{Q}_v=\operatorname{Cr}(F_v,K_v,U_v)$ be a class of Galois lattices for G_{A_v} (via j_v) containing $L_v(u_x)$ for every x and containing $L_v(\rho)$. Then for every $M\ge 0$*

$$\operatorname{cc}(\rho;u,M)\le\sum_{v\mid\ell}\operatorname{dd}\big(\mathcal{Q}_v,L_v(\rho)^\vee(1)\big).$$

Proof. Write $\mathcal{Z}=\mathcal{Z}_u(\rho;\ell^M)$ and, for $v\mid\ell$, let $\mathcal{C}_v$ be the module of $c\colon G_E\to(\mathcal{O}/\ell^M)^d$ whose restriction to G_{A_v} obeys every relation obeyed by all of $Z_f(L_v(\rho))$.

The crystalline relations are the local ones. A relation θ on G_{A_v} extended by zero to $\tilde\theta$ on G_E satisfies $\sum_{g\in G_E}\tilde\theta(g)c(g)=\sum_{g\in G_{A_v}}\theta(g)c(g)$. Hence c obeys every element of $\mathcal{R}_{\mathrm{cris}}(\rho)$ if and only if $c\in\bigcap_{v\mid\ell}\mathcal{C}_v$, and

$$\operatorname{cc}(\rho;u,M)=\operatorname{length}_{\mathcal{O}}\Big(\mathcal{Z}/\mathcal{Z}\cap\textstyle\bigcap_v\mathcal{C}_v\Big).$$

Splitting over the places. The map $\mathcal{Z}/(\mathcal{Z}\cap\bigcap_v\mathcal{C}_v)\to\bigoplus_{v\mid\ell}\mathcal{Z}/(\mathcal{Z}\cap\mathcal{C}_v)$ induced by the quotient maps is injective (its kernel is $\bigcap_v(\mathcal{Z}\cap\mathcal{C}_v)$ modulo itself), and there are finitely many $v\mid\ell$. Length is monotone under injections and additive on finite direct sums (in $\mathbb{N}\cup\{\infty\}$), so

$$\operatorname{cc}(\rho;u,M)\le\sum_{v\mid\ell}\operatorname{length}_{\mathcal{O}}(\mathcal{Z}/(\mathcal{Z}\cap\mathcal{C}_v)).$$

Each place. For $v\mid\ell$ apply Lemma 7.7.6 with $\Gamma=G_{A_v}$, $j=j_v$, $G=G_E$, η the inclusion, $m=M$ and $\mathcal{Q}=\mathcal{Q}_v$: its hypotheses are that $\mathcal{Q}_v$ contains $L_v(u_x)$ and $L_v(\rho)$, and its module $\mathcal{C}$ is $\mathcal{C}_v$. It gives $\operatorname{length}_{\mathcal{O}}(\mathcal{Z}/(\mathcal{Z}\cap\mathcal{C}_v))\le\operatorname{dd}(\mathcal{Q}_v,L_v(\rho)^\vee(1))$. Summing gives the claim. □

Lemma 7.7.6. *Let ℓ be a prime, Γ a topological group with an open embedding $j\colon \Gamma \to G_\ell$, G a group, $\eta\colon \Gamma \to G$ a homomorphism, $\mathcal{O}$ a coefficient ring, Y a finite set, $u_x\colon G \to M_n(\mathcal{O})$ $(x \in Y)$ and $\rho\colon G \to M_d(\mathcal{O})$ homomorphisms, and $m \geq 0$. Let $\mathcal{Q} = \mathrm{InClass}(F, K, U)$ be a class of Galois lattices for Γ containing $\mathcal{O}^n$ with Γ acting by $u_x \circ \eta$ for every x, and containing $L = \mathcal{O}^d$ with Γ acting by $\rho \circ \eta$. Let $\mathcal{C}$ be the module of $c\colon G \to (\mathcal{O}/\ell^m)^d$ such that $c \circ \eta$ obeys every relation $\theta\colon \Gamma \to M_d(\mathcal{O})$ obeyed by all elements of $Z_f(L)$. Then*

$$\mathrm{length}_{\mathcal{O}}\Big(\mathcal{Z}_u(\rho;\ell^m)/\big(\mathcal{Z}_u(\rho;\ell^m)\cap\mathcal{C}\big)\Big) \leq \mathrm{dd}\big(\mathcal{Q}, L^\vee(1)\big).$$

Proof. Put $K_\ell = \overline{\mathbb{Q}}_\ell^{\,j(\Gamma)}$, so that Γ is identified topologically with G_{K_ℓ} for a finite extension $K_\ell/\mathbb{Q}_\ell$. All cohomology in the proof is continuous cohomology for this group. If $m = 0$, the quotient in the statement is zero. Assume $m > 0$ and put $a = \ell^m$ and $L = \mathcal{O}^d$ with its stated action.

By Lemma 7.4.6, the actions and crystalline cocycles of all potentially crystalline lattices here are continuous; their rational representations are de Rham, and the $B_{\max}$ and B_{cris} cocycle conditions agree. The lemma also supplies finite freeness and the rational crystalline-cocycle dimension formula used below.

We construct an actual lift for each Ribet cocycle. Let

$$A = \prod_{x\in Y} M_n(\mathcal{O}), \qquad D(g) = (u_x(g) - 1)_{x\in Y}, \qquad N = \mathrm{span}_{\mathcal{O}}\{D(g) : g \in G\}.$$

Let $w \in \mathcal{Z}_u(\rho; a)$. Its defining relations make the rule

$$f\Big(\sum_g b_g D(g)\Big) = \sum_g b_g w(g)$$

a well-defined $\mathcal{O}$-linear map $N \to L/aL$. The identity $u(h)D(g) = D(hg) - D(h)$ and the cocycle identity for w show that N is stable under left multiplication by $u(h)$ and $f(u(h)v) = \rho(h)f(v)$.

Choose k such that $N \cap a^k A \subseteq aN$. Such a k exists by elementary divisors: in a suitable basis of the finite free module A, write $N = \bigoplus_{i=1}^{s} \varpi^{b_i}\mathcal{O}e_i$, with $b_i \geq 0$ and ϖ a uniformiser; it suffices that $k\, v_\varpi(a) \geq v_\varpi(a) + \max_i b_i$. If $N = 0$, any $k \geq 1$ suffices. Therefore f extends to a map

$$t : Y_w = N + a^k A \longrightarrow L/aL, \qquad t(n + a^k v) = f(n).$$

It is well defined since $f(aN) = 0$, and is equivariant for the left action of G. The module Y_w is finite free and contains $a^k A$. Hence it is a full lattice in $A \otimes \mathbb{Q}_\ell$. Restricted along η, its rational representation is the direct sum of the representations $u_x \circ \eta$, each repeated n times. It lies in $\mathcal{Q}$: direct sums preserve (CY1), (CY2) and (CY3), and replacing a lattice by another full lattice changes neither the period representation, its jump multiplicities, nor its period operators.

The map $b(g) = D(\eta(g)) \in Y_w$ is a cocycle and $t(b(g)) = w(\eta(g))$. The vector $a^k 1 \in a^k A \subseteq Y_w$ satisfies

$$g(a^k 1) - a^k 1 = a^k b(g).$$

Since a is invertible in $B_{\max}$, this exhibits b itself as a coboundary after tensoring with $B_{\max}$. Thus $b \in Z_f(Y_w)$. We have proved that every restriction of a Ribet cocycle is an equivariant image of a crystalline cocycle of a lattice of $\mathcal{Q}$. This construction does not assert that it is the reduction of a cocycle of L.

We next give the finite duality comparison needed for such images. Choose an integral linear functional $f_0 : \mathcal{O} \to \mathbb{Z}_\ell$ for which $(x, y) \mapsto f_0(xy)$ is perfect over $\mathbb{Z}_\ell$. It exists because the inverse

different of the finite local extension $\mathcal{O}[1/\ell]/\mathbb{Q}_\ell$ is a free rank-one $\mathcal{O}$-module: if δ generates it, take $f_0(x) = \mathrm{Tr}(\delta x)$. Evaluation followed by f_0 identifies $L' = L^\vee(1)$ with the $\mathbb{Z}_\ell$-Tate dual of the underlying $\mathbb{Z}_\ell$-lattice of L. Put

$$V = L/aL, \quad V' = L'/aL', \quad A_f = \mathrm{red}\, Z_f(L), \quad A'_f = \mathrm{red}\, Z_f(L'),$$

where the last two modules are modules of continuous cocycles, before quotienting by coboundaries.

These reductions are exact annihilators under the local cup pairing on cocycles. Here are the details, including their sizes. Write $d_0 = \mathrm{rank}_{\mathbb{Z}_\ell} L$ and $n_0 = [K_\ell : \mathbb{Q}_\ell]$. By local cohomological finiteness, Theorem A.3.2 and Theorem A.3.1, $Z^1(K_\ell, L)$ is finitely generated: its quotient by coboundaries is $H^1(K_\ell, L)$, and the coboundaries are an image of L. The module $Z_f(L)$ is a submodule, hence finitely generated and free; it is saturated in the functions $\Gamma \to L$, since division by a nonzero scalar is possible for its period witness. Its reduction therefore has kernel $aZ_f(L)$, and the same assertions hold for L'.

A rational continuous cocycle has bounded image because Γ is compact, so a power of ℓ multiplies it into the integral lattice; its period witness scales by the same power. After rationalising, the quotient of $Z_f(L)$ by coboundaries is $H^1_f(K_\ell, L \otimes \mathbb{Q}_\ell)$, by the period comparison already proved. Bloch–Kato's dimension formula [28], Corollary 3.8.4, gives

$$\mathrm{rank}_{\mathbb{Z}_\ell} Z_f(L) = d_0 + \dim_{\mathbb{Q}_\ell} D_{\mathrm{dR}}(L \otimes \mathbb{Q}_\ell)/\mathrm{Fil}^0.$$

The formula for L' is analogous. For the two Tate-dual de Rham representations the filtration jumps are paired as u and $-u-1$; exactly one of these is negative. Their two de Rham quotient dimensions consequently sum to $n_0 d_0$. Thus

$$|A_f|\,|A'_f| = \ell^{m(2+n_0)d_0} = |V|^{2+n_0}.$$

Rational Bloch–Kato orthogonality [28], Proposition 3.8, makes the cup product of the integral crystalline cocycles zero: its class in $H^2(K_\ell, \mathbb{Z}_\ell(1))$ maps to zero rationally, and this integral group is $\mathbb{Z}_\ell$, hence torsion free. Their reductions are therefore orthogonal.

For clarity, finite Tate duality gives the corresponding size of annihilators on cocycles as well as on classes. Write $B^1(V)$ for finite coboundaries. For any module B of cocycles of V' containing $B^1(V')$, perfect duality on H^1 gives

$$|\mathrm{Ann}(B)|\,|B| = |B^1(V)|\,|B^1(V')|\,|H^1(K_\ell, V)| = |V|^{2+n_0};$$

the last equality uses $|B^1(V)| = |V|/|H^0(K_\ell, V)|$, the analogous identity for V', and the local Euler characteristic formula. Both A_f, A'_f contain all finite coboundaries, by lifting their defining vectors integrally. Their orthogonality and the displayed size identity imply $A_f = \mathrm{Ann}(A'_f)$. This argument is valid at $\ell = 2$ as well. The local duality statements apply to the finite local field K_ℓ; equivalently one may realise K_ℓ as the completion of a number field by approximating a defining polynomial and applying Krasner's lemma.

Let $H = Z_f(L') \cap (L')^{\perp_{\mathcal{Q}}}$ and let $\overline{H}$ be its reduction in A'_f. If a continuous cocycle $s : \Gamma \to V$ has the form $t \circ b$, with $b \in Z_f(Y_0)$, $Y_0 \in \mathcal{Q}$ and $t : Y_0 \to V$ equivariant, then s annihilates $\overline{H}$. Indeed, lift t to an $\mathcal{O}$-linear map $q : Y_0 \to L$, possible since Y_0 is free. Its defect of equivariance is divisible by a. The evaluation form

$$\psi(y \otimes z) = z(q(y)) \quad \text{on } Y_0 \otimes L'$$

therefore satisfies $g\psi - \psi = ac_P(g)$ for an integral cocycle c_P. This cocycle is crystalline, with period witness ψ/a. Together with f_0 these are exactly the data of a pairing in the definition

of cup-orthogonality. Its cup product with b and any element of H is a coboundary by that definition, and is the ordinary evaluation cup product of s with the reduction of that element. This proves the assertion. The same applies to every element of A_f, using $Y_0 = L$ and the reduction map.

Let S be the module of restrictions along η of $\mathcal{Z}_u(\rho; a)$. Its elements have the preceding form by our construction, so $A_f + S \subseteq \mathrm{Ann}(\overline{H})$. Finite duality and $A_f = \mathrm{Ann}(A_f')$ give

$$|S/(S \cap A_f)| \leq |\mathrm{Ann}(\overline{H})/A_f| = |A_f'/\overline{H}| \leq |Z_f(L')/H|.$$

The last inequality follows from the surjective reduction map on these quotients; if the last quotient is infinite the asserted length bound is immediate. All finite modules here are $\mathcal{O}$-modules, so comparison of cardinalities is comparison of $\mathcal{O}$-lengths, dividing logarithms by the logarithm of the residue-field cardinality.

Finally let B be the module of functions $\Gamma \to V$ obeying every relation of $Z_f(L)$. Reductions of its elements obey those relations, so $A_f \subseteq B$. By definition $\mathcal{C}$ is the inverse image of B under restriction along η. The first isomorphism theorem and this inclusion yield

$$\begin{aligned} \mathrm{length}_{\mathcal{O}}(\mathcal{Z}_u(\rho; a)/(\mathcal{Z}_u(\rho; a) \cap \mathcal{C})) &= \mathrm{length}_{\mathcal{O}}(S/(S \cap B)) \\ &\leq \mathrm{length}_{\mathcal{O}}(S/(S \cap A_f)) \\ &\leq \mathrm{length}_{\mathcal{O}}(Z_f(L')/H) = \mathrm{dd}(\mathcal{Q}, L^{\vee}(1)). \end{aligned}$$

This is the required inequality. □

Proposition 7.7.7. *Let D be admissible data, ℓ a prime, $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$, ϑ a twist, and (O, c) a lift setting for ϑ with source rank r' and rank difference t; put $n = r' + t$. Let R be an ℓ-adic representation of rank r', main-summand like with string length t and jumps J; let J' be a function from the embeddings $E \to \mathbb{C}$ to finite multisets of integers and S a set of finite places of E; let Y be a finite set, $\pi \in Y$, and ρ_x $(x \in Y)$ ℓ-adic representations of rank n of Ribet type $(O, c; t, J', S)$; let ϵ be a bijection placing the blocks. For $v \mid \ell$ define the class $\mathcal{Q}_v = \mathrm{Cr}(F_v, K_v, U_v)$ for G_{A_v} by: F_v the trivial filter $\perp$ if $v \mid p_0 p_1$ and $\top$ otherwise; $K_v(s, Q)$ if and only if $v \mid p_0 p_1$ and Q kills s at A_v on every representation of rank n of Ribet type $(O, c; t, J', S)$; $U_v(\gamma_g)$ the set of members of $J'(\sigma_{e_v|_E, g})$.*

Then for all large coefficient rings $\mathcal{O}$ the following holds. Let $T, T_0\colon G_E \to M_{r'}(\mathcal{O})$ and $u_x\colon G_E \to M_n(\mathcal{O})$ $(x \in Y)$ be homomorphisms such that u_x is a lattice in ρ_x, u_π is the block lattice of T with string t placed by ϵ, T_0 is a lattice in R, and $T = T_0$ on G_{A_v} for every $v \mid \ell$. Then for every $v \mid \ell$ the class $\mathcal{Q}_v$ contains $L_v(u_x)$ for every $x \in Y$ and $L_v(\mathrm{blk}_T(i))$ for every $i \in \{*, 0, \ldots, t-1\}$, and

$$\sum_{i \in \{*, 0, \ldots, t-1\}} \sum_{v \mid \ell} \mathrm{nl}\, \mathrm{dd}\Big(\mathcal{Q}_v,\, L_v\big(\mathrm{blk}_T(i)\big)^{\vee}(1)\Big) \leq r' \cdot \mathrm{loc}_\ell.$$

Proof. U_v is well defined. Every $\mathbb{Z}_\ell$-algebra map $\mathcal{O} \to \mathbb{C}_\ell$ is γ_g for some $g \in G_\ell$. By (RT4), ρ_π has the jumps J' at A_v, so for every lattice of ρ_π, $J'(\sigma_{e_v|_E, g})$ lists the jumps of its local lattice at γ_g; two g with the same γ_g therefore give the same multiset.

Large rings. Let $\mathcal{O}_0$ be a coefficient ring above which the conclusion of Proposition 7.7.11 holds for D, ℓ, ι, the charts $(e_v|_E, j_v)$ and the weight system J; J is a main-summand weight system of rank r' and length t by (MS3). Fix $\mathcal{O} \supseteq \mathcal{O}_0$ and T, T_0, u_x as in the statement, and $v \mid \ell$.

Step 1: the lattices $L_v(u_x)$ lie in $\mathcal{Q}_v$. By (RT4) at $v \mid \ell$, ρ_x is of finite type at A_v, so $L_v(u_x)$ is potentially crystalline, which is (CY1) when $F_v = \bot$ (the supremum of $\bot$ and the filter near 1 is the filter near 1); if $v \nmid p_0p_1$, ρ_x is good at A_v, so $L_v(u_x)$ is crystalline, which is (CY1) for $F_v = \top$. (CY2): the jumps of $L_v(u_x)$ at γ_g are listed by $J'(\sigma_{e_v|_E,g})$, whose members form $U_v(\gamma_g)$. (CY3): if $K_v(s,Q)$ holds then Q kills s on every representation of the Ribet type, in particular on ρ_x, and by (RT1) on its lattice u_x.

Step 2: the summands lie in $\mathcal{Q}_v$. Via ϵ, $L_v(u_\pi) = \bigoplus_i L_v(\mathrm{blk}_T(i))$ as Galois lattices for G_{A_v}, and the inclusions and projections are equivariant. (CY1): $B_{\max} \otimes L_v(u_\pi) = \bigoplus_i B_{\max} \otimes L_v(\mathrm{blk}_T(i))$ equivariantly, a period fixed along a filter has fixed components, and the projection of a spanning set spans each summand. (CY2): a γ-semilinear map on a summand extends by zero to the sum, so $\mathrm{jump}(L_v(\mathrm{blk}_T(i)),\gamma,u) \le \mathrm{jump}(L_v(u_\pi),\gamma,u)$, and a jump of a summand lies in $U_v(\gamma)$ by Step 1. (CY3): the $B_{\max}$-linear operator of s on $B_{\max} \otimes L_v(u_\pi)$ (determined by its values on the spanning periods) is the direct sum of those of the summands, so Q kills it only if it kills each. Jump multiplicities are additive over the direct sum for the same reason:

$$\mathrm{jump}(L_v(u_\pi),\gamma,u) = \sum_i \mathrm{jump}(L_v(\mathrm{blk}_T(i)),\gamma,u).$$

Step 3: the hypotheses (i)–(iv) of Theorem 7.7.12 at v, for $L_{\mathrm{main}} = L_v(T)$ and $L_e = L_v(\mathcal{O}(-e))$, $e < t$, with $(F,K,U) = (F_v,K_v,U_v)$ and $(e,j) = (e_v|_E, j_v)$. (i) If $v \mid p_0p_1$, then $t \le t_D$ by (MS5), and Lemma 7.7.8 gives $\ell \in \{p_0,p_1\}$ and that $K_v(s,\cdot)$ is of tame type $(\ell, r_D, (r_D+t_D)r_D)$ for every inertial s. If $v \nmid p_0p_1$, then $F_v = \top$ and K_v holds for no pair. (ii) If $u \in U_v(\gamma_g)$, then u is a member of $J'(\sigma_{e_v|_E,g})$, so $\mathrm{jump}(L_v(u_\pi),\gamma_g,u) \ne 0$, and by the additivity of Step 2 some summand has the jump u at γ_g. (iii) is Lemma 7.7.10, applied to R, T_0 and T. (iv) $\mathrm{rank}_{\mathcal{O}} L_v(T) = r'$; moreover $\mathrm{rank}_{\mathcal{O}} L_v(\mathcal{O}(-e)) = 1$.

Step 4: the sum. By Steps 2 and 3 the families $(L_v(\mathrm{blk}_T(i)))_i$, $v \mid \ell$, with the classes $\mathcal{Q}_v$ satisfy every hypothesis of Proposition 7.7.11 over $\mathcal{O} \supseteq \mathcal{O}_0$, whose conclusion is the displayed bound. Steps 1 and 2 are the membership claims. □

Lemma 7.7.8. *Let D be admissible data, ℓ a prime, $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$, ϑ a twist, (O,c) a lift setting for ϑ with source rank r', $0 \le t \le t_D$, J' a function from the embeddings $E \to \mathbb{C}$ to finite multisets of integers, S a set of finite places of E and $n \ge 1$. Let v be a place of E above ℓ with $v \mid p_0p_1$. Then $\ell \in \{p_0,p_1\}$, and for every coefficient ring $\mathcal{O}$ and every $s \in G_{A_v}$ with $j_v(s)$ inertial, the property $K_v(s,\cdot)$ of $Q \in \mathcal{O}[X]$,*

$$K_v(s,Q) \iff Q \text{ kills } s \text{ at } A_v \text{ on every } R\colon G_E \to \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell) \text{ of Ribet type } (O,c;t,J',S),$$

is of tame type $(\ell,\, r_D,\, (r_D+t_D)\, r_D)$.

Proof. The residue characteristic of v is both ℓ and one of p_0,p_1; hence $\ell = p_i$ for some i. By Lemma 4.2.66, this prime splits completely in E. In particular its residue fields are $\mathbb{F}_\ell$, and exactly one place of each complex-conjugate pair above ℓ is chosen. Indeed the factors of (π_M) in the quadratic imaginary subfield choose one prime above each p_i, whereas $(\bar\pi_M)$ chooses the other.

We first construct a multiset $\mathcal{U}$, depending on the fixed local element and the lift setting but not on the representation, such that

$$\#\mathcal{U} = r' + t, \qquad \forall y \in \mathcal{U}\ \exists\, 1 \le d_y \le r_D : y^{\ell^{d_y}-1} = 1, \tag{1}$$

and its root polynomial kills that element on every representation in the assertion.

Suppose first that v is chosen. Write $P_v = \mathrm{tl}(c, v)$, the scaled label polynomial of Definition 7.5.3, (RT7). It is a monic label of degree r' over $\mathbb{F}_\ell$, with nonzero constant term; scaling its roots preserves these properties. Every root x therefore belongs to $\mathbb{F}_{\ell^{d_x}}^\times$ for some $1 \le d_x \le r'$. Here d_x is the degree of its irreducible factor, which is at most the degree of P_v. Include t further roots equal to 1, obtaining the roots with multiplicity of $P_v(X)(X-1)^t$.

Put $d_* = r'!$. All these roots lie in $\mathbb{F}_{\ell^{d_*}}^\times$. Fix the faithful residue-field character T_v used in the definition of the local type. There is an integer a_{tm} giving the tame exponent of $j_v(s)$ on this finite field: choose a uniformiser π_v, a root $z_v^{\ell^{d_*}-1} = \pi_v$, and write the character value of the residue of $j_v(s)(z_v)/z_v$ as $\exp(2\pi i a_{\mathrm{tm}}/(\ell^{d_*}-1))$. This is possible since the exponent is prime to the residue characteristic and inertia acts on these roots by the corresponding roots of unity. Changing a_{tm} by a multiple of $\ell^{d_*}-1$ has no effect on any root under consideration. Set

$$\mathcal{U} = \big[\iota(T_v(x)^{a_{\mathrm{tm}}}) : P_v(x)(x-1)^t = 0\big],$$

with algebraic multiplicities. The labelled condition (RT3), applied to the Ribet polynomial (RT7), says precisely that

$$\prod_{y \in \mathcal{U}} (X - y) \tag{2}$$

kills s at A_v. The condition holds for every representation of that type, so this is a common polynomial. Its degree is $r'+t$. The order of the image of a root of P_v divides $\ell^{d_x}-1$, because T_v is multiplicative; the added root 1 has this property with $d_x = 1$. This proves (1), since $r' \le r_D$.

For completeness, transport to the unchosen place uses the actual conjugate self-duality, rather than an identification of chosen and unchosen labels. If v is unchosen, apply the preceding construction at $\bar{v}$ to the inertial element $c\, j_v(s)^{-1} c^{-1}$, where c is complex conjugation. The resulting multiset still has (1). The conjugate self-duality (MS1) identifies the representation at the conjugate place with its dual, up to a power of the cyclotomic character. To justify that identification from the trace formulation, work over the algebraically closed characteristic-zero field $\overline{\mathbb{Q}}_\ell$. The Ribet type (RT7), through (RT6) and (RT4), supplies (MS1), including nondegeneracy of the trace pairing on the finite-dimensional matrix span. Item1 of Lemma 7.7.9 therefore makes R semisimple. Conjugation $g \mapsto g^c$ is an automorphism of G_E, so $g \mapsto R(g^c)$ is semisimple. The dual of a simple finite-dimensional representation is simple: the annihilator of a proper nonzero invariant subspace in the dual would be a proper nonzero invariant subspace in the original. Thus duality preserves semisimplicity, as does twisting by a nonzero scalar character. In particular

$$g \longmapsto \chi_{\mathrm{cyc}}(g)^{1-\max(t,1)} \big(R(g^{-1})\big)^{\mathsf{T}}$$

is semisimple. The trace identity of (MS1) is exactly equality of the characters of these last two representations. Item2 of Lemma 7.7.9 identifies them, giving the asserted conjugate duality with its actual cyclotomic twist.

All the representations under consideration are potentially crystalline at both places by (RT4), since these are level primes. Their inertia operators on potentially crystalline periods have finite image. Duality of crystalline periods carries an inertia operator to its inverse transpose. The cyclotomic twist contributes no inertia on these periods: its crystalline period is generated by the usual Tate period and its associated Weil–Deligne inertia is trivial. Consequently the operator of $c\, j_v(s)^{-1} c^{-1}$ at $\bar{v}$ is conjugate to the transpose of the operator of $j_v(s)$ at v. A polynomial kills one if and only if it kills the other. Thus (2) kills at v as well. This reasoning works on every local realization in (RT1); the scalar polynomial and its roots are independent of that realization.

Let

$$e_{\mathrm{tm}} = \operatorname*{lcm}_{1 \le d \le r_D} (\ell^d - 1).$$

By (1), $y^{e_{\mathrm{tm}}} = 1$ for every $y \in \mathcal{U}$. A root of unity of order dividing $\ell^{d_y} - 1$ lies in the unramified extension of $\mathbb{Q}_\ell$ of degree d_y: its reduction is in $\mathbb{F}_{\ell^{d_y}}^{\times}$, and Hensel's lemma lifts that reduction uniquely, since the derivative of $X^{\ell^{d_y}-1} - 1$ is a unit at a root. Hence its minimal polynomial m_y over $\mathbb{Q}_\ell$ belongs to $\mathbb{Z}_\ell[X]$, is monic, and has degree at most d_y. Set

$$Q_{\mathrm{tm}} = \prod_{y \in \mathcal{U}} m_y.$$

It is monic, with degree at most $(r' + t)r_D \le (r_D + t_D)r_D$, and vanishes on $\mathcal{U}$.

Finally, every inertia operator on potentially crystalline periods has finite order: over a finite extension where the representation is crystalline, the open inertia subgroup acts trivially on its period module. In characteristic zero a finite-order operator is semisimple, since $X^N - 1$ has no repeated roots. Because (2) kills it, its eigenvalues belong to the set underlying $\mathcal{U}$. Every polynomial vanishing on that set therefore kills it. Apply this to $X^{e_{\mathrm{tm}}} - 1$ and to the image of Q_{tm} in $\mathcal{O}[X]$. These are exactly the two requirements for tame type $(\ell, r_D, (r_D + t_D)r_D)$. No equality between n and $r' + t$ was used: the common annihilator is supplied by the prescribed type, regardless of the representation's rank. □

Lemma 7.7.9. *Let k be an algebraically closed field of characteristic zero and G a group. All representations below are finite dimensional over k.*

1. *If $\rho : G \to \mathrm{GL}(V)$ has nondegenerate trace pairing $(a, b) \mapsto \mathrm{tr}_V(ab)$ on $A = \mathrm{span}_k \rho(G)$, then V is a semisimple G-module.*
2. *If $\rho : G \to \mathrm{GL}(V)$ and $\sigma : G \to \mathrm{GL}(W)$ are semisimple and $\mathrm{tr}\,\rho(g) = \mathrm{tr}\,\sigma(g)$ for every $g \in G$, then they are isomorphic as G-representations.*

Proof. For every representation, its matrix span is a finite-dimensional algebra with identity: products of group matrices are group matrices. A subspace is stable under this algebra if and only if it is stable under the group.

The trace pairing kills the radical. Let J be the Jacobson radical of A. It is nilpotent by the classical radical theorem and Artin–Wedderburn structure theorem (Jacobson, Basic Algebra II, second edition, 1989). For $a \in J$ and $b \in A$, the element ab belongs to J, so some power of ab is zero. As an endomorphism of V it is nilpotent and has trace zero. Nondegeneracy therefore forces $a = 0$. Hence $J = 0$ and the same classical structure theorem writes A as a finite product of full matrix algebras over k.

Here is the module decomposition explicitly. Let e_i be the central identity of the i-th factor, and $e_{ab}^{(i)}$ its matrix units, with size d_i. Any A-module X decomposes as $\bigoplus_i e_i X$. In $e_i X$ put $X_i = e_{11}^{(i)} X$. Every vector has the unique expression

$$x = \sum_{a=1}^{d_i} e_{a1}^{(i)} x_a, \qquad x_a = e_{1a}^{(i)} x \in X_i.$$

Existence follows from $\sum_a e_{aa}^{(i)} = e_i$ and uniqueness follows by applying each $e_{1a}^{(i)}$. In a basis of X_i this identifies $e_i X$ with $\dim_k X_i$ copies of the standard simple module k^{d_i}. Applying this to V proves item1. For $V = 0$ the conclusion is immediate and no structure theorem for the zero algebra is needed.

Equal traces recover the multiplicities in characteristic zero. For item2, if $V = W = 0$ there is nothing to prove. Otherwise let

$$B = \mathrm{span}_k\{(\rho(g), \sigma(g)) : g \in G\} \subseteq \mathrm{End}_k(V) \times \mathrm{End}_k(W).$$

The B-module $V \oplus W$ is semisimple by hypothesis and the observation in the first paragraph. Its action is faithful by construction. Let J_B be its nilpotent radical. On a simple summand S the subspace $J_B S$ is a submodule. If it were nonzero it would be S, and iteration would give $J_B^a S = S$ for every a, contradicting nilpotence. Thus J_B kills every simple summand and hence kills the faithful module $V \oplus W$. It follows that $J_B = 0$.

Write $B = \prod_i \mathrm{M}_{d_i}(k)$ using the same classical theorem. The explicit matrix-unit decomposition above gives multiplicities m_i and n_i for V and W. The trace identity on group elements extends k-linearly to all of B, since those pairs span B. At the central identity e_i the two traces are $m_i d_i$ and $n_i d_i$. Their equality in a characteristic-zero field implies the equality of integers $m_i = n_i$, since $d_i > 0$. Choosing an isomorphism between the multiplicity spaces in every factor yields a B-module isomorphism $V \simeq W$ and therefore a G-module isomorphism. No assertion of this integer recovery in positive characteristic is used. □

Lemma 7.7.10. *Let D be admissible data, ℓ a prime, $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$, R an ℓ-adic representation of rank r' that is main-summand like with string length t and jumps J, $\mathcal{O}$ a coefficient ring, $T_0\colon G_E \to M_{r'}(\mathcal{O})$ a lattice in R, v a place of E above ℓ, and $T\colon G_E \to M_{r'}(\mathcal{O})$ a homomorphism with $T(g) = T_0(g)$ for all $g \in G_{A_v}$. Then for every $g \in G_\ell$:*

1. *$J(\sigma_{e_v|_E, g})$ lists the jumps of $L_v(T) = L_v(\mathrm{blk}_T(*))$ at γ_g;*
2. *for $0 \le e < t$, $\{e\}$ lists the jumps of $L_v(\mathcal{O}(-e)) = L_v(\mathrm{blk}_T(e))$ at γ_g.*

Proof. Item 1. As T and T_0 agree on G_{A_v}, $L_v(T) = L_v(T_0)$ as Galois lattices for G_{A_v}. By (MS2), part of (MS3), R has the Hodge–Tate jumps J at A_v: along the chart (e_v, j_v), the jumps of the local lattice of a lattice in R at the coefficient embedding γ_g are listed by J at the complex embedding $\iota^{-1} \circ g^{-1} \circ e_v|_E = \sigma_{e_v|_E, g}$. Applied to T_0 this is item 1.

Item 2. Let $L = \mathcal{O}$ with $\Gamma = G_{A_v}$ acting by χ^{-e}, χ the cyclotomic character (through j_v). A γ_g-semilinear $\lambda\colon \mathcal{O} \to \mathbb{C}_\ell$ is $\lambda(x) = \gamma_g(x)\, y$ with $y = \lambda(1)$. As χ takes values in $\mathbb{Z}_\ell^\times$ and γ_g is $\mathbb{Z}_\ell$-linear, the condition $\lambda(\chi(h)^{-e} x) = \chi(h)^{-u}\, h\lambda(x)$ reads $\chi(h)^{-e}\gamma_g(x) y = \chi(h)^{-u} h(\gamma_g(x))\, h(y)$. For h near 1, h fixes the finite extension $\gamma_g(\mathcal{O})[1/\ell]$, so the condition becomes

$$h(y) = \chi(h)^{\,u-e}\, y \qquad \text{for all } h \text{ in an open subgroup } H.$$

Shrink H if necessary so that its image in G_ℓ is an open subgroup fixing the finite coefficient field $\gamma_g(\mathcal{O})[1/\ell]$. Every such subgroup is G_F for a finite extension $F/\mathbb{Q}_\ell$. If $u \neq e$, the displayed equation is

$$\chi(h)^{e-u} h(y) = y \qquad (h \in G_F).$$

Apply Theorem A.3.17(2) with $p = \ell$ and the nonzero integer $j = e - u$: it gives $y = 0$. Thus $\mathrm{jump}(L, \gamma_g, u) = 0$. If $u = e$, apply Theorem A.3.17(1) to G_F: its invariants in $\mathbb{C}_\ell$ are F, since a finite extension is complete. Taking the union over open subgroups contained in the chart and fixing the coefficient field gives $\overline{\mathbb{Q}}_\ell$. Indeed every algebraic element is fixed by such a subgroup after intersection with its open stabilizer. Therefore the solution space is $\overline{\mathbb{Q}}_\ell \cdot \gamma_g$, of dimension 1. Both clauses hold for every prime, including $\ell = 2$, and the exponent $j = e - u$ agrees with the jump convention χ^{-u} in the definition. So $\{e\}$ lists the jumps. □

Proposition 7.7.11. *Let D be admissible data, ℓ a prime and $\iota\colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$ an isomorphism. For every place v of E above ℓ fix an embedding $e_v\colon E \to \overline{\mathbb{Q}}_\ell$ inducing v and an open embedding $j_v\colon \Gamma_v \to G_\ell$ onto the subgroup of elements fixing $e_v(E)$ pointwise. Let J be a main-summand weight system of rank r' and length t', with $1 \le r' \le r$. Then for all large coefficient rings $\mathcal{O}$ the following holds. Suppose that for every $v \mid \ell$ there are Galois lattices $(L_{v,c})_{c \in \{\mathrm{main}\} \sqcup \{0,\dots,t'-1\}}$*

over $\mathcal{O}$ (with $\Gamma = \Gamma_v$) and (F_v, K_v, U_v) satisfying (i)–(iv) of Theorem 7.7.12 for $(e, j) = (e_v, j_v)$, that $\operatorname{rank}_{\mathcal{O}} L_{v,c} = 1$ *for $c < t'$, and that every $L_{v,c}$ lies in* $\mathrm{Cr}(F_v, K_v, U_v)$. *Then*

$$\sum_c \sum_{v \mid \ell} \operatorname{nl} \operatorname{dd}\big(\mathrm{Cr}(F_v, K_v, U_v), L_{v,c}^\vee(1)\big) \le r' \cdot \mathrm{loc}_\ell.$$

Proof. Large rings. For each of the finitely many $v \mid \ell$, Theorem 7.7.12 gives a coefficient ring $\mathcal{O}_v$ above which its conclusion holds at v. The compositum of the finitely many finite Galois extensions of $\mathbb{Q}_\ell$ with rings of integers $\mathcal{O}_v$ is finite Galois; its ring of integers $\mathcal{O}_0$ contains every $\mathcal{O}_v$. Fix $\mathcal{O} \supseteq \mathcal{O}_0$.

Each place. Put $n_v = [G_\ell : j_v(\Gamma_v)]$. Since $j_v(\Gamma_v)$ is the absolute Galois group of the closure E_v of $e_v(E)$, $n_v = [E_v : \mathbb{Q}_\ell]$, and $\sum_{v \mid \ell} n_v = [E : \mathbb{Q}] = 2f$ (E is a CM field with f infinite places). By Theorem 7.7.12 at v, with (iv) and $\operatorname{rank} L_{v,c} = 1$ for $c < t'$,

$$\sum_c \operatorname{nl} \operatorname{dd}\big(\mathrm{Cr}(F_v, K_v, U_v), L_{v,c}^\vee(1)\big) \le n_v \Big(r' \operatorname{db}_\ell + t' \frac{\operatorname{db}_\ell}{t} \Big) \le n_v \, (r' + 1) \operatorname{db}_\ell \le 2 n_v \, r' \operatorname{db}_\ell,$$

using $t' \le t$ and $r' \ge 1$.

Sum over places. Summing over $v \mid \ell$ gives at most $2 \cdot 2f \cdot r' \operatorname{db}_\ell = r' \cdot 4f \operatorname{db}_\ell = r' \operatorname{loc}_\ell$. □

The bound at one place (Theorem 7.7.12) has two cases. At $\ell \in \{p_0, p_1\}$ inertia acts through a tame type, and a cup exponent explicit in the type exists (Proposition 7.7.14). At the other primes the class is purely crystalline, and a Kummer chart whose letters record which embeddings are b-places separates the thick letters, where the jumps are of the size b, from the thin ones (Lemma 7.7.17); the main summand has few low jumps. In both cases the lattices enter through their Tate duals, whose jumps are given by the Hodge–Tate comparison [298, 87]. The cup exponents come from writing a crystalline lattice as a Breuil–Kisin module (Proposition 7.7.16). This is the integral p-adic Hodge theory of [160, 25] (see also [161, 84, 312, 26, 89], and [88] for the Fontaine–Laffaille range), made explicit enough to keep track of every power of ℓ.

Theorem 7.7.12. *Let D be admissible data, ℓ a prime, $\iota \colon \mathbb{C} \to \overline{\mathbb{Q}}_\ell$ an isomorphism, $e \colon E \to \overline{\mathbb{Q}}_\ell$ an embedding, and $j \colon \Gamma \to G_\ell$ an open embedding onto the subgroup of elements fixing $e(E)$ pointwise. Let J be a main-summand weight system of rank r' and length t'. Then for all large coefficient rings $\mathcal{O}$ the following holds. Let (L_c) be Galois lattices over $\mathcal{O}$ indexed by $c \in \{\mathrm{main}\} \sqcup \{0, 1, \dots, t' - 1\}$, and let F, K, U be a filter, a relation and jump sets such that:*

- *(i) either $\ell \in \{p_0, p_1\}$ and, for every inertial s, the set $\{Q : K(s, Q)\}$ is of tame type $(\ell, r, (r + t)r)$; or $F = \top$ and $K = \bot$;*
- *(ii) every $u \in U(\gamma)$ is a jump of some L_c at γ;*
- *(iii) for every $g \in G_\ell$, $J(\sigma_{e,g})$ lists the jumps of L_{main} at $\gamma_g \colon a \mapsto g(a)$, and $\{c\}$ lists the jumps of L_c at γ_g for $c < t'$;*
- *(iv) $\operatorname{rank}_{\mathcal{O}} L_{\mathrm{main}} = r'$.*

Then for every c with $L_c \in \mathrm{Cr}(F, K, U)$,

$$\operatorname{nl} \operatorname{dd}\big(\mathrm{Cr}(F, K, U), L_c^\vee(1)\big) \le [G_\ell : j(\Gamma)] \cdot \operatorname{rank}_{\mathcal{O}} L_c \cdot \frac{\operatorname{db}_\ell}{x_c}, \qquad x_{\mathrm{main}} = 1, \ x_c = t \ (c < t').$$

Proof. Write $n_\Gamma = [G_\ell : j(\Gamma)]$. Fix the index $j_0 \le m$ supplied by (DW1) of Definition 6.6.14. Put

$$\eta = h^2 + 1, \quad W = 4t, \quad \delta_0 = (2j_0 + 1)h - 2t, \quad S(\sigma) = \kappa(\sigma) + \delta_0 = S_{j_0}(\sigma).$$

All these quantities are the actual data quantities. By Lemma 7.7.31, $\delta_0 \ge 0$, the required crystalline size conditions hold, and the tame height and numerical comparisons below hold. By Lemma 7.7.32, choose a coefficient-ring threshold above which a chart, primitive letter root and thickness functions exist for this completion. This choice depends on the fixed data and completion, not on the subsequent lattices. Fix any coefficient ring above that threshold and lattices and class satisfying the statement.

Every coefficient embedding $\gamma : \mathcal{O} \to \mathbb{C}_\ell$ extends to some $g_\gamma \in G_\ell$. Put $\sigma_\gamma = \sigma_{e,g_\gamma}$ and $\varepsilon_\gamma = \mathrm{sg}(\sigma_\gamma)$. The hypotheses (ii)–(iii) imply

$$u \in U(\gamma) \quad \Longrightarrow \quad u \in J(\sigma_\gamma) \text{ or } u = c \text{ for some } 0 \le c < t'. \tag{18}$$

Indeed the jump of a summand is read from its listed multiset. This does not require the representative g_γ to be unique.

We record explicitly the windows and duality used in both cases. A low main jump has $|u| \le 4mh \le h^2$, by Lemma 4.2.67; a character jump is between 0 and $t-1$, also in $[-\eta, \eta]$. A high jump satisfies

$$\kappa_{j_0}(\sigma_\gamma) - t \le -\varepsilon_\gamma u \le \kappa_{j_0}(\sigma_\gamma) + t.$$

This interval is contained in $[S(\sigma_\gamma), S(\sigma_\gamma) + W]$. Thus $U(\gamma)$ fits $(\eta, -\varepsilon_\gamma, S(\sigma_\gamma), W)$. The set $-U(\gamma)-1$ fits the opposite windows $(\eta, \varepsilon_\gamma, S(\sigma_\gamma), W)$. For a low jump this follows from $|u+1| \le h^2 + 1$; for a character it follows from $c + 1 \le t \le \eta$; for a high jump it follows by widening the preceding interval by 1 at each end, which stays inside the displayed far interval because $t \ge 1$.

Fix c for which L_c belongs to the class, and put

$$V_c = L_c^\vee(1), \quad \rho_c = \mathrm{rank}_{\mathcal{O}} L_c, \quad x_c = 1 \ (c = \mathrm{main}), \quad x_c = t \ (c < t').$$

The lattice V_c is in $\mathrm{Cr}(F, K^-, -U - 1)$, with $K^-(s, Q) = K(s^{-1}, Q)$. Here is the admissibility check for the possibly nontrivial filter. Choose a finite spanning family of periods of L_c, each fixed along F and near 1, and intersect their stabilizers. The intersection is an open subgroup, large for both filters. The direct period bridge Lemma 7.4.6 makes the restricted rational representation crystalline in the usual sense. Its dual is crystalline by Theorem A.3.9; a crystalline period basis of the dual is fixed by that same subgroup and spans, so it is admissible along the required filter. The twist is crystalline. The comparison Theorem A.3.11 gives

$$\mathrm{jump}(V_c, \gamma, u) = \mathrm{jump}(L_c, \gamma, -u - 1), \tag{19}$$

because dualizing a $\mathbb{C}_\ell(-v)$-component and twisting by the cyclotomic character produces $\mathbb{C}_\ell(v+1)$, of jump $-v - 1$. Finally the period operator of an inertial element on the twisted dual is the inverse transpose of the operator on L_c; the cyclotomic crystalline period has trivial inertia. Thus a polynomial killing the inverse element on L_c kills the element on V_c. This checks all three class conditions, and the rank of V_c is ρ_c.

Tame case. Let $\ell = p_i$. By Lemma 4.2.66, the chosen completion is $\mathbb{Q}_\ell$; hence j is onto and all $\sigma_{e,g}$ coincide. The sign and the far start in the windows are consequently independent of γ. Apply Proposition 7.7.14(d) to V_c, with

$$(r, N, \eta, W, b) = (r, (r + t)r, h^2 + 1, 4t, S(\sigma_{e,1})).$$

The class and polynomial hypotheses are the duality check above and (i). The strict height inequality is Lemma 7.7.31(2). It gives the cup exponent

$$E_* = 3r^2((r+t)r+1)^2 + 150(\eta + W + 1).$$

By Proposition 7.7.13(a) and Lemma 7.7.31(2), since $1 \le x_c \le t$,

$$\operatorname{nl}\operatorname{dd}(\mathrm{Cr}(F,K,U),V_c) \le n_\Gamma\, 2E_*\,\rho_c \le n_\Gamma\,\rho_c\,\mathrm{db}_\ell/x_c.$$

Crystalline case. Now $F = \top$ and $K = \bot$. For each γ, replace the allowed dual set by its actual jump support:

$$U_c'(\gamma) = \{u \in -U(\gamma) - 1 : \mathrm{jump}(V_c,\gamma,u) \neq 0\}.$$

By (19) it still contains every jump of V_c, and is contained in the opposite windows already checked. Thus $V_c \in \mathrm{Cr}(\top,\bot,U_c')$. This restriction of the dual sets is important: character jumps from other summands are not imposed on the main summand's dual.

The chart from Lemma 7.7.32, restricted to the representatives g_γ, reads precisely the thickness $[\sigma_\gamma] \in \Phi_b$ and signs ε_γ. Its letter is $g_\gamma(\zeta) = \gamma(\zeta)$. Every clause of letters reading thickness therefore survives that restriction. Its thick far start is $b + \delta_0$, and its thin far start is $a/x_1 + \delta_0$, exactly the substitution in Lemma 7.7.31(1).

We check the alternative about low jumps of Proposition 7.7.13(b). If $c = \mathrm{main}$, each main jump has

$$|u| \ge h/2. \tag{20}$$

For low jumps this is $\Delta \le 4|u|$. For high jumps it follows from $|u| \ge \kappa_{j_0}(\sigma) - t \ge h - t \ge h/2$. By (18), a negative member of $U(\gamma)$ must be a main jump and hence satisfies $2u \le -h$. A negative $u \in U_c'(\gamma)$ corresponds by (19) to a nonnegative main jump $-u-1$; (20) gives $2u \le -h$ again. The multiplicity of dual jumps in $[-\eta,\eta]$ is at most the number of original main jumps with $|v| \le \eta + 1 = h^2 + 2 \le 2h^2$. By (DW2) that number is at most $\lfloor r'm/k \rfloor = \lfloor \rho_c m/(kx_c) \rfloor$. Thus the few-low-jump alternative holds with this value of μ.

If $c < t'$, (19) gives the unique dual jump $-c-1$, which lies in $[-\eta,0]$, because $c < t' \le t \le \eta$. Hence the other alternative holds; we may still choose $\mu = \lfloor \rho_c m/(kx_c) \rfloor$, since this alternative imposes no low-jump multiplicity bound.

All hypotheses of Proposition 7.7.13(b) are now established with

$$(Q,m,h,G,b,\delta,\eta,W) = (kt,m,h,a/x_1,b,\delta_0,h^2+1,4t).$$

It follows that the defect is at most

$$n_\Gamma 10^5 \left(\rho_c \left\lfloor \frac{2\lambda_\ell}{kt} \right\rfloor m + \left\lfloor \frac{\rho_c m}{kx_c} \right\rfloor \lambda_\ell\right).$$

Apply Lemma 7.7.31(3) to obtain $n_\Gamma \rho_c\,\mathrm{db}_\ell/x_c$, as required. Both cases use the same originally supplied lattice and class. □

Proposition 7.7.13. *Let ℓ be a prime, $j\colon \Gamma \to G_\ell$ an open embedding, $\mathcal{O}$ a coefficient ring and L a Galois lattice over $\mathcal{O}$; put $n_\Gamma = [G_\ell : j(\Gamma)]$.*

(a) If L is potentially crystalline and e is a cup exponent of L for a class $\mathcal{Q}$, then $\operatorname{nl}\operatorname{dd}(\mathcal{Q},L) \le n_\Gamma \cdot 2e \cdot \mathrm{rank}_{\mathcal{O}} L$.

(b) Let $(Q, m, h, G, b, \delta, \eta, W)$ satisfy (KZ1)–(KZ4), and for h, b put

$$\lambda = v_\ell\big((2b)!\,(\prod_{\max(b-30h^3,0)<a\le b+30h^3} a)^{h^3}\big).$$

Let each embedding $\gamma\colon \mathcal{O} \to \mathbb{C}_\ell$ be thick or thin, with a sign $\varepsilon(\gamma)$; let $b_\gamma = b$ if γ is thick and $b_\gamma = G$ otherwise, and let $U(\gamma)$ fit $(\eta, -\varepsilon(\gamma), b_\gamma + \delta, W)$ and $U'(\gamma)$ fit $(\eta, \varepsilon(\gamma), b_\gamma + \delta, W)$. Let $L \in \mathrm{Cr}(\top, \bot, U')$; let L have few low jumps (h, μ, η, U, U'), or let $U'(\gamma) \subseteq [-\eta, 0]$ for all γ; and let k be a Kummer chart for Γ with a letter root ζ such that the letters read thickness for $(\gamma \mapsto \gamma(\zeta), \mathit{thick}, \varepsilon, Q, h, T, s)$, for some T and s. Then

$$\mathrm{nl}\,\mathrm{dd}\big(\mathrm{Cr}(\top, \bot, U), L\big) \le n_\Gamma \cdot 10^5\Big(\mathrm{rank}_{\mathcal{O}} L \cdot \Big\lfloor \frac{2\lambda}{Q} \Big\rfloor \cdot m + \mu\lambda\Big).$$

Proof. (a). Let K_ℓ be the finite field extension fixed by $j(\Gamma)$, so that Γ is topologically identified with G_{K_ℓ} and $[K_\ell : \mathbb{Q}_\ell] = n_\Gamma$. Apply Lemma 7.4.6 to the actual lattice L. It gives a finite free module $Z_f(L)$ of rank at most

$$(1 + n_\Gamma)\,\mathrm{rank}_{\mathcal{O}} L \le 2n_\Gamma\,\mathrm{rank}_{\mathcal{O}} L.$$

By the cup-exponent hypothesis, $\ell^e Z_f(L) \subseteq Z_f(L) \cap L^{\perp_{\mathcal{Q}}}$. Consequently $Z_f(L)/(Z_f(L) \cap L^{\perp_{\mathcal{Q}}})$ is a quotient of $Z_f(L)/\ell^e Z_f(L)$. The latter is isomorphic to $(\mathcal{O}/\ell^e)^{\mathrm{rank}_{\mathcal{O}} Z_f(L)}$ and has normalised length $e\,\mathrm{rank}_{\mathcal{O}} Z_f(L)$, since $\mathrm{nl}(\mathcal{O}/\ell) = 1$. Monotonicity of length under quotients gives the claimed bound, including $e = 0$ and rank zero.

(b). Write $\rho = \mathrm{rank}_{\mathcal{O}} L$,

$$v_0 = \lambda, \qquad K_0 = \Big\lfloor \frac{2v_0}{Q} \Big\rfloor, \qquad J_0 = \lfloor \log_\ell h^3 \rfloor.$$

We use Proposition 7.7.14; its hypotheses are checked below. Two elementary facts about the actual integer defining v_0 are useful:

$$2b < \ell(v_0 + 1), \qquad 2v_0 < (K_0 + 1)Q. \tag{5}$$

The first follows from $v_\ell((2b)!) \ge \lfloor 2b/\ell \rfloor$, the second from division with remainder. Also, if a positive integer in $(b-30h^3, b+30h^3]$ is divisible by ℓ, then $v_0 \ge h^3$, because that product occurs to the power h^3.

Here and below the four size conditions imply

$$h \ge 99Q^2, \quad m \le h/99, \quad \eta + W \le h^3/(99Q), \quad \delta < \eta, \quad G \ge 99h^3, \quad b \ge 99G(h^3 + 1). \tag{6}$$

In particular $h \ge 99$, $\eta \ge 1$, $m \ge 1$, $\eta \le G$, and $\delta + W \le G$. For each integer $1 \le H \le 4b$,

$$\lfloor \log_\ell H \rfloor \le \frac{\log(4b)}{\log \ell} \le 2\log(4b) < m. \tag{7}$$

We used $\log \ell \ge \log 2 > 1/2$.

We transfer the jump sets from embeddings to letters without assuming thickness is read at a thin embedding when $\ell \le Q$. If a letter receives a jump from a thick embedding, the definition of letters reading thickness determines its thick label and sign. If $\ell > Q$, it determines both for every embedding over that letter. When $\ell \le Q$, a jump from a thin embedding, irrespective of its sign, belongs to $[-2G, 2G]$: its low part has radius $\eta \le G$, and its far part has absolute value

at most $G+\delta+W \le 2G$. Thus the two letter jump sets fit the required opposite windows with low radius $2G$ for $\ell \le Q$, and with the original radius η for $\ell > Q$. The extra root 0 in a letter jump set always belongs to its low window. Put $\beta_i = b+\delta$ at a thick letter and $G+\delta$ otherwise.

Small primes, $\ell \le Q$. In this case $K_0 \ge 1$ and

$$2(b+\delta) < h^2 K_0. \tag{8}$$

Here is a direct check. If $K_0 = 0$, then (5) gives $2b < Q(Q/2+1) \le 3Q^2/2$, contrary to (6). For $K_0 \ge 1$, (5) gives $\lambda < K_0 Q$, hence $2b < Q(K_0 Q+1) \le 2Q^2 K_0$. Thus $b < Q^2 K_0$. Also $\delta < b/2$ by (6), so $2(b+\delta) < 3b < 3Q^2 K_0 \le h^2 K_0$, proving (8).

Apply the sparse-letter assertion Proposition 7.7.14(c) with low radius $2G$, far width W, thick and thin starts $b+\delta, G+\delta$, gap length J_0, approximation parameter $2K_0$, and final auxiliary parameter K_0. We verify its numerical hypotheses. Since $\ell^{J_0} \le h^3 < \ell^{J_0+1}$, $J_0 \ge 1$, and (6) gives

$$10\ell^{J_0}(2G) \le 20Gh^3 \le b+\delta, \qquad 8e \le 8h \le h^3 < \ell^{J_0+1}.$$

The first is used in the unramified alternative, and the second in the constant-sign alternative; precisely one of those alternatives is supplied by letters reading thickness. Its same definition supplies the absence of three thick letters with both gaps between 1 and J_0. The depth inequality follows from (8):

$$2e(b+\delta+10G) \le 4h(b+\delta) < 2h^3 K_0 < \ell^{J_0+1}(2K_0).$$

For the remaining cost inequality, the chart's different bound d_{ch} is at most $\lfloor \log_\ell e \rfloor + 1$, or is zero. By (7), $J_0 < m$ and $d_{\mathrm{ch}} \le m$; hence $J_0 + 1 + d_{\mathrm{ch}} \le 2m \le h$. The integer $2(b+\delta+10G)$ is at most $4b$ by (6), so its logarithm in (7) is at most $m \le hG$. Therefore

$$20(J_0+1+d_{\mathrm{ch}})(2G) + \lfloor \log_\ell 2(b+\delta+10G) \rfloor \le 41Gh < K_0.$$

The last inequality follows from $h^2 K_0 > 2b \ge 198Gh^3$. Also $G+\delta+W \le 2G$, as required for the thin windows. The resulting cup exponent is at most

$$10^3\big(2K_0 + (J_0+1)K_0\big) \le 10^4 K_0(J_0+1) \le 10^4 K_0 m. \tag{9}$$

Large primes with large loss, $\ell > Q$ and $v_0 \ge h^3$. The chart is unramified and $\ell \ge 7$, by letters reading thickness. Apply Proposition 7.7.14(b) with thick and thin starts $b+\delta, G+\delta$, width W, low radius η, polynomial parameter K_0, and $W' = W + 4\eta$. For clarity the required inequalities follow as follows. We have $K_0 \ge 1$, $v_0 < K_0 Q$, and

$$K_0 > 2h^3/Q - 1, \qquad W + 4\eta \le 4h^3/(99Q) \le K_0.$$

By (5) and $Q+1 \le \ell$, $b < \ell(K_0 Q+1)/2 \le K_0 \ell^2/2$. Further $\delta \le \eta \le h^3/(99Q) \le v_0/(99Q) < K_0/99$, so $b+\delta < K_0\ell^2$. Similarly

$$2G \le \frac{2b}{99h^3} < \frac{\ell(v_0+1)}{99h^3} \le K_0\ell/99, \qquad 2\delta < 2K_0/99,$$

where $Q+1 \le h^3$ was used in the middle bound. Hence $2(G+\delta) < K_0\ell$. Positivity and ordering of the two starts are immediate from (6). Finally $2(b+\delta+W+4\eta) \le 4b$, again by (6). Its logarithm is at most $m-1$ by (7), so the cup exponent from (b) is bounded by

$$10^4\big(K_0 + \lfloor \log_\ell 2(b+\delta+W+4\eta) \rfloor\big) \le 10^4(K_0+m-1) \le 10^4 K_0 m. \tag{10}$$

Here $(K_0-1)(m-1) \ge 0$.

In either case (9) or (10), part (a) gives

$$\operatorname{nl}\operatorname{dd} \le 2n_\Gamma \rho\, 10^4 K_0 m \le n_\Gamma 10^5(\rho K_0 m + \mu v_0),$$

which is the desired inequality.

Large primes with small loss, $\ell > Q$ and $v_0 < h^3$. Set $a_0 = 2(v_0+1)$ and $R_0 = 6(a_0+\eta+W)$. No positive multiple of ℓ lies in $(b-30h^3, b+30h^3]$, by the observation following (5). Moreover

$$\ell > 2b/h^3 \ge 198G, \quad R_0 < 13h^3, \quad \delta + R_0 < 30h^3. \tag{11}$$

Indeed $v_0 + 1 \le h^3$ and (6) apply. Thus ℓ divides no nonzero integer in the low window of radius R_0, or within R_0 of either $\pm(G+\delta)$, since all their absolute values are $< \ell$. A multiple within R_0 of $\pm(b+\delta)$ would have positive absolute value in the prohibited product interval, by $\delta + R_0 < 30h^3$. This proves the gap condition at every letter.

The height and separation requirements in Proposition 7.7.14(a) also hold:

$$\beta_i + W + \eta \le (\ell-3)a_0, \qquad R_0 < \beta_i.$$

For the first, (5) gives $b < \ell a_0/2$, whereas $\delta + W + \eta + 3a_0 < 7h^3 < G < \ell a_0/2$, by (6), (11) and $a_0 \ge 2$. The second follows from $R_0 < 13h^3 < G$. The chart is unramified with $\ell \ge 7$, and $\eta \ge 1$, so all hypotheses of that assertion have now been checked.

If $U'(\gamma) \subseteq [-\eta, 0]$ for all γ, its vanishing conclusion gives the result immediately. Otherwise use the few-low-jump alternative. If $v_0 < \lfloor h/5 \rfloor$, then $2a_0 = 4(v_0+1) < h$; no negative allowed jump can lie in $[-a_0, 0)$, since such a jump would satisfy both $2u \le -h$ and $2u \ge -2a_0 > -h$. Again the defect vanishes.

It remains that $v_0 \ge \lfloor h/5 \rfloor$ and the few-low-jump condition holds. In particular $v_0 \ge 1$ and $a_0 + 1 = 2v_0 + 3 \le 6v_0$. From $h \ge 99Q(W+2)$ in (KZ1) we have $v_0 \ge 19Q(W+2)$, whence $W + 1 \le K_0$. The length conclusion of Proposition 7.7.14(a) and the assumed low-jump count now give

$$\operatorname{dd} \le 11 f_{\mathrm{ch}}\big(\mu(a_0+1) + \rho(W+1)\big)\operatorname{length}_{\mathcal{O}}(\mathcal{O}/\ell).$$

Here $f_{\mathrm{ch}} = n_\Gamma$, since the chart is unramified and its degree is n_Γ. Taking normalised length, using $\operatorname{nl}(\mathcal{O}/\ell) = 1$, $m \ge 1$, and the two preceding inequalities yields

$$\operatorname{nl}\operatorname{dd} \le 11 n_\Gamma(6\mu v_0 + \rho K_0) \le 10^5 n_\Gamma(\mu v_0 + \rho K_0 m).$$

This completes all three branches and proves (b). □

Proposition 7.7.14. *Let ℓ be a prime, Γ a topological group with an open embedding $j\colon \Gamma \to G_\ell$, $\mathcal{O}$ a coefficient ring, L a Galois lattice over $\mathcal{O}$, and U, U' jump sets. In (a)–(c), k is a Kummer chart for Γ with letter root $\zeta \in \mathcal{O}$, and $L \in \mathrm{Cr}(\top, \bot, U')$; write $\mathcal{Q} = \mathrm{Cr}(\top, \bot, U)$.*

(a) (Unramified, few low jumps.) Let k be unramified, $\ell \ge 5$, $\eta \ge 1$, $a, W \in \mathbb{N}$, and at each letter i let $b_i \in \mathbb{N}$ and $\varepsilon_i = \pm 1$ with $b_i + W + \eta \le (\ell-3)a$, $6(a+\eta+W) < b_i$, $\mathrm{Ng}(\ell, 6(a+\eta+W), b_i)$, $U_\zeta(i)$ fitting $(\eta, -\varepsilon_i, b_i, W)$ and $U'_\zeta(i)$ fitting $(\eta, \varepsilon_i, b_i, W)$. If no $u \in U(\gamma) \cup U'(\gamma)$ lies in $[-a, 0)$ for any γ, or $U'(\gamma) \subseteq [-\eta, 0]$ for all γ, then $\operatorname{dd}(\mathcal{Q}, L) = 0$. If $\sum_{|u| \le \eta} \mathrm{jump}(L, \gamma, u) \le \mu$ for all γ, then

$$\operatorname{dd}(\mathcal{Q}, L) \le 11 f\big(\mu(a+1) + \operatorname{rank}_{\mathcal{O}} L \cdot (W+1)\big) \cdot \operatorname{length}_{\mathcal{O}}(\mathcal{O}/\ell).$$

(b) (Any pattern.) Let k be unramified, $\ell \ge 7$, $\eta \ge 1$, and let T be a predicate on letters, $0 < G \le b$, $V + 4\eta \le W' \le K$, $b < K\ell^2$, $2G < K\ell$. If at each letter i, with $b_i = b$ for $T(i)$ and $b_i = G$ otherwise, $U_\zeta(i)$ fits $(\eta, -\varepsilon_i, b_i, V)$ and $U'_\zeta(i)$ fits $(\eta, \varepsilon_i, b_i, V)$, then $10^4(K + \lfloor \log_\ell 2(b+W') \rfloor)$ is a cup exponent of L for $\mathcal{Q}$.

(c) *(Sparse thick letters, any ramification.) Let $\eta \geq 1$, T, b_i, ε_i and the windows be as in (b), with $G + V \leq \eta$ and $J \geq 1$; let no three letters with T follow one another along the letter Frobenius with both gaps in $[1, J]$; let either k be unramified, $\ell \geq 7$ and $10\ell^J \eta \leq b$, or ε be constant and $8e \leq \ell^{J+1}$; and let $2e(b+5\eta) \leq \ell^{J+1}\delta$ and $20(J+1+d)\eta + \lfloor \log_\ell 2(b+5\eta) \rfloor \leq X$. Then $10^3(\delta + (J+1)X)$ is a cup exponent of L for $\mathcal{Q}$.*

(d) *(Tame types.) Let j be surjective, F a filter on Γ, K a relation with $K(s, \cdot)$ of tame type (ℓ, r, N) for every inertial s, and $L \in \mathrm{Cr}(F, K^-, U')$, where $K^-(s, Q) = K(s^{-1}, Q)$. Let $\varepsilon = \pm 1$ and $\eta, W, b \in \mathbb{N}$ with $U(\gamma)$ fitting $(\eta, -\varepsilon, b, W)$ and $U'(\gamma)$ fitting $(\eta, \varepsilon, b, W)$ for all γ, and $\ell > b + 6(W + \eta) + r^2(N+1)^2 + 2$. Then $3r^2(N+1)^2 + 150(\eta + W + 1)$ is a cup exponent of L for $\mathrm{Cr}(F, K, U)$.*

Proof. Write $p = \ell$.

From sides to the stated orthogonal module. By Lemma 7.4.6, $Z_f(L)$ is finite free and every crystalline cocycle is continuous. Regard L as a side with parameter lattice $Z_f(L)$, trivial action on that parameter, and cocycle map the identity. Its letter jump sets are $U'_\zeta(i)$. For every Y in the comparison class use the analogous universal side of Y. A pairing of these sides is precisely a pairing of Y, L in Definition 7.2.1; the additional third side is its stated Tate dual side. Consequently the assertion that every such pairing and every pair of parameters has a scaled cup coboundary at exponent h says exactly

$$p^h Z_f(L) \subseteq L^{\perp_{\mathcal{Q}}}. \tag{1}$$

The topology here is the given one; the continuous cochains supplied by the side results apply to every topology making j an open embedding. Thus no passage from algebraic to continuous cohomology is implicit in (1).

In (a), all jumps of the two sides and of the third side are at most $b_i + W + \eta \leq (p-3)a$. For the third side use $-u-v-1$: opposite far windows cannot both contribute a large negative jump, and direct separation into low–low, low–far and far–far gives this bound, since $b_i > 6(a + \eta + W) \geq \eta$. Hence Proposition 7.7.15(3) supplies E^a for all three cokernels. The small-negative-jump or nonpositive condition passes to letter jump sets; the added jump zero causes no problem. Apply Proposition 7.7.29(1) with $\kappa = 0$ and $d = 0$. It gives cup exponent zero, and (1) proves that the dual-defect quotient is zero.

For the length assertion let d_i be the number of embeddings of $\mathcal{O}$ over letter i, let $r_L = \mathrm{rank}_{\mathcal{O}} L$, and apply Proposition 7.7.29(2) to the universal side of L with

$$n_i = f d_i \mu, \qquad r_i = f d_i r_L.$$

These are valid bounds because actual letter multiplicities sum the multiplicities over precisely those embeddings, and the full jump multiset at each embedding has cardinality r_L. It gives one $\mathbb{Z}_p$-submodule $V \subseteq Z_f(L)$, chosen independently of all opposite sides and pairings, of colength at most

$$11 f\big(\mu(a+1) + r_L(W+1)\big) \sum_i d_i.$$

Uniformity gives $V \subseteq Z_f(L) \cap L^{\perp_{\mathcal{Q}}}$ even though V need not be $\mathcal{O}$-linear. Distinct letters have distinct $\theta([i])$, since their Teichmüller difference is a unit. Each embedding belongs to at most one letter, whence $\sum_i d_i \leq \mathrm{rank}_{\mathbb{Z}_p} \mathcal{O}$. If $f_{\mathcal{O}}$ is the residue degree of $\mathcal{O}$, a composition series gives $\mathrm{length}_{\mathbb{Z}_p} M = f_{\mathcal{O}} \,\mathrm{length}_{\mathcal{O}} M$ for any finite-length $\mathcal{O}$-module M, and $\mathrm{rank}_{\mathbb{Z}_p} \mathcal{O} = f_{\mathcal{O}} \,\mathrm{length}_{\mathcal{O}}(\mathcal{O}/p)$. Divide the resulting bound by $f_{\mathcal{O}} > 0$. This proves exactly the length bound in (a), including finiteness.

For (b) and (c), choose these universal sides and apply respectively the arbitrary-pattern and sparse-thick assertions of Proposition 7.7.27. Every hypothesis is precisely the corresponding hypothesis on the letter jump sets in the present statement. Formula (1) then gives the indicated cup exponents with the unchanged constants 10^4 and 10^3.

The tame chart and crystallinity over its subgroup. We give the additional argument for (d); no unramified-chart reduction is used. Put

$$e_0 = \operatorname{lcm}_{1\le i\le r}(p^i-1), \qquad m = r^2, \qquad \kappa = r^2(N+1)^2, \qquad n = b + 6(W+\eta). \tag{2}$$

The empty least common multiple is one. We have $r \le \kappa < p$, with the first inequality also valid at $r = 0$. Thus $f_0 = r!$ is positive and prime to p, and $e_0 \mid p^{f_0} - 1$. Moreover

$$e_0 \le \prod_{i=1}^{r}(p^i - 1) \le p^{r^2} = p^m, \tag{3}$$

including $r = 0$.

