

Stopa stapanja galaksija; veza s udjelom  
bliskih parova i vremenom stapanja

Filip Huško,  
30.01.2020.

Stopa stapanja galaksija; veza s udjelom  
bliskih parova i vremenom stapanja

$$\frac{dN}{dt} = \frac{f}{T}$$

Stopa stapanja galaksija; veza s udjelom  
bliskih parova i vremenom stapanja

$$\frac{dN}{dt}(M_*, z) = \frac{f(M_*, z)}{T(M_*, z)}$$

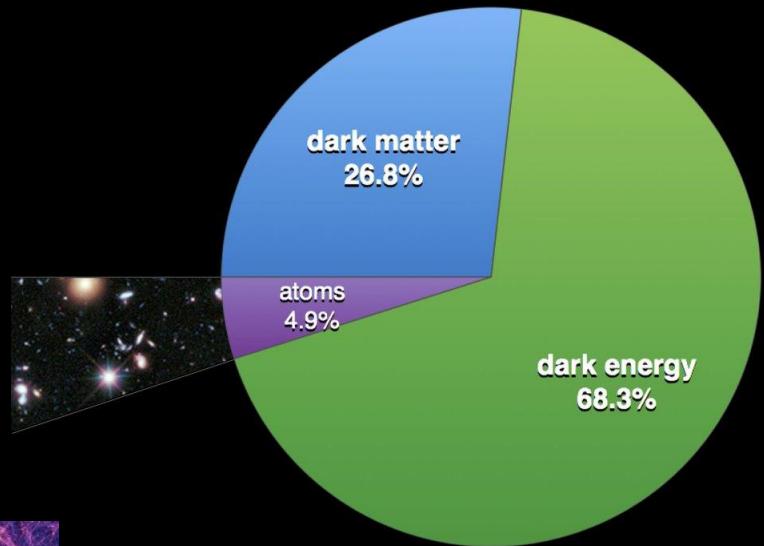

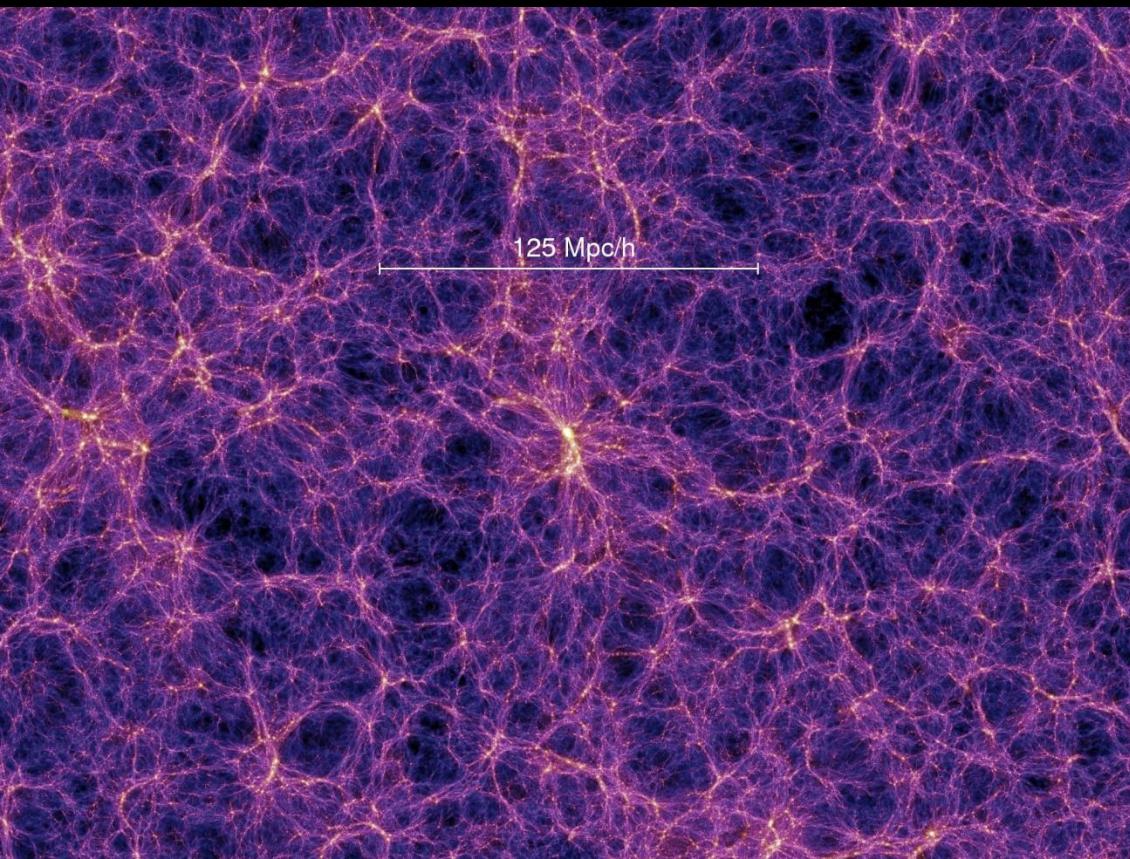

# Stopa stapanja galaksijskih parova; veza s udjelom bliskih parova i vremenom stapanja

$$\frac{dN}{dt}(M_*, z, \mu_*) = \frac{f(M_*, z, \mu_*, r_{\text{sep}}, v_{\text{sep}})}{T(M_*, z, \mu_*, r_{\text{sep}}, v_{\text{sep}})}$$

# N-body kozmološka simulacija:

- Millennium simulacija:  $V=(800 \text{ Mpc})^3$ ,  $(5040)^3$  čestica,  $M_{\text{čestice}} \approx 10^8 M_{\text{sol}}$ , 269 outputa