Identify Γ with $G_{\mathbb{Q}_p}$ by the surjective open embedding j. Choose $\varpi^{e_0} = p$ and the unramified extension of degree f_0, which contains μ_{e_0}. The subgroup fixing its constants and ϖ is open and normal of index prime to p: the associated splitting field of $X^{e_0} - p$ has degree dividing $e_0 f_0$, and both factors are prime to p. Use a compatible tower of p-power roots of ϖ to obtain $z = [\varpi^\flat]$. Put $E = p - z^{e_0}$. It lies in $\ker\theta = \xi A_{\mathrm{inf}}$. In the tilt valuation normalized by $v(\bar{\xi}) = 1$, one has $v(\bar{z}) = 1/e_0$, so the quotient $E/\xi \in A_{\mathrm{inf}}$ has reduction of valuation zero and is a unit. Thus this very E is associated to ξ. The map $\Lambda[[X]] \to A_{\mathrm{inf}}$, $X \mapsto z$, converges in the (p,z)-adic topology; it is injective by reduction modulo p, where the first nonzero series term has strictly smaller valuation than all later terms. It gives the required actual chart with $E = p + z^{e_0}(-1)$. Its stabilizer subgroup just chosen gives the auxiliary Γ' of the chart. The required automorphisms $z \mapsto [\epsilon]^h z$ exist in that subgroup: at each finite level the polynomials $X^{e_0 p^a} - p$ are Eisenstein over the maximal unramified extension, so inertia acts transitively on their roots; the compatible nonempty finite fibers give an automorphism on the inverse limit. The same argument with a primitive e_0-th root in the unramified constants gives an inertial s satisfying

$$sz = \xi z, \qquad \xi \in \Lambda^\times, \quad \bar{\xi} \text{ primitive of order } e_0, \qquad s^h z = \xi^h z. \tag{4}$$

Inertia fixes Λ. Normality holds because the splitting field already contains all e_0-th roots of unity. This is the required tame chart; its different bound is $d = 0$ if $e_0 = 1$ and $d = 1$ otherwise, since $p \nmid e_0$. We may take the letter root in $\mathcal{O}$ to be 1; no enlargement of the coefficient ring is required.

Every lattice in either class is potentially crystalline. The polynomial $X^{e_0} - 1$ allowed at every inertial element says that its inertial period operators have exponent dividing e_0. These operators form a representation of inertia with open kernel: choose a finite extension over which the representation is crystalline, and use its finite-dimensional crystalline periods. Wild inertia is pro-p, so its finite image is trivial, because its exponent divides the prime-to-p integer e_0. Tame inertia is procyclic, and an exponent-e_0 image factors through its cyclic quotient of order e_0. The inertia stabilizer of $\varpi = p^{1/e_0}$ is exactly the kernel of that quotient: over the maximal unramified field the extension $X^{e_0} - p$ is totally tamely ramified of degree e_0, and its automorphisms multiply ϖ by μ_{e_0}. Hence the period inertia is trivial on the inertia of Γ'.

To identify this with the classical crystalline criterion, choose a finite extension over which the representation is crystalline. The canonical $B_{\max}$ comparison with B_{cris} from Lemma 7.4.6 identifies these period inertia operators with the inertia action on D_{pst}, after scalar extension: both act on the same spanning crystalline periods, so they agree. Potential crystallinity gives

monodromy zero. Therefore Theorem 7.1.10(2) gives crystallinity over the finite fixed field of Γ'. The original jump sets are unchanged. This applies to K and K^-, since inversion preserves inertia. We may consequently use universal sides on this same tame chart for every $Y \in \mathrm{Cr}(F, K, U)$ and for L.

A tame polynomial supplies a pure-power killer. We prove the needed quantitative fact rather than assuming it from the tame type. Let a side have all jumps at most n, and let a monic $q \in \mathbb{Z}_p[X]$ kill the inertial period operator β_s on its lattice, with $\deg q = h$. Suppose

$$e_0 \le p^m, \qquad m(h+1) \le \kappa, \qquad n + \kappa + 2 < p. \tag{5}$$

Then p^κ kills its cokernel at every letter.

First $Q = q(X)(X-1)$ kills the period operator on the cocycle extension. Indeed the operator on the trivial parameter quotient is one, so $\beta_s - 1$ maps into the original lattice, on which $q(\beta_s) = 0$. The exactness used here is exactness of tensoring the split underlying lattice sequence, with its triangular action.

We next prove the divisibility that makes most lowering steps free. For x in the actual canonical N of that extension,

$$Q(s)x \in zM. \tag{6}$$

Normality of Γ' makes the conjugate $\mu_h(y) = s^{-h}\mu(s^h y)$ of each crystalline form another crystalline form. Its values on the lattice come from the conjugate $B_{\max}$-linear functional. On a potentially crystalline period vector the identity $\ell_1 \beta_s^h = \ell_{s^h}$ holds for these functionals: the usual semilinear action and the linear period action differ only by the action on a scalar fixed near one; such a scalar lies in a finite unramified field and is fixed by inertia. Check on the spanning period vectors and extend $B_{\max}$-linearly. Thus $Q(\beta_s) = 0$ gives $\sum_h Q_h \mu_h = 0$ on the lattice and then on its rational ambient span, which contains M. In particular

$$\mu(Q(s)x) = \sum_h Q_h\big(s^h \mu_h(x) - \mu_h(x)\big). \tag{7}$$

The uniform canonical N criterion of Proposition 7.7.16, item3(b), supplies one exponent b_0 clearing the crystalline-form values into $\mathcal{S}_B$. Use the actual scalar Galois law of Lemma 7.7.22, item7: every inertial s^h fixes Λ, so

$$z \mid s^h v - v \quad (v \in \mathcal{S}_B) \qquad \text{in } B^+_{\max}.$$

No stability of $\mathcal{S}_B$ under s is required. Clearing the two E^{b_0} denominators in a difference gives

$$E^{2b_0}\big(s^h \mu_h(x) - \mu_h(x)\big) \in zB^+_{\max}.$$

Here $s^h E/E$ is a unit of A_{inf}; its difference from one is divisible by z: power-series subtraction first gives $z \mid s^h E - E = E(s^h E/E - 1)$, and Lemma 7.7.30, with $m = 0, n = 1, h = 1$, cancels the factor E. This verifies the clearing assertion by subtraction of the two fractions. Equation(7) gives the same assertion for every crystalline form on $Q(s)x$. The scalar cancellation premise of the canonical divisibility criterion is precisely Lemma 7.7.30, with powers $m = 0, n = 1$. Normality of Γ' gives $Q(s)x \in M$ by canonical stability. Apply Proposition 7.7.16, item2(d), with divisor z, to obtain (6). Both divisibility and cancellation take place in the actual $B^+_{\max}$, not merely in its de Rham embedding.

Let J_i be the lift ideal with modulus $r_0 = p^{\kappa+1}$. If $p^t z^{k+1} \in J_i$, lift $(p^t z^{k+1} - r_0 u)\mathrm{cst}_i(c)$ to a canonical vector x, for all parameters c, with one common $u \in \mathfrak{S}$, by Lemma 7.7.21, item4.

Write $u = w + zv$, $w \in \Lambda$. Apply $Q(s)$ to the lift and divide by z using (6). Since $Q(1) = 0$, the terms in w cancel. Using (4) on the other terms gives

$$Q(\xi^{k+1})\, p^t z^k \in J_i. \tag{8}$$

The quotient of the lift lies in M and projecting to the letter preserves that property, so (8) is an actual lift-ideal inclusion. More explicitly the modulus correction after division is $r_0 \sum_h Q_h \xi^h s^h v$, a single chart scalar independent of c; thus the universal quantifier in the lift ideal is preserved. Cancellation of z in the ambient Witt vector tensor is valid because it is a unit in $W(\mathbb{C}_p^\flat)$.

The initial bound of Proposition 7.7.15(2) gives $z^\nu \in J_i$ with $(p-1)\nu \le e_0(n+\kappa)$. Condition (5) implies $\nu < e_0$. For $1 \le k < e_0$, the residues $\bar{\xi}^k$ are distinct. Since Q is monic, its reduction has at most $\deg Q = h + 1$ roots. Thus at most $h + 1$ descent steps have $Q(\xi^k)$ nonunit. At all other steps (8) lowers the power of z freely. At an exceptional step Lemma 7.7.23, item(e), with adjacent exponents, lowers the power at cost $1 + v_p(k) \le m$, since $k < e_0 \le p^m$. If $e_0 = 1$, no step is present. Consequently the total cost of lowering ν to zero is at most $m(h + 1) \le \kappa$, and $p^\kappa \in J_i$. The modulus is removed by the actual statement Lemma 7.7.23, item(f), at level zero. This proves the claimed pure-power killer. At $m = 0$, $e_0 = 1$ and $\nu = 0$, so no descent step is required.

The three polynomials and the final exponent. Choose monic polynomials q, q' of degree at most N allowed by $K(s, \cdot)$ and $K(s^{-1}, \cdot)$ respectively. On Y these kill β_s and $\beta_{s^{-1}}$, while on L, by the definition of K^-, they kill $\beta_{s^{-1}}$ and β_s. The inverse orientation is essential here.

A monic polynomial of degree at most N^2 kills the generator on $(Y \otimes L)^\vee(1)$. To construct one, take the characteristic polynomial of multiplication by $X \otimes X$ on the finite free algebra

$$\mathbb{Z}_p[X]/(q') \otimes_{\mathbb{Z}_p} \mathbb{Z}_p[X]/(q).$$

Its rank is $\deg q' \deg q \le N^2$. Cayley–Hamilton gives a polynomial identity on that algebra, hence on the commuting period operators $\beta_{s^{-1}}$ of Y and L. Dualizing this identity gives the desired identity on the inverse dual operator, which is β_s on the Tate dual tensor; the Tate twist has inertial period operator one. Tensor and dual comparison are the canonical crystalline ones, compatible with the split underlying lattice maps, so the polynomial acts on the actual period operator. If one polynomial has degree zero, its value is one and its representation space is zero; the same construction is the zero-rank algebra with characteristic polynomial one, and the assertion remains valid.

The jumps of all three sides are at most n of (2). For the two original sides this follows immediately from the windows. For the third side, at most one of the original jumps is below $-\eta$, so $-u - v - 1 \le b + W + 2\eta \le n$; if $\eta = W = 0$ its upper bound is $b - 1 \le n$. Zero is also at most n. Conditions (5) hold for each of the three polynomials: their degrees are at most N, N, N^2, and $m(h+1) \le r^2(N+1)^2 = \kappa$. The assumed prime inequality is exactly $n+\kappa+2 < p$. We have therefore produced p^κ as a killer for all three cokernels at every letter.

Finally $p > b + 6(W + \eta)$ implies the required gap condition: a nonzero integer in any of those neighborhoods has absolute value at most $b + 6(W + \eta) < p$, so cannot be divisible by p. Apply the generic gap-branch argument of Proposition 7.7.29(1) with $a = 0$. The forbidden interval is empty, and the chart may be ramified. It yields exponent

$$3(\kappa + (48(\eta + W) + 4)d) \le 3\kappa + 150(\eta + W + 1), \tag{9}$$

since $d \le 1$. If $\eta = 0$, this application means the identical generic branch proof, which we spell out at this endpoint: killer points have orders $-u$; deepen level zero to $-u + \eta = -u$ at zero

cost, or to that depth with the same harmless allowance $(48W+4)d$. Opposite windows give one down side with $u \le 0$ and one up side with $u \ge 0$. The down point is a stop of orders $\max(0,-u)$, while the up-side central move has orders $\min(-u,0)$ at zero and $-u$ above, giving residual $\min(u,0)=0$. The all-letter walk of Proposition 7.7.25, which permits $\eta = 0$, gives the same bound (9). No strengthening of the statement of Proposition 7.7.29 is being assumed.

For every lattice Y of the specified class, every pairing, and every pair of crystalline cocycles, (9) is thus a continuous cup coboundary. Formula (1), now for $\mathrm{Cr}(F,K,U)$, proves (d) and completes the proof. □

Proposition 7.7.15. *Let k be a Kummer chart for Γ with ramification e, let S, S' be pairing sides over a coefficient ring $\mathcal{O}$ with letter root ζ, and let P be a pairing of their lattices Y, Y' modulo ℓ^m. Write $\widetilde{X} = W(\mathbb{C}_\ell^\flat) \otimes (Y \times C)$ and $\widetilde{X}'$ likewise, with Γ and φ acting, and $\langle\,,\rangle$ for the $W(\mathbb{C}_\ell^\flat)$-bilinear extension of b_P to the Y- and Y'-components. For $e_3 \ge 0$, a pair $(w,y) \in \widetilde{X} \times \widetilde{X}'$ is* safe *if $\ell^{e_3}\langle w, y\rangle$ lies in the image of $W(\mathfrak{m}^\flat)$; a move of the first component by y with the second at x' is safe if $(y, gx' - x')$ is safe for all $g \in \Gamma'$, and symmetrically.*

1. *(Pairing lemma.) Let x, w lie over $\ell^{e_1}c$ and x', w' over $\ell^{e_2}c'$ ($c \in C$, $c' \in C'$). Assume that the moves by $hx' - x'$ ($h \in \Gamma'$) are safe with x at rest and that four safe moves lead from $(\varphi x, \varphi x')$ through w and w' to (x, x'). Then P is a scaled cup coboundary at (e, c, c') for every $e \ge e_1 + e_2 + e_3$.*

2. *If every jump of S at every letter is at most ω, then for every $\kappa \ge 0$ and every letter i there is a with $(\ell-1)a \le e(\omega+\kappa)$ such that z^a lies in the lift ideal $J_0(i)$ of S with modulus $\ell^{\kappa+1}$.*

3. *If k is unramified, $\ell \ge 5$ and every jump of S at every letter is at most $(\ell-3)(s+t)$, then $\ell^s E^t$ kills the cokernel of S at every letter.*

4. *(Forward-letter bound.) Let $\omega, \omega', J, \kappa \in \mathbb{N}$ and i be a letter. Suppose all jumps of S at all letters are at most ω, and all jumps at $\sigma^t i$ are at most ω' for $1 \le t \le J$, where σ is the letter Frobenius. If*

$$8e \le \ell^{J+1}, \qquad 2Jd\omega' + \frac{(2J+4)\omega'}{\ell-1} + \frac{8e\omega}{\ell^{J+1}} \le \kappa,$$

where d is the chart's different bound, then ℓ^κ kills the cokernel of S at i.

Proof. **The pairing assertion.** Put $B = W(\mathbb{C}_\ell^\flat)$, and $D_m = B \otimes_{\mathbb{Z}_\ell} (\mathbb{Z}/\ell^m)(1)$. Write I_m for the image of $W(\mathfrak{m}^\flat)$ in D_m. We use additive notation in this Tate twist.

First we record the exact Witt facts needed below. The map $\varphi - 1$ is surjective on B/ℓ^m: solve $X^\ell - X = a$ in the algebraically closed field $\mathbb{C}_\ell^\flat$, subtract the chosen Teichmüller lift, divide the remaining error by ℓ, and repeat m times. Its kernel consists of the constant $\mathbb{Z}/\ell^m$. More generally,

$$\varphi v - v \in I_m \quad \Longrightarrow \quad v - 1 \otimes t \in I_m \quad \text{for a unique } t \in (\mathbb{Z}/\ell^m)(1). \tag{1}$$

Indeed, in the first Witt coordinate a negative valuation of v_0 would give valuation $\ell v(v_0) < v(v_0)$ for $v_0^\ell - v_0$, contradicting positive valuation. Thus v_0 is integral, and its residue is in $\mathbb{F}_\ell$. Subtract that constant, divide by ℓ, and repeat. At each step $W(\mathfrak{m}^\flat) \cap \ell B = \ell W(\mathfrak{m}^\flat)$, as is immediate from Witt coordinates over the perfect ideal $\mathfrak{m}^\flat$. This also proves uniqueness, or equivalently

$$(1 \otimes \mathbb{Z}/\ell^m)(1) \cap I_m = 0. \tag{2}$$

The subgroup I_m is preserved by Galois, Frobenius and multiplication by A_{inf}. No assertion of topological nilpotence of Frobenius is being used.

For later continuity, for each fixed $v \in D_m$ one has $gv - v \in I_m$ near 1. Choose a generator of the Tate twist. The cyclotomic character is 1 modulo ℓ^m near 1, and continuity on the finitely many Witt coordinates makes their differences have positive valuation near 1. The same argument applies to a fixed vector in $B \otimes L$, followed by any fixed B-linear map to D_m, provided the action on the finite free lattice L is continuous: write the vector in a lattice basis, make the finitely many lattice-action differences zero modulo ℓ^m, and make each scalar difference sufficiently small to offset the finitely many coefficients of the map. Continuity of the lattice actions and of the crystalline cocycles follows from Lemma 7.4.6. In particular every integral crystalline cocycle is divisible by ℓ^m near 1.

Let π, π' denote the projections to Y, Y'. Define

$$B_0(v,t) = \ell^{e_3} b_P(\pi v, t).$$

It is linear in the second variable; the notation $B_0(v, \pi' v')$ includes projection in both variables. Choose $y \in D_m$ with

$$\varphi y - y = B_0(w, \pi'(\varphi x' - w')) + B_0(x, \pi'(w' - x')), \tag{3}$$

using the surjectivity just proved. For $n \in \mathbb{Z} \times \Gamma$ define

$$F(n) = B_0(nx, n\pi' x') - n(B_0(x, \pi' x') - y) - B_0(x, \pi'(nx' - x')) - y. \tag{4}$$

Here $n\pi' x'$ means the action on the Y'-module, whereas $\pi'(nx')$ also includes the extension cocycle.

For $g \in \Gamma'$, bilinearity, commutation of g with φ, and (3) give

$$\begin{aligned}(\varphi - 1)F(g) = {} & B_0(gw - w, \pi' g(\varphi x' - w')) && (7.13)\\ & - B_0(\varphi x - w, \pi'(g\varphi x' - \varphi x')) && (7.14)\\ & - B_0(w - x, \pi'(gw' - w')) && (7.15)\\ & + B_0(gx - x, \pi' g(w' - x')). && (5)\end{aligned}$$

For completeness, the extension identity used in this expansion is $\pi(gv) = g\pi(v) + \alpha(\pi_C v)(g)$, with the analogous primed identity; φ fixes the constant quotient. Thus all extra extension terms cancel because x, w have the same constant quotient and x', w' have the same constant quotient. The four summands of (5) are exactly the four assumed safe moves. In the second-side convention a safe move by v' with v at rest means safety of $(gv - v, gv')$ for every $g \in \Gamma'$. Consequently (1) supplies a unique function $\kappa : \Gamma' \to (\mathbb{Z}/\ell^m)(1)$ such that

$$F(g) - 1 \otimes \kappa(g) \in I_m. \tag{6}$$

A second expansion of (4), using the same extension identity, gives

$$\begin{aligned}1 \otimes \ell^{e_1+e_2+e_3} b_P(\alpha(c)(g), g\alpha'(c')(h)) = {} & B_0(gx - x, \pi' g(hx' - x')) && (7.16)\\ & + gF(h) - F(gh) + F(g). && (7)\end{aligned}$$

The first term on the right is small by the additional cocycle-difference safety hypothesis. Substitute (6) in (7); Galois stability of I_m and (2) then give the exact equality

$$\ell^{e_1+e_2+e_3} b_P(\alpha(c)(g), g\alpha'(c')(h)) = g\kappa(h) - \kappa(gh) + \kappa(g). \tag{8}$$

We check continuity rather than treating κ as an arbitrary cochain. Near 1 the two cocycles vanish modulo ℓ^m, and (4) reduces to

$$F(g) = gy - y - B_0(x, g\pi' x' - \pi' x').$$

Both terms are small near 1 by the finite-coordinate observation above; hence (2) and (6) show that κ vanishes near 1. Equation (8) and the vanishing of $\alpha'(c')(h)$ modulo ℓ^m for h near 1 give $\kappa(gh) = \kappa(g)$ on one fixed identity neighbourhood, for every g. Thus κ is locally constant. The cup cocycle on Γ is also continuous, by continuity of the lattice actions and the cocycles. Its cohomology class in $H^2(\Gamma, \overline{\mathbb{Q}}_\ell^\times)$ restricts to zero on the open subgroup Γ'. Restriction followed by corestriction multiplies this class by $[\Gamma : \Gamma']$, whereas its values show that it is killed by ℓ^m. These integers are coprime by the chart hypothesis, so the class is zero. This proves item 1 at exponent $e_1 + e_2 + e_3$; multiplication of the cochain by $\ell^{e-e_1-e_2-e_3}$ proves every larger exponent, including $m = 0$.

The actual lift-ideal suppliers. Write $A = A_{\mathrm{inf}}$, $S = \mathcal{S}_{\mathrm{ch}}$, and $J_l(r, i) = J_l(i; r)$. The actual standard-order and common chart-ring lifts are Lemma 7.7.21; the scalar operations, with arbitrary natural modulus r, are Lemma 7.7.23. In particular the following are literal projections of its clauses (b)–(e):

$$\varphi^l(s) \in J_l(r, \sigma^l i) \Longleftrightarrow s \in J_0(r, i), \qquad fE^\omega \in J_1(r, i) \quad (f \in J_0(r, i),\ u \le \omega). \tag{19}$$

$$\ell^c z^n \in J_1(r, \sigma i), \quad \ell a \le n, \quad c + v_\ell(n!) \le b + v_\ell((\ell a)!) \Longrightarrow \ell^b z^a \in J_0(r, i). \tag{20}$$

$$\ell^c z^a E^n \in J_1(r, i) \Longrightarrow \ell^{c+dn+v_\ell(n!)} z^{a+n} \in J_1(r, i). \tag{21}$$

$$\ell^c z^n \in J_0(r, i), \quad m \le n, \quad c + n + v_\ell(n!) \le b + m + v_\ell(m!) \Longrightarrow \ell^b z^m \in J_0(r, i). \tag{22}$$

The forward letter in (20) is σi; the formulas include every prime, including two, and zero exponents.

We now prove item 2. By the τ^h lattice comparison, each $J_0(\ell^{\kappa+1}, i)$ contains τ^h for a common h, as well as $\ell^{\kappa+1}$. Modulo ℓ the tilt valuation ring shows that z is in the radical of (ℓ, τ); hence some common power z^a lies in all these finitely many ideals. Choose the least such a. Since $z^e \in (E, \ell)\mathfrak{S}$, (19) and a binomial expansion give

$$z^{a+e(\omega+\kappa)} \in J_1(\ell^{\kappa+1}, \sigma i) \quad \text{for every } i.$$

Every term either contains $z^a E^\omega$ or contains $\ell^{\kappa+1}$. Put $b = \lfloor (a + e(\omega + \kappa))/\ell \rfloor$. Equation (20), with both valuation exponents equal to zero, gives z^b in every level-zero ideal: there is no multiple of ℓ strictly between ℓb and $a + e(\omega + \kappa)$, so their factorial valuations are equal. Minimality implies $a \le b$, hence $(\ell - 1)a \le e(\omega + \kappa)$, as required.

For item 3 put $q = s + t$, $r = \ell^{q+1}$, and choose a from item 2 with $(\ell - 1)a \le (\ell - 2)q$. Legendre's inequality $(\ell - 1)v_\ell(a!) \le a$ implies

$$(\ell - 2)(a + v_\ell(a!)) \le (\ell - 1)a \le (\ell - 2)q,$$

so $a + v_\ell(a!) \le q$. For every $0 \le m \le q$, multiply z^a up to $z^{\max(a,m)}$ and apply (22); this proves $\ell^{q-m} z^m \in J_0(r, i)$. In particular $\ell^q \in J_0(\ell^{q+1}, i)$. Write $I = J_0(0, i)$; the last membership says $\ell^q \in I + (\ell^{q+1})$, so $(1 - \ell u)\ell^q \in I$ for some $u \in A$. The factor is a unit by ℓ-adic completeness, and therefore the modulus can be removed. Finally

$$\ell^s E^t = \ell^s (z + \ell)^t = \sum_{m=0}^{t} \binom{t}{m} \ell^{q-m} z^m \in I.$$

This is exactly the asserted cokernel killer. The argument includes $s = t = 0$.

The forward-letter bound. We also prove the additional output in item 4, used by Proposition 7.7.27. Suppose the jumps at $\sigma^t i$ are at most ω' for $1 \le t \le J$. Equations (19)–(21) and (20) give the one-step implication

$$\ell^c z^n \in J_0(r, \sigma j) \implies \ell^{c+d\omega'+v_\ell(\omega'!)} z^{\lfloor (n+\omega')/\ell \rfloor} \in J_0(r, j). \tag{23}$$

For (23), multiply by $E^{\omega'}$ to reach level one, apply (21), then (20) with $a = \lfloor (n+\omega')/\ell \rfloor$. The factorial valuations of $n + \omega'$ and ℓa are equal because there is no intervening multiple of ℓ. Starting with the common z^a of item 2 modulo $r = \ell^{\kappa+1}$ and iterating back from $\sigma^J i$ to i, this yields $\ell^c z^n \in J_0(r, i)$ with

$$c \le J(d\omega' + v_\ell(\omega'!)), \qquad n \le a/\ell^J + \omega'/(\ell - 1). \tag{24}$$

The finite geometric sum proves the second inequality; the hypotheses concern the *forward* letters $\sigma^t i$, not the inverse letters.

Legendre's inequality and $(\ell - 1)a \le e(\omega + \kappa)$ imply

$$c \le J(d\omega' + \omega'/(\ell - 1)), \qquad \frac{a}{\ell^J} \le \frac{2e\omega}{\ell^{J+1}} + \frac{\kappa}{4},$$

where the second inequality uses $\ell \le 2(\ell - 1)$ and $8e \le \ell^{J+1}$. Since $v_\ell(n!) \le n$, (24) gives

$$c + n + v_\ell(n!) \le \frac{1}{2}\left(2Jd\omega' + \frac{(2J+4)\omega'}{\ell - 1} + \frac{8e\omega}{\ell^{J+1}}\right) + \frac{\kappa}{2} \le \kappa.$$

Equation (22) removes the remaining z^n, giving $\ell^\kappa \in J_0(\ell^{\kappa+1}, i)$. The unit $1 - \ell u$ argument above removes the modulus. Thus $\ell^\kappa \in J_0(0, i)$, exactly the asserted killer. Zero ω' and $J = 0$ are permitted whenever the displayed hypotheses hold. □

Proposition 7.7.16. *Let ℓ be a prime and Γ a group with an open embedding $j\colon \Gamma \to G_\ell$.*

1. *There is a Kummer chart for Γ.*

2. *Let k be a Kummer chart for Γ, with ring $\mathfrak{S} = \Lambda[[z]] \subset A_{\mathrm{inf}}$ and subgroup Γ'; let ϵ be a compatible system of ℓ-power roots of unity, $\mu = [\epsilon] - 1$, $\tau = \varphi^{-1}(\mu)$, and $B^+_{\mathrm{max}} = A_{\mathrm{max}}[1/\ell] \subset B_{\mathrm{max}}$, which contains A_{inf} and maps to B_{dR}. Let T be a lattice over a coefficient ring $\mathcal{O}$ (viewed over $\mathbb{Z}_\ell$) with an action of Γ that is crystalline over Γ', and let $h \ge 0$ be an integer such that every Hodge–Tate jump of T, as a $\mathbb{Z}_\ell$-representation of Γ', lies in $[-h, h]$. Call an A_{inf}-linear map $\lambda\colon W(\mathbb{C}^\flat_\ell) \otimes_{\mathbb{Z}_\ell} T \to B_{\mathrm{dR}}$ a* crystalline form *if $\lambda(1 \otimes gt) = j(g)\lambda(1 \otimes t)$ for all $g \in \Gamma'$, $t \in T$, and $t \mapsto \lambda(1 \otimes t)$ is the composite of a $\mathbb{Z}_\ell$-linear map $T \to B_{\mathrm{max}}$ with $B_{\mathrm{max}} \to B_{\mathrm{dR}}$. Then there are a finitely generated free $\mathfrak{S}$-submodule $N \subset A_{\mathrm{inf}}[1/\tau] \otimes_{\mathbb{Z}_\ell} T$ and its A_{inf}-span $M = A_{\mathrm{inf}}N$ such that:*

   (a) *$E^h \varphi(N) \subseteq N$;*

   (b) *$\tau^h M \subseteq A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} T$ and $\tau^h(A_{\mathrm{inf}} \otimes_{\mathbb{Z}_\ell} T) \subseteq M$;*

   (c) *$gM \subseteq M$ for every $g \in \Gamma$ with $g\Gamma' g^{-1} \subseteq \Gamma'$;*

   (d) *let $d \in A_{\mathrm{inf}}$ be such that, for all $m \ge 0$ and $r \in A_{\mathrm{inf}}$, if d divides $E^m r$ in B^+_{max} then d divides r in A_{inf}; if $x \in M$ and there is $n \ge 0$ such that $E^n \lambda(x)$ lies in the image of $d\,B^+_{\mathrm{max}}$ in B_{dR} for every crystalline form λ, then $x \in dM$.*

3. *Use the forms, the rings $S = \mathcal{S}_{\mathrm{ch}}, S_B = \mathcal{S}_B$, the value field $\mathcal{K}_0$, and the formulas for $M(T), N(T)$ in Definition 7.7.2, (BF2)–(BF5); these formulas do not require a choice of a letter root or jump sets. The modules in item 2 can be chosen to be these very modules $N(T)$ and $M(T)$. For $l \geq 0$ put*

$$V_l = \{x \in \varphi^l M(T) : \lambda(x) \in \mathcal{K}_0 \text{ for every form } \lambda\}.$$

Then:

(a) *For every S-linear map $f : A_{\mathrm{inf}} \to S$, every finite family x_i of ambient vectors with $\lambda(x_i) \in \mathcal{K}_0$ for every form, each satisfying $a_i x_i \in A_{\mathrm{inf}} \otimes T$ for some nonzero $a_i \in A_{\mathrm{inf}}$, and every $c_i \in A_{\mathrm{inf}}$,*

$$\sum_i c_i x_i = 0 \quad \Longrightarrow \quad \sum_i f(c_i) x_i = 0.$$

(b) *For every $l \geq 0$, V_l is the S-span of $\varphi^l N(T)$. For every crystalline form λ, $E^h \lambda(N(T)) \subset S_B$.*

(c) *If x is an ambient vector with $\tau^a x \in A_{\mathrm{inf}} \otimes T$ for some $a \geq 0$, then*

$$x \in M(T) \iff \exists n \geq 0 \ \forall \lambda \text{ crystalline} : E^n \lambda(x) \in B^+_{\max},$$
$$x \in N(T) \iff \exists n \geq 0 \ \forall \lambda \text{ crystalline} : E^n \lambda(x) \in S_B.$$

(d) *Let $l, A, \delta \geq 0$ be integers with $3e \leq \ell^l$ and $eA \leq \ell^l \delta$. For every $x \in V_l$,*

$$\ell^{A\delta} x \in \mathrm{span}_S\{y \in V_l : \ j(g)\lambda(y) - \lambda(y) \in \mathrm{Fil}^A \text{ for every form } \lambda \text{ and every } g \in \Gamma'\}.$$

Proof. Put $p = \ell$, $A = A_{\mathrm{inf}}$, $S = \mathfrak{S}$ and $B^+ = B^+_{\max}$. Item 1 is Lemma 7.7.17. For the remaining assertions fix a chart, T and h as in item 2, and write $r = \mathrm{rank}_{\mathbb{Z}_p} T$. We first establish the canonical A-lattice, its exact τ bounds and its normaliser stability.

Let K be the fixed field of $j(\Gamma')$, and put $K_0 = \mathrm{Frac}\,\Lambda$. The chart conditions identify $j(\Gamma')$ with the fixer of Λ and $\theta(z)$. Thus $K = \mathrm{Frac}(\Lambda)(\theta(z))$. Weierstrass preparation applied to the chart series $X^e a(X) + p$ replaces it by an associate which is an Eisenstein polynomial of degree e. It follows that $\theta(z)$ is a uniformiser of K, that $\Lambda = W(k_K)$ and that S is the usual Breuil–Kisin ring of K. This argument uses the chart map itself, not a new choice of compatible roots. Forgetting the coefficient ring makes T finite free over $\mathbb{Z}_p$. Continuity follows from Lemma 7.4.6(1). Crystallinity is over this same K: the $B_{\max}$-invariant basis and the standard period-ring comparison $\varphi(B_{\max}) \subset B_{\mathrm{cris}}$ give a B_{cris}-invariant basis after applying Frobenius. Extending that comparison to B_{dR} and using Theorem A.3.16 shows that $T[1/p]$ is de Rham and that $D_{\mathrm{dR}} = K \otimes_{K_0} D_{\mathrm{cris}}$.

Let $\mathfrak{M}$ be the module of Theorem A.3.12, and let $i_0 : S \to A$ be the chart map. Its embedding is $i_{\mathrm{B}} = \varphi_A i_0$: both the coefficients and the variable are carried through Frobenius. Put

$$\mathcal{M}_{\mathrm{B}} = A \otimes_{S, i_{\mathrm{B}}} \mathfrak{M}, \qquad \mathcal{M}_0 = (\varphi_A^{-1} \otimes 1)\mathcal{M}_{\mathrm{B}} \subset A[1/\tau] \otimes_{\mathbb{Z}_p} T. \tag{1}$$

Here the common ambient identification is the one in Theorem A.3.12(2); inverse Frobenius is applied to scalar coordinates in the fixed $\mathbb{Z}_p$-module T. In particular $\mathcal{M}_0$ is finite free over A and becomes the full ambient lattice after inverting τ. Since $i_{\mathrm{B}}(E)$ is associated to $\varphi(\xi) = \widetilde{\xi}$, the Breuil–Kisin Frobenius becomes an isomorphism on $\mathcal{M}_{\mathrm{B}}$ after inverting $\widetilde{\xi}$. Thus $\mathcal{M}_{\mathrm{B}}$ is a

finite free Breuil–Kisin–Fargues module in exactly the convention of Theorem A.3.14. Its étale lattice is the given T, by Theorem A.3.12(1). Write

$$\Xi = D_{\mathrm{dR}}(T[1/p]) \otimes_K B_{\mathrm{dR}}^+ \subset T \otimes_{\mathbb{Z}_p} B_{\mathrm{dR}}.$$

The crystalline comparison Theorem A.3.12(3), followed by extension to B_{dR}^+, identifies the pair of $\mathcal{M}_{\mathrm{B}}$ under Theorem A.3.14 with (T, Ξ).

The Hodge jumps in the hypothesis lie in $[-h, h]$. The de Rham/Hodge–Tate comparison Theorem A.3.11 therefore gives

$$\xi^h \Xi \subset T \otimes B_{\mathrm{dR}}^+ \subset \xi^{-h} \Xi. \tag{2}$$

Choose a filtration-adapted basis d_i with jumps j_i. The graded comparison says that the reductions of $\xi^{-j_i} d_i$ form a basis of the residue space of $T \otimes B_{\mathrm{dR}}^+$. Hence these vectors form a basis over the discrete valuation ring B_{dR}^+, by their determinant. Since $|j_i| \leq h$, both inclusions in (2) follow. The symmetry of the interval makes a convention change of sign immaterial here.

Multiplication of $\mathcal{M}_{\mathrm{B}}$ by μ^b, for an integer b, gives a finite free Breuil–Kisin–Fargues module in the same ambient space. Indeed $\varphi(\mu)/\mu = \widetilde{\xi}$, so its Frobenius becomes an isomorphism after inverting $\widetilde{\xi}$. Its étale lattice is still T, because μ is a unit in $W(\mathbb{C}_p^\flat)$. Its de Rham lattice is $\xi^b \Xi$, since $\mu/\xi = \tau$ is a unit at θ. By (2), the identity on T is a morphism of pairs from $\mu^h \mathcal{M}_{\mathrm{B}}$ to $A \otimes T$, and from $A \otimes T$ to $\mu^{-h} \mathcal{M}_{\mathrm{B}}$. The full-faithfulness assertion of Theorem A.3.14 makes these actual inclusions in the common ambient module. Applying inverse scalar Frobenius gives

$$\tau^h \mathcal{M}_0 \subset A \otimes T \subset \tau^{-h} \mathcal{M}_0. \tag{3}$$

This proves exactly both τ bounds, without an unspecified exponent depending on the lattice.

We supply the scalar intersection calculation needed to identify the canonical module. For every $b \in A[1/\mu]$,

$$b \in A \quad \Longleftrightarrow \quad \varphi^n(b) \in B_{\mathrm{dR}}^+ \quad (n \geq 0). \tag{4}$$

First,

$$\bigcap_{n \geq 0} \ker(\theta \varphi^n : A \to \mathcal{O}_{\mathbb{C}_p}) = \mu A. \tag{5}$$

For the nontrivial inclusion, write an element a of the intersection as $a = \xi c$, $c \in A$, using $\ker \theta = \xi A$. For $n \geq 1$, the geometric-sum formula for the canonical $\xi = \mu/\tau$ gives $\theta(\varphi^n \xi) = p \neq 0$. Thus c satisfies every positive-residue equation. By Lemma 7.7.18, $c \in \tau B^+$; Lemma 7.7.30, with $m = 1$ and $n = h = 0$, gives $c \in \tau A$. Hence $a \in \xi \tau A = \mu A$. Conversely every $\varphi^n \mu$ has residue zero, proving (5).

For (4), write $b = a/\mu^q$. The right-hand tests put every $\varphi^n a$ in Fil^q. If $q > 0$, (5) first gives $a = \mu a_1$, $a_1 \in A$. Each $\varphi^n \mu$ has de Rham order one, because $\log(1 + \varphi^n \mu) = p^n t$; cancellation therefore leaves $\varphi^n a_1 \in \mathrm{Fil}^{q-1}$ for all n. Repeating gives $a \in \mu^q A$, as required. For $q = 0$ nothing is needed. The converse follows from $\varphi(A) = A$.

Next, for every $n \geq 0$,

$$(\varphi^n \mathcal{M}_{\mathrm{B}}) \otimes_A B_{\mathrm{dR}}^+ = \Xi. \tag{6}$$

The Frobenius comparison matrix of $\mathcal{M}_{\mathrm{B}}$ and its inverse have denominators only powers of $\widetilde{\xi}$. For its further twists the possible denominators are $\varphi^j \widetilde{\xi}$, $j \geq 0$. Each is a unit at θ, its θ-value being a nonzero power of p up to a unit. Thus successive Frobenius twists span the same de Rham lattice, which proves (6) from the case $n = 0$.

We also identify precisely what the forms test. Choose a basis of crystalline periods and let P be its matrix in $T \otimes B_{\mathrm{cris}}$. Its inverse rows give crystalline forms in the precise sense of

(BF3). Here the extension to the stated ambient module can be made as follows. The injection $A \subset B_{\mathrm{dR}}$ extends to its fraction field. The ambient module is A-torsion free, since T is finite free and $W(\mathbb{C}_p^\flat)$ is a domain. Its localization is therefore a vector space over $\mathrm{Frac}(A)$ containing $\mathrm{Frac}(A) \otimes T$. Extend each inverse row linearly from this finite-dimensional subspace to the whole localized space by choosing a vector-space complement, and restrict back to the ambient module. Its values on T lie in B_{cris} and have the required equivariance, since the columns of P are invariant. Those are exactly the additional conditions in (BF3); no continuity or equivariance on an unspecified complement is required there. In matrix expressions we extend only the restriction of a form to T, B_{dR}-linearly. If λ is any form, the row λP is fixed by G_K, hence has entries in K by Theorem A.3.16. Conversely these rows span all restrictions of forms to the fractional ambient span of T. Therefore

$$\lambda(y) \in B_{\mathrm{dR}}^+ \text{ for every form } \lambda \quad \Longleftrightarrow \quad y \in \Xi. \tag{7}$$

Only restrictions to that fractional span are used; no uniqueness of an arbitrary form on the larger ambient module is asserted.

An element of $\mathcal{M}_0$ satisfies the conditions of (BF5), by (3), (6) and (7). Conversely let x satisfy (BF5). Since a power of τ puts x in $A \otimes T$, (3) puts it in $\mathcal{M}_0[1/\tau]$. In an A-basis m_i of $\mathcal{M}_0$, write $x = \sum_i a_i m_i$, $a_i \in A[1/\tau]$. Equations (6)–(7) imply

$$\varphi^{m+1}(a_i) \in B_{\mathrm{dR}}^+ \quad (i,\ m \geq 0).$$

Apply (4) to $\varphi(a_i) \in A[1/\mu]$. It gives $\varphi(a_i) \in A$, and hence $a_i \in A$. Thus

$$M(T) = \mathcal{M}_0. \tag{8}$$

In particular the canonical $M(T)$ is finite free over A and satisfies item 2(b).

Normaliser stability follows directly from this canonical description. If $g\Gamma' g^{-1} \subset \Gamma'$ and λ is a form, then $x \mapsto j(g)^{-1}\lambda(gx)$ is again a form: for $h \in \Gamma'$, use $ghg^{-1} \in \Gamma'$ in its equivariance identity. The actions commute with Frobenius and preserve de Rham filtration. Also $g(\tau)/\tau$ is a unit of A, by the cyclotomic character and its binomial power series with unit constant term. Consequently g preserves the τ-saturated ambient span and all the defining filtration tests. This proves $gM(T) \subset M(T)$, namely item 2(c).

We next record two consequences of the scalar chart assertions of Lemma 7.7.22. We use the chart-linear retraction of item 4, $q_0 : A \to S$, $q_0|_S = \mathrm{id}_S$, and its S_B-linear extension. First,

$$B^+ \cap \mathrm{Frac}(S_B) = S_B. \tag{9}$$

Indeed, suppose $c, cd \in S_B$, $c \neq 0$, and $d \in B^+$. For every S-linear endomorphism u of B^+ preserving $A_{\max}$, and every $b \in B^+$, commutation with multiplication by c and cd gives $c\,u(db) = u(cdb) = cd\,u(b)$. Cancellation in the domain B^+ shows that multiplication by d commutes with u. This is exactly the definition of $d \in S_B$, proving (9). Also the extension of q_0 fixes S_B, since it is S_B-linear and takes 1 to 1.

Second, the positive-Frobenius integrality test extends from (4) to

$$b \in B_{\max}, \qquad b \in B^+ \quad \Longleftrightarrow \quad \varphi^n b \in B_{\mathrm{dR}}^+ \quad (n \geq 0). \tag{10}$$

For the nontrivial direction, first let $b \in B^+$ satisfy $\theta\varphi^n b = 0$ for every $n \geq 0$. By divisibility reflection in Lemma 7.7.22(2), $b/\xi \in B^+$. For $n \geq 1$, $\theta(\varphi^n \xi) = p \neq 0$, so b/ξ satisfies all the positive-residue equations. The positive-residue detector Lemma 7.7.18 therefore gives $b/\xi \in$

τB^+, hence $b \in \xi\tau B^+ = \mu B^+$. Each $\varphi^n\mu$ has de Rham order exactly one: $\log(1+\varphi^n\mu) = p^n t$, and the linear coefficient is nonzero. Consequently induction gives

$$\varphi^n b \in \mathrm{Fil}^m \ (n \geq 0) \quad \Longrightarrow \quad b \in \mu^m B^+ \qquad (b \in B^+,\ m \geq 0). \tag{11}$$

For $b = a/\mu^m \in B_{\max}$, the right side of (10) puts every $\varphi^n a$ in Fil^m; (11) cancels the denominator. The converse of (10) follows from $\varphi(B^+) \subset B^+$.

We make explicit the finite-dimensional Frobenius action on crystalline forms; inverse Frobenius on $B_{\max}$ is not required. Let $\lambda_1, \ldots, \lambda_r$ be the inverse rows of P. As invariant vectors for the dual representation they are independent over B_{cris}; the dimension bound of Theorem A.3.16, applied to that continuous dual representation, says that they form a K_0-basis of its crystalline invariant space. Frobenius commutes with Galois and preserves B_{cris}, so for $L = P^{-1}$ one has $\varphi(L) = FL$, $F \in M_r(K_0)$. Applying φ to $LL^{-1} = I$ shows that $\varphi(L)$ is nonsingular. Hence $\det F \neq 0$, and $F \in \mathrm{GL}_r(K_0)$. Since Frobenius on K_0 is an automorphism, this is a bijective semilinear action. The same conclusion holds for every positive iterate.

Every crystalline form is a K_0-linear combination of these rows. To check the assertion also for the $B_{\max}$-valued definition, apply Frobenius to its values: $\varphi(B_{\max}) \subset B_{\mathrm{cris}}$. This last inclusion follows from $\varphi(B^+) \subset B^+_{\mathrm{cris}}$ and $1/\varphi(\mu) \in B_{\mathrm{cris}}$. To see the latter without assuming an inverse in B^+_{cris}, put $c = \varphi(\mu)$. The series $R_c = \sum_{m\geq 1}(-1)^{m+1}c^{m-1}/m$ converges in B^+_{cris}: divided powers of $c \in \ker\theta$ make its mth term a divided power times a scalar of valuation tending to infinity. It satisfies $cR_c = \log(1+c) = pt$, so $c^{-1} = R_c/(pt) \in B_{\mathrm{cris}}$. The resulting crystalline row is a K_0-linear combination of the Frobenius-twisted basis rows. Apply the inverse automorphism of K_0 to those finitely many coefficients and use injectivity of Frobenius to recover the original row. Together with (7), we have proved that all forms are K-linear combinations of the λ_i, whereas all crystalline forms are K_0-linear combinations.

For $x \in M(T)$ and every crystalline form λ, one has the uniform bound

$$E^h\lambda(x) \in B^+. \tag{12}$$

Indeed $x \in T \otimes B^+_{\mathrm{dR}}$, since (3) bounds its denominator by a power of the de Rham unit τ. The inclusion $T \otimes B^+_{\mathrm{dR}} \subset \xi^{-h}\Xi$ in (2), and the fact that every λ_i is integral on Ξ, show $\lambda(x) \in \mathrm{Fil}^{-h}$. This proves the $n = 0$ test for $E^h\lambda(x)$. For $n \geq 1$, write $\lambda^{(n)}$ for the crystalline form whose values on T are φ^n of those of λ. Then

$$\varphi^n(E^h\lambda(x)) = \varphi^n(E)^h\,\lambda^{(n)}(\varphi^n x) \in B^+_{\mathrm{dR}}.$$

The defining tests of $M(T)$ apply to the last factor, and $\varphi^n(E)$ is a de Rham unit. The argument is legitimate in $B_{\max}$: $x \in A[1/\tau] \otimes T$, and $1/\tau = \xi/\mu \in B_{\max}$. Equation (10) proves (12).

Conversely, if x is in the τ-saturated ambient span and, for one $m \geq 0$, all crystalline forms satisfy $E^m\lambda(x) \in B^+$, apply each positive Frobenius power to these inclusions. The factors $\varphi^n(E)$, $n \geq 1$, are de Rham units. Bijectivity of Frobenius on the crystalline-form space therefore gives all the tests $\lambda_i(\varphi^n x) \in B^+_{\mathrm{dR}}$. Their K-linear combinations give the same assertion for every form. Hence $x \in M(T)$. With (12), this proves the first equivalence in item 3(c).

Let N_0 be the S-span of the inverse-Frobenius images of a basis of $\mathfrak{M}(T)$ in (1). The transport of its Breuil–Kisin Frobenius gives

$$N_0 \text{ finite free over } S, \qquad AN_0 = M(T), \qquad \varphi(N_0) \subset N_0[1/E], \tag{13}$$

and the Frobenius matrix belongs to $\mathrm{GL}_r(S[1/E])$. All statements concern the fixed ambient embedding: applying inverse scalar Frobenius to the matrix equality for $\mathfrak{M}(T)$ changes i_{B} to i_0

and its Eisenstein element to the actual E, up to a unit. By Lemma 7.7.19, every crystalline form takes N_0 into $\mathrm{Frac}(S_B)$. Thus every form takes N_0 into $\mathcal{K}_0$.

We first prove item 3(a), independently of the identification of $N(T)$. Apply a crystalline basis form to a relation $\sum_i c_i x_i = 0$ there. Its values at all x_i lie in $\mathcal{K}_0$; item 3 of Lemma 7.7.22, with $a = 0$, says that the exact scalar relation remains exact on replacing c_i by $f(c_i)$. Since the crystalline basis forms separate the fractional ambient span, $\sum_i f(c_i)x_i = 0$. The denominator hypothesis in item 3(a) places every x_i in this fractional span, so no assertion about arbitrary vectors outside that span is used.

It follows that

$$N(T) = N_0. \tag{14}$$

The inclusion $N_0 \subset N(T)$ follows from (8), (13) and the value-field conclusion. For the reverse inclusion choose an S-basis $n_1, \dots, n_r$ of N_0 and write $x \in N(T)$ as $x = \sum_i a_i n_i$, $a_i \in A$. Apply the just-proved relation law to $x - \sum_i a_i n_i = 0$ and the retraction q_0. It gives $x = \sum_i q_0(a_i) n_i$, which is in N_0. This proves finite freeness and the asserted canonical choice of both modules.

Combining (12) with the analytic value-field statement and (9) gives

$$E^h \lambda(N(T)) \subset S_B \tag{15}$$

for every crystalline form. We next prove the second equivalence of item 3(c). Its forward direction is (15). Conversely suppose the indicated τ-saturated x satisfies $E^m \lambda(x) \in S_B$ for all crystalline λ. The already-proved first equivalence gives $x \in M(T)$. In the basis n_i, write $x = \sum_i a_i n_i$, $a_i \in A$, and put

$$C = (\lambda_i(n_j))_{i,j}.$$

This matrix is nonsingular over $\mathrm{Frac}(S_B)$, since it is the change-of-basis matrix between two bases of the period comparison space. The column of all $\lambda_i(x)$ lies in $\mathrm{Frac}(S_B)^r$, so $a = C^{-1}(\lambda_i(x))_i$ does as well. Equation (9) puts every a_i in S_B. The extension of q_0 fixes S_B, and agrees on A with $q_0 : A \to S$; hence $a_i = q_0(a_i) \in S$. Thus $x \in N(T)$.

For $l \geq 0$, repeated use of (13) puts $\varphi^l N(T)$ inside $N(T)$ with denominators finite products of $\varphi^j(E)$. Those products belong to S, so every form takes $\varphi^l N(T)$ into $\mathcal{K}_0$. These vectors form an A-basis of $\varphi^l M(T)$. If $x \in V_l$, write it in that basis and apply the same q_0-relation argument. This proves the first assertion of item 3(b); its second assertion is (15).

For $x \in N(T)$, the bound (3) gives

$$E^h \varphi(x) \in \tau^{-h}(A \otimes T),$$

because μ is a unit times $E\tau$. Moreover, for $m \geq 0$ and every form λ,

$$\lambda(\varphi^{m+1}(E^h \varphi x)) = \varphi^{m+1}(E)^h \lambda(\varphi^{m+2} x) \in B^+_{\mathrm{dR}}.$$

Thus $E^h \varphi x \in M(T)$. By (13) its form values belong to $\mathcal{K}_0$. It is therefore in $N(T)$, proving item 2(a) with the exact exponent h.

The argument so far applies to $T^\vee = \mathrm{Hom}_{\mathbb{Z}_p}(T, \mathbb{Z}_p)$ as well. It is crystalline with the same symmetric Hodge bound, by Theorem A.3.9; the tensor functor in Theorem A.3.12 identifies its embedded lattice with the dual lattice of $M(T)$, and inverse scalar Frobenius preserves this evaluation pairing. This also identifies the dual basis $n_j^\vee$. More explicitly, let Q be the coordinate matrix of n_j in a $\mathbb{Z}_p$-basis of T, so $C = P^{-1}Q$. In the dual basis of $T^\vee$, the vectors $n_j^\vee$ have coordinate matrix $Q^{-\mathsf{t}}$, and the crystalline forms dual to the invariant period basis have row matrix P^{t}. Their value matrix is therefore $P^{\mathsf{t}} Q^{-\mathsf{t}} = C^{-\mathsf{t}}$. Applying (12) to these dual vectors proves

$$E^h C^{-1} \in M_r(B^+). \tag{16}$$

This argument also checks the dual lattice intrinsically: the evaluation pairing of the two published tensor-dual lattices has values in A, and is perfect before and after inverse scalar Frobenius.

We can now prove item 2(d). For $x = \sum_j a_j n_j \in M(T)$, $a_j \in A$, its crystalline-value column is Ca. The assumption in that item gives $E^m Ca \in d(B^+)^r$ for one $m \geq 0$. Multiplication by (16) gives $E^{m+h}a \in d(B^+)^r$. The stipulated cancellation property of d, applied separately to each a_j, gives $a_j \in dA$. Consequently $x \in dM(T)$. This argument includes $d = 0$: the matrix C is nonsingular and then $x = 0$.

It remains to prove the congruence span, keeping track of its uniformity for every form. In Lemma 7.7.20 take

$$Z = E^h C, \qquad Z' = E^h C^{-1}. \tag{17}$$

Equations (15)–(16) give $Z \in M_r(S_B)$, $Z' \in M_r(B^+)$, and $Z'Z = E^{2h} I_r$. Choose the chart element t_0 with $t_0 z = [\varepsilon]z$. It belongs to $j(\Gamma')$ and fixes Λ pointwise. Canonical stability applied to t_0 and t_0^{-1} gives

$$t_0(n_1, \ldots, n_r) = (n_1, \ldots, n_r)H, \qquad H \in \mathrm{GL}_r(A).$$

The equivariance of the forms gives $t_0 C = CH$. The ratio $t_0 E/E$ is an A-unit, since both generate $\ker\theta$; hence

$$t_0 Z = ZG, \qquad G = (t_0 E/E)^h H.$$

Thus all the hypotheses of Lemma 7.7.20 hold with its exponent H equal to $2h$. Apply it with $b = h$. Its factorization becomes

$$\varphi^l C = C_0 V, \tag{18}$$

after cancellation of $\varphi^l(E)^h$, where $C_0 \in \mathrm{GL}_r(B^+)$ is fixed by every g fixing Λ, and V is the evaluated invertible formal matrix. Let $F_l \in \mathrm{GL}_r(K_0)$ be determined by $(\lambda_i^{(l)})_i = F_l(\lambda_i)_i$. Therefore

$$(\lambda_i(\varphi^l n_j))_{i,j} = F_l^{-1} C_0 V. \tag{19}$$

For a coefficient column $y \in S^r$ belonging to the set $\mathcal{Y}_{A,V}$ of the radius lemma, put $x_y = \sum_j y_j \varphi^l n_j$. Then $x_y \in V_l$ by item 3(b), and $Vy - n_y \in E^A(B^+)^r$ for a natural-number column n_y. Equation (19) shows that each $\lambda_i(x_y)$ differs modulo Fil^A from the corresponding entry of $F_l^{-1} C_0 n_y$. These entries are fixed by $j(\Gamma')$: that group fixes Λ, K_0, and the natural numbers. Multiplication by $F_l^{-1} C_0$ preserves Fil^A, since its entries belong to B_{dR}^+. Every form is a K-linear combination of the λ_i; these coefficients are fixed by $j(\Gamma')$ and have de Rham order zero. Since the Galois action also preserves Fil^A, we obtain

$$j(g)\lambda(x_y) - \lambda(x_y) \in \mathrm{Fil}^A \quad (g \in \Gamma',\ \lambda \text{ any form}).$$

The final assertion of Lemma 7.7.20, with precisely the inequalities $3e \leq p^l$ and $eA \leq p^l \delta$, says that these columns y span a submodule containing $p^{4\delta} S^r$. The S-linear map $S^r \to V_l$, $y \mapsto x_y$, is an isomorphism by item 3(b). Its image gives exactly item 3(d). All arguments for rank zero use empty matrices and give the zero modules, so they also prove that case.

□

Lemma 7.7.17. *Let ℓ be prime and $j : \Gamma \to G_\ell$ an open embedding. There is a Kummer chart for Γ which fits Γ. It can be chosen with $\Gamma' = \Gamma$, with coefficient field the maximal unramified subfield of the finite extension $K/\mathbb{Q}_\ell$ fixed by $j(\Gamma)$, and with $\theta(z)$ a uniformiser of K.*

Proof. Write $p = \ell$. The open subgroup $j(\Gamma)$ is G_K for a finite extension $K/\mathbb{Q}_p$. Let K_0 be its maximal unramified subfield, let its residue field be $\mathbb{F}_{p^f}$, and let e be its ramification index.

Thus $ef = [K : \mathbb{Q}_p] = [G_p : j(\Gamma)]$. The canonical Teichmüller copy $\Lambda = W(\mathbb{F}_{p^f})$ in A_{inf} is carried by θ isomorphically onto $\mathcal{O}_{K_0}$: the prime-to-p roots of unity lift uniquely from the residue field. In particular G_K fixes this copy pointwise.

Choose a uniformiser π of K. If $e = 1$, choose $\pi = -p$. Choose compatible roots $\pi_n^p = \pi_{n-1}$, $\pi_0 = \pi$, in $\overline{\mathbb{Q}}_p$, and let $\varpi^\flat$ be the resulting tilt element. Put $z = [\varpi^\flat]$. Then $\theta(z) = \pi$, and z is not a unit. Substitution $X \mapsto z$ defines a Λ-algebra homomorphism

$$\Lambda[[X]] \longrightarrow A_{\mathrm{inf}}.$$

Here convergence uses the usual weak topology of A_{inf}, not convergence in its p-adic topology alone. More explicitly, $z \bmod p$ has positive valuation in $\mathcal{O}_{\mathbb{C}_p}^\flat$, so powers of $z \bmod p$ tend to zero; successively modulo p^n the Witt components give convergent sums in the complete valuation ring of the tilt. Their compatible limits define substitution, and continuity of addition and multiplication verifies the homomorphism identities.

We construct the required unit series without identifying a formal power series with a polynomial. Every element of $\mathcal{O}_K$ is a convergent series $\sum_{n\geq 0} a_n \pi^n$, with a_n Teichmüller representatives in $\mathcal{O}_{K_0}$. Indeed, successively subtract the representative of the residue and divide by π; completeness supplies the limit. Since π^e and $-p$ have the same valuation, there is $v \in \mathcal{O}_K^\times$ with $\pi^e v = -p$. Lift v by this expansion to $A(X) \in \Lambda[[X]]$. Its constant term has nonzero residue, so A is a unit. In the unramified case $v = 1$, and we take $A = 1$. Set

$$E = z^e A(z) + p.$$

Its image under θ is zero.

We check the stronger required assertion that E generates $\ker\theta$. Let ξ be any generator of that kernel. A generator may be chosen as $[p^\flat] - p$, where $p^\flat$ is a compatible system of roots of p; its reduction modulo p has valuation 1, with valuation normalised by $v(p) = 1$ on untilts. Since $E \in (\xi)$, write $E = \xi b$. The reduction of E is $(\varpi^\flat)^e \overline{A}(\varpi^\flat)$; its valuation is $e/e = 1$, because $A(z)$ is a unit. Consequently $\bar{b}$ has valuation zero and is a unit of the tilt valuation ring. An element of A_{inf} whose reduction modulo p is a unit is itself a unit, by p-adic completeness. Thus b is a unit, as required.

Take $\Gamma' = \Gamma$. Its index is one and it contains every element near one. Its image fixes Λ and $\theta(z) = \pi$. Conversely an element of G_p fixing these fixes $K_0(\pi) = K$: the equality follows either from the uniformiser expansion above, or from the Eisenstein minimal polynomial of π, of degree e. Thus the common fixer is exactly $G_K = j(\Gamma')$.

It remains to verify the Kummer translations, including their simultaneous compatibility at every level. Fix $a \geq 0$ and the compatible system ϵ_n of p-power roots of unity used in the chart. For each n, the polynomial $X^{p^n} - \pi$ is Eisenstein over K, hence irreducible. There is therefore a K-embedding carrying π_n to $\epsilon_n^a \pi_n$, and it extends to an element of G_K. The sets

$$C_n = \{g \in G_K : g\pi_n = \epsilon_n^a \pi_n\}$$

are nonempty closed subsets of the compact group G_K, and $C_{n+1} \subseteq C_n$, by compatibility of the roots. Compactness gives $g \in \bigcap_n C_n$. It satisfies $g\varpi^\flat = \epsilon^a \varpi^\flat$, and hence $gz = [\epsilon]^a z$. Pull it back through j. No assertion that this element fixes the roots of unity is needed.

Finally the residue quotient of G_K is the absolute Galois group of $\mathbb{F}_{p^f}$, so it contains a lift of arithmetic Frobenius, acting on the algebraic residue field by $x \mapsto x^{p^f}$. If $j(\Gamma)$ contains inertia, $K/\mathbb{Q}_p$ is unramified, so $e = 1$ and our choice gives $E = z + p$. All the chart conditions have now been checked. The whole-group fixer, the degree identity, the specified unramified case and the Frobenius lift also show that this chart fits Γ. □

Lemma 7.7.18. *For every prime p, including 2, and $y \in B$, if $\theta(\varphi^{j+1}y) = 0$ for every integer $j \geq 0$, then $y = \tau z$ for some $z \in B$.*

Proof. Write $R = \mathcal{O}_{\mathbb{C}_p^\flat}$ and $A = W(R)$. The ring R is a rank-one valuation domain of characteristic p; write ν for its real valuation, with $\nu(0) = +\infty$. Reduction modulo p identifies A/pA with R, the Frobenius induces $r \mapsto r^p$, and A is p-torsion-free, p-adically separated and complete. A bar below means reduction modulo p.

The integral detector. Let

$$I = \bigcap_{j \geq 0} \ker(\theta\varphi^j) \subseteq A.$$

This is an ideal, contains μ, and is p-saturated: if $px \in I$, then $p\theta(\varphi^j x) = 0$ in the characteristic-zero domain $\mathcal{O}_{\mathbb{C}_p}$, hence $x \in I$. The canonical identities are

$$\mu = \xi\tau, \qquad \varphi(\tau) = \mu, \qquad \theta(\varphi^k\xi) = p \quad (k \geq 1).$$

The last follows by applying $\theta\varphi^k$ to $\xi = \sum_{i=0}^{p-1}[\varepsilon^{1/p}]^i$: each summand becomes 1. Modulo p, put $t_0 = \bar{\tau}$. The primitive compatible root system gives $0 < \nu(t_0) < \infty$, and characteristic p gives

$$\bar{\mu} = t_0^p, \qquad \bar{\xi} = t_0^{p-1}.$$

In particular $\nu(\bar{\mu}) = p\nu(t_0)$ and $\nu(\bar{\xi}) = (p-1)\nu(t_0)$.

For $x \in I$, write $x = \xi b$, using $\ker\theta = (\xi)$. Then $\varphi b \in I$: for every $j \geq 0$,

$$0 = \theta(\varphi^{j+1}x) = p\,\theta(\varphi^{j+1}b),$$

so the second factor is zero. Starting with $x_0 = x$, repeat this construction, writing $x_i = \xi b_i$ and $x_{i+1} = \varphi b_i$. For every positive integer r,

$$\nu(\bar{x}_0) = \nu(\bar{\xi})\sum_{i=0}^{r-1} p^{-i} + p^{-r}\nu(\bar{x}_r) \geq \nu(\bar{\xi})\sum_{i=0}^{r-1} p^{-i}.$$

If a reduction is zero the desired inequality is immediate; otherwise this equality follows by multiplicativity of the valuation and $\overline{\varphi b_i} = \bar{b}_i^p$. Taking the limit proves $\nu(\bar{x}) \geq p\nu(\bar{\xi})/(p-1) = \nu(\bar{\mu})$. Thus $\bar{\mu}$ divides $\bar{x}$ in the valuation ring R.

Lift a quotient to $d_0 \in A$. Then $x - \mu d_0 = px_1'$ for some $x_1' \in A$; since both x and μd_0 lie in I, p-saturation implies $x_1' \in I$. Repeat. For each r,

$$x = \mu\sum_{i=0}^{r-1} p^i d_i + p^r x_r', \qquad x_r' \in I.$$

Completeness and separatedness give $x = \mu\sum_{i\geq 0} p^i d_i$. Consequently every $x \in I$ is divisible by μ in A.

If $a \in A$ satisfies $\theta(\varphi^{j+1}a) = 0$ for all $j \geq 0$, then $\varphi a \in I$, so $\varphi a = \mu b = \varphi(\tau)b$. Frobenius is bijective on A because R is perfect. Applying its inverse gives

$$a = \tau\varphi^{-1}(b). \tag{1}$$

Reduction of the actual completed ring modulo τ. Put $T = \xi/p \in A_{\max}$. Every $b \in A_{\max}$ has a restricted-series presentation

$$b = F(T), \qquad F(U) = \sum_{n\geq 0} a_n U^n, \quad a_n \in A, \quad a_n \longrightarrow 0 \text{ } p\text{-adically}.$$

Indeed $A_{\max}$ is the p-adic completion of $A[U]/(pU-\xi)$. Represent successive p-adic differences of an element of that completion by p^r times polynomials in $A[U]$; their sum is a restricted series. This gives the asserted presentation without assuming uniqueness of it.

The sum $a = F(1) = \sum_n a_n$ converges in A. Define

$$G(U) = \sum_{j\geq 0} \left(\sum_{n>j} a_n \right) U^j.$$

Each inner sum converges, and its values tend to zero p-adically as $j \to \infty$. Hence G is restricted and coefficient subtraction gives $F(U) - F(1) = (U-1)G(U)$. Furthermore $\xi - p$ is divisible by τ in A, since

$$\xi - p = \sum_{i=0}^{p-1} ((1+\tau)^i - 1).$$

Write $\xi - p = \tau c$. Thus in $B = A_{\max}[1/p]$,

$$b = a + \tau p^{-1} c G(T).$$

Every $y \in B$ can therefore be written

$$y = p^{-m} a + \tau w, \qquad m \geq 0,\ a \in A,\ w \in B. \tag{2}$$

For every $j \geq 0$, $\theta(\varphi^{j+1}\tau) = \theta(\varphi^j \mu) = 0$. Apply $\theta\varphi^{j+1}$ to (2). Its left side is zero by hypothesis and its τw term is zero; hence $\theta(\varphi^{j+1}a) = 0$. Equation (1) gives $a = \tau a'$, with $a' \in A$. Then $y = \tau(p^{-m}a' + w)$, proving the claim.

All products and sums above occur in the specified actual rings. There is no cancellation by τ in the completed ring, no assumption that Frobenius on B is onto, and no parity restriction: the same geometric sum and valuation argument hold at $p = 2$. □

Lemma 7.7.19. *Put $p = \ell$, $S = \mathcal{S}_{\mathrm{ch}} = \Lambda[[z]]$, and let T be a crystalline lattice over the local field of the chart. Realise the module of Theorem A.3.12 by its specified étale comparison in the actual ambient module, and denote its image by N_{B}. Here its coefficient map is Witt Frobenius and its variable maps to z^p. Put*

$$N_0 = (\varphi_{A_{\mathrm{inf}}}^{-1} \otimes 1) N_{\mathrm{B}}.$$

Thus N_0 is an S-module in the same ambient module, with the direct variable z. For every crystalline form λ of (BF3),

$$\lambda(N_0) \subseteq \mathrm{Frac}(\mathcal{S}_B).$$

No uniform denominator bound is asserted.

Proof. Write $K_0 = \mathrm{Frac}(\Lambda)$, and use the actual embeddings in the statement throughout.

Analytic scalars lie in the bicommutant. Let $\mathcal{O}^{\mathrm{an}} \subset K_0[[z]]$ be the ring in Theorem A.3.13. The chart equation is $E = z^e A(z) + p$, where $A(z) \in S^\times$, and E is a unit times a generator of $\ker\theta$. Consequently

$$z^e/p = (E/p - 1) A(z)^{-1} \in A_{\max}.$$

For $F = \sum_{n\geq 0} c_n z^n \in \mathcal{O}^{\mathrm{an}}$, the defining convergence condition at radius $p^{-1/e}$ gives $v_p(c_n) + n/e \longrightarrow +\infty$. Writing $n = eq + r$, $0 \leq r < e$, shows

$$c_n z^n = c_n p^q z^r (z^e/p)^q \in p^{\,v_p(c_n) + \lfloor n/e \rfloor} A_{\max}.$$

The sum therefore converges in $B^+_{\max}$, with its usual topology having $p^a A_{\max}$ as a neighbourhood basis. This is the natural analytic embedding of Theorem A.3.13.

Let Q be any S-linear endomorphism of $B^+_{\max}$ preserving $A_{\max}$. It is K_0-linear: it commutes with Λ, and commutation with multiplication by p implies commutation with its inverse. Moreover $Q(p^a A_{\max}) \subseteq p^a A_{\max}$, so Q is continuous. For the polynomial partial sums F_d, one has $Q(F_d x) = F_d Q(x)$ for every $x \in B^+_{\max}$. Both sides converge: multiplication by any fixed element of $B^+_{\max}$ is continuous, since that element belongs to $p^{-b} A_{\max}$ for some b. Passing to the limit gives $Q(Fx) = FQ(x)$. By the exact definition (BF4), $F \in \mathcal{S}_B$. Thus

$$\mathcal{O}^{\mathrm{an}} \subseteq \mathcal{S}_B, \qquad \mathcal{O}^{\mathrm{an}}[1/\varphi(\mathscr{L})] \subseteq \mathrm{Frac}(\mathcal{S}_B).$$

Here the Euler product $\varphi(\mathscr{L})$ is nonzero by its constant term 1; no assertion that its inverse is integral in $\mathcal{S}_B$ is needed. Also $S[1/E] \subseteq \mathrm{Frac}(\mathcal{S}_B)$, since polynomial multiplication and then continuity show $S \subseteq \mathcal{S}_B$, and $E \neq 0$.

The effective case on the actual embedded module. First suppose that the weights of T, in the convention of Theorem A.3.13, lie in $[0, h]$. Let $\mathfrak{M}$ denote the direct-embedding module of that theorem. The direct map i_0 and the map i_{B} of Theorem A.3.12 satisfy $i_{\mathrm{B}} = \varphi_{A_{\mathrm{inf}}} \circ i_0$, including on coefficients. The equivariant étale identifications in those two theorems identify

$$N_0 = \mathfrak{M} \quad \text{and} \quad S \cdot \varphi(N_0) = \mathfrak{M}^{\varphi}$$

inside the same $T \otimes W(\mathbb{C}_p^{\flat})$. More explicitly, evaluating an abstract basis through i_{B} gives the coefficientwise Frobenius of its evaluation through i_0; applying $\varphi^{-1}_{A_{\mathrm{inf}}} \otimes 1$ recovers precisely that latter evaluation. The étale identifications agree with the identity on T. This uses their specified comparisons, rather than choosing an abstract module isomorphism. The image of the linearised Frobenius after the direct evaluation is exactly the S-span of these Frobenius vectors.

Choose an S-basis $n_1, \ldots, n_d$ of N_0. Transporting the Breuil–Kisin Frobenius of Theorem A.3.12 through this direct evaluation gives

$$(\varphi n_1, \ldots, \varphi n_d) = (n_1, \ldots, n_d)A, \qquad A \in \mathrm{GL}_d(S[1/E]).$$

Let $d_1, \ldots, d_d$ be a K_0-basis of $D_{\mathrm{cris}}(T[1/p])$. The isomorphism after localisation in Theorem A.3.13, and its agreement with the actual crystalline comparison, express each φn_j as a linear combination of the d_i with coefficients in $\mathcal{O}^{\mathrm{an}}[1/\varphi(\mathscr{L})]$.