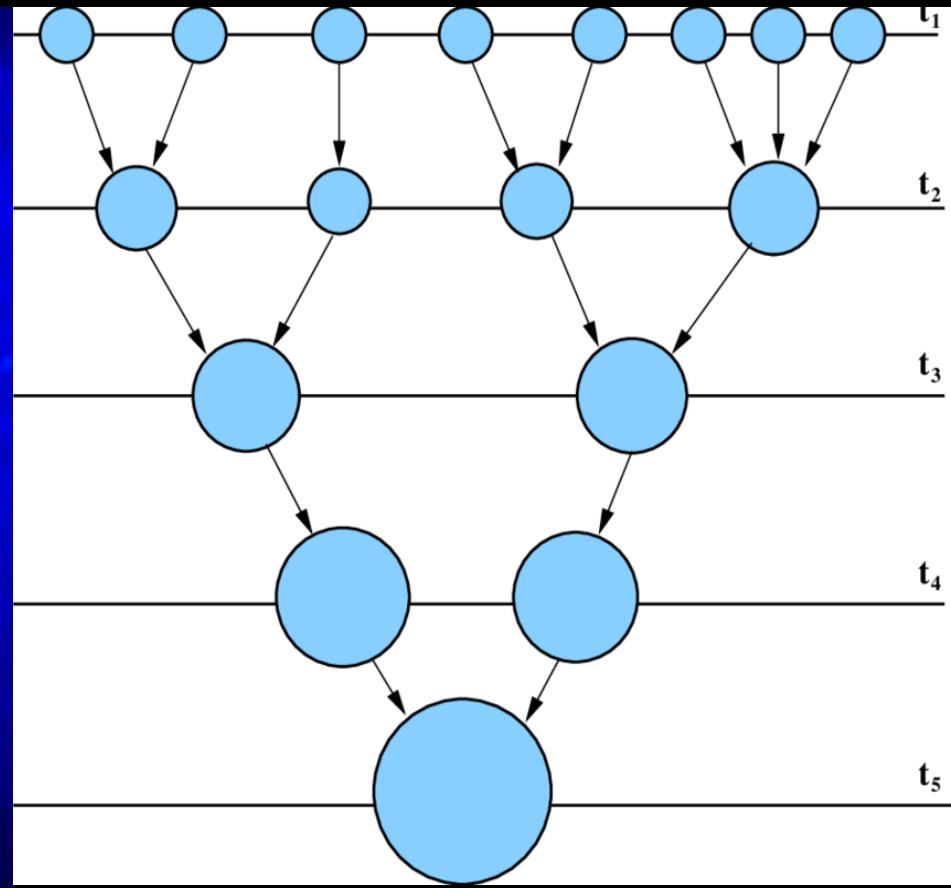

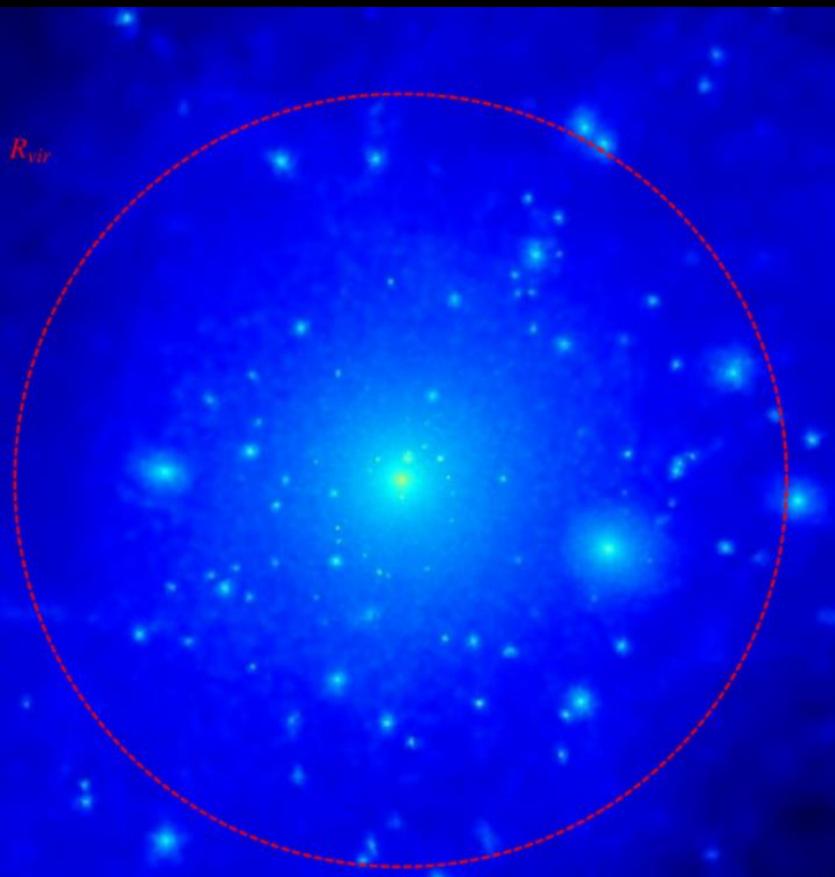

- Planck kozmološki parametri:  $\Omega_m=0.32$ ,  $\Omega_\Lambda=0.68$ ,  $\Omega_b=0.05$ ,  $h=0.067$

# N-body kozmološka simulacija:

- haloi tamne tvari s gustoćom:

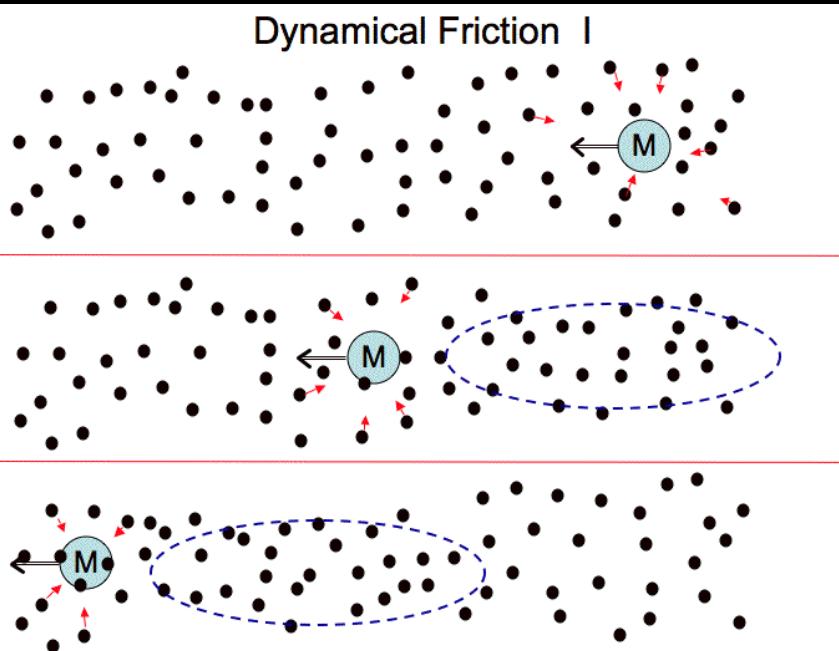

$$\rho(r) = \frac{\rho_0}{r/r_s(1+r/r_s)^2}$$

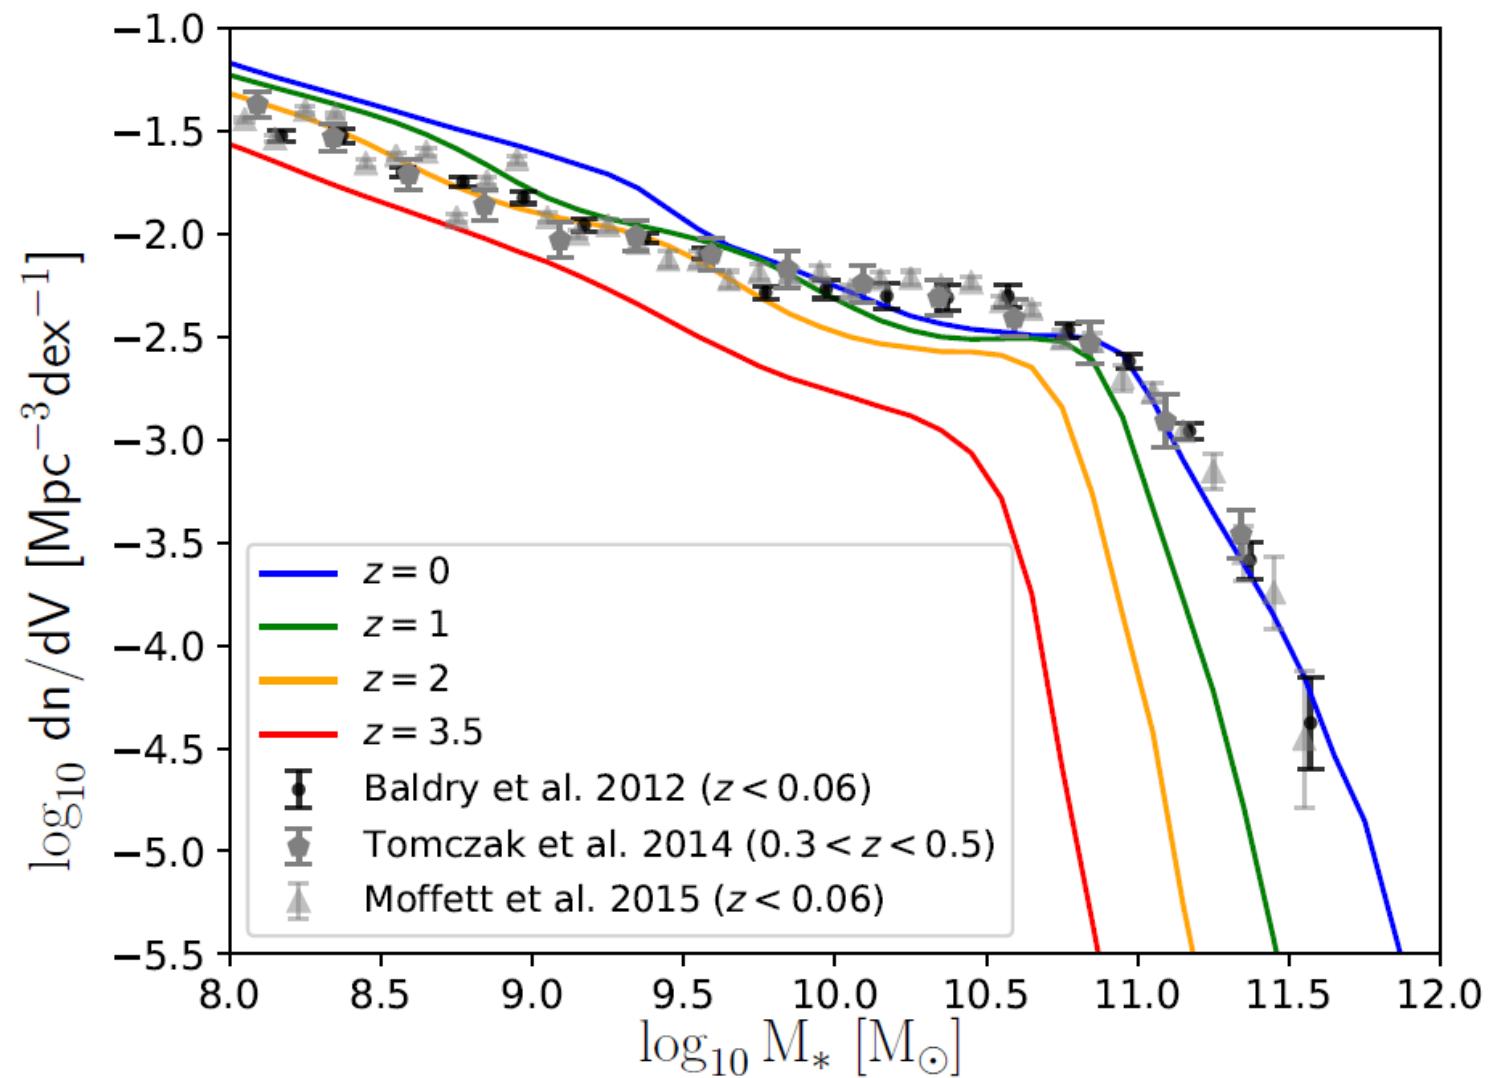

# GALFORM model formacije galaksija:

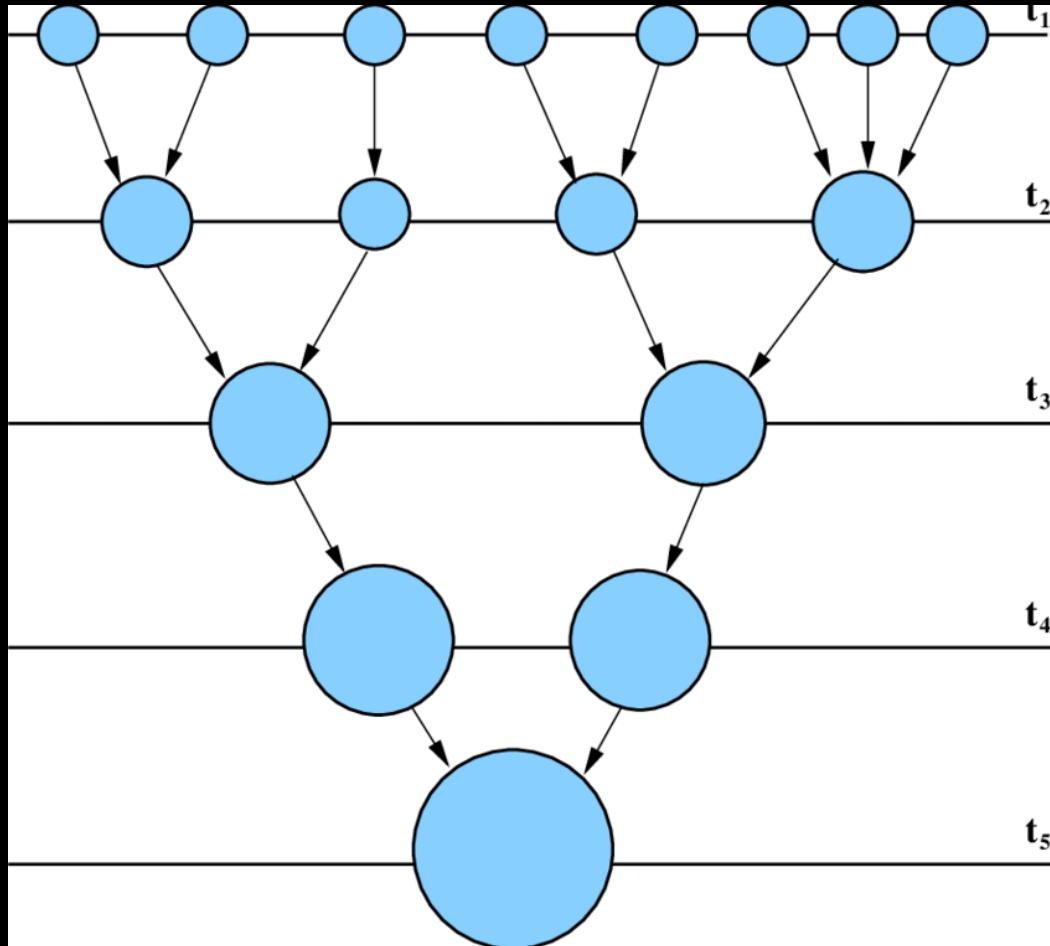

- uključuje upad plina, njegovo izbacivanje kroz supernova i AGN feedback, formacije zvijezda, stapanje galaksija i mnoge druge efekte
- potrebno analitički modelirati upad podhaloa u glavnom halou nakon što se dostigne granična rezolucija

$$\tau \approx \frac{16}{5} \sqrt{\frac{\rho_0}{G}} \frac{r_s}{m \ln(1 + M/m)} R_0^2.$$