The crystalline form λ extends on $T \otimes B_{\max}$ to the $B_{\max}$-linear map defined by its values on T. For the vectors used here it agrees with the given form: item 2 of Theorem A.3.12, followed by inverse Frobenius, puts N_0 in $A_{\mathrm{inf}}[1/\tau] \otimes T$, since $\varphi^{-1}(\mu) = \tau$. Both maps agree on this localisation, by multiplying a vector by a sufficiently large power of the nonzero scalar τ. The same observation applies to $\varphi(N_0)$. Its equivariance implies $\lambda(d_i) \in B^{G_K}_{\max} = K_0$. Indeed the crystalline comparison identifies the fixed vectors with D_{cris}, and the scalar fixed field is K_0. Hence $\lambda(\varphi n_j) \in \mathrm{Frac}(\mathcal{S}_B)$. Multiplying the row of these values by A^{-1}, whose entries belong to $S[1/E]$, proves $\lambda(n_j) \in \mathrm{Frac}(\mathcal{S}_B)$ for every j. This proves the effective case without applying inverse Frobenius to an analytic power series.

Arbitrary signed weights. Choose a rank-one Tate lattice L whose weight is sufficiently large and nonnegative in the convention of Theorem A.3.13 that both L and $T \otimes L$ have all weights nonnegative. The tensor property of Theorem A.3.12, with its specified étale comparison, and coefficientwise inverse Frobenius give literal tensor identifications of the embedded modules

$$N_0(T \otimes L) = N_0(T) \otimes_S N_0(L).$$

Take an S-basis t_L of the rank-one module $N_0(L)$, and a nonzero crystalline form ρ of L. The actual rank-one crystalline comparison implies $\rho(t_L) \neq 0$. The effective case gives $\rho(t_L) \in \mathrm{Frac}(\mathcal{S}_B)$. For the original arbitrary crystalline form λ, its tensor product with ρ is a crystalline form of $T \otimes L$. Applying the effective case again gives, for each $n \in N_0(T)$,

$$\lambda(n)\rho(t_L) = (\lambda \otimes \rho)(n \otimes t_L) \in \mathrm{Frac}(\mathcal{S}_B).$$

Division by the nonzero scalar $\rho(t_L)$ proves the assertion. All comparisons and tensor products used here preserve the original embedded module; no different lattice or auxiliary frame is substituted. □

Lemma 7.7.20. *Let $r \geq 0$, $H \geq 0$, and let $t \in G_{\mathbb{Q}_p}$ fix Λ pointwise and $\theta(z)$, with $t(z) = [\varepsilon]z$. Suppose*

$$Z \in M_r(S_B), \qquad Z' \in M_r(B^+), \qquad Z'Z = E^H I_r, \qquad t(Z) = ZG, \quad G \in M_r(A_{\mathrm{inf}}).$$

For every $l, b \geq 0$ with $3e \leq p^l$, there are an evaluation homomorphism

$$\mathrm{ev}_l : S[[X]] \longrightarrow A_{\mathrm{max}}, \qquad \mathrm{ev}_l(X) = z^{p^l}/p^2,$$

a matrix $\mathcal{V} \in \mathrm{GL}_r(S[[X]])$, and a matrix $C \in \mathrm{GL}_r(B^+)$, such that, putting $V = \mathrm{ev}_l(\mathcal{V})$,

$$\varphi^l(Z) = \varphi^l(E)^b C V.$$

Every $g \in G_{\mathbb{Q}_p}$ fixing Λ pointwise fixes every entry of C. For any $A, \delta \geq 0$ with $eA \leq p^l\delta$, define

$$\mathcal{Y}_{A,V} = \{y \in S^r : \ Vy - n \in E^A(B^+)^r \text{ for some } n \in \mathbb{Z}^r_{\geq 0}\}.$$

Then

$$p^{4\delta} S^r \ \subseteq \ \mathrm{span}_S(\mathcal{Y}_{A,V}).$$

The rank-zero assertions are interpreted using empty matrices and the zero module.

Proof. **The actual scalar chart results apply to these matrices.** By Lemma 7.7.22(4)–(7), choose its single S_B-linear retraction $P : B^+ \to S_B$. It fixes S_B, maps A_{inf} into S and preserves A_{max}. For $\nu = E, z$, $a \geq 0$, and $x \in A_{\mathrm{max}}$, its stated approximation is

$$p^a P(x) = s + \nu^a w, \qquad s \in S, \quad w \in S_B. \tag{R0}$$

We also use the stated Frobenius stability of S_B, separation $\bigcap_n z^n B^+ = 0$, and Galois difference. The hypothesis on t, together with the actual Kummer chart condition, gives a preimage of t in the chart subgroup Γ'; hence that difference assertion gives $\tau z \mid t(y) - y$ for every $y \in S_B$. The separate result Lemma 7.7.30 supplies integral cancellation for every nonnegative m, n, h. These are statements about the actual scalar rings, with no canonical module as an input.

The chart identifies $S = \Lambda[[z]]$; its Frobenius preserves S, acting by Witt Frobenius on coefficients and sending z to z^p. The chart equation $E = p + z^e U(z)$, with $U(z)$ a unit, gives $\theta(z)^e \theta(U(z)) = -p$; thus $z \neq 0$. The compatible primitive cyclotomic system also gives $\tau \neq 0$.

Write $A_0 = A_{\mathrm{inf}}$ and $Q = [\varepsilon]$, to distinguish the coefficient ring from the exponent A in the conclusion. All displayed matrix identities are over the commutative domain B^+; its embeddings of A_0, S, A_{max} are suppressed. The retraction is applied entrywise. Because it fixes S_B and is S_B-linear, $P(TZ) = P(T)Z$ whenever Z has entries in S_B.

A constant matrix normalizes the constant term of Z. Apply P to $p^{-H}Z'Z = p^{-H}E^H I_r$. It gives

$$TZ = p^{-H}E^H I_r, \qquad T = P(p^{-H}Z') \in M_r(S_B). \tag{R1}$$

Every $y \in S_B$ has a decomposition

$$y = c + zw, \qquad c \in \Lambda[1/p], \quad w \in S_B. \tag{R2}$$

Indeed choose k with $p^k y \in A_{\max}$. The scalar approximation for $\nu = z, a = 1$, and $P(y) = y$, gives $p^{k+1}y = s + zw_0$; write the power series representing $s \in S$ as its constant in Λ plus z times another series, then divide by p^{k+1}. Apply (R2) to each entry of T, writing $T = B + zT_1$. Since $E - p \in zS$, also $E^H - p^H \in zS$, including $H = 0$. Equation (R1) becomes

$$BZ = I_r + zW, \qquad W \in M_r(S_B), \quad B \in M_r(\Lambda[1/p]). \tag{R3}$$

Every Galois element fixing Λ fixes B, and so does t. Put $Y = BZ$. Then $t(Y) = YG$.

The scalar difference law gives $\tau z \mid t(Z) - Z$ entrywise. Multiplication by Z' and the hypotheses imply

$$Z'(t(Z) - Z) = E^H(G - I_r).$$

Each entry of $G - I_r$ is integral in A_0. Integral cancellation therefore gives

$$\tau z \mid (G - I_r)_{ij} \quad \text{in } A_0. \tag{R4}$$

The needed lifting-the-exponent identity is an integral identity. For $n \geq 1$, put $v = v_p(n)$. There are $\alpha_n, \beta_n \in A_0$ with

$$\alpha_n(Q^n - 1) = \tau E(p^v + \beta_n z). \tag{R5}$$

Here is a proof valid also for $p = 2$. The period convention gives $Q - 1 = \tau\xi$, and E is associated to ξ. Applying Frobenius repeatedly, with $\varphi(\tau) = Q - 1$, gives

$$Q^{p^v} - 1 = u_v \tau \prod_{a=0}^{v} \varphi^a(E), \qquad u_v \in A_0^\times.$$

For $n = p^v n_0$, the quotient of $Q^n - 1$ by $Q^{p^v} - 1$ is the geometric sum with n_0 terms. It is a unit: $A_0 = W(\mathcal{O}^\flat_{\mathbb{C}_p})$ is local, Q has residue one, and this sum has nonzero residue $n_0 \bmod p$. Each $\varphi^a(E)$, for $a \geq 1$, is congruent to p modulo zA_0, by $E = p + z^e U(z)$ and $\varphi(z) = z^p$. Hence their product equals $p^v + \beta_n z$. Absorb the product of units into α_n. If $v = 0$, use the empty product one and $\beta_n = 0$. This proves (R5).

One row step keeps every cancellation integral. Fix a row index i. Suppose $q \geq 0$, $n \geq 0$, $W_n \in (S_B)^r$ and $A_n \in A_0^r$ satisfy

$$A_n = qY_i - z^{n+1}W_n. \tag{R6}$$

Put $v = v_p(n+1)$, and choose α, β from (R5) for $n + 1$. Write $E = p + zr_0$, $r_0 \in S$. By (R4) and the scalar difference assertion, there is $D \in (B^+)^r$ with

$$W_n(G - I_r) - Q^{n+1}(t(W_n) - W_n) = \tau z D.$$

Expanding $A_nG - t(A_n)$, using $t(Y) = YG$ and $t(z) = Qz$, gives exactly

$$A_nG - t(A_n) = z^{n+1}((Q^{n+1} - 1)W_n - \tau z D).$$

Consequently, with $W'' = \alpha D - (p^v r_0 + \beta E)W_n$, one has

$$\alpha(A_n G - t(A_n)) = \tau z^{n+1}(p^{v+1}W_n - zW''). \tag{R7}$$

The left side lies in A_0^r. Integral cancellation with $h = 0$ proves that the parenthesized vector is the image of a vector $x \in A_0^r$, not merely a fraction in B^+. Apply P to that equality. Since $P(x) \in S^r$ and $P(W_n) = W_n$, we obtain $s_n \in S^r$ and $W_{n+1} \in (S_B)^r$ with

$$p^{v_p(n+1)+1}W_n = s_n + zW_{n+1}. \tag{R8}$$

Set

$$q_{n+1} = p^{v_p(n+1)+1}q, \qquad A_{n+1} = p^{v_p(n+1)+1}A_n + z^{n+1}s_n.$$

Then $A_{n+1} = q_{n+1}Y_i - z^{n+2}W_{n+1}$. Thus the same integral row hypothesis (R6) is available for the next step. Initially take $q = 1$, the integral row $(I_r)_i$, and $W_0 = W_i$ from (R3).

The row recursion produces a unit power series after Frobenius. Put $N = p^l$ and $T = z^N/p^2$. Since E is a multiple of p in $A_{\max}$, the identity $E = p + z^e U(z)$ implies $z^e \in pA_{\max}$, because $U(z)$ is a unit. The inequality $N \geq 3e$ therefore gives $z^N \in p^3 A_{\max}$. Thus $T \in pA_{\max}$ and p-adic completeness defines the evaluation homomorphism ev_l on all of $S[[X]]$. This map sends every unit power series, and every invertible formal matrix, to a unit or an invertible matrix. Also $T \in zB^+$.

For a fixed entry of a row satisfying (R6), put

$$a_n = n - v_p(n!) + 2, \qquad g_n = p^{a_n}\varphi^l(W_{n,j}).$$

The elementary factorial identity gives

$$a_n = \big(n + 1 - v_p((n+1)!)\big) + v_p(n+1) + 1.$$

The first parenthesis is nonnegative: $v_p(m!) \leq m$ for every $m \geq 0$, from the sum $\sum_{k\geq 1}\lfloor m/p^k \rfloor$. Applying φ^l to (R8) consequently gives an exact recursion

$$g_n = d_n + Tg_{n+1}, \qquad d_n = p^{\,n+1-v_p((n+1)!)}\varphi^l(s_{n,j}) \in S. \tag{R9}$$

The exponent on g_{n+1} is correct because multiplication of T by p^2 is $\varphi^l(z)$. For $f(X) = \sum_{n\geq 0} d_n X^n \in S[[X]]$, iteration of (R9), together with the exact decomposition of f into its degree-$< m$ truncation and X^m times its shifted series, shows, for every m, that $g_0 - \mathrm{ev}_l(f) \in T^m B^+ \subseteq z^m B^+$. Separation by powers of z proves equality. At $n = 0$, $a_0 = 2$, so entrywise this constructs $F \in M_r(S[[X]])$ with

$$\mathrm{ev}_l(F) = p^2\varphi^l(W), \qquad \varphi^l(B)\varphi^l(Z) = \mathrm{ev}_l(I_r + XF). \tag{R10}$$

The formal matrix $\mathcal{U} = I_r + XF$ is invertible, with its inverse given coefficientwise by its geometric series. Thus the right side of (R10) is invertible. In a commutative ring, a square product is invertible only if both factors are: take determinants and use the adjugate formula. Hence $\varphi^l(B)$ is invertible in B^+.

Since $E = p + zr_0$,

$$\varphi^l(E) = p\ \mathrm{ev}_l(\gamma), \qquad \gamma = 1 + p\varphi^l(r_0)X \in S[[X]]^\times.$$

Define

$$\mathcal{V} = \gamma^{-b}\mathcal{U}, \qquad C = (p^b\varphi^l(B))^{-1}.$$

Substitution in (R10) now yields $\varphi^{l}(Z) = \varphi^{l}(E)^{b} C \operatorname{ev}_{l}(\mathcal{V})$. Every entry of B lies in $\Lambda[1/p]$; Frobenius preserves that field and commutes with the Galois action. Therefore every element fixing Λ fixes C. This proves the asserted factorization.

Denominator approximation gives the stated exponent 4δ. For every $f \in S[[X]]$ and integer $D \geq 0$, truncation at D, evaluated at $T = z^{N}/p^{2}$, gives

$$p^{2D} \operatorname{ev}_{l}(f) = s + z^{ND} \operatorname{ev}_{l}(f_{D}), \qquad s \in S, \quad f_{D} \in S[[X]]. \tag{R11}$$

Indeed for $f = \sum f_{n} X^{n}$, take $s = \sum_{n<D} p^{2(D-n)} f_{n} z^{Nn}$ and $f_{D} = \sum_{n \geq D} f_{n} X^{n-D}$. The retraction fixes each $\operatorname{ev}_{l}(f)$. To prove this without assuming continuity of P in the z-adic topology, apply P to (R11). Since $s, z \in S_{B}$, the difference $P(\operatorname{ev}_{l}(f)) - \operatorname{ev}_{l}(f)$ is divisible by z^{ND} in B^{+} for every D, after cancellation of the unit p^{2D}. Separation and $N > 0$ give the assertion.

Suppose $eA \leq N\delta$. The relation $z^{e} \in pA_{\max}$ gives $z^{N\delta} = p^{A} y$ for some $y \in A_{\max}$. Equation (R11), with $D = \delta$, and its image under P, therefore give

$$p^{2\delta} \operatorname{ev}_{l}(f) = s + p^{A} P(y \operatorname{ev}_{l}(f_{\delta})).$$

The approximation property for $\nu = E$ and exponent A writes the final term as $s' + E^{A} w$, $s' \in S, w \in S_{B}$. We have proved

$$\text{for every } f \in S[[X]] \text{ there is } s(f) \in S \text{ with } s(f) \equiv p^{2\delta} \operatorname{ev}_{l}(f) \pmod{E^{A} B^{+}}. \tag{R12}$$

No linearity of the choice $s(f)$ is needed.

Apply (R12) entrywise to $\mathcal{V}^{-1}$ and $\mathcal{V}$, obtaining matrices $M, M' \in M_{r}(S)$. Put $V = \operatorname{ev}_{l}(\mathcal{V})$. Modulo E^{A}, they satisfy

$$VM \equiv p^{2\delta} I_{r}, \qquad V(p^{4\delta} I_{r} - MM') \equiv 0.$$

Every column of M is therefore in $\mathcal{Y}_{A,V}$, with natural vector $p^{2\delta} e_{j}$; every column of $p^{4\delta} I_{r} - MM'$ is in that set with natural vector zero. Finally for every $x \in S^{r}$,

$$p^{4\delta} x = (p^{4\delta} I_{r} - MM')x + M(M'x).$$

Both summands lie in the S-span of those columns, proving the asserted inclusion. The argument includes $A = 0$ and $\delta = 0$. In rank zero all matrices are empty and the span inclusion is the equality of zero modules. □

Lemma 7.7.21. *For a fixed chart put $A = A_{\mathrm{inf}}$ and $S = \mathcal{S}_{\mathrm{ch}}$. There is an S-linear map $q_{0} : A \to S$, identity on S, such that the following assertions hold for every lattice L with letter jump sets.*

1. *The formula*

$$R_{L}\left(\sum_{\nu=1}^{r} a_{\nu} v_{\nu}\right) = \sum_{\nu=1}^{r} q_{0}(a_{\nu}) v_{\nu}, \qquad a_{\nu} \in A, \quad v_{\nu} \in N_{\mathrm{loc}}(L),$$

   defines an S-linear retraction from $AN_{\mathrm{loc}}(L)$ onto $N_{\mathrm{loc}}(L)$. It commutes with equivariant lattice maps, in particular the letter projectors and the inclusion and quotient maps of a side extension.

2. *For every $a \geq 0$, $n \in \mathbb{Z}$, form λ, $v \in \mathcal{K}_{a}$, and $y \in AN_{\mathrm{loc}}(L)$,*

$$\lambda(\varphi^{-a} y) - v \in \mathrm{Fil}^{n} \implies \lambda(\varphi^{-a} R_{L} y) - v \in \mathrm{Fil}^{n}.$$

   In particular R_{L} preserves every prescribed order module and every such congruence to a fixed-field constant.

3. *For every $l \geq 0$ and letter i,*

$$\mathfrak{X}_L(i;\mathrm{std}_l) = (\varphi^l M(L))_i, \qquad N_{\mathrm{loc}}(L) \cap \mathfrak{X}_L(i;\mathrm{std}_l) = \big(S \operatorname{span} \varphi^l N(L)\big)_i.$$

4. *For a side S_1, a natural modulus r, $f \in S \cap J_l(i;r)$, there is one $t \in S$ such that every $y \in N_{\mathrm{loc}}(C) \cap \mathfrak{X}_C(i;\mathrm{std}_l)$ has a lift $x \in N_{\mathrm{loc}}(\widetilde{Y}_{S_1}) \cap \mathfrak{X}_{\widetilde{Y}_{S_1}}(i;\mathrm{std}_l)$ with $\pi_{S_1} x = (f - rt)y$. The same t works for all y, hence for all constants.*

Proof. Let $S = \mathcal{S}_{\mathrm{ch}}$, $A = A_{\mathrm{inf}}$. We first construct the coefficient retraction used below. The regular sequence (p, z) in A_{inf} gives

$$\mathrm{gr}_{(p,z)} A_{\mathrm{inf}} = (A_{\mathrm{inf}}/(p,z))[P, Z].$$

This follows degree by degree by reducing a homogeneous relation modulo p, canceling the nonzero $\bar{z}$, and then dividing by p; iteration shows that every coefficient of a homogeneous relation lies in (p, z). The Witt-coordinate description makes A_{inf} complete and separated for (p, z): modulo p^m, the z-adic topology is the complete valuation topology on the finitely many tilt coordinates. Choose a basis $(\bar{b}_j)$ of $A_{\mathrm{inf}}/(p, z)$ over Λ/p, containing 1, and lifts b_j, with the lift of 1 equal to 1. The graded identity, followed by induction on the adic order and completeness, gives

$$A_{\mathrm{inf}} \simeq \varprojlim_n \bigoplus_j S/(p,z)^n S.$$

At each finite order only finitely many coefficients occur. The coordinate at 1 is an S-linear map $q_0 : A_{\mathrm{inf}} \to S$, identity on S. For a finite relation $\sum a_j v_j = 0$ with $v_j \in N_{\mathrm{loc}}(L)$, each vector is denominator-clearable in the ambient lattice and its form values belong to $\mathcal{K}_0$. The exact relation assertion of Proposition 7.7.16 therefore gives $\sum q_0(a_j) v_j = 0$. The coefficient map on $A \otimes_S N_{\mathrm{loc}}$ consequently factors through its actual image AN_{loc}, defining R_L. Its image lies in N_{loc}, and $q_0(1) = 1$ makes it a retraction. An equivariant lattice map takes canonical modules and their localizations to the corresponding canonical modules: integral denominators and Frobenius tests are preserved by pulling back forms, and value-field tests are preserved in the same way. On a finite sum $\sum a_j v_j$, its two composites with R both equal $\sum q_0(a_j) f(v_j)$. This proves naturality, including letter projectors and side maps.

For completeness, values at level a of $v \in N_{\mathrm{loc}}$ belong to $\mathcal{K}_a$. For $x \in N_{\mathrm{loc}}$, choose a finite product P of the E_b with $Px \in M$. Since $P \in S \subset \mathcal{K}_0$, all form values of Px are still in $\mathcal{K}_0$, so $Px \in N$. Thus N_{loc} is exactly this localization of N. Now $E^h \varphi N \subseteq N$ and $\varphi(E_b) = E_{b+1}$ imply $\varphi N_{\mathrm{loc}} \subseteq N_{\mathrm{loc}}$; and $M = AN$ gives $M_{\mathrm{loc}} = AN_{\mathrm{loc}}$ by clearing the finite localization product. Clear a nonzero ambient denominator of $\varphi^{-a} v$, multiply by a power of τ, and express the resulting vector using $M = AN$ and localization. Apply φ^a and then a chart coefficient coordinate which is nonzero on the coefficient of v. The exact relation law preserves this relation. Solving the evaluated relation expresses $\lambda(\varphi^{-a} v)$ as a quotient of finite sums of $\varphi^{-a}(S)$-multiples of $\mathcal{K}_0$-values. These belong to $\mathcal{K}_a$. Thus, for $y = \sum a_j v_j$,

$$\lambda(\varphi^{-a} y) - v = \sum_j \varphi^{-a}(a_j) \lambda(\varphi^{-a} v_j) + \varphi^{-a}(1)(-v).$$

Apply Lemma 7.7.22 to this finite sum, including its last term. It replaces a_j by $q_0(a_j)$ and fixes 1, proving item2 at every integer filtration. Naturality preserves the letter part, so all order modules are preserved.

The finite Hodge basis used in the standard tests. By Lemma 7.4.6 the representation is continuous and de Rham. By Theorem A.3.16, its invariant de Rham space has the full

dimension and gives the comparison isomorphism. Choose a basis d_m of this space adapted to its filtration, separately in each letter part; the projectors are fixed by the subgroup and preserve this filtration. Let u_m be the corresponding jumps. The natural graded comparison of Theorem A.3.11 says that the reductions of $e_m = t^{-u_m} d_m$ form a basis of the integral comparison lattice modulo t. Their comparison matrix has integral entries and unit determinant, hence they form a B_{dR}^+-basis of $B_{\mathrm{dR}}^+ \otimes L$ in that part. The invariant dual forms λ_m, with $\lambda_m(d_n) = \delta_{mn}$, have type u_m, since their values on e_m are t^{-u_m}. Their values extend to actual ambient forms by choosing a complement after localizing A_{inf} at all nonzero elements and extending by zero. All vectors evaluated below have a nonzero integral denominator, so their values do not depend on this auxiliary extension. Every u_m is an actual jump and lies in the prescribed jump set.

Actual standard orders and Frobenius pullback. Use (BF2)–(BF5), (DQ1)–(DQ2), and the invariant Hodge bases just constructed. Write $A = A_{\mathrm{inf}}$, $E_a = \varphi^a(E)$, and $T_l = \varphi^l(\tau)$. A subscript i means intersection with the actual letter-i part.

The following scalar facts are consequences of the fixed Fontaine elements and the chart $E = \xi$ times a unit:

$$T_l = u_l\, \tau \prod_{0 \le a < l} E_a, \qquad u_l \in A^\times, \tag{S1}$$

$$\theta(\varphi^{-a} c) = 0 \ (c \in A) \iff c \in E_a A, \qquad \varphi^{-a}(\tau) \in (B_{\mathrm{dR}}^+)^\times, \tag{S2}$$

and

$$\varphi^r(E_a) \in (B_{\mathrm{dR}}^+)^\times \quad (r \ge 1,\ a \ge 0). \tag{S3}$$

Here and below the scalar in a period-ring assertion is its prescribed image in B_{dR}. For (S1), use $\varphi(\tau) = \mu = \xi\tau$ and iterate, replacing ξ by its unit multiple E. For (S2), the kernel of θ is $\xi A = EA$, and Frobenius is an automorphism of A. Also $\theta(\varphi^{-a}\tau) = \zeta_{\ell^{a+1}} - 1 \neq 0$; this is a unit in the t-adic valuation ring B_{dR}^+. For (S3), $\theta(\varphi^b \xi) = \ell \neq 0$ for $b \ge 1$, directly from $\xi = \sum_{j=0}^{\ell-1} [\epsilon^{1/\ell}]^j$. Multiplication by a unit and its Frobenius images does not change nonvanishing. These facts include $\ell = 2$ and $l = 0$.

Positive Frobenius tests hold on the localization. If $x \in M_{\mathrm{loc}}(L)$, choose a finite product P of the E_a with $Px \in M(L)$. For every form λ and $r \ge 1$,

$$\lambda(\varphi^r(Px)) = \varphi^r(P)\lambda(\varphi^r x) \in B_{\mathrm{dR}}^+.$$

The scalar $\varphi^r(P)$ is a unit by (S3), so

$$\lambda(\varphi^r x) \in B_{\mathrm{dR}}^+ \qquad (r \ge 1). \tag{S4}$$

Each evaluation is on a vector whose denominator can be cleared by an element of A, so the displayed identity follows from A-linearity by clearing that denominator. No evaluation of an arbitrary ambient functional away from its fractional lattice span is involved.

A standard order permits cancellation of a high localization factor. Let $x \in \mathfrak{X}_L(i; \mathrm{std}_l)$, $a \ge l$, and $r \in A$. We prove

$$rE_a x \in A \otimes_{\mathbb{Z}_\ell} L \quad \Longrightarrow \quad rx \in A \otimes_{\mathbb{Z}_\ell} L. \tag{S5}$$

Choose a $\mathbb{Z}_\ell$-basis of L, with integral coordinate functionals κ_s. Let $j = i^{(a)}$. In this letter part choose invariant Hodge vectors $d_m = t^{u_m} e_m$, where the e_m are a B_{dR}^+-basis of the integral comparison lattice, and let λ_m be their invariant dual forms. The integers u_m are actual jumps and λ_m has type u_m. For any denominator-clearable y in that letter part,

$$\kappa_s(y) = \sum_m \kappa_s(d_m)\lambda_m(y), \qquad \kappa_s(d_m) \in \mathrm{Fil}^{u_m}. \tag{S6}$$

The coefficient assertion holds because $d_m = t^{u_m} e_m$ and the integral coordinate functional is B_{dR}^+-valued on the integral comparison lattice. Apply (S6) to $y = \varphi^{-a}x$. Its standard order at level $a \geq l$ gives $\lambda_m(y) \in \mathrm{Fil}^{-u_m}$, so

$$\kappa_s(\varphi^{-a}x) \in \mathrm{Fil}^0 \quad \text{for every } s. \tag{S7}$$

Write the integral vector $rE_a x$ in the chosen lattice basis, with coordinates $c_s \in A$. Then

$$\varphi^{-a}(c_s) = \varphi^{-a}(rE_a)\,\kappa_s(\varphi^{-a}x) \in \mathrm{Fil}^1.$$

By (S2), $c_s = E_a b_s$ for some $b_s \in A$. The vector with coordinates b_s is therefore integral and, after multiplication by E_a, equals $rE_a x$. The ambient module has no A-torsion; cancelling E_a proves (S5).

All localization denominators are absorbed by a power of T_l. Again let $x \in \mathfrak{X}_L(i;\mathrm{std}_l)$. Choose $P = \prod_{\nu=1}^m E_{a_\nu}$ with $Px \in M(L)$, so $\tau^n Px$ is integral for some n. By (S1), $T_l^n Px$ is integral. Remove the factors of P one at a time. At an intermediate stage let y be the product of the remaining factors times x, and suppose $T_l^b E_a y$ is integral. The vector y still has the same standard orders, because the order module is an A-submodule. If $a \geq l$, (S5) cancels E_a. If $a < l$, (S1) gives $T_l/E_a \in A$, so multiplication by this scalar makes $T_l^{b+1}y$ integral. The finite induction proves

$$T_l^b x \in A \otimes L \quad \text{for some } b \geq 0. \tag{S8}$$

Put $y = \varphi^{-l}x$. Applying inverse Frobenius to (S8) gives $\tau^b y \in A \otimes L$, the first condition defining $M(L)$. To verify the other condition, let λ be any form and $r \geq 1$. If $r > l$, (S4) gives $\lambda(\varphi^r y) = \lambda(\varphi^{r-l}x) \in B_{\mathrm{dR}}^+$. If $1 \leq r \leq l$, set $a = l - r < l$. The standard tests for x at level a put every typed invariant Hodge-basis form value on $\varphi^{-a}x = \varphi^r y$ in Fil^0. Any invariant form on that letter part is a finite linear combination of these dual Hodge forms with coefficients in the finite fixed field, hence coefficients in Fil^0. Thus its value too is integral. This proves all positive-Frobenius tests for y, and hence $y \in M(L)$. Frobenius permutes letter projectors, so x lies in the letter-i part of $\varphi^l M(L)$.

The reverse implication has the exact standard orders. Let $y \in M(L)$ in the letter-$i^{(l)}$ part and put $x = \varphi^l y$. Choose n with $\tau^n y \in A \otimes L$. Formula (S1) shows that the product $P = \prod_{a<l} E_a^n$ makes Px τ-saturated integral. Its positive-Frobenius form values are integral: they are those of $\varphi^{r+l}y$, multiplied by $\varphi^r(P) \in A$, for $r \geq 1$. Thus $Px \in M(L)$, so $x \in M_{\mathrm{loc}}(L)$.

For $a \geq 0$, the vector $\varphi^{-a}(\tau^n y)$ belongs to the integral A-lattice. A form of type u on its letter part takes it into Fil^{-u}. The scalar $\varphi^{-a}(\tau)^n$ is a unit by (S2), so y has orders $-u$ at every level. For $x = \varphi^l y$, a test at level $a \geq l$ is exactly the test on y at level $a - l$, giving order $-u$. At $a < l$ it is a positive-Frobenius value on y, giving order 0. This proves

$$\boxed{\mathfrak{X}_L(i;\mathrm{std}_l) = (\varphi^l M(L))_i.} \tag{S9}$$

The argument covers $l = 0$: there are no low factors and no low-level case.

The value-field intersection is precisely the existing descent clause. By (BF5), $N_{\mathrm{loc}}(L)$ consists of localized vectors all of whose form values belong to $\mathcal{K}_0$. The first equality (S9) therefore gives, without any descent assumption,

$$N_{\mathrm{loc}}(L) \cap \mathfrak{X}_L(i;\mathrm{std}_l) = \{x \in \varphi^l M(L) : \lambda(x) \in \mathcal{K}_0 \text{ for every form } \lambda\}_i. \tag{S10}$$

Item 3(b) of Proposition 7.7.16 states exactly that the unprojected set on the right is the S-span of $\varphi^l N(L)$. Applying that assertion to (S10) yields

$$\boxed{N_{\mathrm{loc}}(L) \cap \mathfrak{X}_L(i;\mathrm{std}_l) = (S\,\mathrm{span}\,\varphi^l N(L))_i.} \tag{S11}$$

Equations (S9) and (S11) prove item3.

To prove the common lift assertion, proceed as follows. The definition of $J_l(i;r)$ supplies ONE $t_0 \in A$ and, for each parameter c, a standard-order lift x_c with

$$\pi x_c = (f - rt_0)\mathrm{cst}_i(c).$$

Those standard modules lie in AN_{loc}, since they are $\varphi^l M$ and $M = AN$. Apply R. Its order preservation retains the standard orders, and its image belongs to N_{loc}. Naturality and S-linearity on the constant lattice give

$$\pi R(x_c) = (f - rq_0(t_0))\mathrm{cst}_i(c).$$

Here $f \in S$ and $q_0(1) = 1$. For the trivial parameter lattice, height zero gives $M = A \otimes C$; its canonical value-field part is $S \otimes C$. To see the latter equality directly, apply the exact coefficient relation law to $a(1 \otimes c) - 1(a \otimes c) = 0$ for a vector with value-field coordinates, using q_0; it forces each coordinate $a = q_0(a) \in S$. Frobenius and the letter projectors preserve the constants. Consequently the entire localized standard part of the trivial lattice is the S-span of these constants, at every level. Extend the constructed lifts by S-linearity to arbitrary y in that part. The single scalar $t = q_0(t_0) \in S$ is independent of c and y, as required. □

Lemma 7.7.22. *Put $S = \mathcal{S}_{\mathrm{ch}}$, $A = A_{\mathrm{inf}}$, and let K' be the algebraic field fixed by the chart subgroup. The following assertions hold.*

1. *Every S-linear $q : A \to S$ extends to an $\mathcal{S}_B$-linear map $\widetilde{q} : B^+ \to \mathcal{S}_B$. This extension agrees with q on A.*

2. *For every $c \in K'$ and $n \geq 0$, there is $t \in \mathcal{S}_B$ such that $t - c \in \xi^n B^+_{\mathrm{dR}}$. Moreover, for $b \in B^+$,*

$$E^n \mid b \text{ in } B^+ \quad \Longleftrightarrow \quad b \in \xi^n B^+_{\mathrm{dR}}.$$

   Here the displayed membership uses the fixed period-ring embedding.

3. *For every such q, $a \geq 0$, integer n, and finite families $r_j \in A$, $v_j \in \mathcal{K}_a$,*

$$\sum_j \varphi^{-a}(r_j)v_j \in \mathrm{Fil}^n \quad \Longrightarrow \quad \sum_j \varphi^{-a}(q(r_j))v_j \in \mathrm{Fil}^n.$$

   In particular an exact relation remains exact after this coefficient operation.

4. *Write $p = \ell$. There is an S-linear retraction $q_0 : A \to S$, $q_0|_S = \mathrm{id}$, whose extension $P : B^+ \to \mathcal{S}_B$ is $\mathcal{S}_B$-linear, fixes $\mathcal{S}_B$ pointwise, and satisfies $P(A) = S$ and $P(A_{\max}) \subseteq A_{\max}$. It is continuous for the p-adic topology defined by $A_{\max}$, and*

$$\mathcal{S}_B = \widehat{S[E/p]}^{\,p}[1/p]$$

   inside B^+; the integral completion here is its closure in $A_{\max}$.

5. *For this same P, for $\nu \in \{E, z\}$, $a \geq 0$ and $b \in A_{\max}$, there are $s \in S$ and $w \in \mathcal{S}_B$ with*

$$p^a P(b) = s + \nu^a w.$$

   For every $y \in \mathcal{S}_B$ and all sufficiently large integers k, there are $c \in \Lambda$ and $w \in \mathcal{S}_B$ such that $p^k y = c + zw$.

6. *Frobenius maps $\mathcal{S}_B$ into itself, and $\bigcap_{n\geq 0} z^n B^+ = 0$.*

7. *Put $\tau = \varphi^{-1}([\varepsilon] - 1)$ for the compatible roots of unity of the period-ring convention. For every $\gamma \in G_\ell$ fixing Λ pointwise and every $y \in \mathcal{S}_B$, one has $z \mid \gamma y - y$ in B^+. In addition, for every $g \in \Gamma'$ and $y \in \mathcal{S}_B$,*

$$z\tau \mid gy - y \quad \text{in } B^+.$$

Proof. Write $p = \ell$, $A = A_{\mathrm{inf}}$, and $B^+ = B^+_{\mathrm{max}}$. We first identify the scalar ring in (BF4); the identification is a conclusion, not an additional hypothesis. Put

$$R_A = A[E/p] \subset A[1/p], \qquad R_S = S[E/p], \qquad C_0 = \widehat{R_S}^{\,p}.$$

The completions below are separated completions. Since E and ξ differ by a unit of A, $R_A = A[\xi/p]$ and its p-adic completion is A_{max}. Indeed $A[X]/(pX - \xi)$ embeds in $A[1/p]$: reduction modulo p and cancellation of the nonzero element $\bar{\xi}$ show successively that its defining ideal is p-saturated. Its localization at p is $A[1/p]$, proving the asserted embedding.

A chart-linear retraction. The chart map identifies S with $\Lambda[[z]]$. For clarity, it is injective: a nonzero series, after removing its common power of p, has nonzero reduction in $k[[X]]$; its first nonzero term has strictly smaller valuation at $\bar{z}$ than its subsequent terms. Here $k = \Lambda/p$ and $0 < v(\bar{z}) < \infty$. Thus its value cannot vanish.

The ring A is complete and separated for $I = (p, z)$. One way to check this explicitly is to reduce modulo p^m. The Witt-coordinate description of A/p^m identifies its z-adic topology with the product valuation topology on its finitely many tilt coordinates (multiplication by $z = [\varpi^\flat]$ multiplies these by fixed positive powers of $\varpi^\flat$). Those coordinates are complete. Taking the inverse limit in m proves completeness for the ideals (p^m, z^n), which are cofinal with the powers of I. Also p, z is a regular sequence: A is p-torsion free and $A/p = \mathcal{O}_{\mathbb{C}_p^\flat}$ is a domain in which $\bar{z} \neq 0$. The sequence can be reversed. In fact, if $pa = zb$, reduction modulo p implies $b = pb_1$, so cancellation gives $a = zb_1$.

The elementary regular-sequence calculation consequently gives

$$\mathrm{gr}_I A = (A/IA)[P, Z]. \tag{4}$$

The variables on the right are the initial forms of p, z. This calculation applies without a noetherian hypothesis on A: in each degree the relations are generated by the relation between p and z; reducing successively modulo p and canceling $\bar{z}$ proves that there is no further homogeneous relation. Equivalently, the usual induction for a regular sequence identifies I^n/I^{n+1} with the direct sum of $n + 1$ copies of A/I.

Choose a k-basis $(\bar{b}_j)_{j\in J}$ of A/IA, containing $\bar{b}_0 = 1$, and lifts $b_j \in A$ with $b_0 = 1$. The map $\bigoplus_J S \to A$ sending the jth basis vector to b_j induces an isomorphism modulo every power of (p, z). This follows first modulo (p, z) by the choice of basis and then inductively from (4), since $\mathrm{gr}_{(p,z)} S = k[P, Z]$. Hence

$$A \simeq \varprojlim_n \bigoplus_J S/(p, z)^n S \tag{5}$$

as complete S-modules. Projection to coordinate 0 in (5) defines an S-linear $q_0 : A \to S$ with $q_0(s) = s$ for $s \in S$. Infinite bases cause no infinite summation ambiguity: at every finite adic order the expression in (5) has finite support.

Extensions and the bicommutant. Let $f : A \to A$ be any S-linear map, not necessarily a retraction. Extend it to $A[1/p]$ by $f(a/p^m) = f(a)/p^m$. It commutes with multiplication by E/p, so preserves R_A, and it preserves $p^n R_A$ for every n. It therefore extends uniquely to a

continuous map on $A_{\max}$, and then to a map $\widehat{f} : B^+ \to B^+$. This extension is $S[1/p]$-linear, preserves $A_{\max}$, and commutes with multiplication by E/p. All these assertions follow first on R_A and then by completion.

For $q : A \to S$, this construction maps R_A into R_S. The latter ring has the induced p-adic topology: apply the extension of q_0 on R_A to see that

$$R_S \cap p^n R_A = p^n R_S.$$

Thus C_0 embeds in $A_{\max}$. The extension $\widehat{q}_0$ is an idempotent on $A_{\max}$, and its image is exactly C_0: its values are limits of elements of R_S, and it fixes R_S and hence its closure. In particular this image is closed.

Let $C = C_0[1/p] \subset B^+$. Every S-linear endomorphism F of B^+ preserving $A_{\max}$ commutes with every element of C. Indeed it is automatically $\mathbb{Q}_p$-linear, commutes with E/p, and is p-adically continuous on $A_{\max}$ because it preserves $p^n A_{\max}$. It therefore commutes first with R_S, then with C_0, and then with C. This proves $C \subseteq \mathcal{S}_B$ by the actual bicommutant definition (BF4). Conversely multiplication by $b \in \mathcal{S}_B$ commutes with $\widehat{q}_0$, which is one of those endomorphisms. As $\widehat{q}_0(1) = 1$, this gives

$$b = \widehat{q}_0(b) \in C.$$

We have proved the exact equality

$$\mathcal{S}_B = \widehat{S[E/p]}^{\,p}[1/p]. \tag{6}$$

The same argument shows that every $\widehat{f}$ is $\mathcal{S}_B$-linear, directly from the bicommutant definition. If $f = q$ takes values in S, its extension takes values in $C = \mathcal{S}_B$. This proves item 1, with the claimed agreement on A. It also proves the auxiliary extension assertion for arbitrary S-linear endomorphisms of A that we shall use below.

Divisibility is reflected by the de Rham embedding. Every element of $A_{\max}$ is represented by a restricted series $\sum_{j\geq 0} a_j (E/p)^j$, where $a_j \in A$ tend to zero p-adically. To see surjectivity of this presentation, lift successive polynomial approximations modulo p^n and sum their p-adically convergent corrections. The map to $\mathcal{O}_{\mathbb{C}_p}$ sends this series to $\theta(a_0)$ and is the residue map induced by the fixed embedding into B^+_{dR}.

Let $b \in B^+$ have residue zero. Multiply by a power of p to make it integral and choose the preceding presentation. Then $\theta(a_0) = 0$, so $a_0 = E a_0'$ in A, since E generates $\ker\theta$. Consequently

$$\frac{1}{E}\sum_{j\geq 0} a_j (E/p)^j = a_0' + \frac{1}{p}\sum_{j\geq 1} a_j (E/p)^{j-1} \in B^+.$$

Thus $b/E \in B^+$. Repeating proves that $b \in \xi^n B^+_{\mathrm{dR}}$ implies $b \in E^n B^+$ for every $n \geq 0$: after each division the de Rham order decreases by one, since E is a uniformizer times a de Rham unit. The converse follows from the embedding. This proves the divisibility assertion in item 2, including $n = 0$.

The initial lift of every fixed algebraic constant. Put $\pi = \theta(z)$ and $K_0 = \operatorname{Frac}\Lambda$. The defining chart series is $X^e U(X) + p$, with U a unit. Weierstrass preparation over the complete discrete valuation ring Λ writes it as a unit times a monic Eisenstein polynomial of degree e: its lower coefficients are divisible by p, and its constant coefficient is p times a unit. Evaluation at π is zero. In particular π is algebraic, $K_1 = K_0(\pi)$ is totally ramified of degree e, and $\theta(S) = \mathcal{O}_{K_1}$. Here evaluation of convergent series gives the latter equality: $\Lambda[\pi]$ is already the complete integer ring, and polynomial representatives modulo the monic Eisenstein polynomial give all its elements.

The chart subgroup has image exactly the subgroup of G_p fixing Λ pointwise and fixing π, by both inclusions in the chart condition. The fixed field K' in the statement is therefore K_1, by ordinary finite Galois theory. In the presentation (6), $\theta(C_0) \subseteq \mathcal{O}_{K_1}$: the values of polynomial approximations lie there and converge p-adically. Conversely $S \subset C_0$ already maps onto $\mathcal{O}_{K_1}$. Thus

$$\theta(\mathcal{S}_B) = K'. \tag{7}$$

This proves the required initial lift; it is not inferred merely from a fixed-field name.

For $c \in K'$, choose $s \in \mathcal{S}_B$ with $\theta(s) = c$. Then $s - c \in \xi B^+_{\mathrm{dR}}$. Let P be the minimal polynomial of c over K_0. It is separable. Bezout's identity supplies $a, b \in K_0[X]$ with $aP + bP' = 1$. The polynomial $H(X) = X - b(X)P(X)$ satisfies $H(c) = c$ and $H'(c) = 0$. Thus $H(X) - c$ is divisible by $(X - c)^2$ over $K_0(c)$. Its coefficients are algebraic constants and hence belong to B^+_{dR}. Iterating H starting at s stays in $\mathcal{S}_B$ and doubles the order of its difference from c. This gives any prescribed order n; for $n = 0$ any such initial lift suffices. No inverse of $P'(s)$ in $\mathcal{S}_B$ has been assumed. Item 2 is proved.

Transfer for finite sums with fixed constants. We record the precise consequence of the preceding steps. For any S-linear $f : A \to A$, any finite $c_j \in K'$ and $y_j \in B^+$, put $U = \sum_j c_j y_j$ and $V = \sum_j c_j \widehat{f}(y_j)$, read in B^+_{dR}. For every $m \geq 0$, approximate all c_j by $t_j \in \mathcal{S}_B$ modulo ξ^m. If $U \in \xi^m B^+_{\mathrm{dR}}$, then $\sum_j t_j y_j$ has that same property. Divisibility reflection makes it a multiple of E^m in B^+. Apply the $\mathcal{S}_B$-linear $\widehat{f}$, and then replace t_j back by c_j modulo ξ^m. It follows that $V \in \xi^m B^+_{\mathrm{dR}}$. In the discrete valuation ring B^+_{dR} this proves

$$V = uU \quad \text{for some } u \in B^+_{\mathrm{dR}}. \tag{8}$$

If $U = 0$, apply all m and separatedness to get $V = 0$, and take $u = 0$; otherwise the order inequality gives (8).

All Frobenius levels and value-field denominators. Fix $a \geq 0$ and $q : A \to S$ as in item 3. Regard $f = \varphi^{-a} \circ q \circ \varphi^a$ as an endomorphism of A. It is S-linear, since $\varphi^a(S) \subset S$ and q is S-linear. Thus its extension in (8) is available; no assertion that $f(A) \subset S$ is required.

Let D_a be the K'-subalgebra of B_{dR} generated by the products $b\varphi^{-a}(s)$ with $b \in \mathcal{S}_B$ and $s \in S$. These products form a multiplicative monoid containing 1, so every element of D_a is a finite K'-linear sum of such products. By (BF4), $\mathcal{K}_a = \mathrm{Frac}(D_a)$. Clear a common nonzero denominator in the finitely many v_j, writing $v_j = dw_j$ with $d \in B^\times_{\mathrm{dR}}$ and $w_j \in D_a$. Expand all w_j into finite sums $c_{jk} b_{jk} \varphi^{-a}(s_{jk})$ of this form. Apply (8) to these constants and the elements

$$y_{jk} = b_{jk}\varphi^{-a}(s_{jk} r_j) \in B^+.$$

They belong to B^+ because $\varphi^{-a}(A) = A$ and $\mathcal{S}_B \subset B^+$. The extension is $\mathcal{S}_B$-linear and agrees with f on A, hence

$$\widehat{f}(y_{jk}) = b_{jk}\varphi^{-a}(s_{jk} q(r_j)).$$

Regrouping (8), then multiplying by the common d, proves

$$\sum_j \varphi^{-a}(q(r_j))v_j = u \sum_j \varphi^{-a}(r_j)v_j, \qquad u \in B^+_{\mathrm{dR}}.$$

Every Fil^n for integer n is a B^+_{dR}-module. The desired implication and the exact-relation assertion follow. This covers empty families and zero sums, and completes all three items without any canonical lattice module.

Projection and completed scalar ring. Use the retraction q_0 constructed above by choosing a residue basis containing 1 in the (p, z)-adic coordinate description of A. Its extension

P preserves $A_{\max}$, has image the integral completion C_0 of $S[E/p]$, and fixes C_0. The proved bicommutant equality is $\mathcal{S}_B = C_0[1/p]$, and every such extension is $\mathcal{S}_B$-linear. Thus P fixes $\mathcal{S}_B$, $P(A) = S$, and $P(A_{\max}) \subseteq C_0 \subseteq A_{\max}$. Preservation of $p^n A_{\max}$ proves continuity. This supplies the retraction and projection in clause 4.

Exact approximation, with its printed power of p. Put $X = \xi/p \in A_{\max}$. Suppose $\nu \in S$ and $\xi = pc + \nu d$ with $c, d \in A$. Every restricted series $F(X) = \sum_{j\geq 0} a_j X^j$ admits division

$$F(X) = F(c) + (X - c)G(X), \qquad F(c) \in A,\ G(X) \in A_{\max}.$$

Indeed $F(c) = \sum a_j c^j$ converges p-adically. The coefficient of X^i in the quotient is $\sum_{j>i} a_j c^{j-1-i}$; these sums converge, and their valuations tend to infinity with i, so the quotient is restricted. Since $p(X - c) = \nu d$, this gives $pb = a_1 + \nu b_1$ for every $b \in A_{\max}$, with $a_1 \in A$ and $b_1 \in A_{\max}$. Inductively,

$$p^a b = a_a + \nu^a b_a, \qquad a_a \in A,\ b_a \in A_{\max}.$$

For the induction multiply the previous identity by p, divide b_a once more, and absorb $\nu^a a_1$ into the new element of A. The case $a = 0$ uses $a_0 = 0, b_0 = b$. Applying P gives the asserted $p^a P(b) = q_0(a_a) + \nu^a P(b_a)$.

Both required ν satisfy the hypothesis: for $\nu = E$ use the association $\xi = Eu$; for $\nu = z$ use $E = z^e U + p$ and $\xi = Eu$, giving $\xi = pu + z(z^{e-1}Uu)$. Here u, U are units in the indicated actual rings. For $y \in \mathcal{S}_B$ choose k_0 with $p^{k_0} y \in A_{\max}$. For every $k \geq k_0 + 1$, apply the case $\nu = z, a = 1$ to $p^{k-1}y$, which P fixes. Split the resulting $s \in S = \Lambda[[z]]$ as its constant coefficient plus zs_1. This proves the eventual constant-plus-z assertion with exactly the same P.

Frobenius stability. Write $E = z^e U + p$, $U \in S^\times$. Frobenius preserves S, sends z to z^p, and fixes p. Hence

$$\frac{\varphi(E)}{p} = \frac{(E-p)^p}{p}\,\frac{\varphi(U)}{U^p} + 1 \in S[E/p].$$

The expansion is integral: its term E^p/p is $p^{p-1}(E/p)^p$, and the other coefficients of $(E-p)^p/p$ are integral powers of p times powers of E; this includes $p = 2$. Thus Frobenius preserves $S[E/p]$. It is p-adically continuous and preserves its completion, proving $\varphi(\mathcal{S}_B) \subseteq \mathcal{S}_B$.

Separation by powers of z. Reduction of the defining presentation gives

$$A_{\max}/pA_{\max} \simeq (A/(p, \xi))[X]. \tag{S1}$$

The p-adic completion does not change this reduction. A monic polynomial in X is a non-zero-divisor in this polynomial ring, even though its coefficient ring need not be a domain. Consequently, for a monic $F \in A[X]$, multiplication by $F(X)$ on $A_{\max}$ reflects divisibility by p^r for every r: reduce modulo p, cancel the monic polynomial, and iterate. In particular if $F(X)$ divides $b \in A_{\max}$ in B^+, its quotient is already in $A_{\max}$. Write that quotient as $p^{-r}c$, and cancel p^r from $F(X)c = p^r b$ using the preceding assertion.

We claim $\bigcap_{m\geq 0}(\xi - pu)^m B^+ = 0$ for every $u \in A$. If a nonzero element lay in this intersection, clear a power of p, then remove its largest integral power of p to obtain $b \in A_{\max}$ not divisible by p. Such a largest power exists by p-adic separatedness. Since $\xi - pu = p(X - u)$ and p is a unit in B^+, every $(X - u)^m$ divides b in B^+, and hence in $A_{\max}$ by monic cancellation. Reduction in (S1) gives a nonzero polynomial divisible by the monic polynomial $(X - \bar{u})^m$ for every m. Degree makes this impossible over any coefficient ring. This proves the claim.

Finally take $\xi = Eu$ and $E = z^e U + p$. Then $\xi - pu = z^e Uu$, with $Uu \in A^\times$. An element divisible by every power of z is therefore divisible by every power of $\xi - pu$, and is zero. No closedness of a z-ideal after inverting p was assumed.

The Galois differences. The only additional input for this paragraph is the exact scalar result of Lemma 7.7.18: for $b \in B^+$, the conditions $\theta\varphi^{i+1}(b) = 0$ for all $i \geq 0$ imply $\tau \mid b$ in B^+. We apply this scalar detector to the quotient below.

First let $\gamma \in G_\ell$ fix Λ pointwise, with no assumption on $\theta(z)$, and let $y \in \mathcal{S}_B$. The eventual constant-plus-z assertion gives $p^k y = c + zw$ with $c \in \Lambda$. The element γ fixes c, and $\gamma z/z$ is a unit of A: z is a Teichmuller lift and the Galois action preserves the valuation of its nonzero tilt element, so their quotient is a unit of the tilt valuation ring and its Teichmuller lift is a unit of A. Consequently the exact identity

$$\gamma y - y = p^{-k} z\big((\gamma z/z)\gamma w - w\big)$$

proves $z \mid \gamma y - y$ in B^+. Galois acts on B^+, and no membership of γw in $\mathcal{S}_B$ is required. This proves the z-divisibility assertion, including every inertial γ fixing Λ. For the remaining assertion specialize to $g \in \Gamma'$ and write $gy - y = zb$ with $b \in B^+$.

For each $i \geq 0$, Frobenius stability gives $\varphi^{i+1} y \in \mathcal{S}_B$. Clear a power of p to make it integral in $A_{\max}$, then apply the proved approximation with $\nu = E, a = 1$. It yields

$$p^k \varphi^{i+1} y = s + Ew, \qquad s \in S,\ w \in \mathcal{S}_B.$$

The chart group fixes $\theta(S) = K'$ pointwise and $\theta(E) = 0$. Applying $\theta(g-1)$ proves $\theta\varphi^{i+1}(gy - y) = 0$; Frobenius commutes with Galois and $p^k \neq 0$. In $gy - y = zb$, the other factor has $\theta\varphi^{i+1}(z) = \theta(z)^{p^{i+1}} \neq 0$. Thus $\theta\varphi^{i+1}(b) = 0$ for every i. The separately supplied detector gives $\tau \mid b$, and hence $z\tau \mid gy - y$. No invariance of $\mathcal{S}_B$ under g, and no topological closedness of the ideal $(z\tau)$ in B^+, is needed. □

Lemma 7.7.23. *Put $p = \ell$, $\delta = z\tau$, and $\sigma(i) = i^p$, and let d be the chart's different bound. The following assertions hold for every prime p, including 2, every letter i, and all natural numbers appearing as levels, moduli or exponents.*

(a) Suppose $f \in \mathcal{S}_{\mathrm{ch}} \cap J_l(i;r)$, $g \in \Gamma'$ and $\alpha, \beta, s \in A_{\mathrm{inf}}$. If

$$\delta(s + \beta f) = \alpha(gf - f),$$

then $s \in J_l(i;r)$. At level $l = 1$ the same conclusion holds with δE in place of δ.

(b) For every $s \in A_{\mathrm{inf}}$,

$$\varphi^l(s) \in J_l(\sigma^l i; r) \quad \Longleftrightarrow \quad s \in J_0(i;r).$$

If the jumps of S at i are at most ω, then $f \in J_0(i;r)$ implies $fE^\omega \in J_1(i;r)$.

(c) If $p^c z^n \in J_1(\sigma i; r)$, $pa \leq n$, and

$$c + v_p(n!) \leq b + v_p((pa)!),$$

then $p^b z^a \in J_0(i;r)$.

(d) If $p^c z^a E^n \in J_1(i;r)$, then

$$p^{c+dn+v_p(n!)} z^{a+n} \in J_1(i;r).$$

(e) If $p^c z^n \in J_0(i;r)$, $m \leq n$, and

$$c + n + v_p(n!) \leq b + m + v_p(m!),$$

then $p^b z^m \in J_0(i;r)$.

(f) If $p^c \in J_l(i; p^{c+1})$, then $p^c \in J_l(i; 0)$.

Proof. Write $A = A_{\mathrm{inf}}$, $\mathcal{S} = \mathcal{S}_{\mathrm{ch}}$, and $X_{l,i} = \mathfrak{X}_{\tilde{Y}_S}(i; \mathrm{std}_l)$. Let $\pi = \pi_S$, and abbreviate $\mathrm{cst}_{S,i}(c)$ by c_i. By (DQ4), membership in a lift ideal means exactly

$$s \in J_l(i; r) \quad \Longleftrightarrow \quad \exists t \in A \;\; \forall c \in C \;\; \exists x_c \in X_{l,i} : \pi(x_c) = (s - rt)c_i. \tag{1}$$

Indeed the multipliers taking the entire constant module into $\pi(X_{l,i})$ form an ideal, and $J_l(i; r)$ is its sum with (r). The constants c_i, for $c \in C$, generate the constant module over A, so testing them is sufficient. The constants c_i lie in the trivial lattice's localised standard part at every level: their form values are in the fixed field, so have filtration at least zero, and Frobenius fixes the underlying $1 \otimes c$. The letter projector has coefficients in the chart's unramified ring and preserves these properties. If $s \in \mathcal{S}$, Lemma 7.7.21 permits the same t to be chosen in $\mathcal{S}$, with all x_c in $N_{\mathrm{loc}} \cap X_{l,i}$.

Divided differences and lift ideals. We first prove the following general observation. Let D be either δ, at any level, or δE, at level one. For $f \in \mathcal{S} \cap J_l(i; r)$, choose t, x_c as in (1) with $s = f$. The chart-ring difference $gt - t$ is divisible by D; write $gt - t = Dv$. The module $X_{l,i}$ is stable under Γ': the subgroup fixes the letter coefficients, the forms are equivariant, and it preserves every de Rham filtration. Hence $gx_c - x_c \in X_{l,i}$. By Lemma 7.7.24, for each c there is $y_c \in X_{l,i}$ with $Dy_c = gx_c - x_c$. Since g fixes the constants,

$$D\pi(y_c) = (gf - f - r(gt - t))c_i.$$

If $Ds_0 = \alpha(gf - f)$, this implies

$$D\pi(\alpha y_c) = D(s_0 - r\alpha v)c_i.$$

Multiplication by D is injective on the ambient module of the trivial lattice: both $z\tau$ and E are units in $W(\mathbb{C}_p^\flat)$. For E, its reduction modulo p is nonzero; the same holds for $z\tau$. Cancellation and (1) give $s_0 \in J_l(i; r)$. Apply this with $s_0 = s + \beta f$ and subtract βf, which already belongs to the ideal. This proves (a).

Frobenius and raising the level. The standard-order assertion of Lemma 7.7.21 says

$$\varphi^l(X_{0,i}) = X_{l,\sigma^l i}.$$

Projection commutes with Frobenius, $\varphi^l(c_i) = c_{\sigma^l i}$, $\varphi(r) = r$, and Frobenius is an automorphism of A. Apply φ^l, or its inverse, to every lift and the common scalar witness in (1). This proves the equivalence in (b), with the forward letter $\sigma^l i$.

For its second assertion, multiply every lift in (1) by E^ω. At inverse-Frobenius level zero, this raises the filtration of a form of type u from $-u$ to $\omega - u \geq 0$. At positive inverse-Frobenius levels E is a unit for the de Rham filtration, so no order changes there. One way to see this unit assertion is that $\theta(\varphi^{-a}E) \neq 0$ for $a > 0$: otherwise E would be associated to $\varphi^a E$, whereas $\theta(\varphi^a E) \neq 0$, as follows by evaluating its Eisenstein series at z^{p^a}, whose positive-degree terms have valuation at least $p^a > 1$, while the constant term has valuation one. Thus $E^\omega x_c \in X_{1,i}$; its projection is $(fE^\omega - rtE^\omega)c_i$. Equation (1) proves the assertion.

Two scalar identities. Put $q = [\varepsilon]$. Since E generates $\ker\theta$, the identity $q - 1 = \tau\xi$ gives

$$q - 1 = uE\tau \qquad (u \in A^\times). \tag{2}$$

For each integer $n \geq 1$, with $v = v_p(n)$, there exist $\alpha, \beta \in A$ such that

$$\tau E(p^v + \beta z) = \alpha(q^n - 1). \tag{3}$$

Here is the factorisation proving this, including at $p = 2$. Frobenius sends τ to $q - 1$. Applying its successive powers to (2) and multiplying the resulting associated factors shows that

$$q^{p^v} - 1 \text{ is associated to } \tau \prod_{a=0}^{v} \varphi^a(E).$$

Write $n = p^v n_0$, $p \nmid n_0$. The quotient of $q^n - 1$ by $q^{p^v} - 1$ is the geometric sum of n_0 powers of q^{p^v}. It is a unit: in the residue field of the local ring A, q is one and the sum is the nonzero element n_0 mod p. Each $\varphi^a(E)$ is congruent to p modulo z, since the chart expression is $E = z^e A_0(z) + p$. Therefore $\prod_{a=1}^{v} \varphi^a(E) = p^v + \beta z$ for some $\beta \in A$, proving (3) after absorbing a unit. An empty product when $v = 0$ is one.

For each $n \geq 1$ there are $g \in \Gamma'$, $\omega \in A^\times$ and $X, \upsilon, b_1 \in A$ such that

$$gE = \omega E, \qquad \delta X = \omega^n - 1, \qquad \upsilon X = p^{d+v_p(n)} + E b_1. \tag{4}$$

We give the precise different estimate. Choose g with $gz = qz$; the chart supplies it, and g fixes Λ and θz. Formal power-series subtraction, using (2), gives

$$\delta E \mid gs - s \quad (s \in \mathcal{S}).$$

The generators gE, E of $\ker \theta$ are associated; after cancellation in the last divisibility, $\delta \mid \omega - 1$. Thus $X = (\omega^n - 1)/\delta$ belongs to A.

By Weierstrass preparation for the chart series $z^e A_0(z) + p$, choose a monic Eisenstein polynomial F of degree e and $G \in \mathcal{S}$ with $F(z) = EG$. If $e = 1$, $F' = 1$. If $e > 1$, write $F(T) = \sum_{j=0}^{e} a_j T^j$, with $a_e = 1$. Since $v_p(\theta z) = 1/e$, the nonzero terms $j a_j (\theta z)^{j-1}$ of $F'(\theta z)$ have different fractional valuations $(j-1)/e$. Hence their minimum is unique, and

$$v_p(F'(\theta z)) \leq v_p(e) + (e-1)/e < d.$$

In the case $e = 1$, the corresponding bound is $v_p(F'(\theta z)) = 0 = d$.

Write $gz = z + Ew$, where $w = u\tau z$ by (2). Taylor's polynomial identity gives $F(z + Ew) = F(z) + F'(z)Ew + E^2 w^2 R$. On the other hand this is $g(EG) = \omega E\, gG$. Cancel E, apply θ, and use $\theta(gG) = \theta G$, because g fixes Λ and θz. We obtain

$$\theta(\omega - 1)\theta G = F'(\theta z)\theta w.$$

Thus, in the valuation ring $\mathcal{O}_{\mathbb{C}_p}$, $\theta(\omega - 1)$ divides $p^d \theta\delta$. Moreover $\delta \mid \omega - 1$, and

$$v_p(\theta\delta) = 1/e + 1/(p-1) > 1/(p-1).$$

Here the normalisation of τ follows already from the period convention: $\xi = \sum_{j=0}^{p-1} [\varepsilon^{1/p}]^j$ generates $\ker \theta$, so $\theta[\varepsilon^{1/p}]$ is a nontrivial p-th root of unity, and $v_p(\theta\tau) = 1/(p-1)$. For any nonzero a with $v_p(a) > 1/(p-1)$, binomial expansion shows

$$v_p((1+a)^n - 1) = v_p(a) + v_p(n).$$

Indeed a prime-to-p power has its unique least-valued term na. A p-power step has its unique least-valued term pa, because for $2 \leq j < p$ the term $\binom{p}{j} a^j$ has larger valuation, and $p v_p(a) > 1 + v_p(a)$. Iterating proves the formula. This strict inequality includes $p = 2$. Applying it to $\theta(\omega - 1)$ shows

$$v_p(\theta X) \leq d + v_p(n).$$

The Taylor identity also shows $\theta(\omega-1)\neq 0$, so this cancellation is legitimate. Surjectivity of $\theta : A \to \mathcal{O}_{\mathbb{C}_p}$ now lifts the integral quotient $p^{d+v_p(n)}/\theta X$ to υ, giving (4).

Lowering powers of z at level one. For $n \geq 1$, choose g with $gz = qz$, and apply (3). Multiplying (3) by $p^c z^n$ gives the exact identity

$$\delta E(p^{c+v_p(n)} z^{n-1} + \beta\, p^c z^n) = \alpha(g(p^c z^n) - p^c z^n).$$

Part (a) at level one therefore lowers z^n to z^{n-1}, at price $v_p(n)$, with no change of letter. Starting from the hypothesis of (c), lower from n to pa. The accumulated price is $v_p(n!) - v_p((pa)!)$. The assumed inequality permits multiplication by the remaining nonnegative power of p, giving $p^b z^{pa} \in J_1(\sigma i; r)$. Since $\varphi(p^b z^a) = p^b z^{pa}$, (b) gives $p^b z^a \in J_0(i; r)$. If $n = pa$, no lowering is performed; if $a = 0$, the last descent is to $z^0 = 1$. Thus the proof includes both endpoints.

Trading E for z. Suppose $n \geq 1$, and write $F_0 = p^c z^a E^n \in J_1(i; r)$. Choose (4), and write $gz = z(1+\tau E\upsilon)$, which is possible by the chart-ring divisibility already proved. There is $b_2 \in A$ with $(1+\tau E\upsilon)^a = 1 + \tau E\upsilon b_2$, including $a = 0$. Set $k_n = d + v_p(n)$ and

$$\beta_0 = zb_1 + \upsilon v b_2 \omega^n.$$

Direct multiplication, using $\delta X = \omega^n - 1$ and $\upsilon X = p^{k_n} + Eb_1$, gives

$$\delta E(p^{c+k_n} z^{a+1} E^{n-1} + \beta_0 F_0) = z\upsilon(gF_0 - F_0).$$

By (a), $p^{c+k_n} z^{a+1} E^{n-1} \in J_1(i; r)$. Repeat for $n, n-1, \ldots, 1$. The total price is $\sum_{j=1}^{n}(d + v_p(j)) = dn + v_p(n!)$, proving (d). When $n = 0$, (d) is its hypothesis.

Lowering at level zero. Since $E - p = ze_0$ for some $e_0 \in \mathcal{S}$, equation (3) implies

$$\tau(p^{v_p(n)+1} + z(p^{v_p(n)} e_0 + \beta E)) = \alpha(q^n - 1) \qquad (n \geq 1).$$

Multiply by $p^c z^n$ and apply (a), now with divisor δ. It follows that

$$p^c z^n \in J_0(i; r) \quad \Longrightarrow \quad p^{c+v_p(n)+1} z^{n-1} \in J_0(i; r).$$

Iterating from n down to m costs

$$(n - m) + v_p(n!) - v_p(m!).$$

The inequality in (e) is exactly the assertion that this total cost, added to c, is at most b. Multiplication by the remaining power of p proves (e). Empty iteration covers $m = n$.

Removing the modulus. By definition $J_l(i; r) = J_l(i; 0) + (r)$. If $p^c \in J_l(i; p^{c+1})$, there exist $u \in A$ and $v \in J_l(i; 0)$ with $p^c = v + p^{c+1}u$. Hence $(1 - pu)p^c = v$. The element $1 - pu$ is a unit, with inverse $\sum_{a\geq 0}(pu)^a$ converging in the p-adically complete ring A. Therefore $p^c \in J_l(i; 0)$, proving (f), also when $c = 0$. No part of this proof restricts the natural modulus r or excludes the prime 2. □

Lemma 7.7.24. *Put $\delta = z\tau$. For every lattice L with letter jump sets, $g \in \Gamma'$ and $x \in N_{\mathrm{loc}}(L)$,*

$$D_g x := \frac{gx - x}{\delta} \in A_{\mathrm{inf}} N_{\mathrm{loc}}(L).$$

For every letter i and exponent function o,

$$gx - x \in \mathfrak{X}_L(i; o) \quad \Longrightarrow \quad D_g x \in \mathfrak{X}_L(i; o).$$

Moreover, if $x \in N_{\mathrm{loc}}(L) \cap \mathfrak{X}_L(i;\mathrm{std}_1)$*, then*

$$\frac{gx - x}{\delta E} \in \mathfrak{X}_L(i;\mathrm{std}_1).$$

The quotients are taken in the existing ambient Witt-vector module. For every chart scalar $s \in \mathcal{S}_{\mathrm{ch}}$ *one also has*

$$\delta E \mid gs - s \qquad \text{in } A_{\mathrm{inf}}.$$

Proof. Put $A = A_{\mathrm{inf}}$, $S = \mathcal{S}_{\mathrm{ch}}$, $B^+ = B^+_{\mathrm{max}}$, $E_a = \varphi^a E$, and $\delta = z\tau$. First we record the scalar differences used below. If $g \in \Gamma'$, then g fixes the unramified coefficients and θz. The compatible roots of gz/z therefore form a compatible system of p-power roots of unity, so $gz = q^c z$ for $q = [\varepsilon]$ and $c \in \mathbb{Z}_p$. Since

$$q - 1 = \tau\xi, \qquad \xi = uE, \quad u \in A^\times,$$

the convergent binomial identity for $q^c - 1$ gives

$$\delta E \mid gz - z.$$

Formal power-series subtraction, or its finite truncations followed by completeness, now gives

$$\delta E \mid gs - s \quad (s \in S). \tag{1}$$

This includes $s = E_a$ for every a.