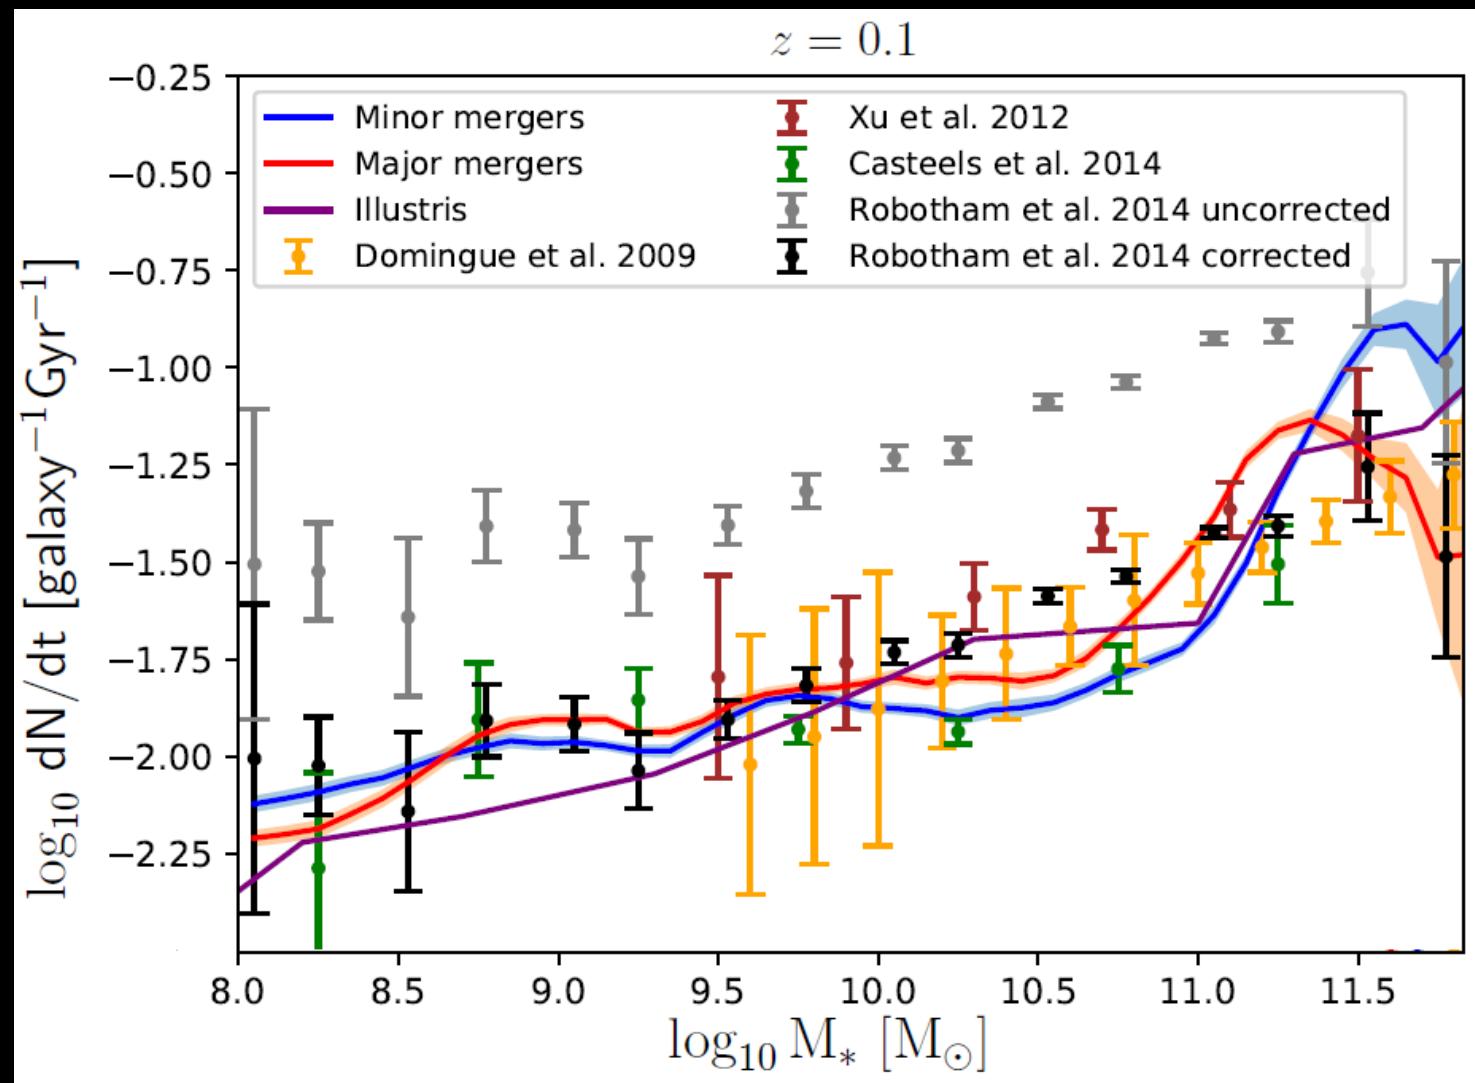

## Stopa stapanja u GALFORM-u:

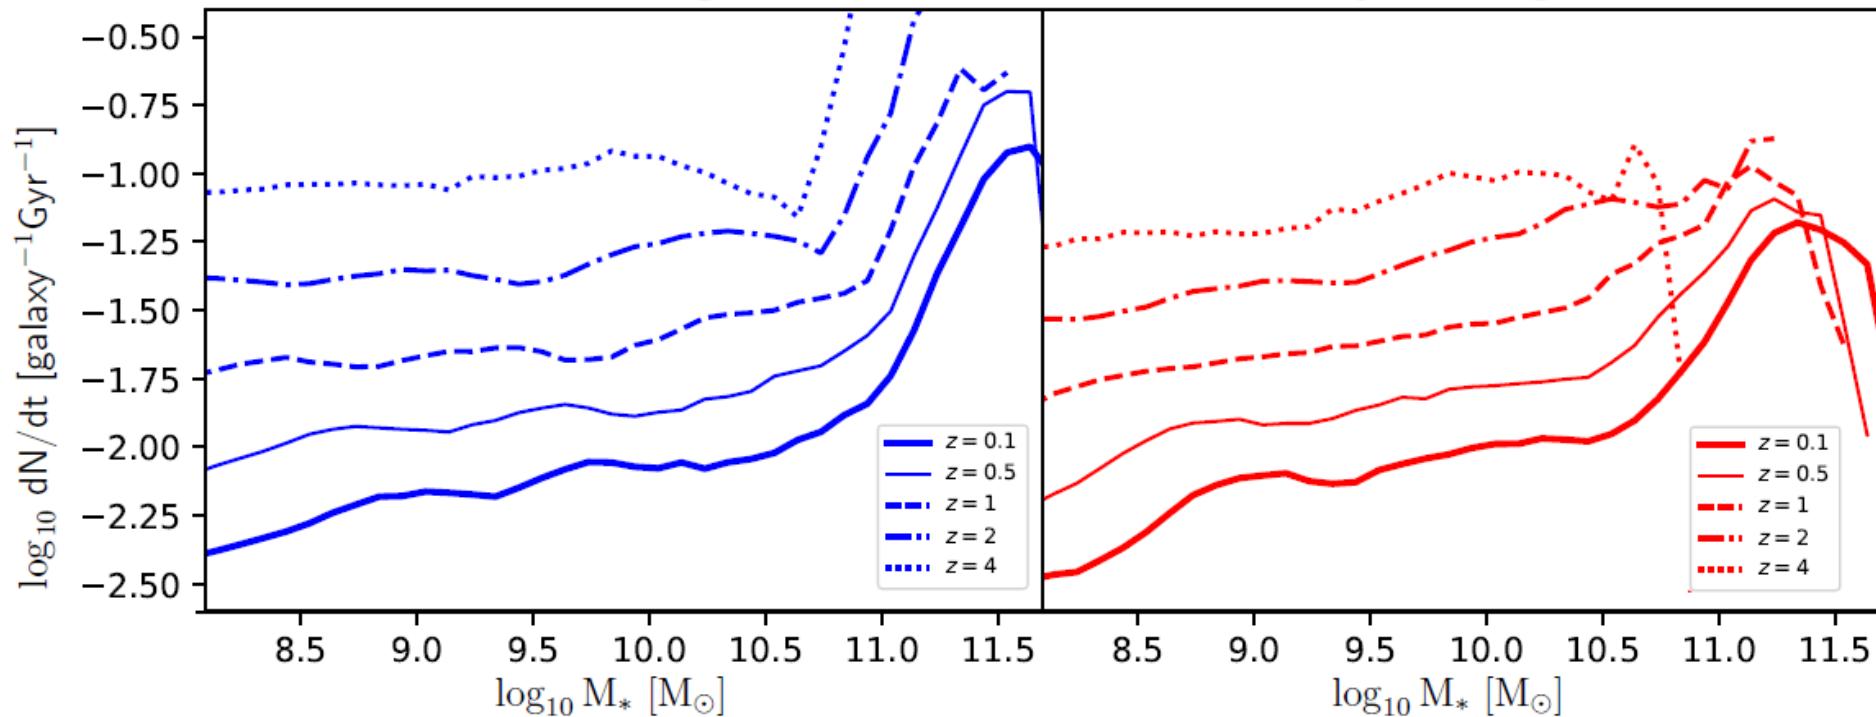

$$\frac{dN}{dt} = \frac{\Delta N_{\text{merg}}}{\Delta N \Delta t}$$

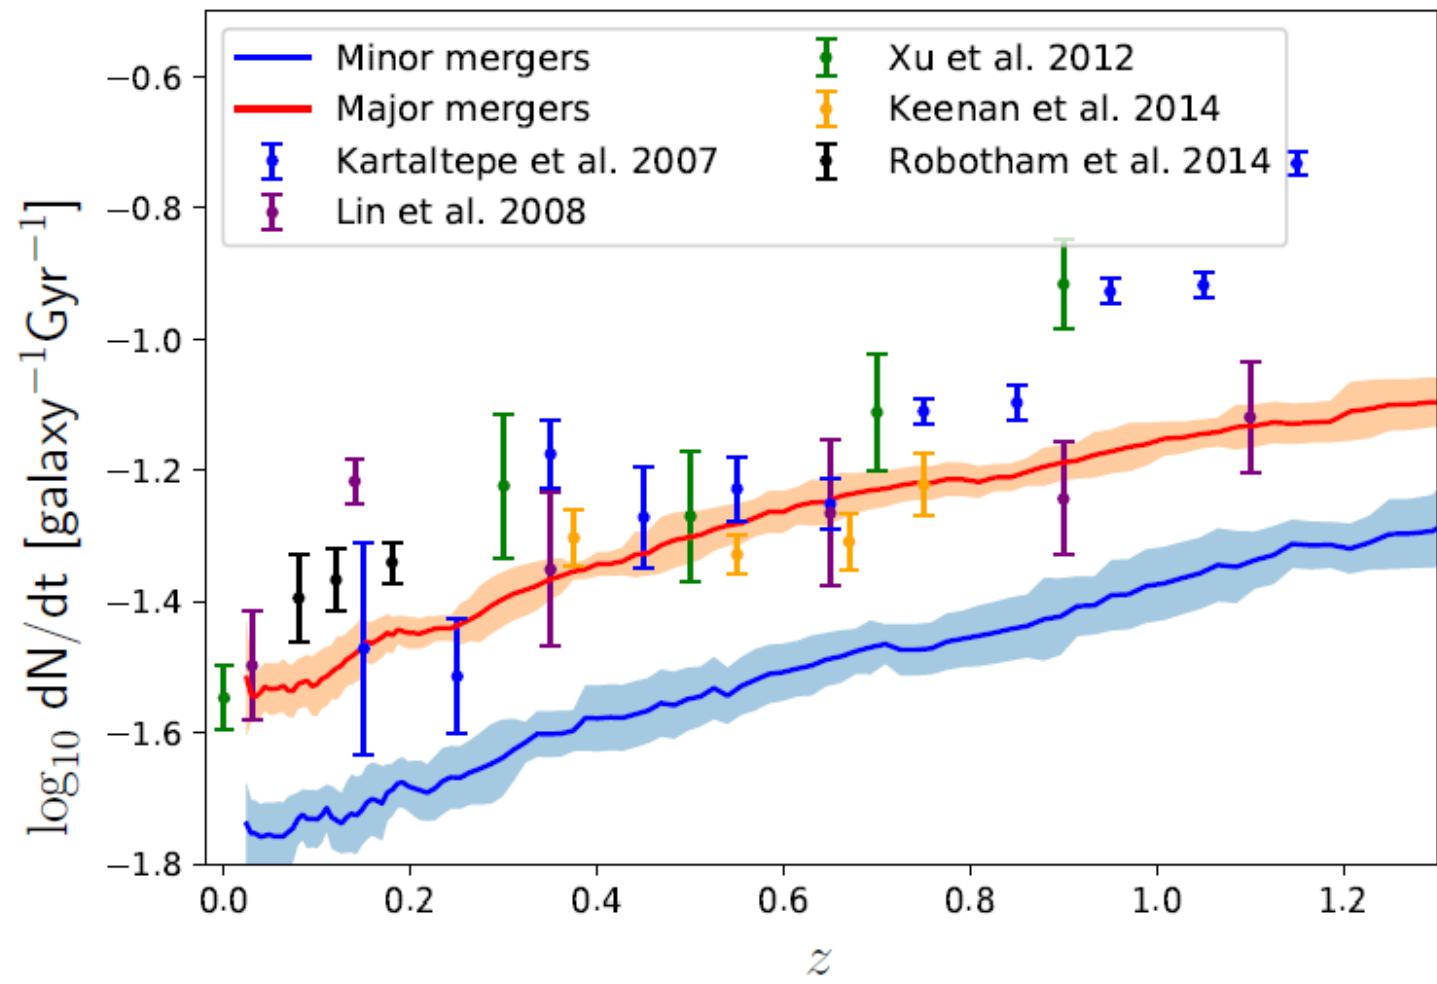

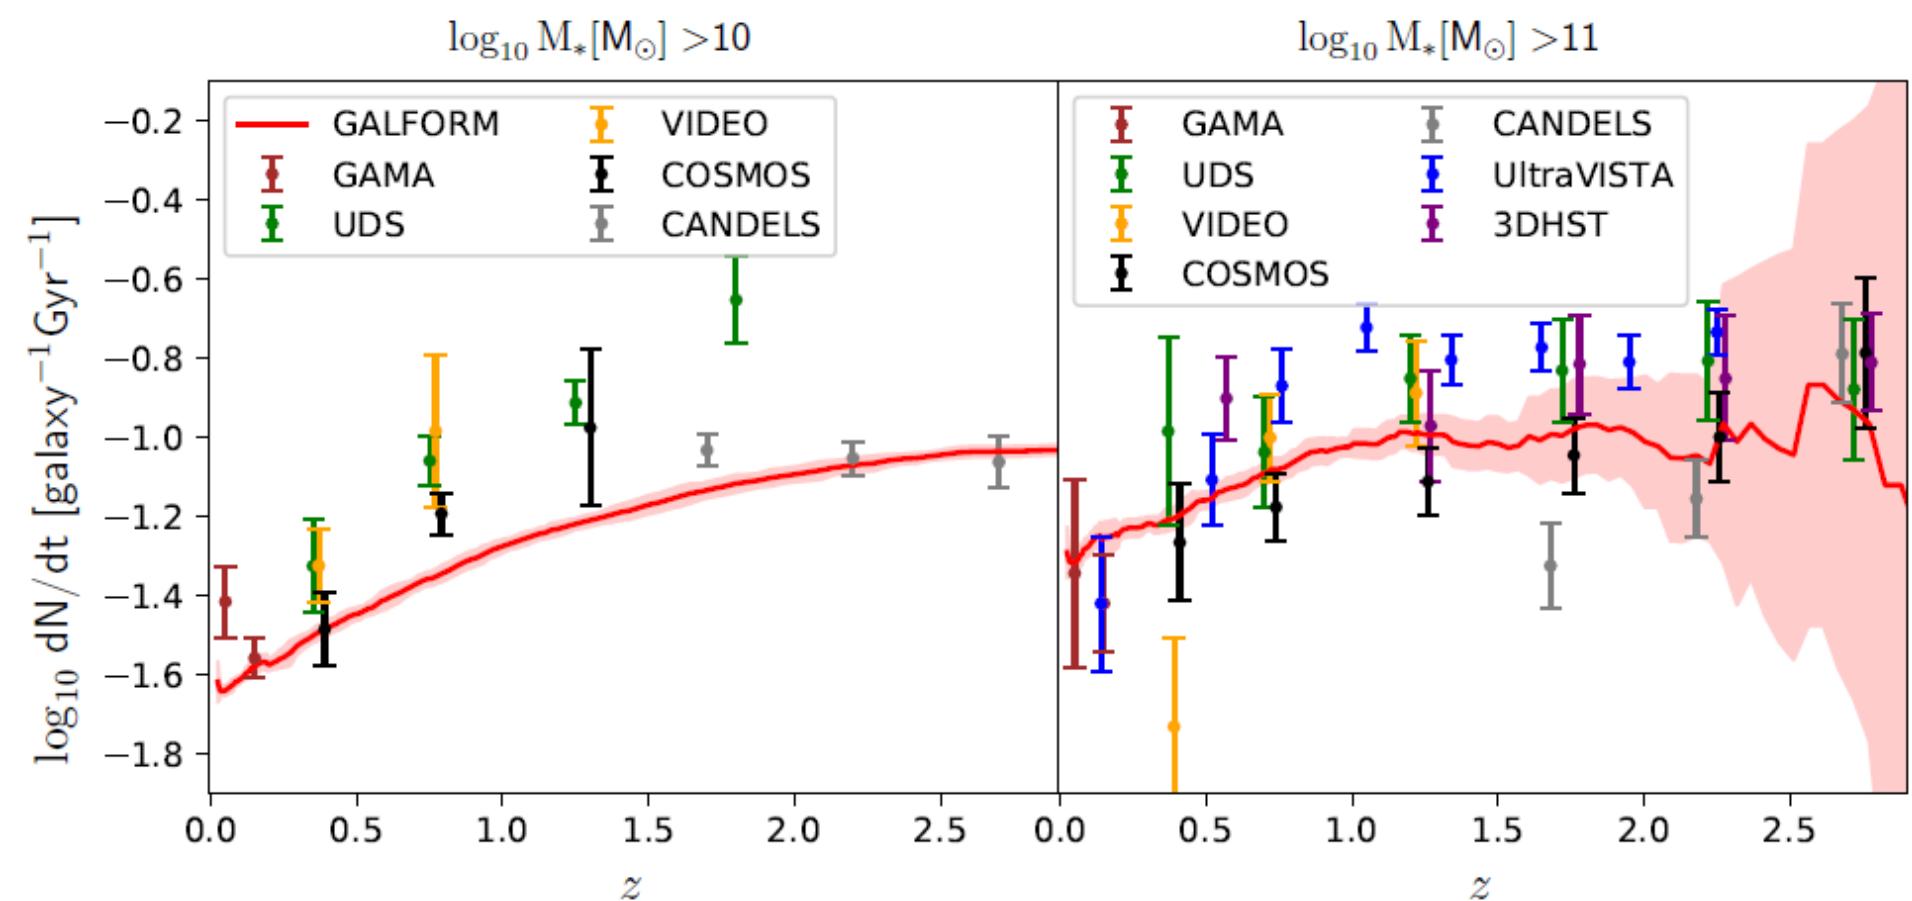

Minor mergers

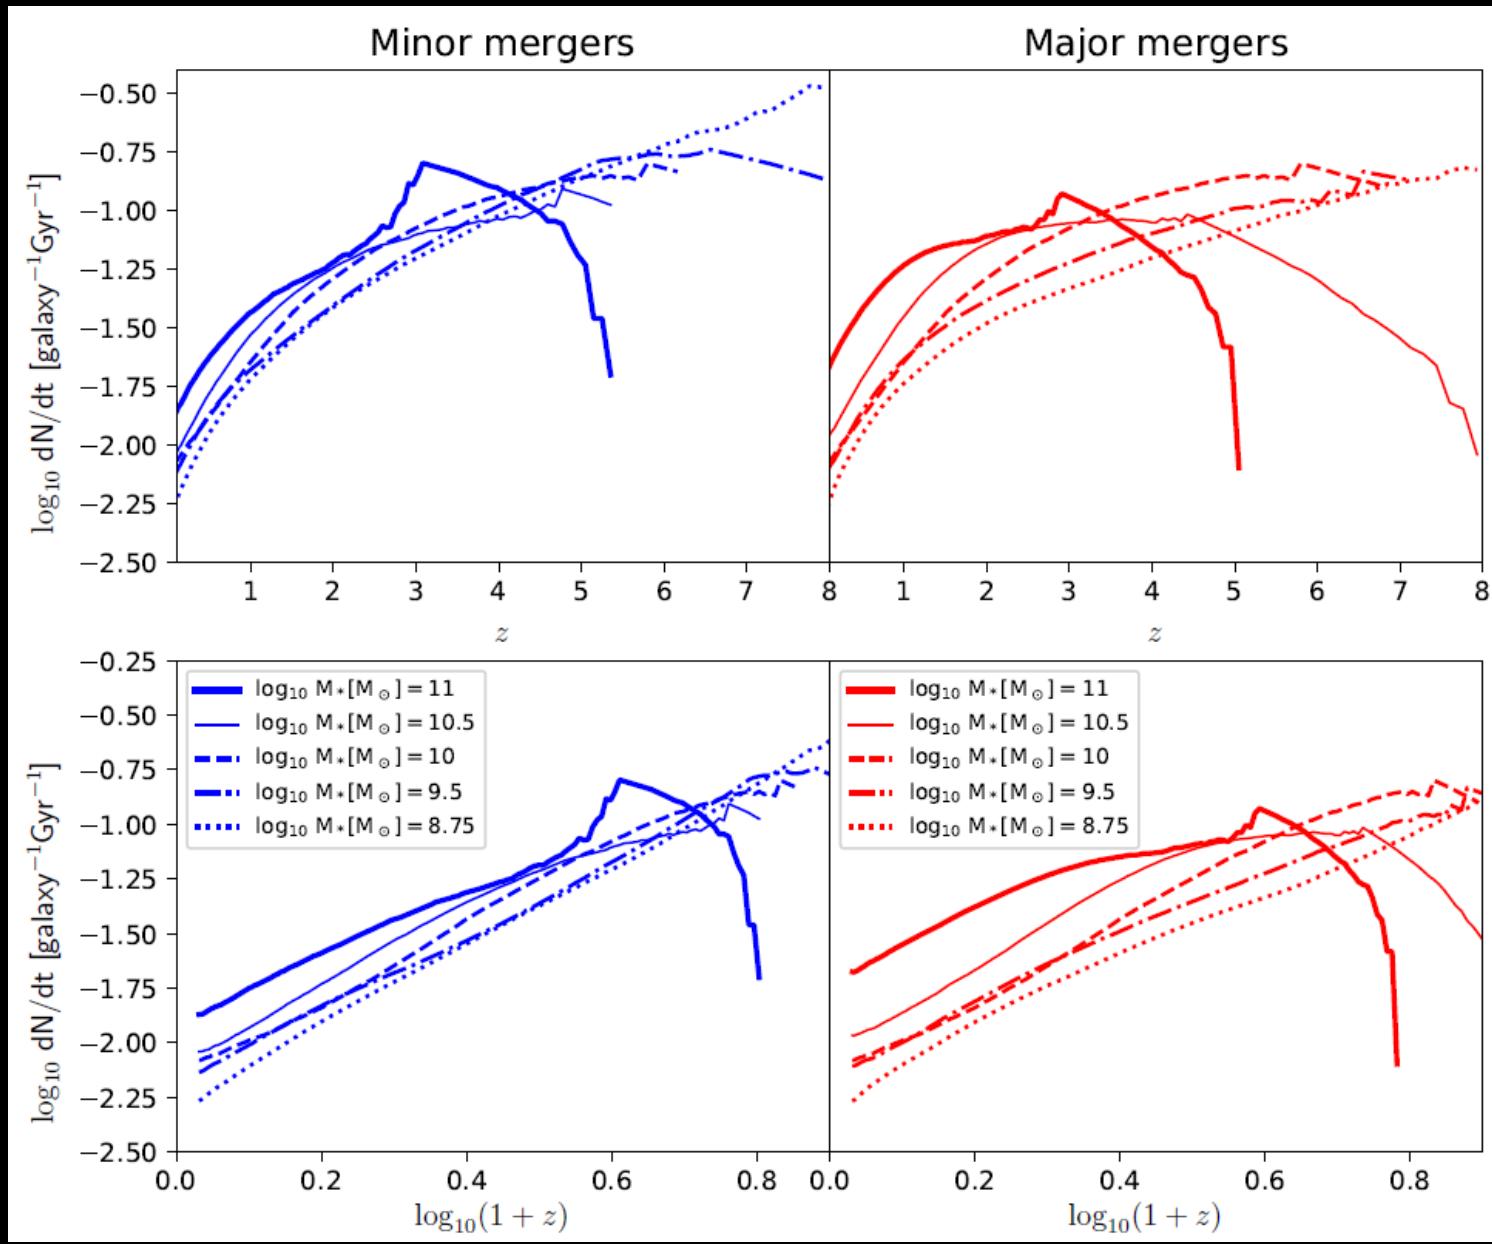

Major mergers