Division on the actual canonical module. Suppose first that $x \in N(L)$. By Proposition 7.7.16, for every crystalline form λ,

$$s = E^h \lambda(x) \in \mathcal{S}_B$$

for a common h. Item7 of Lemma 7.7.22 gives $gs - s \in \delta B^+$. Also $gE - E \in \delta A$ by (1). Consequently

$$E^{2h}(g\lambda(x) - \lambda(x)) \in \delta B^+. \tag{2}$$

Indeed put $u = gE/E \in A^\times$. Equation (1) gives $u - 1 \in \delta A$; therefore

$$E^h(g\lambda(x) - \lambda(x)) = u^{-h} gs - s \in \delta B^+,$$

which is stronger than (2). The vector $gx - x$ lies in $M(L)$, by canonical Galois stability. The cancellation theorem Lemma 7.7.30 with powers $1, 1$ gives precisely the scalar hypothesis of Proposition 7.7.16, item2(d), for $d = \delta$. Applying that criterion to (2), and using equivariance of λ, gives

$$gx - x \in \delta M(L). \tag{3}$$

Every $x \in N_{\mathrm{loc}}(L)$ is killed into $N(L)$ by a finite product of the E_a: clear its localization denominator into $M(L)$; multiplication by this product preserves its $\mathcal{K}_0$-valued tests, so the result is in the actual $N(L)$. It therefore suffices to pass (3) backwards through one denominator. Suppose $E_a x$ already has the required property. Then

$$g(E_a x) - E_a x = E_a(gx - x) + (gE_a - E_a)gx.$$

The second term divided by δ belongs to $AM_{\mathrm{loc}}(L) = AN_{\mathrm{loc}}(L)$, by (1), canonical Galois stability, and localization. The left side divided by δ belongs there by induction. Hence $E_a(gx - x)/\delta$

belongs there. This module is saturated by the E_a, because it is the A-span of the localization, so (3) follows for x. This proves the first assertion.

Orders are unchanged by division by δ. For every inverse-Frobenius level a,

$$\theta(\varphi^{-a}z) \neq 0, \qquad \theta(\varphi^{-a}\tau) = \zeta_{p^{a+1}} - 1 \neq 0.$$

Thus $\varphi^{-a}\delta$ is a unit of B^+_{dR}. The quotient in the first assertion belongs to the actual localized ambient module. For every typed form,

$$\lambda(\varphi^{-a}((gx - x)/\delta)) = \varphi^{-a}(\delta)^{-1}\lambda(\varphi^{-a}(gx - x)).$$

Multiplication by this de Rham unit preserves every integer filtration. The letter part is unchanged, since g fixes the letter coefficients and δ is a scalar. This proves the prescribed-order assertion.

The additional level-one factor. Let $x \in N_{\mathrm{loc}}(L) \cap \mathfrak{X}_L(i; \mathrm{std}_1)$. Its value $v = \lambda(x)$ at level zero lies in $\mathcal{K}_0 \cap B^+_{\mathrm{dR}}$, for every form in a tested type. Choose $b \geq 0$ and $r \in A$ with $\theta(r) = p^b\theta(v)$. Then $r - p^b v \in \mathrm{Fil}^1$. Applying Lemma 7.7.22 with the coefficient retraction of Lemma 7.7.21 gives

$$v - p^{-b}q_0(r) \in \mathrm{Fil}^1.$$

Since g fixes S modulo E, equation (1) implies $gv - v \in \mathrm{Fil}^1$. Equivariance identifies this difference with $\lambda(gx - x)$. Dividing by δE consequently leaves it in Fil^0, the required level-zero standard order. At a level $a \geq 1$, both $\varphi^{-a}\delta$ and $\varphi^{-a}E$ are de Rham units. For the latter assertion, E is associated to ξ, and $\theta(\varphi^{-a}\xi) \neq 0$, since it is the geometric sum of a primitive p^{a+1}-th root with p terms. Hence division preserves the standard order $-u$ at those levels. The vector itself lies in the actual localized module, by the first assertion and saturation by E. All level-one standard tests and the letter part are therefore satisfied. Together with (1), this proves the remaining assertions. □

Proposition 7.7.25. *Let k be a Kummer chart for Γ, S, S' pairing sides over $\mathcal{O}$ paired by P, with parameter lattices C, C'. A* point *of S at i over $c \in C$ with orders o and depth h means a vector $x \in N_{\mathrm{loc}}(\tilde{Y}_S)$ with $\pi_S x = \mathrm{cst}_{S,i}(c)$, $x \in \mathfrak{X}_{\tilde{Y}_S}(i; o)$, and $gx - x \in \mathfrak{X}_{\tilde{Y}_S}(i; h)$ for every $g \in \Gamma'$, using (DQ1)–(DQ3).*

1. *(Points exist.) If $\ell^\kappa E^s$ kills the cokernel of S at i, then for every $c \in C$ there is a point of S at i over $\ell^\kappa c$ with orders and depth $(a, u) \mapsto -u - s[a = 0]$.*

2. *(Order rule.) Let ν be a point of the Tate dual side of P over ℓ^κ at the letter l steps before i, with orders antitone in the jump, and let w, y lie over 0 in the two extensions with orders o_w, o_y at i. If at every level a and all jumps $u \in S(\cdot)$, $u' \in S'(\cdot)$ at the letter a steps before i the order of $\varphi^l\nu$ at $-u - u' - 1$ plus $o_w(a, u) + o_y(a, u')$ is positive, then the pairs $(z\tau w, y)$ and $(w, z\tau y)$ are safe for κ ($\tau = [\epsilon^{1/\ell}] - 1$). Moreover, a first-side move by a kernel vector w is safe against a point q' if the same inequality holds with o_y replaced by the depth of q'; a second-side move by a kernel vector y is safe against a point q if it holds with o_w replaced by the depth of q.*

3. *(The walk.) Let $\eta, \kappa, e, e' \in \mathbb{N}$. Let some letters be cuts, every Frobenius orbit meeting the cut set; let $l(i) > 0$ be the least positive distance back to a cut. Let $t(i) \in \mathbb{N}$ at each cut. Assume that at each cut i: $\ell^\kappa E^{t(i)}$ kills the cokernel of the Tate dual side of P; there are standard points $x(i)$ of S over $\ell^e c$ and $x'(i)$ of S' over $\ell^{e'} c'$ (orders $-u$, lowered by η at level 0; depth $-u$, raised by $t(i)$ at level 0 and by η below level $l(i)$); and one side has a stop at i (a point over the same constant with orders $\max(0, -u - \eta)$ below level $l(i)$ and*

$-u$ from there on) while the other side moves safely from $\varphi^{l(i)}$ of its point at the previous cut to its point at i. Then P is a scaled cup coboundary at (N, c, c') for every $N \in \mathbb{N}$ with $N \geq e + e' + \kappa$.

Proof. **Carriers and elementary filtration rules.** All order modules and projections below are (DQ1)–(DQ4); no abstractly isomorphic replacement is used. Put $\Delta = z\tau$. A point's depth is the condition on every Galois difference in the statement, not invariance of the point itself.

The strict kernel inclusion, including M, M_{loc}, N_{loc}, every actual letter part and every order module, is Lemma 7.7.26, item2. Its hypotheses are precisely this side extension with the same jump sets. Thus a vector over zero in the actual extension is uniquely a vector of the kernel lattice with exactly the same order tests. The same result, item1, supplies the constant-modulo-filtration interpretation of depth at every integer level.

We use two further consequences of the same actual order calculus. Frobenius shifts orders by

$$F_{l,b}o(a,u) = \begin{cases} b, & a < l, \\ o(a-l,u), & a \geq l. \end{cases} \tag{1}$$

It sends a point of orders o and depth h to one of orders $F_{l,0}o$ and depth $F_{l,1}h$. At $a \geq l$ this is the identity $\mu(\varphi^{-a}\varphi^l x) = \mu(\varphi^{-(a-l)}x)$. Below l, orders are zero by the positive-Frobenius tests for the localized module. For depth, use the exact factorization

$$g\varphi^l x - \varphi^l x = \varphi^l(\Delta)\,\varphi^l((gx - x)/\Delta).$$

The divided-difference quotient has the original depth orders by Lemma 7.7.24; after Frobenius it has shifted orders with zero below l. At $a < l$, $\varphi^a E$ divides $\varphi^l\tau$, so the displayed scalar factor raises those orders to one. This proves precisely $F_{l,1}h$. All localization denominators are units at the positive-Frobenius tests. Equal-constant differences have kernel orders the minimum of the endpoint orders.

For an equivariant $\mathcal{O}$-bilinear map, Lemma 7.7.26, item3, preserves the actual canonical and localized carriers and gives precisely the order inequality

$$h(a,v) \leq o_1(a,u) + o_2(a,u') \qquad (u + u' \leq v).$$

This is the full typed inequality, not merely equality of type sums. Its hypotheses will be checked explicitly below.

Point supply. By (DQ4), $\ell^\kappa E^s \mathrm{cst}_i(c)$ lifts to the standard order module of the extension. Retract this lift into its actual localized canonical module. The retraction commutes with the projection and fixes constants, by Lemma 7.7.21. Divide by E^s. This changes the level-zero order by $-s$ and no other order, and leaves the projection $\ell^\kappa \mathrm{cst}_i(c)$. Galois preserves every order module, so the Galois differences have the same lower orders. This proves item1, also for zero exponents or zero parameter.

Order safety. Put $D = (Y \otimes_{\mathcal{O}} Y')^\vee(1)$ and let $\nu_1 = \varphi^l\nu$; write $r = F_{l,0}o_\nu$. Strictness just proved identifies the two kernel vectors with $w_0 \in Y$ and $y_0 \in Y'$ in the actual localized order modules. Set

$$h(a,v) = 1 - r(a, -v - 1).$$

The assumed strict inequality, integrality of the exponents, and antitonicity of r imply $h(a,v) \leq o_w(a,u) + o_y(a,u')$ whenever $u + u' \leq v$. The bilinear rule therefore puts $w_0 \otimes y_0$ in the actual tensor module of orders h. The extension of D has the integral equivariant evaluation pairing

$$((\lambda, a), t) \longmapsto \ell^m\lambda(t) + a\psi(t)$$

with values in $\mathcal{O}(1)$; equivariance is precisely $g\psi - \psi = \ell^m c_P(g)$. A third-side type s and a tensor type v contributing to the Tate jump -1 satisfy $s+v \le -1$, hence $r(a,s)+h(a,v) \ge 1$. A second application of the bilinear rule shows that its value ξ_0 on $(\nu_1, w_0 \otimes y_0)$ has standard orders for $\mathcal{O}(1)$, whose sole jump is -1. Thus $\xi_0 \in M(\mathcal{O}(1))$ by the standard-order characterization of Lemma 7.7.21. The frame's height-one comparison gives $\tau\xi_0 \in A_{\mathrm{inf}} \otimes \mathcal{O}(1)$.

Reduce by the coefficient functional of P modulo ℓ^m. Since ν_1 lies over $\ell^\kappa \mathrm{cst}_i(1)$, this reduction of ξ_0 is $\ell^\kappa b_P(w_0, y_0)$. Multiplication by z takes every integral Witt vector into the small Witt part, because all coordinates of z have positive tilt valuation. Hence the reduction of $z\tau\xi_0$ is small. This proves both safe pairs in item2.

For the first-side move, divide $gq' - q'$ by Δ. The actual divided-difference and order-preservation statement Lemma 7.7.24 places the quotient in the actual kernel module with the depth orders of q'. Apply the second safe-pair assertion and cancel the two scalar factors Δ, Δ^{-1}. For a second-side move use $(gq - q)/\Delta$ and gy; the kernel/order module of y is Galois stable. This gives exactly safety of $(gq - q, gy)$. The extra localized-point hypothesis is thus retained where it is needed.

The four moves at a cut. Write

$$R_\eta(a,u) = -u - \eta[a=0], \quad D_{t,\eta,l}(a,u) = -u + t[a=0] + \eta[a<l],$$

and let $Q_{\eta,l}$ be the stop order in the statement. A killer with E-exponent t at the letter l steps back supplies a third point of orders R_t by item1. Define

$$B_{l,t}(a,v) = \begin{cases} 1, & a < l, \\ t - v, & a = l, \\ -v, & a > l. \end{cases}$$

There is the exact identity

$$F_{l,0}R_t(a, -u - u' - 1) + B_{l,t}(a, u + u') = 1. \tag{2}$$

Thus the order-safety rule applies whenever move orders plus resting-point depth are at least $B_{l,t}$.

Let $l, l_0 > 0$ be the current and preceding cut gaps, with killers t, t_0. Two elementary inequalities establish the outer moves:

$$B_{l,t_0}(a, u+v) \le \min(Q_{\eta,l}, F_{l,0}R_\eta)(a,u) + F_{l,1}D_{t_0,\eta,l_0}(a,v), \tag{3}$$

$$B_{0,t}(a, u+v) \le \min(R_\eta, Q_{\eta,l})(a,u) + D_{t,\eta,l}(a,v). \tag{4}$$

In (3), below l the summands are $0, 1$; at l they are $-u-\eta, -v+t_0+\eta$; above l they are $-u, -v+\eta[a-l<l_0]$. In (4), at zero they are $-u-\eta, -v+t+\eta$; between zero and l their sum is at least $-u-v$; from l onward they are $-u, -v$. These exhaust all levels and prove both inequalities.

Put $A = \varphi^l x_0$, $A' = \varphi^l x_0'$, for the preceding-cut points. If the first side has stop q while the second move $A' - x'$ is safe with q at rest, choose $w = q, w' = x'$. Inequality (3) proves the move $A - q$ safe with A' at rest; the middle move is the explicit stop hypothesis; (4) proves $q - x$ safe with x' at rest; the final move is zero. If the second side has stop q', choose $w = A, w' = q'$. The first move is zero, (3) proves the second, the central first-side move is the stop hypothesis, and (4) proves the fourth. This is exactly the required path

$$(A, A') \longrightarrow (w, A') \longrightarrow (w, w') \longrightarrow (x, w') \longrightarrow (x, x').$$

Each side retains its own constant and exponent; $e = e'$ is not assumed.

Summing the walk and checking the extra cocycle safety. For each letter let $d(i) = 0$ at a cut and $d(i) = l(i)$ otherwise, and set

$$X_i = \varphi^{d(i)} x(i^{(d(i))}), \qquad A_i = \varphi^{l(i)} x(i^{(l(i))}),$$

with primed analogues. The least-positive predecessor relation gives $l(i) = d(i^{(1)}) + 1$. Reindexing the finite letter set therefore gives $\varphi \sum_i X_i = \sum_i A_i$ and the primed identity. At cuts use the four moves above; elsewhere $A_i = X_i, A'_i = X'_i$ and the path is zero.

We must also check the additional cocycle-difference safety in the pairing lemma. If $X_i = \varphi^d x_j$, its depth is $H = F_{d,1} D_{t_0,\eta,l_0}$, with $l_0 > 0$. Both this depth and the kernel orders of $hX'_i - X'_i$ are H. The needed inequality is

$$B_{d,t_0}(a, u + v) \le H(a, u) + H(a, v).$$

For $a < d$ it says $1 \le 2$; at $a = d$ it says $t_0 - u - v \le 2t_0 + 2\eta - u - v$; above d the right side is $-u - v + 2\eta[a - d < l_0]$. Thus the second-side move by $hX'_i - X'_i$ with X_i at rest is safe for every h.

Different-letter pairings vanish: balance for the coefficient root gives $([i] - [j])b = 0$, and this scalar is a unit when $i \ne j$. All safety conditions consequently sum letter by letter. The constants sum to $\ell^e(1 \otimes c)$ and $\ell^{e'}(1 \otimes c')$, since the letter projectors sum to one. Apply item1 of Proposition 7.7.15 to the summed four-move path and the additional cocycle safety just checked. Its continuous coboundary has every exponent $N \ge e + e' + \kappa$. This proves item3. □

Lemma 7.7.26. *Put $K_{\mathrm{fix}} = \overline{\mathbb{Q}}_\ell^{j(\Gamma')}$, embedded canonically in B_{dR}.*

1. *For $y \in B_{\mathrm{dR}}$ and any integer n, if $gy - y \in \mathrm{Fil}^n$ for every $g \in \Gamma'$, there is $c \in K_{\mathrm{fix}}$ with $y - c \in \mathrm{Fil}^n$.*

   Let L be a lattice with letter jump sets $U(i)$, $x \in M_{\mathrm{loc}}(L)$ in the letter-i part, and $h : \mathbb{N} \times \mathbb{Z} \to \mathbb{Z}$. Then

   $$gx - x \in \mathfrak{X}_L(i; h) \quad (g \in \Gamma')$$

   if and only if, for every $a \ge 0$, $u \in U(i^{(a)})$, and form λ of type u there, there is $c \in K_{\mathrm{fix}}$ such that

   $$\lambda(\varphi^{-a} x) - c \in \mathrm{Fil}^{h(a,u)}.$$

   If $x \in \mathfrak{X}_L(i; o)$ and $gx - x \in \mathfrak{X}_L(i; h)$ for every $g \in \Gamma'$, then x has orders

   $$(a, u) \longmapsto \begin{cases} h(a, u), & o(a, u) > 0, \\ \min(h(a, u), 0), & o(a, u) \le 0. \end{cases}$$

2. *Let S be a pairing side with extension $0 \to Y \xrightarrow{\iota} \tilde{Y}_S \to C \to 0$, with the same sets $S(i)$ used on Y and $\tilde{Y}_S$. Every form on Y extends to a form on $\tilde{Y}_S$; for each letter i and integer u, a form of type u at i has an extension of that same type. The induced inclusion of ambient modules strictly preserves all the following modules:*

   $$\iota^{-1} M(\tilde{Y}_S) = M(Y), \qquad \iota^{-1} M_{\mathrm{loc}}(\tilde{Y}_S) = M_{\mathrm{loc}}(Y),$$
   $$\iota^{-1} N_{\mathrm{loc}}(\tilde{Y}_S) = N_{\mathrm{loc}}(Y), \qquad \iota^{-1} \mathfrak{X}_{\tilde{Y}_S}(i; o) = \mathfrak{X}_Y(i; o).$$

   It commutes with the letter projectors. Thus every vector in any displayed module for $\tilde{Y}_S$ whose projection to the ambient module of C is zero is the image of a unique vector in the corresponding module for Y.

3. *Let L_1, L_2, L_3 be lattices with letter jump sets U_1, U_2, U_3, and let $b : L_1 \times L_2 \to L_3$ be an equivariant $\mathcal{O}$-bilinear map. Its $W(C^\flat)$-bilinear extension maps $M(L_1) \times M(L_2)$ into $M(L_3)$, and likewise maps the corresponding pairs of M_{loc} and of N_{loc} into those modules for L_3.*

   If $x_r \in \mathfrak{X}_{L_r}(i; o_r)$, $r = 1, 2$, and

$$h(a, v) \le o_1(a, u) + o_2(a, u')$$

   whenever $a \ge 0$, $u \in U_1(i^{(a)})$, $u' \in U_2(i^{(a)})$, $v \in U_3(i^{(a)})$, and $u + u' \le v$, then $b(x_1, x_2) \in \mathfrak{X}_{L_3}(i; h)$. Moreover $b(\mathrm{pr}_i x_1, x_2) = \mathrm{pr}_i b(x_1, x_2)$.

Proof. Write $B = B_{\mathrm{dR}}$ and $B^+ = B^+_{\mathrm{dR}}$ in this proof only. The image $j(\Gamma')$ is an open subgroup of G_ℓ, hence is $G_{K_{\mathrm{fix}}}$ for a finite extension $K_{\mathrm{fix}}/\mathbb{Q}_\ell$. The canonical inclusion $K_{\mathrm{fix}} \subset B^+$ reduces to its given inclusion in $\mathbb{C}_\ell$. In particular a nonzero element of K_{fix} has t-adic order zero.

Invariants modulo an integer filtration are constants. The graded piece $\mathrm{Fil}^j B/\mathrm{Fil}^{j+1} B$ is $\mathbb{C}_\ell(j)$. Tate's invariant calculation says that its $G_{K_{\mathrm{fix}}}$-invariants vanish for $j \neq 0$, whereas those for $j = 0$ are K_{fix}; see [298], Section 3, and [10]. Let $gy - y \in \mathrm{Fil}^n$ for all g. Choose an integer $j \le n$ with $y \in \mathrm{Fil}^j$, possible since $B = \bigcup_j \mathrm{Fil}^j$. If $j < n$, the class of y in the j-th graded piece is invariant. For $j \neq 0$ it is zero, so $y \in \mathrm{Fil}^{j+1}$. At $j = 0$ its class is the image of some $c \in K_{\mathrm{fix}}$; subtract this fixed constant, obtaining an element of Fil^1 with the same difference condition. Continue through the finitely many indices below n. This gives $y - c \in \mathrm{Fil}^n$, with $c = 0$ if index zero was not encountered. This argument includes negative n.

For an element in $M_{\mathrm{loc}}(L)$, some nonzero element of A_{inf} multiplies it into $A_{\mathrm{inf}} \otimes L$: multiply its localization denominator by the power of τ in the definition of $M(L)$. Thus values of forms on it are determined by their restrictions to $1 \otimes L$. Equivariance on that lattice and A_{inf}-linearity imply

$$\lambda(\varphi^{-a}(gx - x)) = g\lambda(\varphi^{-a}x) - \lambda(\varphi^{-a}x). \tag{1}$$

One proves this first on a finite sum of elementary tensors and then clears a nonzero A_{inf}-denominator; its image in B is nonzero.

The modules $M_{\mathrm{loc}}(L)$ are Galois stable. Indeed $g\tau = (1 + \tau)^{\chi_{\mathrm{cyc}}(g)} - 1$, so $g\tau/\tau$ is a unit: the convergent binomial series for this quotient has constant coefficient $\chi_{\mathrm{cyc}}(g) \in \mathbb{Z}_\ell^\times$ and its remaining terms lie in the maximal ideal of A_{inf}. The element E generates $\ker\theta$ up to a unit; Galois preserves that ideal and commutes with Frobenius, so it also preserves each ideal $(\varphi^a(E))$. The integral lattice is stable, and (1) preserves the positive-Frobenius integrality tests for $M(L)$. The letter parts are stable because Γ' fixes the chart's unramified coefficient ring. Apply the constant assertion to each value in (1). Conversely, if that value is a constant modulo $\mathrm{Fil}^{h(a,u)}$, its Galois difference lies in the same filtration, since g fixes the constant and preserves the filtration. The definition of $\mathfrak{X}$ now gives exactly the equivalence in item 1.

For the improvement, fix a tested value $v = \lambda(\varphi^{-a}x)$, put $r = o(a, u)$, $s = h(a, u)$, and write $v - c \in \mathrm{Fil}^s$, $c \in K_{\mathrm{fix}}$. Since $v \in \mathrm{Fil}^r$, one has $c \in \mathrm{Fil}^{\min(r,s)}$. If $r > 0$ and $s > 0$, this forces $c = 0$, so $v \in \mathrm{Fil}^s$. If $r > 0$ and $s \le 0$, the same conclusion already follows from $\mathrm{Fil}^r \subseteq \mathrm{Fil}^s$. If $r \le 0$, the fact $c \in \mathrm{Fil}^0$ gives $v \in \mathrm{Fil}^{\min(s,0)}$. These are precisely the stated orders.

Every kernel form extends with its specified letter type. We record how a form is extended to an ambient module when only its values on the finite lattice have been prescribed. Put $Q = \mathrm{Frac}(A_{\mathrm{inf}})$, with its canonical inclusion in B. The ambient module is A_{inf}-torsion free. After localizing it at the nonzero elements of A_{inf}, it is a Q-vector space containing the Q-span of $1 \otimes L$. Choose a Q-linear complement of that finite-dimensional span. A prescribed $\mathbb{Z}_\ell$-linear map $L \to B$ extends Q-linearly on the span and by zero on the complement; restriction

to the ambient module is an A_{inf}-linear functional with exactly those prescribed lattice values. Equivariance of a form is required on the lattice, so equivariant prescribed values produce a form. Values on all denominator-clearable vectors are independent of this extension choice.

Let μ be a form on Y, and first suppose $\mu(1\otimes Y)\subseteq \mathrm{Fil}^n$. Choose a $\mathbb{Z}_\ell$-basis of the parameter lattice C. For each basis vector c, the crystalline cocycle $\alpha(c)$ has a witness $w_c\in B_{\max}\otimes_{\mathbb{Z}_\ell} Y$ with $gw_c - w_c = 1\otimes\alpha(c)(g)$. Extend $\mu|_Y$ B-linearly on $B\otimes Y$, and set $b_c=\mu(w_c)$, using $B_{\max}\subset B$. Equivariance of this extension gives

$$gb_c - b_c = \mu(1\otimes\alpha(c)(g))\in \mathrm{Fil}^n \quad (g\in\Gamma').$$

By the first part, choose $a_c\in K_{\mathrm{fix}}$ with $b_c-a_c\in\mathrm{Fil}^n$, and extend $c\mapsto b_c-a_c$ $\mathbb{Z}_\ell$-linearly. On the lattice $Y\oplus C$, prescribe

$$\nu(y,c)=\mu(1\otimes y)+(b_c-a_c). \tag{2}$$

The equation for b_c and the action $g(y,c)=(gy+\alpha(c)(g),c)$ show directly that $\nu(g(y,c))=g\nu(y,c)$. All prescribed values lie in Fil^n. Extend to the ambient module by keeping the original μ on its Y-summand and extending the C-values as just described. This gives a form extending the actual μ, with the same global filtration bound on the lattice. Without a filtration bound the same construction uses b_c itself and gives an extension of every form.

Now suppose only that μ is of type u at a specified letter i. Its two summands $\mu_i=\mu\circ\mathrm{pr}_i$ and $\mu_{\neq i}=\mu\circ(1-\mathrm{pr}_i)$ are forms, since the letter projectors commute with Γ'. The first has all lattice values in Fil^{-u}. Extend it by (2), with $n=-u$, to ν_i; extend $\mu_{\neq i}$ without a bound to $\nu_{\neq i}$. Then

$$\nu=\nu_i\circ\mathrm{pr}_i+\nu_{\neq i}\circ(1-\mathrm{pr}_i) \tag{3}$$

restricts exactly to μ. It has type u at i: the second term vanishes there, while pr_i carries the integral lattice into its A_{inf}-span and A_{inf} maps into B^+, so the first term still takes that lattice into Fil^{-u}. This proves the typed extension assertion for every integer u.

The inclusion ι is a split inclusion of underlying $\mathcal{O}$-modules; hence its ambient extension is injective and reflects the A_{inf}-span of the integral lattice. It commutes with Frobenius and the letter projectors. Restricting extension forms gives kernel forms, and the extension assertions prove the converse testing implication. Therefore the τ-saturation and every positive-Frobenius test defining M are both preserved and reflected. Clearing the same finite product of $\varphi^a(E)$ proves the assertion for M_{loc}. Testing values in the same field $\mathcal{K}_0$ with all forms gives the assertion for N_{loc}. Testing the same integer type and order with the typed extensions (3) gives the assertion for each $\mathfrak{X}(i;o)$; the sets $S(i)$ are identical on the two sides, as stipulated. Finally exactness of the underlying direct sum $Y\oplus C$, and hence of its ambient modules, identifies the kernel with the image of ι. This proves item 2 without a retraction.

An adapted invariant Hodge basis gives the precise tensor inequality. We give the finite-dimensional comparison used here explicitly. For a lattice L, put $V=L[1/\ell]$ and $D=(B\otimes_{\mathbb{Q}_\ell}V)^{G_{K_{\mathrm{fix}}}}$. The crystalline hypotheses give a continuous de Rham representation by Lemma 7.4.6. The de Rham comparison and its graded Hodge–Tate comparison ([44], Theorem 5.2.1 and Proposition 6.3.2) give $\dim_{K_{\mathrm{fix}}}D=\dim_{\mathbb{Q}_\ell}V$ and the comparison isomorphism. The letter projectors are defined over K_{fix} and preserve the filtrations. In each letter part choose a K_{fix}-basis d_m of D adapted to its filtration, with filtration jumps u_m. The graded comparison says that the reductions of $t^{-u_m}d_m$ are a basis of the corresponding $\mathbb{C}_\ell$-space: they are exactly its Hodge–Tate comparison basis. Thus

$$e_m=t^{-u_m}d_m$$

is a B^+-basis of the corresponding integral comparison lattice. Indeed its matrix has entries in B^+ and has invertible reduction modulo t, so its determinant is a unit. The integers u_m occur

among the actual jumps at that letter, hence among its stipulated jump set. This also checks the sign: the dual invariant form λ_m, characterized by $\lambda_m(d_n) = \delta_{mn}$, takes e_m to t^{-u_m}, and has type u_m. It extends to an actual ambient form by the extension-of-functionals argument above, with zero values on the other letter parts. All evaluations below are on denominator-clearable vectors, so this extension choice has no effect.

Let λ be any form on L_3, of type v at a letter j. Choose such invariant bases d_m, d'_n for the letter-j parts of L_1, L_2, and let λ_m, λ'_n be their invariant dual forms. Put

$$c_{mn} = \lambda\big(b(d_m, d'_n)\big) \in B.$$

Every c_{mn} is $G_{K_{\mathrm{fix}}}$-invariant, by equivariance of b, λ and invariance of the two basis vectors. Thus $c_{mn} \in K_{\mathrm{fix}}$, by the invariant-field calculation of the de Rham comparison. As b is integral and $\mathcal{O}$-bilinear, its extension sends the two letter-j integral comparison lattices into the letter-j integral comparison lattice of L_3. Therefore

$$\lambda\big(b(e_m, e'_n)\big) = t^{-u_m - u'_n} c_{mn} \in \mathrm{Fil}^{-v}.$$

A nonzero $c_{mn} \in K_{\mathrm{fix}}$ has t-adic order zero. Consequently

$$c_{mn} \neq 0 \quad \Longrightarrow \quad u_m + u'_n \leq v. \tag{4}$$

For denominator-clearable vectors y, x in these letter parts, finite-dimensional bilinearity gives the exact finite expansion

$$\lambda(b(y, x)) = \sum_{m,n} c_{mn} \lambda_m(y) \lambda'_n(x). \tag{5}$$

No assertion about arbitrary analytic expansions is involved.

Apply (5) to $y = \varphi^{-a} x_1$, $x = \varphi^{-a} x_2$ at $j = i^{(a)}$. Frobenius commutes with the extended pairing. Each summand with nonzero coefficient lies in

$$\mathrm{Fil}^{\,o_1(a,u_m) + o_2(a,u'_n)} \subseteq \mathrm{Fil}^{h(a,v)}$$

by (4) and the hypothesis. Coefficients in K_{fix} preserve every filtration. Finite addition proves the required target test for every form of type v at j.

It remains to check the actual module carriers in item 3. The extension of an integral bilinear map preserves A_{inf}-spans of lattices. Thus powers of τ clearing two inputs multiply to a power clearing their pairing. For any positive Frobenius level and any target form, use (5) on the full spaces, summing over all letter parts and omitting the type restriction. Its coefficients are still in $K_{\mathrm{fix}} \subset B^+$. Every factor value lies in B^+ by the positive-Frobenius tests defining $M(L_1), M(L_2)$, so the output passes every such test. This proves preservation of M. Multiplying the two localization denominators proves preservation of M_{loc}. If the inputs lie in N_{loc}, their values under every invariant dual form in (5) lie in the same field $\mathcal{K}_0$; its inclusion of K_{fix} and closure under sums and products prove preservation of N_{loc}.

Finally $\mathcal{O}$-linearity in the first variable implies $b(\zeta x_1, x_2) = \zeta b(x_1, x_2)$. Apply the displayed polynomial formula for pr_i in (BF2) to obtain $b(\mathrm{pr}_i x_1, x_2) = \mathrm{pr}_i b(x_1, x_2)$. The output is therefore in the required letter part, and the target order tests already proved put it in $\mathfrak{X}_{L_3}(i; h)$. □

Proposition 7.7.27. *Let k be a Kummer chart for Γ, S, S' pairing sides over $\mathcal{O}$ paired by P, with $c \in C$, $c' \in C'$. Let $\eta \geq 1$, $V, G, b \in \mathbb{N}$, a predicate T on letters (the* thick *letters) and signs $\varepsilon(i)$. Assume that at every letter i the jump set $S(i)$ fits the windows $(\eta, -\varepsilon(i), b_i, V)$ and $S'(i)$ fits $(\eta, \varepsilon(i), b_i, V)$, where $b_i = b$ if $T(i)$ and $b_i = G$ otherwise.*

1. *(Sparse thick letters.) Let $G + V \le \eta$ and $J \ge 1$, and let no three thick letters follow one another along the letter Frobenius with both gaps in $[1, J]$. Assume that either k is unramified, $\ell \ge 7$ and $10\ell^J\eta \le b$, or ε is constant and $8e \le \ell^{J+1}$. Let $\delta, X \in \mathbb{N}$ with $2e(b + 5\eta) \le \ell^{J+1}\delta$ and $20(J + 1 + d)\eta + \lfloor \log_\ell 2(b + 5\eta) \rfloor \le X$. Then P is a scaled cup coboundary at $(10^3(\delta + (J + 1)X), c, c')$.*

2. *(Any pattern.) Let k be unramified, $\ell \ge 7$, $0 < G \le b$ and $V + 4\eta \le W \le K$, with $b < K\ell^2$ and $2G < K\ell$. Then P is a scaled cup coboundary at $(10^4(K + \lfloor \log_\ell 2(b + W) \rfloor), c, c')$.*

Proof. We give a common cut argument and verify both choices of cuts. Throughout this proof $p = \ell$. Write $i^{(a)}$ for the letter a steps before i, and put

$$R_t(a, u) = -u + t[a = 0], \quad D(t, \eta, l)(a, u) = -u + t[a = 0] + \eta[a < l],$$
$$Q_{\eta,l}(a, u) = \begin{cases} \max(0, -u - \eta), & a < l, \\ -u, & a \ge l. \end{cases}$$

The shift of an order system by φ^l is zero below l and its old order at $a - l$ from l on. The depth shift is one below l, as proved in Proposition 7.7.25. Set

$$C_{s,\eta,l} = \mathrm{imp}(R_{-s}, D(s, \eta, l + 1)), \qquad c_a(m) = v_p(|m|) + d + 3a, \quad v_p(0) = 0. \tag{1}$$

The finite-step statement Lemma 7.7.28 raises a finite set of steps at the sum of these costs and gives the improved orders in (1).

A common finite scheme. Use auxiliary width w, starts β_i, shifts s_i, and nonnegative integers $B, n, J, s_0, G_0, X, \delta, \kappa$ satisfying

$$\begin{gathered} V + 4\eta \le w, \quad n + \lambda + (J + 1 + d)w + dG_0 \le X, \qquad \lambda = \lfloor \log_p(2B) \rfloor, \\ 12((J + 1)X + \delta) < \kappa, \quad e(2B) \le p^{J+1}\delta, \quad 8e \le p^{J+1}, \\ \beta_i + s_i + w \le 2B, \quad G_0 \le (p - 1)n, \quad s_i + w \le pn, \\ \beta_i + w \le (p - 3)s_0 \quad \text{if } p \ge 5. \end{gathered} \tag{2}$$

A permitted cut i is of either of these two kinds: $s_i = 0$ and $\beta_{\sigma^t i} + w \le G_0$ for $1 \le t \le J$; or the chart is unramified, $p \ge 5$, $s_i < \beta_i$ and $s_0 \le \kappa + s_i$. Here σ is the forward letter Frobenius, so these next-J conditions have the orientation required by Proposition 7.7.15(4).

At a first-kind cut the forward-letter bound supplies the killer p^κ. Indeed every jump of either side and of the third side is at most $\beta_i + w \le 2B$. For the third side its nonzero jumps are $-u - v - 1$: when both original jumps are far, their opposite signs leave absolute sum at most V; when one is low the upper bound is $\beta_i + V + \eta$; when both are low it is 2η. These are all at most $\beta_i + w$, using $\eta \ge 1$ and $V + 4\eta \le w$. The three terms in that forward bound are at most

$$2JX + (2J + 4)X + 8\delta < \kappa$$

by (2). At a second-kind cut, the unramified bound supplies $p^\kappa E^{s_i}$ since all jumps are at most $(p - 3)s_0 \le (p - 3)(\kappa + s_i)$. Thus all three sides have this killer at every permitted cut. Also $s_i = 0$ or both $s_i < \beta_i$ and $d = 0$.

We record an explicit finite cost bound. At level $a < 2J + 2$, take the union of the two closed integer windows of radius $r + w$, centered at zero and at the negative far start appropriate to that side, where $r = s_i$ for $a = 0$ and $r = 0$ otherwise. It has at most $4(r + w) + 2$ integers; every integer in it has absolute value at most $2B$. For nonzero integers count their multiples of

p^v, $1 \le v \le \lambda$. Each interval of length $2(r+w)$ has at most $2(r+w)/p^v + 1$ such multiples. Therefore the sum of their valuations is at most

$$\frac{4(r+w)}{p-1} + 2\lambda \le 8n + 2\lambda.$$

The zero integer costs no valuation. If $r > 0$, then $a = 0$ and $d = 0$, so there is no remaining cost. Otherwise $4w + 2 \le 5w$ since $w \ge 4$, and $d + 3a \le 6(J + 1 + d)$. Hence the cost at this level is at most $8n + 2\lambda + 30w(J+1+d) \le 30X$. Summing gives total cost at most $60(J+1)X$, and consequently

$$\kappa + 4\delta + \sum_{\text{windows}} c_a(m) \le 25\kappa. \tag{3}$$

For the last inequality subtract the left side from 25κ and use $24\kappa > 288((J+1)X + \delta)$.

Let the least positive distance to the preceding cut be $l \le 2J + 1$. A killer point starts with orders and depth R_{-s_i}. Deepen it to $D(s_i, \eta, l+1)$. The required steps occur only at $a \le l$. At zero their endpoints are $-u - s_i \le m < -u + s_i + \eta$, and at $1 \le a \le l$ they are $-u \le m < -u + \eta$. A low jump puts these steps within radius $s_i + 2\eta$ of zero at level zero, and 2η at other levels. A far jump puts them within radius $s_i + V + \eta$, or $V + \eta$, of the appropriate far start. All lie in the windows just counted. Thus (3) supplies points over $p^{25\kappa}$ with own orders $C_{s_i,\eta,l}$ and depth $D(s_i, \eta, l+1)$.

These points have the pole bound $R_{-\eta}$. At level zero, if $u \ge -s_i$ is a jump then $u \ge -\eta$: this is immediate for $s_i = 0$, and otherwise a negative far jump would have $u \le -\beta_i < -s_i$. If $u < -s_i$, the positive initial order improves to the depth. Otherwise $-\eta - u \le 0$ and $-\eta - u$ is at most the depth, hence at most its minimum with zero. At positive levels the improved orders dominate $-u$ directly. Their depth is exactly the plain depth

$$D(s_i, \eta, l+1) = D(s_i, \eta, l) + \eta[a = l]. \tag{4}$$

Plain stops. Suppose all letters between the preceding cut and the current one have one common sign, except for far windows ending at or below η. One side is down, with jumps $u \le \eta$ below l, and its partner is up, with jumps $u \ge -\eta$ there. The down point itself is a stop. At zero and at $0 < a < l$, its improved order is nonnegative when the initial order was nonpositive, and otherwise its depth dominates $\max(0, -u - \eta)$. At $a = l$ and above its orders dominate $-u$.

For completeness the central safe move has a separate numerical check. For the moving up side the minimum of the current and preceding transported pole bounds is

$$M(a,u) = \begin{cases} \min(-u - \eta, 0), & a = 0, \\ \min(-u, 0), & 0 < a < l, \\ -u - \eta, & a = l, \\ -u, & a > l. \end{cases}$$

The resting depth (4) is respectively $-v + s_i + \eta$, $-v + \eta$, $-v + \eta$ and $-v$. Against the third-side killer at the current cut the required complementary bound is $s_i - u - v$ at zero and $-u - v$ above. The residuals are $\min(0, u + \eta) = 0$, $\eta + \min(0, u) \ge 0$, zero and zero. This proves the safe central move, including the essential extra η at level l.

The long-gap point from the frame radius. We prove the actual point supplier needed when signs change. Work on an unramified chart. Let $L > 0$, $3 \le p^L$, $A \le p^L\delta$. Suppose E^s kills at a letter j, all jumps at its L preceding levels are at most g, and

$$N = s + g \sum_{a<L} p^a < A. \tag{5}$$

Suppose p^{κ} kills at $j^{(L)}$. Then there is a point at j, over $p^{\kappa+4\delta}c$, with own orders $\mathrm{std}_L + A[a = 0, u < -N]$ and depth $\mathrm{std}_L + A[a = 0]$, where std_L is zero below L and $-u$ from L on.

Here is a proof on the canonical module, including the parameter correction. Take a point y over c of orders R_{-s}, and multiply it by

$$F(E) = E^s \prod_{a<L} E_a^g, \qquad E_a = (E-p)^{p^a} + p.$$

This is monic as a polynomial in E, of degree N. Its orders are at least $g - u$ below L and $-u$ above, hence it belongs to the actual standard module of level L. Apply Proposition 7.7.16's radius assertion to it with parameters L, A, δ. It writes $p^{4\delta}F(E)y$ as a finite $\mathfrak{S}$-linear combination of points in the same $\varphi^L M$ with all form values invariant modulo Fil^A. Project to the letter j. All these projected points have standard orders and Galois differences with those orders raised by A at level zero: equivariance of every form and commutation with the letter projector prove this assertion. Call such points constants modulo E^A.

Every scalar in $\mathfrak{S} = \Lambda[[z]]$ has finite expansions to every order in $E = z + p$, with coefficients in Λ, by repeated division with constant remainder. Expanding the finite scalar combination therefore gives

$$p^{4\delta}F(E)y = \sum_{h \le N} E^h \xi_h + E^{N+1} y_1, \tag{6}$$

where each ξ_h is a constant modulo E^A and y_1 has standard orders. Coefficient extraction is legitimate with these integral modules. If $\xi + Ey'$ has a positive level-zero order on a given jump, then ξ has positive order there; its invariance modulo E^A and the improved-order rule raise that order to A. Subtract ξ and divide by E; induction proves that in an expansion (6), the coefficient ξ_N has order A on every line where the whole expression has order greater than N, provided the target order is at most A. Apply this with target $\min(A, g - u)$. In particular ξ_N has order A at $u < -N$.

Apply the same coefficient argument to the trivial quotient, subtracting the scalar expansion of $p^{4\delta}F(E)\mathrm{cst}_j(c)$. Its difference expansion is zero, so every line has target order A. Monicity and $N < A$ give

$$w = \pi\xi_N - p^{4\delta}\mathrm{cst}_j(c) \in E^A(\text{trivial standard module of level } L).$$

The transported pure-power killer at $j^{(L)}$ lifts $p^{\kappa}E^{-A}w$ to an actual vector v in the extension's same standard module. Then

$$x = p^{\kappa}\xi_N - E^A v$$

lies over $p^{\kappa+4\delta}c$ and has exactly the asserted lower bounds for its own orders and depth. All operations were on the actual modules and maps; no independent frame or merely isomorphic lattice has been substituted.

Now let a current cut have preceding distance l, with a pivot at level t and $l = t + J + 1$. Assume the chart is unramified, $p \ge 5$, the preceding cut has shift zero, and for some $\omega \ge \eta$

$$s_0 + \omega \sum_{a=0}^{J} p^a < \beta_{i^{(t)}}. \tag{7}$$

Assume every nonpivot level below l has the opposite sign to the pivot or a far window ending at most η, and every level strictly between pivot and preceding cut has far endpoint at most ω. The side with negative far window at the pivot has jumps there at most η, and at the other J levels before that cut at most ω. It has killer E^{s_0} at the pivot by (2), and p^{κ} at the preceding

cut. Apply (5) with $L = J + 1$, $A = 2B$, $s = s_0$, $g = \omega$. The inequality $N < A$ follows from (7) and $\beta \le 2B$; the radius conditions follow from (2).

Transport this point by φ^t to the current cut. Its exact (orders,depth) table is

$$\begin{array}{c|c|c} a < t & 0 & 1 \\ a = t & 2B\,1_{u<-N} & 2B \\ t < a < l & 0 & 0 \\ a \ge l & -u & -u. \end{array} \tag{8}$$

Raise only the depths $(a, 0)$ for $t < a < l$ to one. These steps belong to the counted windows, so (3) gives a point over $p^{25\kappa}c$. Its depth is $2B$ at the pivot, one elsewhere below l, and $-u$ from l on. It is a stop: nonpivot jumps are at least $-\eta$, so their required stop order is zero; at the pivot low jumps again require zero, whereas a negative far jump satisfies $u \le -\beta < -N$ and has available order $2B \ge \beta + V - \eta \ge -u - \eta$. This covers the endpoints as well.

The central moving side has jumps $u \le \eta$ at every nonpivot level below l, and $u < \eta + 2B$ at the pivot. Its difference orders are the minimum of $C_{s_i,\eta,l}$ and the shift by l of C_{0,η,l_0} at the preceding cut. For $a < l$ this minimum is at least $\min(\eta - u, 0)$; off the pivot it is zero, so adding resting depth one gives the required bound one. At the pivot, if $u \le \eta$ its sum with $2B$ is at least one; otherwise integer strictness gives $\eta - u + 2B \ge 1$. At $a \ge l$ both cut orders are at least $-u$, so adding $-v$ gives $-u - v$. These are precisely the complementary bounds for the transported third killer p^κ from the preceding cut. The safe-move rule proves the central move. Which side rests is determined by the sign at the pivot.

We have proved the following consequence of (2): if every letter has a permitted cut at distance at most $2J + 1$, and every interval after a nearest cut has either the plain common-sign form or the long-gap form (7), then the walk of Proposition 7.7.25 applies. Its point exponents are 25κ on each side and its third exponent is κ, so it gives every cup exponent at least 51κ.

Sparse thick letters. Set

$$w = 5\eta,\ B = b + 5\eta,\ n = G_0 = 10\eta, \quad s_i = 0, \quad \beta_i = b_i, \quad R = (J + 1)X + \delta, \quad \kappa = 12R + 1.$$

For $p \ge 5$ choose $s_0 = \lfloor (b + 10\eta)/(p - 3) \rfloor + 1$; if $p < 5$ put $s_0 = 0$, since no condition involving it is used. We verify all of (2). The cost left side is $\lambda + \eta(5J + 15 + 15d)$, at most X by the assumed $\lambda + 20(J + 1 + d)\eta \le X$. The strict κ condition and depth condition are immediate. The ramification bound is assumed in the constant-sign alternative; in the unramified alternative $e = 1$, $p \ge 7$, $J \ge 1$, so $8 \le p^{J+1}$. Since $G, V \le \eta$, $\beta_i + w \le 2B$, $V + 4\eta \le w$, $G_0 \le (p - 1)n$, and $w \le pn$. Finally $\beta_i + w \le b + 10\eta \le (p - 3)s_0$ by Euclidean division. These include the cases $b = 0$ and $\delta = 0$ whenever allowed by the original hypotheses.

Cut at a letter exactly when its next J successors are thin. Such a letter is a first-kind permitted cut since $\beta + w = G + 5\eta \le 6\eta \le G_0$ on these successors. We give the finite combinatorial argument. If a thick letter is not a cut, its predecessor at distance $J + 1$ is a cut. Otherwise a thick letter among the next J successors of that predecessor, the original thick letter, and a thick successor witnessing its failure to be a cut would form three thick letters with both gaps in $[1, J]$, contrary to sparseness. Every letter has a cut within $2J + 1$ steps back: test its predecessor at distance $J + 1$; if this is not a cut, a thick successor of it lies at distance $r \in [1, J]$ back from the original letter. If that thick letter is not a cut, its predecessor at distance $J + 1$ is one, at distance at most $2J + 1$.

For a nearest cut at distance l, a thick position $0 < r < l$ must satisfy $r + J + 1 = l$. The cut's next J successors are thin, giving $l - r \ge J + 1$; if strict, the preceding paragraph would give a nearer cut at $r + J + 1$. Thus only positions zero and $t = l - J - 1$ can be thick in this interval.

Test the plain condition with the sign at position zero. If it fails, an opposite-sign position $0 < t < l$ has $\beta + V > \eta$, and so is thick. All other nonzero positions are thin, the original position has the opposite sign to the pivot, and all positions strictly beyond the pivot have far endpoint at most η. The constant-sign alternative is impossible, so the chart is unramified, $p \ge 7$ and $b \ge 10p^J\eta$. Taking $\omega = \eta$, the strict long-gap condition holds:

$$s_0 + \eta \sum_{a=0}^{J} p^a \le \frac{b + 10\eta}{4} + 1 + 2p^J\eta < b.$$

Indeed with $A_0 = p^J\eta \ge 7$, $\eta \le A_0$ and $b \ge 10A_0$, the difference from b is at least $3A_0 - 1 > 0$. This proves all long-gap hypotheses, including the zero shift at the preceding cut. The common scheme therefore gives exponent 51κ. Since $X \ge 20(J + 1 + d)\eta \ge 40$, we have $R \ge 1$, and

$$51\kappa = 612R + 51 \le 663R \le 10^3 R.$$

This is the first assertion.

An arbitrary pattern. Put

$$q = \lfloor b/p \rfloor, \quad H = \lfloor \log_p(2(b + W)) \rfloor, \quad s_i = \begin{cases} (q - 7K)_+, & T(\sigma i), \\ 0, & \text{otherwise}, \end{cases}$$

and use

$$J = 1, \quad n = K, \quad B = b + W, \quad w = W, \quad G_0 = G + W,$$
$$\delta = 4K, \quad X = 3K + H, \quad s_0 = q + 12K, \quad \kappa = 120K + 24H + 1.$$

Here $K \ge W \ge 4\eta \ge 4$, $q < Kp$, and $pq \le b < p(q + 1)$. The cost condition in (2) is $K + H + 2W \le 3K + H$. The strict κ condition is equality plus one. The depth bound follows from $2(b + W) \le 4Kp^2$, and $8 \le p^2$. Also $\beta_i + s_i + W \le b + q + W \le 2(b + W)$, and $2(G + W) < Kp + 2K \le 2(p - 1)K$. For the remaining far bound,

$$(p - 3)(q + 12K) - (b + K) > -3q + (12p - 37)K - p > (9p - 37)K - p \ge (8p - 37)K > 0.$$

Thus $\beta_i + W \le (p - 3)s_0$. The shift bound follows by cases: if $q \le 7K$ then $s_i + W \le K \le pK$; otherwise it is at most $q - 6K < pK$. Hence every clause of (2) holds.

Choose as cuts the letters with $s_i < \beta_i$. Thick letters are cuts since $s_i \le q < b$. Every letter with thin successor is also a cut, since its shift is zero and $G > 0$. Consequently there is a cut one or two steps back from every letter. A cut with thin successor is of the first permitted kind. A cut with thick successor is of the second kind because $s_0 = q + 12K \le s_i + 19K \le s_i + \kappa$; if $q < 7K$ the same inequality follows with $s_i = 0$. Thus all cuts are permitted.

If the nearest distance is one, the plain condition is automatic. If it is two and the previous sign equals the current sign, the same is true. In the remaining case the previous letter is not a cut, so it is thin and the current letter is thick; moreover $G \le s_{\mathrm{prev}} \le (q - 7K)_+$, hence $q \ge G + 7K$. The cut two steps back has shift zero. Take pivot zero and $\omega = G + W$. Then $\omega \le q - 6K$ and

$$s_0 + \omega(1 + p) \le pq + 2q + (6 - 6p)K < pq + (6 - 4p)K < pq \le b.$$

The nonpivot letter has opposite sign, its far endpoint is ω, and $\eta \le W \le \omega$. This verifies every long-gap condition. All nearest-cut possibilities have now been covered, including zero shifts and floor equalities. The common scheme gives exponent 51κ, and

$$51\kappa = 6120K + 1224H + 51 \le 10^4(K + H)$$

since $K \ge 1$. This proves the second assertion. □

Lemma 7.7.28. *Fix a side with extension lattice L, quotient $\pi : L \to C$, and subgroup Γ'. Write $\mathcal{N} = N_{\mathrm{loc}}(L)$. A vector over a constant at letter i is a vector $x \in \mathcal{N}$ with $\pi x = \mathrm{cst}_i(c)$ for some c. It has depth h if $gx - x \in \mathfrak{X}_L(i;h)$ for every $g \in \Gamma'$. An additive map $A : \mathcal{N} \to \mathcal{N}$ has cost e if for every such i, h, x,*

$$Ax - p^e x \in \ker \pi \cap \mathfrak{X}_L(i;h).$$

Put $c_a(n) = v_p(|n|) + d + 3a$, with $v_p(0) = 0$.

1. *For every $a \geq 0, n \in \mathbb{Z}$, there is an additive map B of cost $c_a(n)$ such that, simultaneously for every $x \in \mathcal{N}$ and invariant form λ,*

$$\left[\forall g,\ \lambda(\varphi^{-a}(gx - x)) \in \mathrm{Fil}^n\right] \Longrightarrow \left[\forall g,\ \lambda(\varphi^{-a}(gBx - Bx)) \in \mathrm{Fil}^{n+1}\right].$$

2. *For every finite $I \subset \mathbb{N} \times \mathbb{Z}$, there is one additive map A_I of cost $\sum_{(a,n)\in I} c_a(n)$. For every letter i, vector over a constant of depth h, and function h', it has depth h' after applying A_I, provided*

$$h(a,u) \leq n < h'(a,u) \Longrightarrow (a,n) \in I$$

for every a, every actual jump u at the letter a steps before i, and every integer n.

All operators are chosen before the vector, form, letter and depth functions. They preserve depths already attained.

Proof. We write $\theta_a = \theta\varphi^{-a}$, $E_a = \varphi^a E$, $\delta = z\tau$, and use the normalization $v_p(p) = 1$. The image $\pi_a = \varphi^{-a} E_a$ in B^+_{dR} is a uniformizer. Also $\varphi^{-a}\delta$ is a unit there: its image under θ is nonzero, since z is a nonzero Teichmuller lift and $\theta_a\tau$ is a nontrivial root of unity minus one.

A scalar first-order observation. Let q_0 be the coefficient retraction of Lemma 7.7.21. If $v \in \mathcal{K}_a \cap \mathrm{Fil}^0$, choose an integer $b \geq 0$ such that $p^b\theta(v)$ is integral, and then choose $r \in A_{\mathrm{inf}}$ with $\theta_a(r) = p^b\theta(v)$. Thus $\varphi^{-a}(r) - p^b v \in \mathrm{Fil}^1$. Apply the scalar coefficient law of Lemma 7.7.22 to this two-term relation, using $q_0(1) = 1$. It gives

$$v - \varphi^{-a}(p^{-b} q_0(r)) \in \mathrm{Fil}^1. \tag{1}$$

Consequently a finite sum of Galois operators which is invariant on S modulo E_a is invariant on $\mathcal{K}_a \cap \mathrm{Fil}^0$ modulo Fil^1. Indeed use (1), linearity, and the Galois stability of the filtration; division by p^b does not affect the de Rham filtration.

The scalar step at a nonzero integer. Put $q = [\varepsilon]$. Choose $g \in \Gamma'$ with $gz = q^{p^a} z$. Write $gE = \omega_0 E$, with $\omega_0 \in A^\times_{\mathrm{inf}}$, and $\omega = \varphi^a\omega_0$. Then

$$gE_a = \omega E_a, \qquad E_a \mid gs - s \quad (s \in S), \qquad \delta \mid \omega^n - 1 \quad (n \in \mathbb{Z}).$$

For the second assertion apply θ_a: q^{p^a} has image one and g fixes the unramified coefficients. For the third, formal power-series subtraction gives $\delta E \mid gE - E$, hence $\delta \mid \omega_0 - 1$; Frobenius sends δ to a multiple of δ. Negative powers cause no change because ω_0 is a unit.

For $n \neq 0$, set $X = (\omega^n - 1)/\delta$. We claim

$$v_p(\theta_a X) \leq d + 3a + v_p(|n|). \tag{2}$$

Here are the derivative and valuation details. By Weierstrass preparation the series $E = p + z^e A(z)$ is a unit times a monic Eisenstein polynomial F of degree e; write $F(z) = EG(z)$. If $e = 1$, $F' = 1$ and $d = 0$. Otherwise, at the root θz, the nonzero terms $jF_j(\theta z)^{j-1}$ have distinct

fractional valuations $(j-1)/e$; the minimum is unique and is at most $v_p(e)+(e-1)/e<d$. Thus $v_p(F'(\theta z))\le d$. Taylor expansion of $F(gz)$, followed by cancellation of E and application of θ, yields

$$\theta(G)\theta(\omega_0-1)=F'(\theta z)\,u\,p^a\theta(\delta)$$

with u a unit. The higher Taylor terms vanish because $gz-z$ is divisible by E. Therefore

$$0<v_p(\theta(\omega_0-1))\le d+a+v_p(\theta\delta),\qquad v_p(\theta(\omega_0-1))>1/(p-1).$$

The last strict inequality follows from $\delta\mid\omega_0-1$ and $v_p(\theta\delta)=1/e+1/(p-1)$. Binomial expansion now gives, including $p=2$,

$$v_p(\theta(\omega_0^n-1))=v_p(\theta(\omega_0-1))+v_p(|n|).$$

For a prime-to-p power the unique least-valued term is the linear one; in a p-power step it is pA, since $v_p(A)>1/(p-1)$. Iterate and use units for negative powers. Finally

$$v_p(\theta_a\delta)=p^{-a}(1/e+1/(p-1)),\qquad v_p(\theta\delta)-v_p(\theta_a\delta)\le 2a.$$

The last inequality is equality zero for $a=0$; for $a\ge 1$ the left side is at most $2\le 2a$. These formulas prove (2).

Surjectivity of $\theta_a:A_{\mathrm{inf}}\to\mathcal{O}_{\mathbb{C}_p}$ now supplies $\upsilon\in A_{\mathrm{inf}}$ with

$$\upsilon X-p^{c_a(n)}\in E_aA_{\mathrm{inf}}. \tag{3}$$

For a value $y\in\mathcal{K}_a\cap\mathrm{Fil}^n$, apply (1) to $\pi_a^{-n}y$. Since $g\pi_a=\varphi^{-a}(\omega)\pi_a$ and g is trivial on $\varphi^{-a}S$ modulo Fil^1, we obtain

$$gy-\varphi^{-a}(\omega^n)y\in\mathrm{Fil}^{n+1}. \tag{4}$$

For $x\in\mathcal{N}$, a form λ, and a fixed-field constant c with $y=\lambda(\varphi^{-a}x)-c\in\mathrm{Fil}^n$, put

$$Tx=p^{c_a(n)}x-\upsilon(gx-x)/\delta.$$

Values of x at every inverse-Frobenius level lie in $\mathcal{K}_a$. To check this from the actual module definitions, clear an ambient denominator of $\varphi^{-a}x$, express it in the A_{inf}-span of N_{loc}, apply φ^a, and apply a nonzero chart coordinate to this finite relation. Exact relation preservation makes the relation persist. Its nonzero coefficient is in S, and solving it after evaluating the form gives a quotient of sums of $\varphi^{-a}(S)$-multiples of $\mathcal{K}_0$-values, hence an element of $\mathcal{K}_a$.

By equivariance, (4), $\delta X=\omega^n-1$, and the fact that $\varphi^{-a}\delta$ is a de Rham unit,

$$\lambda(\varphi^{-a}((gx-x)/\delta))-\varphi^{-a}(X)y\in\mathrm{Fil}^{n+1}.$$

Together with (3) this gives

$$\lambda(\varphi^{-a}Tx)-p^{c_a(n)}c\in\mathrm{Fil}^{n+1}. \tag{5}$$

The zero step. Let $m=p^{d+3a}$, and choose $t_jz=q^jz$, $0\le j<m$. Modulo E_a, every element of S has a polynomial representative in z with unramified coefficients (division by the distinguished series E_a). Put $\zeta=\theta_a(q)$, a primitive p^a-th root, with $\zeta=1$ when $a=0$. On a monomial uz^b,

$$\theta_a\Big(\sum_{j<m}t_j(uz^b)\Big)=\theta_a(u)\theta_a(z)^b\sum_{j<m}\zeta^{jb}.$$

This is zero if $p^a\nmid b$, since $p^a\mid m$. If $b=p^ab'$, the monomial is fixed under θ_a by every element of Γ', since $\varphi^{-a}u$ is unramified and θz is fixed. Thus $\sum t_j$ is invariant on S modulo E_a. By (1)

it is invariant modulo Fil^1 on every integral $\mathcal{K}_a$-value. The constant-modulo-filtration assertion of Lemma 7.7.26 shows that its value is a fixed-field constant modulo Fil^1. This uses the sum itself, never its average. In this case set $Tx = \sum_{j<m} t_j x$.

Descent to the actual module and cost. In both cases $T = p^{c_a(n)} + \sum_j v_j(t_j - 1)/\delta$, with coefficients $v_j \in A_{\mathrm{inf}}$. By Lemma 7.7.24 its image lies in $A_{\mathrm{inf}} N_{\mathrm{loc}}$. Set $B = R_L T$, using Lemma 7.7.21. This is additive. If x lies over a constant of depth h, each $(t_j x - x)/\delta$ has orders h, lies over zero, and retraction preserves both assertions. Therefore $Bx - p^{c_a(n)} x \in \ker \pi \cap \mathfrak{X}_L(i; h)$: this is exactly the cost property. Retraction preserves (5) and its zero-step counterpart. Applying Lemma 7.7.26 first to the input and then to the output proves item1.

Finite sets of steps. Induct on I, removing (a, n) with maximal second coordinate. In the target h', lower each value $h'(a, u) = n + 1$ to n, leaving other values unchanged; call the result h''. Every required step from h to h'' belongs to the remaining set. Indeed if the removed pair were required, the larger pair $(a, n+1)$ would be required in I, contradicting maximality. Apply the remaining-set operator and then the one-step operator for (a, n). Its cost property retains depth h''; item1 raises exactly the lowered form tests. This proves the required depth h'. Costs add: if A, B have costs e, f, then

$$BAx - p^{e+f} x = (BAx - p^f Ax) + p^f (Ax - p^e x),$$

and both terms belong to the same kernel order module because A preserves the original depth. The empty-set operator is the identity. Every choice precedes the letter, vector, form and depth functions, as required. □

Proposition 7.7.29. *Let k be a Kummer chart for Γ and S, S' pairing sides over $\mathcal{O}$ paired by P. Let $\eta \geq 1$, $a, W, \kappa \in \mathbb{N}$, and at each letter i let $b_i \in \mathbb{N}$, $\varepsilon(i) = \pm 1$, with $S(i)$ fitting $(\eta, -\varepsilon(i), b_i, W)$ and $S'(i)$ fitting $(\eta, \varepsilon(i), b_i, W)$, and $\mathrm{Ng}(\ell, n, b_i)$ for $n = 6(a + \eta + W)$.*

1. *Let $\ell^\kappa E^a$ kill the cokernels of S, S' and of the Tate dual side of P at every letter, and assume that no jump of S or S' lies in $[-a, 0)$, or that k is unramified and all jumps of S' lie in $[-\eta, 0]$. Then P is a scaled cup coboundary at (H, c, c') for all c, c' and every $H \geq 3(\kappa + (8n + 4)d)$. If k is unramified and the jumps of S' lie in $[-\eta, 0]$, it suffices that $\ell^\kappa E^a$ kill the cokernels of S and of the Tate dual side, and $H \geq 2\kappa$.*

2. *(Few low jumps.) Let k be unramified, $\ell \geq 5$, and at every letter i let $b_i + W + \eta \leq (\ell - 3)a$ and $6(a + \eta + W) < b_i$, with $S(i)$ fitting $(\eta, \varepsilon(i), b_i, W)$. Let n_i and r_i bound f times the number of jumps of Y over i in $[-\eta, \eta]$ and in $S(i)$, with multiplicity. Then there is a $\mathbb{Z}_\ell$-submodule $V \subseteq C$ with $\mathrm{length}_{\mathbb{Z}_\ell}(C/V) \leq 11 \sum_i (n_i(a + 1) + r_i(W + 1))$ such that for every side T whose jump sets fit $(\eta, -\varepsilon(i), b_i, W)$, every pairing P' of the lattices of T and S, every $c \in C_T$ and $c' \in V$, P' is a scaled cup coboundary at $(0, c, c')$.*

Proof. **Actual uniform depth operators.** Put $\Delta = z\tau$, $E_j = \varphi^j E$, and $c_j(n) = v_\ell(|n|) + d + 3j$, with $v_\ell(0) = 0$. Use Lemma 7.7.28 on this SAME localized extension module. Its cost means exactly that the correction from $\ell^b x$ is a kernel vector of the original depth orders. Its one operator for a finite step set is chosen before the point, form, letter and depth functions. If a larger cost is allowed, multiply the output by the remaining power of ℓ; this preserves all de Rham orders and raises the constant exponent accordingly.

Use the actual coefficient map q_0 and natural retraction R of Lemma 7.7.21. Both preserve every specified letter and order. Strictness for kernel vectors is Lemma 7.7.26, item2. Its item1

also gives the improvement rule

$$\operatorname{imp}(o,h')(j,u)=\begin{cases}h'(j,u), & o(j,u)>0,\\ \min(h'(j,u),0), & o(j,u)\le 0.\end{cases} \tag{4}$$

The first cup bound, gap branch. Write $n_0=6(a+\eta+W)$ and $D_0=(8n_0+4)d$. By the gap condition every nonzero integer within n_0 of $0,b_i,-b_i$ is prime to ℓ. The union of the corresponding closed intervals has at most $8n_0+4$ elements. Each level-zero step there costs d, including zero under our convention. Thus its total price is at most D_0.

The killer supplies a point of orders and depth $R_{-a}(j,u)=-u-a[j=0]$. Deepen it at level zero to $H(j,u)=-u+(a+\eta)[j=0]$. Each required step belongs to the preceding union: on a low jump its distance from zero is at most $2a+2\eta$, and on a far jump its distance from one of $\pm b_i$ is at most $2a+\eta+W$, both bounded by n_0. No other level changes. The resulting point is over $\ell^{\kappa+D_0}c$. The prohibition of jumps in $[-a,0)$ removes its pole. Explicitly, at level zero either $u<-a$, so its initial order is positive and (4) gives $a+\eta-u\ge -u$, or $u\ge 0$, so $\min(a+\eta-u,0)\ge -u$. Above zero the orders remain $-u$. Hence both sides have points without pole, of depth H, at every letter.

Take every letter to be a cut, with gap one and Tate-dual killer $\ell^{\kappa}E^{a}$. At a letter one side has all jumps at most η (its far interval is negative), and the other has all jumps at least $-\eta$. The first point is a stop: at a negative jump its positive order improves by (4), and at $0\le u\le\eta$ its depth is nonnegative, giving stop order zero. For the other side the difference from its preceding Frobenius point has orders $\min(-u,0)$ at level zero and $-u$ above. Against the resting depth $a+\eta-v$ at zero, the safe-move rule has residual $\eta+\min(u,0)\ge 0$, since $u\ge-\eta$; above zero it has residual zero. This proves the required central safe move, not only the stop order. The roles may switch at each letter. Apply Proposition 7.7.25 to obtain a cup coboundary at $3\kappa+2D_0$, hence at every $H\ge 3(\kappa+D_0)$ as claimed.

The unramified nonpositive branch. Here $d=0$, so all of the preceding level-zero steps are free. Put $t=a+\eta$. For S, deepen a killer point to depth $a+t-u$ at zero and $-u$ above; the steps lie within n_0 of $0,\pm b_i$. Formula (4) leaves a pole of at most t. The nonpositive side S' has killer 1: item2 of Proposition 7.7.15 at $\omega=\kappa=0$ forces its coordinate power to be zero, and the unit $1-\ell u$ removes the modulus. It therefore has points over c' without pole; freely deepen them to the same depth $a+t-u$ at zero.

If S has negative far interval, it has jumps at most t, while S' has jumps at least $-t$. The preceding stop argument works, with the moving side's preceding pole zero. If S has positive far interval, its jumps are at least $-t$. Construct a stop on S' by taking Frobenius of its preceding point, then freely deepening at level zero from depth one to $a+t-u$. Its orders are zero at zero and $-u$ above, since $-\eta\le u\le 0$ and $\eta\le t$. Its depth is at least

$$a+t-u\quad(j=0),\qquad t-u\quad(j=1),\qquad -u\quad(j>1).$$

The moving S difference has orders $\min(-u-t,0)$ at zero, $-u-t$ at one, and $-u$ above. The safe-move residual is respectively zero, zero and zero, using $u\ge -t$ in the first case. Thus the central safe move again holds. The walk uses point exponents $\kappa,0$ and third-side exponent κ, and gives precisely 2κ. This proves the full first item, including its stronger final assertion; no killer for S' was assumed.

Primitive integral relations. For the remainder the chart is unramified. Write $R_t(j,u)=-u+t[j=0]$, and let $m_i(u)$ be the actual multiplicity of u at i. Denote by $X_i(o)$ the localized order module, by $D_i(h)$ the localized points over constants whose Galois differences have orders h, by $K_i(h)$ its kernel vectors with orders h, and put

$$\mathrm{DC}_i(t,h)=\pi\big(X_i(R_t)\cap D_i(h)\big). \tag{5}$$

All modules and lengths in what follows are over $\mathbb{Z}_\ell$; π takes values in the actual letter part of the parameter lattice.

We first prove the integral relation used to control length. Suppose $o(j,u) < o(j,v)$ for every smaller jump $v < u$ at $i^{(j)}$. Among $fm_{i^{(j)}}(u) + 1$ vectors $x_s \in X_i(o)$ there is a combination with one coefficient equal to 1 of the form $W + Z$, where W gains one on every level-zero exponent and Z gains one at (j,u). Indeed the de Rham comparison and its natural graded comparison, Theorem A.3.16, Theorem A.3.11, applied using Lemma 7.4.6, identify the graded type-u form space at this letter with the dual of its weight-u Hodge space. To see the sign and dimension directly, choose invariant comparison vectors $d_h = t^{u_h} e_h$ with (e_h) an integral comparison basis. Their invariant duals have type u_h; the type-u quotient retains exactly the duals with $u_h = u$. Its dimension is therefore the actual multiplicity $m_{i^{(j)}}(u)$. Choose at most that many forms of type u spanning modulo type $u-1$. Divide their values on $\varphi^{-j} x_s$ by the common filtration generator. Their residues give a finite matrix over $\mathbb{C}_\ell$. Choose a nonzero minor of its rank having largest absolute value. Cramer's rule expresses all rows in the selected rows with coefficients in $\mathcal{O}_{\mathbb{C}_\ell}$. Lift these coefficients through θ, then apply φ^j. Subtracting the corresponding combinations of selected vectors cancels the leading terms. Forms of smaller type already have one extra exponent by strictness, so all forms of type u gain the claimed exponent, while all other orders remain. Retract to the actual localized module. Write each retracted coefficient as $q_0(A_{sh}) = w_{sh} + E b_{sh}$, where $w_{sh} \in \Lambda = W(\mathbb{F}_{\ell^f})$. This is possible since $E = z + \ell$ and division modulo E leaves a constant. The vectors $(w_{sh})_h$ lie in a free $\mathbb{Z}_\ell$-module of rank at most $fm_{i^{(j)}}(u)$. A nonzero relation between them can be divided by a coefficient of least valuation, giving coefficients $\beta_s \in \mathbb{Z}_\ell$ with one $\beta_s = 1$. Then

$$\sum_s \beta_s x_s = E \sum_{s,h} \beta_s b_{sh} x_{s(h)} + \sum_s \beta_s R\left(x_s - \sum_h A_{sh} x_{s(h)} \right). \tag{6}$$

These are precisely W and Z. Thus the residue degree enters through integral coefficient vectors, not through a replacement of length by dimension.