$$\log_{10} M_* [\text{M}_\odot] = 10.8$$

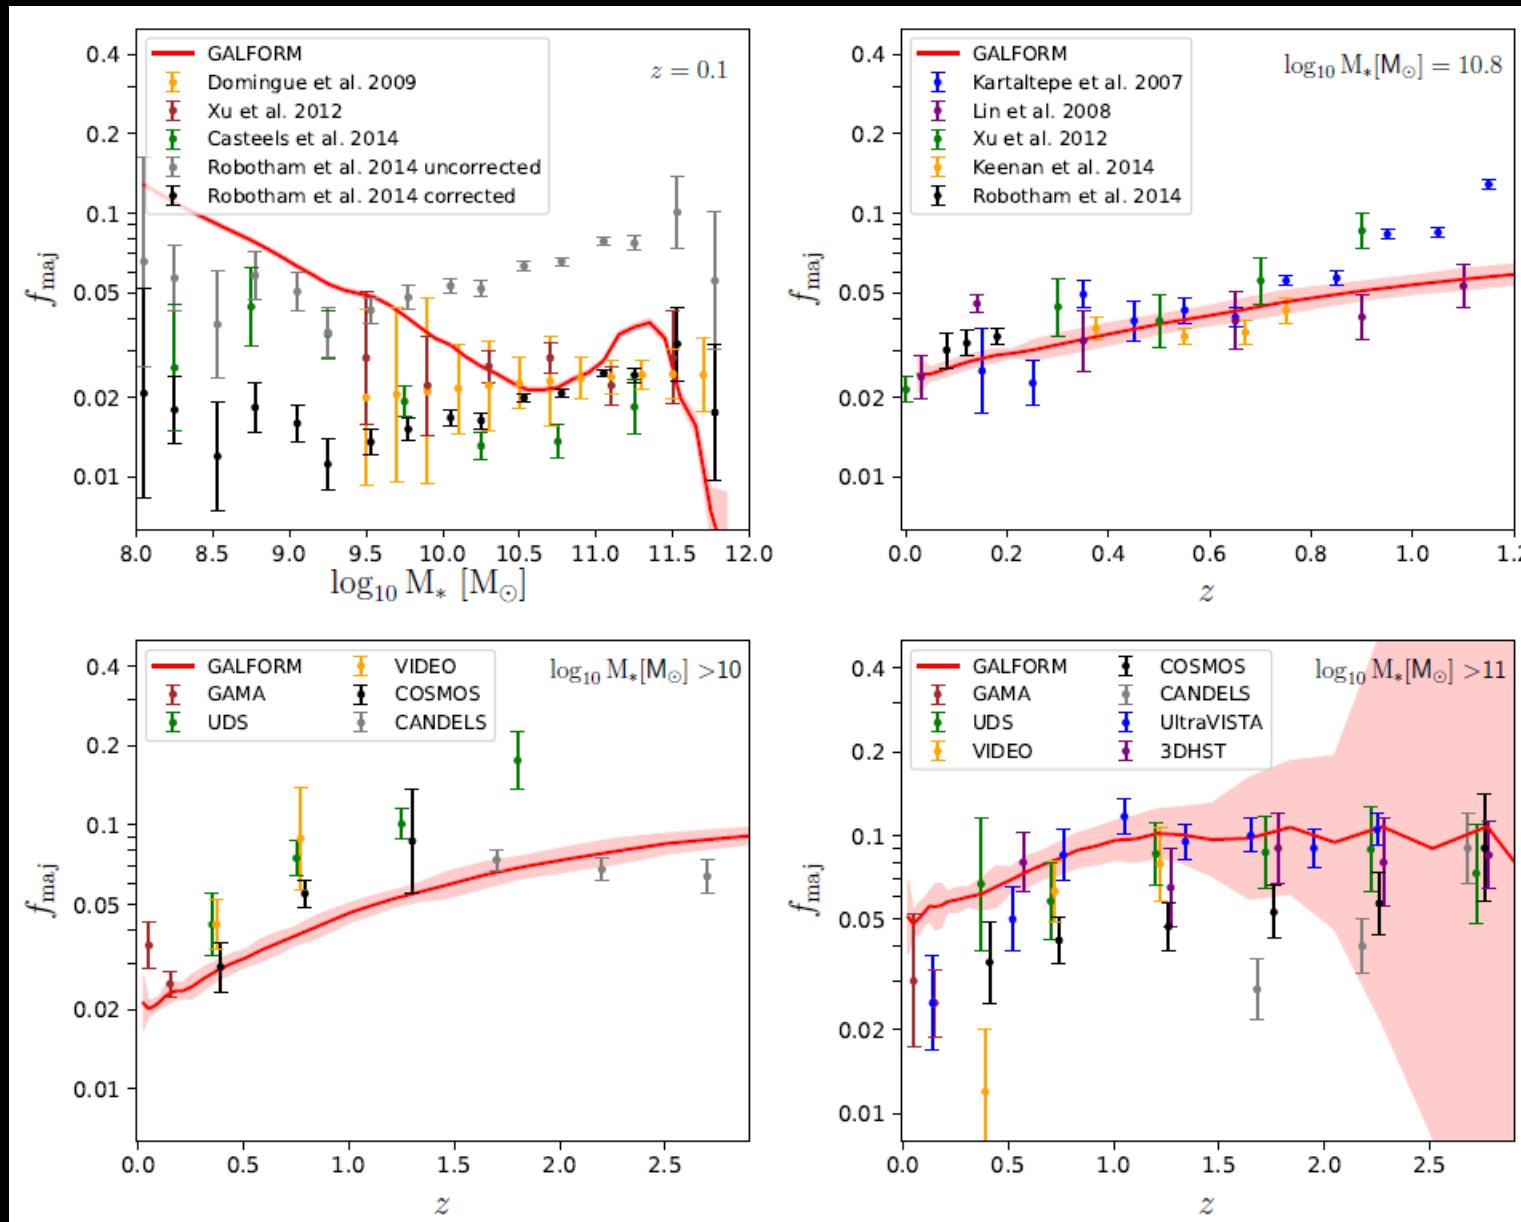

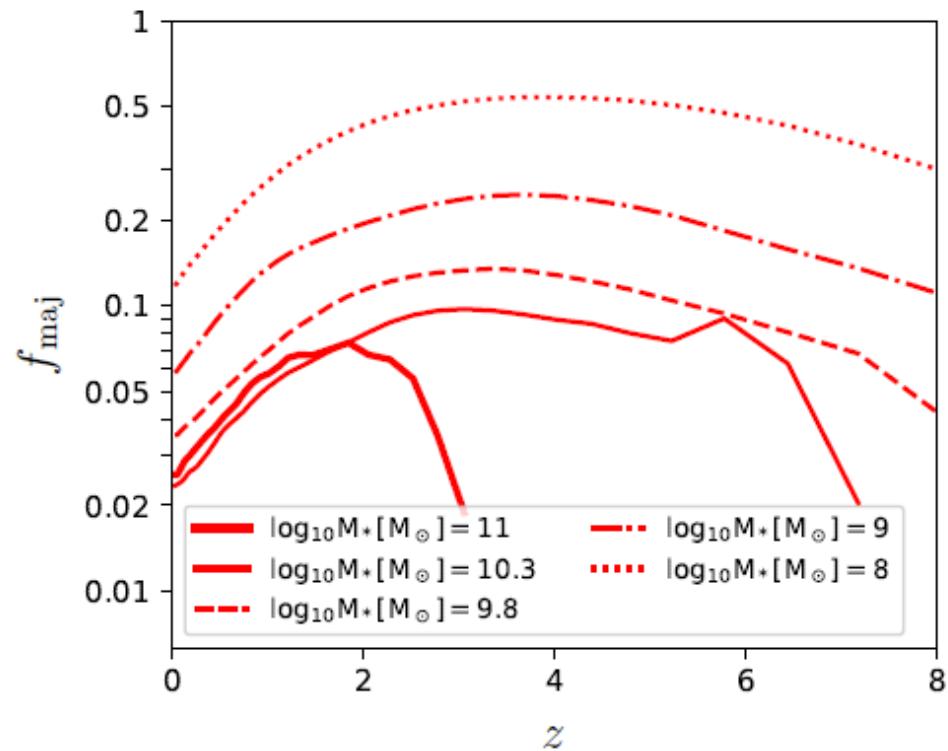

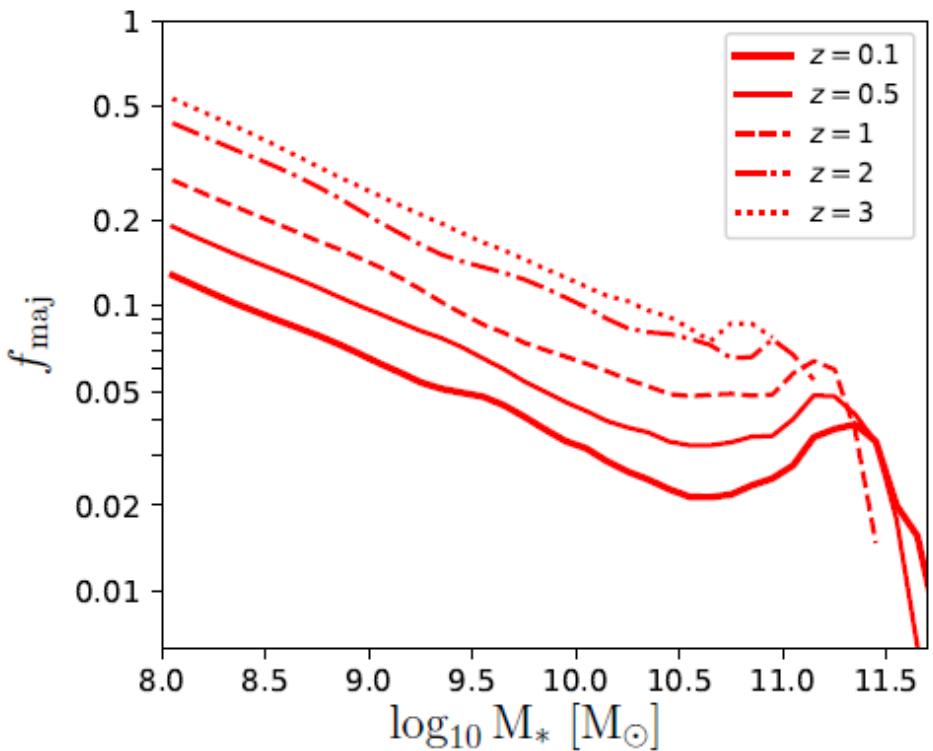

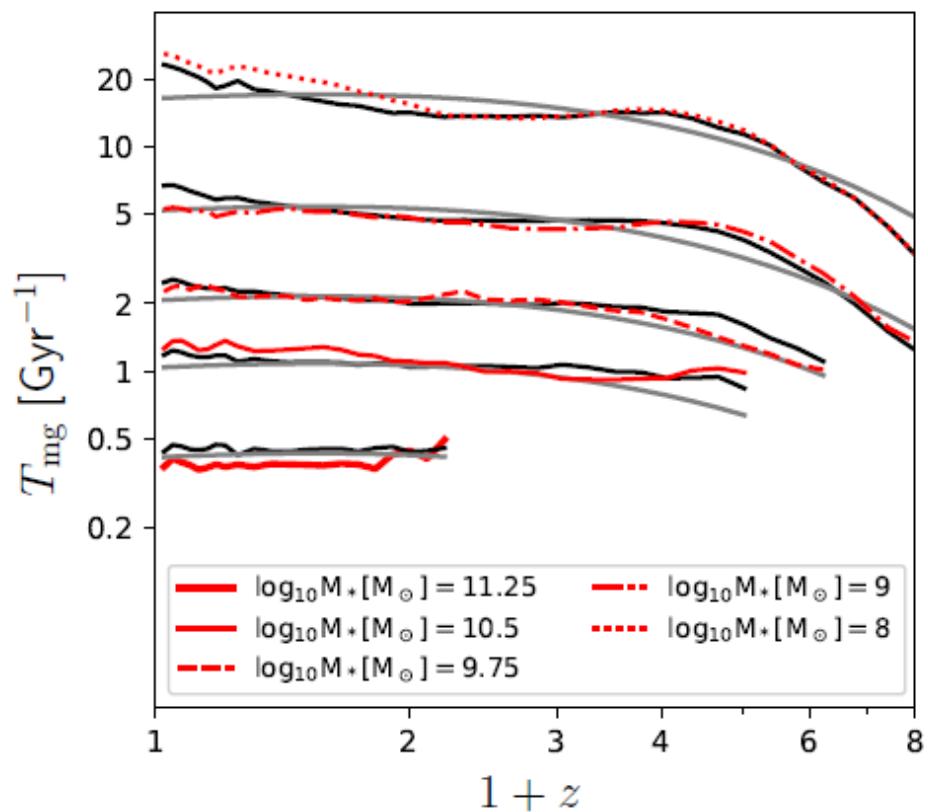

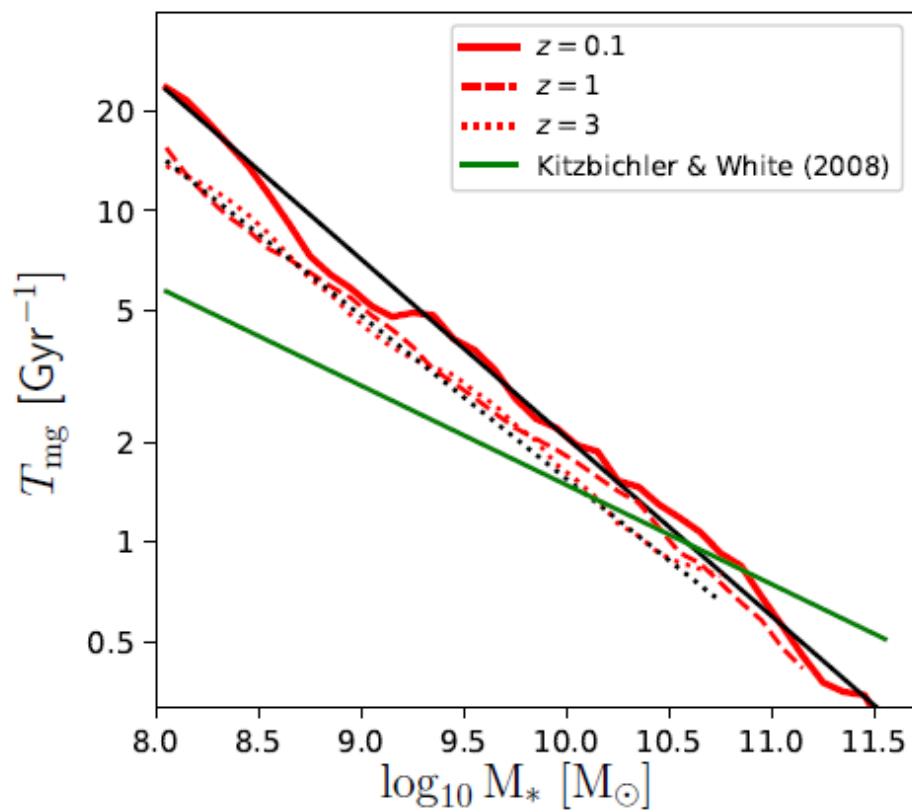

# Udio bliskih parova u GALFORM-u:

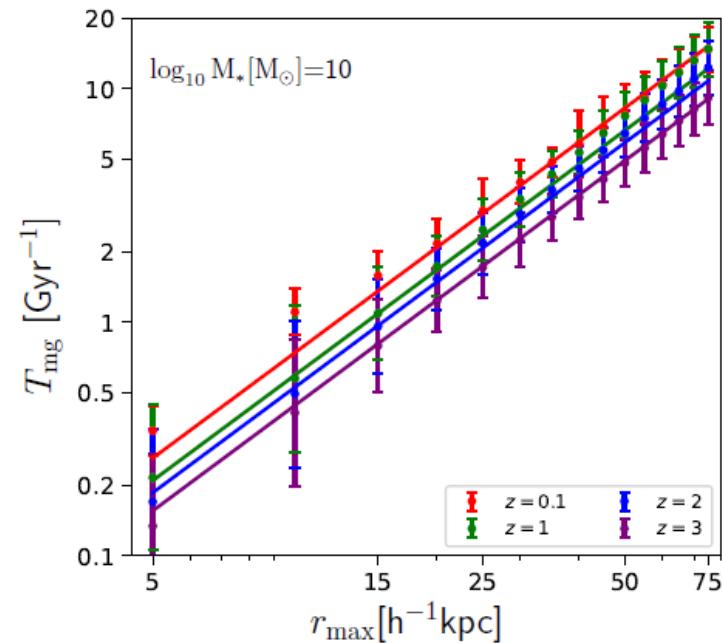

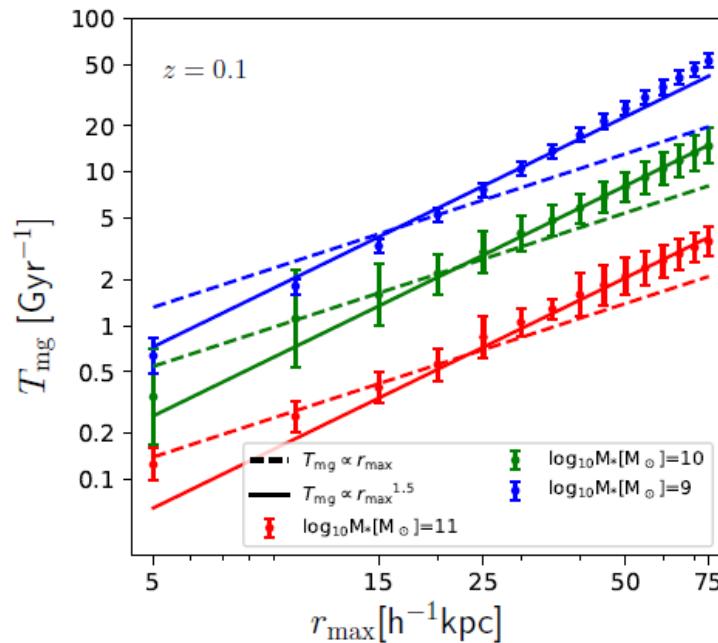