Here is the elementary length criterion we shall use. If Q is killed by ℓ^A and any $N+1$ elements of $Q[\ell]$ have a relation with one coefficient 1, then $\operatorname{length} Q \le AN$. Reduce these relations modulo ℓ to get $\dim_{\mathbb{F}_\ell} Q[\ell] \le N$. Induct on A using $0 \to Q[\ell] \to Q \xrightarrow{\ell} \ell Q \to 0$ and $(\ell Q)[\ell] \subseteq Q[\ell]$. This proves finite length as well, without assuming finite generation.

Raise just $h(j,u)$ by one, obtaining h^+. Assume $h(j',v) \ge -v$ on every jump, strictness at smaller jumps at level j, and

$$\text{no multiple of } \ell \text{ lies strictly between } h(0,v) \text{ and } h(0,v) + \ell^j \quad \text{for every } v. \tag{7}$$

Here zero is also a multiple. Put $X = X_i(R_0) \cap D_i(h)$, $X^+ = X_i(R_0) \cap D_i(h^+)$ and $K = K_i(h)$. The quotient $Q = X/(X^+ + K)$ surjects onto $\mathrm{DC}_i(0,h)/\mathrm{DC}_i(0,h^+)$. The depth operator proves $\ell^{c_j(h(j,u))} Q = 0$: its correction lies in K, and K has no pole since $h \ge R_0$.

For $N = fm_{i^{(j)}}(u)$ lift $N+1$ elements of $Q[\ell]$ to x_s. Write $\ell x_s = x_s^+ + k_s$, with $x_s^+ \in X^+$ and $k_s \in K$. Strictness of the kernel inclusion for all forms identifies k_s with actual vectors of Y of orders h. Apply (6) to them: $\sum \beta_s k_s = W + Z$, where $W \in K_i(h + 1_{\text{level }0})$ and $Z \in K_i(h^+)$. Thus for $x_0 = \sum \beta_s x_s$, $\ell x_0 - W \in D_i(h^+)$. The zero-cost level-zero depth operator B raises the depth of W from $h + 1_{\text{level }0}$ to $h + \ell^j 1_{\text{level }0}$: (7) makes all its intervening steps prime to ℓ. Its correction preserves kernel orders. Since (7) excludes crossing zero, the improved-order formula (4) gives

$$BW = E^{\ell^j} W', \qquad W' \in K_i(h).$$

The binomial identity for $E = z+\ell$ gives $E^{\ell^j} = E_j + \ell r$ with $r \in \mathfrak{S}$. Set $k_0 = rW' - (Bx_0 - x_0) \in K$. Then

$$\ell(x_0 - k_0) = B(\ell x_0 - W) + E_j W'. \tag{8}$$

Both summands have Galois differences of orders h^+. Multiplication by ℓ is invertible in every de Rham filtration, so it can be cancelled in this assertion. Thus $x_0 - k_0$ has depth h^+, and still has no pole, since both x_0 and k_0 have none. It lies in X^+. This proves the required primitive relation in $Q[\ell]$, and hence

$$\text{length}\, \frac{\mathrm{DC}_i(0,h)}{\mathrm{DC}_i(0,h) \cap \mathrm{DC}_i(0,h^+)} \leq c_j(h(j,u))\, fm_{i^{(j)}}(u). \tag{9}$$

To reach an antitone target depth at level j, always raise the least jump not yet at its target. At every smaller jump the target is already attained and is strictly larger than the current value at this jump. Thus strictness for (9) holds at each step. At $j = 0$, condition (7) is empty; at $j > 0$ the level-zero depths remain fixed. Summing (9) proves the sum-of-costs bound, with multiplicities, for an arbitrary finite sequence of such increases. Depth decreases at other levels cost nothing. Intersections, rather than an assumed nesting of the original endpoints, justify the triangle inequality for these relative lengths.

Removing the pole and choosing one submodule. Put $D = R_{2a+\eta}$. The unramified cokernel estimate in Proposition 7.7.15 supplies E^a as a killer whenever the jumps are at most $(\ell - 3)a$. All jumps here have this bound. Starting from its point of orders R_{-a} and using the free level-zero steps within the three prescribed neighborhoods gives depth D. Formula (4) gives orders

$$o = \mathrm{imp}(R_{-a}, D). \tag{10}$$

No jump lies in $[-a, -\eta)$: low jumps are at least $-\eta$, negative far jumps are below $-a$, and positive far jumps are positive. Consequently $o \geq R_{-\eta}$. This supplies every constant with pole at most η and depth D. The unramified estimate also supplies the killer ℓ^a with E-exponent zero. Its initial orders are R_0; the same free deepening gives depth D and orders $\mathrm{imp}(R_0, D) \geq R_t$ for every $t \leq 0$. Thus ℓ^a times every constant has every prescribed nonpositive pole bound with this depth.

Remove the pole successively from R_t to R_{t+1} for $-\eta \leq t < 0$. The quotient of constants is killed by ℓ^a by the preceding observation. Apply (6) at $(0,t)$ to any $fm_i(t) + 1$ representatives. The extension has the same multiplicity as Y at the negative jump t, because its quotient is trivial. Both terms in (6) gain at least the exponent $(0,t)$. The depth D and (4) then improve the other exponents to R_{t+1}: at $u < t$ the original exponent $t - u$ was positive; at $u = t$ the raised exponent is one; at $u > t$ the desired exponent is at most zero. Hence the primitive relation holds in this pole-removal quotient. The length criterion bounds this loss by $afm_i(t)$. Summing over t gives

$$\text{length}\, \frac{\mathrm{range}(\mathrm{cst}_i)}{\mathrm{range}(\mathrm{cst}_i) \cap \mathrm{DC}_i(0,D)} \leq an_i. \tag{11}$$

If $\varepsilon(i) = 1$ set $h_i = D$. If $\varepsilon(i) = -1$, set

$$h_i(0,u) = b_i + W + a + \eta, \quad h_i(1,u) = W + 1 - u + 2a\, 1_{[-\eta,\eta]}(u), \quad h_i(j,u) = -u \quad (j \geq 2). \tag{12}$$

We bound the further loss from D to (12). Let N_i be the least multiple of ℓ at least $b_i + W + a + \eta$, and first change the level-zero depth to the constant N_i. On a low line the steps are nonnegative and their total valuation is at most $v_\ell((N_i - 1)!) \leq (N_i - 1)/(\ell - 1) \leq a + 1$, using $N_i < b_i + W + a + \eta + \ell \leq (\ell - 2)a + \ell$. On a negative far line a nonzero multiple y in the interval of steps satisfies $y \leq N_i - \ell < b_i + W + a + \eta$ and $y \geq 2a + \eta - u \geq b_i + 2a + \eta$. Its distance from

b_i is less than $6(a+\eta+W)$, contrary to the gap condition. Thus far lines cost zero. Applying (9) at level zero costs at most $(a+1)n_i$.

Next raise level one to (12) and lower level zero from N_i to its target. Condition (7) holds since $(N_i, N_i+\ell)$ has no multiple of ℓ. There are $W+1+2a1_{\mathrm{low}}(u)$ steps at each line of the preceding letter. Every step is zero or prime to ℓ, by its location within the prescribed neighborhood of zero or a far endpoint; hence its cost is exactly 3. The target is antitone on the jump set: within a window it has slope -1, and across windows the gap $b_{i^{(1)}} > 6(a+\eta+W)$ dominates the possible change $2a$. The level-one loss is therefore at most $3(W+1)r_{i^{(1)}} + 6an_{i^{(1)}}$. Combining with (11), for either sign the loss at letter i is at most

$$(2a+1)n_i + 3(W+1)r_{i^{(1)}} + 6an_{i^{(1)}}. \tag{13}$$

Select now, before choosing any opposite side or pairing,

$$V = \bigcap_i \mathrm{cst}_i^{-1}\big(\mathrm{DC}_i(0,h_i)\big) \subseteq C. \tag{14}$$

The map from C/V to the direct sum of the corresponding one-letter quotients is injective. Frobenius permutes the letters, so (13) gives

$$\mathrm{length}(C/V) \le \sum_i \big((8a+1)n_i + 3(W+1)r_i\big) \le 11\sum_i \big(n_i(a+1) + r_i(W+1)\big). \tag{15}$$

This is an integral length bound for the single module (14).

Uniform orthogonality and the special third point. Fix only now an arbitrary T, P', c and $c' \in V$. At each letter choose the point y_i of S supplied by (14), with own orders R_0 and depth h_i. For T the construction (10) gives x_i over c, own orders o and depth D, with no power of ℓ. Its orders dominate $R_{-\eta}$. Both point families are standard with parameters $(a,\eta,1)$: $D \ge R_{a+\eta}$, and in the negative case $h_i(0,v) - (a+\eta-v) = b_i + W + v \ge 0$, while $h_i(1,v) \ge -v$.

All jumps of the third side are zero or $w = -u-v-1$. Opposite windows place them in the union

$$[-(2\eta+W+1), 2\eta+W], \quad [b_i-\eta-1, b_i+W+\eta-1], \quad [-b_i-W-\eta-1, -b_i+\eta]. \tag{16}$$

They are at most $(\ell-3)a$; the first interval has this bound since $b_i > 6(a+\eta+W)$. Thus E^a kills the third cokernel. We also require a particular deep point there. Start with its point over 1, own orders and depth R_{-a}, and deepen level zero to R_a. Every required step is within radius $a+2\eta+W+1 \le 6(a+\eta+W)$ of 0 or $\pm b_i$ by (16). Each is zero or prime to ℓ, so its cost is zero. Its own orders are

$$z = \mathrm{imp}(R_{-a}, R_a), \qquad z(0,w) = \begin{cases} a-w, & w < -a, \\ \min(a-w, 0), & w \ge -a, \end{cases} \quad z(j,w) = -w \ (j>0), \tag{17}$$

and its depth is R_a. Notice that these are improved own orders, not merely the orders of a standard killer point. The function $z(j,\cdot)$ is antitone.

If $\varepsilon(i) = 1$, T is the down side, so x_i is a stop: its improved orders and depth dominate $\max(0, -u-\eta)$ at zero and $-u$ above. The moving difference $\varphi y_{i^{(1)}} - y_i$ has own orders $\min(-v, 0)$ at zero and $-v$ above, since both y points have own orders R_0. Here $v \ge -\eta$. Against the resting depth $a+\eta-u$, the sum at zero is at least $a-u-v$ because $\eta + \min(v,0) \ge 0$. The ordinary third killer of orders R_{-a} therefore gives a strictly positive sum, since $w = -u-v-1$. Above zero the sum is exactly $-w-u-v = 1$. This proves the central second safe move.

If $\varepsilon(i) = -1$, S is the down side and y_i is a stop, by its own orders R_0 and depth (12). Use the special third point (17) at $i^{(1)}$, transported by Frobenius. Its own orders are zero at level zero and $z(j-1, w)$ at level $j \geq 1$. The moving difference $\varphi x_{i^{(1)}} - x_i$ has orders

$$M_0(u) = \min(o(0,u), 0), \quad M_1(u) = \min(-u, o(0,u)), \quad M_j(u) = -u \ (j \geq 2).$$

We check the strict order inequality against (12) at every level. At zero, $M_0(u) \geq \min(-a - u, 0) \geq -a - b_i - W$, so adding $h_i(0, v)$ gives at least $\eta > 0$. At one write $w = -u - v - 1$. The universal bounds $z(0, w) \geq -a - w$ and $M_1(u) \geq -a - u$ suffice if v is low: adding $W + 1 - v + 2a$ gives $W + 2$. If v is far and u is low, then $|w| \geq b_{i^{(1)}} - \eta - 1 > a$; hence $z(0, w) = a - w$, and adding the other two bounds gives $W + 2$. Finally if both are far, opposite windows give $|u + v| \leq W$, $M_1(u) = -u$ and $z(0, w) \geq -(W + 1) - w$; the sum is at least 1. These three cases exhaust all jumps at the preceding letter, regardless of its sign. At every level at least two the sum is $-w - u - v = 1$. Thus the central first safe move holds as well.

We have obtained a stop with its required central safe move at every letter. The outer moves, global assembly, additional cocycle safety and continuity are exactly those proved in Proposition 7.7.25, applied with every letter a cut and point and third-side exponents zero. Therefore P' is a scaled cup coboundary at $(0, c, c')$. The construction of V preceded T, P', c and used none of them, proving the claimed uniformity. Together with (15) this proves the second item and completes the proof. □

Lemma 7.7.30. *For all integers $m, n, h \geq 0$ and all $a \in A$, one has*

$$\tau^m z^n \mid E^h a \text{ in } B^+ \quad \Longrightarrow \quad \tau^m z^n \mid a \text{ in } A.$$

Proof. Write $A = W(\mathcal{O}_{\mathbb{C}_p^\flat})$. Its Witt-vector construction makes A complete and separated for the p-adic topology, makes multiplication by p injective, and identifies

$$A/pA = \mathcal{O}_{\mathbb{C}_p^\flat}.$$

The latter ring is a domain. Thus p is prime in A, and A is a domain: the first nonzero p-adic coefficients of two nonzero elements multiply to a nonzero coefficient of their product. We use the actual rings

$$A_{\max} = A[T]\widehat{/(pT - \xi)}^{\,p}, \qquad B^+ = A_{\max}[1/p], \tag{Tcan1}$$

not the localization $A[1/p]$. The fixed period-ring embeddings place A and B^+ inside the de Rham period field B_{dR}; in particular they are domains and nonzero elements of A remain nonzero in B^+. These are the standard period rings of the stated convention, with their usual embeddings ([44]). Fontaine's map has kernel ξA and target the domain $\mathcal{O}_{\mathbb{C}_p}$, so ξA is prime.

Principal ideals generated by an element nonzero modulo p are saturated and closed. Let $y \in A$ have nonzero reduction modulo p. If $yb \in pA$, reducing modulo p in the domain A/pA gives $b \in pA$. Repetition, using injectivity of multiplication by p, proves

$$yb \in p^N A \quad \Longrightarrow \quad b \in p^N A \qquad (N \geq 0). \tag{Tcan2}$$

Also, if $pb = yc$, reduction modulo p gives $c = pc_1$; cancellation of p gives $b = yc_1$. Iterating this implication proves

$$p^N b \in yA \quad \Longrightarrow \quad b \in yA. \tag{Tcan3}$$

Suppose $b \in \bigcap_{N \geq 1}(yA + p^N A)$. For each N choose $c_N \in A$ with $b - yc_N \in p^N A$. Then $y(c_{N+1} - c_N) \in p^N A$, so (Tcan2) gives $c_{N+1} - c_N \in p^N A$. Completeness of A gives a limit $c =$

$\lim_N c_N$. Multiplication by y is p-adically continuous, and $b - yc_N$ tends to zero; separatedness therefore gives $b = yc$. We have proved

$$\bigcap_{N\geq 1} (yA + p^N A) = yA. \tag{Tcan4}$$

No Noetherian hypothesis on A or on A/yA is used.

Reduction modulo (y, p^N) reflects divisibility from B^+. Assume in addition that $\xi - pb_0 \in yA$ for some $b_0 \in A$. For $N \geq 1$ put $Q_N = A/(y, p^N)$. Sending T to the class of b_0 defines a ring map

$$A[T]/(pT - \xi) \longrightarrow Q_N.$$

It exists because the defining relation maps to $pb_0 - \xi = 0$. Since $p^N Q_N = 0$, it factors through reduction modulo p^N of the source ring. Projection from its p-adic completion in (Tcan1) consequently gives a ring map

$$F_N : A_{\max} \longrightarrow Q_N$$

whose restriction to A is the quotient map. Equivalently, an element of the completion is represented at precision p^N, and applying the factored map is independent of that representative.

Let $a_0 \in A$ and suppose $a_0 = yv$ in B^+. Write $v = w/p^k$ with $w \in A_{\max}$ and $k \geq 0$. Equality in the localization means that for some $j \geq 0$,

$$p^j(p^k a_0 - yw) = 0 \quad \text{in } A_{\max}.$$

Thus, putting $K = k + j$ and $w' = p^j w$, we have the exact equality $p^K a_0 = yw'$ in $A_{\max}$. This argument does not assume that completion alone clears denominators inside A. Applying F_N gives $p^K a_0 \in yA + p^N A$ for every N. By (Tcan4), $p^K a_0 \in yA$, and (Tcan3) then gives $a_0 \in yA$. We have established

$$A \cap yB^+ = yA \quad \text{if } \bar{y} \neq 0 \text{ in } A/pA \text{ and } \xi \in (p, y)A. \tag{Tcan5}$$

The Eisenstein factor can be removed. Suppose also $\theta(y) \neq 0$. Since $\ker\theta = \xi A$, this means $\xi \nmid y$. If $y \mid E^h a$ in B^+, (Tcan5), applied to the element $E^h a \in A$, gives $y \mid E^h a$ in A. The chart relation makes E associated to ξ, so $y \mid \xi^h a$ in A. If $h > 0$, write $\xi^h a = yb$. Primality of ξA and $\xi \nmid y$ give $b = \xi b_1$. Cancellation of the nonzero ξ in the domain A gives $\xi^{h-1} a = yb_1$. Induction on h, including $h = 0$, proves

$$y \mid E^h a \text{ in } B^+ \quad \Longrightarrow \quad y \mid a \text{ in } A \tag{Tcan6}$$

under the three scalar hypotheses just checked.

Both actual factors satisfy the scalar hypotheses. For $y = \tau = [\varepsilon^{1/p}] - 1$, the actual compatible cyclotomic system has $\theta(\tau) = \zeta_p - 1 \neq 0$, where ζ_p is primitive. Modulo p, τ is $\varepsilon^{1/p} - 1$ in the tilt. If it were zero, $\varepsilon^{1/p} = 1$ would imply $\theta(\tau) = 0$, a contradiction. The defining formula for ξ gives

$$\xi - p = \sum_{i=0}^{p-1} \big((1+\tau)^i - 1\big) \in \tau A.$$

Thus $\xi \in (p, \tau)A$. This formula and nonvanishing hold also for $p = 2$, when $\theta(\tau) = -2 \neq 0$.

For $y = z$, let $u \in A^\times$ be the image of the chart's unit series. The chart equations are

$$E = z^e u + p, \qquad e \geq 1, \qquad \xi = vE \quad (v \in A^\times).$$

Applying θ gives $\theta(z)^e\theta(u) = -p \neq 0$, so $\theta(z) \neq 0$. Since $z = [\varpi^\flat]$, its reduction modulo p is $\varpi^\flat$. This is nonzero: otherwise $z = 0$, contrary to $\theta(z) \neq 0$. Finally $\xi - pv = vz^e u \in zA$ because $e \geq 1$. Hence $\xi \in (p, z)A$. These checks use no restriction on p beyond primality. The nonzero ξ used above can also be seen directly modulo p: the geometric-sum formula gives $\bar{\xi} = \bar{\tau}^{\,p-1} \neq 0$ in the tilt domain.

Consequently (Tcan6) holds separately for $y = \tau$ and $y = z$. Both have nonzero image in B^+ by the fixed embeddings.

Remove all factors without changing the ambient rings. Induct on $m+n$. If $m+n = 0$, the divisor is 1 and the conclusion is immediate. Otherwise choose $y = \tau$ if $m > 0$, and $y = z$ if $m = 0$, $n > 0$, and write $\tau^m z^n = yq$ with q the product with that exponent reduced by one. From $yq \mid E^h a$ in B^+ one has $y \mid E^h a$, so (Tcan6) gives $a = ya_1$ with $a_1 \in A$. If $E^h a = yqb$ in B^+, substitution and cancellation of the nonzero y in that domain yield $E^h a_1 = qb$. The induction hypothesis gives $q \mid a_1$ in A, and therefore $yq \mid a$ in A. This proves the assertion for every $m, n, h \geq 0$, including zero exponents and $p = 2$. □

Lemma 7.7.31. *For $0 \leq j_0 \leq m$, put*

$$Q_* = kt, \quad G_* = \frac{a}{x_1}, \quad \delta_* = (2j_0 + 1)h - 2t, \quad \eta_* = h^2 + 1, \quad W_* = 4t.$$

Then:

1. *δ_* is a nonnegative integer and $(Q_*, m, h, G_*, b, \delta_*, \eta_*, W_*)$ satisfies (KZ1)–(KZ4).*
2. *Put $N_* = (r + t)r$ and $E_* = 3r^2(N_* + 1)^2 + 150(\eta_* + W_* + 1)$. For $\ell = p_i$, $i = 0, 1$, and every complex embedding σ,*

$$\ell > S_{j_0}(\sigma) + 6(W_* + \eta_*) + r^2(N_* + 1)^2 + 2.$$

   For every integer $1 \leq x_{\mathrm{div}} \leq t$, $2E_* \leq \mathrm{db}_\ell / x_{\mathrm{div}}$.

3. *For every prime ℓ, every integer $\rho \geq 0$, and every $1 \leq x_{\mathrm{div}} \leq t$,*

$$10^5 \left(\rho \left\lfloor \frac{2\lambda_\ell}{kt} \right\rfloor m + \left\lfloor \frac{\rho m}{k x_{\mathrm{div}}} \right\rfloor \lambda_\ell \right) \leq \rho \, \frac{\mathrm{db}_\ell}{x_{\mathrm{div}}}.$$

Proof. We make the comparisons with the actual global scales explicit. By Lemma 4.2.67 and Proposition 2.3.5,

$$\begin{aligned} &x \geq e^{6.4 \cdot 10^{15}}, \quad x^5 \leq r \leq 3x^5, \quad 1 \leq k \leq r, \quad m \leq r/2, \quad t = 5r, \\ &x^{10^6} \leq x_1, \quad x_1^{10^6} \leq b, \quad (\log b)^{100} \leq x. \end{aligned} \tag{15}$$

In particular all the polynomial comparisons below already hold for $x \geq 100$ and $r \geq 100$, which (15) supplies. We will use the stronger bounds

$$G_* = \frac{xb}{x_1} \geq x\, x_1^{999999} \geq 99r^{24}, \qquad x_1 \geq 99x(r^{24} + 1), \qquad b \geq r^{18}, \qquad b \geq 100r^{16}. \tag{16}$$

For example $r^{24} \leq 3^{24}x^{120}$, so the second inequality follows from $99x(3^{24}x^{120} + 1) \leq x^{10^6}$. The first follows from $x_1 \geq x^{10^6}$, and the last two from $b \geq x^{10^{12}}$ and $r \leq 3x^5$. These are inequalities of positive monomials; $x \geq 100$ is much more than needed.

For item 1, $Q_* = kt \le 5r^2$, $W_* = 20r$, and $m \le r/2$. Therefore

$$99(Q_*^2 + (W_*+1)Q_* + Q_* + W_* + m) \le 2\cdot 10^4 r^4 \le r^8 = h.$$

Indeed the summand before multiplication by 99 is at most $25r^4 + 100r^3 + 10r^2 + 21r \le 200r^4$. This proves (KZ1), including $Q_* > 0$. The first bound in (16) gives $99h^3 \le G_*$. The second gives

$$99G_*(h^3+1) = \frac{99x(r^{24}+1)}{x_1}\, b \le b,$$

proving (KZ2). Since $\log b \le x^{1/100}$,

$$2\log(4b) \le 2x^{1/100} + 2\log 4 < \sqrt{x} \le m$$

for $x \ge 100$; this proves (KZ3). Finally

$$0 < h - 10r \le \delta_* \le (2m+1)h \le (r+1)r^8 < r^{16} + 1 = \eta_*.$$

For the remaining (KZ4) inequality,

$$99((\eta_* + W_*)Q_* + \eta_* + h) \le 10^3 r^{18} \le r^{24} = h^3.$$

The first inequality follows on inserting $\eta_* = r^{16}+1$, $W_* = 20r$, $Q_* \le 5r^2$; for $r \ge 100$ the leading coefficient is 495 and the other positive terms together are less than $505r^{18}$. The second uses $r^6 \ge 10^3$. Item 1 is proved.

For item 2, $N_* = 6r^2$, so $N_* + 1 \le 7r^2$. Also $\eta_* + W_* + 1 = r^{16} + 20r + 2 \le 2r^{16}$. Hence

$$E_* \le 147r^6 + 300r^{16} \le 500r^{16}, \qquad 2E_* \le 10^3 r^{16}. \tag{17}$$

The actual far-window start satisfies $S_{j_0}(\sigma) = \kappa(\sigma) + \delta_* \le b + (r+1)r^8 \le 2b$. Here $\kappa(\sigma) \le b$, since $x/x_1 \le 1$. Furthermore

$$6(W_* + \eta_*) + r^2(N_*+1)^2 + 2 \le 6(20r + r^{16} + 1) + 49r^6 + 2 \le 10r^{16} \le b.$$

Consequently the right side of the required height inequality is at most $3b < b^{10} \le p_i$.

Since M is the product of the two distinct level primes, $v_{p_i}(M) = 1$. Using $m \ge 1$, $k \le r$, $x_{\mathrm{div}} \le t = 5r$, and nonnegativity of λ_ℓ,

$$\frac{\mathrm{db}_{p_i}}{x_{\mathrm{div}}} \ge 10^6 \frac{m}{kt}\, b \ge 2\cdot 10^5\, \frac{b}{r^2} \ge 2\cdot 10^5 r^{16} \ge 2E_*,$$

where $b \ge r^{18}$ in (16) and (17) were used.

For item 3, $x_{\mathrm{div}} \le t$ and positivity of k, x_{div} give

$$\left\lfloor \frac{2\lambda_\ell}{kt} \right\rfloor \le \frac{2\lambda_\ell}{kx_{\mathrm{div}}}, \qquad \left\lfloor \frac{\rho m}{kx_{\mathrm{div}}} \right\rfloor \le \frac{\rho m}{kx_{\mathrm{div}}}.$$

Thus its left side is at most $3\cdot 10^5 \rho m \lambda_\ell/(kx_{\mathrm{div}})$. This is at most $10^6 \rho m(bv_\ell(M) + \lambda_\ell)/(kx_{\mathrm{div}}) = \rho\, \mathrm{db}_\ell/x_{\mathrm{div}}$. This also covers $\rho = 0$ and $\lambda_\ell = 0$. □

Lemma 7.7.32. *Let ℓ be prime, $e : E \to \overline{\mathbb{Q}}_\ell$ an embedding, and let $j : \Gamma \to G_\ell$ be an open embedding onto the elements fixing $e(E)$. For all sufficiently large coefficient rings $\mathcal{O}$, there exist a Kummer chart $\mathfrak{c}$ for Γ, a primitive $(\ell^{f_\mathfrak{c}} - 1)$-th root $\zeta \in \mathcal{O}$, a predicate $\mathcal{T}_\mathrm{b}$ on $\mathbb{C}_\ell$, and a sign function ε_b on $\mathbb{C}_\ell$, such that the letters read thickness for*

$$\mathrm{lt}(g) = g(\zeta), \qquad \mathrm{th}(g) \iff [\sigma_{e,g}] \in \Phi_b, \qquad \varepsilon(g) = \mathrm{sg}(\sigma_{e,g}),$$
$$Q = kt, \quad h = r^8, \quad (\mathcal{T}_\mathrm{b}, \varepsilon_\mathrm{b}), \qquad g \in G_\ell.$$

Proof. Let K_ℓ be the closure of $e(E)$. Choose the chart in Lemma 7.7.17, which fits Γ, and write $e_{\mathfrak{c}}, f_{\mathfrak{c}}$ for its index and residue degree. Its degree identity gives

$$e_{\mathfrak{c}} f_{\mathfrak{c}} = [K_\ell : \mathbb{Q}_\ell].$$

Its coefficient field is the maximal unramified subfield $K_{\ell,0}$ of K_ℓ. To check this identification directly, the image of the coefficient Witt ring is fixed by G_{K_ℓ}, and $\theta(z)$ satisfies the Eisenstein power-series equation $X^{e_{\mathfrak{c}}} A + \ell = 0$. Weierstrass preparation replaces this by an Eisenstein polynomial of degree $e_{\mathfrak{c}}$. Thus the coefficient field together with $\theta(z)$ has degree $e_{\mathfrak{c}} f_{\mathfrak{c}}$, and equals K_ℓ; the extension over the coefficient field is totally ramified. Consequently $K_{\ell,0}$ has degree $f_{\mathfrak{c}}$.

By Lemma 4.2.66, the index is at most $[E : \mathbb{Q}] = 2f \leq h$. In particular $e_{\mathfrak{c}} \leq h$. Choose a primitive root ζ of order $\ell^{f_{\mathfrak{c}}} - 1$ in $K_{\ell,0}$, using Teichmüller lifts of its residue field. It generates $K_{\ell,0}$ over $\mathbb{Q}_\ell$, including the case of residue field $\mathbb{F}_2$, where the degree is one. Choose a finite Galois coefficient extension containing ζ. Every coefficient ring containing its ring of integers contains the same root; this gives precisely the eventual quantifier.

Put $c_{\mathrm{cyc}} = q_1 d$. If $\ell \mid c_{\mathrm{cyc}}$, then

$$\ell \leq kt. \tag{12}$$

Indeed the prime divisors of $q_1 = 3q_0 l_0(s) 2^s$ already divide q_0, as $2 \cdot 3 \mid q_0$. Thus $\ell \leq \max(q_0, d) \leq C_P \leq \log x$. The final inequality follows from (AD1); and $\log x \leq kt$ follows from Lemma 4.2.67, since $k \geq r/2$, $t = 5r$, $r \geq x^5$, and x is larger than $e^{6.4 \cdot 10^{15}}$.

If $\ell \nmid c_{\mathrm{cyc}}$, the completion K_ℓ is unramified by Lemma 4.2.66; the chart is therefore unramified. Also $\ell \geq 7$, since $2, 3, 5, 7 \mid q_0$. In this case $K_\ell = K_{\ell,0} = \mathbb{Q}_\ell(\zeta)$. Thus equality $g(\zeta) = g'(\zeta)$ implies equality of the restrictions of g, g' to K_ℓ. Since this unramified field is Galois, the inverse restrictions agree too, so

$$\sigma_{e,g} = \sigma_{e,g'}. \tag{13}$$

Thickness and sign are consequently functions of the letter in this case.

We next show that when $\ell \mid c_{\mathrm{cyc}}$, all embeddings over b-places have the same CM sign. If $\ell \mid q_1$, then $\ell \mid (d+1)/4$. For odd ℓ this follows from $q_0 \mid 2(d+1)$; for $\ell = 2$ it follows from $16 \mid q_0$. Set $u_0 = e((1 + \sqrt{-d})/2)$. Opposite signs of $\sigma_{e,g}, \sigma_{e,g'}$ would mean that a local Galois automorphism exchanges u_0 and $1 - u_0$. They would have the same absolute value. But their product is $(d+1)/4$, of absolute value less than one, whereas their sum is one. Equal absolute values then force each to have absolute value less than one, contradicting the ultrametric inequality for their sum.

If $\ell \mid c_{\mathrm{cyc}}$ and $\ell \nmid q_1$, then $\ell = d$. A local Galois element acts on the roots of unity of order q_0 by a power d^{n_0}, since these roots have order prime to d and lie in an unramified extension. For two embeddings with opposite CM signs, the ratio of their infinite-place classes modulo q_0 is therefore $-d^{n_0}$. Here is the sign convention in this computation: the chosen embedding of the infinite place of σ sends a cyclotomic root to its value under σ, raised to $\mathrm{sg}(\sigma)$; comparing these two powers gives the product of the two signs times the local Frobenius power. Both b-places have class -1 modulo q_0, so their ratio is 1. This would give $d^{n_0} \equiv -1 \pmod{q_0}$. However $d \equiv q_0/2 - 1 \pmod{q_0}$, $4 \mid q_0$, and hence $d^2 \equiv 1 \pmod{q_0}$. Its powers are 1 or $q_0/2 - 1$, neither equal to -1, as $q_0 \geq 18480$. This is a contradiction. The sign assertion is proved.

Define

$$\mathcal{T}_{\mathrm{b}}(w) \iff \exists g \in G_\ell : \ [\sigma_{e,g}] \in \Phi_b \text{ and } g(\zeta) = w.$$

In the unramified case define $\varepsilon_{\mathrm{b}}(w)$ to be the sign of any such letter representative, choosing an arbitrary sign if there is none. More generally representatives of every nonempty fibre may be used, so that (13) determines signs also at thin fibres. In the conductor-dividing case choose the

common sign of the b-place embeddings and make ε_{b} constant; if there are no such embeddings choose either constant sign. These definitions give the required thickness equivalence and sign whenever the embedding is thick. If $Q < \ell$, (12) forces the unramified case, and (13) gives them at every embedding. They also give exactly the unramified-or-constant-sign alternative in the definition.

It remains to check the three-letter prohibition when $\ell \le Q$. Let $J_{\mathrm{orb}} = \lfloor \log_\ell h^3 \rfloor$. We first bound its range by the actual sparseness interval:

$$2J_{\mathrm{orb}} < l_0(s). \tag{14}$$

Indeed $h^3 = r^{24}$, so $2J_{\mathrm{orb}} \le 48 \log_2 r \le 288 \log_2 x$, using $r \le 3x^5 \le x^6$. On the other hand $s = 22 \log_2 m \ge 11 \log_2 x$ by $m \ge \sqrt{x}$, and $l_0(s) > 27s \ge 297 \log_2 x$, giving (14).

Suppose three thick letters occur at $w, w^{\ell^\alpha}, w^{\ell^{\alpha+\alpha'}}$, where $1 \le \alpha, \alpha' \le J_{\mathrm{orb}}$. Choose g_0, g_1, g_2 giving these letters and b-place embeddings. Put $q_{\mathrm{ur}} = q_1^{(\ell)}$, the prime-to-$\ell$ part of q_1. The roots of unity of order q_{ur} in $e(E)$ lie in $K_{\ell,0}$: reduction identifies roots of unity of order prime to ℓ with the Teichmüller roots in the residue field. Since ζ generates this field, the two letter equalities imply that $g_2 g_1^{-1}$ and $g_2 g_0^{-1}$ act on these roots by the powers $\ell^{\alpha'}$ and $\ell^{\alpha+\alpha'}$, respectively. The same place-class computation just given, now modulo q_{ur}, shows that, writing $v_i = [\sigma_{e,g_i}]$,

$$v_1/v_2 \equiv \epsilon_1 \ell^{\alpha'}, \qquad v_0/v_2 \equiv \epsilon_0 \ell^{\alpha+\alpha'} \pmod{q_{\mathrm{ur}}},$$

for signs $\epsilon_i \in \{\pm 1\}$. All three places lie in Φ_b, and $0 < \alpha' < \alpha + \alpha' < l_0(s)$ by (14). This contradicts the sparseness in (AD3) and Definition 2.3.2, applied at $\ell \le kt$. The prohibition follows, completing every clause of letters reading thickness. □

A Quoted results

The Appendix states the published results on which the proofs rest, each in the notation of the paper and with its source, grouped by field. Where a proof needs a published theorem in a form that is not in print, that form is proved in the body where it is first used, and only the printed theorem is quoted here. One convention is used only in the quotations, and it opens the Appendix: abelian schemes with cubical line bundles and their degenerations [220, 77, 43, 215].

Notation for abelian schemes is that of [220], [215] and [77]. For a scheme S, an **abelian scheme** $A \to S$ is a smooth proper group scheme with geometrically connected fibres, and a **semiabelian scheme** $G \to S$ is a smooth separated commutative group scheme whose fibres are extensions of abelian varieties by tori. We write $A^\vee$ for the dual abelian scheme, $e\colon S \to A$ for the unit section, $[n]$ for multiplication by n, $A[n]$ for its kernel and $T_\ell A$, $V_\ell A = T_\ell A \otimes \mathbb{Q}_\ell$ for the Tate modules. A **polarised abelian scheme** $(A, \mathcal{L})$ carries a relatively ample line bundle $\mathcal{L}$ with polarisation $\phi_{\mathcal{L}}\colon A \to A^\vee$, and $e_n\colon A[n] \times A[n] \to \mu_n$ is the Weil pairing of $\phi_{\mathcal{L}}$. Line bundles are given by an open cover and transition functions; $\bigotimes_i f_i^*\mathcal{L}^{\otimes n_i}$ is the tensor combination of pull-backs along morphisms f_i. A **rigidified** line bundle is a pair $(\mathcal{L}, r)$ with $r\colon e^*\mathcal{L} \cong \mathcal{O}_S$, and a **cubical structure** on it is a trivialisation of

$$\Theta(\mathcal{L}) = \bigotimes_{\varnothing \neq I \subseteq \{1,2,3\}} m_I^*\mathcal{L}^{\otimes(-1)^{|I|+1}}$$

on A^3 (m_I the partial sums) satisfying the symmetry and cocycle conditions of [215], Ch. I; $\mathcal{G}(\mathcal{L})$ is the theta group. For $S = \operatorname{Spec} V$ with V a complete discrete valuation ring with fraction field K, a **semiabelian model** of an abelian variety A_K is a semiabelian scheme G/V with $G_K \cong A_K$; its formal completion is the extension $\tilde{G}$ (**Raynaud extension**) of an abelian scheme by a torus, which is **split** if the torus is split; and **degeneration data** and the **Mumford uniformisation** $A_K^{\mathrm{an}} = \tilde{G}_K/Y$ are as in [77], Ch. II–III and [221]. A **p-divisible group** over a ring R is written $\mathcal{G}$, with Tate module $T_p\mathcal{G}$, Lie algebra $\operatorname{Lie}\mathcal{G}$, invariant differentials $\omega_{\mathcal{G}}$ and, over the ring of integers of a complete algebraically closed field C, Hodge–Tate map $\alpha_{\mathcal{G}}\colon T_p\mathcal{G} \to \omega_{\mathcal{G}^\vee}$ [255]. An action of a ring O with involution on A (or G, $\mathcal{G}$) is a ring homomorphism $O \to \operatorname{End}(A)$ compatible with the Rosati involution where a polarisation is given. This notation holds wherever abelian varieties occur in this paper.

A.1 Analytic number theory

These are classical results of analytic number theory, used mostly in Section 2 [64, 214, 308, 144]: Chebyshev's bound [116]; the continuation and the functional equations of Dirichlet L-functions, going back to Riemann [242], with Dirichlet's non-vanishing at $s = 1$; and the values at the non-positive integers, with the theorem of von Staudt and Clausen [317]. Four results are quantitative: the prime number theorem in progressions of Thorner and Zaman [307], in the line of Linnik and Gallagher [189, 93]; the Siegel–Walfisz theorem [314, 279]; the transformation formula for the theta function of a primitive character; and the Pólya–Vinogradov inequality. The section closes with Hecke L-functions [128, 294, 296, 224, 182] and Kronecker's first limit formula [329].

Lemma A.1.1. *For every integer $n \geq 1$, $\prod_{p \leq n} p < 4^n$, the product running over the primes $p \leq n$. Consequently, for every real $x \geq 0$,*

$$\sum_{p \leq x} \log p \leq x \log 4.$$

Proof. See [116, Chapter XXII] (the bound $\vartheta(n) < 2n\log 2$, by the argument of Erdős with the middle binomial coefficient); see also [214] (Chebyshev estimates, Chapter 2). The second form follows from the first: for $x \geq 1$ the sum equals $\log \prod_{p \leq \lfloor x \rfloor} p < \lfloor x \rfloor \log 4 \leq x \log 4$, and for $0 \leq x < 2$ it is 0. □

Theorem A.1.2. *Let $N \geq 1$ and let χ be a Dirichlet character modulo N. The function defined for $\operatorname{Re} s > 1$ by $\sum_{n \geq 1} \chi(n) n^{-s}$ extends to a meromorphic function $L(s,\chi)$ on $\mathbb{C}$. If $\chi \neq \chi_{0,N}$, this function is entire. If $\chi = \chi_{0,N}$, its only pole is a simple pole at $s = 1$, with residue $\varphi(N)/N$. In particular $\zeta(s)$ is holomorphic on $\mathbb{C} \setminus \{1\}$, and $\zeta(s) - \frac{1}{s-1}$ extends to an entire function whose value at $s = 1$ is γ:*

$$\zeta(s) = \frac{1}{s-1} + \gamma + O(|s-1|) \qquad (s \to 1).$$

Proof. [214] (the analytic continuation of $\zeta(s)$ with its Laurent expansion at $s = 1$, and of $L(s,\chi)$), [64], [308]. Notation as in the references: $L(s,\chi)$ for a character χ modulo N, with Euler factors 1 at the primes dividing N; for $\chi = \chi_{0,N}$ one has $L(s,\chi_{0,N}) = \zeta(s) \prod_{p \mid N} (1 - p^{-s})$, whence the residue $\prod_{p \mid N}(1 - p^{-1}) = \varphi(N)/N$. □

Theorem A.1.3. *Let $q \geq 3$ and let χ be a primitive Dirichlet character modulo q. Let $a \in \{0,1\}$ with $\chi(-1) = (-1)^a$, let $\tau(\chi) = \sum_{m=1}^{q} \chi(m) e^{2\pi i m/q}$ be its Gauss sum, and put*

$$\xi(s,\chi) = \Big(\frac{q}{\pi}\Big)^{(s+a)/2} \Gamma\Big(\frac{s+a}{2}\Big) L(s,\chi).$$

Then $\xi(s,\chi)$ is entire, $|\tau(\chi)| = q^{1/2}$, and with $W(\chi) = \tau(\chi)/(i^a q^{1/2})$, so that $|W(\chi)| = 1$,

$$\xi(s,\chi) = W(\chi)\, \xi(1-s, \overline{\chi}) \qquad (s \in \mathbb{C}).$$

Proof. [64] (Chapter 9, the functional equation in the form $\xi(1-s,\overline{\chi}) = \frac{i^a q^{1/2}}{\tau(\chi)} \xi(s,\chi)$, and Chapter 2 for $|\tau(\chi)| = q^{1/2}$), [214] (Chapter 10). Notation as in the references, except that the root number is written $W(\chi) = \tau(\chi)/(i^a q^{1/2})$, the inverse of Davenport's factor $i^a q^{1/2}/\tau(\chi)$ (the two have modulus 1). □

Theorem A.1.4. *Let $N \geq 1$ and let χ be a Dirichlet character modulo N with $\chi \neq \chi_{0,N}$. Then $L(1,\chi) \neq 0$.*

Proof. Dirichlet's theorem, [214] (the non-vanishing of $L(1,\chi)$ in the proof of Dirichlet's theorem on primes in arithmetic progressions), [64]. Notation as in the references; $L(1,\chi)$ is the value at $s = 1$ of the entire function of Theorem A.1.2, equal to the conditionally convergent series $\sum_{n \geq 1} \chi(n)/n$. □

Theorem A.1.5. *The function $\xi(s) = \pi^{-s/2}\, \Gamma(s/2)\, \zeta(s)$ is holomorphic on $\mathbb{C} \setminus \{0,1\}$ and satisfies*

$$\xi(1-s) = \xi(s) \qquad (s \in \mathbb{C} \setminus \{0,1\}).$$

Moreover $\zeta(0) = -\frac{1}{2}$.

Proof. Riemann's functional equation, [214] (Chapter 10), [64] (Chapter 8), [308] (Chapter II). Notation as in the references; ξ here is the completed zeta function without the factor $\frac{1}{2}s(s-1)$ of Riemann's normalisation, so that it has simple poles at $s = 0$ and $s = 1$. The value $\zeta(0) = -\frac{1}{2}$ follows from the functional equation and the residue 1 of ζ at $s = 1$. □

Theorem A.1.6. *Let $f \geq 1$ and let χ be a primitive Dirichlet character modulo f (for $f = 1$, $\chi = \chi_{0,1}$ and $L(s,\chi) = \zeta(s)$). For every integer $k \geq 1$,*

$$L(1-k,\chi) = -\frac{B_{k,\chi}}{k}, \qquad B_{k,\chi} = f^{\,k-1} \sum_{a=1}^{f} \chi(a)\, B_k\Big(\frac{a}{f}\Big),$$

where $L(1-k,\chi)$ is the value of the meromorphic continuation, which is holomorphic at $1-k$.

Proof. [317], Chapter 4, Theorem 4.2, with Proposition 4.1 for the expression of $B_{k,\chi}$ through Bernoulli polynomials. Washington's n is our k; for $f = 1$ his $B_{k,1}$ is $B_k(1)$, so that $\zeta(0) = -B_1(1) = -\frac{1}{2}$. □

Theorem A.1.7. *Let the Bernoulli numbers $B_j \in \mathbb{Q}$ be defined by $t/(e^t - 1) = \sum_{j \geq 0} B_j t^j / j!$. Then $B_0 = 1$, $B_1 = -\frac{1}{2}$, $B_j = 0$ for every odd $j \geq 3$, and for every even $j \geq 2$*

$$B_j + \sum_{\substack{p \text{ prime} \\ (p-1) \mid j}} \frac{1}{p} \in \mathbb{Z}.$$

Proof. [317], Chapter 5, Theorem 5.10 (von Staudt–Clausen); the values B_0, B_1 and the vanishing for odd $j \geq 3$ follow from the generating function, since $t/(e^t - 1) + t/2$ is even ([317], Chapter 4). Notation as in the reference. □

Theorem A.1.8. *For an integer $M \geq 2$, an integer b and real X let $\vartheta(X; M, b) = \sum \log p$, the sum over the primes $p \leq X$ with $p \equiv b \pmod M$.*

1. *For every integer $M \geq 2$ the product $\prod_{\chi \bmod M} L(s,\chi)$ has no zero in the region $\operatorname{Re} s \geq 1 - 1/(13 \log(M(|\operatorname{Im} s| + 3)))$, except possibly one real zero $\beta_1 < 1$. If it exists, it is called the* exceptional zero modulo M*; there is then exactly one real non-principal character χ_1 modulo M with $L(\beta_1, \chi_1) = 0$.*

2. *There are absolute, effectively computable constants $c_4 > 0$ and A_4 such that for every integer $M \geq 2$, every integer b with $\gcd(b, M) = 1$ and every real $X \geq M^{12}$,*

$$\Big|\vartheta(X; M, b) - \frac{X - \chi_1(b) X^{\beta_1}/\beta_1}{\varphi(M)}\Big| \leq A_4\Big(e^{-c_4 \log X / \log M} + e^{-c_4 (\log X)^{3/5} (\log\log X)^{-1/5}}\Big) \frac{X - \chi_1(b) X^{\beta_1}/\beta_1}{\varphi(M)},$$

where the term $\chi_1(b) X^{\beta_1}/\beta_1$ is omitted (in both places) when there is no exceptional zero modulo M.

Proof. [307]: item 1 is the statement on the exceptional zero in Section 1.1 (from McCurley's zero-free region for $\prod_{\chi \bmod q} L(s,\chi)$), item 2 is Corollary 1.4 with Remark 1.5 (numbering of arXiv:2108.10878v2). Notation: $q \mapsto M$, $a \mapsto b$, $x \mapsto X$; the left side of Corollary 1.4 is $\vartheta(X; M, b)$; its main term $\lambda x/\varphi(q)$ with $\lambda = \lambda(x, q, a, x) = 1 - \chi_1(a) x^{\beta_1 - 1}/\beta_1$ (Remark 1.5; $\lambda = 1$ if β_1 does not exist) is $(X - \chi_1(b) X^{\beta_1}/\beta_1)/\varphi(M)$; the implied constant of its O-term is A_4. That $\beta_1 < 1$ is the classical non-vanishing of $L(s,\chi)$ on $\operatorname{Re} s \geq 1$. □

Theorem A.1.9. *For an integer $q \geq 1$, an integer a and a real number X put $\psi(X;q,a) = \sum \Lambda(n)$, the sum over the integers $1 \leq n \leq X$ with $n \equiv a \pmod q$. For every $A > 0$ there are constants $c_A > 0$ and $C_A > 0$ such that*

$$\Big|\psi(X;q,a) - \frac{X}{\varphi(q)}\Big| \leq C_A\, X \exp\!\big(-c_A\sqrt{\log X}\big)$$

for every real $X \geq 2$, every integer q with $1 \leq q \leq (\log X)^A$ and every integer a with $\gcd(a,q) = 1$.

Proof. This is the Siegel–Walfisz theorem, [64], Chapter 22, and [214], Section 11.3. For $q = 1$ it is the prime number theorem with the de la Vallée Poussin error term. The constants are not effective (Siegel's theorem); only their existence is used. □

Theorem A.1.10. *There is an absolute constant $c_{\mathrm{PV}} > 0$ such that for every integer $q \geq 2$, every Dirichlet character $\chi \neq \chi_{0,q}$ modulo q, every integer a and every integer $N \geq 0$,*

$$\Big|\sum_{a < n \leq a+N} \chi(n)\Big| \leq c_{\mathrm{PV}}\, q^{1/2} \log q.$$

Proof. G. Pólya and I. M. Vinogradov (1918); [214, Theorem 9.18], [64, Chapter 23]. Notation as in the references: the character need not be primitive, and the sum runs over an arbitrary interval of integers of length N. □

Theorem A.1.11. *Let $q \geq 3$, let χ be a primitive Dirichlet character modulo q, let $a \in \{0,1\}$ with $\chi(-1) = (-1)^a$, and let $\tau(\chi) = \sum_{m=1}^{q} \chi(m) e^{2\pi i m/q}$. For real $x > 0$ put*

$$\Theta_a(x,\chi) = \sum_{n \in \mathbb{Z}} n^a \chi(n)\, e^{-\pi n^2 x/q}.$$

Then $|\tau(\chi)| = q^{1/2}$, and for every $x > 0$

$$\Theta_a(x,\chi) = \frac{\tau(\chi)}{i^a q^{1/2}}\; x^{-a-1/2}\; \Theta_a(x^{-1}, \overline{\chi}).$$

Proof. [64, Chapter 9] (the functions $\psi(x,\chi)$ for even and $\psi_1(x,\chi)$ for odd χ, and their transformation formulae, obtained by Poisson summation), and [64, Chapter 2] for $|\tau(\chi)| = q^{1/2}$. Notation map: Davenport's $\psi(x,\chi)$ and $\psi_1(x,\chi)$ are $\Theta_0(x,\chi)$ and $\Theta_1(x,\chi)$; he writes the constant through $\tau(\overline{\chi})$, which is the same constant because $\tau(\chi)\tau(\overline{\chi}) = \chi(-1)\, q$. □

Theorem A.1.12. *Let F be a number field and χ a unitary Hecke character of F.*

1. *For every Schwartz–Bruhat function f on $\mathbb{A}_F$ the zeta integral $Z(f,\chi,s)$ continues meromorphically to $\mathbb{C}$ and $Z(f,\chi,1-s) = Z(\hat{f},\chi^{-1},s)$. It is entire unless χ is trivial on C_F^1, that is $\chi = |\cdot|_{\mathbb{A}}^{i\tau}$ for some $\tau \in \mathbb{R}$; in that case its only poles are at most simple poles at $s = -i\tau$ and $s = 1 - i\tau$.*

2. *$\xi(s,\chi)$ continues meromorphically to $\mathbb{C}$, with the poles described in item 1, and $\xi(s,\chi) = W(\chi)\,\xi(1-s,\overline{\chi})$ with $W(\chi)W(\overline{\chi}) = 1$. If $\chi = |\cdot|_{\mathbb{A}}^{i\tau}$, the continued $L(s,\chi)$ has a simple pole with nonzero residue at $s = 1 - i\tau$.*

3. *If χ is not of the form $|\cdot|_{\mathbb{A}}^{i\tau}$, the continuation of $L(s,\chi)$ is holomorphic and has no zeros in* $\operatorname{Re} s \geq 1$.

Proof. Items 1 and 2 are Hecke's theorem in the adelic form of Tate's thesis: [296], Main Theorem 4.4.1 and Section 4.5 (with $\xi(s,\chi) = W(\chi)\xi(1-s,\overline{\chi})$ obtained from item 1 for the standard choice of f); [128]; [224], Chapter VII, Theorem 8.5 and Corollary 8.6 for the completed L-function. Applying the functional equation twice gives $W(\chi)W(\overline{\chi}) = 1$. For $\chi = |\cdot|_{\mathbb{A}}^{i\tau}$, $L(s,\chi)$ is the Dedekind zeta function $\zeta_F(s+i\tau)$ up to finitely many Euler factors that are holomorphic and non-zero near $s = 1 - i\tau$, so the residue statement is the class number formula. Item 3 is the non-vanishing of Hecke L-functions on $\operatorname{Re} s = 1$: [182], Chapter XV, Section 5; for $\operatorname{Re} s > 1$ it follows from the absolutely convergent Euler product. □

Theorem A.1.13. *Let $\tau = x + iy$ with $y > 0$, and for $\operatorname{Re} s > 1$ put*

$$E(\tau, s) = \sum_{(m,n)\in\mathbb{Z}^2\setminus\{(0,0)\}} \frac{y^s}{|m+n\tau|^{2s}}.$$

Use the Weierstrass normalisation

$$\begin{aligned} g_2(\tau) &= 60 \sum_{(m,n)\neq(0,0)} (m+n\tau)^{-4}, \\ g_3(\tau) &= 140 \sum_{(m,n)\neq(0,0)} (m+n\tau)^{-6}, \\ \Delta_{\mathrm{W}}(\tau) &= g_2(\tau)^3 - 27 g_3(\tau)^2. \end{aligned}$$

Then $\Delta_{\mathrm{W}}(\tau) \neq 0$, and $E(\tau,s)$ continues meromorphically to a neighbourhood of $s = 1$, with a simple pole of residue π and

$$\lim_{s\to 1}\left(E(\tau,s) - \frac{\pi}{s-1}\right) = 2\pi\left(\gamma - \log 2 - \frac{1}{12}\log\frac{y^6|\Delta_{\mathrm{W}}(\tau)|}{(2\pi)^{12}}\right).$$

Proof. This is Kronecker's first limit formula in the Weierstrass normalisation. Williams [329], definition (7.10) and Theorem 7.19, equation (7.20), uses the SAME all-integer-pairs series and gives the constant $2\pi(\gamma - \log 2 - \log(\sqrt{y}\,|\eta(\tau)|^2))$. His definition (4.39) is precisely $\Delta_{\mathrm{W}} = (60G_4)^3 - 27(140G_6)^2$, and the Jacobi normalisation (4.42) is $\Delta_{\mathrm{W}} = (2\pi)^{12}\eta^{24}$. Therefore

$$\log(\sqrt{y}\,|\eta(\tau)|^2) = \frac{1}{12}\log\frac{y^6|\Delta_{\mathrm{W}}(\tau)|}{(2\pi)^{12}},$$

which gives exactly the displayed version. The nonvanishing and local meromorphic continuation are part of these classical statements. No coprimality restriction or quotient by $(m,n) \mapsto (-m,-n)$ is used. □

A.2 Algebraic number theory, class field theory and CM abelian varieties

The field E of the datum is a cyclotomic extension of an imaginary quadratic field, and these are results on the arithmetic of such fields [224, 317]: the classical facts on units, class groups and discriminants in towers [212, 202]; class field theory [53, 9, 260, 297], with Chebotarev's density theorem [54], Hasse's norm theorem [123], Landherr's classification of hermitian forms [180, 249],

the decomposition of primes in cyclotomic fields [203] and the reciprocity law for the Brauer group of $\mathbb{Q}$ [265, 201]; Gauss sums, with Stickelberger's factorisation [290] and the Davenport–Hasse relation [65, 145]; and abelian varieties and elliptic curves with complex multiplication [220, 27, 266, 282, 281, 39, 77, 178].

Lemma A.2.1. *Let α be an algebraic integer such that $|\sigma(\alpha)| = 1$ for every field embedding $\sigma\colon \mathbb{Q}(\alpha) \to \mathbb{C}$. Then α is a root of unity.*

Proof. This is Kronecker's theorem; see [317], Chapter 1 (Lemma 1.6 there: an algebraic integer all of whose conjugates have absolute value 1 is a root of unity). Notation map: the conjugates of α are the values $\sigma(\alpha)$ of the embeddings σ of $\mathbb{Q}(\alpha)$ into $\mathbb{C}$. In the uses in this project α lies in a number field K; every embedding of $\mathbb{Q}(\alpha)$ into $\mathbb{C}$ is the restriction of an embedding of K, so it suffices that $|\tau(\alpha)| = 1$ for every embedding $\tau\colon K \to \mathbb{C}$. □

Theorem A.2.2. *Let K be a number field with r_1 real embeddings and r_2 conjugate pairs of complex embeddings. Its roots of unity form a finite cyclic group $\mu(K)$, and*

$$\mathcal{O}_K^{\times} \simeq \mu(K) \times \mathbb{Z}^{r_1+r_2-1}$$

as abelian groups.

Proof. This is Dirichlet's unit theorem, including the torsion subgroup identification; see [224, Chapter I]. □

Theorem A.2.3. *Let K be a number field of degree n, with r_2 pairs of nonreal embeddings. Every ideal class of K contains a nonzero integral ideal $\mathfrak{a}$ satisfying*

$$N_{K/\mathbb{Q}}\mathfrak{a} \le \frac{n!}{n^n}\left(\frac{4}{\pi}\right)^{r_2} |\operatorname{disc}(K)|^{1/2}.$$

Proof. This is Minkowski's ideal-class bound; see [224], the geometry of numbers and finiteness of the ideal class group. The ideal norm is the absolute index $|\mathcal{O}_K/\mathfrak{a}|$, and r_2 counts conjugate pairs, so the displayed constant has the standard normalization. □

Theorem A.2.4. *Let $F \subseteq L$ be number fields, and let*

$$C_{L/F} = \{a \in L : \operatorname{Tr}_{L/F}(a\mathcal{O}_L) \subseteq \mathcal{O}_F\}, \qquad \mathfrak{D}_{L/F} = C_{L/F}^{-1}.$$

Then

$$|\operatorname{disc}(L)| = |\operatorname{disc}(F)|^{[L:F]} N_{L/\mathbb{Q}}(\mathfrak{D}_{L/F}).$$

Proof. This is the different–discriminant and discriminant tower formula of [212, §5.2, Lemma 5.5 and Theorem 5.7]. Here $\mathfrak{D}_{L/F}$ is the relative different defined by the inverse trace codifferent, $N_{L/\mathbb{Q}}$ is the absolute ideal norm, and disc denotes the absolute field discriminant. □

Theorem A.2.5. *Let L/K be a finite abelian extension of number fields with Galois group G. For each $\chi \in \widehat{G} = \operatorname{Hom}(G, \mathbb{C}^{\times})$, let $\mathfrak{f}_0(\chi)$ be the finite part of the conductor of the finite-order Hecke character obtained by composing χ with the Artin map for L/K. Then the relative discriminant ideal is*

$$\mathfrak{d}_{L/K} = \prod_{\chi \in \widehat{G}} \mathfrak{f}_0(\chi).$$

For $K=\mathbb{Q}$, this says that the absolute discriminant of L is the product of the positive integer conductors of the corresponding primitive Dirichlet characters.

Proof. This is the conductor–discriminant formula, [202, Chapter V, Theorem 3.27]. The ideal denoted $\mathrm{disc}(L/K)$ there is $\mathfrak{d}_{L/K}$ here, and its factor $f_0(\chi\circ\phi_{L/K})$ is the finite conductor ideal $\mathfrak{f}_0(\chi)$. Over $\mathbb{Q}$, the norm of that ideal is the conductor of the corresponding primitive Dirichlet character, so taking ideal norms gives the last assertion. □

Theorem A.2.6. *Let L/F be a finite Galois extension of number fields and $C\subseteq \mathrm{Gal}(L/F)$ a subset stable under conjugation. Then the set of finite places v of F unramified in L whose Frobenius class in $\mathrm{Gal}(L/F)$ is contained in C has Dirichlet density $\#C/[L:F]$.*

Proof. [54]; in the form stated (Dirichlet density): [224], Chapter VII, Theorem 13.4. For a conjugation-stable C apply the theorem to each conjugacy class contained in C and add the densities. □

Theorem A.2.7. *1. Let K be a non-archimedean local field. There is a continuous injective homomorphism $\mathrm{Art}_K\colon K^\times\to G_K^{ab}$ with dense image such that every uniformiser acts as an arithmetic Frobenius on K^{ur} and, for every finite abelian extension L/K, the composite $K^\times\to\mathrm{Gal}(L/K)$ is surjective with kernel $\mathrm{N}_{L/K}L^\times$. Every open subgroup of finite index of $K^\times$ is $\mathrm{N}_{L/K}L^\times$ for a unique finite abelian L/K.*

2. Let F be a number field. There is a continuous surjective homomorphism $\mathrm{Art}_F\colon C_F\to G_F^{ab}$ with kernel C_F^0, compatible with the local Artin maps at every finite place, sending the class of an idele supported at a finite place v unramified in a finite abelian L/F to Frob_v on L when its v-component is a uniformiser and to 1 when it is a unit, and sending the idele -1 at a real place w to complex conjugation at w. The map $L\mapsto \mathrm{N}_{L/F}C_L$ is an inclusion-reversing bijection between finite abelian extensions of F and open subgroups of finite index of C_F; in particular ray class fields exist and are unramified outside their modulus.

Proof. [260]; [297]; [9]; [224], Ch. V and VI. □

Theorem A.2.8. *Let L/F be a finite abelian extension of number fields. There is a continuous surjective homomorphism*

$$\mathrm{rec}_{F,L}: C_F\longrightarrow \mathrm{Gal}(L/F),\qquad \ker\mathrm{rec}_{F,L}=N_{L/F}C_L.$$

Its pullback to $\mathbb{A}_F^\times$ kills $F^\times$. For every place v of F and $w\mid v$, its restriction to $F_v^\times$ is the local reciprocity map into $D_w=\mathrm{Gal}(L_w/F_v)$, followed by inclusion in $\mathrm{Gal}(L/F)$; its local kernel is $N_{L_w/F_v}L_w^\times$. At finite v, local units map onto inertia. At an unramified finite place, units map to 1 and a uniformiser maps to arithmetic Frobenius. At a real place becoming complex, positive elements map to 1 and negative elements to complex conjugation; at a split real or complex place the local map is trivial.

Proof. This is global Artin reciprocity and its local compatibility: [202, Chapter V, Proposition 5.2 and Theorem 5.3; Chapter I, Theorem 1.1 and 1.6]. The real normalization follows from $N_{\mathbb{C}/\mathbb{R}}\mathbb{C}^\times=\mathbb{R}_{>0}$. □

Theorem A.2.9. *Let K be a number field and $\mathfrak{m}$ a non-zero ideal of $\mathcal{O}_K$. Let $I_K(\mathfrak{m})$ be the group of fractional ideals of K coprime to $\mathfrak{m}$, and $P_K(\mathfrak{m})$ its subgroup of principal ideals (α) with $\alpha\equiv 1 \pmod{}^\times\mathfrak{m}$. Put $\mathrm{Cl}_K(\mathfrak{m})=I_K(\mathfrak{m})/P_K(\mathfrak{m})$, let h_K be the class number of K and $\mathcal{O}_{K,\mathfrak{m}}^\times$ the group of units $u\in\mathcal{O}_K^\times$ with $u\equiv 1 \pmod{\mathfrak{m}}$.*

1. $\mathrm{Cl}_K(\mathfrak{m})$ *is finite, of order*
$$|\mathrm{Cl}_K(\mathfrak{m})| = \frac{h_K\,|(\mathcal{O}_K/\mathfrak{m})^\times|}{[\mathcal{O}_K^\times : \mathcal{O}_{K,\mathfrak{m}}^\times]}.$$

2. *There is a finite abelian extension L/K, the ray class field of K modulo $\mathfrak{m}$, unramified at every prime ideal of K not dividing $\mathfrak{m}$, such that the Artin map $\mathfrak{p} \mapsto (\frac{L/K}{\mathfrak{p}})$ on the prime ideals $\mathfrak{p} \nmid \mathfrak{m}$, extended multiplicatively to $I_K(\mathfrak{m})$, is surjective onto $\mathrm{Gal}(L/K)$ with kernel $P_K(\mathfrak{m})$. In particular a prime ideal $\mathfrak{p} \nmid \mathfrak{m}$ has trivial Artin symbol in L/K if and only if $\mathfrak{p} \in P_K(\mathfrak{m})$.*

3. *Through this isomorphism every character of $\mathrm{Gal}(L/K)$ is a character of $\mathrm{Cl}_K(\mathfrak{m})$, and the primitive Hecke character inducing it has conductor dividing $\mathfrak{m}$; in particular its norm is at most $\mathrm{N}\mathfrak{m}$.*

Proof. This is classical class field theory (Takagi's existence theorem and Artin's reciprocity law in ideal-theoretic form); see [224], Ch. VI. Item 1 is the exact sequence for the ray class group modulo $\mathfrak{m}$ (with a modulus without infinite places); item 2 is the existence of the ray class field and the reciprocity isomorphism $\mathrm{Cl}_K(\mathfrak{m}) \cong \mathrm{Gal}(L/K)$ given by the Artin symbol; item 3 is the definition of the conductor of a character of $\mathrm{Cl}_K(\mathfrak{m})$, the smallest modulus through which it factors, which divides $\mathfrak{m}$. Neukirch writes $J^{\mathfrak{m}}$, $P^{\mathfrak{m}}$ and $\mathrm{Cl}_K^{\mathfrak{m}}$ for $I_K(\mathfrak{m})$, $P_K(\mathfrak{m})$ and $\mathrm{Cl}_K(\mathfrak{m})$. □

Theorem A.2.10. *Let $n \geq 1$, $L = \mathbb{Q}(\zeta_n)$, and identify $\mathrm{Gal}(L/\mathbb{Q})$ with $(\mathbb{Z}/n\mathbb{Z})^\times$ by $\sigma_u(\zeta_n) = \zeta_n^u$. For a rational prime p, write $n = p^a n'$, $p \nmid n'$. At any prime of L above p, the inertia and decomposition groups are respectively*
$$I_p = \{u : u \equiv 1 \pmod{n'}\}, \qquad D_p = \{u : u \equiv p^b \pmod{n'} \text{ for some } b \geq 0\}.$$
In particular the ramification index is $\varphi(p^a)$; $L/\mathbb{Q}$ is unramified outside n.

For every intermediate field $\mathbb{Q} \subseteq E \subseteq L$, restriction sends these groups onto the inertia and decomposition groups at the restricted prime of E. Thus those groups are the images of I_p, D_p in $\mathrm{Gal}(E/\mathbb{Q})$. All notation is local.

Proof. These are the classical cyclotomic decomposition formulas. The p-power cyclotomic factor is totally ramified at p; the prime-to-p factor is unramified, with arithmetic Frobenius acting by $\zeta_{n'} \mapsto \zeta_{n'}^p$. The Chinese remainder identification gives the displayed groups. Restriction of decomposition and inertia groups in a finite Galois tower gives the final assertion. See [203, §6, Proposition 6.2 and Theorem 6.4]. □

Theorem A.2.11. *Let F be a number field and $\delta, x \in F^\times$. Suppose that for every real embedding $\sigma\colon F \to \mathbb{R}$ there are $a, b \in \mathbb{R}$ with $\sigma(x) = a^2 - \sigma(\delta)b^2$, and that for every finite place v of F there are $a, b \in F_v$ with $x = a^2 - \delta b^2$ in F_v. Then there are $a, b \in F$ with $x = a^2 - \delta b^2$.*

Proof. This is Hasse's norm theorem [123] for the extension $F(\sqrt{\delta})/F$, which is cyclic of degree at most 2; see [224], Chapter VI, Section 4. *Notation.* If δ is not a square in F, then $a^2 - \delta b^2$ is the norm of $a + b\sqrt{\delta}$ from $E = F(\sqrt{\delta})$, and the local hypothesis at a place v says that x is a norm from $E \otimes_F F_v$; at a complex place this holds for every x, so complex places are omitted. If $\delta = d^2$ is a square in F, the conclusion holds without hypotheses: $x = a^2 - \delta b^2$ with $a = (x+1)/2$, $b = (x-1)/(2d)$. □

Theorem A.2.12. *Let E be a CM field and $G, G' \in \mathrm{M}_r(E)$ nondegenerate hermitian matrices ($\bar{G}^\top = G$, $\bar{G'}^\top = G'$). Suppose that for every embedding $\tau\colon E \to \mathbb{C}$ the hermitian matrices $\tau(G)$ and $\tau(G')$ have the same signature, and that $\det G' = z\bar{z}\det G$ for some $z \in E$. Then there is $\gamma \in \mathrm{GL}_r(E)$ with*

$$\bar{x}^\top \bar{\gamma}^\top G\,\gamma\, y = \bar{x}^\top G'\, y \qquad \text{for all } x, y \in E^r,$$

that is, the hermitian forms of G and G' are isometric.

Proof. Landherr's theorem [180]; see [249], Chapter 10: for a quadratic extension E/F of number fields, two nondegenerate hermitian forms over E are isometric if and only if they have the same dimension, the same discriminant in $F^\times/\mathrm{N}_{E/F}(E^\times)$, and the same signature at every real place of F that does not split in E. Only the sufficiency is quoted. *Notation.* Here F is the maximal totally real subfield of E, so every real place of F is complex in E and every embedding τ of E restricts to a real place of F; the signature at that place is the signature of $\tau(G)$, which does not depend on the choice of τ above it, since the other choice gives the complex conjugate of $\tau(G)$, whose signature is the same. The determinant of a hermitian matrix lies in $F^\times$, and the condition $\det G' = z\bar{z}\det G$ says that the discriminants agree modulo $\mathrm{N}_{E/F}(E^\times)$ (with $z \neq 0$, as both determinants are nonzero). The isometry is the displayed identity, that is $\bar{\gamma}^\top G\gamma = G'$. $\square$

Theorem A.2.13. *Let $m \geq 2$ be an integer, $K = \mathbb{Q}(\mu_m) \subset \overline{\mathbb{Q}}$, and for $t \in (\mathbb{Z}/m\mathbb{Z})^\times$ let $\sigma_t \in \mathrm{Gal}(K/\mathbb{Q})$ be the automorphism with $\sigma_t(\zeta) = \zeta^{\tilde{t}}$ for $\zeta \in \mu_m$, where $\tilde{t} \in \{1, \dots, m-1\}$ is the representative of t. Let $\mathfrak{p}$ be a prime ideal of $\mathcal{O}_K$ not dividing m, p its residue characteristic, $k = \mathcal{O}_K/\mathfrak{p}$ and $q = |k|$, so that $m \mid q-1$. Let $\chi_\mathfrak{p}\colon k^\times \to \mu_m$ be the m-th power residue character: $\chi_\mathfrak{p}(x \bmod \mathfrak{p})$ is the element of μ_m congruent to $x^{(q-1)/m}$ modulo $\mathfrak{p}$, for $x \in \mathcal{O}_K \setminus \mathfrak{p}$. Fix a primitive p-th root of unity $\zeta_p \in \overline{\mathbb{Q}}$ and put, for $j \in \mathbb{Z}$,*

$$\mathrm{g}_\mathfrak{p}(j) = \sum_{c \in k^\times} \chi_\mathfrak{p}(c)^{-j}\, \zeta_p^{\mathrm{Tr}_{k/\mathbb{F}_p}(c)} \in \mathbb{Q}(\mu_{mp}).$$

Then:

1. *if $m \nmid j$, then $\mathrm{g}_\mathfrak{p}(j)\,\mathrm{g}_\mathfrak{p}(-j) = \chi_\mathfrak{p}(-1)^j\, q$;*
2. *$\mathrm{g}_\mathfrak{p}(1)^m \in K$, and as ideals of $\mathcal{O}_K$*

$$\mathrm{g}_\mathfrak{p}(1)^m\, \mathcal{O}_K = \prod_{t \in (\mathbb{Z}/m\mathbb{Z})^\times} \sigma_t^{-1}(\mathfrak{p})^{\tilde{t}}.$$

Proof. We use Stickelberger's valuation theorem in the following precise normalization [181], Chapter 1, Section 2, Theorem 2.1, printed p.6. If $q = p^f$, $\mathfrak{P}$ is a prime above p of $\mathbb{Q}(\mu_{q-1})$, $\omega(x) \equiv x \pmod{\mathfrak{P}}$, and $\mathfrak{Q}$ is its unique extension to $\mathbb{Q}(\mu_{q-1}, \zeta_p)$, then

$$\mathrm{ord}_\mathfrak{Q}\left(\sum_{x \in \mathbb{F}_q^\times} \omega(x)^{-a} \zeta_p^{\mathrm{Tr}(x)}\right) = s_p(a), \qquad 0 < a < q-1,$$

where $s_p(a)$ is the sum of the base-p digits of a. The prime valuation on the left is integer-normalized, so $\mathrm{ord}_\mathfrak{Q}(p) = p-1$. The character, additive trace and minus sign in the exponent are as displayed; this theorem has no oddness restriction on p. We now give the conversion to the present statement for every residue degree f.

The product identity and descent of the power. Put $\alpha = \chi_{\mathfrak{p}}^{-j}$ and $\lambda(x) = \zeta_p^{\mathrm{Tr}(x)}$. If $m \nmid j$, α is nontrivial. In the product of the sums for α and α^{-1} write $x = uy$:

$$\sum_{u \neq 0} \alpha(u) \sum_{y \neq 0} \lambda((u+1)y).$$

The inner sum is $q-1$ for $u = -1$ and -1 otherwise, because λ is nontrivial. Since $\sum_{u \neq 0} \alpha(u) = 0$, the result is $q\alpha(-1)$. As $\chi_{\mathfrak{p}}(-1)^2 = 1$, this equals $q\chi_{\mathfrak{p}}(-1)^j$, proving item 1. In particular these sums are nonzero.

Let $L = K(\zeta_p)$. For $c \in \mathbb{F}_p^\times$, the automorphism fixing K and taking ζ_p to ζ_p^c takes $\mathrm{g}_{\mathfrak{p}}(1)$ to $\chi_{\mathfrak{p}}(c)\mathrm{g}_{\mathfrak{p}}(1)$, by substituting $x = c^{-1}u$. Its m-th power is therefore fixed by $\mathrm{Gal}(L/K)$ and belongs to K. This remains valid for $p = 2$, when that group is trivial.

The valuation at the fixed prime uses the inverse residue character. Choose a prime $\mathfrak{P}$ of $T = \mathbb{Q}(\mu_{q-1})$ above $\mathfrak{p}$. Its residue field is k: indeed the order of p modulo $q-1 = p^f - 1$ is f, so its residue degree is f. Reduction identifies its Teichmuller character ω on $k^\times$. With $a = (q-1)/m$, both $\chi_{\mathfrak{p}}(x)$ and $\omega(x)^a$ reduce to x^a, and reduction is injective on roots of unity of order prime to p. Thus

$$\chi_{\mathfrak{p}} = \omega^a.$$

For $1 \leq t < m$ prime to m, take the automorphism of L fixing ζ_p and restricting to σ_t on K. It takes $\mathrm{g}_{\mathfrak{p}}(1)$ to $\mathrm{g}_{\mathfrak{p}}(t)$. The character in this last sum is precisely ω^{-at}; reduce at to its representative modulo $q-1$ before applying the digit formula. The extension T/K is unramified at p, and adjoining ζ_p has ramification index $p-1$. Since $p \nmid m$, the valuation at $\mathfrak{p}$ on K gives p valuation 1. Consequently

$$\mathrm{ord}_{\mathfrak{p}}(\mathrm{g}_{\mathfrak{p}}(t)^m) = \frac{m}{p-1} s_p(at \bmod (q-1)).$$

The repeated primes give the full factorisation. For $0 < b < q-1$, cyclic permutation of its f base-p digits gives

$$\frac{s_p(b)}{p-1} = \sum_{i=0}^{f-1} \left\{ \frac{p^i b}{q-1} \right\}.$$

Indeed the representatives of $p^i b$ modulo $q-1$ are precisely the cyclic rotations of those digits; their sum is $s_p(b)(1 + p + \cdots + p^{f-1})$. Apply this to the representative of at. We obtain

$$\mathrm{ord}_{\sigma_t^{-1}(\mathfrak{p})}(\mathrm{g}_{\mathfrak{p}}(1)^m) = m \sum_{i=0}^{f-1} \left\{ \frac{p^i t}{m} \right\} = \sum_{i=0}^{f-1} \widetilde{p^i t}.$$

Here the first equality also uses $\mathrm{ord}_{\mathfrak{p}}(\sigma_t z) = \mathrm{ord}_{\sigma_t^{-1}\mathfrak{p}}(z)$. The decomposition subgroup of $\mathfrak{p}$ in $K/\mathbb{Q}$ is generated by σ_p, the arithmetic residue Frobenius $x \mapsto x^p$, and has order f. Hence $\sigma_u^{-1}\mathfrak{p} = \sigma_t^{-1}\mathfrak{p}$ exactly when u runs through $t, pt, \ldots, p^{f-1}t$ modulo m. The preceding sum is exactly the exponent of this prime in the displayed product of item 2, including all repetitions.

Finally every Gauss sum is an algebraic integer. Item 1 shows that its product with the opposite-character sum is a root of unity times q, so it has no prime divisor away from p. The valuations just computed therefore prove equality of the two ideals.

Changing ζ_p to ζ_p^c multiplies the sum by $\chi_{\mathfrak{p}}(c)$, an m-th root of unity; changing the additive character by its inverse is the case $c = -1$. Neither change alters the ideal. Replacing the multiplicative character by its inverse would instead replace t by $-t$ in its exponents. The negative exponent in the statement is thus essential, and is the one used throughout this proof. □

Theorem A.2.14. *Let k be a finite field of characteristic p, k'/k a finite extension of degree s, $\zeta_p \in \overline{\mathbb{Q}}$ a primitive p-th root of unity, and for a finite field $\kappa \supseteq \mathbb{F}_p$ and a character $\alpha\colon \kappa^\times \to \overline{\mathbb{Q}}^\times$ put $\mathrm{g}_\kappa(\alpha) = \sum_{c\in\kappa^\times} \alpha(c)\,\zeta_p^{\mathrm{Tr}_{\kappa/\mathbb{F}_p}(c)}$. If α is a nontrivial character of $k^\times$, then*

$$-\mathrm{g}_{k'}(\alpha \circ \mathrm{N}_{k'/k}) = \bigl(-\mathrm{g}_k(\alpha)\bigr)^s.$$

Proof. The Davenport–Hasse relation [65]; see also [317], Chapter 6, and [145]. Notation as in the references, with the additive character $c \mapsto \zeta_p^{\mathrm{Tr}_{\kappa/\mathbb{F}_p}(c)}$ of κ; the trace of k' is the trace of k composed with $\mathrm{Tr}_{k'/k}$. □

Theorem A.2.15. *Let K be a number field. For a finite place v, the local invariant is an isomorphism $\mathrm{inv}_v : \mathrm{Br}(K_v) \to \mathbb{Q}/\mathbb{Z}$. For a real place it identifies $\mathrm{Br}(K_v)$ with $\frac{1}{2}\mathbb{Z}/\mathbb{Z}$, and at a complex place $\mathrm{Br}(K_v) = 0$. The localization and invariant maps form an exact sequence*

$$0 \longrightarrow \mathrm{Br}(K) \xrightarrow{(\mathrm{res}_v)_v} \bigoplus_v \mathrm{Br}(K_v) \xrightarrow{(\beta_v)_v \mapsto \sum_v \mathrm{inv}_v(\beta_v)} \mathbb{Q}/\mathbb{Z} \longrightarrow 0.$$

Proof. [202], Chapter IV, Section 4 (local invariants), and Chapter VIII, Theorem 4.2 (the fundamental exact sequence). □

Theorem A.2.16. *Let V be a complex vector space of finite dimension $r \geq 0$, let H be positive-definite Hermitian, and let $\Lambda \subset V$ be a full lattice self-dual for $E = \operatorname{Im} H$. Let $\alpha : \Lambda \to \{1, -1\}$ satisfy*

$$\alpha(x + y) = \alpha(x)\alpha(y)e^{\pi i E(x,y)}.$$

Then the space of entire functions satisfying

$$F(z + x) = \alpha(x)e^{\pi H(z,x)+\pi H(x,x)/2}F(z) \quad (x \in \Lambda)$$

has complex dimension exactly one. Equivalently, with $\mathsf{U}_x F(z) = e^{-\pi H(z,x)-\pi H(x,x)/2}F(z + x)$, the theta space defined by $\alpha(x)\mathsf{U}_x F = F$ has dimension one. This applies to the original sign semicharacter; no theta vector is replaced.

Proof. This is the principal-polarisation case of classical theta theory and abelian Riemann–Roch [220]. Here is the hypothesis comparison. Appell–Humbert identifies the displayed automorphy space with $H^0(A, \mathcal{L}(H, \alpha))$ on $A = V/\Lambda$. Positivity of H makes this line bundle ample and A projective. Self-duality means that the integral alternating form E is unimodular; thus its polarisation has degree one. Riemann–Roch gives $\chi(\mathcal{L})^2 = 1$. Positivity gives $\chi(\mathcal{L}) > 0$, while vanishing for an ample line bundle on a complex abelian variety gives $H^i(A, \mathcal{L}) = 0$ for $i > 0$. Hence $h^0(A, \mathcal{L}) = \chi(\mathcal{L}) = 1$. The two automorphy conventions agree since $\alpha(x)^{-1} = \alpha(x)$. When $r = 0$, the torus is a point and the space consists of constants. □

Theorem A.2.17. *Let $k \subset \mathbb{C}$ be an imaginary quadratic field with ring of integers $\mathcal{O}_k$.*

1. *(Algebraicity.) If Z is an elliptic curve over $\mathbb{C}$ with $\mathrm{End}(Z) \cong \mathcal{O}_k$, then $j(Z)$ is an algebraic number; hence there are a number field $M \subset \mathbb{C}$ and an elliptic curve Z_M over M with $Z_M \otimes_M \mathbb{C} \cong Z$, and M may be chosen so that every endomorphism of $Z_M \otimes_M \mathbb{C}$ is defined over M.*

2. *(Potentially good reduction.) If M is a number field and Z_M an elliptic curve over M whose endomorphism ring over $\overline{M}$ is an order in an imaginary quadratic field, then Z_M has potentially good reduction at every finite place of M: there is a finite extension M'/M such that $Z_M \otimes_M M'$ has good reduction at every finite place of M', that is, extends to an abelian scheme over $\mathcal{O}_{M'}$.*

Proof. Item 1: the algebraicity of $j(Z)$ (indeed $k(j(Z))$ is the Hilbert class field of k) is the first main theorem of complex multiplication for elliptic curves (Deuring; Shimura–Taniyama), [281], Chapter II, §4, Theorem II.4.3; an elliptic curve over $\mathbb{C}$ with algebraic j-invariant is defined over $\mathbb{Q}(j)$, and its endomorphisms, finitely many generators of a $\mathbb{Z}$-module of rank 2, are defined over a finite extension (each is defined over $\overline{\mathbb{Q}}$ because homomorphisms between abelian varieties over an algebraically closed field do not change under extension to a larger algebraically closed field). Item 2: J.-P. Serre and J. Tate [266], §4, Theorem 6 (an abelian variety with complex multiplication, over a field with a discrete valuation with finite residue field, has potentially good reduction at every place), and [281], Chapter II, §6, for elliptic curves; the global extension M' is obtained since Z_M has good reduction outside finitely many places and good reduction persists under finite extensions; an elliptic curve over M' with good reduction at every finite place is the generic fibre of its Néron model, an abelian scheme over $\mathcal{O}_{M'}$ ([39], §1.4). The notation agrees with that of the sources. □

Theorem A.2.18. *Let $K \subset \mathbb{C}$ be an imaginary quadratic field and let $I \subset K$ be a nonzero fractional $\mathcal{O}_K$-ideal. Let $g_2(I), g_3(I)$ be its Weierstrass invariants, put $\Delta(I) = g_2(I)^3 - 27 g_3(I)^2$, and use the usual normalisation*

$$j(I) = 1728\, g_2(I)^3 / \Delta(I).$$

Then $j(I)$ is an algebraic integer.

Proof. This is the classical integrality theorem for singular moduli: [204], Corollary 12.16, printed page 125. Choose an oriented $\mathbb{Z}$-basis ω_1, ω_2 of I with $\tau = \omega_2/\omega_1$ in the upper half-plane. Then $\tau \in K$, and scaling invariance gives $j(I) = j(\mathbb{Z} + \mathbb{Z}\tau) = j(\tau)$. Corollary 12.16 states exactly that $j(\tau)$ is an algebraic integer for such an imaginary-quadratic τ. □

Theorem A.2.19. *Let S be a noetherian normal scheme, let $U \subseteq S$ be a dense open subscheme, and let G, H be semiabelian schemes over S. Every homomorphism of U-group schemes*

$$f_U : H_U \longrightarrow G_U$$

extends uniquely to a homomorphism of S-group schemes $f : H \to G$.

Proof. This is the semiabelian homomorphism extension theorem, [77, Chapter I, Proposition 2.7]; see also [178, Proposition 3.3.1.5]. The base is noetherian and normal, the subscheme is open and dense, and both group schemes are semiabelian, exactly as required by that theorem. □

Theorem A.2.20. *Let p be a prime, $K/\mathbb{Q}_p$ finite, and $L \subset \overline{\mathbb{Q}}_p$ a finite coefficient field containing every image of K under a $\mathbb{Q}_p$-embedding. Let $\eta : G_K^{\mathrm{ab}} \to \mathcal{O}_L^{\times}$ be continuous, and let $V = L(\eta)$, regarded also as a $\mathbb{Q}_p$-representation. Write $\mathrm{Art}_K : K^{\times} \to G_K^{\mathrm{ab}}$ for arithmetic reciprocity.*

1. *If integers a_τ, indexed by $\tau : K \hookrightarrow L$, satisfy*

$$\eta(\mathrm{Art}_K(u)) = \prod_{\tau : K \hookrightarrow L} \tau(u)^{a_\tau}$$

on some open subgroup of $\mathcal{O}_K^\times$, then V is Hodge–Tate and its labelled Hodge–Tate weight at τ is $-a_\tau$.

2. *The representation V is crystalline if and only if there exists a morphism of $\mathbb{Q}_p$-tori*

$$A : \mathrm{Res}_{K/\mathbb{Q}_p}\,\mathbb{G}_m \longrightarrow \mathrm{Res}_{L/\mathbb{Q}_p}\,\mathbb{G}_m$$

such that $\eta(\mathrm{Art}_K(u)) = A(u)$ for every $u \in \mathcal{O}_K^\times$.

Proof. The first assertion is the local algebraicity theorem of Tate, with its weight calculation, in [261], Chapter III, Appendix A.5, Theorem 2, and A.6, Corollary 2. Arithmetic reciprocity sends a unit u to an element on which the Lubin–Tate character has value u^{-1}; its distinguished Hodge–Tate weight is 1. Thus an exponent a_τ gives weight $-a_\tau$ with the stated cyclotomic convention. The second assertion is the crystalline abelian-character theorem of Fontaine–Serre, [264], Section 2.3, Theorem 5 and Corollary 2, in the local reciprocity formulation. □

A.3 Galois cohomology and p-adic Hodge theory

The Galois cohomology rests on the duality theorems of Tate and Poitou [295, 299, 150, 265, 201, 225], and the local conditions above ℓ are those of Bloch and Kato [28]. The p-adic Hodge theory is Fontaine's [85, 86, 87, 44], with Berger's theorem [22] and the Weil–Deligne description of crystalline representations [302]. With them come the theorem of Ax, Sen and Tate [298, 10], the logarithms of formal group laws [124, 193], and Mazur's representability of framed deformations [196, 168].

Theorem A.3.1. *Let F be a number field, v a finite place of F, ℓ a prime, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with a continuous action of G_{F_v}. Then:*

1. *$H^i(F_v, M)$ is finite for every $i \geq 0$, and $H^i(F_v, M) = 0$ for $i \geq 3$;*
2. *$H^2(F_v, \mu_{\ell^r}) \cong \mathbb{Z}/\ell^r\mathbb{Z}$, and for $i = 0, 1, 2$ the cup product*

$$H^i(F_v, M) \times H^{2-i}(F_v, M^\vee) \longrightarrow H^2(F_v, \mu_{\ell^r})$$

is a perfect pairing of finite groups;

3. *if $v \nmid \ell$ and I_v acts trivially on M, then $H^1_{\mathrm{ur}}(F_v, M)$ and $H^1_{\mathrm{ur}}(F_v, M^\vee)$ are the exact annihilators of each other under the pairing in item 2 with $i = 1$;*
4. *(local Euler characteristic formula) $\#H^1(F_v, M) = \#H^0(F_v, M)\,\#H^2(F_v, M)\,(\#M)^{[F_v:\mathbb{Q}_\ell]}$ if $v \mid \ell$, and $\#H^1(F_v, M) = \#H^0(F_v, M)\,\#H^2(F_v, M)$ if $v \nmid \ell$.*

Proof. This is Tate's local duality theorem and Tate's local Euler characteristic formula, [295]; in the form stated: [201], Chapter I, Corollary 2.3 (item 1 and the perfect pairing of item 2, with $H^2(F_v, \mu_{\ell^r}) = \mathrm{Br}(F_v)[\ell^r] \cong \mathbb{Z}/\ell^r\mathbb{Z}$ by the invariant map), Theorem 2.6 (item 3) and Theorem 2.8 (item 4); see also [265], Chapter II, Section 5. Notation: Milne's K is F_v, his M^D is $M^\vee$, and his H^1_{nr} is H^1_{ur}. □

Theorem A.3.2. *Let G be a profinite group and ℓ a prime such that $H^i(G, M)$ is finite for every $i \geq 0$ and every finite discrete G-module M of ℓ-power order. Let $\mathcal{O}$ be the ring of integers of a finite extension of $\mathbb{Q}_\ell$ and T a finitely generated $\mathcal{O}$-module with a continuous $\mathcal{O}$-linear action of G (ℓ-adic topology on T). Then for every $i \geq 0$ the continuous cochain cohomology group $H^i(G, T)$ is a finitely generated $\mathcal{O}$-module.*

Proof. [299], Section 2: for a finitely generated $\mathbb{Z}_\ell$-module T with continuous action and finite $H^i(G, T/\ell T)$, the groups $H^i(G, T)$ are finitely generated $\mathbb{Z}_\ell$-modules; see also [225], Chapter II, Section 7. This gives the statement. Indeed, T is finitely generated over $\mathbb{Z}_\ell$ because $\mathcal{O}$ is; a finitely generated $\mathbb{Z}_\ell$-module on which $\mathcal{O}$ acts is a finitely generated $\mathcal{O}$-module; and Tate's hypothesis is the case $M = T/\ell T$ of ours. For $G = G_{F_v}$ with F_v a finite extension of $\mathbb{Q}_p$ (any p) the hypothesis holds by Theorem A.3.1(1). □

Theorem A.3.3. *Let F be a number field, ℓ any prime, S a finite set of places containing all archimedean places and all places above ℓ, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with continuous $G_{F,S}$-action. Put $H^i(M) = H^i(G_{F,S}, M)$ and*

$$\mathcal{H}^i(F_v, M) = \begin{cases} H^i(F_v, M), & v \text{ finite}, \\ \widehat{H}^i(\mathrm{Gal}(\mathbb{C}/F_v), M), & v \mid \infty, \end{cases} \qquad P^i(M) = \prod_{v \in S} \mathcal{H}^i(F_v, M).$$

Here the archimedean groups are Tate cohomology: at a complex place they are zero in every degree; at a real place with conjugation c_v,

$$\begin{aligned} \widehat{H}^0(F_v, M) &= M^{c_v}/(1 + c_v)M, \\ \widehat{H}^1(F_v, M) &= \ker(1 + c_v)/(c_v - 1)M, \\ \widehat{H}^2(F_v, M) &= \widehat{H}^0(F_v, M). \end{aligned}$$

For $i = 0, 1, 2$, let $\lambda^i_M : H^i(M) \to P^i(M)$ be restriction, followed in degree zero at infinity by the quotient to Tate cohomology, and put $\mathrm{Sha}^i_S(F, M) = \ker \lambda^i_M$ for $i = 1, 2$. Write the superscript $*$ for Pontryagin duality. Then:

1. *The global groups $H^i(M)$ and the finite-place local groups $H^i(F_v, M)$ are finite for every $i \geq 0$, and all groups $P^i(M)$ for $i = 0, 1, 2$ are finite.*

2. *The canonical Poitou–Tate pairing*

$$\mathrm{Sha}^1_S(F, M) \times \mathrm{Sha}^2_S(F, M^\vee) \longrightarrow \mathbb{Q}/\mathbb{Z}$$

   is perfect.

3. *There is an exact sequence*

$$\begin{aligned} 0 \longrightarrow H^0(M) \xrightarrow{\lambda^0_M} P^0(M) \xrightarrow{\beta^0} H^2(M^\vee)^* \longrightarrow H^1(M) \xrightarrow{\lambda^1_M} P^1(M) \\ \xrightarrow{\beta^1} H^1(M^\vee)^* \longrightarrow H^2(M) \xrightarrow{\lambda^2_M} P^2(M) \xrightarrow{\beta^2} H^0(M^\vee)^* \longrightarrow 0. \end{aligned}$$

   The maps are the canonical Poitou–Tate maps, and

$$\beta^i((x_v)_v)(y) = \sum_{v \in S} \mathrm{inv}_v\big(x_v \cup \mathrm{res}_v\, y\big), \qquad y \in H^{2-i}(M^\vee).$$

   At infinity the cup product is the Tate cup product and restriction is interpreted in Tate cohomology. The invariant at a real place is the usual inclusion of the Brauer group of $\mathbb{R}$ into $\frac{1}{2}\mathbb{Z}/\mathbb{Z}$; the complex summand is zero.

Proof. This is [201], Chapter I, Theorem 4.10, with the archimedean Tate-cohomology convention specified immediately before that theorem. Its part (a) gives the perfect pairing in item 2, and part (b), together with the local-duality identifications of the local products, gives the sequence and maps in item 3. Finiteness for finite S is Chapter I, Corollary 4.15 (printed p. 62); part (c) identifies the groups in degrees at least three with the finite product of the real-place cohomology groups. Finite-place local finiteness is Chapter I, Corollary 2.3. Milne's K, G_S, M^D are respectively $F, G_{F,S}, M^\vee$ here. The order of M is invertible outside S, because S contains the places above ℓ. No exclusion of real places or of the prime 2 is made. The local duality maps identify β^i with the dual of $\lambda^{2-i}_{M^\vee}$, with the displayed cup-product normalization.

If ℓ is odd, every real-place Tate group is killed by 2, by finite-group Tate cohomology, and by ℓ^r, because its cochain groups are ℓ^r-torsion. Bezout's identity therefore makes it zero in every degree. Complex-place Tate cohomology is zero because its Galois group is trivial. If F has no real place, all archimedean places are complex, so this vanishing holds for every prime. Under either condition, the local products in degrees $0, 1, 2$ reduce canonically to the products over the finite places $S_f = \{v \in S : v \nmid \infty\}$. Deleting the zero archimedean summands preserves the restriction maps, the cup-product duality maps and the connecting Poitou–Tate maps. In particular, the positive-degree localization kernels and their canonical pairing are computed by the finite-place products. Global finiteness and the Euler characteristic formula retain their stated meanings, with ordinary invariants in the archimedean numerator. The terminal exact sequence reduces by the same deletion of zero real Tate summands, and its final term is $H^0(G_{F,S}, M^\vee)^*$. These specializations impose no additional hypothesis on the all-prime statements.

□

Theorem A.3.4. *Let F be a number field, M a finite discrete continuous G_F-module, and $M^* = \mathrm{Hom}(M, \mu_n)$ for an integer n annihilating M. For every place v choose a subgroup $L_v \subseteq H^1(F_v, M)$, equal to $H^1(G_{F_v}/I_v, M^{I_v})$ at all but finitely many finite places. Let $L_v^\perp$ be its annihilator under local Tate duality, using Tate cohomology at infinity. Let $H^1_L(F, M)$ and $H^1_{L^\perp}(F, M^*)$ be the inverse images of these local conditions under global restriction. Both groups are finite and*

$$\frac{\#H^1_L(F, M)}{\#H^1_{L^\perp}(F, M^*)} = \frac{\#H^0(F, M)}{\#H^0(F, M^*)} \prod_v \frac{\#L_v}{\#H^0(F_v, M)}.$$

Here H^0 means ordinary invariants at every place; all but finitely many product factors are one.

Proof. This is the Greenberg–Wiles theorem in [63], Theorem 2.19. □

Theorem A.3.5. *Let F be a number field, ℓ any prime, S a finite set of places containing all places above ℓ and all archimedean places, $r \geq 1$, and M a finite $\mathbb{Z}/\ell^r\mathbb{Z}$-module with continuous $G_{F,S}$-action. Local actions are obtained through decomposition groups. Then:*

1. *$H^i(G_{F,S}, M)$ is finite for every $i \geq 0$.*
2. *Tate's global Euler characteristic formula is*

$$\frac{\#H^0(G_{F,S}, M)\,\#H^2(G_{F,S}, M)}{\#H^1(G_{F,S}, M)} = \prod_{v|\infty} \frac{\#H^0(F_v, M)}{|\#M|_v}.$$

The factors $H^0(F_v, M)$ in this formula are ordinary invariants, including at real and complex places; the archimedean absolute value is the usual absolute value at a real place and its square at a complex place.

3. *With the superscript $*$ denoting Pontryagin duality, the sequence*

$$H^2(G_{F,S},M)\longrightarrow\left(\bigoplus_{\substack{v\in S\\ v\nmid\infty}}H^2(F_v,M)\right)\oplus\left(\bigoplus_{\substack{v\in S\\ v\text{ real}}}\widehat{H}^2(F_v,M)\right)\longrightarrow H^0(G_{F,S},M^\vee)^*\longrightarrow 0$$

is exact. Here $\widehat{H}^2(F_v,M)=M^{c_v}/(1+c_v)M$ at a real place. The first map is restriction, the complex-place Tate summands are zero, and the second map sends $(x_v)_v$ to the functional

$$y\longmapsto\sum_{v\in S}\mathrm{inv}_v(x_v\cup\mathrm{res}_v\,y).$$

The real-place summands use Tate cup products and the real Brauer invariant; finite-place summands use ordinary local cohomology.

Proof. Items 1 and 3 follow from [201], Chapter I, Theorem 4.10 and Corollary 4.15 (printed p. 62). In particular, item 3 is its final three terms, also displayed in Chapter I, Remark 5.2(c), with the archimedean cohomology understood in the Tate sense. Item 2 is Chapter I, Theorem 5.1: the Euler characteristic there is precisely the truncated quotient of the orders in degrees zero, one and two displayed above, also when real places and the prime 2 occur. Its archimedean numerator uses ordinary invariants, not Tate degree-zero groups. The hypotheses match because S is finite, nonempty, contains infinity, and the order of M is invertible outside S. Milne's K, G_S, M^D are $F, G_{F,S}, M^\vee$.

If ℓ is odd, every real-place Tate group is killed by 2, by finite-group Tate cohomology, and by ℓ^r, because its cochain groups are ℓ^r-torsion. Bezout's identity therefore makes it zero in every degree. Complex-place Tate cohomology is zero because its Galois group is trivial. If F has no real place, all archimedean places are complex, so this vanishing holds for every prime. Under either condition, the local products in degrees $0,1,2$ reduce canonically to the products over the finite places $S_f=\{v\in S : v\nmid\infty\}$. Deleting the zero archimedean summands preserves the restriction maps, the cup-product duality maps and the connecting Poitou–Tate maps. In particular, the positive-degree localization kernels and their canonical pairing are computed by the finite-place products. Global finiteness and the Euler characteristic formula retain their stated meanings, with ordinary invariants in the archimedean numerator. The terminal exact sequence reduces by the same deletion of zero real Tate summands, and its final term is $H^0(G_{F,S},M^\vee)^*$. These specializations impose no additional hypothesis on the all-prime statements.

□

Theorem A.3.6. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M, and V a de Rham representation of G_M on a finite-dimensional $\mathbb{Q}_\ell$-vector space. Let $D_{\mathrm{dR}}(V)=(B_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)^{G_M}$ with the filtration $\mathrm{Fil}^iD_{\mathrm{dR}}(V)=(\mathrm{Fil}^iB_{\mathrm{dR}}\otimes_{\mathbb{Q}_\ell}V)^{G_M}$, and let $H^1_f(G_M,V)$ be the kernel of $H^1(G_M,V)\to H^1(G_M,B_{\mathrm{cris}}\otimes_{\mathbb{Q}_\ell}V)$. Then*

$$\dim_{\mathbb{Q}_\ell}H^1_f(G_M,V)=\dim_{\mathbb{Q}_\ell}(D_{\mathrm{dR}}(V)/\mathrm{Fil}^0D_{\mathrm{dR}}(V))+\dim_{\mathbb{Q}_\ell}H^0(G_M,V).$$

Proof. [28], Corollary 3.8.4 ("In particular,

$$\dim_{\mathbf{Q}_p}H^1_f(K,V)=\dim_{\mathbf{Q}_p}(DR(V)/DR(V)^0)+\dim_{\mathbf{Q}_p}H^0(K,V)",$$

for V a de Rham representation of $\mathrm{Gal}(\overline{K}/K)$, K finite over $\mathbf{Q}_p$). *Notation.* Their K, p, $DR(V)$, $DR(V)^0$ are M, ℓ, $D_{\mathrm{dR}}(V)$, $\mathrm{Fil}^0 D_{\mathrm{dR}}(V)$; their $H^1_f(K,V)$ is the kernel of $H^1(K,V) \to H^1(K, B_{\mathrm{crys}} \otimes V)$, which is the local condition of Definition 7.1.16 at a place above ℓ (a class lies in the kernel exactly when a representing cocycle c satisfies $c(g) \otimes 1 = gy - y$ for some $y \in V \otimes B_{\mathrm{cris}}$). □

Theorem A.3.7. *Let ℓ be a prime, M a finite extension of $\mathbb{Q}_\ell$ with absolute Galois group G_M, and V a de Rham representation of G_M on a finite-dimensional $\mathbb{Q}_\ell$-vector space; put $V^*(1) = \mathrm{Hom}_{\mathbb{Q}_\ell}(V, \mathbb{Q}_\ell) \otimes \chi_{\mathrm{cyc}}$. Let*

$$\langle\ ,\ \rangle \colon H^1(G_M, V) \times H^1(G_M, V^*(1)) \longrightarrow H^2(G_M, \mathbb{Q}_\ell(1))$$

be the cup product followed by the evaluation map $V \otimes_{\mathbb{Q}_\ell} V^*(1) \to \mathbb{Q}_\ell(1)$. Then $H^1_f(G_M, V)$ and $H^1_f(G_M, V^*(1))$ are exact annihilators of each other: a class $c \in H^1(G_M, V)$ lies in $H^1_f(G_M, V)$ if and only if $\langle c, y\rangle = 0$ for every $y \in H^1_f(G_M, V^*(1))$, and symmetrically.

Proof. [28], Proposition 3.8 (case $l = p$, under the hypothesis made there that V is de Rham). *Notation.* Their K, p, V, V^* are M, ℓ, V, $\mathrm{Hom}_{\mathbb{Q}_\ell}(V, \mathbb{Q}_\ell)$; their $H^1_f(K,V)$ is the kernel of $H^1(K,V) \to H^1(K, B_{\mathrm{crys}} \otimes V)$, ours; the pairing is the cup product into $H^2(K, \mathbb{Q}_p(1)) \cong \mathbb{Q}_p$. □

Theorem A.3.8. *Let ℓ be a prime and F_v a finite extension of $\mathbb{Q}_\ell$, with absolute Galois group G_{F_v} and inertia subgroup I_{F_v}. Then $H^1_f(G_{F_v}, \mathbb{Q}_\ell) \subseteq H^1(G_{F_v}, \mathbb{Q}_\ell) = \mathrm{Hom}_{\mathrm{cont}}(G_{F_v}, \mathbb{Q}_\ell)$ consists exactly of the homomorphisms that vanish on I_{F_v}.*

Proof. [28], Example 3.9 (case $r = 0$: "$H^1_f(K, \mathbb{Q}_p) \subset \mathrm{Hom}(\mathrm{Gal}(\overline{K}/K), \mathbb{Q}_p)$ are the unramified homomorphisms"). *Notation.* Their K, p are F_v, ℓ; their H^1_f is the kernel of $H^1(K,V) \to H^1(K, B_{\mathrm{crys}} \otimes V)$, which is the local condition of Definition 7.1.16 at a place above ℓ. □

Theorem A.3.9. *Let p be a prime and K a finite extension of $\mathbb{Q}_p$. If V and V' are crystalline finite-dimensional continuous $\mathbb{Q}_p$-linear representations of G_K, then every G_K-stable subspace of V, every quotient of V by a G_K-stable subspace, $V \oplus V'$, $V \otimes_{\mathbb{Q}_p} V'$ and the dual V^* are crystalline.*

Proof. [85]; [44], Theorem 5.2.1 (the category of B-admissible representations of an (F,G)-regular ring B is stable under subobjects, quotients, direct sums, tensor products and duals) with $B = B_{\mathrm{cris}}$, which is $(\mathbb{Q}_p, G_K)$-regular ([44], §9.1). *Notation.* Here a B_{cris}-admissible representation V of G_K is a crystalline one, i.e. $\dim_{K_0}(B_{\mathrm{cris}} \otimes_{\mathbb{Q}_p} V)^{G_K} = \dim_{\mathbb{Q}_p} V$, with K_0 the maximal unramified subfield of K. □

Theorem A.3.10. *Let p be a prime, $K/\mathbb{Q}_p$ finite, $P_0 = \mathrm{Frac}\, W(\overline{k}_K)$, and U a potentially semistable finite-dimensional $\mathbb{Q}_p$-representation of G_K. Its completed Deligne module*

$$A = \bigcup_{H \subseteq I_K \text{ open}} (B_{\mathrm{st}} \otimes_{\mathbb{Q}_p} U)^H$$

has dimension $\dim_{\mathbb{Q}_p} U$ over P_0, finite inertia action and nilpotent monodromy. The representation U is semistable exactly when I_K acts trivially on A, and crystalline exactly when that action is trivial and $N = 0$. The Weil–Deligne representation is obtained from this module by Fontaine's Weil functor; its inertia action and monodromy are those of A.

Proof. Fontaine [86], Theorem 2.3.2, Remark 2.3.3(a),(c), and construction 2.3.7, with $\ell = p$. Good reduction there means crystalline when $\ell = p$ (Section 2.1). □

Theorem A.3.11. *Let $K_\ell/\mathbb{Q}_\ell$ be finite and let V be a finite-dimensional continuous de Rham representation of G_{K_ℓ}. Then V is Hodge–Tate and the natural graded comparison identifies*

$$\operatorname{gr} D_{\mathrm{dR}}(V) = D_{\mathrm{HT}}(V), \qquad D^j_{\mathrm{HT}}(V) = (\mathbb{C}_\ell(j) \otimes_{\mathbb{Q}_\ell} V)^{G_{K_\ell}}.$$

Equivalently, there is a G_{K_ℓ}-equivariant decomposition

$$\mathbb{C}_\ell \otimes_{\mathbb{Q}_\ell} V \simeq \bigoplus_j \mathbb{C}_\ell(-j) \otimes_{K_\ell} \operatorname{gr}^j D_{\mathrm{dR}}(V).$$

In particular $\mathbb{Q}_\ell(1)$ has its de Rham filtration jump in degree -1, although its Hodge–Tate weight under the cyclotomic-positive convention is $+1$.

Proof. This is the de Rham to Hodge–Tate comparison theorem; see [44], Proposition 6.3.2 and Example 6.3.1 (p. 76). □

Theorem A.3.12. *Let ℓ be a prime, K a finite extension of $\mathbb{Q}_\ell$ with residue field k, $W = W(k)$, $K_0 = W[1/\ell]$, π a uniformiser of K and $E(u) \in W[u]$ its Eisenstein polynomial. Let $\mathfrak{S} = W[[u]]$, with the Frobenius φ that is the Frobenius of W on coefficients and sends u to u^ℓ. Fix $\pi^\flat \in \mathcal{O}^\flat_{\mathbb{C}_\ell}$ corresponding to a compatible system of ℓ-power roots of π, put $K_\infty = \bigcup_n K(\pi^{1/\ell^n})$, fix a compatible system $\epsilon \in \mathcal{O}^\flat_{\mathbb{C}_\ell}$ of primitive ℓ-power roots of unity and put $\mu = [\epsilon] - 1 \in A_{\mathrm{inf}}$; let $i_{\mathrm{B}} : \mathfrak{S} \to A_{\mathrm{inf}}$ be the ring map whose restriction to W is Witt Frobenius and with $u \mapsto [\pi^\flat]^\ell$; this map commutes with Frobenius. A* Breuil–Kisin module *is a finitely generated $\mathfrak{S}$-module $\mathfrak{M}$ with an isomorphism $\varphi_{\mathfrak{M}} \colon (\mathfrak{M} \otimes_{\mathfrak{S},\varphi} \mathfrak{S})[1/E] \to \mathfrak{M}[1/E]$. Then there is a fully faithful tensor functor $T \mapsto \mathfrak{M}(T)$ from $\mathbb{Z}_\ell$-lattices T in crystalline representations V of G_K to finite free Breuil–Kisin modules such that:*

1. *$\mathfrak{M}(T)$ is characterized by a φ- and G_{K_∞}-equivariant identification*

$$\mathfrak{M}(T) \otimes_{\mathfrak{S},i_{\mathrm{B}}} W(\mathbb{C}^\flat_\ell) \cong T \otimes_{\mathbb{Z}_\ell} W(\mathbb{C}^\flat_\ell).$$

2. *there is a φ- and G_{K_∞}-equivariant identification $\mathfrak{M}(T) \otimes_{\mathfrak{S},i_{\mathrm{B}}} A_{\mathrm{inf}}[1/\mu] \cong T \otimes_{\mathbb{Z}_\ell} A_{\mathrm{inf}}[1/\mu]$;*
3. *$\mathfrak{M}(T) \otimes_{\mathfrak{S},i_{\mathrm{B}}} B^+_{\mathrm{cris}} = D_{\mathrm{cris}}(V) \otimes_{K_0} B^+_{\mathrm{cris}}$ as submodules of $\mathfrak{M}(T) \otimes_{\mathfrak{S},i_{\mathrm{B}}} B_{\mathrm{cris}} = T \otimes_{\mathbb{Z}_\ell} B_{\mathrm{cris}} = D_{\mathrm{cris}}(V) \otimes_{K_0} B_{\mathrm{cris}}$.*

Proof. [25], Theorem 4.4, gives the fully faithful tensor functor and its characterization in item 1. The comparison of item 2 is Remark 4.5(i), established in the discussion before Proposition 4.34 using Lemma 4.26; item 3 is Remark 4.5(ii) and Proposition 4.34. The embedding is the one specified in Section 4.4 before Lemma 4.30: it acts by Witt Frobenius on $W(k)$ as well as sending u to $[\pi^\flat]^\ell$. The prime denoted p there is ℓ here. These assertions are Kisin's theorem in the stated Breuil–Kisin convention; the functor is not asserted to be exact. □

Theorem A.3.13. *Let $K/\mathbb{Q}_p$ be finite, $K_0 = W(k)[1/p]$, π a uniformiser, $P(u)$ its monic Eisenstein polynomial, and $\mathfrak{S} = W(k)[[u]]$, with $\varphi(u) = u^p$ and coefficient Witt Frobenius. Put*

$$\mathcal{O}^{\mathrm{an}} = \left\{ \sum_{n \geq 0} a_n u^n \in K_0[[u]] : v_p(a_n) + rn \longrightarrow +\infty \text{ for every } r > 0 \right\},$$
$$\mathscr{L} = \prod_{a \geq 0} \varphi^a(P(u)/P(0)).$$

Let T be a crystalline $\mathbb{Z}_p$-lattice with weights in $[0,h]$, using the convention that $\mathbb{Q}_p(1)$ has weight -1. Let $\mathfrak{M}$ be its Breuil–Kisin module for the direct embedding $u \mapsto [\pi^\flat]$, in the actual étale comparison with $W(\mathbb{C}_p^\flat)$, and put $\mathfrak{M}^\varphi = \operatorname{im}(\varphi^*\mathfrak{M} \to \mathfrak{M})$. There is a Frobenius-equivariant inclusion

$$D_{\mathrm{cris}}(T[1/p]) \otimes_{K_0} \mathcal{O}^{\mathrm{an}} \longrightarrow \mathfrak{M}^\varphi \otimes_{\mathfrak{S}} \mathcal{O}^{\mathrm{an}},$$

which is an isomorphism after inverting $\varphi(\mathscr{L})$. Under the natural embedding $\mathcal{O}^{\mathrm{an}} \to B_{\max}^+$, the induced comparison is the actual crystalline comparison inside $T \otimes B_{\max}$. The element $\varphi(\mathscr{L})$ maps to a unit of $B_{\max}^+$.

Proof. [17], Section 2.1.6, equation (2.1.9), and Proposition 2.1.10(1), citing [160], Lemma 1.2.6. The direct embedding and the étale identification are fixed in Sections 2.1.1–2.1.2 and Lemma 2.1.8; its footnote distinguishes this embedding from the coefficient-Frobenius embedding of Theorem A.3.12. Here $P, \mathcal{O}^{\mathrm{an}}, \mathscr{L}, T, \mathfrak{M}^\varphi$ are respectively $E(u), \mathcal{O}^{\mathrm{rig}}, \lambda, V, M^\varphi$ of that reference. The stated weight convention is its footnote 4. No assertion about the chart bicommutant or arbitrary signed weights is included. □

Theorem A.3.14. *Let C be a complete algebraically closed extension of $\mathbb{Q}_p$, put $A = A_{\mathrm{inf}}(\mathcal{O}_C)$, and let B_{dR}^+ be the completion at $\ker\theta$, with fraction field B_{dR}. A finite free Breuil–Kisin–Fargues module is a finite free A-module M equipped with an isomorphism*

$$\Phi_M : (A \otimes_{\varphi,A} M)[1/\widetilde{\xi}] \longrightarrow M[1/\widetilde{\xi}].$$

For such an object, put

$$T_M = (M \otimes_A W(C^\flat))^{\Phi_M \otimes \varphi = 1}.$$

There are natural identifications

$$M \otimes_A W(C^\flat) = T_M \otimes_{\mathbb{Z}_p} W(C^\flat), \qquad M[1/\mu] = T_M \otimes_{\mathbb{Z}_p} A[1/\mu].$$

In the resulting common de Rham space put

$$\Xi_M = M \otimes_A B_{\mathrm{dR}}^+ \subset T_M \otimes_{\mathbb{Z}_p} B_{\mathrm{dR}}.$$

The functor $M \mapsto (T_M, \Xi_M)$ is an equivalence with the category of pairs consisting of a finite free $\mathbb{Z}_p$-module T and a B_{dR}^+-lattice Ξ in $T \otimes B_{\mathrm{dR}}$. The morphisms of pairs are exactly the $\mathbb{Z}_p$-linear maps $f : T \to T'$ whose de Rham extension carries Ξ into Ξ'. In particular every such map extends uniquely to a morphism of the corresponding Breuil–Kisin–Fargues modules.

Proof. [25], Theorem 4.28, is Fargues' classification in this convention. The displayed étale identifications are Lemma 4.26; the precise full-faithfulness assertion is also explained in Remark 4.29. The de Rham completion here is at θ, and the Frobenius is inverted at $\widetilde{\xi}$, as in Definition 4.22. □

Theorem A.3.15. *Let ℓ be a prime, $K/\mathbb{Q}_\ell$ a finite extension in $\overline{\mathbb{Q}}_\ell$ and V a finite-dimensional $\mathbb{Q}_\ell$-vector space with a continuous linear action of G_K. If V is de Rham, that is,*

$$\dim_K (B_{\mathrm{dR}} \otimes_{\mathbb{Q}_\ell} V)^{G_K} = \dim_{\mathbb{Q}_\ell} V,$$

then V is potentially semistable: the union over all finite extensions K'/K in $\overline{\mathbb{Q}}_\ell$ of the invariants $(V \otimes_{\mathbb{Q}_\ell} B_{\mathrm{st}})^{G_{K'}}$ is a $\mathbb{Q}_\ell^{\mathrm{ur}}$-vector space of dimension $\dim_{\mathbb{Q}_\ell} V$.

Proof. This is Berger's theorem [22], in the notation of [85]. □

Theorem A.3.16. *Let p be a prime, $K/\mathbb{Q}_p$ finite, K_0 its maximal unramified subfield, and V a continuous $\mathbb{Q}_p$-representation of dimension d. Then*

$$B_{\mathrm{cris}}^{G_K} = K_0, \qquad B_{\mathrm{dR}}^{G_K} = K.$$

For either $(B, E) = (B_{\mathrm{cris}}, K_0)$ or (B_{dR}, K), put $D_B(V) = (B \otimes_{\mathbb{Q}_p} V)^{G_K}$. The natural B-linear G_K-equivariant map

$$B \otimes_E D_B(V) \longrightarrow B \otimes_{\mathbb{Q}_p} V$$

is injective, and

$$\dim_E D_B(V) \leq d.$$

Equality holds if and only if this map is an isomorphism. In the crystalline case equality is exactly crystallinity over K, and in the de Rham case it is exactly the de Rham property over K.

Proof. These are Brinon–Conrad [44], Theorem 4.4.13 (printed page 64), the invariant-field calculation preceding Theorem 9.1.5 and Proposition 9.1.6 (page 131), and Theorem 5.2.1(1) (page 68), applied to the regular period rings. The crystalline comparison is also displayed in Proposition 9.1.9 and equation (9.1.4) (pages 133–134). □

Theorem A.3.17. *Let p be a prime, $F \subset \overline{\mathbb{Q}}_p$ a finite extension of $\mathbb{Q}_p$, $F_\infty = F(\mu_{p^\infty})$, $\widehat{F}_\infty$ the closure of F_∞ in $\mathbb{C}_p$, $\mathfrak{m}_{F_\infty}$ the maximal ideal of the valuation ring of F_∞, and $H_F = \mathrm{Gal}(\overline{\mathbb{Q}}_p/F_\infty) \subseteq G_F$, acting on $\mathbb{C}_p$ by continuity.*

1. *(Ax–Sen–Tate) For every closed subgroup H of $G_{\mathbb{Q}_p}$, $\{c \in \mathbb{C}_p : hc = c \text{ for all } h \in H\}$ is the closure in $\mathbb{C}_p$ of the fixed field of H in $\overline{\mathbb{Q}}_p$. In particular the H_F-invariants of $\mathbb{C}_p$ form $\widehat{F}_\infty$, and the G_F-invariants form F.*
2. *(Tate) If $j \neq 0$ is an integer and $c \in \mathbb{C}_p$ satisfies $\chi_{\mathrm{cyc}}(g)^j\, gc = c$ for all $g \in G_F$, then $c = 0$.*
3. *(Tate) For every finite extension $L \subset \overline{\mathbb{Q}}_p$ of F_∞ with valuation ring $\mathcal{O}_L$, $\mathrm{Tr}_{L/F_\infty}(\mathcal{O}_L) \supseteq \mathfrak{m}_{F_\infty}$.*

Proof. Tate [298], Section 3: item 3 is the statement that the cyclotomic tower is deeply ramified (the different of a finite extension of the layers tends to the unit ideal), proved for a totally ramified $\mathbb{Z}_p$-extension; F_∞ is such an extension of $F(\mu_{p^n})$ for n large, and a finite extension of F_∞ is a finite extension of that $\mathbb{Z}_p$-extension. Item 2 is $H^0(G_F, \mathbb{C}_p(j)) = 0$ for $j \neq 0$, in the notation $\mathbb{C}_p(j) = \mathbb{C}_p \otimes \mathbb{Z}_p(j)$, where an invariant $c \otimes \epsilon^{\otimes j}$ is exactly a solution of $\chi_{\mathrm{cyc}}(g)^j gc = c$. Item 1 for closed subgroups of $G_{\mathbb{Q}_p}$ in general is due to Ax [10], Sen and Tate; see also [44], Section 2 and the chapter on Sen theory, for all three items. □

Theorem A.3.18. *Let R be a commutative $\mathbb{Q}$-algebra and let $F(X, Y)$ be a commutative formal group law of finite dimension $d \geq 1$ over R. There is a unique strict isomorphism from F to the d-dimensional additive formal group law. Explicitly, this is an invertible formal map $\ell(X) \in R[[X_1, \ldots, X_d]]^d$ with zero constant term, linear term X, and*

$$\ell(F(X, Y)) = \ell(X) + \ell(Y).$$

Proof. This is the Q-theorem of [124], Chapter II, Corollary (11.1.6), p. 64. The coefficient algebra A and dimension m there are R and d here; the additive law $\widehat{\mathbb{G}}_a^m$ is coordinatewise addition. A strict isomorphism is an isomorphism of formal group laws with identity linear term. $\square$

Theorem A.3.19. *Let ℓ be a prime and $\mathcal{O}$ a coefficient ring with residue field of characteristic ℓ. Let $\mathrm{CNL}_{\mathcal{O}}$ be the category of complete Noetherian local $\mathcal{O}$-algebras A for which $\mathcal{O} \to A$ is local and induces an isomorphism $\mathbb{F}_{\mathcal{O}} \cong A/\mathfrak{m}_A$, with the local $\mathcal{O}$-algebra homomorphisms as morphisms. A profinite group Γ satisfies* Mazur's condition Φ_ℓ *if $\mathrm{Hom}_{\mathrm{cont}}(\Gamma', \mathbb{F}_\ell)$ is finite for every open subgroup $\Gamma' \subseteq \Gamma$.*

1. *If Γ satisfies Φ_ℓ and $\bar{\rho}\colon \Gamma \to \mathrm{GL}_n(\mathbb{F}_{\mathcal{O}})$ is continuous, the functor on $\mathrm{CNL}_{\mathcal{O}}$ sending A to the set of continuous homomorphisms $\rho\colon \Gamma \to \mathrm{GL}_n(A)$ reducing to $\bar{\rho}$ is represented by an object $R^{\square}$ of $\mathrm{CNL}_{\mathcal{O}}$ and a universal lift $\rho^{\square}\colon \Gamma \to \mathrm{GL}_n(R^{\square})$.*
2. *For a number field F and a finite set S of places of F, $G_{F,S}$ satisfies Φ_ℓ.*

Proof. [196, §1.1–1.2]: item 2 is Mazur's observation that $\mathrm{Hom}(\Gamma', \mathbb{F}_\ell)$ for an open $\Gamma' \subseteq G_{F,S}$ classifies abelian extensions of exponent ℓ of a number field unramified outside S, finite in number by class field theory (Hermite–Minkowski); item 1 is the framed form of his existence theorem (Schlessinger's criteria hold for the functor of lifts without any irreducibility hypothesis, and Φ_ℓ makes its tangent space $Z^1(\Gamma, \mathrm{ad}\,\bar{\rho})$ finite-dimensional, so the pro-representing ring is Noetherian). Notation: $R^{\square}$, $\rho^{\square}$ as there; $\mathrm{CNL}_{\mathcal{O}}$ is Mazur's category of complete Noetherian local $\mathcal{O}$-algebras with residue field $\mathbb{F}_{\mathcal{O}}$. $\square$

A.4 Automorphic forms and Galois representations

The quotations fall into four groups. The first gives the foundations of automorphic forms on unitary groups: moderate growth and the finiteness of class numbers, reduction theory, the compactness criteria and the finiteness of the volume, and strong approximation [33, 38, 208, 37, 216, 167, 233]. The second gives the published inputs of the Galois representations of Section 7.1: the local Langlands correspondence [122, 130, 254, 318], the Galois representations of polarised regular algebraic cuspidal representations and their local–global compatibility [15, 16, 276, 56, 47, 48], the discrete spectrum of GL_n and the Whittaker expansion [207, 149, 269, 230], Tadić's classification of the unitary dual [292], and base change [177, 185]. The third consists of local results on representations of GL_n over a p-adic field: depth-zero cuspidal types [74], Shotton's results on types of compact type [278, 106], Zelevinsky's classification [332, 24], spherical Hecke algebras [248, 50, 109], and the factorisation of representations of a product [23, 80]. The fourth is the analytic theory of theta and Eisenstein series: Siegel's formula and the Siegel–Weil formula in Weil's convergent range [280, 323, 139, 121] (for the regularised formula see [176]), and the continuation of Siegel Eisenstein series [184]. From these the body proves the form of the Rallis inner product formula that it uses (Theorem 6.5.13), by the doubling method [237, 238, 231] in the form of Li [187], and the discreteness of the cuspidal spectrum (Theorem 7.6.14; see [100, 7, 72]).

Theorem A.4.1. *All symbols are local to this statement and to the results that cite it. Let G be a connected reductive group over a number field F and $G(F_\infty) = G(F \otimes_{\mathbb{Q}} \mathbb{R})$. For a faithful representation $\rho\colon G \to \mathrm{GL}_m$ defined over F put*

$$\|g\|_\rho = \prod_v \max_{a,b}(1, |\rho(g)_{ab}|_v, |\rho(g^{-1})_{ab}|_v) \qquad (g \in G(\mathbb{A}_F)),$$

the product over all places v of F with the normalised absolute values (finitely many factors are $\neq 1$), and let $\|g\|_{\rho,\infty}$ be the product over the archimedean places, for $g \in G(F_\infty)$.

(N) *For faithful representations ρ, ρ' of G over F there are $c, a > 0$ with $\|g\|_{\rho'} \leq c\,\|g\|_\rho^a$ on $G(\mathbb{A}_F)$. For norms $\|g\|_1, \|g\|_2$ on $G(F_\infty)$ of the form $\max(1, \|\pi(g)\|, \|\pi(g^{-1})\|)$, π a faithful algebraic representation of the real algebraic group $G(F_\infty)$ and $\|\cdot\|$ a norm on matrices (in particular $\|\cdot\|_{\rho,\infty}$, and $\sum_{a,b}(|\pi(g)_{ab}| + |\pi(g^{-1})_{ab}|)$), there are $c, a > 0$ with $\|g\|_2 \leq c\,\|g\|_1^a$.*

(K) *For every open compact subgroup K_f of $G(\mathbb{A}_{F,f})$ there are finitely many $x_1, \ldots, x_h \in G(\mathbb{A}_{F,f})$ with $G(\mathbb{A}_F) = \bigcup_{i=1}^h G(F)\, x_i\, G(F_\infty) K_f$.*

(M) *Let K_f and $x_1, \ldots, x_h$ be as in (K), and $\varphi\colon G(\mathbb{A}_F) \to \mathbb{C}$ continuous, left $G(F)$-invariant and right K_f-invariant. If for every i there are $C_i, N_i \geq 0$ with $|\varphi(x_i g)| \leq C_i \|g\|_{\rho,\infty}^{N_i}$ for all $g \in G(F_\infty)$, then there are $C, N \geq 0$ with $|\varphi(g)| \leq C\,\|g\|_\rho^N$ for all $g \in G(\mathbb{A}_F)$.*

Proof. (N) is the equivalence of norms on adelic and real reductive groups, [38] and [208], I.2.2. (K) is the finiteness of class numbers, [33]. (M) is the passage from the classical moderate growth of the functions $g \mapsto \varphi(x_i g)$ on $G(F_\infty)$ to the adelic moderate growth of φ, by reduction theory (Siegel sets), in the dictionary between classical and adelic automorphic forms of [38] and [208], I.2.

□

Theorem A.4.2. *All symbols are local to this statement and to the results that cite it. Let E/F be a CM extension of a totally real number field, V a nondegenerate hermitian space over E, and $G = \mathrm{U}(V)$, a connected reductive group over F. Let $P_0 = M_0 N_0$ be a minimal parabolic subgroup of G defined over F with a Levi decomposition over F, A_0 the maximal F-split torus in the centre of M_0, Δ the set of simple roots of A_0 in N_0, and $K = \prod_v K_v$ a maximal compact subgroup of $G(\mathbb{A}_F)$ with $G(\mathbb{A}_F) = P_0(\mathbb{A}_F)K$. Let A^+ be the identity component of the group of real points of the maximal $\mathbb{Q}$-split subtorus of $\mathrm{Res}_{F/\mathbb{Q}} A_0$, embedded in $A_0(\mathbb{A}_F)$ at the archimedean places. For a compact set $\omega \subseteq P_0(\mathbb{A}_F)$ and $t > 0$ the* Siegel set *is*

$$\mathfrak{S}(\omega, t) = \{p\,a\,k :\ p \in \omega,\ a \in A^+,\ |\alpha(a)| \geq t \text{ for all } \alpha \in \Delta,\ k \in K\}.$$

Then there are a compact ω and $t > 0$ with $G(\mathbb{A}_F) = G(F)\,\mathfrak{S}(\omega, t)$.

Proof. Quoted: Borel [34] (reduction theory for arithmetic groups, Siegel sets) and Godement [103], in the adelic form recalled by Mœglin and Waldspurger [208], Chapter I.2. Notation: G here is $\mathrm{U}(V)$ of the hermitian spaces of the project, $G(\mathbb{A}_F) = G_V$, $G(F) = \Gamma_V$. □

Theorem A.4.3. *Let U be a unipotent linear algebraic group over a number field F. Then $U(F)$ is a discrete subgroup of $U(\mathbb{A}_F)$, the quotient $U(F)\backslash U(\mathbb{A}_F)$ is compact, and $U(\mathbb{A}_F)$ is unimodular.*

Proof. **Quotation.** Discreteness and compactness: [37] (the unipotent case of the compactness criterion; proof by induction along a central series of U over F with quotients $\mathbb{G}_a$, using that F is discrete and cocompact in $\mathbb{A}_F$). Unimodularity (proof): at every place v the modular function of $U(F_v)$ is $g \mapsto |\det \mathrm{Ad}(g)|_v$ on the Lie algebra (true for real, complex and p-adic Lie groups), and $\mathrm{Ad}(g)$ is unipotent for unipotent g, so $U(F_v)$ is unimodular; $U(\mathbb{A}_F)$ is the restricted product of the $U(F_v)$ with respect to compact open subgroups, and its Haar measure is the restricted product of local Haar measures, so its modular function is the product of the local ones, hence trivial. □

Theorem A.4.4. *Let F be a number field and G a connected reductive group over F that has no nontrivial character defined over F. Then $G(F)$ is a discrete subgroup of $G(\mathbb{A}_F)$, and $G(F)\backslash G(\mathbb{A}_F)$ is compact if and only if G contains no nontrivial F-split torus.*

Proof. [37] and [216]; in this form over a number field see [233], Chapter 5. Notation: a group without nontrivial F-split torus is called F-anisotropic there; for a torus this is the absence of nontrivial F-rational characters. □

Theorem A.4.5. *Let V be a hermitian space over E whose form is definite at some complex embedding τ of E (that is, $\tau(h(x,x)) \neq 0$ for every $0 \neq x \in V$). Then Γ_V is a discrete subgroup of G_V and $\Gamma_V\backslash G_V$ is compact. Consequently, for every Haar measure μ of G_V, every measurable fundamental domain $\mathcal{F}$ of Γ_V in G_V has $\mu(\mathcal{F}) < \infty$, and every continuous left Γ_V-invariant function on G_V is bounded.*

Proof. **Quotation.** For a connected reductive group G over a number field F without nontrivial F-rational characters, $G(F)$ is a discrete subgroup of $G(\mathbb{A}_F)$, and $G(F)\backslash G(\mathbb{A}_F)$ is compact if and only if G is F-anisotropic, i.e. contains no nontrivial F-split torus [37] (and Mostow–Tamagawa [216]); over F this is the statement over $\mathbb{Q}$ applied to the restriction of scalars of G to $\mathbb{Q}$.

Bridge: $G = \mathrm{U}(V)$ satisfies the hypotheses. It is connected reductive (a form of GL_n, $n = \dim_E V$). Over $\bar{F}$, $\mathrm{U}(V) \cong \mathrm{GL}_n$ and its characters are the powers $\det^k$; the Galois descent datum of $\mathrm{U}(V)$ is $g \mapsto (g^*)^{-1}$ followed by the nontrivial automorphism of E/F, which sends $\det^k$ to $\det^{-k}$, so the only F-rational character is trivial.

G contains no nontrivial F-split torus. Let $\lambda\colon \mathbb{G}_m \to \mathrm{U}(V)$ be a cocharacter defined over F. The F-vector space V is a representation of the split torus $\mathbb{G}_m$, so $V = \bigoplus_{a\in\mathbb{Z}} V_a$ with $\lambda(t)x = t^a x$ for $x \in V_a$, $t \in F^\times$; each V_a is an E-subspace, since $\lambda(t)$ is E-linear. For $x \in V_a$, $y \in V_b$ and $t \in F^\times$, $h(x,y) = h(\lambda(t)x, \lambda(t)y) = t^a c(t)^b h(x,y) = t^{a+b}h(x,y)$, and $F^\times$ is infinite, so $h(x,y) = 0$ unless $a + b = 0$. If λ were nontrivial, some V_a with $a \neq 0$ would contain $x \neq 0$, and then $h(x,x) = 0$ because $2a \neq 0$; but $\tau(h(x,x)) \neq 0$ by definiteness. Hence every F-cocharacter is trivial, and so is every F-split torus (it is generated by the images of its cocharacters).

So Γ_V is discrete and $\Gamma_V\backslash G_V$ compact. **Consequences.** G_V is a locally compact second countable group and Γ_V a discrete subgroup; a Haar measure μ induces a G_V-invariant Radon measure $\bar{\mu}$ on $\Gamma_V\backslash G_V$ with $\mu(\mathcal{F}) = \bar{\mu}(\Gamma_V\backslash G_V)$ for every measurable fundamental domain $\mathcal{F}$, and $\bar{\mu}$ of a compact space is finite. A continuous left Γ_V-invariant function factors through a continuous function on the compact quotient, hence is bounded. □

Theorem A.4.6. *Let F be a number field and H a connected reductive linear algebraic group over F. Suppose every algebraic group homomorphism $H \to \mathbb{G}_m$ defined over F is trivial. Then $H(F)$ is discrete in $H(\mathbb{A}_F)$, and for a Haar measure on $H(\mathbb{A}_F)$ the quotient measure induced by counting measure on $H(F)$ has finite volume.*

Proof. The adelic finite-volume theorem of Borel–Harish-Chandra, in its number-field formulation: [37]; see [233], Chapter 5. The hypothesis is the absence of nontrivial F-rational algebraic characters. The group denoted here by H is the reductive group of that criterion, and the quotient is its full adelic quotient, with counting measure on the rational subgroup. □

Theorem A.4.7. *Let F be a number field with ring of adeles $\mathbb{A}_F$, let U be a unipotent linear algebraic group over F, and let S be a nonempty finite set of places of F. Put $F_S = \prod_{v\in S} F_v$ and let $\mathbb{A}_F^S$ be the restricted product of the completions F_v, $v \notin S$, with respect to their rings of integers, so that $\mathbb{A}_F = F_S \times \mathbb{A}_F^S$ and $U(\mathbb{A}_F) = U(F_S) \times U(\mathbb{A}_F^S)$. Then the diagonal image of $U(F)$ is dense in $U(\mathbb{A}_F^S)$; equivalently, $U(F)\,U(F_S)$ is dense in $U(\mathbb{A}_F)$.*

In particular, if S is the set of archimedean places, $F_\infty = F_S$ and $\mathbb{A}_{F,f} = \mathbb{A}_F^S$, then for every open subgroup $K \le U(\mathbb{A}_{F,f})$

$$U(\mathbb{A}_{F,f}) = U(F)\,K \qquad \text{and} \qquad U(\mathbb{A}_F) = U(F)\,U(F_\infty)\,K.$$

Proof. Strong approximation for unipotent groups: V. Platonov and A. Rapinchuk, Algebraic groups and number theory [233], Chapter 7 (strong approximation), the unipotent case. Over a field of characteristic zero a unipotent group is split, i.e. it has a central series of F-subgroups with successive quotients isomorphic to the additive group, and the statement is the strong approximation theorem for the additive group (F is dense in $\mathbb{A}_F^S$ for $S \neq \emptyset$) carried along that series.

□

Theorem A.4.8. *Let K be a number field, $\mathbb{A}_K$ its ring of adeles, and H a connected, simply connected, absolutely almost simple linear algebraic group over K. Let S be a finite set of places of K, and let $\mathbb{A}_K^S$ be the ring of adeles of K with the components at the places of S omitted, so that $H(K)$ embeds diagonally in $H(\mathbb{A}_K^S)$. If the group $H_S = \prod_{v\in S} H(K_v)$ is not compact, then $H(K)$ is dense in $H(\mathbb{A}_K^S)$.*

Proof. Kneser [167]; Platonov [232]; stated in this form (for global fields, with the converse) as [239, Theorem 2.3]; see also [233], §7.4. Notation: Rapinchuk's G, $\mathbb{A}_S$, G_S are our H, $\mathbb{A}_K^S$, H_S; only the sufficiency half is quoted. □

Theorem A.4.9. *Let K be a finite extension of $\mathbb{Q}_p$, W_K its Weil group, $|\cdot|$ the normalised absolute value of K, and $\mathrm{Art}_K\colon K^\times \to W_K^{\mathrm{ab}}$ the local Artin map, normalised so that uniformisers go to geometric Frobenius elements. There is a family of bijections rec_K, one for each $n \ge 1$, from the set of isomorphism classes of irreducible smooth representations of $\mathrm{GL}_n(K)$ over $\mathbb{C}$ to the set of isomorphism classes of n-dimensional Frobenius-semisimple Weil–Deligne representations of W_K over $\mathbb{C}$, such that:*

(Ln1) $\mathrm{rec}_K(\chi) = \chi \circ \mathrm{Art}_K^{-1}$ *for every smooth character χ of $K^\times = \mathrm{GL}_1(K)$;*

(Ln2) $\mathrm{rec}_K(\pi \otimes (\chi \circ \det)) = \mathrm{rec}_K(\pi) \otimes \mathrm{rec}_K(\chi)$ *for every π and every smooth character χ of $K^\times$;*

(Ln3) $\det \mathrm{rec}_K(\pi) = \mathrm{rec}_K(\omega_\pi)$, *where ω_π is the central character of π, and $\mathrm{rec}_K(\pi^\vee) = \mathrm{rec}_K(\pi)^\vee$;*

(Ln4) $L(s, \pi_1 \times \pi_2) = L(s, \mathrm{rec}_K(\pi_1) \otimes \mathrm{rec}_K(\pi_2))$ *and $\varepsilon(s, \pi_1 \times \pi_2, \psi) = \varepsilon(s, \mathrm{rec}_K(\pi_1) \otimes \mathrm{rec}_K(\pi_2), \psi)$ for all π_1, π_2 and every non-trivial additive character ψ of K;*

(Ln5) *π is supercuspidal if and only if $\mathrm{rec}_K(\pi)$ is irreducible (in particular has monodromy 0);*

(Ln6) *(compatibility with the Langlands classification) if π is the Langlands quotient of a multisegment $(\Delta_1, \dots, \Delta_r)$, i.e. the unique irreducible quotient of the normalised parabolic induction of $Q(\Delta_1) \otimes \cdots \otimes Q(\Delta_r)$ with the segments ordered so that Δ_i does not precede Δ_j for $i < j$, where $Q(\Delta)$ is the essentially square-integrable representation attached to the segment Δ, then $\mathrm{rec}_K(\pi) \cong \bigoplus_{i=1}^r \mathrm{rec}_K(Q(\Delta_i))$.*

The family is uniquely determined by (Ln1), (Ln2), (Ln3), (Ln4) on supercuspidal representations together with (Ln6).