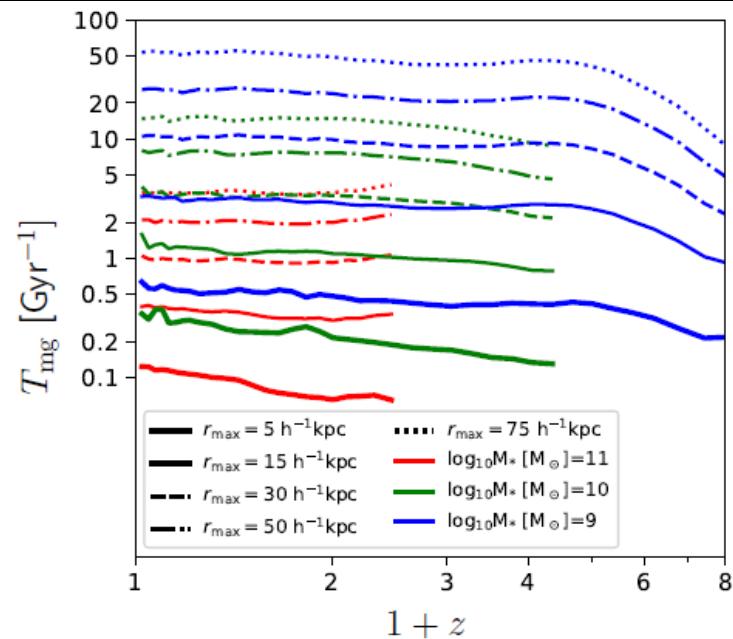

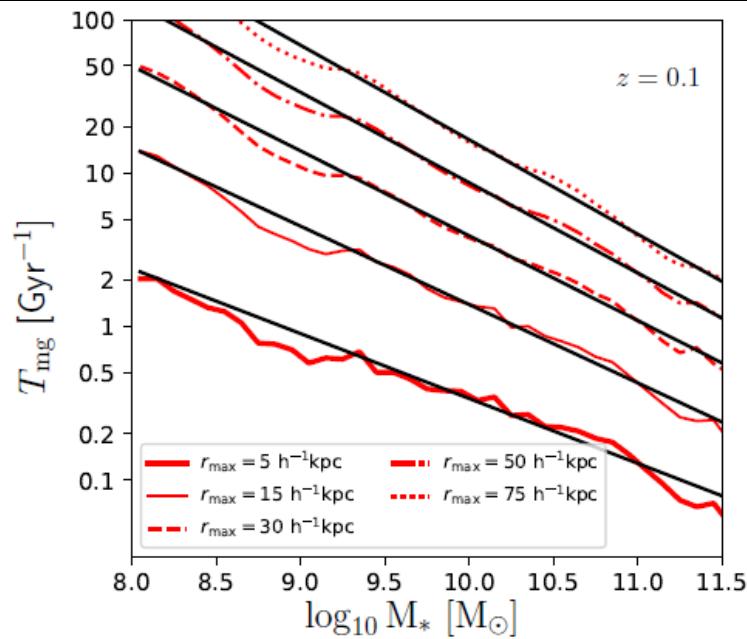

$$f(M_*, z, \mu_*, r_{\text{sep}}, v_{\text{sep}})$$

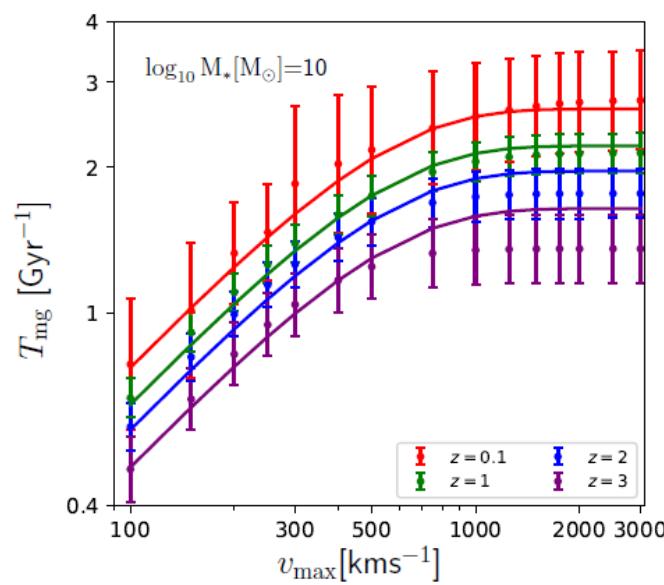

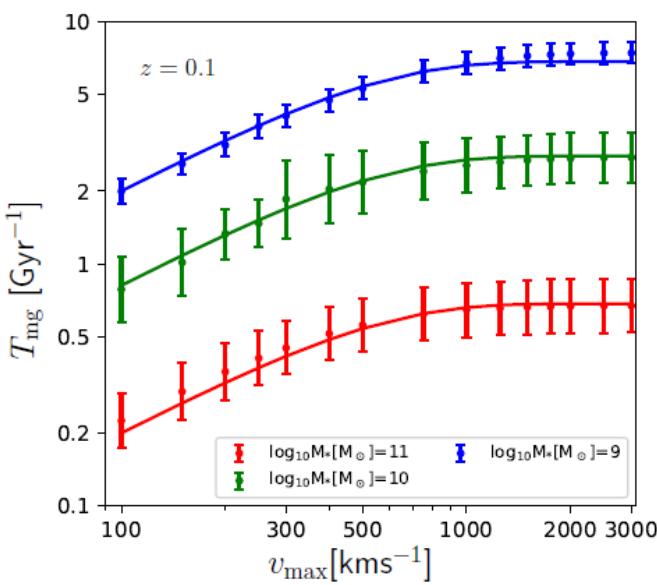

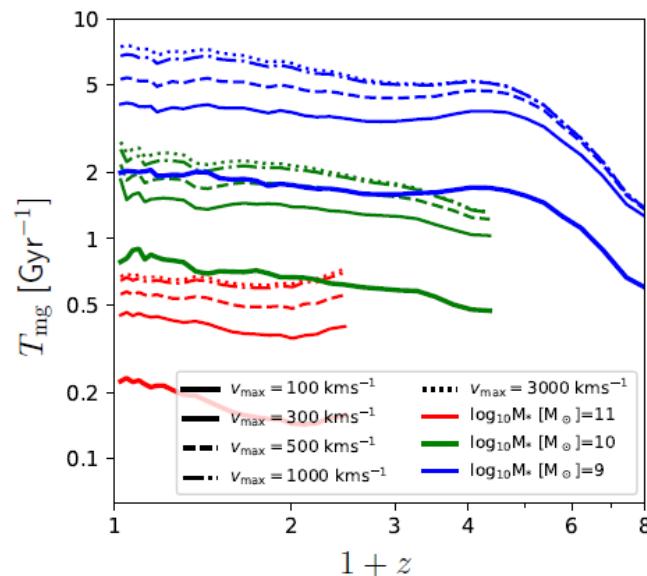

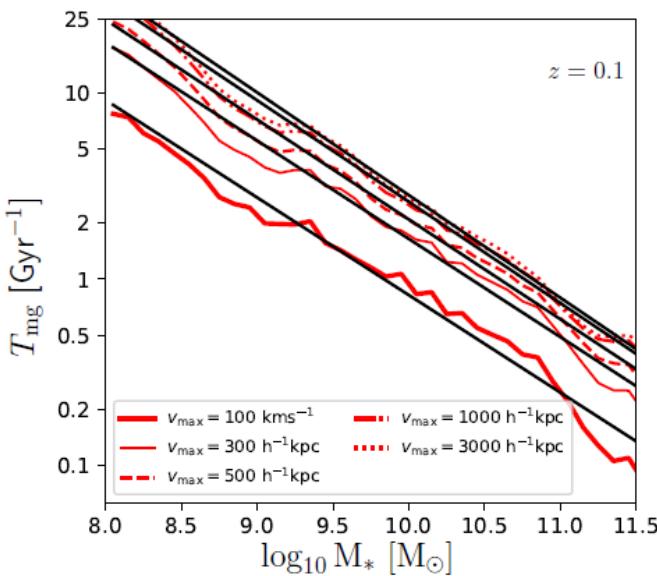

# Vremenska skala stapanja u GALFORM-u:

$$T_{\text{mg}} = 2.2 \text{ Gyr} \times r_{\text{max},20}^{1.5} \text{erf}(v_{\text{max},0}^{0.75}) \times \\ \times M_{*,10}^{-0.5} (1+z)^{0.5} e^{-0.14z}$$

## Zaključak:

- stopa stapanja je općenito veća za masivnije galaksije i ranija vremena, osim za galaksije masivnije od neke granične mase ( $M_* \approx 10^{11} M_{\text{sol}}$ )
- stopa stapanja se dobro slaže s opservacijama, i kao funkcija zvjezdane mase i crvenog pomaka
- udio velikih bliskih parova se dobro slaže s opservacijama za masivnije galaksije ( $M_* > 10^{10} M_{\text{sol}}$ ), a lošije za manje masivne
- pronađena je empirijska formula za vremensku skalu stapanja kao funkcija mase i crvenog pomaka, kao i selekcijskih varijabli