Proof. Existence: [122], Theorem A (properties (Ln1)–(Ln5) for supercuspidal representations, and the extension to all irreducible smooth representations through the Bernstein–Zelevinsky and Zelevinsky classification, Introduction and Section VII); independently [130]; uniqueness by Henniart's characterisation through L- and ε-factors of pairs. The extension to all representations by (Ln6) and the resulting properties (Ln1)–(Ln4) for all π are explained in Harris–Taylor, loc. cit., and in Wedhorn [318], Sections 3 and 4. Normalisation: Harris and Taylor normalise Art_K so that uniformisers correspond to geometric Frobenius elements, as here; their rec is the map of this statement. □

Theorem A.4.10. *Let $K/\mathbb{Q}_p$ be finite, and let rec_K be the local Langlands correspondence normalized by geometric Frobenius, as in Theorem A.4.9. For every irreducible smooth complex representation π of $\mathrm{GL}_n(K)$ there is a unique unordered tuple of supercuspidal representations σ_j of $\mathrm{GL}_{n_j}(K)$, with $\sum_j n_j = n$, such that π is an irreducible subquotient of their normalized parabolic induction. If $\mathrm{rec}_K(\pi) = (r, N)$, then*

$$(r^{\mathrm{ss}}, 0) \simeq \bigoplus_j \mathrm{rec}_K(\sigma_j).$$

Thus, for any tuple of supercuspidals whose normalized induction has π as a subquotient, the displayed formula holds with that tuple.

Proof. The existence and uniqueness of the supercuspidal support are [24, Theorem 2.9]; see also [319, 2.2.3–2.2.4]. The displayed compatibility is precisely [319, Proposition 4.3.3], the supercuspidal-support form of the extension of the Harris–Taylor correspondence by the Bernstein–Zelevinsky classification. Its reciprocity normalization is the geometric-Frobenius normalization. No assertion that the monodromy is determined by the support is made. □

Theorem A.4.11. *Let F be a CM field, F^+ its maximal totally real subfield, c complex conjugation, $n \geq 1$, ℓ a rational prime and $\iota : \overline{\mathbb{Q}}_\ell \simeq \mathbb{C}$. Let π be a regular algebraic cuspidal automorphic representation of $\mathrm{GL}_n(\mathbb{A}_F)$, and let $\chi : \mathbb{A}_{F^+}^\times/(F^+)^\times \to \mathbb{C}^\times$ be continuous, with $\chi_v(-1) = (-1)^n$ at every infinite place, such that*

$$\pi^c \simeq \pi^\vee \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det).$$

Write $a_{\tau,1} \geq \cdots \geq a_{\tau,n}$ for the highest weights such that π_∞ has the infinitesimal character of the dual of the algebraic representation of highest weight a. There is a continuous semisimple representation

$$r_{\ell,\iota}(\pi) : G_F \longrightarrow \mathrm{GL}_n(\overline{\mathbb{Q}}_\ell)$$

with the following properties.

1. *For every finite $v \nmid \ell$,*

$$\iota\,\mathrm{WD}(r_{\ell,\iota}(\pi)|_{G_{F_v}})^{F\text{-}ss} \simeq \mathrm{rec}_{F_v}(\pi_v \otimes |\det|_v^{(1-n)/2}).$$

2. *It is de Rham at every $v \mid \ell$. In the Hodge–Tate convention in which the cyclotomic character has weight -1, its weights at $\tau : F \hookrightarrow \overline{\mathbb{Q}}_\ell$ are*

$$\{a_{\iota\tau,1} + n - 1, a_{\iota\tau,2} + n - 2, \ldots, a_{\iota\tau,n}\}.$$

3. *If $v \mid \ell$ and π_v has an Iwahori fixed vector, the isomorphism in (1) holds also at v; the local representation is semistable, and is crystalline when π_v is unramified.*

Proof. These are conclusions (2), (3) and (4) of [15, Theorem 2.1.1]. The definitions of a polarized pair and its weight are those in Section 2.1 of that work. The Hodge–Tate convention is its convention $\mathrm{HT}(\epsilon_\ell) = \{-1\}$; the reciprocity map sends uniformizers to geometric Frobenius. No assertion concerning an arbitrary ramified place above ℓ is included. □

Theorem A.4.12. *Let F be a number field and fix a unitary character ξ of $F^\times\backslash\mathbb{A}_F^\times$. Let $L^2_{\mathrm{disc}}(\mathrm{GL}_N, \xi)$ be the discrete part of the space of automorphic functions that transform under the adelic centre by ξ and are square-integrable modulo the centre. If τ is a unitary cuspidal automorphic representation of $\mathrm{GL}_m(\mathbb{A}_F)$ and $k \geq 1$, the normalised induction*

$$\tau|\det|^{(k-1)/2} \times \tau|\det|^{(k-3)/2} \times \cdots \times \tau|\det|^{(1-k)/2}$$

to $\mathrm{GL}_{km}(\mathbb{A}_F)$ has a unique irreducible quotient $J(\tau, k)$. Its central character is ω_τ^k, and it occurs with multiplicity one in $L^2_{\mathrm{disc}}(\mathrm{GL}_{km}, \omega_\tau^k)$. Every irreducible constituent of $L^2_{\mathrm{disc}}(\mathrm{GL}_N, \xi)$ is exactly one such $J(\tau, k)$, with $km = N$ and $\omega_\tau^k = \xi$; the pair (τ, k) is unique up to isomorphism of τ.

Proof. This is the main theorem of [207], Introduction, pp. 605–606, for number fields. Their equal-block cuspidal datum $V_1^{\otimes k}$ is the datum denoted here by $\tau^{\otimes k}$, and their quotient $J(V)$ is $J(\tau, k)$. Their induction is normalised, with descending exponents $((k-1)/2, \ldots, (1-k)/2)$. The theorem gives the decomposition for a fixed unitary central character; varying that character gives the stated classification. □

Theorem A.4.13. *Let F be a number field, let $m \geq 2$, and let $\psi : F\backslash\mathbb{A}_F \to \mathbb{C}^\times$ be a nontrivial unitary additive character. Write U_m for the upper triangular unipotent subgroup of GL_m and put*

$$\psi_{U_m}(u) = \psi(u_{1,2} + \cdots + u_{m-1,m}).$$

For a smooth cuspidal automorphic form φ define

$$W_\varphi(g) = \int_{U_m(F)\backslash U_m(\mathbb{A}_F)} \varphi(ug)\psi_{U_m}(u)^{-1}\, du.$$

With the quotient Haar measure of mass one, its cuspidal Fourier expansion is

$$\varphi(g) = \sum_{\gamma \in U_{m-1}(F)\backslash \mathrm{GL}_{m-1}(F)} W_\varphi\left(\begin{pmatrix} \gamma & 0 \\ 0 & 1 \end{pmatrix} g\right).$$

The expansion converges absolutely, locally uniformly in g. In particular the Whittaker transform is injective on the cuspidal space, and every irreducible cuspidal automorphic representation of $\mathrm{GL}_m(\mathbb{A}_F)$ has a nonzero global Whittaker functional. For $m = 1$ the latter assertion holds with trivial unipotent group and $W_\varphi = \varphi$.

Proof. The cuspidal Fourier expansion of Shalika and Piatetski-Shapiro, [269, 230]. The character on the maximal unipotent subgroup is the nondegenerate character obtained by summing its simple-root coordinates. The displayed formula uses the standard block embedding of GL_{m-1} and normalised quotient measure. The nonvanishing assertion is the immediate consequence that a form whose Whittaker transform vanishes has zero Fourier expansion. □

Theorem A.4.14. *Let K be a non-archimedean local field of characteristic zero and write $\nu(g) = |\det g|_K$. Products below are normalised parabolic inductions. If c is a finite multiset of essentially square-integrable representations of general linear groups over K, write $L(c)$ for the Langlands quotient obtained by arranging the real exponents of its members in nonincreasing order.*

1. *For an irreducible unitary square-integrable representation δ and $h \geq 1$, put*

$$u(\delta, h) = L\big(\{\delta\nu^{(h-1)/2-a} : 0 \leq a < h\}\big).$$

The building blocks

$$u(\delta, h), \qquad \nu^{\alpha}u(\delta, h) \times \nu^{-\alpha}u(\delta, h) \quad (0 < \alpha < 1/2)$$

are unitary. Every finite product of building blocks is irreducible and unitary. Every irreducible unitary representation is such a product, uniquely up to permutation of the building blocks.

2. *If an irreducible unitary representation π admits a nondegenerate Whittaker model, it has an irreducible induced presentation*

$$\pi \cong \delta_1\nu^{e_1} \times \cdots \times \delta_b\nu^{e_b}, \qquad -\tfrac{1}{2} < e_j < \tfrac{1}{2},$$

where all δ_j are irreducible unitary square-integrable representations; the factors may be arranged with $e_1 \geq \cdots \geq e_b$.

3. *If $L(c)$ and $L(d)$ are unitary, then*

$$L(c) \times L(d) \cong L(c + d).$$

In particular the induction on the left is irreducible, and the Langlands multiset of this induction is the multiset union, with multiplicities.

Proof. The unitary classification in the first assertion is [292], Theorem A and Appendix Theorem A.10, in the notation $u(\delta, h)$ introduced immediately before Appendix Theorem A.8. The third assertion is Appendix Corollary A.7(i), p. 375; its multisets $c, d \in M(D)$ are multisets of essentially square-integrable representations, and addition is multiset union. The generic specialization in the second assertion is stated explicitly in [207], I.10–I.11, pp. 639–640: in the unitary decomposition the Speh half-lengths are zero when there is a Whittaker model. Their parameters v_j are the e_j here and satisfy the strict inequalities $-1/2 < v_j < 1/2$. All three assertions concern smooth irreducible complex representations and normalised induction. □

Theorem A.4.15. *Let F be an imaginary CM field, $n \geq 1$, ℓ a prime, and $\iota : \overline{\mathbb{Q}}_\ell \longrightarrow \mathbb{C}$ an isomorphism. Let (π, χ) be regular algebraic, essentially conjugate self-dual and cuspidal: π is cuspidal on $\mathrm{GL}_n(\mathbb{A}_F)$ and regular algebraic, $\chi : \mathbb{A}_{F^+}^{\times}/(F^+)^{\times} \longrightarrow \mathbb{C}^{\times}$ is continuous with $\chi_v(-1)$ independent of $v \mid \infty$, and*

$$\pi^c \simeq \pi^{\vee} \otimes (\chi \circ \mathrm{N}_{F/F^+} \circ \det).$$

Let $r_{\ell,\iota}(\pi)$ denote the associated continuous semisimple Galois representation, uniquely characterized by its unramified local Langlands compatibility outside a finite set, with geometric-Frobenius normalization and twist $|\det|^{(1-n)/2}$. For a place $v \mid \ell$, put

$$D = \iota\,\mathrm{WD}\big(r_{\ell,\iota}(\pi)|_{G_{F_v}}\big)^{F\text{-}ss}, \qquad D' = \mathrm{rec}_{F_v}\big(\pi_v \otimes |\det|_v^{(1-n)/2}\big).$$

Then $D \prec D'$ in the following precise sense. Their semisimplified Weil representations are isomorphic. Partition the irreducible Weil representations into equivalence classes modulo unramified character twists. On each such class, decompose the corresponding Weil–Deligne summand as a direct sum of special representations $\mathrm{Sp}_{m_j}(s_j)$, order their positive block lengths $m_1 \geq m_2 \geq \cdots$, and pad the list with zeros. For every class and every $k \geq 1$,

$$\sum_{j=1}^{k} m_j(D) \leq \sum_{j=1}^{k} m_j(D').$$

Moreover $D \simeq D'$ if π has Shin-regular weight: either n is odd, or, writing π_∞ with the infinitesimal character of the dual of an algebraic representation of highest weights $a_{\tau,1} \geq \cdots \geq a_{\tau,n}$, there are an embedding τ and an odd $j < n$ with $a_{\tau,j} > a_{\tau,j+1}$.

Proof. This is [16, Theorem 1.1]. The regular algebraic essentially conjugate self-dual cuspidal pair is defined on printed page 168; its common real sign is not prescribed. The associated representation and its uniqueness by unramified compatibility are recalled on printed pages 165 and 169. The Shin-regular condition and the relation $\prec$ are defined on printed pages 169–170. The theorem is on printed page 170 and applies to every $v \mid \ell$, without an Iwahori hypothesis. Its normalization is geometric Frobenius, as fixed on printed page 167. □

Theorem A.4.16. *Let F be a totally real field with $[F : \mathbb{Q}] \geq 2$, let E/F be a totally imaginary quadratic extension, and let U be an inner form of the quasi-split unitary group in $n \geq 1$ variables for E/F. Let σ occur in the discrete automorphic spectrum of U, with σ_∞ discrete series. Assume property $(*)$: for a pseudo-coefficient f_∞ of σ_∞, the integer traces $\operatorname{tr} \sigma'_\infty(f_\infty)$, for discrete automorphic σ' with $\sigma'_f \cong \sigma_f$, have the same sign as $\operatorname{tr} \sigma_\infty(f_\infty)$.*

Then there are positive integers $n_1, \ldots, n_s$ with $\sum_i n_i = n$ and discrete automorphic representations π_i of $\mathrm{GL}_{n_i}(\mathbb{A}_E)$ with $\pi_i^c \cong \pi_i^\vee$ such that $\pi = \boxplus_i \pi_i$ is a weak base change of σ. Here $\pi_v = \bigotimes_{w \mid v} \pi_w$ is viewed on $(\operatorname{Res}_{E/F} \mathrm{GL}_n)(F_v)$. At every split finite place v the correspondence $\sigma_v \mapsto \pi_v$ is local base change. At every finite v where E/F and U are unramified and σ_v is spherical, π_v is its unramified local base change. At infinity π_∞ is cohomological, with the coefficient system of the archimedean base-change construction, and its infinitesimal character is the base change of that of σ_∞. If, in addition, every π_i is cuspidal, then π_∞ itself is the archimedean base change of σ_∞.

Property $(*)$ is automatic when $U(F \otimes_{\mathbb{Q}} \mathbb{R})$ is compact.

Proof. This is [177], Corollaire 5.3, with the standing hypotheses at the beginning of Section 5 and the compactness remark immediately preceding the corollary. The notation θ_{n_i}-invariant there means $\pi_i^c \cong \pi_i^\vee$. Weak base change is defined in Section 4.10; the cohomological coefficient system is the one in Lemma 4.4 of Section 4.6. As in loc. cit., the last archimedean conclusion is stated only under the additional hypothesis that every discrete summand is cuspidal. The statement makes no splitting assumption at a chosen coefficient prime, no quasi-splitness hypothesis at the finite places and no hypothesis that E/F is unramified at the finite places. □

Theorem A.4.17. *Let $F/\mathbb{Q}_p$ be finite, with residue field k of cardinality q, and let F_d/F be unramified of degree $d \geq 1$, with residue field k_d. Let $\theta : k_d^\times \to \mathbb{C}^\times$ have Frobenius orbit of size d, and let ρ_θ be its cuspidal Green representation of $\mathrm{GL}_d(k)$, equivalently the genuine Deligne–Lusztig representation $(-1)^{d-1} R^\theta_{k_d^\times}$. If an irreducible admissible smooth complex representation π of $\mathrm{GL}_d(F)$ contains the inflation of ρ_θ on $\mathrm{GL}_d(\mathcal{O}_F)$, then its local Langlands parameter, with uniformisers corresponding to geometric Frobenius, has monodromy zero and*

$$\operatorname{rec}_F(\pi)|_{I_F} \simeq \bigoplus_{\sigma \in \mathrm{Gal}(k_d/k)} (\theta^\sigma \circ \operatorname{Art}_{F_d}^{-1})|_{I_F}.$$

The characters on the right are inflated through residue units.

Proof. This is [74, Proposition 2.4.1(i)]. The representation denoted $(-1)^{d-1} R^\theta_T$ there is the regular cuspidal Green representation in this statement. Its coefficient field is transported from an algebraic closure of a characteristic-zero local field to $\mathbb{C}$ by the chosen field isomorphism. Local reciprocity is geometric in their Harris–Taylor local Langlands convention. □

Theorem A.4.18. *Let $F/\mathbb{Q}_p$ be finite, $G=\mathrm{GL}_n(F)$, $K=\mathrm{GL}_n(\mathcal{O}_F)$, and let the coefficient field be an algebraic closure of a characteristic-zero local field of residue characteristic $\ell\neq p$. In Shotton's notation, $\mathcal{I}_0$ is the set of basic inertial types (restrictions to inertia of irreducible Weil representations), and $\mathcal{I}$ consists of finitely supported functions $\mathcal{P}:\mathcal{I}_0\to\mathrm{Part}$, of weighted degree n. A discrete pair attached to $\mathcal{P}$ has, for every part a of $\mathcal{P}(\tau_0)$, one essentially discrete-series factor on $\mathrm{GL}_{a\dim\tau_0}(F)$ on the cuspidal line τ_0. Write $\sigma(\mathfrak{S}_{\mathcal{P}})$ for the compact representation constructed from that partition data in [278, Definition 6.17]: for the associated simple-character data it is $\mathrm{Ind}_J^K(\kappa\otimes\nu)$, with ν the specified irreducible representation of J/J^1. All simple characters and their extensions are chosen compatibly as in that construction. For any $\mathcal{P},\mathcal{P}'$ of degree n, any discrete pair (M',π') in the inertial class attached to $\mathcal{P}'$, and any parabolic Q' with Levi M', normalized parabolic induction satisfies*

$$\dim\mathrm{Hom}_K\Big(\sigma(\mathfrak{S}_{\mathcal{P}}),\mathrm{Ind}_{Q'}^G\pi'\Big)=\prod_{\tau_0\in\mathcal{I}_0}m(\mathcal{P}(\tau_0),\mathcal{P}'(\tau_0)).$$

Here $m(\lambda,\mu)$ is the multiplicity of the sign-twisted Specht representation indexed by λ in $\mathrm{Ind}_{S_\mu}^{S_{|\mu|}}\mathrm{sgn}$, zero for unequal sizes and one for two empty partitions.

Proof. Quoted from [278, Theorem 6.20]. □

Theorem A.4.19. *Let $F/\mathbb{Q}_p$ be finite, $G=\mathrm{GL}_n(F)$, $K=\mathrm{GL}_n(\mathcal{O}_F)$, and let the coefficient field be an algebraic closure of a characteristic-zero local field of residue characteristic $\ell\neq p$. In Shotton's notation, $\mathcal{I}_0$ is the set of basic inertial types (restrictions to inertia of irreducible Weil representations), and $\mathcal{I}$ consists of finitely supported functions $\mathcal{P}:\mathcal{I}_0\to\mathrm{Part}$, of weighted degree n. A discrete pair attached to $\mathcal{P}$ has, for every part a of $\mathcal{P}(\tau_0)$, one essentially discrete-series factor on $\mathrm{GL}_{a\dim\tau_0}(F)$ on the cuspidal line τ_0. Write $\sigma(\mathfrak{S}_{\mathcal{P}})$ for the compact representation constructed from that partition data in [278, Definition 6.17]: for the associated simple-character data it is $\mathrm{Ind}_J^K(\kappa\otimes\nu)$, with ν the specified irreducible representation of J/J^1. All simple characters and their extensions are chosen compatibly as in that construction. Let (M',π') be a discrete pair of type $\mathcal{P}'$ and let $L(M',\pi')$ be its irreducible Langlands quotient, with the segment convention of [278, Section 3.5]. If*

$$\mathrm{Hom}_K(\sigma(\mathfrak{S}_{\mathcal{P}}),L(M',\pi'))\neq 0,$$

then $\mathcal{P}'(\tau_0)$ is dominated by $\mathcal{P}(\tau_0)$ for every $\tau_0\in\mathcal{I}_0$. Dominance requires equal sizes and the inequalities of all initial partial sums. The inertial type of the quotient is $\tau_{\mathcal{P}'}$ for Shotton's normalized parameter r_ℓ.

Proof. Quoted from [278, Corollary 6.21(1)]. □

Theorem A.4.20. *Let k be finite and $\bar G=\mathrm{GL}_n(k)$. For a finitely supported partition function $\bar{\mathcal{P}}$ on the irreducible cuspidal representations ρ of finite general linear groups, with $\sum_\rho d_\rho|\bar{\mathcal{P}}(\rho)|=n$, let*

$$\pi_{\bar{\mathcal{P}}}=\mathrm{HC\text{-}Ind}\boxtimes_{\rho,j}\mathrm{St}(\rho,\bar{\mathcal{P}}(\rho)_j).$$

Let $\sigma_{\bar{\mathcal{P}}}$ be the finite irreducible Green representation with the sign-twisted partition convention of [278, Definitions 6.1 and 6.7]. Then

$$\dim\mathrm{Hom}_{\bar G}(\sigma_{\bar{\mathcal{P}}},\pi_{\bar{\mathcal{P}}'})=\prod_\rho m(\bar{\mathcal{P}}(\rho),\bar{\mathcal{P}}'(\rho)).$$

The Kostka convention is $m(\lambda,\mu)>0$ precisely when λ dominates μ, with $m(\lambda,\lambda)=1$; partitions of unequal size have multiplicity zero.

Proof. Quoted from [278, Corollary 6.10], with the partition convention of Section 6.1. □

Theorem A.4.21. *Let $F/\mathbb{Q}_p$ be finite. In the homogeneous simple-character construction of [278, Sections 6.9–6.10], choose one endo-class, compatible extensions κ, κ^2, a maximal compact subgroup K, and groups $J^1 \triangleleft J \subset K$. Thus $\bar{G} = J/J^1$ is a finite general linear group over the residue field of the stratum extension, and $\kappa|_{J^1}$ is the irreducible Heisenberg representation. Let $M^0 \subset M^2$ be a Levi, Q^2 a parabolic of G with Levi M^2, and let (M^2, π^2) be a discrete pair in the inertial class of a partition function $\mathcal{P}'$. Let $\bar{\mathcal{P}}'$ be its partition function on the finite cuspidal representations corresponding to these same simple types. Then, as representations of $\bar{G}$,*

$$\operatorname{Hom}_{J^1}\left(\kappa, \operatorname{Ind}_{Q^2}^{G} \pi^2\right) \simeq \pi_{\bar{\mathcal{P}}'},$$

where induction is normalized and $\pi_{\bar{\mathcal{P}}'}$ is the finite Harish–Chandra induction of the generalized Steinberg factors with the specified parts.

Proof. Quoted from [278, Corollary 6.19]. □

Theorem A.4.22. *Let F be a nonarchimedean local field and let σ_a be irreducible smooth complex representations of $\mathrm{GL}_{n_a}(F)$, for $1 \le a \le d$. Suppose that, whenever $a \neq b$, no supercuspidal representation in the cuspidal support of σ_a is an unramified twist of a supercuspidal representation in the cuspidal support of σ_b. Then the normalized parabolic induction*

$$\sigma_1 \times \cdots \times \sigma_d$$

to $\mathrm{GL}_{n_1+\cdots+n_d}(F)$ is irreducible.

Proof. By the multisegment classification, write each σ_a as the irreducible representation of a multisegment. The hypothesis puts every segment from two different multisegments on different unramified cuspidal lines; such segments cannot be linked. The assertion is therefore [332, Proposition8.5], which identifies the induced product with the irreducible representation of the union multisegment. □

Theorem A.4.23. *Let K be a nonarchimedean local field of characteristic zero, $n \ge 1$, and B the upper triangular Borel subgroup of $\mathrm{GL}_n(K)$. Let $\chi_i = \mu_i |\cdot|_K^{s_i}$ be smooth characters of $K^\times$, where μ_i is unitary and $s_i \in \mathbb{R}$. If $s_1 \ge \cdots \ge s_n$, the normalized parabolic induction*

$$\operatorname{Ind}_{B}^{\mathrm{GL}_n(K)}(\chi_1 \otimes \cdots \otimes \chi_n)$$

has a unique irreducible quotient. This quotient is the Langlands quotient for the multisegment of singleton characters $\{\chi_1\}, \ldots, \{\chi_n\}$.

Proof. This is the singleton-segment case of the Bernstein–Zelevinsky classification, [332], Theorem 6.1 in its quotient formulation. The convention is normalized induction from the upper Borel and the decreasing real-exponent order. Equivalently, group equal real exponents into tempered principal-series blocks; this is the usual Langlands standard module. The quotient formulation and this convention are displayed in Wedhorn [318], Sections 2.2.9 and 2.3.9. □

Theorem A.4.24. *Let F_v be a finite extension of $\mathbb{Q}_p$, with ring of integers $\mathcal{O}_{F_v}$, uniformiser ϖ_v and residue cardinality q_v. Put $G_v = \mathrm{GL}_n(F_v)$ and $K_v = \mathrm{GL}_n(\mathcal{O}_{F_v})$, where $n \ge 1$, and give G_v Haar measure with $\mathrm{vol}(K_v) = 1$. Let σ be an irreducible smooth complex representation of G_v with $\sigma^{K_v} \neq 0$. Then $\dim_{\mathbb{C}} \sigma^{K_v} = 1$. There are unramified characters $\chi_1, \ldots, \chi_n$ of $F_v^\times$, in a*

Langlands order, for which σ is the Langlands quotient of the normalised upper-Borel induction of $\chi_1 \otimes \cdots \otimes \chi_n$. The unordered multiset

$$\{\alpha_{\sigma,1}, \dots, \alpha_{\sigma,n}\}, \qquad \alpha_{\sigma,i} = \chi_i(\varpi_v),$$

is uniquely determined by σ. Here normalised induction means $f(bg) = \delta_{B_v}(b)^{1/2}(\chi_1 \otimes \cdots \otimes \chi_n)(b) f(g)$, with G_v acting by right translation. For $0 \le k \le n$, put

$$D^{+}_{v,k} = K_v \,\mathrm{diag}(\varpi_v 1_k, 1_{n-k}) K_v.$$

The operator $\int_{D^{+}_{v,k}} \sigma(g)\,dg$ on σ^{K_v} is multiplication by

$$q_v^{k(n-k)/2} e_k(\alpha_{\sigma,1}, \dots, \alpha_{\sigma,n}),$$

where e_k is the elementary symmetric polynomial and $e_0 = 1$.

Proof. This is the spherical principal-series parametrisation together with Tamagawa's minuscule-generator formula. For the parametrisation by singleton-segment Langlands quotients, see [318], (4.1.3)–(4.1.6); the normalised-induction and right-translation convention is also explicit in [50], Section 2, with the spherical line in Corollary 2.2 and the principal-series embedding in Proposition 2.6. For the operator formula, [109], Section 2, fixes Haar volume one, and (3.14) gives the Satake transform of $1_{D^{+}_{v,k}}$ as $q_v^{k(n-k)/2}\,\mathrm{Tr}(\bigwedge^k \mathbb{C}^n)$. Evaluating at the spherical parameter, as in (6.2)–(6.7) there, gives the displayed eigenvalue. The cases $k = 0, n$ are respectively the unit and the scalar central double coset. □

Theorem A.4.25. *Let H_1, H_2 be locally compact, totally disconnected, second countable groups. A representation of a totally disconnected group on a complex vector space is* admissible *if every vector has an open stabiliser and the vectors fixed by any open compact subgroup form a finite-dimensional space. Then for every irreducible admissible representation σ of $H_1 \times H_2$ on W there are irreducible admissible representations π_1 of H_1 on W_1 and π_2 of H_2 on W_2 and a linear isomorphism $W_1 \otimes W_2 \to W$ intertwining $\pi_1 \otimes \pi_2$ with σ; π_1 and π_2 are unique up to equivalence. Conversely, $\pi_1 \otimes \pi_2$ is irreducible and admissible for irreducible admissible π_1, π_2.*

Proof. Bernstein–Zelevinsky [23], Chapter I (irreducible admissible representations of a direct product of two l-groups), and Flath [80] (the lemma for two factors underlying the restricted tensor product theorem). Map of notation: l-group = locally compact totally disconnected group; countability at infinity is used for Schur's lemma. □

Theorem A.4.26. *Let E/F be a CM extension, let V be a nondegenerate hermitian space over E of dimension n with form $\langle\,,\rangle$, let $G = \mathrm{U}(V)$, and let $a \ge 1$ be an integer with $2a < n$. For an F-algebra R write $V_R = V \otimes_F R$ and let $\mathrm{gram}\colon V_R^a \to \mathrm{Herm}_a(R)$, $\mathrm{gram}(x) = (\langle x_i, x_j\rangle)_{i,j}$, be the Gram map, Herm_a denoting hermitian $a \times a$ matrices over $E \otimes_F R$. For a place w of F let dx_w be the Haar measure on $V_{F_w}^a$ that is self-dual for the pairing $(x,y) \mapsto \psi_w(\mathrm{tr}_{E_w/F_w} \sum_i \langle x_i, y_i\rangle)$, and db_w the Haar measure on $\mathrm{Herm}_a(F_w)$ that is self-dual for $(b,b') \mapsto \psi_w(\mathrm{tr}\, bb')$. Let $\Phi = \Phi_\infty \otimes \bigotimes_{w<\infty} \Phi_w$, where Φ_∞ is a smooth compactly supported function on $V_{F_\infty}^a$, $F_\infty = F \otimes_{\mathbb{Q}} \mathbb{R}$, each Φ_w is a Schwartz–Bruhat function on $V_{F_w}^a$, and Φ_w is the characteristic function of $(L \otimes \mathcal{O}_{F_w})^a$ for all but finitely many w, for an $\mathcal{O}_E$-lattice $L \subset V$ (an* admissible test function*). Let $T \in \mathrm{Herm}_a(F)$ be nondegenerate. Then:*

1. *for every Haar measure μ on $G(\mathbb{A}_F)$, the quotient $[G]$ has finite volume $\mu([G])$;*

2. *for every place w (with ∞ standing for the product of the archimedean places), the image under* gram *of the measure $\Phi_w\,dx_w$, restricted to the open set of x with* $\det \mathrm{gram}(x)$ *invertible, has a continuous density $b \mapsto g_w(\Phi_w, b)$ with respect to db_w on the open set of nondegenerate matrices, and the product $\prod_{w<\infty} g_w(\Phi_w, T)$ converges;*

3. *the function $\vartheta_T(g) = \sum_{X \in V^a,\ \mathrm{gram}(X)=T} \Phi(g^{-1}X)$ on $[G]$ is integrable, and*

$$\frac{1}{\mu([G])} \int_{[G]} \vartheta_T(g)\, d\mu(g) = g_\infty(\Phi_\infty, T) \prod_{w<\infty} g_w(\Phi_w, T).$$

Proof. [323], Chapter VI, section 52, Theorem 5 and formula (41), together with Chapter III, section 37, Proposition 6 and formula (29), and Chapter IV, section 42. In Weil's notation take $k = F$, the algebra with involution $\mathrm{End}_E(V)$ with its adjoint involution, and $X = V^a$. This is type (I_2) with $\epsilon = 1/2$, so his condition (B) is $n > 2a$. His invariant map is $x \mapsto x^* h x$, namely the displayed Gram map. The auxiliary local hypothesis of Theorem 5 holds at a finite place: condition (B) gives a nonempty full-rank zero-Gram fibre there by section 38, and Witt extension makes the full local unitary group transitive on each full-rank Gram fibre. If r is the Witt index of V, then $r \le n/2$ and hence $n - r > a$; Proposition 8 in section 51 gives absolute convergence. Formula (41), with its normalized Haar specialization, gives the asserted mean as the product of the local relative-gauge integrals. Proposition 6 identifies these with continuous pushforward densities; section 42 gives absolute convergence of the product. Nondegenerate T forces every tuple in its fibre to have full rank, so its full-rank sum is ϑ_T.

The following calculation identifies the measures, with no unspecified local scalar. Choose rational F-bases on $X = V^a$ and $Y = \mathrm{Herm}_a$. Let dx_w^0, db_w^0 be the coordinate measures obtained from the ψ_w-self-dual measure on F_w. For the two nondegenerate F-bilinear pairings displayed in the statement let B_X, B_Y be their matrices in these bases. Fourier inversion and linear change of variables give

$$dx_w = |\det B_X|_w^{1/2} dx_w^0, \qquad db_w = |\det B_Y|_w^{1/2} db_w^0.$$

Let g_w^0 be the pushforward density for the same Gram map with the coordinate measures dx_w^0, db_w^0. Consequently the relative density for the measures in the statement is

$$g_w(\Phi_w, T) = \left|\frac{\det B_X}{\det B_Y}\right|_w^{1/2} g_w^0(\Phi_w, T).$$

Both determinants lie in $F^\times$. The product formula makes the product of the displayed positive factors equal to one, including the archimedean factors; only finitely many finite factors differ from one. Thus the product of Weil's relative-gauge densities equals the product in the statement, also at dyadic and split places. This is a measure comparison, with no Weil-index factor.

Weil uses the Haar measure for which the right quotient has volume one. Inversion transfers it to the left quotient because $\mathrm{U}(V)$ is unimodular, replacing the action uX by $g^{-1}X$ and preserving total volume. For any Haar μ, its normalization is $\mu/\mu([G])$, so the mean is unchanged. Quotient finiteness (item 1) is the classical finite-volume theorem for unitary groups (Borel–Harish-Chandra). Smooth compactly supported archimedean test functions belong to the Schwartz space used there, as do the given finite factors. For hermitian b, b', $\mathrm{tr}(bb') \in F_w$, so the matrix pairing also equals $\frac{1}{2}\mathrm{Tr}_{E_w/F_w} \mathrm{tr}(bb')$, if written in that alternative convention. □

Theorem A.4.27. *Let E/F be a CM extension, $n \ge 1$ an integer, W a skew-hermitian space over E of dimension $2n$ and Witt index n with a polarisation $W = W^+ \oplus W^-$ into maximal*

isotropic subspaces, $P \subset \mathrm{U}(W)$ the Siegel parabolic subgroup stabilising W^+, and K_G a maximal compact subgroup of $\mathrm{U}(W)(\mathbb{A}_F)$ with $\mathrm{U}(W)(\mathbb{A}_F) = P(\mathbb{A}_F)K_G$. For $g = pk$ with $p \in P(\mathbb{A}_F)$, $k \in K_G$, let $a(g) \in \mathrm{GL}(W^+)(\mathbb{A}_E)$ be the action of p on W^+ and $|a(g)| = |\det a(g)|_{\mathbb{A}_E}$. Let V be a hermitian space over E of dimension m and Witt index r, and suppose

$$m > n \qquad \text{and} \qquad m - r > n.$$

Let χ be a Hecke character of E whose restriction to $\mathbb{A}_F^\times$ is η^m, let ω be the Weil representation of $\mathrm{U}(W)(\mathbb{A}_F) \times \mathrm{U}(V)(\mathbb{A}_F)$ attached to ψ_{add} and χ on the Schrödinger model $\mathcal{S}(V^n(\mathbb{A}_F))$ of the polarisation, and let $\Phi \in \mathcal{S}(V^n(\mathbb{A}_F))$ be K_G-finite with archimedean component a polynomial vector of the Fock model. Put $s_0 = \frac{m-n}{2}$,

$$f_\Phi^{(s)}(g) = |a(g)|^{\,s-s_0}\,(\omega(g,1)\Phi)(0), \qquad E(g,s,\Phi) = \sum_{\gamma \in P(F)\backslash \mathrm{U}(W)(F)} f_\Phi^{(s)}(\gamma g),$$

so that $f_\Phi^{(s)}$ is a section of the normalised induction $\mathrm{Ind}_P^{\mathrm{U}(W)}(\chi\,|\det|^s)$ and the series converges absolutely for $\mathrm{Re}\, s > n/2$ and continues meromorphically to $s \in \mathbb{C}$. Let dh be the Haar measure on $\mathrm{U}(V)(\mathbb{A}_F)$ with $\mathrm{vol}([\mathrm{U}(V)]) = 1$. Then:

1. *for every $g \in \mathrm{U}(W)(\mathbb{A}_F)$ the theta integral*

$$I(g,\Phi) = \int_{[\mathrm{U}(V)]} \sum_{x \in V^n(F)} (\omega(g,h)\Phi)(x)\, dh$$

   converges absolutely;

2. *$E(g,s,\Phi)$ is holomorphic at $s = s_0$, and for every $g \in \mathrm{U}(W)(\mathbb{A}_F)$*

$$E(g,s_0,\Phi) = I(g,\Phi).$$

Proof. For $m > 2n$ this is Weil's Siegel–Weil formula [323], the Eisenstein series being absolutely convergent at s_0 since $\mathrm{Re}\, s_0 > n/2$; item 1 is Weil's convergence criterion (absolute convergence of the theta integral for all Φ when $r = 0$ or $m - r > n$, ibid.). For $n < m \le 2n$ and $m - r > n$, holomorphy at s_0 is due to Ikeda [143] (see also Tan [293] for the poles of Siegel Eisenstein series on $\mathrm{U}(n,n)$), and the identity $E(g,s_0,\Phi) = I(g,\Phi)$ is the main theorem of Ichino [140], with the setting and normalisations of [139]. Map of notation: Ichino's $G = \mathrm{U}(n,n)$ is $\mathrm{U}(W)$, his $H = \mathrm{U}(V)$, $\omega_Q = \omega_{Q,\psi,\chi}$ is ω, $f_\Phi^{(s)}$, s_0, $E(g, f_\Phi^{(s)})$ and $I_Q(g,\Phi)$ (with $\mathrm{vol}(H(F)\backslash H(\mathbb{A})) = 1$) are as displayed; the constant in the identity is 1. □

Theorem A.4.28. *Let E/F be a CM extension, ψ a nontrivial character of $\mathbb{A}_F/F$, V a hermitian space over E of dimension m, W a skew-hermitian space over E of dimension $2n \ge 2$ and Witt index n, and $\mathbb{W} = \mathrm{Res}_{E/F}(V \otimes_E W)$ with the symplectic form of Theorem A.5.4. Let $L, L' \subset W$ be complementary maximal isotropic subspaces, $P \subset \mathrm{U}(W)$ the stabiliser of L, and $\mathbb{X} = \mathrm{Res}_{E/F}(V \otimes_E L')$, $\mathbb{Y} = \mathrm{Res}_{E/F}(V \otimes_E L)$, complementary Lagrangians of $\mathbb{W}$ defined over F. Let χ be a character of $\mathbb{A}_E^\times/E^\times$ with $\chi|_{\mathbb{A}_F^\times} = \eta^m$, and ω the Weil representation $\omega_{\psi,\chi}$ of $\mathrm{U}(W)(\mathbb{A}_F) \times \mathrm{U}(V)(\mathbb{A}_F)$ on $\mathcal{S}(\mathbb{X}(\mathbb{A}_F))$ of Theorem A.5.4 with the splitting character χ on $\mathrm{U}(W)$ and the trivial character on $\mathrm{U}(V)$. Let dh be the Haar measure on $\mathrm{U}(V)(\mathbb{A}_F)$ for which $[\mathrm{U}(V)]$ has volume 1. Suppose*

$$m > 2n.$$

Then for every $\Phi \in \mathcal{S}(\mathbb{X}(\mathbb{A}_F))$ and every $g \in \mathrm{U}(W)(\mathbb{A}_F)$:

1. *for $\gamma \in \mathrm{U}(W)(F)$ the value $(\omega(\gamma g,1)\Phi)(0)$ depends only on the coset $P(F)\gamma$, and the series*

$$E(g,\Phi)=\sum_{\gamma\in P(F)\backslash \mathrm{U}(W)(F)}(\omega(\gamma g,1)\Phi)(0)$$

converges absolutely;

2. $\displaystyle\int_{[\mathrm{U}(V)]}\sum_{x\in\mathbb{X}(F)}\left|(\omega(g,h)\Phi)(x)\right|dh<\infty$;

3. $\displaystyle E(g,\Phi)=\int_{[\mathrm{U}(V)]}\sum_{x\in\mathbb{X}(F)}(\omega(g,h)\Phi)(x)\,dh$.

Proof. This is Weil's Siegel formula in the range where the Eisenstein series converges absolutely and the theta integral converges absolutely, for every Schwartz–Bruhat function, [323]; for unitary dual pairs with Kudla's splitting it is stated in this form (the convergent case of the Siegel–Weil formula, constant 1 for the probability Haar measure) in [139], Introduction, and [121], Section 1; the orthogonal analogue in this form, with the attribution to Weil, is in Kudla and Rallis [174, 175]. The hypotheses: $s_0=(m-n)/2>n/2$ is Godement's range of absolute convergence of the Siegel Eisenstein series of $\mathrm{U}(W)$, and Weil's convergence criterion for the theta integral ($r=0$ or $m-r>n$, r the Witt index of V) holds since $r\le m/2<m-n$. Notation map: $(\omega(g,1)\Phi)(0)$ is the standard section $f_\Phi^{(s_0)}(g)$ of the degenerate principal series induced from P (the unipotent radical of P acts on $\mathcal{S}(\mathbb{X}(\mathbb{A}_F))$ by multiplication by characters and its Levi by substitutions, so evaluation at 0 is P-equivariant, with trivial factor on $P(F)$), $E(g,\Phi)=E(g,s_0,\Phi)$, and the right side of (3) is $I(g,\Phi)$. □

Theorem A.4.29. *Let E/F be a CM extension, Y a nondegenerate hermitian or skew-hermitian space over E of dimension $2n\ge 2$ and Witt index n, $G=\mathrm{U}(Y)$, $L\subset Y$ a maximal isotropic subspace, $P\subset G$ its stabiliser, $a(p)\in\mathrm{GL}(L)(\mathbb{A}_E)$ the action of $p\in P(\mathbb{A}_F)$ on L, and K a maximal compact subgroup of $G(\mathbb{A}_F)$ with $G(\mathbb{A}_F)=P(\mathbb{A}_F)K$. Fix a basis of Y and put $\|g\|=\prod_v\max_{i,j}\max(|g_{ij}|_v,|(g^{-1})_{ij}|_v)$ for $g\in G(\mathbb{A}_F)$. Let μ be a unitary Hecke character of E and, for $s\in\mathbb{C}$, let f_s be a K-finite flat section of the normalised induction $I(s)=\mathrm{Ind}_{P(\mathbb{A}_F)}^{G(\mathbb{A}_F)}(\mu(\det a)\,|\det a|_{\mathbb{A}_E}^{s})$ (that is, $f_s(pk)=\mu(\det a(p))\,|\det a(p)|_{\mathbb{A}_E}^{s+n/2}f_0(k)$ with $f_0|_K$ independent of s), and*

$$E(g,f_s)=\sum_{\gamma\in P(F)\backslash G(F)}f_s(\gamma g)\qquad(\mathrm{Re}\,s>\tfrac{n}{2}),$$

absolutely and locally uniformly convergent there. Then $s\mapsto E(g,f_s)$ continues to a meromorphic function on $\mathbb{C}$ for every g, and for every compact set $\Omega\subset\mathbb{C}$ there are a nonzero polynomial Q, an integer $N\ge 0$ and $C>0$ such that, for every $g\in G(\mathbb{A}_F)$, $s\mapsto Q(s)E(g,f_s)$ is holomorphic on a neighbourhood of Ω and

$$|Q(s)\,E(g,f_s)|\le C\,\|g\|^N\qquad(s\in\Omega,\ g\in G(\mathbb{A}_F)).$$

Proof. This is Langlands' meromorphic continuation of Eisenstein series, Langlands [184], in the form with locally uniform moderate growth of Mœglin and Waldspurger [208], Chapter IV (continuation of Eisenstein series induced from cuspidal data on the Levi factor; here the cuspidal datum is the character $\mu\circ\det$ of the Levi factor $\mathrm{GL}(L)$, and K-finite flat sections of $I(s)$ are the holomorphic families of that chapter), applied to the reductive group G over F

and its maximal parabolic P. Absolute convergence for $\operatorname{Re} s > \frac{n}{2}$ is Godement's criterion ($\frac{n}{2}$ is the exponent ρ_P normalised for $|\det a|$). Map of notation: the Siegel Eisenstein series $E(g, f_s)$ displayed in the statement is the Eisenstein series $E(\lambda, \phi)$ of the cited works for $\lambda = s\,\varpi_P$, ϖ_P the fundamental weight $|\det a|$ of P; $\|\cdot\|$ is a height on $G(\mathbb{A}_F)$ in their sense. $\square$

A.5 Representations of real, p-adic and finite groups, and the Weil representation

The quotations fall into four groups. The first is harmonic analysis on compact groups and on locally compact abelian groups [112, 320, 163, 296]. The second is the Weil representation [322]: the theorem of Stone and von Neumann in Mackey's form [195], the metaplectic group, the global Weil representation of unitary dual pairs with Kudla's splitting [172, 121], the Siegel–Levi formulas [191, 170], and the Fock model of Bargmann, Segal and Shale [14, 257, 268] (see [83, 157, 136]). The third is real groups and their discrete series [119]: the formal degree [251, 131], Blattner's formula as proved by Hecht and Schmid [127], Miličić's decay bound for matrix coefficients [199], Schur orthogonality, Helgason's change of variables [129] and Goodman's Wishart density [104]; together with the polynomial representations of GL_n [92, 91, 151, 194, 135, 71, 67, 211, 137]. The fourth is Green's theory of the characters of GL_r over a finite field [106, 194], which builds the idempotent that cuts out the target forms.

Theorem A.5.1. *Let K be a compact Hausdorff topological group. There is a unique regular Borel probability measure ν on K such that*

$$\int_K f(bk)\,d\nu(k) = \int_K f(kb)\,d\nu(k) = \int_K f(k^{-1})\,d\nu(k) = \int_K f\,d\nu$$

for every continuous $f\colon K \to \mathbb{C}$ and every $b \in K$.

Proof. This is the existence and uniqueness of Haar measure for locally compact groups ([112]; [320]), specialised to a compact group: a left Haar measure of a compact group is finite, hence normalisable to total mass 1; the modular function is a continuous homomorphism $K \to \mathbb{R}_{>0}$ with compact image, hence trivial, so the left Haar measure is also right invariant and inversion invariant. $\square$

Theorem A.5.2. *Let E be a number field with adele ring $\mathbb{A}_E$, let ψ_E be the standard additive character of $\mathbb{A}_E$ (trivial on E), and let μ be the Haar probability measure on the compact group $\mathbb{A}_E/E$.*

(a) The map $\xi \mapsto (z \mapsto \psi_E(\xi z))$ is an isomorphism of E onto the group of continuous characters of $\mathbb{A}_E/E$.

(b) If $G\colon \mathbb{A}_E/E \to \mathbb{C}$ is continuous and $\sum_{\xi\in E} |\widehat{G}(\xi)| < \infty$, where

$$\widehat{G}(\xi) = \int_{\mathbb{A}_E/E} \psi_E(\xi z) G(z)\,d\mu(z),$$

then $G(0) = \sum_{\xi\in E} \widehat{G}(\xi)$.

Proof. (a) is [296], Section 4.1 (the character group of $\mathbb{A}_E/E$ is E, through any nontrivial character of $\mathbb{A}_E$ trivial on E). (b) is Fourier inversion on the compact abelian group $\mathbb{A}_E/E$, whose dual is E by (a): a continuous function with absolutely summable Fourier coefficients is the uniform sum of its Fourier series; evaluated at 0, with the coefficient at $-\xi$ written as $\widehat{G}(\xi)$, this is the displayed identity. Notation map: ψ_E is Tate's standard character $\psi(x) = \prod_v \psi_v(x_v)$. $\square$

Theorem A.5.3. *Let F be a number field, $\mathbb{W}$ a finite-dimensional F-vector space with a non-degenerate alternating form B, $\mathbb{W} = \mathbb{X} \oplus \mathbb{Y}$ a decomposition into complementary Lagrangian subspaces defined over F, $\beta = B|_{\mathbb{X}\times\mathbb{Y}}$, ψ a nontrivial character of $\mathbb{A}_F/F$, and ρ_ψ the Schrödinger realisation of the Heisenberg representation on $L^2(\mathbb{X}(\mathbb{A}_F))$:*

$$(\rho_\psi(u_0+v_0)\varphi)(u) = \psi(\beta(u,v_0)+\tfrac{1}{2}\beta(u_0,v_0))\varphi(u+u_0) \qquad (u,u_0\in\mathbb{X}(\mathbb{A}_F),\ v_0\in\mathbb{Y}(\mathbb{A}_F)).$$

Then the metaplectic group $\mathrm{Mp}(\mathbb{W})(\mathbb{A}_F)$, the extension of $\mathrm{Sp}(\mathbb{W})(\mathbb{A}_F)$ by $\mathbb{C}^1$ on which the Weil representation ω_ψ is defined, is the group of pairs (σ, U) with $\sigma \in \mathrm{Sp}(\mathbb{W})(\mathbb{A}_F)$ and U a unitary operator of $L^2(\mathbb{X}(\mathbb{A}_F))$ such that

$$U\,\rho_\psi(w)\,U^{-1} = \rho_\psi(\sigma w) \qquad (w\in\mathbb{W}(\mathbb{A}_F)),$$

with $(\sigma,U)\mapsto\sigma$ the projection and $\omega_\psi(\sigma,U)=U$. Every such U maps the Schwartz–Bruhat space $\mathcal{S}(\mathbb{X}(\mathbb{A}_F))$ onto itself.

Proof. This is Weil's construction of the metaplectic group and of the Weil representation for the locally compact abelian group $\mathbb{X}(\mathbb{A}_F)$, [322]: the unitary operators normalising the Heisenberg representation form a group (Weil's $\mathbf{B}_0$), the Stone–von Neumann theorem shows that the operators over a given σ form one coset of $\mathbb{C}^1$ and that every $\sigma \in \mathrm{Sp}(\mathbb{W})(\mathbb{A}_F)$ occurs, and these operators induce automorphisms of $\mathcal{S}(\mathbb{X}(\mathbb{A}_F))$. Notation map: Weil's $\mathbf{r}_0(s)$ for $s\in\mathrm{Mp}$ is U; his $U(w)$ is $\rho_\psi(w)$. Changing the realisation of the Heisenberg representation by a unitary equivalence conjugates the whole statement. □

Theorem A.5.4. *Let E/F be a quadratic extension of number fields with quadratic character $\eta = \eta_{E/F}$ of $\mathbb{A}_F^\times/F^\times$, ψ a nontrivial character of $\mathbb{A}_F/F$, S a hermitian space of dimension m and T a skew-hermitian space of dimension n over E, and $\mathbb{W} = \mathrm{Res}_{E/F}(S\otimes_E T)$ with the symplectic form $\mathrm{tr}_{E/F}(\langle\,,\rangle_S\otimes\overline{\langle\,,\rangle_T})$, so that $\mathrm{U}(S)\times\mathrm{U}(T)\to\mathrm{Sp}(\mathbb{W})$. Let χ_S,χ_T be characters of $\mathbb{A}_E^\times/E^\times$ with $\chi_S|_{\mathbb{A}_F^\times}=\eta^m$ and $\chi_T|_{\mathbb{A}_F^\times}=\eta^n$. Then:*

(i) the metaplectic extension $\mathrm{Mp}(\mathbb{W})(\mathbb{A})\to\mathrm{Sp}(\mathbb{W})(\mathbb{A})$ splits over the image of $\mathrm{U}(S)(\mathbb{A})\times\mathrm{U}(T)(\mathbb{A})$ by a homomorphism $\tilde\iota_\chi$ determined by χ_T on $\mathrm{U}(S)(\mathbb{A})$ and χ_S on $\mathrm{U}(T)(\mathbb{A})$, which is the product of the local splittings and restricts on $\mathrm{U}(S)(F)\times\mathrm{U}(T)(F)$ to the canonical splitting of $\mathrm{Sp}(\mathbb{W})(F)$;

(ii) consequently $\omega_{\psi,\chi}=\omega_\psi\circ\tilde\iota_\chi$ is a representation of $\mathrm{U}(S)(\mathbb{A})\times\mathrm{U}(T)(\mathbb{A})$ on the Schwartz space $\mathcal{S}(\mathbb{X}(\mathbb{A}))$ of a Lagrangian $\mathbb{X}$ of $\mathbb{W}$ (the Schrödinger model of the Weil representation ω_ψ), and for every $\varphi\in\mathcal{S}(\mathbb{X}(\mathbb{A}))$ the theta distribution $\theta(\varphi)=\sum_{x\in\mathbb{X}(F)}\varphi(x)$ satisfies $\theta(\omega_{\psi,\chi}(\gamma)\varphi)=\theta(\varphi)$ for $\gamma\in\mathrm{U}(S)(F)\times\mathrm{U}(T)(F)$.

Proof. (i) is Kudla's splitting of metaplectic covers over unitary dual pairs, [172], globalised and normalised as in [121], Section 1. (ii) Weil's theorem: the Weil representation ω_ψ of $\mathrm{Mp}(\mathbb{W})(\mathbb{A})$ on $\mathcal{S}(\mathbb{X}(\mathbb{A}))$ exists and θ is invariant under the image of $\mathrm{Sp}(\mathbb{W})(F)$ under its canonical splitting [322]; composing with $\tilde\iota_\chi$ and using the last clause of (i) gives (ii). □

Theorem A.5.5. *Let F be a number field, let ψ be a nontrivial unitary character of $\mathbb{A}_F/F$, and let X,Y be finite-dimensional F-vector spaces in perfect bilinear duality β. Write $X_\mathbb{A}=X(\mathbb{A}_F)$ and $Y_\mathbb{A}=Y(\mathbb{A}_F)$. Use the dual Haar measures for which $X(F)\backslash X_\mathbb{A}$ and $Y(F)\backslash Y_\mathbb{A}$ have volume one. Let $\mathcal{H}_\beta$ be the Hilbert space, modulo almost-everywhere equality, of measurable functions satisfying*

$$G(u+a,v+b)=\psi(-\beta(a,v))G(u,v) \quad (a\in X(F),\ b\in Y(F))$$

almost everywhere, with finite squared norm

$$\|G\|^2 = \int_{(X(F)\backslash X_{\mathbb{A}})\times(Y(F)\backslash Y_{\mathbb{A}})} |G(u,v)|^2 \, du\, dv.$$

For $\varphi \in \mathcal{S}(X_{\mathbb{A}})$ the series

$$Z_\psi\varphi(u,v) = \sum_{a\in X(F)} \psi(\beta(a,v))\varphi(u+a)$$

converges locally uniformly and defines a continuous representative. It extends uniquely to a unitary isomorphism $Z_\psi : L^2(X_{\mathbb{A}}) \longrightarrow \mathcal{H}_\beta$, whose inverse is

$$(Z_\psi^{-1}G)(u) = \int_{Y(F)\backslash Y_{\mathbb{A}}} G(u,v)\, dv$$

for almost every u. For Schwartz functions the inverse identity holds pointwise.

Proof. This is the adelic specialization of Weil's unitary theta transform: [322], Chapter I, paragraphs 16–18, equations (20), (22), (23), pp. 164–167. □

Theorem A.5.6. *Let F be a nonarchimedean local field of characteristic zero, let $|\cdot|_F$ be its normalised absolute value, let ψ be a nontrivial unitary additive character of F, and let $m, n \geq 1$ be integers. For the type-II reductive dual pair $\mathrm{GL}_m(F) \times \mathrm{GL}_n(F)$, the Weil representation with its standard linear splitting has a Schrödinger realisation on the Schwartz–Bruhat space $\mathcal{S}(M_{m\times n}(F))$ given by*

$$(\omega_\psi(a,b)\varphi)(x) = |\det a|_F^{-n/2} |\det b|_F^{m/2} \varphi(a^{-1}xb), \qquad a \in \mathrm{GL}_m(F),\ b \in \mathrm{GL}_n(F),\ x \in M_{m\times n}(F).$$

The displayed formula specifies the splitting and the action convention.

Proof. This is the type-II Schrödinger formula in Kudla [173], Remark 6.3, pp. 53–54. It is quoted with the variables and the determinant exponents of that formula. □

Theorem A.5.7. *Let k be a nonarchimedean local field of characteristic zero, K/k a quadratic etale algebra with involution c and associated quadratic character η, and $\psi : k \to S^1$ a nontrivial continuous character. Let V be a nondegenerate hermitian K-space of rank $m \geq 1$, and let W_q be the standard hyperbolic skew-hermitian space of rank $2q$, $q \geq 1$, with matrix $\begin{pmatrix} 0 & 1_q \\ -1_q & 0 \end{pmatrix}$ in its conjugate-first convention. Use the tensor symplectic form $\frac{1}{2}\operatorname{Tr}_{K/k}(\overline{h_{W_q}} \otimes h_V)$. For a unitary character $\chi : K^\times \to S^1$ with $\chi|_{k^\times} = \eta^m$, the Kudla circle Weil representation with splitting characters $(\chi, 1)$ has a Schrödinger realization on $\mathcal{S}(V^q)$. In its standard matrix coordinates, for $a \in \mathrm{GL}_q(K)$ and*

$$m(a) = \begin{pmatrix} a & 0 \\ 0 & \bar{a}^{-\mathsf{T}} \end{pmatrix},$$

its action is exactly

$$(\omega_\chi(m(a))\varphi)(x) = |\det a|_K^{m/2} \chi(\det a)\varphi(xa).$$

This is the unitary Weil representation with its usual Heisenberg covariance. The assertion includes $K = k \times k$.

Proof. [191], Section 2A, pp.929–931: the local algebra is explicitly allowed to be split on p.929, and the splitting and the displayed Siegel-Levi formula are on p.930. The other splitting character is 1, compatible with the even rank $2q$. The symbols r, m, χ there are q, m, χ here. The conjugation on the skew-hermitian factor and the half-trace tensor form are retained. □

Theorem A.5.8. *Let V, W be nondegenerate complex hermitian and skew-hermitian spaces of ranks $r, t > 0$, respectively, with the first form conjugate-linear in the first argument and the second linear in the first. Use $B(v \otimes w, v' \otimes w') = \mathrm{Re}((v, v')\langle w, w'\rangle)$, a nontrivial real additive character, and Kudla's doubled splittings. Let ξ, ξ' be unitary characters of $\mathbb{C}^\times$ restricting to $\mathrm{sgn}^t, \mathrm{sgn}^r$ on $\mathbb{R}^\times$. In the standard diagonal/antidiagonal Witt coordinates of the doubles, on the indicated matrix Schwartz spaces,*

$$\omega^H_{W,\xi}(m_{\Delta V}(A))\varphi(Z) = \xi(\det A)|\det A|^{-t}\varphi(A^{-1}Z), \quad A \in \mathrm{GL}_r(\mathbb{C}),$$

$$\omega^H_{V,\xi'}(m_{\Delta W}(D))\varphi(Z) = \xi'(\det D)|\det D|^{r}\varphi(ZD), \quad D \in \mathrm{GL}_t(\mathbb{C}).$$

Here $|\cdot|$ is ordinary complex absolute value. The original factor splitting is the restriction of its doubled splitting to the first summand, whose image lies in the first metaplectic factor.

Proof. [170], Sections 3.2–3.3 and Lemma 3.1(a),(b), equations (3.7),(3.10), pp.47–49. The displayed first-summand restriction is the definition in Section 3.3, p.47. □

Theorem A.5.9. *Let A be a second countable locally compact abelian group with a Haar measure, and let $\widehat{A}$ be its Pontryagin dual. On $L^2(A)$ define the unitary operators*

$$(U_a f)(x) = f(x + a), \qquad (V_\chi f)(x) = \chi(x) f(x) \qquad (a \in A,\ \chi \in \widehat{A}),$$

so that $U_a V_\chi = \chi(a)\, V_\chi U_a$.

(i) A bounded operator on $L^2(A)$ that commutes with every U_a and every V_χ is a scalar multiple of the identity.

(ii) Let $a \mapsto U'_a$ and $\chi \mapsto V'_\chi$ be strongly continuous unitary representations of A and of $\widehat{A}$ on a separable Hilbert space $\mathcal{H}$ such that $U'_a V'_\chi = \chi(a)\, V'_\chi U'_a$ for all a, χ. Then there are a separable Hilbert space $\mathcal{K}$ and a unitary isomorphism $\Phi\colon \mathcal{H} \to L^2(A) \mathbin{\widehat{\otimes}} \mathcal{K}$ with

$$\Phi U'_a = (U_a \otimes 1)\Phi, \qquad \Phi V'_\chi = (V_\chi \otimes 1)\Phi \qquad (a \in A,\ \chi \in \widehat{A}).$$

Proof. This is the theorem of Stone and von Neumann in the generality of locally compact abelian groups, due to Mackey [195]; it is also the starting point of Weil's treatment of the Heisenberg group of $A \times \widehat{A}$ [322]. Notation: Mackey's pair of commuting representations of A and $\widehat{A}$ satisfying the Weyl relation is the pair (U', V') of (ii); his canonical pair is (U, V) on $L^2(A)$. □

Theorem A.5.10. *Let k be a nonarchimedean local field of characteristic 0, K a quadratic field extension of k with its nontrivial automorphism, η the quadratic character of $k^\times$ attached to K, and ψ a nontrivial additive character of k. Let V be a hermitian and W a skew-hermitian K-space of finite dimensions m and n; let $-W$ be W with the negated form, $W^\square = W \oplus (-W)$, and $\iota\colon \mathrm{U}(W) \times \mathrm{U}(W) \to \mathrm{U}(W^\square)$ the block-diagonal inclusion. Let χ be a character of $K^\times$ with $\chi|_{k^\times} = \eta^m$. Fix a complete polarisation $\mathbb{X} \oplus \mathbb{Y}$ of the symplectic k-space $\mathbb{W} = \mathrm{Res}_{K/k}(V \otimes_K W)$; it is also a complete polarisation of $\mathbb{W}^- = \mathrm{Res}_{K/k}(V \otimes_K (-W))$ (the same space with the negated form), and $(\mathbb{X} \oplus \mathbb{X}) \oplus (\mathbb{Y} \oplus \mathbb{Y})$ is one of $\mathbb{W}^\square = \mathbb{W} \oplus \mathbb{W}^-$. For $W' \in \{W, W^\square\}$ let $\omega_{W'}$ be the Weil*

representation ω_ψ of $\mathrm{U}(W')$ in the Schrödinger model on $\mathcal{S}(\mathbb{Y})$, resp. $\mathcal{S}(\mathbb{Y}\oplus\mathbb{Y})$, pulled back by Kudla's splitting of the metaplectic cover over $\mathrm{U}(W')$ attached to χ. Then for all $g_1, g_2 \in \mathrm{U}(W)$ and $f_1, f_2 \in \mathcal{S}(\mathbb{Y})$,

$$\omega_{W^\square}(\iota(g_1,g_2))\,(f_1\otimes\overline{f_2}) = \chi(\det g_2)\,(\omega_W(g_1)f_1)\otimes\overline{(\omega_W(g_2)f_2)},$$

where $(f\otimes\overline{f'})(y_1,y_2) = f(y_1)\overline{f'(y_2)}$; that is, $\omega_{W^\square}\circ\iota \cong \omega_W \boxtimes \big((\chi\circ\det)\otimes\omega_W^\vee\big)$, the contragredient being realised by complex conjugation.

Proof. Kudla's splittings of the metaplectic cover over unitary groups [172]; the doubling identity, with the inverse-character correction of the second splitting and the conjugated centre of the second metaplectic factor, is [121], Lemma 1.1, Lemma 2.1(i) and Proposition 2.2(i),(ii). Map of notation: $\mathbb{W}^-$ carries the Weil representation for the negated form, which on $\mathcal{S}(\mathbb{Y})$ is the complex conjugate of ω_ψ; the product of the two Schrödinger models is the Schrödinger model of $\mathbb{W}^\square$ for $\mathbb{Y}\oplus\mathbb{Y}$; the factor $\chi(\det g_2)$ is the product of the splitting of $\mathrm{U}(-W)$ attached to χ with the conjugate of the splitting of $\mathrm{U}(W)$. □

Theorem A.5.11. *Let $n \geq 1$, let $h(u,v) = \sum_k u_k\bar{v}_k$ on $\mathbb{C}^n$, and let W be the real symplectic space $\mathbb{C}^n$ with $\omega = \operatorname{Im} h$. Every element of the symplectic Lie algebra $\mathfrak{sp}(W)$ is uniquely of the form $X_{m,n}\colon u \mapsto mu + n\bar{u}$ with $m,n \in M_n(\mathbb{C})$, $m^* = -m$, $n^{\mathsf{T}} = n$; the maximal compact subgroup $K = \{u \mapsto ku : k \in \mathrm{U}(n)\}$ of $\mathrm{Sp}(W)$ has Lie algebra $\{X_{m,0}\}$. Let $H(W) = W\times\mathbb{R}$ with $(w,s)(w',s') = (w+w', s+s'+\omega(w,w'))$, let $\mathrm{Mp}(W)\to\mathrm{Sp}(W)$ be the metaplectic double cover and $\tilde{K}$ the preimage of K. Let $\mathcal{F}_n$ be the **Fock space** of entire functions f on $\mathbb{C}^n$ with*

$$\|f\|^2 = \pi^{-n}\int_{\mathbb{C}^n} |f(z)|^2 e^{-|z|^2}\,d\lambda(z) < \infty,$$

and $\mathcal{P}\subset\mathcal{F}_n$ the polynomials. Then:

(FK1) the monomials $z^\alpha/\sqrt{\alpha!}$ ($\alpha\in\mathbb{N}^n$) form an orthonormal basis of $\mathcal{F}_n$; on $\mathcal{P}$ the adjoint of multiplication by z_k is $\partial_k = \partial/\partial z_k$;

(FK2) the formula $\rho(w,s)f(z) = e^{is}\,e^{-|w|^2/2}\,e^{\sum_j w_j z_j}\,f(z-\bar{w})$ defines an irreducible unitary representation ρ of $H(W)$ on $\mathcal{F}_n$ with central character $s\mapsto e^{is}$; $\mathcal{P}$ consists of smooth vectors, and $d\rho(w) = L(w) = \sum_j w_j z_j - \sum_j \bar{w}_j\partial_j$ on $\mathcal{P}$, so that $[L(w),L(w')] = 2i\,\omega(w,w')$;

(FK3) (Stone–von Neumann) every irreducible unitary representation of $H(W)$ with central character $s\mapsto e^{is}$ is unitarily equivalent to ρ;

*(FK4) (Segal–Shale–Weil) there is a unique unitary representation ω_{osc} of $\mathrm{Mp}(W)$ on $\mathcal{F}_n$ with $\omega_{\mathrm{osc}}(\tilde{g})\rho(w,s)\omega_{\mathrm{osc}}(\tilde{g})^{-1} = \rho(gw,s)$ for all $\tilde{g}\in\mathrm{Mp}(W)$ over $g\in\mathrm{Sp}(W)$ and $(w,s)\in H(W)$ (the **oscillator representation**);*

(FK5) $\mathcal{P}$ is the space of $\tilde{K}$-finite vectors of ω_{osc}, it consists of smooth vectors, and for every $X_{m,n}\in\mathfrak{sp}(W)$ and $P\in\mathcal{P}$

$$d\omega_{\mathrm{osc}}(X_{m,n})P = \sum_{k,l}\Big(m_{kl}\,z_k\partial_l P + \tfrac{1}{2}n_{kl}\,z_k z_l P - \tfrac{1}{2}\bar{n}_{kl}\,\partial_k\partial_l P\Big) + \tfrac{1}{2}\operatorname{tr}(m)\,P;$$

on every smooth vector f of ω_{osc}, $d\omega_{\mathrm{osc}}(X_{m,n})f$ is the same differential operator applied to the entire function f;

*(FK6) the **vacuum** $\{f\in\mathcal{P} : \partial_j f = 0\ (1\leq j\leq n)\}$ is the line $\mathbb{C}\cdot 1$; $\tilde{K}$ acts on it by a character χ with $d\chi(X_{m,0}) = \frac{1}{2}\operatorname{tr}(m)$, so $\chi^2 = \det$ (through $\tilde{K}\to K\cong\mathrm{U}(n)$).*

Proof. Bargmann [14] (the Fock space, (FK1), the Fock realisation of the canonical commutation relations); the Stone–von Neumann theorem (FK3), [195] and [83, Ch. 1]; Segal [257], Shale [268] and Weil [322] for (FK4); the Fock model of the oscillator representation and its infinitesimal action (FK5)–(FK6) in [157], §§1–2, and in Folland [83], Ch. 1 and Ch. 4; see also [136]. Map of notation: the creation operators are z_k, the annihilation operators ∂_k; the complex structure of W is multiplication by i and $\omega = \operatorname{Im} h$; the normalisation of the Fock measure is chosen so that $[\partial_k, z_l] = \delta_{kl}$ and $z_k^* = \partial_k$.

Consistency of the normalisations. With $A(X)$ the right-hand side of (FK5): $X \mapsto A(X)$ is a Lie algebra homomorphism for the bracket $[X, X'] = XX' - X'X$ of real-linear maps (for $X = X_{m,0}$, $X' = X_{0,n}$ the bracket is $X_{0,mn+nm^{\intercal}}$; for $X = X_{0,n}$, $X' = X_{0,n'}$ it is $X_{n\bar{n}'-n'\bar{n},0}$, and the constants $\frac{1}{2}\operatorname{tr}$ arise from $[\partial_i\partial_j, z_k z_l]$), each $A(X)$ is skew-adjoint on $\mathcal{P}$, and $[A(X), L(w)] = L(Xw)$. Since $\mathcal{P}$ is irreducible under the operators $L(w)$ and $\mathfrak{sp}(W)$ is perfect, A is the only map with these commutators; hence the normalisation of (FK5) is forced by (FK2) and (FK4). The clause on smooth vectors follows from the one on $\mathcal{P}$: $\tilde{K}$-finite vectors are dense in the smooth vectors for their topology, $d\omega_{\mathrm{osc}}(X)$ is continuous there, and convergence in $\mathcal{F}_n$ implies locally uniform convergence of entire functions and of all their derivatives. □

Theorem A.5.12. *Let $\mathfrak{g}$ be a complex semisimple Lie algebra, G a connected complex Lie group with Lie algebra $\mathfrak{g}$, $\mathfrak{g}_{\mathbb{R}} \subseteq \mathfrak{g}$ a real form with Cartan involution θ, and $G_{\mathbb{R}}$ the connected subgroup of G with Lie algebra $\mathfrak{g}_{\mathbb{R}}$. Assume $G_{\mathbb{R}}$ has a compact Cartan subgroup $T_{\mathbb{R}}$, contained in a maximal compact subgroup $K_{\mathbb{R}}$; let $\mathfrak{t}$ be the complexified Lie algebra of $T_{\mathbb{R}}$, Φ the root system of $(\mathfrak{g}, \mathfrak{t})$, $W_{\mathbb{R}}$ the Weyl group of the compact roots, $\Lambda \subseteq i\mathfrak{t}_{\mathbb{R}}^*$ the lattice of differentials of characters of $T_{\mathbb{R}}$, $(\,\cdot\,,\cdot\,)$ the form on $i\mathfrak{t}_{\mathbb{R}}^*$ induced by the Killing form, Φ^+ a positive system with half-sum ρ, and $q = \frac{1}{2}\dim G_{\mathbb{R}}/K_{\mathbb{R}}$. Let $U_{\mathbb{R}}$ be the connected subgroup of G whose Lie algebra is a compact real form of $\mathfrak{g}$ stable under θ (extended complex-linearly), let ω be a left-invariant holomorphic differential form of top degree on G such that the measure $|\omega|$ induced on $U_{\mathbb{R}}$ has total mass 1, and let $\mu_{\mathbb{R}}$ be the measure $|\omega|$ induced on $G_{\mathbb{R}}$ (a Haar measure). Let $\nu \in \rho + \Lambda$ be regular and dominant for Φ^+, and let Θ_ν be the unique invariant eigendistribution on $G_{\mathbb{R}}$ that decays at infinity and whose restriction to the regular elements of $T_{\mathbb{R}}$ is*

$$\Theta_\nu|_{T_{\mathbb{R}}} = (-1)^q \frac{\sum_{w \in W_{\mathbb{R}}} \varepsilon(w)\, e^{w\nu}}{\prod_{\alpha \in \Phi^+} (e^{\alpha/2} - e^{-\alpha/2})}.$$

Then:

(a) Θ_ν is the global character of a discrete series representation of $G_{\mathbb{R}}$; every discrete series character is of this form, and discrete series characters are determined by their restrictions to the regular elements of $T_{\mathbb{R}}$;

(b) if $G_{\mathbb{R}}$ is linear, the global character of Harish-Chandra's discrete series π_ν is Θ_ν;

(c) every discrete series representation of $G_{\mathbb{R}}$ with global character Θ_ν has formal degree, with respect to $\mu_{\mathbb{R}}$,

$$d = \prod_{\alpha \in \Phi^+} \frac{(\nu, \alpha)}{(\rho, \alpha)}.$$

Proof. (a) is Harish-Chandra's theorem as stated in [251], §3, Theorem (Harish-Chandra) on pp. 95–96 with the remarks following it, where $\nu = \lambda + \rho$ with $\lambda \in \Lambda$; the setting (G, $G_{\mathbb{R}}$, $T_{\mathbb{R}} \subseteq K_{\mathbb{R}}$, compact real forms allowed) is that of §3, pp. 90 and 94–95. (c) is Harish-Chandra's formula for the formal degree, [251], §4, p. 103 ("$d_i = \prod_{(\lambda+\rho,\alpha)>0}(\lambda + \rho, \alpha)/(\rho, \alpha)$" for $\lambda + \rho$

dominant for Φ^+, so that the index set is Φ^+), with the normalisation of Haar measure fixed on p. 100 (Haar measure on $U_{\mathbb{R}}$ of total mass one, expressed as the restriction of a holomorphic top-degree form on G, restricted to $G_{\mathbb{R}}$) and $d_i = \mu(\{i\})$ the formal degree of §3, p. 91. (b): for $G_{\mathbb{R}}$ linear, [131], Theorem 5.4 (1) (after Knapp, Theorem 12.7) gives the restriction of the global character of π_ν to $T_{\mathbb{R}}$ as $(-1)^q \sum_{w\in W_{\mathbb{R}}} \det(w) e^{w\nu}/D$ with $D = e^\rho \prod_{\alpha\in\Phi^+}(1-e^{-\alpha})$, $\Phi^+ = \{\alpha : (\nu,\alpha) > 0\}$ (Definition 4.13 and (5.1) there), which is the expression above; by (a) the character of the discrete series π_ν is therefore Θ_ν. □

Theorem A.5.13. *Let G be a connected linear semisimple Lie group, K a maximal compact subgroup and $T \subseteq K$ a compact Cartan subgroup, with Lie algebras $\mathfrak{g}_0, \mathfrak{k}_0, \mathfrak{t}_0$ and complexifications $\mathfrak{g}, \mathfrak{k}, \mathfrak{t}$. Let Φ be the root system of $(\mathfrak{g},\mathfrak{t})$, Φ_c (compact roots, root space in $\mathfrak{k}$) and $\Phi_n = \Phi \setminus \Phi_c$, W_c the Weyl group of Φ_c, $P \subseteq i\mathfrak{t}_0^*$ the lattice of differentials of characters of T, $\langle\,,\rangle$ a W-invariant inner product on $i\mathfrak{t}_0^*$. For λ in $\rho + P$ regular for Φ (ρ the half-sum of the roots of any positive system) let π_λ be Harish-Chandra's discrete series with parameter λ, let Φ^+ be the positive system for which λ is dominant, $\Phi_c^+ = \Phi^+ \cap \Phi_c$, $\Phi_n^+ = \Phi^+ \cap \Phi_n$, and ρ_c, ρ_n the half-sums of Φ_c^+, Φ_n^+. For $\nu \in i\mathfrak{t}_0^*$ let $\mathcal{P}_n(\nu)$ be the number of families $(n_\beta)_{\beta\in\Phi_n^+}$ of nonnegative integers with $\nu = \sum_\beta n_\beta \beta$. Then for every $\mu \in \rho_c + P$ that is regular and dominant for Φ_c^+, the multiplicity in π_λ of the irreducible representation of K with highest weight $\mu - \rho_c$ is*

$$m_\lambda(\mu) = \sum_{w\in W_c} \varepsilon(w)\, \mathcal{P}_n(w\mu - \lambda - \rho_n),$$

$\varepsilon(w)$ the sign of w.

Proof. This is Blattner's conjecture, proved by Hecht and Schmid [127] for linear semisimple groups; in the parametrisation by Harish-Chandra parameters it is stated in this form in [11], Section 2.2, formula (1). □

Theorem A.5.14. *Let G be a connected semisimple Lie group with finite centre, K a maximal compact subgroup, and assume that G has a compact Cartan subgroup $T \subseteq K$. Let $\mathfrak{g}_0, \mathfrak{k}_0, \mathfrak{t}_0$ be the Lie algebras, $\mathfrak{g}, \mathfrak{k}, \mathfrak{t}$ their complexifications, Φ the root system of $(\mathfrak{g},\mathfrak{t})$ and $(\,\cdot\,|\,\cdot\,)$ the inner product on $i\mathfrak{t}_0^*$ induced by the Killing form. A root $\alpha \in \Phi$ is* compact *if its root space lies in $\mathfrak{k}$ and* noncompact *otherwise. Let $\Lambda \subseteq i\mathfrak{t}_0^*$ be the lattice of differentials of characters of T, ρ the half-sum of the positive roots for some ordering, and for $\alpha \in \Phi$*

$$k(\alpha) = \frac{1}{4} \sum_{\beta\in\Phi} |(\alpha|\beta)|.$$

For a nonsingular $\lambda \in \Lambda + \rho$ (orthogonal to no root) let π_λ be the discrete series representation of G with Harish-Chandra parameter λ; by Harish-Chandra, $\pi_\lambda \cong \pi_\mu$ if and only if λ, μ are conjugate under the Weyl group of $(\mathfrak{k},\mathfrak{t})$, and every irreducible square-integrable unitary representation of G is equivalent to some π_λ. Let $\sigma(k\exp X) = \|X\|$ ($k \in K$, X in the orthogonal complement $\mathfrak{p}_0$ of $\mathfrak{k}_0$ for the Killing form, $\|\cdot\|$ the Killing-form norm on $\mathfrak{p}_0$). Then for every nonsingular $\lambda \in \Lambda + \rho$ and every $\kappa > 0$ the following are equivalent:

(i) $|(\lambda|\alpha)| \geq \kappa\, k(\alpha)$ for every noncompact root $\alpha \in \Phi$;

(ii) for every K-finite matrix coefficient c of π_λ there are real numbers $M, q > 0$ such that

$$|c(x)| \leq M\, \Xi(x)^{1+\kappa}\, (1+\sigma(x))^q \qquad (x \in G).$$

Proof. This is the Theorem of the Introduction of Miličić [199] (statement on p. 60; the implication (ii)⇒(i) is due to Trombi and Varadarajan). There Ξ and σ are Harish-Chandra's K-biinvariant functions, Ξ being the function of Theorem A.5.15. □

Theorem A.5.15. *Let G, K, $\mathfrak{a}$, Σ^+, m_α, $\mathfrak{a}^+$ be as in Theorem A.5.16, $\rho = \frac{1}{2}\sum_{\alpha\in\Sigma^+} m_\alpha \alpha$, $\mathfrak{n} = \bigoplus_{\alpha\in\Sigma^+} \mathfrak{g}_\alpha$, $N = \exp\mathfrak{n}$, and for $x \in G$ let $H(x) \in \mathfrak{a}$ be defined by the Iwasawa decomposition $x \in K\exp(H(x))N$. Harish-Chandra's function is*

$$\Xi(x) = \int_K e^{-\rho(H(xk))}\,dk \qquad (x \in G),$$

dk the Haar probability measure of K. Then:

(HX1) Ξ is continuous, $\Xi(k_1xk_2) = \Xi(x)$ for $k_1, k_2 \in K$, and $0 < \Xi(x) \le \Xi(1) = 1$;

(HX2) $\int_K \Xi(xky)\,dk = \Xi(x)\,\Xi(y)$ for all $x, y \in G$;

(HX3) there are $C_\Xi > 0$ and $d_\Xi \ge 0$ such that for every $H \in \overline{\mathfrak{a}^+}$

$$e^{-\rho(H)} \le \Xi(\exp H) \le C_\Xi\, e^{-\rho(H)}\,(1 + \|H\|)^{d_\Xi},$$

for any norm $\|\cdot\|$ on $\mathfrak{a}$ (the constant depends on the norm).

Proof. Harish-Chandra [118] (the function $\Xi = \varphi_0$ and its estimate); Gangolli and Varadarajan [95], §4.6 (Theorem 4.6.4: the upper bound, stated for real reductive groups of Harish-Chandra's class, which contains the closed connected linear groups stable under conjugate transpose); Wallach [315], §4.5 (properties of Ξ, both bounds); Knapp [163], Ch. VII. (HX2) is the functional equation characterising spherical functions, $\Xi = \varphi_0$ being the elementary spherical function with parameter 0 (Helgason [129], Ch. IV, §2). In (HX1), $\Xi \le 1$ because $\Xi(x) = \langle \pi(x)v, v\rangle$ for the unit K-fixed vector v of the unitary principal series $\mathrm{Ind}_{MAN}^{G}(1)$. Notation: the Iwasawa convention $G = KAN$ with H the A-projection of xk and ρ the half sum of the roots of $\mathfrak{n}$. □

Theorem A.5.16. *Let $G \subseteq \mathrm{GL}_N(\mathbb{C})$ be a closed connected subgroup with $g^* \in G$ for all $g \in G$, let $K = G \cap \mathrm{U}(N)$, let $\mathfrak{g}$ be the Lie algebra of G and $\mathfrak{p} = \{X \in \mathfrak{g} : X^* = X\}$. Let $\mathfrak{a} \subseteq \mathfrak{p}$ be a maximal abelian subspace, $\Sigma \subseteq \mathfrak{a}^*$ the set of restricted roots (the nonzero α with $\mathfrak{g}_\alpha = \{X \in \mathfrak{g} : [H, X] = \alpha(H)X\ \forall H \in \mathfrak{a}\} \ne 0$), $m_\alpha = \dim_{\mathbb{R}} \mathfrak{g}_\alpha$, Σ^+ a system of positive restricted roots and $\mathfrak{a}^+ = \{H \in \mathfrak{a} : \alpha(H) > 0\ \forall \alpha \in \Sigma^+\}$. Then $G = K\exp(\overline{\mathfrak{a}^+})K$, and for every Haar measure dg of G there is a constant $c > 0$ such that for every Borel function $f\colon G \to [0, \infty]$*

$$\int_G f(g)\,dg = c\int_K \int_{\mathfrak{a}^+} \int_K f(k_1\exp(H)k_2) \prod_{\alpha\in\Sigma^+} (\sinh\alpha(H))^{m_\alpha}\,dk_1\,dH\,dk_2,$$

where dk_1, dk_2 are the Haar probability measure of K and dH is a Lebesgue measure on $\mathfrak{a}$.

Proof. Harish-Chandra; see Helgason [129], Chapter I, §5, no. 2 (integral formulas for the Cartan decomposition, the noncompact case), Theorem 5.8, for connected semisimple groups with finite centre, and Knapp [164], Chapter VIII, §3 (decompositions of Haar measure), for reductive groups in the sense of Chapter VII, §2, which include every closed linear group stable under conjugate transpose with finitely many components (op. cit. VII.2). The decomposition $G = K\exp(\overline{\mathfrak{a}^+})K$ is the KAK decomposition (Knapp, op. cit., Theorem 7.39). Both sides are Radon measures in f that agree on $C_c(G)$, hence on all Borel $f \ge 0$. Notation: K is the maximal compact subgroup fixed by the Cartan involution $g \mapsto (g^*)^{-1}$, $\mathfrak{p}$ its -1 eigenspace. □

Theorem A.5.17. *Let $j \in \{\pm 1\}^n$, $G = \mathrm{U}(J_j)$, $K = K_j$, let $\mathfrak{g}_0 = \{X \in M_n(\mathbb{C}) : X^* J_j + J_j X = 0\}$ be the Lie algebra of G, so that $M_n(\mathbb{C}) = \mathfrak{g}_0 \oplus i\mathfrak{g}_0$, and let $(\pi, \mathcal{H})$ be an irreducible unitary representation of G. A vector $v \in \mathcal{H}$ is K-finite if $\pi(K)v$ spans a finite-dimensional subspace; $\mathcal{H}_K$ denotes the space of K-finite vectors.*

1. *(Admissibility.) For every irreducible representation δ of K, the closed span $\mathcal{H}_\delta$ of all K-subrepresentations of $\mathcal{H}$ isomorphic to δ is finite-dimensional.*
2. *(Analyticity.) Every $v \in \mathcal{H}_K$ is an analytic vector: $g \mapsto \pi(g)v$ is a real-analytic map $G \to \mathcal{H}$. In particular v is smooth, $d\pi(X)v = \frac{d}{dt}\pi(e^{tX})v|_{t=0}$ exists for $X \in \mathfrak{g}_0$, and $d\pi(X)v \in \mathcal{H}_K$.*
3. *(Submodules.) Extend $d\pi$ complex-linearly to $M_n(\mathbb{C})$. If $\mathcal{W} \subseteq \mathcal{H}_K$ is a subspace stable under $\pi(K)$ and under $d\pi(Z)$ for all $Z \in M_n(\mathbb{C})$, then its closure is $\pi(G)$-stable; hence $\mathcal{W} = 0$ or $\mathcal{W}$ is dense in $\mathcal{H}$.*

Proof. [117]; see [163], Chapter VIII (admissibility of irreducible unitary representations of linear connected reductive groups, analyticity of K-finite vectors of admissible representations, and the correspondence between closed invariant subspaces and $(\mathfrak{g}, K)$-submodules). $\mathrm{U}(J_j) \cong \mathrm{U}(p, q)$ is a linear connected reductive group in the sense of that book, with maximal compact subgroup K_j. Map of notation: $\mathcal{H}_K$ is the Harish-Chandra module of π. □

Theorem A.5.18. *Let G be a unimodular locally compact group with Haar measure μ, and let $(\sigma, \mathcal{H})$ be an irreducible strongly continuous unitary representation of G such that $g \mapsto \langle b_0, \sigma(g)a_0\rangle$ lies in $L^2(G, \mu)$ for some nonzero $a_0, b_0 \in \mathcal{H}$. Then every matrix coefficient $g \mapsto \langle b, \sigma(g)a\rangle$ $(a, b \in \mathcal{H})$ lies in $L^2(G, \mu)$, and there is a real number $d_\sigma > 0$, the **formal degree** of σ with respect to μ, such that for all $a, b, a', b' \in \mathcal{H}$*

$$\int_G \langle b, \sigma(g)a\rangle \, \overline{\langle b', \sigma(g)a'\rangle} \, d\mu(g) = \frac{\langle a', a\rangle \, \langle b, b'\rangle}{d_\sigma},$$

the integrand being μ-integrable. Replacing μ by $\lambda\mu$ $(\lambda > 0)$ replaces d_σ by d_σ/λ.

Proof. Godement, Sur les relations d'orthogonalité de V. Bargmann I, II, C. R. Acad. Sci. Paris 225 (1947); in textbook form [163], Chapter IX (square-integrable representations), where it is stated with the inner product linear in the first argument: $\int_G (\sigma(g)a, b)\overline{(\sigma(g)a', b')}\, dg = d_\sigma^{-1}(a, a')\overline{(b, b')}$. Map of notation: $(x, y) = \langle y, x\rangle$, so $(\sigma(g)a, b) = \langle b, \sigma(g)a\rangle$, $(a, a') = \langle a', a\rangle$ and $\overline{(b, b')} = \langle b, b'\rangle$. Integrability is that of a product of two square-integrable functions. For a real reductive group whose centre is compact (for example a finite product of groups $\mathrm{U}(p, q)$), the discrete series representations are exactly the irreducible unitary representations satisfying the hypothesis, and d_σ is Harish-Chandra's formal degree [119]; for a group with non-compact centre the statement applies to G/Z (square integrability modulo the centre), which is not the form stated here. □

Theorem A.5.19. *For $k \geq 1$ and a nonincreasing $\lambda \in \mathbb{Z}^k$ put*

$$d_k(\lambda) = \prod_{1 \leq i < j \leq k} \frac{\lambda_i - \lambda_j + j - i}{j - i}.$$

Let K be a field of characteristic 0 and $\nu \in \mathbb{Z}^k$ nonincreasing with $\nu_k \geq 0$. Let $\nabla_K(\nu)$ be the K-vector space of polynomials P in the entries of a $k \times k$ matrix of indeterminates X that are homogeneous of degree ν_b in the entries of column b for each b, and satisfy

$$P(X_{\bullet b} + T\, X_{\bullet a}, (X_{\bullet c})_{c \neq b}) = P(X) \qquad (1 \leq a < b \leq k)$$

as a polynomial identity in a further indeterminate T (adding a multiple of an earlier column to a later column does not change P). Let $\mathrm{GL}_k(K)$ act on $\nabla_K(\nu)$ by $(g\cdot P)(X)=P(g^{\mathsf T}X)$. Then $\nabla_K(\nu)$ is an irreducible rational GL_k-module of highest weight ν with respect to the diagonal torus and the upper triangular Borel subgroup, and

$$\dim_K \nabla_K(\nu) = d_k(\nu).$$

Proof. The space of polynomial functions P on $k\times k$ matrices with $P(Xb)=\prod_j b_{jj}^{\nu_j}P(X)$ for all invertible upper triangular b (equivalently: homogeneous of degree ν_b in column b and invariant under adding multiples of earlier columns to later ones) is the induced module $H^0(\nu)$ of GL_k in its standard realisation on the coordinate ring ([151], Part II, Chapter 2; the polynomial functions on M_k give all of it because $\nu_k\geq 0$), which in characteristic 0 is irreducible of highest weight ν (with the action $(g\cdot P)(X)=P(g^{\mathsf T}X)$ the product $\prod_j D_j^{\nu_j-\nu_{j+1}}$ of powers of the leading principal minors D_j, with $\nu_{k+1}=0$, is a highest weight vector: for upper unitriangular g the matrix $g^{\mathsf T}X$ arises from X by adding multiples of earlier rows to later rows, which fixes every D_j, and a diagonal t multiplies D_j by $t_1\cdots t_j$), and its dimension is given by Weyl's dimension formula ([92], Lecture 15 and Theorem 24.3, or [151], II.5.10). Notation: d_k is Weyl's product $\prod_{\alpha>0}\langle\nu+\rho,\alpha^\vee\rangle/\langle\rho,\alpha^\vee\rangle$ for GL_k with positive roots e_i-e_j, $i<j$. □

Theorem A.5.20. *Let $N\geq 1$ and let $\mu\in\mathbb{Z}^N$ be nonincreasing, $\mu_1\geq\cdots\geq\mu_N$. Let χ_μ be the character of the irreducible continuous representation of the unitary group $\mathrm{U}(N)$ of highest weight μ, for the diagonal torus and the Borel subgroup of upper triangular matrices. If $x_1,\dots,x_N\in\mathbb{C}$ have modulus one and are pairwise distinct, then $\det(x_j^{N-i})_{i,j=1}^N=\prod_{i<j}(x_i-x_j)\neq 0$ and*

$$\chi_\mu\bigl(\mathrm{diag}(x_1,\dots,x_N)\bigr)=\frac{\det(x_j^{\mu_i+N-i})_{i,j=1}^N}{\det(x_j^{N-i})_{i,j=1}^N}.$$

Proof. H. Weyl's character formula for $\mathrm{U}(N)$, equivalently for the polynomial (after a power of the determinant) representations of $\mathrm{GL}_N(\mathbb{C})$: the character at $\mathrm{diag}(x)$ is the Schur function $s_\mu(x)$, the quotient of the alternant of the exponents $\mu+\delta$, $\delta=(N-1,\dots,1,0)$, by the Vandermonde determinant [92] (Lecture 24, and Lecture 6 with Appendix A for GL_N), [91] (Chapter 8). The irreducible continuous representations of $\mathrm{U}(N)$ are the restrictions of the irreducible rational representations of $\mathrm{GL}_N(\mathbb{C})$ (Weyl's unitary trick), with the same highest weights; for μ with negative entries one multiplies by $\det^{-\mu_N}$, which multiplies both sides by $(x_1\cdots x_N)^{\mu_N}$. Notation: χ_μ is the trace of the representation; the Vandermonde identity $\det(x_j^{N-i})=\prod_{i<j}(x_i-x_j)$ is classical. □

Theorem A.5.21. *Let K be a compact Hausdorff group with Haar probability measure dk, and for every irreducible continuous representation π of K on a finite-dimensional complex vector space let $\chi_\pi=\operatorname{tr}\pi$ be its character. Then:*

(i) for irreducible π,π', $\int_K \chi_\pi(k)\,\overline{\chi_{\pi'}(k)}\,dk$ is 1 if $\pi\cong\pi'$ and 0 otherwise;

(ii) if $f\in L^2(K)$ satisfies $f(yky^{-1})=f(k)$ for every $y\in K$ and almost every k, and $\int_K f(k)\,\overline{\chi_\pi(k)}\,dk=0$ for every irreducible π, then $f=0$ almost everywhere.

Equivalently, the characters of the irreducible representations, one for each isomorphism class, form an orthonormal basis of the closed subspace of class functions in $L^2(K)$.

Proof. Peter–Weyl theorem and Schur orthogonality for compact groups: [163], Chapter I, §5 (the Peter–Weyl theorem and its corollary on class functions; (i) is Schur's orthogonality of characters). Notation: χ_π is the trace of π (any continuous finite-dimensional representation of a compact group is unitary for some inner product, so the unitarity assumed there is no restriction). $\square$

Theorem A.5.22. *Let G be a connected semisimple Lie group with finite centre, $G = KAN$ an Iwasawa decomposition, M the centraliser of A in K, and for $x \in G$ write $x = \kappa(x)\exp(H(x))n(x)$ with $\kappa(x) \in K$, $H(x) \in \mathfrak{a}$, $n(x) \in N$. Let $\rho \in \mathfrak{a}^*$ be half the sum of the positive restricted roots (those occurring in the Lie algebra of N), counted with multiplicity, and dk the Haar probability measure of K. Then for every continuous function f on K with $f(km) = f(k)$ for $k \in K$, $m \in M$, and every $g \in G$,*

$$\int_K f(\kappa(gk))\, e^{-2\rho(H(gk))}\, dk = \int_K f(k)\, dk.$$

Proof. [129], Chapter I, Lemma 5.19 (the map $kM \mapsto \kappa(gk)M$ of K/M has Jacobian $e^{-2\rho(H(gk))}$). It is the identity that makes the Poisson kernel $e^{-2\rho(H(gk))}$ a probability density on K/M. $\square$

Theorem A.5.23. *Let $m \geq 1$, let E_{ij} $(1 \leq i, j \leq m)$ be the standard basis of $\mathfrak{gl}_m = \mathfrak{gl}_m(\mathbb{C})$ and $\mathfrak{gl}_{m-1} \subseteq \mathfrak{gl}_m$ the span of the E_{ij} with $i, j \leq m-1$. Finite-dimensional irreducible $\mathfrak{gl}_m$-modules correspond bijectively (up to isomorphism) to tuples $\lambda = (\lambda_1, \dots, \lambda_m) \in \mathbb{C}^m$ with $\lambda_i - \lambda_{i+1} \in \mathbb{Z}_{\geq 0}$; the module $L(\lambda)$ contains a non-zero vector ξ, unique up to a scalar, with $E_{ii}\xi = \lambda_i \xi$ for all i and $E_{ij}\xi = 0$ for $i < j$ (the highest weight λ).*

(i) (Branching.) For $m \geq 2$ the restriction of $L(\lambda)$ to $\mathfrak{gl}_{m-1}$ is isomorphic to the direct sum of pairwise inequivalent irreducible modules $L'(\nu)$ over the tuples $\nu = (\nu_1, \dots, \nu_{m-1})$ with $\lambda_i - \nu_i \in \mathbb{Z}_{\geq 0}$ and $\nu_i - \lambda_{i+1} \in \mathbb{Z}_{\geq 0}$ for $1 \leq i \leq m-1$, each with multiplicity one.

(ii) (Capelli determinant.) Put $E(u) = u\,1 + E$ and

$$A_m(u) = \sum_{\sigma \in S_m} \operatorname{sgn}\sigma\; E(u)_{\sigma(1)1}\, E(u-1)_{\sigma(2)2} \cdots E(u-m+1)_{\sigma(m)m} \in \mathrm{U}(\mathfrak{gl}_m)[u].$$

Then $A_m(u)$ acts on $L(\lambda)$ as the scalar $\prod_{i=1}^m (u + \lambda_i - i + 1)$, for every $u \in \mathbb{C}$.

Proof. Quoted: Molev [210] (Handbook of Algebra, Vol. 4). The highest-weight parametrisation is stated at the opening of Section 2 (formula (2.1) and the sentence after it); item (i) is Theorem 2.1 with the betweenness conditions (2.2) (the branching rule of Gelfand–Tsetlin and Zhelobenko); item (ii) is formula (2.39) of Theorem 2.20 for the top row, where $A_m(u) = E(u)^{1\cdots m}_{1\cdots m}$ is the quantum minor (2.35) (Molev notes before Proposition 2.22 that $A_m(u)$ is the Capelli determinant) and $l_{mi} = \lambda_{mi} - i + 1$, $\lambda_{mi} = \lambda_i$ for every Gelfand–Tsetlin pattern of $L(\lambda)$; as the Gelfand–Tsetlin vectors form a basis of $L(\lambda)$, $A_m(u)$ acts as the stated scalar. The same statements are in Molev's monograph [211] (Chapter 7 and Section 1.6 with the evaluation homomorphism). Notation: $A_m(u)$ as displayed in (ii) is the quantum minor (2.35) of Molev written in column form. $\square$

Theorem A.5.24. *Let $n \geq 1$ and $w = (w_1, \dots, w_n)$ indeterminates. For $e = (e_1, \dots, e_n) \in \mathbb{N}^n$ let $a_e(w) = \det(w_i^{e_j})_{1 \leq i,j \leq n}$, and let $\delta_n = (n-1, n-2, \dots, 1, 0)$, so that $a_{\delta_n}(w) = \prod_{1 \leq i < i' \leq n}(w_i - w_{i'})$. Let $\lambda = (\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_n \geq 0)$ be a partition with at most n parts, $|\lambda| = \sum_i \lambda_i$.*

(a) $a_{\lambda+\delta_n}$ *is divisible by* a_{δ_n} *in* $\mathbb{Z}[w]$*, and the quotient, the* Schur polynomial

$$s_\lambda(w) = a_{\lambda+\delta_n}(w)/a_{\delta_n}(w),$$

equals $\sum_T w^T$*, the sum over the semistandard Young tableaux* T *of shape* λ *with entries in* $\{1,\dots,n\}$*, where* $w^T = \prod_i w_i^{\#\{\text{entries of } T \text{ equal to } i\}}$*. In particular* s_λ *is homogeneous of degree* $|\lambda|$ *and all its coefficients are non-negative integers.*

(b) (Hook-content formula.) $s_\lambda(1,\dots,1) = \prod_{x\in\lambda} \dfrac{n+c(x)}{h(x)}$*, where for the cell* $x=(i,j)$ *of the diagram of* λ *(row* i*, column* j*) the content is* $c(x) = j-i$ *and the hook length is* $h(x) = \lambda_i - j + \lambda'_j - i + 1$*,* λ' *the conjugate partition.*

Proof. Classical; see [194], Chapter I: (a) is the definition of s_λ as a quotient of alternants, Ch. I, (3.1), together with the combinatorial description, Ch. I, (5.12) (Jacobi's bialternant formula and Littlewood's tableau formula); (b) is Ch. I, §3, Example 4, at $q=1$ (Stanley's hook-content formula). Notation: w plays the role of the negatives of the entries of one block of a weight in the application; s_λ is used only inside the calculus of the Chern-root ring. □

Theorem A.5.25. *Let* V *and* W *be finite-dimensional complex vector spaces. For a partition* λ*, let* S_λ *be the Schur functor with highest weight* λ*, and put* $S_\lambda V = 0$ *when* λ *has more than* $\dim V$ *nonzero parts. For every integer* $d \geq 0$ *there is an isomorphism of representations of* $\mathrm{GL}(V)\times\mathrm{GL}(W)$

$$\mathrm{Sym}^d(V\otimes W) \simeq \bigoplus_{\lambda\vdash d} S_\lambda V \otimes S_\lambda W.$$

Each nonzero summand is irreducible and occurs with multiplicity one. Equivalently, for the action $((g,h)\cdot P)(Z) = P(g^t Z h)$ *on polynomials in an* a *by* b *matrix, the summand of shape* λ *is spanned by the matrix coefficients of the rectangular Schur matrix* $S_\lambda(Z)$ *and is isomorphic to* $S_\lambda\mathbb{C}^a \otimes S_\lambda\mathbb{C}^b$*.*

Proof. This is the classical polynomial Cauchy decomposition, or $(\mathrm{GL}(V),\mathrm{GL}(W))$ duality; see [135] and, for the characteristic-free form with Schur functors, [3], Section III.1. The convention for the displayed polynomial action uses the coordinate variables as $V\otimes W$. With the pullback action on the coordinate ring of $\mathrm{Hom}(W,V)$ one instead replaces the appropriate factor by its dual. The rectangular Schur matrix is the functorial map on the Young realization, so its coefficients give the indicated copy of the tensor product. No oscillator, theta-functional or derivative normalization is included in this theorem. □

Lemma A.5.26. *Let* A *be a commutative ring, let* $\mathcal{R}$ *and* $\mathcal{K}$ *be finite totally ordered sets, and let* $A[x]$ *be the polynomial ring over* A *in the indeterminates* $x_{a,c}$ *(*$a\in\mathcal{R}$*,* $c\in\mathcal{K}$*). For a partition* λ *a tableau of shape* λ *with entries in a totally ordered set is* standard *if its entries increase weakly along each row and strictly down each column. For tableaux* S *with entries in* $\mathcal{R}$ *and* T *with entries in* $\mathcal{K}$ *of the same shape* λ*, with columns* $S^{(1)},\dots,S^{(\lambda_1)}$ *and* $T^{(1)},\dots,T^{(\lambda_1)}$ *of lengths* $\lambda'_1 \geq \cdots \geq \lambda'_{\lambda_1}$*, the* bideterminant *is*

$$(S\,|\,T) = \prod_{k=1}^{\lambda_1} \det\bigl(x_{S_i^{(k)},T_l^{(k)}}\bigr)_{1\leq i,l\leq\lambda'_k},$$

and $(\emptyset\,|\,\emptyset)=1$*. Then the bideterminants* $(S\,|\,T)$*, where* λ *runs over all partitions and* S*,* T *over the standard tableaux of shape* λ *with entries in* $\mathcal{R}$ *and* $\mathcal{K}$*, form a basis of the free* A*-module* $A[x]$*.*

Proof. This is the standard basis theorem of Doubilet, Rota and Stein [73], in the characteristic-free form of [71] and [67] (§1), where it is proved over an arbitrary commutative ring by the straightening law. Map of notation: those papers write a bitableau with the minors along the rows of the diagram (row-strict tableaux); transposing the diagram gives the column convention used here, in which every column of $(S|T)$ is one minor. $\square$

Theorem A.5.27. *Let k_0 be a finite field with q elements and $r \geq 1$. For every label c of degree r over k_0, let $d_1, \dots, d_t$ be the degrees of the monic irreducible factors of c. Then:*

(a) there is $\epsilon_c \in \{\pm 1\}$ such that $\epsilon_c \Xi_c$ is the character of an irreducible complex representation of $\mathrm{GL}_r(k_0)$;

(b) if $c \neq c'$ are labels of degree r, the irreducible characters $\epsilon_c \Xi_c$ and $\epsilon_{c'} \Xi_{c'}$ are distinct;

(c) $$|\Xi_c(1)| = \frac{\prod_{i=1}^{r}(q^i - 1)}{\prod_{j=1}^{t}(q^{d_j} - 1)}.$$

Proof. [106]: the characters of $\mathrm{GL}_r(\mathbb{F}_q)$ attached to a squarefree polynomial (each irreducible factor carrying the partition (1)), their irreducibility and the parametrisation of the irreducible characters (Section 8), and the degree formula. Equivalently, in the language of Deligne and Lusztig ([69], Theorem 6.8 and Corollary 7.2): $\epsilon_c \Xi_c = \pm R_T^{\theta}$ for the maximal torus $T \cong \prod_j \mathbb{F}_{q^{d_j}}^{\times}$ and the character θ obtained from the roots of c and the fixed faithful character, which is in general position because c is squarefree with nonzero roots; $R_T^{\theta}(1) = \pm |\mathrm{GL}_r(\mathbb{F}_q)|_{p'}/|T|$. Notation: Ξ_c is Green's character of the label c; $|\mathrm{GL}_r(\mathbb{F}_q)|_{p'} = \prod_{i=1}^{r}(q^i - 1)$, $|T| = \prod_j (q^{d_j} - 1)$. $\square$

Theorem A.5.28. *Let k_0 be a finite field, $r \geq 1$, and c a label of degree r over k_0 that is irreducible in $k_0[X]$. Then Ξ_c or $-\Xi_c$ is the character of an irreducible cuspidal representation of $\mathrm{GL}_r(k_0)$, and e_c is a central idempotent. Consequently, for every proper parabolic subgroup of $\mathrm{GL}_r(k_0)$ with unipotent radical U and all $h, t \in \mathrm{GL}_r(k_0)$,*

$$\sum_{u \in U} e_c(h\,u\,t) = 0,$$

where $e_c(g)$ denotes the coefficient of g in e_c.

Proof. The first assertion is Green's theorem on the characters of GL_r over a finite field: the character attached to a single irreducible polynomial of degree r (with the partition (1)) is, up to the sign $(-1)^{r-1}$, an irreducible cuspidal ("discrete series") character [106]. For an irreducible character χ the element $\frac{\chi(1)}{|G|}\sum_g \overline{\chi(g)}\, g$ is the central idempotent of χ, and replacing χ by $-\chi$ does not change it; so e_c is that idempotent.

For the consequence let (π, X) realise $\chi = \pm\Xi_c$. Cuspidality means $X^{U'} = 0$ for the unipotent radical U' of every proper parabolic subgroup, that is $\sum_{u \in U'} \pi(u) = 0$. Given U, h, t, the group $U' = t^{-1}Ut$ is again such a radical, and $hut = (ht)(t^{-1}ut)$, so

$$\sum_{u \in U} \overline{\chi(hut)} = \overline{\mathrm{tr}\Big(\pi(ht) \sum_{u' \in U'} \pi(u')\Big)} = 0.$$

Multiplying by $\chi(1)/|G|$ (with the sign of $\pm$ absorbed as above) gives the claim. $\square$

Theorem A.5.29. *Let q be a prime power and $s \geq 1$, let $d_1, \dots, d_s \geq 1$, and let ρ_i be an irreducible cuspidal complex representation of $\mathrm{GL}_{d_i}(\mathbb{F}_q)$. Suppose $\rho_i \not\cong \rho_j$ whenever $i \neq j$ and $d_i = d_j$. Put $n = \sum_i d_i$, and let $P \leq \mathrm{GL}_n(\mathbb{F}_q)$ be the block upper triangular parabolic with Levi $\prod_i \mathrm{GL}_{d_i}(\mathbb{F}_q)$. Then*

$$\mathrm{Ind}_P^{\mathrm{GL}_n(\mathbb{F}_q)} \mathrm{Inf}_{\prod_i \mathrm{GL}_{d_i}(\mathbb{F}_q)}^{P} \bigotimes_i \rho_i$$

is irreducible.

More precisely, let $c = \prod_{i=1}^{s} f_i$ be a label over $\mathbb{F}_q$, factored into its distinct monic irreducible factors, and put $d_i = \deg f_i$. For each i, let ρ_{f_i} be the irreducible cuspidal representation of $\mathrm{GL}_{d_i}(\mathbb{F}_q)$ with character $\epsilon_{f_i}\Xi_{f_i}$, where $\epsilon_{f_i} \in \{1, -1\}$. Then there is a sign $\epsilon_c \in \{1, -1\}$ such that $\epsilon_c \Xi_c$ is the character of

$$\mathrm{Ind}_P^{\mathrm{GL}_{\deg c}(\mathbb{F}_q)} \mathrm{Inf}_{\prod_i \mathrm{GL}_{d_i}(\mathbb{F}_q)}^{P} \bigotimes_i \rho_{f_i},$$

where P is the block upper triangular parabolic with these block sizes. For $a \in \mathbb{F}_q^\times$, the representation ρ_{X-a} is one-dimensional and its order as a multiplicative character of $\mathbb{F}_q^\times$ is the multiplicative order of a.

Proof. The first assertion is the distinct-cuspidal specialization of [106], Section 8, Theorem 13, pp. 439–440. In Green's parametrization a cuspidal factor corresponds to one simplex with partition (1), and the hypothesis makes these simplexes distinct. Theorem 13 states that the corresponding circle product is the irreducible character with that partition-valued parameter. The circle product is induction from the block parabolic of the product character on its diagonal blocks, by the definition in the introduction, pp. 402–403.

For the label assertion, the polynomial-to-simplex correspondence of Section 7, p. 439, associates to every irreducible factor f_i its Frobenius simplex. A squarefree label assigns partition (1) to each of these distinct simplexes and the empty partition to all others. Thus the same displayed formula in Theorem 13 is exactly the stated parabolic induction; the signs merely replace the Green functions by their irreducible characters. There is no additional scalar or determinant twist. In degree one, write $a = \varepsilon^h$ for a generator ε of $\mathbb{F}_q^\times$. The degree-one instance of Green's formula in Theorem 14, p. 443, is the character $x \mapsto \theta(x)^h$, where $\theta(\varepsilon)$ is a primitive $(q-1)$-st root of unity compatible with the fixed naming character. Its order is $(q-1)/\gcd(h, q-1)$, which is exactly the order of a. □

Theorem A.5.30. *Let W be a finite-dimensional symplectic $\mathbb{Q}_p$-space, let*

$$H(W) = W \times \mathbb{Q}_p, \qquad (w,t)(w',t') = (w + w', t + t' + \tfrac{1}{2}\langle w, w' \rangle),$$

and fix a nontrivial continuous unitary character $\psi : \mathbb{Q}_p \to \mathbb{C}^\times$. Fix a Schrödinger representation S_ψ with central character ψ. For every smooth complex representation M of $H(W)$ on which the centre acts by ψ, the evaluation map

$$S_\psi \otimes_{\mathbb{C}} \mathrm{Hom}_{H(W)}(S_\psi, M) \longrightarrow M, \qquad s \otimes T \longmapsto T(s)$$

is an isomorphism. The functors $M \mapsto \mathrm{Hom}_{H(W)}(S_\psi, M)$ and $N \mapsto S_\psi \otimes N$ are mutually inverse equivalences with complex vector spaces.

Proof. This is the fixed-central-character smooth Stone–von Neumann equivalence. See Sug Woo Shin, *Abelian varieties and Weil representations*, Theorem 4.15, its p-adic version in section 4.6, and the classical symplectic-coordinate identification in section 6.2. Over $\mathrm{Spec}\,\mathbb{C}$, quasi-coherent

modules are complex vector spaces. Pushing the centre through ψ identifies weight-one representations of the central $\mathbb{C}^\times$-extension with the displayed fixed-central-character representations. [277]. □

Theorem A.5.31. *All symbols introduced here are local to this statement and to the results that cite it. Let $k \geq a \geq 1$ be integers and let X be a random $k \times a$ complex matrix whose k rows are independent, each with density $\pi^{-a}\exp(-x^*x)$ with respect to Lebesgue measure on $\mathbb{C}^a = \mathbb{R}^{2a}$. Then $W = X^*X$ has, with respect to the measure $dW = \prod_i dW_{ii} \prod_{i<j} d(\operatorname{Re} W_{ij})\, d(\operatorname{Im} W_{ij})$ on hermitian $a \times a$ matrices, the density*

$$\frac{\det(W)^{k-a}\exp(-\operatorname{tr} W)}{\tilde{\Gamma}_a(k)} \quad \text{on positive definite } W, \quad 0 \quad \text{elsewhere}, \qquad \tilde{\Gamma}_a(k) = \pi^{a(a-1)/2}\prod_{j=0}^{a-1}\Gamma(k-j).$$

Proof. [104]: the complex Wishart distribution with $n = k$ degrees of freedom, dimension $p = a$ and covariance $\Sigma = I$ (rows $\mathcal{CN}(0, I)$, density $\pi^{-a}\det\Sigma^{-1}\exp(-x^*\Sigma^{-1}x)$), density $\det(W)^{n-p}\exp(-\operatorname{tr}\Sigma^{-1}W)/(\det(\Sigma)^n\tilde{\Gamma}_p(n))$ with $\tilde{\Gamma}_p(n) = \pi^{p(p-1)/2}\prod_{j=1}^{p}\Gamma(n-j+1)$. Notation map: $n \mapsto k$, $p \mapsto a$, $\prod_{j=1}^{a}\Gamma(k-j+1) = \prod_{j=0}^{a-1}\Gamma(k-j)$. □

Theorem A.5.32. *Let F be a nonarchimedean local field, $G = \mathrm{GL}_n(F)$ and $T \subset B$ the diagonal torus and upper Borel. Fix a uniformizer and smooth characters $\chi_i : \mathcal{O}_F^\times \to \mathbb{C}^\times$. Put $\chi = \bigotimes_i \chi_i$ and*

$$c_{ij} = \min\{c \geq 1 : \chi_i\chi_j^{-1}|_{1+\mathfrak{p}_F^c} = 1\}.$$

Let J_χ be generated by $T(\mathcal{O}_F)$ and

$$1 + \mathfrak{p}_F^{\lfloor c_{ij}/2 \rfloor}E_{ij} \quad (i < j), \qquad 1 + \mathfrak{p}_F^{\lceil c_{ij}/2 \rceil}E_{ij} \quad (i > j),$$

and let ρ_χ extend χ, trivially on these root groups. Let H_χ be the product of general linear groups on the coordinate classes with equal χ_i, with diagonal torus T, upper Borel B_χ and Iwahori I_χ. Extend χ_i to $\widetilde{\chi}_i$ by value one at the uniformizer.

Then (J_χ, ρ_χ) is a type for $[T, \widetilde{\chi}]$. There is a support-preserving, involution-preserving isomorphism

$$\mathcal{H}(H_\chi, I_\chi) \simeq \mathcal{H}(G, \rho_\chi)$$

and an induced exact equivalence from the category generated by ρ_χ to that generated by I_χ-fixed vectors. Support corresponds through the common extended affine Weyl group. The isomorphism can be chosen so that this equivalence sends

$$i_B^G(\widetilde{\chi}\nu) \;\longmapsto\; i_{B_\chi}^{H_\chi}(\nu)$$

for every unramified ν, with normalized induction. No restriction on the characteristic or residue characteristic of F is required.

Proof. These are the general-linear cases of [243, Theorems 6.3, 7.7, 8.2 and 9.4; Corollary 7.9; Remark 4.14]. Notation map: χ is Roche's character of ${}^0T$; J_χ, ρ_χ are his (J, ρ) from Definition 3.3; H_χ has root system $\{e_i - e_j : \chi_i = \chi_j\}$. The Weyl stabilizer is the product of the symmetric groups on those classes, so the component group is trivial. Both compact subgroups have Haar mass one. Theorem 9.4 uses the chosen extension and normalized induction; Remark 4.14 gives the unrestricted general-linear case. □

Theorem A.5.33. *Let K be a non-archimedean local field, let $\nu(g) = |\det g|_K$, and let ρ be an irreducible supercuspidal complex representation of $\mathrm{GL}_m(K)$. For $h \geq 1$, set $n = mh$ and let $\Delta = [\rho, \nu^{h-1}\rho]$ be the segment of length h. Denote by $\delta(\Delta)$ the unique irreducible subrepresentation of the normalised induction*

$$\nu^{h-1}\rho \times \nu^{h-2}\rho \times \cdots \times \rho;$$

equivalently it is the unique irreducible quotient of the induction in the reversed order.

For the upper block-triangular parabolic subgroup $P_{n-i,i}$, with diagonal Levi $\mathrm{GL}_{n-i}(K) \times \mathrm{GL}_i(K)$ and unipotent radical $U_{n-i,i}$, write

$$r_{n-i,i}(\pi) = \delta_{P_{n-i,i}}^{-1/2} \otimes \pi_{U_{n-i,i}}.$$

For $0 < i < n$, this Jacquet module of $\delta(\Delta)$ is zero unless m divides i. If $i = mp$, where $0 < p < h$, then

$$r_{n-i,i}\big(\delta([\rho, \nu^{h-1}\rho])\big) \cong \delta([\nu^p\rho, \nu^{h-1}\rho]) \boxtimes \delta([\rho, \nu^{p-1}\rho]).$$

These are isomorphisms of the actual Jacquet modules, not just identities of semisimplifications.

Proof. [332, Proposition 9.5], with the segment representation $\langle\Delta\rangle^t$ of Section 9.1 denoted here by $\delta(\Delta)$. The orientation is fixed by Section 9.1: it is a subrepresentation of the descending induction and a quotient of the ascending induction. The ordered Levi has the larger, upper block first; the right block of rank mp receives the lower segment $[\rho, \nu^{p-1}\rho]$. The induction and Jacquet functors are those of [24, Sections 1.8 and 2.2–2.3]: upper block-triangular parabolics, right translation in induction, the factor $\delta_P^{1/2}$ in induction and the factor $\delta_P^{-1/2}$ on unipotent coinvariants. In Example 9.2 of [332], the centered character segment $[|\cdot|_K^{(1-h)/2}, |\cdot|_K^{(h-1)/2}]$ gives the ordinary Steinberg representation of $\mathrm{GL}_h(K)$. □

A.6 Lattices, geometry of numbers and linear algebra

These are results on lattices and determinants: Banaszczyk's transference theorems [12] and Minkowski's second theorem [52]; the mass of a maximal hermitian lattice, by Shimura's exact formula [270, 97, 99, 303], which goes back to Siegel's mass formula [280]; the inequalities of Fischer, Hadamard and Cauchy–Schwarz [113, 133]; Amitsur's formula for the determinant of a sum [6, 240, 82]; and Witt's extension theorem for hermitian forms [249].

Theorem A.6.1. *Let $d \geq 1$, let $\mathcal{E}$ be a real inner product space of dimension d with norm $\|\cdot\|$, let $\Gamma \subset \mathcal{E}$ be a lattice (the subgroup generated by a basis of $\mathcal{E}$) and $\Gamma^* = \{u \in \mathcal{E} : \langle u, y\rangle \in \mathbb{Z} \text{ for all } y \in \Gamma\}$ its dual lattice. Let $\lambda > 0$ be such that $\|u\| \geq \lambda$ for every nonzero $u \in \Gamma^*$. Then for every $t \in \mathcal{E}$ there is $y \in \Gamma$ with*

$$\|t - y\| \leq \frac{d}{2\lambda}.$$

Equivalently, the covering radius $\mu(\Gamma) = \min\{r > 0 : \Gamma + rB = \mathcal{E}\}$ (B the closed unit ball) satisfies $\mu(\Gamma)\,\lambda_1(\Gamma^*) \leq d/2$, where $\lambda_1(\Gamma^*)$ is the least norm of a nonzero vector of Γ^*.

Proof. Banaszczyk [12]: the quantity $\eta_d = \sup_\Gamma \mu(\Gamma)\lambda_1(\Gamma^*)$, the supremum over all lattices in $\mathbb{R}^d$, satisfies $\eta_d \leq d/2$ for every d. Notation: the paper writes n, L, L^* for d, Γ, Γ^* and works in $\mathbb{R}^n$ with its Euclidean inner product; an isometry $\mathcal{E} \cong \mathbb{R}^d$ carries Γ, Γ^*, μ and λ_1 to the objects of the paper. Since $\lambda \leq \lambda_1(\Gamma^*)$, $\mu(\Gamma) \leq d/(2\lambda_1(\Gamma^*)) \leq d/(2\lambda)$, and the minimum defining $\mu(\Gamma)$ is attained, which gives the first form. □

Theorem A.6.2. *Let $n \geq 1$, let $\mathbb{R}^n$ carry its Euclidean inner product $u \cdot v$ and norm $\|\cdot\|$, let $\Gamma \subset \mathbb{R}^n$ be a lattice (the subgroup generated by n linearly independent vectors) and $\Gamma^* = \{u \in \mathbb{R}^n : u \cdot v \in \mathbb{Z} \text{ for all } v \in \Gamma\}$ its dual lattice. For $1 \leq i \leq n$ let $\lambda_i(\Gamma) = \min\{s > 0 : \dim \operatorname{span}_{\mathbb{R}}(\Gamma \cap \{\|v\| \leq s\}) \geq i\}$ be the i-th successive minimum. Then*

$$\lambda_i(\Gamma)\,\lambda_{n-i+1}(\Gamma^*) \leq n \qquad (1 \leq i \leq n).$$

Proof. [12]: the quantity $\xi_n = \sup_\Gamma \max_{1\leq i\leq n} \lambda_i(\Gamma)\lambda_{n-i+1}(\Gamma^*)$ satisfies $\xi_n \leq n$ for every n. Notation: the paper writes L, L^* for Γ, Γ^*; the definitions of the dual lattice and of the successive minima are those of the paper. □

Theorem A.6.3. *Let $n \geq 1$, let $\mathbb{R}^n$ carry a Euclidean inner product with norm $\|\cdot\|$ and the Lebesgue measure of that inner product, let $B_n = \{y : \|y\| \leq 1\}$, of volume $\operatorname{vol}(B_n) = \pi^{n/2}/\Gamma(\frac{n}{2}+1)$, and let $\Gamma \subset \mathbb{R}^n$ be a lattice of covolume $\operatorname{cv}(\Gamma)$. For $1 \leq i \leq n$ let $\lambda_i(\Gamma) = \min\{r > 0 : \dim \operatorname{span}_{\mathbb{R}}(\Gamma \cap rB_n) \geq i\}$. Then there are linearly independent $y_1, \ldots, y_n \in \Gamma$ with $\|y_i\| = \lambda_i(\Gamma)$, and*

$$\lambda_1(\Gamma)\cdots\lambda_n(\Gamma)\operatorname{vol}(B_n) \leq 2^n \operatorname{cv}(\Gamma).$$

Proof. [52], Chapter VIII (Minkowski's second theorem, stated there for every convex symmetric body; here the body is the unit ball B_n), and the remarks there that the successive minima are attained by linearly independent lattice points. Notation: Cassels writes Λ and $d(\Lambda)$ for the lattice and its determinant ($= \operatorname{cv}(\Gamma)$), F for the distance function ($F(y) = \|y\|$), and V for the volume of $F(y) \leq 1$. □

Theorem A.6.4. *All symbols introduced here are local to this statement and to the results that cite it. Let E be a CM field with maximal totally real subfield F such that E/F is unramified at every finite place, and let $j \geq 1$. An integral lattice M in a definite hermitian space W over E is* maximal *if no integral lattice of W contains it properly. For a maximal ideal $\mathfrak{p}$ of $\mathcal{O}_F$ let $M_\mathfrak{p} = (\mathcal{O}_F \setminus \mathfrak{p})^{-1}M$, $q_\mathfrak{p} = |\mathcal{O}_F/\mathfrak{p}|$, and*

$$\lambda_\mathfrak{p}(M) = \begin{cases} \dfrac{q_\mathfrak{p}^{\,j} - (-1)^j}{q_\mathfrak{p}+1} & \text{if } \mathfrak{p} \text{ is inert in } E \text{ and } (M_\mathfrak{p})^\vee \neq M_\mathfrak{p}, \\ 1 & \text{otherwise,} \end{cases}$$

the dual taken in W with respect to $(\mathcal{O}_F \setminus \mathfrak{p})^{-1}\mathcal{O}_E$. Then there is a real number $c(E,j) > 0$ such that for every definite hermitian space W over E of dimension j and every maximal integral lattice M in W:

1. *the genus of M is the set of all maximal integral lattices of W;*
2. *$\lambda_\mathfrak{p}(M) = 1$ for almost all $\mathfrak{p}$, and $\operatorname{mass}(M) = c(E,j)\prod_\mathfrak{p} \lambda_\mathfrak{p}(M)$;*
3. *(explicit value) let $d = [F:\mathbb{Q}]$, d_F the discriminant of F, χ the quadratic Hecke character of F attached to E/F, $\chi^i = 1$ for even i and $\chi^i = \chi$ for odd i, $L_F(s,\chi^i)$ the Hecke L-function of χ^i over F (for $i \geq 2$ the absolutely convergent Euler product $\prod_\mathfrak{p}(1-\chi^i(\mathfrak{p})q_\mathfrak{p}^{-i})^{-1}$; for $i = 1$ its value at $s = 1$). If M is unimodular ($M^\vee = M$), then*

$$\operatorname{mass}(M) = 2\,d_F^{\,j^2/2} \prod_{i=1}^{j} \Big(\frac{(i-1)!}{(2\pi)^i}\Big)^d L_F(i,\chi^i),$$

and this number is $c(E,j)$.

Proof. [97], Propositions 4.4 and 4.5 (Shimura's exact mass formula for maximal lattices in totally definite hermitian spaces, derived from Proposition 2.13 there through Bruhat–Tits theory; the stabiliser of a maximal lattice at a finite place is a maximal parahoric subgroup). As printed: for a maximal lattice Λ in a totally definite hermitian space V of dimension m over a totally imaginary quadratic extension L of a totally real field k of degree d, with G the unitary group of V, $\mathrm{Mass}(\Lambda) = \big(2^{-md} L(M)\tau(G)\big) \prod_{v\in S} \lambda_v$, where $L(M) = \prod_{r=1}^{m} L(1-r, \chi^r)$ (loc. cit., (4.2); the mass is positive and equals this expression with $L(M)$ replaced by $|L(M)|$, whose sign is that of item (iii)), $\tau(G) = 2$ ((4.3), Kottwitz, Ono), and, at a finite place v unramified in L, $v \in S$ if and only if v does not split and $V \otimes_k k_v \cong V_\alpha$ with $\alpha \notin \mathbb{N}L_v^\times$, in which case $\lambda_v = (q_v^m + 1)/(q_v + 1)$ for odd m and $\lambda_v = (q_v^m - 1)/(q_v + 1)$ for even m, that is $\lambda_v = (q_v^m - (-1)^m)/(q_v + 1)$ (loc. cit., Tables 1 and 2 and Propositions 4.4, 4.5; ramified places, which also lie in S, do not occur here). The condition $v \in S$ is the condition $(M_\mathfrak{p})^\vee \neq M_\mathfrak{p}$ of the statement: by loc. cit., (3.2), (3.3), (3.8), the maximal lattices of V_α are the conjugates of $\Delta^n + \mathcal{O}_{L_v}$ with the form $\alpha x\bar{y}$ on the last summand ($m = 2n+1$), respectively of Δ^n or $\Delta^{n-1} \oplus \mathcal{O}_D$ ($m = 2n$), with Δ the self-dual hyperbolic plane (the different is trivial), and the representative α is a unit exactly when it is a norm; so a maximal lattice is self-dual if and only if $v \notin S$. The mass of Λ is defined there as $\mathrm{Mass}(K)$, the volume of $G(k)\backslash G(\mathbb{A})$ for the Haar measure giving $K = G(k\otimes\mathbb{R}) \times \prod_v K_v$ volume 1, K_v the stabiliser of Λ_v ((2.2), (4.1)). Item (i) is the classical fact that the maximal lattices of a hermitian space form one genus ([270]; locally, the maximal lattices of a hermitian space over a $\mathfrak{p}$-adic field are conjugate under its unitary group, Jacobowitz 1962, [147]), on which the mass formula rests. Map of notation: the group is $\mathrm{U}(W)$, the mass of $K = \prod_v \mathrm{Stab}(M_v)$ is $\sum 1/|\Gamma_i|$ over the classes of the genus of M, which is $\mathrm{mass}(M)$; the constant $c(E, j)$ is the global factor of the formula, which depends only on the quasi-split inner form, i.e. on E/F and j. Since E/F is unramified at the finite places, the inverse different of E/F is $\mathcal{O}_E$, so $h(M, M) \subseteq \mathcal{O}_E$ if and only if $h(x, x) \in \mathcal{O}_F$ for all $x \in M$: maximality with respect to the scale (as here) and with respect to the norm ideal (as in the paper) agree. At split places every maximal lattice is self-dual and its factor is 1; no ramified place occurs.

Item (iii) is the exact mass formula for unimodular hermitian lattices, [303], Theorem 2.3.4 and its formula (2.6), which is the mass formula of Gan–Yu [99], Theorem 10.20, with the Tamagawa number $\tau(\mathrm{U}(W)) = 2$ (Kottwitz, Ono):

$$\mathrm{Mass}(\Lambda) = \Big(\prod_{i=1}^{j} (2\pi)^i/(i-1)!\Big)^{-d} |\mathcal{O}_F/\mathfrak{d}_{E/F}|^{j(j+1)/4}\, \tau\, d_F^{j^2/2} / \prod_v \beta_v,$$

where at a finite place v unramified in E the local density of a unimodular lattice is $\beta_v^{-1} = \prod_{i=1}^{j} L_{F_v}(i, \chi^i)$ (loc. cit., Lemma 2.2.4, from $|\mathrm{U}_j(\mathbb{F}_q)| = q^{j(j-1)/2} \prod_i (q^i - (-1)^i)$ and $|\mathrm{GL}_j(\mathbb{F}_q)|$ for the smooth reductive model of the stabiliser, [99], Theorem 7.3), and the product over v is written as $\prod_i L_F(i, \chi^i)$ (loc. cit., before (2.9)). Map of notation: their n, d, Λ, χ_E are our j, d, M, χ; since E/F is unramified at every finite place, $\mathfrak{d}_{E/F} = \mathcal{O}_F$, there is no place $v \mid d_{E/F}$, and $|\mathcal{O}_F/\mathfrak{d}_{E/F}| = 1$; for definite W the group $\mathrm{U}(W)(F\otimes\mathbb{R})$ is compact, their Haar measure $\mu_{c,\mathbb{R}}$ has total volume 1, and $\mathrm{Mass}(\Lambda) = \sum_{[g]} 1/|\Gamma_g|$ over the classes of the genus with $\Gamma_g = \mathrm{Aut}$ of the class representative, which is $\mathrm{mass}(M)$. A unimodular M is maximal (an integral $M' \supseteq M$ satisfies $M' \subseteq M'^\vee \subseteq M^\vee = M$) and has $\lambda_\mathfrak{p}(M) = 1$ for every $\mathfrak{p}$, so by item (ii) $\mathrm{mass}(M) = c(E, j)$; as $\mathcal{O}_E^j$ with $h(x, y) = \sum \bar{x}_i y_i$ is unimodular, $c(E, j)$ is the displayed number. Equivalently (loc. cit., (2.9), by the functional equations), $c(E, j) = (-1)^s\, 2^{1-jd} \prod_{i=1}^{j} L_F(1-i, \chi^i)$ with $s = 0$ for odd j and $s = jd/2$ for even j. □

Lemma A.6.5. *Let C be a finite set and $G \in M_C(\mathbb{C})$ a positive definite hermitian matrix. For a finite family $v = (v_i)_{i\in I}$ in $\mathbb{C}^C$ put $\mathrm{Gr}_G(v) = (v_i^* G v_k)_{i,k\in I}$, and for two families $v = (v_i)_{i\in I}$, $w = (w_k)_{k\in I}$ indexed by the same finite set put $\mathrm{Gr}_G(v, w) = (v_i^* G w_k)_{i,k\in I}$.*

(a) ***Fischer.*** *If* $M = \begin{pmatrix} M_{11} & M_{12} \\ M_{21} & M_{22} \end{pmatrix}$ *is a positive semidefinite hermitian matrix with square diagonal blocks* M_{11}, M_{22}, *then* $0 \le \det M \le \det M_{11} \cdot \det M_{22}$.

(b) ***Hadamard.*** *If* $h \in \mathbb{R}$ *and* $v_i^* G v_i \le e^h$ *for all* $i \in I$, *then* $0 \le \det \mathrm{Gr}_G(v) \le e^{\#I\, h}$.

(c) ***Cauchy–Schwarz.*** $|\det \mathrm{Gr}_G(v,w)|^2 \le \det \mathrm{Gr}_G(v) \cdot \det \mathrm{Gr}_G(w)$.

(d) ***Change of basis.*** *Let* $\Theta\colon V \to S$ *be a linear map of finite-dimensional complex inner product spaces and* $w = (w_p)$ *a basis of* V. *Then* $\det(\langle \Theta w_p, \Theta w_q\rangle)_{p,q} = \det(\Theta^*\Theta) \cdot \det(\langle w_p, w_q\rangle)_{p,q}$.

Proof. Quoted. (a) is Fischer's inequality and (b) Hadamard's inequality for positive semidefinite hermitian matrices ([133], Theorem 7.8.5 and Theorem 7.8.1); for (b), $\mathrm{Gr}_G(v)$ is the Gram matrix of v for the positive definite form $(a,b) \mapsto a^*Gb$, hence positive semidefinite with diagonal entries $v_i^*Gv_i \in [0, e^h]$. (c) The form $(a,b) \mapsto a^*Gb$ induces on $\bigwedge^{\#I} \mathbb{C}^C$ a positive semidefinite hermitian form with $\langle v_1 \wedge \cdots \wedge v_n, w_1 \wedge \cdots \wedge w_n\rangle = \det \mathrm{Gr}_G(v,w)$ (Cauchy–Binet), and (c) is the Cauchy–Schwarz inequality for it. (d) Let e be an orthonormal basis of V and W the matrix with $w_q = \sum_p W_{pq} e_p$. Then $(\langle \Theta w_p, \Theta w_q\rangle) = W^*AW$ and $(\langle w_p, w_q\rangle) = W^*W$ with $A = (\langle \Theta e_p, \Theta e_q\rangle)$ the matrix of $\Theta^*\Theta$ in e; take determinants. □

Theorem A.6.6. *Let* C *be a commutative ring,* $N, k \ge 1$ *integers,* $A_1, \dots, A_k \in \mathrm{M}_N(C)$, *and* $t_1, \dots, t_k$ *commuting indeterminates. For a word* $w = i_1 i_2 \cdots i_p$ *in the alphabet* $\{1, \dots, k\}$ *put* $A_w = A_{i_1} A_{i_2} \cdots A_{i_p}$ *and* $t_w = t_{i_1} t_{i_2} \cdots t_{i_p}$. *Then, in the ring of formal power series* $C[[t_1, \dots, t_k]]$,

$$\det\Bigl(1 - \sum_{i=1}^{k} t_i A_i\Bigr) = \prod_{w} \det(1 - t_w A_w),$$

the product running over all Lyndon words w *in the alphabet* $\{1, \dots, k\}$ *(the non-empty words that are strictly smaller, for the lexicographic order, than each of their proper suffixes); it converges in the* $(t_1, \dots, t_k)$*-adic topology, since* t_w *has degree equal to the length of* w *and there are finitely many words of each length.*

Proof. [6]; short proof from Lyndon's factorisation of the free monoid by C. Reutenauer and M.-P. Schützenberger [240]; the form used here is [82, (1.12)], applied to the matrices $t_i A_i$ with entries in $C[[t_1, \dots, t_k]]$. The identity is one of formal power series with coefficients that are integral polynomials in the entries of the A_i, so it holds over every commutative ring. □

Theorem A.6.7. *Let* K *be a field of characteristic different from* 2 *with an automorphism* $x \mapsto \bar{x}$ *of order* 2, *let* V *be a finite-dimensional* K*-vector space and* $h\colon V \times V \to K$ *a nondegenerate hermitian form (*h *is biadditive,* $h(ax, by) = \bar{a}\, b\, h(x,y)$ *and* $h(y,x) = \overline{h(x,y)}$ *for* $a, b \in K$, $x, y \in V$*). Let* $U \subseteq V$ *be a subspace and* $\sigma\colon U \to V$ *an injective* K*-linear map with* $h(\sigma u, \sigma u') = h(u, u')$ *for all* $u, u' \in U$. *Then there is a* K*-linear isometry* s *of* (V, h) *with* $s|_U = \sigma$.

Proof. This is Witt's theorem for hermitian forms; see [249], Chapter 7 (Witt's theorem for regular ε-hermitian spaces over a division ring with involution; here the division ring is the field K, $\varepsilon = 1$ and the involution is $x \mapsto \bar{x}$). Notation map: a regular hermitian space is a pair (V, h) with h nondegenerate; an isometry $U \to \sigma U$ of subspaces is an injective linear map preserving h. The statement is the special case of a commutative division ring; it is stated for the linear-second convention of the project, which differs from the linear-first convention by exchanging the arguments of h and does not change the isometries. □

Theorem A.6.8. *Let F_v be a finite extension of $\mathbb{Q}_p$, E_v/F_v a quadratic field extension with nontrivial automorphism $x \mapsto \bar{x}$, and $\mathrm{N} = \mathrm{N}_{E_v/F_v}$. For a nondegenerate hermitian space (W, h) over E_v of dimension $r \geq 1$, the determinant $\det\big(h(w_i, w_j)\big)_{i,j}$ of the Gram matrix of a basis (w_i) lies in $F_v^\times$, and its class $d(W) \in F_v^\times/\mathrm{N}(E_v^\times)$ does not depend on the basis. Two nondegenerate hermitian spaces over E_v of the same dimension are isometric if and only if they have the same class d.*

Proof. [147] (the classification of hermitian spaces over local fields); see also [249], Chapter 10. Notation: Jacobowitz's discriminant of a space is the class $d(W)$ here. The determinant lies in F_v because the Gram matrix H satisfies $\bar{H}^\top = H$, so $\overline{\det H} = \det H$; a change of basis by $g \in \mathrm{GL}_r(E_v)$ replaces H by $\bar{g}^\top H g$ and $\det H$ by $\mathrm{N}(\det g)\det H$. □

Theorem A.6.9. *Let E be a number field with ring of integers $\mathcal{O}_E$ and Dedekind zeta function ζ_E, and let $r \geq 1$ be an integer. For every complex number s with $\operatorname{Re} s > r$ the series*

$$\sum_{L} [\mathcal{O}_E^r : L]^{-s},$$

over all $\mathcal{O}_E$-submodules $L \subseteq \mathcal{O}_E^r$ of finite index, converges absolutely, and

$$\sum_{L} [\mathcal{O}_E^r : L]^{-s} = \prod_{j=0}^{r-1} \zeta_E(s-j).$$

Proof. This is Solomon's formula for the zeta function of the order $\mathcal{O}_E$ acting on the free module $\mathcal{O}_E^r$ [286]. Notation: the sum over submodules of finite index of $\mathcal{O}_E^r$ is the zeta function $\zeta_{\mathcal{O}_E^r}(s)$ of the module there, the index $[\mathcal{O}_E^r : L]$ is the cardinality of $\mathcal{O}_E^r/L$, and ζ_E is the Dedekind zeta function of E; in the case $E = \mathbb{Q}$ the formula reads $\sum_L [\mathbb{Z}^r : L]^{-s} = \zeta(s)\zeta(s-1)\cdots\zeta(s-r+1)$. □

Theorem A.6.10. *Let k be an algebraically closed field of characteristic zero and A a finite-dimensional associative unital k-algebra. Its Jacobson radical J is a nilpotent two-sided ideal, and A/J is isomorphic to a finite product of full matrix algebras $\mathrm{M}_{d_i}(k)$. In particular, if $J = 0$, then A itself is such a product.*

Proof. The radical theorem for finite-dimensional algebras and the Artin–Wedderburn theorem; see N. Jacobson, Basic Algebra II, second edition, 1989, the structure theory of Artinian rings. Over an algebraically closed field every finite-dimensional division algebra is the field itself: each element has an eigenvalue for its left multiplication and therefore differs from that scalar by a noninvertible element. □

Acknowledgements

This paper was prepared with the assistance of Aleph, an AI research assistant for mathematics, using AI models from Anthropic (Claude), OpenAI (ChatGPT) and Google (Gemini) together with bespoke models, as well as Claude Code and Codex for converting the Lean source into structured definitions and results in conventional language. The author thanks J. Adriazola for sharing his parallel work on GitHub and A. Dujella and M. Kazalicki for helpful comments. All credit for the proof belongs to Alpöge; all errors of exposition are ours.
